Among the most widely recognized and ceaseless issues in the social insurance framework worldwide is the swarming of crisis rooms (ER); prompting numerous genuine inconveniences. Ruler Faisal Specialist Hospital and Research Center used health care analytics techniques to recognize regions of inadequacy and propose potential upgrades to ER execution. The venture executed arrangements and monitored two pointers (ER length of stay (LOS)), reflecting proficiency, and level of patients leaving without treatment, reflecting viability of the ER. A review investigation of 26,948 ER experiences in 2014 was done in January 2015. Analytics methods were utilized to recommend process overhaul in view of results. Two suggestions were executed; a Fast-Track for bring down acuity ER patients and an interior waiting zone, for those patients who can remain vertical and extra an ER bed. 32.8% of ER patients had bring down acuity levels and under 0.5% of them were admitted to the hospital. In the wake of executing the two arrangements, the aggregate ER LOS was lessened from 20h out of 2014 to under 12h of every 2016; 40% improvement (Khalifa et al., 2016). The rates of patients left without being seen remained around 3.5%, while the rates of patients left before total treatment was fundamentally lessened from 13.5% out of 2014 to 5.5% of every 2016. Subsequently, the aggregate level of patients left without treatment was diminished from 17% of every 2014 to 9% of every 2016, with half change. Every single other factor was the same, including quantities of ER visits, Patient Acuity Level, working staff, working hours, and the tally of ER beds. Health care analytics strategies can be utilized to recognize regions of insufficiency, potential changes, and prescribe viable answers for positively improve ER execution. More arrangements ought to be inspected, for example, group triaging, patients palmar filtering, and setting a doctor in triage. Additionally, more pointers ought to be monitored, for example, the adequacy of ER treatment including the rates of revisits.

As health care in modern communication technology has been made secured using advanced security technology, a still advanced cloud computing platform (Rath et al., 2017) is currently being used for easy access of health information and better control with new encryption method. The encoded information will be secured in the cloud using provable information possession plot. To improve the assurance and security, the primal based security technique is used as a piece of securing the social protection information. The proposed framework gives better security. Using this proposed procedure, the exactness of therapeutic administrations information is ensured and conspicuous confirmation of archive piece nearness in the cloud is performed. This procedure furthermore reinforces incorporation, alteration and cancelation of the information and tries to diminish the calculation time of the server. The surprise attacks are made with encoded information and the results shows that the proposed plan beats with improved security in information accumulating when appeared differently in relation to the present methods.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Health care Monitoring frameworks are logically advancing with the possibility to change the way social insurance is as of now conveyed. A Smart Health Monitoring System, for example, the one composed in this investigation, means to computerize understanding monitoring errands. In the present investigation we have composed and built up a GSM (Global System for Mobile) based brilliant wearable framework with 3-hub Accelerometer, 3-lead ECG recording framework and constant NIBP examination framework. The gadget is fit for distinguishing sudden fall situations, heart abnormalities and hyper/hypotension; in this way rendering it suitable for constant monitoring, self-conclusion and remote finding purposes. The framework is likewise fit for sending notices to social insurance experts quickly after the discovery of any of the previously mentioned health care abnormalities with the goal that the vital advances are taken. The total examination and assessment of the signs procured from the patient have been performed utilizing a product stage: NI LabVIEW. It is a savvy, keen and wearable health care monitoring framework that is of monstrous significance not exclusively to the elderly and post-agent (Rath et al., 2017) patients, yet in addition to those dwelling in remote areas and are unequipped for bearing costly social insurance in urban hospitals or facilities.

5. CONCLUSION

In modern age, there are many prominent change in way of life of persons in metropolitan city and due to change in life style, furthermore there is possibility of more medical issues in urban zones. With the advancement of technology and its development in health care section, the lifestyle of people in metro urban regions with far reaching volume of masses is also affected by various application and organization systems. Along these lines by and by most of the urban groups are changing into savvy urban zones by getting motorized systems in each possible portion. With a target of building up another social insurance framework for ambulances in an urban city, the chapter presents a cutting edge description on health and human services control framework with enough security feature for key vehicles so the goal of safe driving uniquely in emergency situation can be satisfied in genuine sense. security solution of health care as it uses advanced technology of automating vehicles, big data analytics, swarm intelligence as well as VANET.

Chapter 71
Shared Electronic Health Records as Innovation: An Australian Case

Troy Pullen
Queensland State Archives, Australia

Latif Al-Hakim
University of South Australia, Australia

ABSTRACT

Based on the Diffusion of Innovation theory, this chapter addresses the following research question: Whether factors of diffusion of innovation theory influence care providers' willingness to adopt Shared Electronic Health Records (SEHRs). Data was collected through a self-administered questionnaire distributed to over 5000 active members of the Australian Medical Association Queensland. A total of 588 valid responses were received from currently active care providers in Queensland. Multiple regression analysis and Chi-Square analysis were conducted to test the research hypotheses and answer the research question. The data revealed that while 72% of those surveyed were willing to adopt SEHRs, significant differences existed between public and private sector care providers and across the various tiers of the health system. In relation to the factors influencing future willingness to adopt, the variables comprising relative advantage were shown to have a significant impact upon future willingness to adopt shared electronic health records. The findings from this chapter will benefit those responsible for the future introduction of SEHRs, specifically by allowing policy makers to target the factors that influence care providers' willingness to adopt.

INTRODUCTION

An electronic health record provides each individual with a secure and private lifetime record of their key health history and care within the health system. The record is available electronically to authorised health care providers and in selected instances to the individual anywhere, anytime, in support of

high quality care (Health Canada, 2004, p. 3). 'The introduction of an electronic record should enable healthcare workers much greater access to timely, reliable and accurate data' (Conrick, 2006, p. 12). In addition, Conrick states that 'great gains are envisioned at the hospital interface, where quick access to a patient's medication record could be life saving'.

The development of electronic health records and the sharing of these records provides the foundation for the 'innovation' to be developed and implemented in this study. The shared electronic health record (SEHR) is not a recent innovation. The concept of SEHRs began at least 40 years ago, but the first implementations did not begin until the 1980s, and with the exception of a few countries in Europe, is still very low (Royal Australian College of General Practitioners, 2004; Schloeffel, 2004a). 'For over thirty years, there have been predictions that the widespread clinical use of computers was imminent. Yet the 'wave' has never broken' (Berner, Detmer, & Simborg, 2005, p. 3). However, due to factors such as technology interoperability problems and the previous lack of strong incentives from Governments, the widespread clinical use of computers has previously never progressed past the concept stage. The recent diffusion of SEHRs by Government's (e.g. Australia's proposed Personally Controlled Electronic Health Record (PCEHR)) has brought the innovation back into the spotlight.

Recently, much work has been undertaken to develop SEHRs to meet specific needs and requirements of various stakeholders. Countries over the past decade which invested significant resources to develop shared electronic health systems, and Standards for these systems include the UK, Netherlands, USA, Indonesia, Australia and Canada (Detmer & Gillings, 2000; Schloeffel, 2004a).

Defining Electronic Health Records

The International Standard ISO 20514 defines an electronic health record as (Schloeffel, 2004b):

A repository of information regarding the health of a subject of care in computer processable form, stored and transmitted securely, and accessible by multiple authorised users. It has a commonly agreed logical information model which is independent of EHR systems. Its primary purpose is the support of continuing, efficient and quality integrated health care and it contains information which is retrospective, concurrent and prospective.

Briggs (2000, p. 18) provides the following definition of electronic health records that was developed for the Australian system, HealthConnect:

An electronic longitudinal collection of personal health information, usually based on the individual, entered or accepted by health care providers, which can be distributed over a number of sites or aggregated at a particular source. The information is organized primarily to support continuing, efficient and quality health care. The record is under the control of the consumer and is stored and transmitted securely.

It is any information relating to the past, present or future physical/mental health, or condition of an individual which resides in electronic system(s) used to capture, transmit, receive, store, retrieve, link, and manipulate multimedia data for the primary purpose of providing health care and health related services.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Based on these definitions, there appears a common link. Both discuss electronic information (past and present) about individuals which can be shared between users, with the aim of improving health care and health services.

Additionally, the International Standard ISO 20514 (Schloeffel, 2004b) defines an electronic health system as:

A system for recording, retrieving, and manipulating information in electronic health records, or more broadly as the set of components that form the mechanism by which electronic health records are created, used, stored, and retrieved. It includes people, data, rules and procedures, processing and storage devices, and communication and support facilities

Early work in medical informatics focused on clinical computing with a clear goal – to improve clinical decisions and reduce medical errors – essentially though electronic access to procedure results, faster access to relevant medical information in the literature, and, from the beginning, decision support functions such as reminders and alerts (Berner et al., 2005). In the 1970s, its use centred on collating patient data and the possibility of electronically linking primary and secondary care emerged. In the '80s computers were introduced to the consulting room; and in the '90s the internet provided the potential to obtain and review useful information during the consultation (Mitchell & Sullivan, 2001; Richards, Bolton, Veale, & Quinlan, 1999). Today, in addition to providing care providers' with a number of clinical benefits such as up to date information, SEHRs are proposed to enable the secure sharing of health information between an individual's healthcare providers, whilst enabling the individual to control who can access their electronic health records (Commonwealth_of_Australia, 2011).

THE ROLE OF TECHNOLOGY

The adoption and implementation of SEHR systems consists of a range of initiatives which inevitably initially involve the introduction of new health information technology (IT) to support SEHR systems. Health IT is regarded as an essential tool for hospitals navigating the road to patient safety and implementation of SEHRs (Furukawa, Raghu, Spaulding, & Vinze, 2008). Successful implementations of health IT systems has the potential to positively influence care providers' willingness to adopt SEHRs. Research suggests that user attitudes towards IT systems are a critical factor in influencing care providers' willingness to adopt SEHRs (Castillo, Martínez-García, & Pulido, 2010)

Health IT systems are becoming increasingly critical in the daily roles of care providers'. For example, general practice is central to the coordination of health care provision with 85% of Australians interacting with a general practitioner each year (Britt, Miller & Charles 2007). It is reported that 98% of Australian general practices are computerised, with 64% recording clinical information in the form of progress notes (McInnes, Saltman & Kidd 2006). Further, a Royal Australian College of Physicians survey of 1,266 Specialists found that 97.5% of respondents had access to computers at work (Osborn et al. 2009). Today, the use of technology in health care has extended to include mobile devices such as tablets and smart phones. Mobile devices offer flexibility and ease of access to patient information (Solomon 2011). In addition to care provider use of mobile technologies, customers are using a range of mobile devices to view patient medical records such as history, medication and problem lists, and allergies (GE 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Further to the role played by health IT systems in general, the development of SEHRs has been credited with improving efficiency in health care; has the potential to increase the quality of care in hospitals, and reduce costs of clinical care (Burke & Menachemi, 2004; Darr, Harrison, Chakked, & Shalom, 2003; Lorence & Jameson, 2002).

Generally, following the implementation of SEHRs, healthcare providers are deemed to benefit via availability of information at the point of care, better information storage and retrieval, efficiency of storage space and time, more accurate records, improved drug management, improved legibility and presentation, better security and integration of clinical and administrative functions (Jefferson, 1998). Shared electronic health records enable patients to have easy-to-access information about their medical history, including medications, test results and allergies, allowing them to make informed choices about their healthcare and be active participants in their healthcare (Commonwealth of Australia 2011). Additional benefits to patients include improved prescribing of medications, improved referrals (based on the patient summary) and access to computer based patient education materials. In addition, Jefferson (1998) states that the government and healthcare system in general is believed to benefit from cost savings. There are heavy expenses nationwide with the duplication of diagnostic tests (Dearne, 2005). 'That can certainly come down if we have readily available health records so that blood tests, X-rays and MRI's do not need to be repeated by every lot of treating doctors', stated then Federal Health Minister, Mr. Abbott (Dearne, 2005).

Despite the potential benefits, access to patient records has previously often been incomplete and disorganised. This was due to the decentralized and defragmented nature of health systems (Commonwealth of Australia 2011; Kohn 2000). This is supported by Briggs (2000b), who states that, 'the majority of health care records in Australia exist as discrete paper based entities held at a variety of different locations, resulting in a fragmented picture of individuals' health needs and health histories'. Medical records can typically be stored in separate systems across GPs, hospitals, emergency departments, outpatients' clinics, diagnostic units and specialists' rooms. A clinician therefore could access only those records stored in their own files, while access for patients was extremely limited (Aap, 2004). In a study conducted by the RAND Corp. in the United States relating to the creation of an electronic health system through a unique patient identification number for every person, a number of benefits were realised. These benefits included a reduction in medical errors, increasing the overall efficiency of patient treatment, and protection of patient privacy (Carayon 2009).

The development of an integrated SEHR network has the potential to benefit patient care substantially. The Commonwealth Department of Health and Ageing (Commonwealth of Australia 2011) states that the purpose of SEHRs is to address the information fragmentation that currently exists in relation to personal health information. Further, Briggs (2000b, p.8) states that 'Electronic records and transmission of personal health information can provide a powerful tool to link the isolated islands and fragments of information that currently exist'.

A majority of American health care executives believe SEHR systems will have a positive long term financial impact on their organization, despite costs and other barriers to adoption (McGee, 2004). The key is not the technology, but how the technology can be utilised to reinvent health care (Berner et al., 2005).

The current Australian healthcare system operates in a mixed mode of using paper-based and electronic-based systems for collecting and sharing health information. A number of different eHealth applications are in wide use in a number of different areas in the health sector including patient administration systems (PAS), clinical information systems (CIS), diagnostic imaging systems, pathology systems, and practice management systems (National E-Health Transition Authority 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As clinical computer use in general practice becomes more widespread, evidence of its benefits is being accumulated. For example, 'computerised prescription software packages that are being used widely in Australian general practice and have the potential to improve the quality use of medicines through providing the general practitioner with information about medications, access to clinical guidelines and warnings about potential contraindications, adverse reactions and allergies' (Royal Australian College of General Practitioners, 2004, p. 74). Prescriptions are legible and accurate and allow audits of prescribing for individual patients and the practitioner's patient population. Individualised consumer medicine information can be produced at the time a prescription is generated (Royal Australian College of General Practitioners, 2004).

AUSTRALIAN INITIATIVES IN E-HEALTH

Early trials conducted throughout the past decade have confirmed the early evidence that health care quality can be significantly improved through health information (Detmer & Gillings 2000). Over the next two decades, e-health could deliver a positive impact on quality and access of health care. These early studies have found that these positive impacts are likely to improve cost effectiveness of health care, which should lead to better evaluation of health status and outcomes (Detmer & Gillings, 2000). In addition, Detmer and Gillings state that a benefit of allowing patient access to electronic health systems is that more knowledgeable patients will likely support rising standards of medical care and research and result in better management of the knowledge base. These findings from Detmer and Gillings in 2000 remain relevant today, with the "Concept of Operations" relating to the introduction of a personally controlled electronic health record system" (National E-Health Transition Authority 2011) containing a number of the same benefits for individuals and healthcare providers alike, stating the system will enhance the way healthcare is delivered.

Across Australia, many programs have been, and are currently being undertaken to provide not only doctors and GPs with adequate electronic medical access, but also patients. Prior to 2010, a number of SEHR initiatives have been developed. The Concept of Operations document referred to above (National E-Health Transition Authority 2011) for the personally controlled e-health records (PCEHR) system summarises the history of Australian initiatives relating to eHealth. Consideration of SEHRs in Australia started with the National Electronic Health Records Taskforce (NEHRT) in 2000, which was commissioned by the Australian Government to consider the potential for a network of electronic health records. The recommendations of the NEHRT led to the creation of the HealthConnect program and work on a range of trials on SEHRs progressed initially through HealthConnect and MediConnect programs in Tasmania, Queensland, New South Wales, South Australia, Western Australia and the Northern Territory.

In addition to the above trials, in 2004 New South Wales developed a $19.4 million pilot program called Health e-link. As part of Health e-link, clinicians and patients in NSW could retrieve information including prescriptions issued, blood test results, x-rays and hospital discharge notes for example. Tests would not have to be repeated unless absolutely needed, nor would patients and carers have to recall from memory all aspects of care they received in the past (Aap, 2004). This initiative allowed patients to access their full medical records online. In addition, health professionals – including GPs, specialists and emergency department clinicians – were able to see a patient's detailed medical history (Aap, 2004).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In 2005 it was recognised that for eHealth to progress further in Australia, key infrastructure and standards were required, and the National E-Health Transition Authority (NEHTA) was established. The development of the Personally Controlled Electronic Health Record (PCEHR) system is a result of the NEHTA, and follows on from the initiative known as HealthConnect. Below is a brief description of HealthConnect and PCEHR.

HealthConnect

HealthConnect was Australia's first health information network. The network involved the collection, storage and exchange of consumer health information via a secure network and within strict privacy safeguards to provide better integration of care and improved outcomes across the health care system (Health Connect, 2004a). The HealthConnect initiative was a partnership between the Australian, State and Territory Governments. The initiative aimed to improve safety and quality in health care by facilitating the development and establishment of a range of standards based products and services that would enable the secure exchange of information between health care providers and consumers. Privacy, security and timeliness of information flows to improve the delivery of health services were the key drivers of this initiative (Australian General Practice Network 2007).

Personally Controlled Electronic Health Records

The most recent update on Australian initiatives in SEHRs is the move towards personally controlled electronic health records (PCEHR). In April 2011, the Commonwealth Department of Health and Ageing released a 'concept of operations' for the Federal Government's $466.7 million PCEHR system set to be made available to the general public from July 2012 (ZDNet 2011).

The PCEHR system is Australia's national approach to SEHRs. The national solution extends the concepts of SEHRs and includes the required infrastructure and legislative requirements necessary to implement such a comprehensive solution. The Concept of 'Operations maps out the SEHRs function, possible information as well as proposed security and privacy settings and how the system will connect with clinical systems.

The PCEHR system focuses not only on health care administration, but also enables the secure sharing of health information between an individual's healthcare providers, while enabling the individual to control who can access their PCEHR (Commonwealth of Australia 2011). When patients visit their local GP, specialist or emergency department, the PCEHR system will allow the care provider to access patient health records at a click of a button.

The implementation of a national e-Health system addresses one of the greatest challenges faced by the Australian health system — the fragmentation of information spread across a vast number of different locations and systems (National E-Health Transition Authority 2011). The Commonwealth Department of Health and Ageing and the National E-Health Transition Authority (NEHTA) is currently working with each of the Australian State and Territory Health Departments to implement a range of foundations, including Healthcare Identifiers, Discharge Summaries and Secure Messaging, all of which will be required for the PCEHR System (National E-Health Transition Authority 2011).

COUNTER ARGUMENTS AGAINST THE IMPLEMENTATION OF SEHR

Despite the evidence of the benefits associated with quality information, at the point of patient care, the recognition that SEHRs could improve health care quality, reduce medical errors, and reduce health care costs is still not sufficient motivation to overcome resistance to the system's adoption. Without strong physician demand, Berner, Detmer and Simborg (2005) state that hospital and practice administrators do not see sufficient potential financial return to try to overcome this resistance either in the inpatient or outpatient setting. Claburn (2004) acknowledges that while some physicians initially resisted the technology, that is now changing. 'There's increasing emphasis on the quality of care, and increasing litigation' (Claburn, 2004). Human errors which could possibly be prevented by electronic health systems could wind up costing a hospital a million dollars in a lawsuit (Claburn, 2004). Therefore, as previously stated, a strong objective of initiatives such as HealthConnect and the current PCEHR is to encourage early uptake and installation of the system to help realise its benefits sooner rather than later. This study aims to identify those variables with the greatest potential to influence care providers' willingness to adopt SEHRs. In addition, there are three main challenges facing the implementation of SEHR systems. These are infrastructure challenges, care providers privacy concerns and consumer privacy concerns.

Infrastructure Challenges

Shared Electronic Health Record technology has a great potential to save lives as well as money, with the benefits far outweighing the initial implementation costs. However, these potential benefits can only be realised if the various systems in place across the country 'exist', and can 'talk' to each other. While rapidly improving in recent years, one primary factor identified is the lack of technology infrastructure at doctors' offices, especially small practices (Hare, 2001; McGee, 2004). Implementing this infrastructure comes at a significant cost, particularly to small practices. Secondly, the lack of interoperability between SEHRs has been a major barrier towards the deployment of shared electronic health systems (Schloeffel, 2004a). The challenge, therefore, lies in developing a national framework for infrastructure, privacy and security and common standards to support the reliable flow of information across the health sector (Health Connect, 2004b). Conrick (2006, p. 12) states that 'The introduction of standards for technology and language will enable greater connectivity and understanding between clinicians while supporting data analysis and audit'.

In order to overcome the challenges of system interoperability, as part of the development of the PCEHR program, e-health lead implementation sites have been established around Australia to deploy components of electronic health record systems, providing valuable learning to inform the implementation of the national PCEHR system (Commonwealth of Australia 2011).

Care Providers Privacy Concerns

Systems of SEHRs have traditionally proved very difficult to design and implement successfully. 'Issues to be overcome include: reassuring care providers and consumers that their privacy will be protected; the need to stick to agreed terminology; the challenges surrounding entering data on the record; providing decision support tools which health care providers value; and ensuring access only to authorized users' (Briggs, 2000, p. 21). Key questions are how much security is enough, who owns the record(s), and who

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

gets to use the data (Detmer & Gillings, 2000). There are concerns that a system such as the PCEHR system may be used to check doctors' prescribing habits or consumer entitlements like medications at concession rates (Darr et al., 2003; Merkes, 2000).

In addition to concerns that SEHRs may be used to check care providers' prescribing habits, the discoverability of data under legal proceedings encourages silence about errors committed or observed. Errors and safety issues can go undetected and unreported, both externally and within health care organisations (Kohn, 2000). Kohn (2000, p. 127) states that the 'Fear of legal discoverability or involvement in the legal process is believed to contribute to underreporting of errors'.

Further to the concerns raised above, it has been identified that there are also enormous dangers in information overload, especially in diagnosis and treatment contexts (Burgess, Gray, & Fiddian, 2004; L. Burke & Weill, 2005; Clarke, 2001; Farman, Honeyman, & Kinirons, 2003; Kerr & Norris, 2004; Lott, 1997; Murray & Lynn, 1996). The discussion relating to the amount of information available on the internet alone provides some context to the depth of information – both useful and otherwise, which must be taken into account.

Consumer Privacy Concerns

International surveys indicate that the public is particularly anxious about privacy in the context of electronic health related issue. A report by the California HealthCare Foundation found that 67% of the national respondents felt "somewhat" or "very concerned" about the privacy of their personal medical records (Bishop, Holmes, & Kelley 2005).

As relevant to the PCEHR system as to the context in which the statement was made over a decade ago, Neame and Kluge (1999) point out that 'accepting the benefit of technology is easy; offsetting it against risk is harder'. The potential for breaches of confidentiality may render patients less ready to share confidences with doctors and render doctors less likely to record them - both of which are detrimental to good clinical care (Keeley, 2000). For example, over 66% of respondents to a survey on electronic health records felt that electronic health records could reduce medical errors. Further, nearly 13% of respondents withhold personal information—such as existing health problems—which could *reduce* errors (Angst & Agarwal 2009).

DIFFUSION OF INNOVATION THEORY

This research examining the implementation of shared electronic health records (SEHRs) utilises Diffusion of Innovation theory (Rogers 1995) as a basis for its theoretical framework. Kale and Arditi (2010) state that diffusion of innovation has received significant interest from a wide range of disciplines such as management, economics, marketing, and sociology for more than four decades. This interest has generated a rich literature. Kale and Arditi (2010) conclude that the emergent picture from this literature is that the cumulative adoption of an innovation generally follows a S-shaped curve composed of: 1) an initiation and implementation phase with slow growth; 2) an adoption phase with fast growth; and 3) a saturation phase with decelerating growth (Mahajan et al. 1990).

Innovation diffusion models adopt a conceptual framework for understanding the diffusion of the innovation process (Kale & Arditi 2010). Diffusion is the process by which an innovation is communicated through certain channels over time among the members of a social system (Rogers 2003). Diffusion is

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

a communication process in which adopters persuade those who have not yet adopted to adopt (Valente 1995). Subsequently, different research approaches have been set forth in the literature to explain the observed S-shaped curve e.g., Bass 1969, Moore 1995, and Rogers 1995.

The term innovation refers to ideas, practices or objects that are perceived as new by an individual or other unit of adoptions (Rogers 1995). An innovation diffusion model focuses on describing and explaining the adoption process as a process of innovation diffusion at the aggregate level (Kale & Arditi 2010). The main objective of innovation diffusion models such as those used by Bass (1969) and Rogers (1995) is to explain or predict rates or patterns of innovation adoption over time (Mahajan et al. 1990).

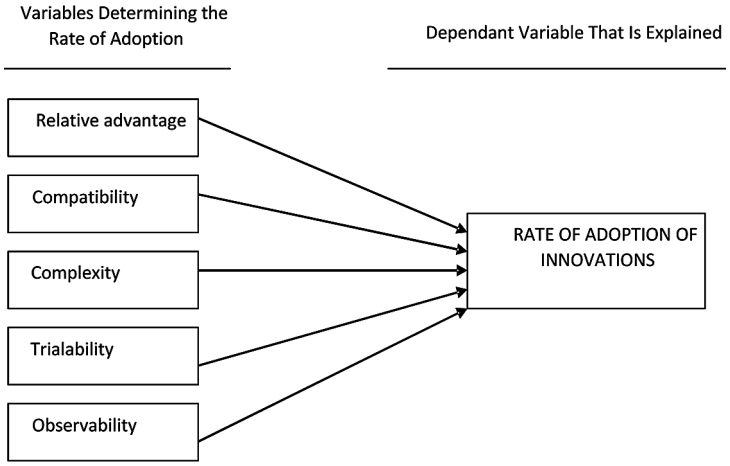
Rogers (1995) states that the characteristics of an innovation, as perceived by individuals, help to explain adoption rates. This is also consistent with other studies, which have found that the attitude of adopters to the various characteristics of an innovation influences adoption rates (Darr et al. 2003; Mahajan et al. 1990; Teng, Grover, & Güttler 2002). Variables which affect rate of adoption of an innovation, as determined by Rogers (1995), are:

1. Relative advantage;
2. Compatibility;
3. Complexity;
4. Trialability; and
5. Observability.

Rogers' framework of variables determining rate of adoption is illustrated in Figure 1.

Once the factors identified by Rogers were applied to the research, some adaptation to the theoretical framework was required in order to ensure relevance to the subject matter – adoption of SEHRs. In the context of this study, care providers' willingness to adopt SEHRs is measured. The section below outlines the rationale for focusing on care providers' willingness to adopt as opposed to measuring rate of adoption of SEHRs.

Figure 1. Rogers' framework of variables (adopted from Rogers, 1995)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Predicting Willingness to Adopt

The timing of this research is such that, at this point, SEHR use by care providers is not at a stage of diffusion where it is feasible to assess actual adoption behaviours. Similar to a study conducted by Angst and Agarwal (2009), for the most part, there are few cases in which SEHRs are stored in interoperable systems or made available via the internet to care providers or patients. Further to this, a study by Peterson et al. (2009) found that in America, the percentage of physicians using 'fully functional' electronic health record systems (e.g. incorporating extensive clinical features) only grew from three to four percent between 2006 and 2008.

Therefore, as yet, while care providers typically have not adopted the technology; they can form attitudes and beliefs about the concept of participating in adoption of SEHRs. Therefore use must be assessed through perceptual measures rather than actual opt-in behaviour. Consequently, this research will ascertain whether care providers would choose to opt-in to an SEHR system if they are given the choice in the near future. Therefore, the variable—*willingness to adopt* — is integrated into the innovation model as a means of estimating actual future behaviour.

As an additional factor impacting care providers willingness to adopt, due to the nature of implementation of Government initiatives such as that of HealthConnect or PCEHRs – the basis for a national framework of SEHRs - these projects by nature have a *mandatory* adoption procedure. Adoption of SEHRs is therefore unlike other innovations where individuals can *choose* whether to implement or not based on Rogers' variables identified above. For mandatory implementation, as the term suggests, adoption will result in *all relevant* people within the specified community adopting the innovation. Measuring rate of adoption would then become irrelevant because eventually, all members in the specified community will have to adopt the innovation. As outlined above, what may be highly variable however is adopters' *willingness to adopt*.

Willingness to adopt may impact strongly on the cost and length of the implementation process. Information provided in this Chapter has identified that the widespread clinical use of SEHRs amongst care providers is currently in its infancy. In order to promote acceptance across all care providers, considerable effort needs to be made to identify those factors which may affect willingness to adopt. By identifying those factors that have a positive or negative impact upon willingness to adopt an innovation, the effectiveness of the implementation program may be improved. This study therefore focuses upon the factors impacting upon willingness to adopt an innovation.

Research to ascertain willingness to adopt an innovation will invariably require some adaptation to the variables Rogers presented for measuring rate of adoption. The first variable Rogers identified as affecting an innovation's rate of adoption is relative advantage. Relative advantage gauges the degree of advantage gained from implementation of an innovation, compared to the previous system/s used. If an innovation has a perceived advantage or disadvantage over what it is designed to replace, those adopting the innovation will be either more, or less willing to adopt based on the degree of advantage the new innovation has. For example, if an innovation produces a cost saving to an organisation of 10 percent, those adopting would be more *willing*. Therefore, relative advantage can still be considered an important variable which may impact upon willingness to adopt SEHRs.

Compatibility is the second variable used by Rogers to analyse rate of adoption. As outlined by Rogers, compatibility can be viewed in terms of being consistent with existing values and procedures. Compatibility in relation to the current study can be viewed from a number of perspectives. Firstly, compatibility may be viewed from the perspective of technology usage. Those who indicated that they

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

have a high level of technology usage may be likely to have positive attitudes towards technology, and be more likely to find SEHRs more compatible with current systems. Consequently, based on positive compatibility, care providers may be more willing to adopt. Additionally, compatibility can potentially challenge existing values. If innovations challenge deeply embedded work patterns or subcultures, care providers may be reluctant to make the innovation part of their work routines (Buell 2009; Darr et al. 2003; Reid 2010; Wu et al. 2010). Effective communication can enable or disable the adaptiveness needed to navigate change successfully (More & McGrath, 2002). Therefore, compatibility with existing values or procedures could be considered relevant in influencing a care provider's willingness to adopt SEHRs.

The third variable identified by Rogers as affecting rate of adoption is complexity. Again, like relative advantage and compatibility, complexity is a factor which could impact upon an individual's willingness to adopt. For example, if a system of SEHRs is perceived to pose complexities in terms of: (a) meeting regulatory and legal requirements; or (b) technical difficulties, care providers may be less willing to adopt the new system (Wu et al. 2010).

The fourth variable which Rogers presents as impacting upon rate of adoption is trialability. The notion of trialability refers to the ability to trial an innovation before making the eventual decision to implement or not to implement an innovation. However, in the case of mandatory implementation, individuals have no individual ability to trial an innovation and then choose whether to adopt or not. Therefore, trialability could be considered as not directly influencing an individual's willingness to adopt. However SEHRs, as explored earlier in this chapter, have been trialled in the national SEHR initiative of HealthConnect and other smaller pockets within individual states of Australia. These trials have taken place over the past several years, with the aim of ensuring the system runs reliably and can be efficiently implemented nation wide. Therefore, those not involved in the HealthConnect or PCEHR trials have the capacity to learn about the results of the trials, and analyse feedback from those participating in trials. Therefore, while individuals themselves cannot trial SEHRs, they do have the capacity to analyse results of trials conducted by the Government. The results of these official trials may therefore either positively or negatively, influence care providers' willingness to adopt SEHRs.

Observability is the final variable which Rogers uses to measure rate of adoption of an innovation. Observability relates to those involved in the adoption process being able to observe the results of an innovation. Observability in this study is similar in nature to the previous variable, trialability. While an individual cannot observe the results of a trial of SEHRs in their own organisation before deciding to adopt, they have the capacity to observe the results gained from official trials. In the context of this study, observability may influence care providers' willingness to adopt from analysing the willingness to adopt across various tiers of medical professionals or across public and private hospitals.

Determining the factors which have the greatest potential for influencing willingness to adopt innovations would be considered highly desirable. In the case of this study, the innovation is SEHRs. The desirability of being able to identify factors likely to impact upon willingness to adopt could have significant potential for policy makers, both within and beyond the concept of SEHRs. By targeting those factors which may influence willingness to adopt, the adoption process can become a more efficient, streamlined process which meets the demands of the adopters'. The current study is specifically targeting care providers' perceptions of relative advantage compatibility, complexity and observability via analysing the willingness to adopt SEHRs. Supporting the focus upon relative advantage, compatibility and complexity, Carter and Bellanger (2005) state that after an extensive literature review, Tornatzky and Klein (1982) conclude that relative advantage, compatibility and complexity are the most relevant

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

characteristics to adoption research. Teng et al. (2002) supports this position by stating that the most important characteristics which influence adoption of technological innovations (e.g. SEHRs) are: relative advantage, compatibility and complexity. However, we are considering observability from different aspects, that is, through analysing the responses for the willingness to adopt across various tiers of medical professionals as well as across public and private hospitals.

RESEARCH METHODOLOGY

Target Population

The population used for this research was all currently active Health care providers registered with the Australian Medical Association Queensland (AMAQ). This population consisted of approximately 5013 members, located throughout Queensland. The roles of these care providers' could be broken down into the following categories: Specialists; General Practitioners; Residents; Registrars; Salaried Specialists and Senior Medical Officers. These members were assumed to have some degree of awareness of SEHRs. AMAQ member knowledge of SEHRs may have possibly been gained from potential involvement in trials of the HealthConnect system, interaction with colleagues involved with HealthConnect, and/or as a result of extensive levels of regulation developed for each of the respective states (Briggs 2000; Health Connect 2004a; Health Connect 2004b; Parker, Hewitt, & McWilliam, 2004).

Data was collected through a mail survey sent to all active members of the AMAQ. The survey was distributed by the AMAQ mail house, but returned directly to USQ to protect confidentiality of AMAQ members.

Survey Design

Ideally interviews would have been carried out, but this was not possible owing to budget, time and geographic constraints. The questionnaire was organized into the following five themes;

Part A: Demographics,
Part B: Technology,
Part C: Patient Care,
Part D: Legislation,
Part E: Shared Electronic Health Records.

These themes cover the many facets of SEHRs, and provide data about the perceived factors which influence care providers' willingness to adopt SEHRs. Questions relating to demographic detail were added in order to assist in data collection and to form the basis of comparisons across business sectors and regional differences.

A number of methods were used in the survey design to assist in building the response rate. In order to increase the response rate, Nicastro (1999) states that the covering letter should provide details relating to who should complete the questionnaire and suggests that it should be attached to the survey. It was felt to be important that the covering letter illustrated the importance of the use of technology to facilitate

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the management, and sharing of information in order to aid efficient patient care. Zikmund (2003) additionally suggests that the covering letter should explain that the questions are simple and to the point, and that a follow up email or letter to remind the respondent to complete the survey would be sent.

Data Preparation and Techniques Used

Prior to any analysis, variables were recoded for consistency and applicability. The data was entered into SPSS, and was checked for accuracy by running frequency distributions and any out of range values were checked. Whilst some cases showed the presence of outliers, none were deemed to be inconsistent and therefore all were retained in the analysis. SPSS was also used to check for missing values. The percentage of missing values for all variables was small.

Responses to interval scale questions such as those measured on a 5-point Likert scale were recoded so as the positive responses were assigned a higher number compared to negative responses. For example, 'Very poorly' was recoded as a '1', 'Poorly' recoded as '2', 'Adequate' remained as '3', 'Very well' was recoded as '4', 'Excellent' recoded as '5'.

It was considered appropriate to apply parametric testing procedures on the 5-point Likert scale in which this hypothesis is based. A review of the literature found that Likert scales are commonly treated as interval data for testing purposes, even though the data is ordinal in nature (Goldstein & Hersen, 1984; Jaccard & Wan, 1996; Shaughnessy & Zechmeister, 1990; Sisson & Stocker, 1989), facilitating parametric data analysis. The application of parametric tests to Likert scales has been validated by the fact that these tests do not affect Type I and Type II errors dramatically (Jaccard & Wan, 1996).

Hair et al (1998, p. 14) defines multiple regression as 'the appropriate method of analysis when the research problem involves a single metric dependent variable presumed to be related to two or more metric independent variables'. In addition to the definition provided by Hair et al, Zikmund (2003, p. 576) states that multiple regression analysis is 'an analysis of association in which the effects of two or more independent variables on a single, interval scaled or ratio scaled dependant variable are investigated simultaneously'.

Chi-Square analysis was used to examine the strength of the association between collected data and the specified distribution. Specifically related to this study, Chi-Square tests are used to analyse any statistically significant difference in willingness to adopt SEHRs between the different tiers of the health system within Queensland, and to test for any statistically significant differences in willingness to adopt SEHRs between care providers from public and private sector health facilities within Queensland.

Research Hypotheses

This research considers the shared electronic records as innovation and raises the following questions: Which of factors of diffusion of innovation theory influence care providers' willingness to adopt shared electronic health records (SEHRs). The study considers four factors of diffusion of innovation theory. These factors are relative advantage, compatibility, complexity and observability. The study excludes the trialability for the reasons stated earlier. In order to answer the research question, four hypotheses are established. These are as follows:

Hypothesis 1: That the variables comprising relative advantage have the potential to influence willingness to adopt shared electronic health records;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 2: That the variables comprising compatibility with existing systems and practices have the potential to influence willingness to adopt shared electronic health records;

Hypothesis 3: That the variables comprising complexity have the potential to influence willingness to adopt shared electronic health records;

Hypothesis 4: That the willingness to adopt shared electronic health records varies across the three tiers of the health system within Queensland (observability 1);

Hypothesis 5: That the willingness to adopt shared electronic health records varies across public and private sector health facilities within Queensland (observability 2).

DATA ANALYSIS: DESCRIPTIVE ANALYSIS

Response Rate

A total of 588 valid responses (complete responses from those currently active members registered with the AMAQ) were received. The valid response rate was 11.73%.

Principal Role as the Respondents

Based on valid responses, 214 (36.4%) respondents indicated that their principal role was that of a Specialist; 202 (34.4%) operated as a General Practitioner; 101 (17.2%) described their role as that of Resident or Registrar; 43 (7.3%) were a Salaried Specialist and 16 (2.7%) respondents indicated that their primary role as a care provider was acting as a Senior Medical Officer (refer Table 1). A small number of responses (2%) were received for 'Other'. These responses included 'Medical Assessor', 'Medical Research' and 'Private Emergency Department'.

Sector Operated in by the Respondents

Table 2 provides an overview of the sectors operated in by respondents. Almost half of the respondents (49.9%) indicated that they operated within the Private sector (Table 2). One third of the respondents (33.6%) indicated that they operated solely within the Public sector, and 16.5% respondents operated within both the public and private sectors.

The greater number of respondents from the private sector could potentially impact trialling methods of SEHRs, and eventual willingness to adopt. Adoption of SEHRs has historically been trialled more widely within the public sector. The increased exposure to SEHRs within the public sector could potentially lead to a greater willingness to adopt from public sector employees.

Hospital Size

The majority of the respondents (45.4%) indicated that they operated within a large hospital. A large hospital is defined as one which has more than 200 beds. One hundred and seventeen (21.8%) of the respondents indicated that they operated within a small hospital (refer Table 3)

Description of Work Category

Respondents were asked to best describe the type of work organisation they were involved with. Two hundred and seventy nine respondents (47.6%) indicated that they worked within a Hospital/Medical Care environment (Table 4). The next largest respondent group was made up of those working within Group Practice (26.8%), with the self employed professional group the third most prominent category (18.6% of respondents). Additionally, 26 respondents (4.4%) indicated that they worked within two or more categories simultaneously.

Computer Applications Used

The medical community represents a diverse community. Within different roles and environments, many types of computer applications are likely to be used. Of interest to this study, current usage of technology may influence perceptions of SEHR compatibility with current systems. Respondents were asked to identify those applications which they commonly use in their daily tasks (Table 5).

The three most commonly used computer applications indicated by respondents were:

- Administrative (481 responses);
- Database searching (442 responses); and
- Colleague interaction (395 responses).

To positively influence care providers' perceptions of SEHRs and their willingness to adopt, the most commonly used applications identified by care providers' in their daily activities should be identified as strengths of SEHRs. Therefore, the implementation of SEHRs could therefore target improvements in the way in which care providers' interact with technology applications in areas such as administrative use, database searching, and colleague interaction.

Level of Technology Change over the Past Five Years

The technology section of the survey initially identified care providers' perceptions in regard to the level of change in technology throughout the past five years. Table 6 illustrates that the majority of respondents (79.2%) identified either an increase (42.4%) or a large increase (36.8%) in the level of technological change over the past five years.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Computer applications used by the respondents

Technology Type	Frequency	Percent
Administrative	481	82.1

	Total	585	99.8	100.0	
Missing	System	1	.2		
Total		586	100.0		

Ease of Use of Technology

Ease of use of technology could be considered a significant factor in determining individuals' acceptance of technology. Technology which is easy or common to use, such as most typical Windows packages, are often accepted with greater ease. This theme was certainly demonstrated by responses to this question in the survey. The vast majority of respondents (96.6%) indicated that ease of use of technology would positively influence acceptance of technology (refer Table 7).

Table 7. Respondents' answers to the question: 'Do you perceive 'ease of use' technology as a factor which would influence acceptance of technology?'

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Yes	564	96.2	96.2	96.2
	No	20	3.4	3.4	100
	Total	584	99.7	100.0	
Missing	System	2	0.3		
Total		588	100.0		

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Level of Input towards Technology Use within Organisation

The next section of the technology area sought to identify whether respondents had any input into the level of technology usage within their organisations. Prior input in the development or implementation of technology could potentially influence willingness to adopt SEHRs. Approximately half of the respondents (52.7%) indicated that they had had some degree of input into the level of technology usage within their organisation (Table 8).

Perceptions of Usefulness of Technology

This component of the technology section identified personal perceptions of the use of technology for work purposes. Table 9 indicates that the majority of respondents (87.9%) rated technology, in varying degrees, as being useful in performing work duties.

Based on the results of the above table, in order to positively influence care providers' willingness to adopt technology - specifically SEHRs, the technology needs to be perceived as a tool which will enable improved work performance. These improvements must be able to be clearly defined through a number of key benefits – namely compatibility with existing work practices and applications, and relative ease of use.

Table 8. Respondents' answers to the question: 'Have you had any input into the level of technology used within your organisation?'

Ability of Technology to Provide Autonomy

Respondents were asked to identify their perceptions regarding the impact of technology, specifically whether the use of technology facilitates professional autonomy. Approximately two-thirds of respondents (63%) indicated that technology did provide some degree of professional autonomy (Table 10). These findings were verified with a follow up question which was reworded, asking respondents to consider whether technology threatens work autonomy. Consistent with the first response, approximately three quarters of respondents (78.4%) indicated that they did not perceive technology as threatening their work autonomy.

The next question identified care providers' perceptions as to whether technology could lead to managerial control. Again, consistently with the previous two questions, approximately two-thirds of respondents (66.8%) identified that they did not perceive technology as leading to managerial control over their work (Table 11).

The results indicate that care providers do not appear threatened by technology, in that the majority of respondents indicated that the use of technology does not threaten work autonomy or lead to managerial control, but rather helps facilitate professional autonomy.

Perceived Impact of Technology on Care Provider Performance

Respondents' were asked to provide an indication as to whether they perceived technology as improving their performance as a care provider. Once again, results were consistent with previous responses, and over three quarters of respondents (77.7%) indicated that they perceived the use of technology as improving their performance as a care provider (Table 12).

Types of Technology Used within Daily Practice

After establishing attitudes and perceptions towards technology and the role it plays within the daily environment of the care provider, the next section of the survey identified those common activities performed by care providers' which utilised technology. The activity which care providers' identified as most commonly using technology for was data entry (77.8%). The use of technology for 'reference' and for 'treatment' use were the second and third most commonly identified uses of technology in patient care (67.7% and 60.5% respectively, refer Table 13).

As indicated above, there were a number of responses to 'Other' for this section. The most common response category for 'Other' was the use of technology to identify patient trends/statistical collection/ diagnosis investigation (11 responses).

DATA ANALYSIS: HYPOTHESES TESTING

Multiple Regression Analysis

The results of the multiple regression analysis for Relative advantage, Compatibility and Complexity are shown in Table 14.

Table 13. The most common daily uses of technology

Technology Type	Frequency	Percentage
Data entry	455	77.8
Reference	396	67.7
Treatment	354	60.5
Clinical visits	289	49.4
Decision Support	287	49.1

Table 14. Model summary for regression analysis: Hypotheses one, two and three

Dimension	R Square	Regression Coefficient (B)		Sig
Relative advantage	.108	Perceived benefits of technology	.334	.000
		Perceived advantages of SEHRs		
Compatibility	.239	Perceived potential to improve communication between care providers		.000
		Perceived compatibility of SEHRs with care providers values relating to patient care		
Complexity	.008	Perceived complexity relating to information and records management		.037
		Perceived complexity relating to compliance		

Hypothesis 1: Relative Advantage

The value of R Square (10.8%) for Relative advantage was statistically significant (df = 2, 551; p = <.001). The regression model suggests that 10.8% of the variation in care providers' future willingness to adopt SEHRs could be explained from the variables comprising Relative advantage alone. Although the R Square value may be seemingly low (the large sample size can decrease the R Square value), it is still a statistically significant result, though some caution is needed when interpreting the results.

An examination of the beta coefficients showed that the variables comprising perceptions of the benefits of technology (Beta = .334; p = <.001) and perceptions of the advantages of SEHRs (Beta = .334; p = <.001) were significant predictors for care providers' future willingness to adopt SEHRs, indicating a positive linear relationship between Relative advantage and willingness to adopt.

An analysis of the findings also revealed that the perceived benefits of technology had a potential influence on care providers' future willingness to adopt SEHRs compared to the perceived advantages of SEHRs, with $F > 34$ and $\rho \leq 0.001$ (Table 15). While caution is needed giving the low R square ($R^2 = 0.108$), hypothesis 1 is supported.

Hypothesis 2: Compatibility

The value of R Square (23.9%) for Compatibility was statistically significant (df = 2, 551; p = <.001). The regression model suggests that 23.9% of the variation in care providers' future willingness to adopt SEHRs could be predicted from the variables comprising Compatibility alone. Similarly to the findings from the multiple regression analysis of Relative advantage, the results for Compatibility need to be interpreted with caution given the low R Square value.

An examination of the beta coefficients showed that the variables comprising perceived potential to improve communication between care providers (Beta = .501; p = <.001) and perceived compatibility of SEHRs with care providers values relating to patient care (Beta = .334; p = <.001) were significant predictors for care providers' future willingness to adopt SEHRs, indicating a positive linear relationship between Compatibility and willingness to adopt SEHRs.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 15. Summary of hypothesis testing for Relative advantage

Hypothesis	R Square	Df	F	Sig Level	Accept/ Reject
H_1 That the variables comprising relative advantage have the potential to influence willingness to adopt shared electronic health records.	.108	2,551	34.539	<.001	Accept

Further analysis of the findings (Table 16) revealed that perceived compatibility of SEHRs with care providers' value had a significant influence (ρ =0.001) on care providers' willingness to adopt SEHRs. Accordingly, hypothesis 2 is supported.

Hypothesis 3: Complexity

Although the regression model suggests that less than one percent of the variation in care providers' future willingness to adopt SEHRs could be explained from the variables comprising Complexity alone, the value of R Square (<1%) for Complexity was statistically significant (df = 2, 551; p = .037).

An examination of the beta coefficients showed that the variables comprising perceived complexity relating to compliance (Beta = .113; p = <.015) were statistically significant predictors for care providers' future willingness to adopt SEHRs. Perceived complexity relating to information and records management requirements was not a significant predictor (Beta = .006; p = .903).

More detailed analysis of the findings revealed that the complexity has very low R square ($R^2 = 0.12$) with insignificant value (ρ > 0.037). Accordingly, hypothesis 3 is rejected

Hypothesis 4: Willingness to Adopt Across Three Tiers

The fourth hypothesis tests that willingness to adopt shared electronic health records varies across the three tiers of the health system within Queensland.

Table 16. Summary of hypothesis testing for Compatibility

Hypothesis	R Square	Df	F	Sig Level	Accept/ Reject
H_2 That the variables comprising compatibility with existing systems and practices have the potential to influence willingness to adopt shared electronic health records.	.239	2,551	87.886	<.001	Accept

Table 17. Summary of hypothesis testing for Complexity

Hypothesis	R Square	Df	F	Sig Level	Accept/ Reject
H_3 That the variables comprising complexity have the potential to influence willingness to adopt shared electronic health records.	.012	2,551	3.313	.037	Reject

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chi-Square analysis was chosen to test for significant difference in future willingness to adopt SEHRs between the three independent groups of the health system (i.e. General Practitioners; Specialists; and Hospital staff) so as to examine the strength of the association between collected data and the specified distribution. The p-value is the probability of observing a Chi-square statistic at least as large as the one actually observed, given that there is no association between a variable of data occurring by chance (Zikmund 2003). Results of the Chi-Square test for hypothesis four are presented below in Table 18.

The output in Table 17 shows that the value of chi-square (χ^2) = 27.275 and the degrees of freedom on which this was based, was 8. These results show that there is sufficient statistical evidence to indicate that willingness to adopt shared electronic heath records varies across the three tiers of the health system within Queensland, (χ^2= 27.275, df = 8, p=.001). Hence, there is sufficient statistical evidence to support hypothesis four.

A comparison of means across the tiers of the health sector demonstrates that Hospital staff had the highest willingness to adopt, with a mean score of 3.65 (Table 19). Specialists had the next highest willingness to adopt, with a mean score of 3.12, and GPs had a mean score of 3.09.

Hypothesis 5: Willingness to Adopt Across Health Facilities

The fifth hypothesis tests that willingness to adopt shared electronic health records varies across public and private sector health facilities within Queensland.

This hypothesis was tested using Chi-Square analysis to test for any statistically significant results relating to willingness to adopt SEHRs between public and private sector health facilities within Queensland. The Chi-Square analysis test assumes that there is no significant difference between the expected and the observed results (Garson 2009). Results of the Chi-Square test for hypothesis five are presented below in Table 20.

Table 18. Chi-Square Test on difference between different tiers of the health system and future willingness to adopt SEHRs

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	27.275[a]	8	.001
N of Valid Cases	540		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 7.50.			

Table 19. Comparison of mean willingness to adopt across the tiers of the health system

Role	Mean	N	Std. Deviation
GP	3.09	191	1.184
Specialist	3.12	199	1.126
Hospital Staff	3.65	150	1.081
Total	3.26	540	1.159

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 20. Chi-Square Test on difference between public and private sectors for future willingness to adopt SEHRs

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	39.717[a]	4	.000
N of Valid Cases	465		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 9.10.			

The output in Table 20 shows the value of chi-square (χ^2) = 39.717 and the degrees of freedom on which this was based, was 4. These results show that there is sufficient statistical evidence to indicate that willingness to adopt SEHRs with the sector the care provider works in within Queensland, (χ^2= 39.717, df = 4, p=.000). Hence, there is sufficient statistical evidence to support hypothesis five. Figure 2 provides a graphical representation of the public and private sectors future willingness to adopt SEHRs.

In both the public and private sectors, 'Extremely against' was recorded the least. Within the private sector, 'Some concerns' was higher than 'Somewhat willing', 'Very willing' and 'Extremely willing', but in public sector respondents, it was less. Public sector respondents were over represented in the 'Extremely willing' category, with 52 actual responses (compared to the expected total of 37.2. The greatest difference existed within the 'Extremely against' category, where 91.3% of the responses consisted of private sector respondents.

A comparison of mean scores for future willingness to adopt between the public and private sector (Table 21) finds that the public sector has a greater willingness to adopt SEHRs, with a mean score of 3.69 (compared to 3.02 for the private sector).

In conclusion, the results for testing the five hypotheses are as follow (Table 22).

Figure 2. Bar chart illustrating difference between public and private sector future willingness to adopt SEHRs

Table 21. Comparison of mean willingness to adopt between public and private sector

Sector Recoded	Mean	N	Std. Deviation
Public	3.69	184	1.044
Private	3.02	281	1.174
Total	3.29	465	1.170

Table 22. Results of testing the five hypotheses

No.	Hypothesis	Accept/ Reject
1	That the variables comprising relative advantage have the potential to influence willingness to adopt shared electronic health records	Accept
2	That the variables comprising compatibility with existing systems and practices have the potential to influence willingness to adopt shared electronic health records	Accept
3	That the variables comprising complexity have the potential to influence willingness to adopt shared electronic health records	Reject
4	That the willingness to adopt shared electronic health records varies across the three tiers of the health system within Queensland (observability 1);	Accept
5	That the willingness to adopt shared electronic health records varies across public and private sector health facilities within Queensland (observability 2).	Accept

VALIDITY TESTING

A number of tests of the validity of the model for Relative advantage, Compatibility and Complexity were investigated as follows:

- The Durbin-Watson statistics (Table 23) for Relative advantage, Compatibility and Complexity indicated that there was no significant first-order serial correlation among the residuals (Zikmund 1991).
- A normal plot of regression standardised residuals for the dependent variable indicated a relatively normal distribution (Figures 3 and 4 show the normal plot of regression standardised residuals for relative advantage and compatibility).
- A scatterplot of residuals against predicted showed no clear relationship between residuals and predicted values consistent with the assumption of linearity (Coakes and Steed 1996).

The outcome of the three tests validate our results regarding hypotheses 1, 2 and 3.

Table 23. Durbin-Watson statistics for Relative advantage, Compatibility and Complexity

Variable	Durbin-Watson Statistic
Relative advantage	2.134
Compatibility	2.082
Complexity	2.106

STUDY LIMITATIONS

Like other research works, this study has several limitations, including the timing of the survey, low response rate and conducting the study in Queensland only.

The questionnaire for this study was administered in 2005, this was before any widespread trialling (or implementation) of SEHRs had commenced within Australia. As a consequence, it is likely that the responding Australian Medical Association Queensland (AMAQ) registered health care providers may have had a limited understanding of SEHRs. Because of the potential for limited understanding, respondents may not have been able to provide valid perceptions of the Relative advantage, Compatibility and Complexity aspects of adopting SEHRs. Given that the findings of the study are not what the literature suggested, the study may have been ambitious given the possible restrictions (e.g. potentially as a result of the limited experience of care providers' with SEHRs at the time of survey administration) related to care providers' offering data on perceptions relating to the various aspects of SEHRs.

Considering the attempt of the Federal Government to implement SEHR technology through their Personally Controlled Electronic Health Record (PCEHR) scheme by July 2012, views of care providers' could potentially have changed due to the upcoming implementation. Indeed, future research to compare care providers' perspectives of SEHRs given the national implementation of the PCEHR system could prove valuable to compare any changes.

In addition to the development and implementation of national programs such as the PCEHR system, a cultural change is occurring within the Australian public sector. Recently, the Commonwealth government recognised that, to be more relevant to its stakeholders, it needs to foster a culture of openness. To that end, a 'Declaration of Open Government' has been developed (Department of Finance and Deregulation 2010). Community expectations about improved access to government records and information have implications for how government manages public sector information. The move towards open government recognises that the value of public sector information as a national strategic resource can be enhanced when it is openly accessible and easily reusable.

Specifically within Queensland, reforms include the change from 'Freedom of Information' to 'Right to Information', moving to a push model for data publication. These changes have resulted in the introduction of the *Right to Information Act 2009* and *Information Privacy Act 2009*, replacing the previous *Freedom of Information Act 1992.* These changes in philosophy towards information resources and an open government may result in changes to responses to this study, and perhaps reinforce the importance of the need for effective information and records management practices. Supporting and maintaining the link between good information and records management practices and ongoing open access to government information is critical, and something which SEHRs have great potential in facilitating.

The data collection instrument utilised for this study could also be considered a limitation. All information including future willingness to adopt SEHRs were self reported by respondents. While self administered questionnaires are considered a generally accepted measure of administration (Zikmund 2003), future replications of the study could use other objective measures to obtain more valid and reliable results. Such methods could include interviews and observations.

The administration method of this questionnaire could also be considered a limitation. While distribution of the survey by mail can be considered a typical way to distribute surveys (Zikmund 2003), there are a number of limitations. For example, respondents could not be identified. Because respondents were not able to be identified, this made it impossible to test for non-response bias, which could have

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

affected results. The distribution of the survey by mail also does not ensure that the intended recipient completed the survey. For example, if the recipient was different to the intended person, their views may be different and therefore results could be inaccurate.

A number of techniques were utilised in this study with the aim of reducing the potential for non-response bias and to ensure the most appropriate person completed the survey. For example, a cover letter outlining potential benefits and relevance to the care provider was developed and attached to the survey so as to influence the care provider to complete the survey. The large sample size, covering all active members of the AMAQ, was also used in an attempt to ensure responses representing the views of the care provider community were attained.

A final potential limitation of this study is the survey of only Queensland care providers' on a topic that is not limited in scope to Queensland only, but contains implications for care providers' across Australia (given the planned introduction of the PCEHR System from July 2012). Given that the role of care providers' is consistent across Australia, it is not envisaged that the focus on Queensland based care providers' would create the potential for high levels of bias.

CONCLUSION

This study sought to investigate three key factors which may impact upon care providers' future willingness to adopt shared electronic health records (SEHRs) i.e. care providers' perceptions of relative advantage, care providers' perceptions of compatibility with existing values, systems and practices, and care providers' concerns about complexity. The study employs an adaptation of Rogers' (1995) Diffusion of Innovation (DOI) theory.

Despite the benefits of SEHRs, their widespread implementation has been extremely slow to date. Previous implementation attempts have been ad hoc, and have not adequately addressed key care provider and patient concerns such as those dealing with privacy and infrastructure requirements. Being able to identify factors which may explain the slow uptake of SEHRs could be considered highly desirable, both within and beyond the concept of SEHRs. By targeting those factors which may influence willingness to adopt, the adoption process could become a more efficient process targeted to address the concerns of the adopters.

To gain a deeper understanding of the issues involved and to explore the study's research questions fully, the quantitative phase of the research involved a self administered questionnaire involving all active Australian Medical Association Queensland (AMAQ) registered health care providers from the public and private sector. The goal of the questionnaire was to identify from a care providers' perspective, factors which have the most significant impact upon future willingness to adopt SEHRs. The questionnaire was sent to currently active health care providers registered with the AMAQ. This population consisted of approximately 5013 care providers, located throughout Queensland. A total of 588 valid responses were received from currently active care providers registered with the Australian Medical Association of Queensland (AMAQ) for the study (valid response rate of 11.73%).

The majority of respondents (36.4%) indicated that their principal role was that of a Specialist. The Brisbane City region had the greatest representation of the 14 distinct demographic areas identified by the AMAQ (25.3%). Approximately half of all respondents operated within the private sector.

A number of issues related to technology, specifically respondents' general attitudes towards the use of technology within their roles as care providers were examined. The majority of care providers' (79.2%) indicated a large to very large change in the level of technology change over the past five years.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Factors which care providers' identified as greatly influencing their acceptance of technology included ease of use; providing continuity of patient care; and improving quality of patient care. When asked to identify whether technology had the potential to provide benefit throughout a number of identified areas, the overwhelming response was that technology has great potential to provide benefits, however to date has not fully realised its actual potential.

When respondents were asked about Commonwealth and State legislation relating to recordkeeping, and the subsequent management of patient information, approximately three-quarters of respondents (73.6%) indicated that they did not have an understanding of the relevant Commonwealth or State legislation. Care providers also indicated that increased privacy legislation has had a considerable impact on their work practices. Increased privacy legislation has meant that care providers' have had to improve documentation relating to patient information, while it has also made it more difficult to access records and contact relatives of patients.

Specifically relating to SEHRs, over half of the respondents (57.6%) were not aware of trials which have been conducted throughout Australia. However, of those aware of the trials, the majority indicated that the results of these trials would not influence their willingness to adopt SEHRs (82.6%). Generally, respondents were more willing to adopt SEHRs in the future (72%) rather than currently (63.5%). The factors identified which would most positively influence care providers' willingness to adopt SEHRs related to improved patient care, reduced workloads and reduced complexity. The main problems identified by care providers relating to implementation of SEHRs included privacy/complexity and compliance issues.

Overall, based on an assessment of general attitudes towards technology and SEHRs, the majority of respondents could be assumed as having a positive attitude towards the use of technology for general day to day use, and also for patient care. However, care providers indicated that the expected benefits of technology have not typically been realised to date. Shared electronic health records divided opinion, with the majority of respondents indicating some level of degree of willingness to adopt and implement SEHRs, provided various potential benefits were realised. Based on care provider perceptions of a SEHR system such as HealthConnect/PCEHR, the biggest challenge to overcome would appear to be the critical issues of complexity and factors relating to relative advantage such as workloads, and demonstrating the ability of SEHRs to achieve stated benefits.

Findings revealed that Relative advantage had a statistically significant potential to influence care providers' future willingness to adopt SEHRs. Additionally, dimension one (perceived benefits of technology) was found to have a greater potential to influence care providers' future willingness to adopt SEHRs compared to the variables comprising dimension two (perceived advantages of SEHRs) of Relative advantage.

Multiple regression analysis for Compatibility found that this factor had the potential to have a statistically significant influence on care providers' future willingness to adopt SEHRs. Of the two dimensions comprising Compatibility, dimension two (perceived compatibility of SEHRs with care providers' values relating to patient care) had a greater potential to influence willingness to adopt compared to the variables best described as perceived potential to improve communication between care providers (dimension one).

Multiple regression analysis found that Complexity also had the potential to have a statistically significant influence on care providers' future willingness to adopt SEHRs. Of the two dimensions comprising Complexity (perceptions of complexity relating to information and records management considerations and perceptions of the complexity relating to compliance), only dimension two produced statistically significant results.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Following the testing of hypotheses one to three, the data was then analysed to determine whether any variation existed between the three tiers of the health system within Queensland future willingness to adopt SEHRs (i.e. GPs, Specialists and Hospital staff). Findings revealed that there was a statistically significant variation at the $\alpha = 0.05$ level in future willingness to adopt SEHRs across the three tiers, therefore supporting null hypothesis four. Responses indicate that overall, Hospital staff were more willing to adopt SEHRs with GP's the least willing based on a comparison of responses to 'Extremely willing' and 'Very willing'.

Finally, variation to future willingness to adopt SEHRs between the public and private sector was investigated in hypothesis five. The data revealed that there was sufficient evidence to support the null hypotheses at the $\alpha = 0.05$ level, indicating that a statistically significant variation existed between the public and private sector's future willingness to adopt SEHRs. While both the public and private sector featured similar response rates to 'Extremely willing' or 'Very willing' to adopt SEHRs in the future, the private sector contained a much greater number or respondents who were not willing to adopt (with responses to 'Extremely against' or 'Some concerns') compared to similar responses from public sector respondents.

Following the data analysis for the study's hypotheses, potential limitations were then addressed. Potential limitations were identified in two key areas, (a) the timing of the survey and (b) statistical testing methods. The timing of the study was identified as a potential limitation because it was likely that the respondents to the study had a limited knowledge of SEHRs (due to limited trials or implementation throughout Queensland, and Australia), which meant that the results did not correspond with findings from the literature review. The statistical testing methods posed potential limitations as the impact of Relative advantage, Compatibility and Complexity on willingness to adopt was not clear. Subsequently, logistic regression was used to identify whether the strength of the findings could be improved. Results of the logistic regression were consistent with previous testing (i.e. that Relative advantage, Compatibility and Complexity had the potential to be statistically significant predictors of care providers' future willingness to adopt SEHRs), and provided improved results relating to the strength of the relationships.

ACKNOWLEDGMENT

The research is part of the PhD work conducted by the first author (Dr Pullen) under the supervision of Dr H. Maguire and the second author, Associate Professor L. Al-Hakim. The PhD degree was granted to Dr Pullen by the University of Southern Queensland in 2012. The authors would like to thanks the Australian Medical association of Queensland (AMAQ) for the valuable support and assistance in distributing the questionnaire among care providers in Queensland. The authors would like to extend their thanks to Queensland State Archives for their support.

KEY TERMS AND DEFINITIONS

Compatibility: Compatibility can be viewed in terms of being consistent with existing values and procedures. In relation to innovation, compatibility is the degree to which an innovation is perceived as being consistent with the existing values, experiences, and needs of potential adopters.

Complexity: In relation to innovation, complexity is the degree to which an innovation is perceived as difficult to understand and use. New ideas that are simpler to understand will be adopted more rapidly than innovations that require the development of new skills and understandings.

Diffusion: Diffusion is an action of spreading something widely. In this chapter, this term is associated with innovation.

E-Health: E-health is a reference to the process of managing health information electronically.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Electronic Health Record: A repository of information regarding the health of a subject of care (individuals) in a computerised form, stored and transmitted securely, and accessible by multiple authorised users such as general practitioners and emergency doctors.

Healthcare Provider: An individual provides healthcare services to patients.

HealthConnect: HealthConnect is Australia's first health information network, which involves the collection, storage and exchange of individual's health information via a secure network.

Observability: Observability relates to those involved in the adoption process being able to observe the results of the adoption. In relation to innovation, observability can be defined as the degree to which an innovation are visible to others. More observable innovations are more likely to be adopted.

Relative Advantage: In relation to innovation, relative advantage gauges the degree of advantage gained from implementation of an innovation, compared to the previous systems used. It can also be described as the degree to which an innovation is perceived as better than the idea it supersedes. The greater the perceived relative advantage of an innovation, the more rapid will be its rate of adoption.

Trialability: The notion of trialability refers to the ability to trial an idea, process or system before making the eventual decision to implement or not to implement the idea, process or system. In relation to innovation, triability can be described as the degree to which an innovation may be experimented with on a limited basis.

Chapter 72
Electronic Medical Record Implementation Challenges for the National Health System in Greece

Dimitrios G. Katehakis
Institute of Computer Science (ICS), Greece

ABSTRACT

The purpose of this work is to expose challenges related to the implementation of quality electronic medical record (EMR) systems in public hospitals in Greece, a country where the national health system (NHS) has already acquired electronic medical records (EMRs). The level of EMR implementation, together with organizational maturity at a hospital level, are explored. What is discovered is that there are different adoption levels, not recorded in a systematic manner. The majority of physicians are either reluctant to implement EMRs or do not know options available to them. Implications include not continuous flow of events, cut off of critical information, lower quality of health services, patients not empowered to carry with them clinically significant information, unnecessary repetition of medical procedures and higher costs. It is concluded that focus should be paid on enabling the use of quality, interoperable and secure EMRs to better support medical decision, in an effort to improve the health of the population and to better control costs.

INTRODUCTION

Hospitals are complex institutions, devoted to the provision of patient treatment. They have specialized administrative, medical and nursing staff, as well as medical equipment. A hospital information system (HIS) encompasses the set of information technology (IT) applications used to manage hospital operations concerned with the administrative and clinical aspects of providing medical services within its boundaries. Subsequently, clinical and medical patient care activities are considered to be at the core of any HIS.

The EMR is defined as the electronic patient record created by providers for specific encounters in hospitals and ambulatory environments (Habib 2010; Kierkegaard, 2011). In contrast, the electronic health record (EHR) is a longitudinal electronic record of patient health information generated by one or more encounters in any care delivery setting (Health Information and Management Systems Society, 2011). Unlike the EMR and the EHR, the personal health record (PHR) refers to a representation of health records related to the care of the patient that is managed by the patient (Tang et al., 2006).

With the growth of mobile computing, the number of records regarding personal health is increasing exponentially. That leads to the need for an integrated method of storing health-related data which could be used by health care providers and patients (Roehrs et al., 2017). Connecting to the EMR requires shifting from paper, establishing interfaces to link islands of information based on certain workflows, and semantically homogenising the produced information. It is not difficult for any health professional to see the direct benefits of using EHR and having both administrative and clinical data that are accessible, comparable, communicable, and confidential (Iakovidis, 1998). Streamlining patient information flow and its accessibility to other healthcare providers through national, regional and/ or patient controlled services has the potential to improve care quality and patient safety over time.

Today, comparable and high-quality administrative and clinical data form the basis for effective and efficient management of public and clinical health. All current national initiatives focus on how to control costs and improve services. That is why electronic prescription (ePrescription – the ability to send readable and error-free prescriptions electronically from the healthcare provider to the pharmacy) and electronic reimbursement (eReimbursement – the ability to submit and follow-up electronically on claims with health insurance organizations) services seem to be of high priority together with electronic identification initiatives. Development of national infrastructures to support cross-border services is high on the agenda (World Health Organization and International Telecommunication Union, 2012; European Commission, 2012) and a move towards connecting the patient's team of healthcare providers to facilitate informed decision making.

Healthcare in Greece is provided by the NHS, or ESY (Greek: Εθνικό Σύστημα Υγείας, ΕΣΥ). It consists of a universal health care system provided through national health insurance, and private health care. In 2000, the Greek government, in accordance with the European Union (EU) recommendations, procured an operational program for implementing the information society strategy for Greece in a coherent and integrated way (Katehakis et al., 2011). The program aimed to provide IT support for regional health authorities and the public health organizations they supervise, to achieve better management of human resources, performance, containment of total cost, and continuous improvement of processes. Foreseen benefits included an upgraded quality of services to citizens through business process re-engineering and reduction of medical errors, secure exchange of medical information, and efficient access to the EHR.

That resulted in the introduction of modern IT systems for the vast majority of hospitals in the country. Incidentally, the conclusion of this effort coincided with the beginning of the economic crisis in the country, which subsequently led to an increasing number of admissions to public healthcare facilities, and deterioration of self-rated health (Kastanioti et al., 2013; Simou et al., 2014). The intention of the paper is not to discuss the challenges of the Greek healthcare system but rather challenges related to EMR implementation within the Greek NHS. An in-depth description of the NHS in Greece is beyond the scope of this work.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the section that follows the methods used for conducting this work are described, EMR characteristics are outlined, the digitization status in the NHS of Greece is presented, EMR adoption at a hospital level is explored together with key factors contributing to EMR adoption. In the results section, EMR implementation challenges in Greece are described, followed by some discussion and conclusions in the corresponding sections.

METHODS

In order to conduct this work, a literature review was performed on established work, and information was retrieved from available published material and websites. Emphasis was paid on examining available source in regards to clarifying EMR characteristics, documenting EMR implementation status in Greece, reviewing work related to EMR adoption levels, and examining factors affecting EMR and EHR adoption.

In the following subsections, EMR characteristics are clarified, and the distinction between the concepts of EMR, EHR, and PHR is further explained. EMR implementation status in Greece, relevant legislation, and plans for the future are presented. Reference is made to the extent that medical files are digitized and interconnected as well as to remaining steps that have to be taken so that full advantage of interoperability is achieved on the road towards the EHR and efficient linking with personal health records (PHRs). The Healthcare Information and Management Systems Society (HIMSS) approach towards establishing EMR adoption levels is examined as well as factors contributing to EMR and EHR adoption.

EMR Characteristics

The EMR consists of electronic copies of medical records produced in a physician's office, a clinic or a hospital. It can include patient, hospital, and healthcare professional details, encounter details, clinical information, diagnoses, medication, operations, treatments, etc. The most important quality EMR systems characteristic is related to access to information in a secure and legitimate manner.

EMRs are meant to create legible and organized recordings and to access clinical information about individual patients and can serve as a data source for an EHR. The EHR is an essential tool for improving both the safety and quality of health care. However, physicians must actively use these systems to accrue the benefits (Ajami et al., 2013). The gains from EHR systems depend on meaningful sharing and rely on access to information regardless of place and time, and from re-using information for multiple purposes (Dobrev et al., 2010; Prey et al., 2016). That results in less time searching for information and more quality time with patients. Improved organisational efficiency and secondary uses of data are typically amongst the most commonly expected benefits (Black 2011). The EHR usually reflects the partial view of a health care provider without the ability for patients to control or interact with their data.

The EMR can be used to compose the EHR and is patient centric. EMRs and electronic health records (EHRs) are used by physicians to improve the quality of care and contain costs. Whereas EMR is usually considered an internal organizational system, the EHR is defined as an inter-organizational system. The EHR is primarily episodic, could be longitudinal, and incorporates administrative, financial, and clinical data. The concept of EHR extends beyond the boundaries of a health care provider and includes the concept of timelessness. Main advantage of EHR is the availability of cross-provider medical information.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The use of EHR requires the presence of a certain user and system attributes, and numerous organizational and environmental facilitators. That is why the EMR in a public hospital cannot be easily shared today among several hospitals. In many cases, this information exchange cannot be made electronically even within the boundaries of a single hospital.

Healthcare providers play a critical role in the adoption and utilization of health IT, including EMRs in hospitals (Cresswell et al., 2015). However, many healthcare professionals, from nurses to ambulatory care physicians, are still reluctant to utilize the available technologies, leading to limited system use and, eventually, system failure (Bowens et al., 2010; Linder, 2006).

Recently, a digital platform for patient-centred medical care known as PHR was introduced, as an enabler for self-management of medical records. PHRs are online systems used by patients, supporting a person-centred functionality, and could be cradle-to-grave. They support the shift from institution-centred care to citizen-centred care, paying emphasis on continuity of care from prevention to management of chronic conditions. On the contrary to EMRs and EHRs, the PHR is not a legal record. PHR enables integration of main information components in the EMR and EHR systems.

EMRs, EHRs, and PHRs can reside on different platforms under various technologies and standards. Although EMRs contain local information and provide fast and accurate delivery, the major advantage of EHR in medical practice is the availability of cross-provider medical information. Medical information integration leads to a dramatic change in personalized care but also poses serious challenges and threats to security and privacy. (Heart et al., 2016).

EMR Implementation Status in Greece

During the period 2000-2006, in the frame of the 3rd Community structural assistance programme, Greece started developing IT solutions for the majority of the –at that time- seventeen Health Regions. More than 60% of the NHS hospitals of Greece were covered by the programme and had purchased integrated information systems to support the regional health authorities they belonged to. These included:

- Enterprise resource planning (ERP) systems to support costing, general ledger, analytical accounting, budgeting, payable accounts, receivable accounts, human resources management, assets management, materials management, supply chain management, funds management, contract management, etc.;
- Patient administration applications for patient management such as admissions, discharge, transfers, bookings, accounts, etc.;
- Medical applications to support all healthcare organization processes related to the provision of medical and nursing care for outpatient clinics, emergency rooms, diagnostic procedures, medical documentation, doctor letters, medical history, order entry management, nursing stations, etc.;
- Laboratory information systems (LIS);
- Radiology information systems (RIS);
- In limited cases picture archive and communications systems (PACS);
- Management information systems (MIS);
- Applications for primary care to support the electronic storage and management of patient data, regarding visits to primary care providers.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, as the development of the "Integrated Information System" for each region was procured separately, they resulted in different systems without interoperability among them, as well as between hospitals belonging to the same health region in several cases. That was further complicated following the merging of the seventeen first health regions into seven, and the (at the moment) ongoing effort to introduce a new integrated information system to support hospitals not financed by the 3rd Community structural assistance programme. In addition, in 2011, the Ministry of Health and Social Solidarity announced its intention to cut back the number of beds and hospitals in the country from 131 hospitals with 35,000 beds to 83 hospitals with 33,000 beds. An attempt to have the archives of patient medical records digitized in 2014 was suspended in 2015.

The latest published information, in regards to hospital digitization status at the Hellenic NHS, is depicted in Table 1 (Hellenic Ministry of Health and Social Solidarity, 2012). It is important to note that almost all hospitals in the country were operating integrated hospital information systems in 2012; even partially. More than 70 hospitals reported operating an EMR for a basic package of medical, nursing and/ or administrative processes, as displayed in Table 1.

Today, despite the positive effects of EMR usage in medical practices, the level of digitization of EMRs in the Greek NHS is not recorded in a systematic manner and progress made is not reported accurately. No conclusion can be reached in regards to hospital EMR implementation maturity level in the NHS hospitals of Greece, apart from the fact that EMR adoption lags behind all other HIS subsystems. Paper still rules in most of the cases, especially as far as access to legacy records is concerned.

Greek eHealth policy (2014-2020) set as priorities the restructuring of primary healthcare, pooling of financial resources, introducing new managerial and administrative methods, adopting cost effectiveness and monitoring mechanisms, and developing policies for better resource allocation. The Ministry of Health (MoH) has the overall responsibility for electronic health (eHealth) in Greece. The development of an electronic patient record is a major objective and a priority of the National Health System (Milieu Ltd and Time.lex, 2013; EU Directorate-General for Health and Food Safety, 2014).

In November 2010 Law 3892/ 2010 put in place the national ePrescription system and the obligation to submit prescription and dispense medications electronically. The law describes duties of doctors and pharmacists, as well as access rights including for patient access to own information.

Table 1. Operation of basic information subsystems in hospitals of the NHS in Greece (as of 2012)

Information System	Full Operation	Partial Operation	Level of Adoption
Pharmacy	131	0	100%
Materials Management	130	1	99%
Patients Accounting Office	131	0	100%
Admissions Office	130	1	99%
Outpatient Clinics Admissions Office	108	11	91%
General Ledger	129	2	98%
Human Resources	69	15	58%
Ward Management – ePrescription	100	12	89%
LIS	81	20	80%
EMR	30	43	41%

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In December 2013 Law 4213/2013, transposing Directive 2011/24/EU (Quinn et al., 2011) in Greece on the application of patients' rights in cross-border healthcare and other provisions, was published.

In February 2014 Law 4238/2014 on the Primary National Health Network placed the responsibility for primary care under the auspices of the Ministry of Health. Following that law, Greece has set the legislative framework for the adoption of an EHR system. Article 51(4) provides for the creation of EHRs for all Greek citizens. It also provides for the inclusion of a minimum patient summary (PS) data set, as well as the responsibility of doctors for the creation and maintenance of EHRs.

During the past few years a multitude of eHealth services have been introduced to support ePrescription for primary care, eConfirmation for insurance status verification, eReimbursement (e-ΔΑΠΥ), electronic booking, and a business intelligence system that is in a position to automatically retrieve operational data to feed the MoH.

Priorities set in September 2016 by the National Council of Electronic Health Governance (Εθνικό Συμβούλιο Διακυβέρνησης Ηλεκτρονικής Υγείας) were the following:

- Creation of the National ehealth Interoperability Framework to support standardized interfaces;
- Creation of an eprescription services framework to support the functional integration of services nationwide;
- Creation of the legal framework for the operation of a national EHR;
- Creation of the National Contact Point for ehealth to support cross-border ehealth services.

At the time, this paper was prepared no national EHR system had been realised in Greece.

The HIMMS EMR Adoption Model

Understanding the performance of EMR in hospitals is a challenge in the health care context, and to that extent, several models have been developed so far (Carvalho, 2016). One of the most prominent models is the HIMSS Maturity Model for EMR used to identify EMR stages of maturity from the limited departmental systems to paperless EMR environment (HIMSS Analytics, 2008). The HIMSS EMR Adoption Model (EMRAM) consists of eight stages, described in Table 2. According to HIMSS Analytics, the structure of this model ensures that a stage is reached only when all their applications are operational. Every level is described in terms of its requirements.

HIMSS facilitates the development of IT solutions for healthcare mostly in order to systematically improve its quality, safety, and efficiency. The vision includes the creation of mutually interconnected and harmoniously co-functioning EMRs of patients which would connect distinct entities on the market and service providers.

EMRAM is a certification method that makes an assessment of maturity and degree of implementation of EMR possible and it has acquired worldwide recognition. The programme is a reference point for improving the level of implementation of IT solutions, and for moving away from medical documentation on paper to electronic medical documentation. If the percentage of health units belonging to each of these levels is monitored in a systematic manner, then it is possible to measure the progress being made on the road towards the full paperless hospital. That already happens in Canada and the US (Garets et al., 2006; HIMSS Analytics, 2008).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. The EMRAM reference system determines the level of EMR implementation in a healthcare organization (i.e. a hospital) in a scale from 0 to 7. Level 7 corresponds to a fully-paperless hospital (i.e. all patient records are kept in electronic form). That enables the managers of such establishments to see what level they are on and what steps they would have to take to improve their score.

Stage	Cumulative Capabilities
Stage 7: Complete EMR, Data Analytics To Improve Care	The hospital no longer uses paper charts to deliver and manage patient care and has a mixture of discrete data, document images, and medical images within its EMR environment. Data warehousing is being used to analyse patterns of clinical data to improve the quality of care and patient safety and care delivery efficiency. Clinical information can be readily shared via standardized electronic transactions (i.e. continuity of care document) with all entities that are authorised to treat the patient, or a health information exchange (i.e., other non-associated hospitals, ambulatory clinics, sub-acute environments, employers, payers and patients in a data sharing environment). The hospital demonstrates summary data continuity for all hospital services (e.g. inpatient, outpatient, emergency department, and with any owned or managed ambulatory clinics). Blood products and human milk are included in the closed-loop medication administration process.
Stage 6: Physician Documentation (Templates), Full Clinical Decision Support Systems (CDSS), Closed Loop Medication Administration	Full physician documentation with structured templates and discrete data is implemented for at least one inpatient care service area for progress notes, consult notes, discharge summaries or problem list & diagnosis list maintenance. Level three of clinical decision support guides all clinician activities related to protocols and outcomes in the form of variance and compliance alerts. The closed loop medication administration with the bar coded unit dose medications environment is fully implemented. The electronic medication administration record application (EMAR) and bar coding or other auto identification technology, such as radio frequency identification, are implemented and integrated with computerised practitioner order entry (CPOE) and pharmacy to maximise point of care patient safety processes for medication administration. The "five rights" of medication administration are verified at the bedside with the scanning of the bar code on the unit does medication and the patient identification (ID).
Stage 5: Full radiology PACS	A full complement of radiology PACS provides medical images to physicians via an intranet and displaces all film-based images. Cardiology PACS and document imaging are scored with extra points.
Stage 4: CPOE; Clinical Decision Support (Clinical Protocols)	CPOE for use by any clinician licensed to create orders is added to the nursing and clinical data repository (CDR) environment along with the second level of clinical decision support capabilities related to evidence-based medicine protocols. If one inpatient service area has implemented CPOE with physicians entering orders and completed the previous stages, then this stage has been achieved.
Stage 3: Clinical Documentation, CDSS (Error Checking)	Nursing/clinical documentation (e.g. vital signs, flow sheets, nursing notes, EMAR is required and is implemented and integrated with the CDR for at least one inpatient service in the hospital; care plan charting is scored with extra points. The EMAR is implemented. The first level of clinical decision support is implemented to conduct error checking with order entry (i.e., drug/drug, drug/ food, drug/lab conflict checking normally found in the pharmacy information system). Medical image access from PACS is available for access by physicians outside the Radiology Department via the organisation's intranet.
Stage 2: CDR, Controlled Medical Vocabulary, CDS, health information exchange (HIE) Capable	Major ancillary clinical systems feed data to a CDR that provides physician access for reviewing all orders and results. The CDR contains a controlled medical vocabulary and the clinical decision support/rules engine (CDS) for rudimentary conflict checking. Information from document imaging systems may be linked to the CDR at this stage. The hospital may be HIE capable at this stage and can share whatever information it has in the CDR with other patient care stakeholders.
Stage 1: All Three Ancillaries Installed - Lab, Rad, Pharmacy	All three major ancillary clinical systems are installed (i.e., pharmacy, laboratory, and radiology).
Stage 0: All Three Ancillaries Not Installed	The organization has not installed all of the three key ancillary department systems (laboratory, pharmacy, and radiology).

Understanding the level of medical records digitization within a health unit is a colossal challenge for Greek hospitals. Today, very few hospitals have EMR solutions that can effectively reduce medical errors or improve the quality and efficiency of patient care. The EHR can be established only if the EMRs of the various care delivery organizations have evolved to a level that can create and support a robust exchange of information between the involved stakeholders.

Factors Contributing to EMR and EHR Adoption

It is commonly agreed that information contained in the EHR is critical to support clinical care and the longitudinal EHR is of high value. Still, it must be collected and assembled from multiple sources, and this is particularly challenging. The assembly of quality, semantically meaningful and consistent data has been until now almost impossible, and this is the reason why so many efforts are made towards developing EHRs.

Since health information is regarded by many as being among the most confidential of all types of personal information (Fernández-Alemán, 2012), security concerns are considered to be one of the main reasons behind resistance shown to widespread EHR adoption (Boonstra et al., 2014). From the physicians' perspective, concerns regarding privacy and confidentiality have been found to hinder physicians' acceptance and EHR adoption, demonstrating how these issues can impact EHR use that extends beyond patients' reservations (Ben-Assuli, 2015).

In the past three decades, several studies have extracted antecedents to the user adoption of health information systems. According to (Najaftorkaman et al., 2014) factors contributing to the user adoption of EMRs are classified in eight categories: individual factors, psychological factors, behavioural factors, environmental factors, organizational factors, financial factors, legal factors, and technical factors. Training is also considered to be a critical part of EMR implementation and, as reported by (Nechyporenko et al., 2015), to perform it appropriately, an educational approach should be developed individually for each specific hospital facility.

However, knowing these factors do not necessarily lead to successful implementations unless the unique characteristics of the implementation environment are examined in relation to these factors, and particular attention is paid to encouraging and facilitating change. Implementation must be carefully coordinated and appropriately planned for the production of outcomes acceptable to the stakeholders involved. Organizational issues must be considered with caution, and the appropriate political support must be in place to decisively resolve outstanding issues.

RESULTS – EMR CHALLENGES IN GREECE

Although the majority of the hospitals of the NHS in Greece has acquired EMRs, the actual utilization of the investment made is still kept low. As already described there is no published evidence on how the EMR adoption level is progressing in Greece during the past few years. The latest published material comes from 2012.

While the EMR has many useful features to help optimize health care processes, some healthcare professionals find the whole system too complex and feel that they could provide excellent care to patients, even without an EMR. Others do not possess the financial resources to start efficient EMR use as they do not even know where and how to profile available systems to their individual needs. When applied correctly, the EMR serves as a very useful tool for maintaining critical medical information and increases the efficiency of workflows. That said, there are a number of challenges that must be overcome if one wants to reap the full benefits of EMRs.

Key challenges and concerns in Greece are related to linking with the workflow (lack of systems interoperability, this hinders successful adoption causing resistance to change), making best use of the champions (non-financial incentives are equally important to clinic staff as financial ones), and post

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

implementation follow up and support (financing the transition and sustainability model) to secure the way forward. The following sections focus on these factors that need to be taken into consideration towards effective exploitation of EMRs in the hospitals of the NHS in Greece.

Link with the Workflow

Usually, hospital infrastructures are closed networks restricted for administrative and clinical support. In order to support integrated workflows, it is vital that health IT systems adopt nationally accepted data standards that facilitate semantic interoperability. Besides the need for having established a national infrastructure, all relevant legal and regulatory enablers should need also be put in place as well.

Data entered once, used anywhere is the key concept. That requires fully interfaced ICT solutions in a stable and standardized manner. Fundamental principles to follow include the exploitation of available open standards and best practices, the adoption of an interoperability framework tailored to national needs, and implementation based on planning. This will allow for the development of quality EMRs, the development, maintenance and evolution of a scalable, secure, and affordable infrastructure to support incremental evolution building upon existing systems, while adding new capabilities as they become available. Issues related to usability and efficient linking with the workflow shall, therefore, need be addressed.

Today the means for establishing patient identification in Greece is based on AMKA, which is the social security number issued in the country. Common national identification approach should be followed in line with European Regulation (EU) No 910/2014, commonly known as eIDAS (Melin et al., 2016). In the future, a combination of national identity providers may provide the means towards proper end user authentication for EMRs.

Trust and security is a critical area in which healthcare presents demanding and challenging needs. IT security in healthcare systems, services, and applications is positioned as a major concern due to the high privacy and confidentiality requirements of sensitive healthcare data (ENISA, 2015). Private data needs to be accessed by professionals having a qualified role, with the consent of the patient and under strict audit controls. Medical data must only be disclosed or shared after the patient is identified and authenticated with sufficient accuracy.

In order to enable workflow automation for the effective sharing of clinically significant information EMR data will have to be shared with well-defined processes, EMRs must contain reliable content, and use agreed semantics, i.e. common terminology. That is expected to effectively facilitate, amongst other, organized referrals, e.g. from primary healthcare to hospital physicians.

Efforts are currently made towards that direction by the MoH for the creation of the National eHealth Interoperability Framework to support standardized interfaces which is expected to focus not only at a cross-border, national, or regional level but also within certain healthcare organizations (i.e. hospitals) and also to provide for reaching citizens at home, based on certain use cases. This ecosystem of services has the potential to tackle longstanding HIS challenges and open new avenues for research (Koumaditis et al., 2015). This is a strategic approach that needs to be further supported at all levels starting from technical, to semantic, to organisational, and all the way to legal. This effort should be aligned with available best practices, current experience, and available standards (eHealth Network 2015; European Commission, 2015; European Commission, 2017).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Make the Best Use of Champions

At the individual level, human factors play a major role in the design of an intervention, determining usability and ultimately adoption, despite the fact that organisational issues are critical in a strategically planning deployment that ultimately influences adoption (Greenhalgh et al., 2004).

Innovative technologies alone cannot lead to revolutionary changes. What is needed is cultural transformation and a new healthcare providers' cooperation model that does away with existing information silos. EHRs should not be looked as a side-process or administrative tool, but rather as an inseparable part of the health care process. Although it is the physician and the payer that frequently control the type and quality of care patient receives (Petru, 2016), implementing the smart hospital vision requires considering continuous adaptation, clinical outcome, efficiency in the supply chain and care processes and enhancement of own capabilities in regard to patient services (Kharbanda et al., 2017). Qualified human resources are a key ingredient for success. Education, training and continuous professional development for all, including for those citizens and patients which are capable and motivated to become engaged in their own care, should be strongly promoted (Stroetmann et al., 2011).

An important factor influencing user adoption is user confidence. Professionals should be encouraged with a clear motivation system and an explicit presentation of realistically envisioned benefits. Effective communication can facilitate engagement and acceptance. Individual initiatives should not be rejected, but if they meet certain quality criteria should be exploited to become part of the solution.

Finance the Transition and Sustainability Model

Quality and secure EMR deployment do not come without cost. Both initial costs, as well as the extra expenses to support personnel and operation of such systems, should be taken into consideration (Iakovidis, 1998). Without the right stimulation, hospitals will not be interested in improving their EMR-related competence (Hoyt, 2016). As already been suggested by (Fragidis et al., 2011), Greece needs to invest significant financial resources and work towards standards creation in order to gain the benefits of EHR for its citizens in the near future. Funding should be provided and assured, while responsibilities for sustainability should be clearly defined.

As far as Greece is concerned investments for initial acquisition and setup have already been made, as described in previous sections. Adoption level is still low, and no uniform way of evaluating and establishing comparable service level agreements with vendors providing technical support are in place. Without a considerable, coordinated effort, which will likely include realigning financial incentives, EHR adoption in hospitals will lag behind. That will have to be combined with the quality of care incentives in order for the EMR adoption to be successful. Nevertheless, these investments are unlikely to pay back unless end-users, healthcare providers and patients alike, endorse them. As already noted by (Berg, 2001), the success of any technological healthcare innovation will be eventually decided on the work floor.

DISCUSSION

Very often medical personnel in hospitals is called to support a clinical decision on top of missing or incomplete information. Diagnosis is mostly based on medical history, but medical histories may be incomplete in each EMR system and patient information dispersed in a manner that cannot be easily

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

assembled. Medical personnel spend significant time in search and re-entry of information. Today there is much physician dissatisfaction with EMRs due to poor usability, and it is not unreasonable to think that improving physician satisfaction with EMRs may also improve patient satisfaction (Kanter, 2016). Performing quality analysis on EMR implementation by capturing consumer expectations using multi-dimensional research instruments such as SERVQUAL (Parasuraman, 1988) may provide valuable insights in regard to the dimensions that are related to service quality gap when it is applied to different settings.

Ongoing work at an EU level seeks to create a common set of standards to embrace the national diversity and facilitate interoperability. Electronic prescribing is considered to be one of the major reasons for the push for EMRs. Large-scale deployment of cross-border ePrescription and PS services are expected to actively refine and improve already available software infrastructures in order to support patients' rights effectively in cross-border healthcare (Katehakis et al., 2017). In the case of PS, both patient and health professional may have access to the person's PS and other relevant documents as smoothly as at home. Top-down pressure call for integrated EMRs. On the other hand, EU member states need to be open and flexible in the design of joint solutions and to be able to ensure the implementation of the decided solutions nationally.

Patients are the ones who are expected to benefit most from the use of EHRs. For this to happen EMRs must be in a position to interoperate with each other. EMRs should be trustworthy, trusted, and usable for their purposes while individual patient health data should be reused. EHR is based on patient consent and requires security standards to create a sense of security and reliability. Implementations should follow modern approaches and provide technical measures that safeguard the privacy and confidentiality of the patients' EMRs, compatible with relevant data protection and confidentiality laws. The outcome should be acceptable to the medical community. The foreseen introduction of a new identity in Greece, encompassing digital features (like e.g. for digital signing), is expected to act as an enabler for safer EMRs.

The EC and the Member States together already explore cooperation opportunities in the wider eGovernment field on topics like ID management, secure infrastructures, data protection, access rights, thereby also avoiding the duplication of efforts while at the same time work on facilitators to boost evolution. The recently introduced General Data Protection Regulation enshrines a wide range of existing and new rights for individuals in respect of their personal data (The European Union, 2016). These include the right to be forgotten, the right to request the porting of one's personal data to a new organisation, the right to object to certain processing activities and also to decisions taken by automated processes. According to (ENISA, 2015) member states need to implement widely accepted security standards to achieve interoperability, while trustworthiness should be the responsibility of the country (i.e. national and/ or regional authorities). EHRs must protect both patients' EMRs and physicians' integrity.

Major challenges are likely to include continuing debates surrounding security issues (i.e. breaches of confidentiality that may lead to an erosion of confidence in the healthcare system, changing the way individuals interact with the system) and the capacity to meaningfully analyse data that become available (i.e. EMR data quality). According to (Accenture, 2016), for the majority of EHR systems, consumers believe that the benefits of sharing medical information electronically outweigh the risks. To them, effective treatment is the top priority. Social networking tools already enable patients to find each other, support each other, learn from each other and help each other to take decisions. All this happens outside of the healthcare system (Pitsch, 2016). From the perspective of patients, it is evident that solutions for sharing medical information electronically are needed.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

We will not be able to build the EHR unless the EMRs generated and maintained by physicians are put together. Key actions that need to be taken on the way towards quality EHRs are the following:

- Establish a national interoperability framework and let EMRs interoperate with each other and with EHRs. Widespread adoption by physicians will require the EHR system to make their professional lives easier, not more complex, and will need to provide a clear benefit to their clinical activities. To do this implementation should be meaningful and based on appropriate technical characteristics and common implementation standards to facilitate the improvement of data quality;
- Raise awareness. Expose best practices. Inform everyone that EMR systems are available. Meet expectations. Provide guidelines and resources for quality and secure enablement. Use incentives for motivating EMR adoption and use;
- Professionally establish robust eHealth services by financing standardization and quality assurance. Establish a way to monitor and control progress. A balance between long and short-term objectives should be maintained. The magnitude of the investment needed should not be underestimated if the EHR implementation is to be successful.

CONCLUSION

Our ability to connect places where healthcare is provided and sharing of medical data is expected to close the gap that traditionally limits the provision of high-quality health services. EMR is the cornerstone for providing content to evolving eHealth services. Yesterday this information was kept in a medical file closed in a doctor's cabinet, today it is processed by clinical decision support systems and tomorrow it will be analysed by artificial intelligence systems to support effective disease management and decision support. Semantic interoperability, when achieved, is expected to improve quality, safety, efficiency and efficacy of healthcare delivery. If we want to improve the health of the population, we need quality and secure EMRs.

The effort has to be paid towards giving meaning to the EMR systems already available at the Greek NHS. That will require gradual implementation based on planning as well as the evolution of the already existing infrastructure. The focus should be paid on operation and interconnection of individual EMRs as well as standardizing quality, in line with international practices. To this extent, effort will be required towards testing, certification, and application. At the same time, the development of comprehensive policies for privacy, consent management, and access to EMRs and the EHR will be required, together with the corresponding legislation and participation encouragement.

By building on existing human effort and experience and already available infrastructure, the significant funding that will be required can be controlled better. By having the entire EHR available, it will be far more possible to tailor medical care to each individual's clinical needs and empower healthcare professionals and citizens to take informed decisions. Furthermore, health IT will enable improved clinical outcomes, while at the same time benefit global research and science.

Chapter 73
Ethics of Electronic Health Record Systems

Brian J. Galli
Long Island University – Post, USA

ABSTRACT

This article describes how healthcare and IT are combatting the ethical implications of electronic health records (EHRs) in order to make them adopted by over 90% of small practices. There is a lack of trust in EHRs and uneasiness about what they will accomplish. Furthermore, security concerns have become more prevalent as a result of increased hacker activity. The objective of this article is to analyze these ethical issues in an effort to eliminate them as a hinderance to EHR implementation. As of now, 98% of all hospitals use EHRs. Between 2009 and 2015, the government allocated money and resources for incentive programs to get EHRs into every healthcare providers' office. During this time period, over $800 million dollars facilitated EHR implementation. Using this as a tool EHRs negative perception can be revitalized and combated with the meaningful use program. This article will highlight the ethical implications of EHRs and suggest ways in which to avoid them to make EHRs available in every healthcare provider.

INTRODUCTION

Information technology (IT) and systems (IS) are now very well integrated into aspects of today's society. The various technologies and systems that deal with an abundance of information yield great power, but also raise various issues. Unfortunately, many people exploit technology for personal gain, at the cost of others. This technology element makes ethics an extremely important aspect in IT.

Ethics in IT, also known as information ethics, concentrates on the creation, control, and use of information technology, and how it relates to the principles that govern society. The best practice to prevent technology misuse is to instantiate standards that avert such issues.

Creation is the development process that a technology employs. This can be the development of a new product or the implementation of an IS or IT. Project management is the most important aspect of creation. If the team doesn't utilize good tactics, they may overlook harmful issues. Control relates to the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

software or technology distributor, maintenance of an IT or IS, and information management. Control focuses on ethical codes, legal or implied, that employees follow.

The final aspect is the use of IT or IS. Users cannot abuse privileges, especially if it is access to trade secrets or personnel files. Similar to control, use has a foundation in the company's code of ethics and corporate environment. Ethical breaches lead to legal, financial, and social difficulties. When a new IT or IS introduced, ethical implications arise concerning creation, control, and/or use; it is crucial to comprehend what ethical implications may arise.

The paper is organized as follows: the background section presents the needed foundational knowledge on the subject matter; it also presents the objective of the study. The research methods section presents how the methods used to identify and analyze the articles that served as the basis for achieving the objective of the study. The findings section outlines the analysis and findings from the execution of the research methods. The next section presents the discussion of the findings and analysis executed from the study; it also presents recommendations that should be used when applying ethics and EHRs in project/IT environments. The final section outlines the general conclusions and potential next steps as a means to close out this research study.

BACKGROUND

The healthcare industry must address all ethical implications in technology since it deals with highly sensitive information. As a result, a culture of ethical practices and standardized processes is nurtured. Electronic Health Record (EHR) systems are one technology that complies with ethical standards because of the way in which it handles patient information (Waegemann, 2003). Waegemann (2003) explains the purpose of EHR systems:

The concept of an EHR--electronic storage and instant availability of information to authorized practitioners--is often combined with the advantages of an electronic healthcare system, including enhanced access to medical information and greater efficiency. EHR promoters even claim that full access to health information might bring cures for certain diseases, such as AIDS. Healthcare is getting more complex every day. Today, multiple specialists are involved in most patients' healthcare, and paper records cannot keep practitioners completely informed. (p. 1)

EHRs play a pivotal role in keeping practitioners informed and connected. Its data can be collated and analyzed on a grander scale, thus enabling researchers to view and create trends about various health issues. It wasn't until recently that EHRs became more widespread and accepted. According to Tripathi (2012), EHRs have undergone vast transformation in the past 50 years. Predecessors to EHRs existed in the 1960s and early '70s. In the 1990s, the modern EHR came into fruition and practice. EHRs were slowly implemented because a lack of standardization in the market and little motivation from providers (Waegemann, 2003).

In 2009, EHRs experienced a substantial boom in innovation and adoption as a result of the Health Information Technology for Economic and Clinical Health (HITECH) Act (Tripathi, 2012). The HITECH Act contains a provision entitled the American Recovery and Reinvestment Act (ARRA), which add an incentive program and funding assistance to eligible facilities (CMS, 2016). Both HITECH and ARRA "motivated a fragmented customer base to act more like a single customer with coherent demand," thus

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

setting the stage for market standardization (Tripathi, 2012). Even with such changes, it is challenging for HER benefits to become more widespread. EHRs face ethical implications in healthcare and information technology, as discussed in the proceeding sections.

Study Objective

Healthcare faces important ethical questions because of the strict standards guiding the industry. Based on Figure 1, of all the hospitals that are eligible for assistance through HITECH, 98% demonstrated meaningful use of health IT and/or EHR implementation (Tripathi, 2012). Office-based health care professionals implementing EHRs experience more concern in maintaining and/or implementing EHRs.

As it is seen in Figure 2, only 57% of office-based health professionals use health IT and/or implement EHRs (Anderson, 2007). This affirms the notion that there is more concern in maintaining EHRs in office-based locations. Juxtaposed to the 98% of hospitals, there is an implication that either office-based healthcare professionals don't rely on the advanced patient information management an EHR provides, or there are roadblocks preventing them from implementing. Such roadblocks can translate to various ethical issues, as this paper suggests (Waegemann, 2003).

Office of the National Coordinator for Health Information Technology. (2016, February). 'Hospitals Participating in the CMS EHR Incentive Programs,' Health IT Quick-Stat #45. dashboard.healthit.gov/quickstats/pages/FIG-Hospitals-EHR-Incentive-Programs.php.)

Some ethical issues can have a positive impact, such as finding and correcting care inequalities across racial or gender lines. Another positive implication is to more accurately diagnose illnesses via collective data. However, there are also negative ethical implications. This paper will review the clouded ethical nature of EHRs and Health IT by analyzing contested issues, positive and negative, surrounding EHRs and key ethical principles. Before advancing to the findings in this research, it is important to comprehend what research methods were implemented.

RESEARCH METHODS

In order to perform a study on this topic, a systematic literature search (traditional narrative review) was performed. The traditional narrative review synthesizes the primary literature and explores potential heterogeneity. In this study, the review helped perform a literature review on the current fields of study and identify the potentially valuable pieces.

The traditional narrative review involved searching for literature in a 10-year window due to the main reason that EHR systems have become more prevalent in the last 10 years with the advancement in technology in the medical/healthcare field. A previous investigation into this topic also revealed that most studies into ethics of electronic health records have occurred in the previous 10 years, which added justification to looking back 10 years.

Our study's search strategy, following Stuck et al. (1999), consisted of three stages: first Scopus, ISI, Elsevier, and other universal research databases were used; second, we checked the references in existing articles; third, we asked experts for their recommendations. To run the queries within the online databases, keywords and phrases were explored (note: no filters were used and all combinations of keywords and phrases were considered). Our systematic search was conducted using selected general keywords (including: Ethics, Electronic Health Record, Healthcare, Information Technology, Information Systems).

Executing the searches returned 60 pieces of literatures (N = 60). We ended the search at saturation point - in other words when, combining the different keywords and adding new ones, we obtained articles already selected. To filter this large swath of literature, a meta-analysis was performed to filter out and identify the critical pieces. Furthermore, the meta-analysis was valuable in identifying potential gaps. Meta-analysis is a technique to aid going more in-depth into previous research. It is a systematic

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

method for combining relevant quantitative and qualitative data from different studies to develop one conclusion with greater statistical power. The meta-analysis conclusion is statistically stronger than the analysis of any single study because it incorporates an increased number of subjects, more diversity, and accumulated results.

From the original pieces of literature, the databases and searches were performed again using the authors' names. Using a search filter refined this analysis; the aim of a search filter is to unearth information of interest from a database. A simple filter for a query consists of single or combined words entered into the search parameters. Within search parameters, Boolean algebra is used to form relationships to further refine the output of query requests. The most commonly used Boolean functions are "AND", "OR" and "NOT."

For search filter development, two aspects need to be considered and balanced. They are sensitivity and precision (Taylor et al. 2003; Popay et al. 2004; Vaughan, 2004). Sensitivity is the ability of a filter to find all relevant material in the database, while precision is its ability to reject irrelevant material. A filter with a high emphasis on sensitivity will tend to include less and irrelevant material whereas a higher precision will more often reject some potentially relevant information. That is why it is crucial that both aspects be balanced to ensure that valuable information is not filtered out, but also so that irrelevant information is not filtered in.

The study investigator's approach was to develop a filter with a high level of sensitivity and then make further adjustments towards a desirable precision. Important material search listings obtained from early versions of the filter were examined. Then, common and key terms within this material (and in relevant cited literature) were incorporated to develop the filter's sensitivity. It was made sure that the filter incorporated a wildcarding of some terms.

From the precision perspective, examining common categories of irrelevant material returned by the more developed filter made the precision adjustment. After additional experimentation, the structure of the filter was adjusted based on the usage and placement of the "AND" operator and bracketing of the "OR" function. In practice, the combination of the specific requirements linked by the "AND" operator largely excluded irrelevant material to a workable level. For this study, the search filter included an "AND" relationship and "OR" (with brackets) to search for keywords and phrases. The filter developed specifically for this study was then applied to the search parameters of each database utilized in the initial search.

After literature was identified from the first set of queries, it was possible to examine the reference sections of each identified study. Therefore, more related studies are found. In some ways, the filter results demonstrated limited success in finding relevant materials in the wider gray literature. Gray literature is any material that is not commercially published. It includes working papers, business documents, government reports, educational reports, institutional reports, dissertations, technical reports, and conference proceedings. Gray material is found through manual searches, involving examination of reference lists from relevant studies obtained in searches, qualitative studies, relevant journals, books, and articles. This involved manual examination of relevant journal indexes.

Manual searching incorporates general and technical oriented Internet search engines and databases. Some include Google, British Library, US Library of Congress, Yahoo, and National Technical Information Service. As a final measure of robustness, to add in the systematic review of the available and relevant material, based on critical literature obtained, the study utilized direct correspondence with authors identified from the above processes. In so doing, additional information and studies could be noted to further support the objective of this paper.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Overall, the meta-analysis helped reduce N of 60 relevant studies to a more condensed and rich sub-sample size of 35 pieces (n=35), with 58.3% of the total literature found. From the papers identified, to further identify the themes and concepts that are presented in this paper, textual analysis was performed. This is a method used to describe and understand the traits of the 35 papers identified from the research literature review. A textual analysis enabled mapping and describing the content, functions, and structure of the literature identified.

Within the context of textual analysis, one of the common methods used is known as content analysis, in which a researcher used the literature to identify, process, enumerate, and analyzes specific themes and specific messages as well as message characteristics embedded in these texts. In this study, both qualitative content analysis (i.e. the meanings associated with messages as well as the number of times message factors occur) and quantitative content analysis (a systematic and step-by-step procedure that is used to address research questions/test hypotheses) were utilized.

Once qualitative and quantitative content analysis tools were complete, the results were categorized into specific themes and patterns through the use of affinity diagramming (a tool to organize ideas in a logical manner). The results of the affinity diagramming served as the basis for the themes and sections outlined and discussed throughout the paper. From the filtering and affinity diagraming process, the 35 articles were further reduced to 20 that studied the scope of the factors under scrutiny.

We limited our study selection to works that clearly explore the relationship or associations between the variables in the scope of our work. Amongst them, only the studies that provide sufficient information to assess a causal relationship between the factors being studied were included. Furthermore, we decided to exclude papers that did not explore the association between the factors being studied; the reason being that in these papers do not seek to understand any of the relationships or causal impacts as well as casual factors between the variables being explored in the study. These papers/studies would not measure/study the effect that our research study sought to explore.

At the end of this next-phased selection and filtering process, we came up with a reduced set of 20 papers on the variables being explored in the study. Some authors presented an analysis of more than one independent sample or studied more than one transition in the same paper. These estimates were treated as independent and were all included into our analysis. We accepted the estimates from final models only. When the same author published two papers using the same dataset and the same model specification, an average estimate was calculated based on the reported outcomes. However, when the same dataset was used, but a different model was estimated, we included both estimates in order to avoid the possibility of a study selection bias.

Overall, the selection of studies began with an N of 60 potential articles that could be used in this research. But the complete search procedure gave our study a total of 20 (33.33% of the of original population of selected papers) papers/studies that previously explored the variables being explored in the study. Thorough review of the 20 identified papers/articles showed that these pieces of literature varied in the focus and depth of the study of ethics in relation to healthcare and IT.

From a descriptive and trait perspective, the compilation of these papers showed that the relation of ethics in the area of healthcare and IT involved three major themes/traits, those being: organizational, legal, and ethical principles. The 20 studies/papers identified for this paper are categorized based on theme below in Table 1 (note: some studies overlapped into more than one category based on the research it pursued, but each study was categorized into 1 theme that best describes the study). Table 1 shows the categorization and frequency of each of the three themes/traits identified from the research execution.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Meta-Analysis Results by Identified Category

Category	Number of Articles (Frequency)	Article/Paper Authors
Organizational	8 (40% of total articles)	Ozair et al., 2015 Tripathi, 2012 Menachemi & Collum, 2011 Anderson, 2007 Taylor et al., 2003 Popay et al., 2004 Vaughan, 2004 Kazley et al., 2014
Legal	7 (35% of total articles)	Waegemann, 2003 CMS, 2016 Stuck et al., 1999 Palvia et al., 2015 Reynolds, 2015 Health IT, 2015 Cortelyou-Ward, Noblin, & Martin, 2011
Ethical Principles	5 (25% of total articles)	Ben-Assuli, 2015 HHS, 2015 Hodge et al., 1999 Layman, 2008 Noblin, Cortelyou-Ward & Ton, 2011

From a relational and causal perspective, review of the 20 identified papers/articles indicate that these pieces of literature analyzed ethics and healthcare and IT with different statistical methods (some not at all) as well as in depth of the study, especially in the scope of the amount of variables/factors explored in the study. The use of statistical analysis and exploration of different variables/factors in these studies helps to add value and depth to the conclusions drawn from our research study.

Table 2 presents a summary of the statistical methods the 20 studies used in their research. Table 3 presents a summary of the number variables/factors studied in each of the 20 studies, which shows the depth that the study explored.

The next section presents the findings of the research methods in the scope of these major traits and from the statistical methods used to perform the previous studies.

FINDINGS: ETHICS IN HEALTHCARE AND IT

Ethics is a set of moral actions that a group adheres to. It is applicable to healthcare and IT. To avoid confusion as to what the accepted right and wrong behavior is, codes, standards, or laws will define right and wrong for perceivable situations. In order to understand ethical issues concerning EHRs, ethics ought to be broken down further into the following characteristics: organizational, legal, and ethical principles.

Organizational

One of the largest bodies with the most influence over EHR implementation is the government. While other bodies come close to this influence, after 2009, the power shifted from the market to the government. The power shift was due in part to the Health Information Technology for Economic and Clinical

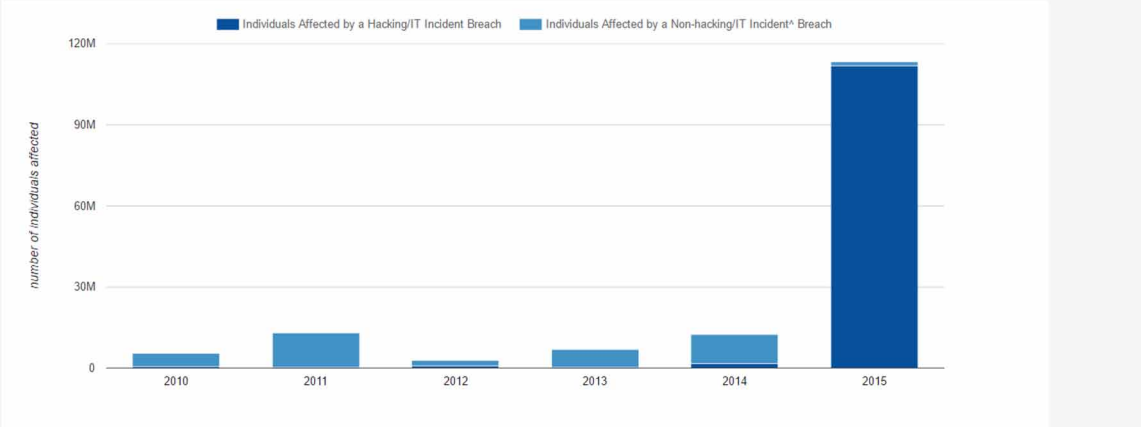
Health Act (Ben-Assuli, 2015). This was not an unethical act intended to disenfranchise involved parties. The government merely noticed that EHR would become a future necessity. However, there was a lack of motivation to make it a priority because, despite the benefits, implementation is time consuming and costly (Ozair et al., 2015).

The HITECH Act instantiated a program through the CMS that would incentivize healthcare providers to get on board with EHRs. This, in addition to getting 98% of hospitals on EHRs (according to Figure 1), helped move the market towards standardization (Tripathi, 2012). HITECH, and its child act ARRA, set requirements that healthcare institutions comply with. In order to qualify for and get compensation, the EHR system must meet certain criteria that are indicative of standardization, according to the acts (Menachemi & Collum, 2011).

Prior to HITECH, EHR developers implemented their own systems that were not linked with each other. Furthermore, there were no security standards to protect against millions of security breaches each year (see Figure 3). The EHR vendors, only after the government intervention in 2009, began working in a more concise manner to find solutions and build security that facilitated different systems to work together (Kazley et al., 2014). Prior, there was a "lack of ability to exchange clinical data with laboratories and hospitals," and this proved to be "a major barrier for smaller physician practices" because while hospitals have their own facilities, it is hard for small practices to get access to the facilities (Anderson, 2007). Anderson (2007) suggested that a solution to sharing barriers is to certify vendor EHR programs. Such a solution requires a form of standardization, which HITECH creates.

Another issue vendors caused was the "cost barrier," which dissuaded small practices from adopting EHR systems in the first place (Anderson, 2007). There is viable good solution for this issue, since vendors allocate resources to create a product and expect to be paid for it. It is hard to discern if the costs are overpriced, because vendors get away with such a grey area. HITECH and other initiatives have invested around $800 million toward EHR adoption since 2009, which has since then grown (Palvia, Jacks, Brown, 2015).

Figure 3. Breaches of Unsecured Protected Health Information. Number of individuals affected by protected health information breaches: 2010 – 2015



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In spite of the increased spending and governmental initiatives, many healthcare providers are still reluctant to adopt EHRs. This lack of urgency is attributed in part to the issues encountered at various stages of the implementation process in an organization (Palvia et al., 2015). Based upon Figure 2, while there have been significant increases in hospital adoption of EHR, this is not reflected in small clinics, because of implementation.

Many issues stemming from the implementation process include the stakeholder not feeling aligned with the benefits of the EHR. It is possible that stakeholders will back out and not adopts implementation (Palvia et al., 2015). The lack of urgency to adopt EHRs comes from the stakeholder's tendency to not be involved in the implementation process. They ought to be more involved. The lack of involvement can provoke a disconnect between the stakeholder and the EHR system. It is important to note that the stakeholder's perception of the systems use influences their desire to remain involved. Stakeholders' genuine interest is imperative for successful adoption.

Finally, something that is a potential point of contention between the vendor and the stakeholder incorporates security and privacy of the EHR system (Waegemann, 2003). Organizational characteristics in hospitals and smaller healthcare facilities have an impact on the adoption and implementation of EHRs. It raises similar ethical implications to the proceeding characteristics.

Legal

Ethics pertaining to legal issues are prevalent in healthcare on both the medical and vendor or IT side. Malpractice and negligence are unfortunate occurrences to be dealt with, which decreases the interest of facilities to pursue EHR implementation. When an EHR is installed, negligence can occur in two ways. The IT professional may improperly implement a part of the system, causing extended downtime or file corruption. If this is not a breach of duty to care, then it is not legal negligence (Reynolds, 2015). However, mistakes such as this one maintain a measurable impact, especially on the project management team or process. If the offending party is brought to court and the act is ruled a breach of duty to care, and then there are potential legal ramifications for the individual and company (Anderson, 2007).

The second issue in which negligence may occur is after an EHR is installed. If it is not properly maintained and updated, maintenance issues may surmount (Menachemi & Collum, 2011). The risk of losing patient files or having a security breach is more prevalent because of this form of negligence. This is one of the barriers and reasons that many practitioners in the healthcare industry may not trust EHR systems.

Another issue that EHR systems face is reliability, which is especially true in facilities with heavy involvement in emergency situations (Menachemi & Collum, 2011). EHRs need to be quality, safety-critical systems since they handle sensitive information that relates to life or death situations. Neglecting to design and implement safety-critical systems is not permissible. Instead, the facilities ought to use special development methodology to ensure the system is within acceptable risk factors and that vendors are protected for liability (Reynolds, 2015).

EHRs produce various implications for medical professionals. The EHR documents information without prejudice. Therefore, if a medical staff member makes a mistake, liability of the staff member and the entire facility are increased (Ben-Assuli, 2015). It is possible, however, that with EHRs, staff member will make less mistakes, thus reducing the number of malpractice claims. It is deemed that "this reduction is potentially the result of increased communication among caregivers, increased legibility and completeness of patient records, and increased adherence to clinical guidelines" (Menachemi

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Collum, 2011). Medical staffs are held accountable for their actions, regardless of their facility or resources. With EHRs, their accountability remains, but there is a level of forgiveness for human error, because the system can catch innocent mistakes before causing issues.

In the healthcare industry, privacy is a crucial domain. Patient-physician confidentiality is one of the most prominent aspects of healthcare privacy, in which a doctor will not, and cannot, reveal patient information. EHRs must ensure that patient privacy is maintained. EHRs are generally quite secure, and personal medical information is only accessible by authorized practitioners (Kazley et al., 2014).

The Health Insurance Portability and Accountability Act (HIPAA) of 1996 promote the compliance of EHRs with patient confidentiality. HIPAA's coverage of an individual's rights over the privacy and security of their health information consists of two rules, The Privacy Rule and The Security Rule. The two rules are outlined as follows (HHS, 2015).

The Privacy Rule, a Federal law, gives you rights over your health information and sets rules and limits on who can look at and receive your health information. The Privacy Rule applies to all forms of individuals' protected health information, whether electronic, written, or oral. The Security Rule is a Federal law that requires security for health information in electronic form.

HIPAA contains a rule that adds provisions to the HITECH Act to strengthen privacy and security measures (HHS, 2015). These provisions must be met as part of the EHR incentive program in order to protect patient information confidentiality. Some are concerned about the legitimacy of EHR privacy since many EHRs utilize web interfaces (Anderson, 2007). To someone who does not fully comprehend the technology, this is a valid concern. However, EHRs that incorporate a web interface is often more secure because of this identified issue, which would have a greater likelihood of appearing.

While privacy and confidentiality are fairly easy to maintain, use of an EHR "increases opportunities for invasions of privacy by dispersing health data through interceptable telecommunications, thus magnifying the risks of breaching patient-physician confidentiality." (Hodge et al., 1999). Such intrusions might appear contradictory to the legal and ethical safe guards that have been implemented through acts. The contradiction arises, however, because there is a thin line between information security and privacy. There is no doubt that once a security breach occurs and patient information is compromised, privacy will be invaded. Unfortunately, once private information is connected to the World Wide Web, those individuals become easier targets for different forms of malicious attacks.

In 2015, the security breach affecting the most people was "Hacking/IT Incident". In previous years, security breaches were less effective and precipitated from non-hacking, unintentional scenarios (Figure 3). During the same time period, the most common attack was "Theft", followed by "Unauthorized Access/Disclosure." Table 4 demonstrates these attacks.

It is evident that as technology advances, so do the risks involved with using technology. There are several regulations in place to attempt bolstering security as a means to protect patient privacy and confidentiality. However, with the exception to the statistical outlier in 2015, most security breaches in healthcare occur because of the lack of training in basic cyber security that healthcare employees are given.

Many security threats also precipitate from stolen devices or improperly managed access. Hodge et al. (1999) described the impediment of health privacy, security, and technology by suggesting changes to HIPAA or other health privacy legislation. Hodge et al. state, "Health-related computer technology requires a weighing of competing interests toward devising effective policies to protect the public." The legal characteristics of implementing EHRs concerning negligence, liability, privacy, and security are reasons that EHR implementation has been slow in America (Anderson, 2007). The proceeding section will further discuss the ethical principles involved in implementing EHRs.

Ethical Principles

The final characteristic of ethics in EHR implementation is general ethical principles, which includes social responsibility. Healthcare and IT have a responsibility to ensure that its code of ethics is upheld, despite rapid industry changes. In order to understand this ethical identity crisis, ethical principles that define EHRs ought to be explained. Layman (2008) chose two ethical principles, beneficence and autonomy, to outline EHRs intentions and failures.

Beneficence relates to the intentions of EHRs. EHRs' intention is to improve the quality of healthcare. This is considered a good and valuable intention. Government programs and laws, such as HITECH, focus heavily on combating issues that EHRs experience before regulation or standardization existed. EHRs exist to help others, and therefore cannot be considered malicious by nature. Unfortunately, it is important to note that however good EHR intentions may be, "beneficence is not assured" (Layman, 2008).

When EHRs face heavy criticism surrounding security, many will not call it a good system. As mentioned in the previous section, security breaches often result from stolen devices that do not have proper security protection installed. Furthermore, such theft, outside of 2015, is one of the highest causes for security breaches (Ben-Assuli, 2015).

Another reason many will not consider EHRs as a good system is because its users are poorly trained. This directly endangers the system's security and privacy. The patients' confidentiality is put into the hands of staff that do not know how to manage and protect the information. As a result, the true good

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

that EHRs can bring to patients and healthcare are ignored. As one knows, successful implementation can help cure diseases and save many lives (Ben-Assuli, 2015). There is a visible reduction in costs when advanced EHR systems are implemented, as demonstrated in Figure 2. Furthermore, EHRs can reduce malpractice. Even though they are supported by government initiatives, they are still questioned.

The next ethical principle, per Layman (2008), is autonomy. EHRs are known for being potentially unethical because of who gains the right to control patients' health information. Even with HIPAA regulations, some feel uncomfortable about which health data is released to. This uncomfortable feeling is where the concept of informed consent becomes crucial. Informed consent closely follows the idea that "information of a patient should be released to others only with the patient's permission or allowed by law" (Ozair et al., 2015). Therefore, any secondary use of a patient's health information that Palvia et al. (2015) discusses would be deemed illegal. The concept of illegality contradicts the good and valuable aspects behind data sharing. If people generally feel uncertain about sharing health data, then EHRs may not be considered good in nature anymore. However, a study found that "50% of respondents were concerned that their records would be linked outside their primary doctor's office, although 79% of them recorded that they believed making health records electronic was a good idea" (Layman, 2008). Many people believe that it is ethically incorrect to transfer information without informing a patient.

Autonomy relies closely on the concept of access. There is an added possibility that a minority group is denied access to certain care. The reason can be overtly racist or based primarily off economic status. EHRs offer the potential to view in-depth information that carries social, as well as medical, information about patients. However, this concept dances on a fine line. It can be seen as counter intuitive to the concept of autonomy, and thus perpetuating inequalities, especially if there is "public disclosure of personal health information of certain disadvantaged groups." (Layman, 2008).

Examining the issues inflicting EHRs through such ethical principles yields a different perspective on the qualities of an EHR. EHRs contain both positive and negative attributes. Healthcare and IT are ethically motivated fields. There is a professional and social responsibility to ensure that EHRs are not unethically abused (Palvia et al., 2015). The ethical characteristics outlined in the previous subsections demonstrate why it is challenging to implement EHRs. However, it is concluded that the positive ethical impacts of EHRs make it worth the implementation process.

In conclusion, this study found that the impact and relationship that ethics has with IT and IS in the context of healthcare revolve around three main traits. They include organizational, legal, and ethical principles. Therefore, there are some ethical implications and recommendations that a practitioner ought to be aware of as they execute the development and implementation of EHR systems. These are discussed in the following section.

DISCUSSION

Implication of the Ethics in Project Management and IT

EHRs are complex systems that require a great deal of planning and project management. Understanding the ethical issues can sway a decision in project implementation that directly impacts the EHRs and their effectiveness. When initiating the process to create an EHR system, communicating with the staff

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and patients is crucial to discern what each party expects from the system (Noblin, Cortelyou-Ward & Ton, 2011). It is important to take notice of concerns that can be addressed to reduce the possibility of future ethical issues from arising.

Once the vision and issues are identified, selecting a vendor is the next step. EHRs need to function as reliable, high quality systems. This comes as a job of the vendor. Privacy and Security are two ethical issues that are key in the implementation of an EHR. It is important to know whether or not a vendor is reliable and has good security credibility. With EHRs, cost saving is not the goal, as usability, reliability, and desire functionality are primary components paralleled in importance with ethical issues (Kazley et al., 2014). If patients are concerned about what will happen to their information once it is stored with the vendor or data management party, it is a good idea to negotiate for an informed consent policy that permits patients to opt out of data aggregation.

As Table 5 and Table 6 demonstrates, there is evidence to support the notion that a good EHR system will save money compared to a lesser one. It is a necessity that during implementation, "constant tracking of project progress and tight regulation of project tasks, personnel, communications, and budget" are maintained (Noblin et al., 2011). Even when money should not be a crucial factor, it is in this case, because controlling the budget along with strict monitoring and quality control is part of successful EHR implementation. It is also important to maintain quality control of documentation and data entry.

As part of healthcare implementation, security over who has access to patient data is highly important. This will help avoid ethical issues from occurring in the future and uphold the privacy and ethical laws put in place. EHR implementation is a rigorous process, but the issues that may occur should implementation be achieved poorly are more drastic (Tripathi, 2012).

The ethical issues with security and privacy in EHRs translate to general information technology. Most of the issues that EHRs face occur from improperly trained, or even untrained employees, who are carless with their access and handling of sensitive data. EHR impediments set a good example in what to look for in IT security. It is usually difficult for a hacker to get past network security, but he/she can use other means to get credentials out of unsuspected employees, especially when they are poorly trained on using the new system. Thus, EHRs will provide a lesson in maintaining and ensuring privacy (Kazley et al., 2014).

Table 5. Cost Estimate Sensitivity Analysis

	Base Estimate Propensity Strata N = 5,163,794	Base Estimate Propensity Matched Sample N = 152,008
EHR cost/administration	$7207	$7103
Non-EHR cost/administration	$7938	$8005
Cost difference	$731[a]	$902[a]

P values were calculated using multivariable Log-linked Gamma Distributed Generalized Linear Model.
[a]*P* <.0001. *P* values were calculated using multivariable Log-linked Gamma Distributed Generalized Linear Model.
EHR indicates electronic health record.
Covariates include: patient age, gender, race, All Patient Refined Diagnosis Related Groups (APDRG) mortality and severity, neonatal or maternal status, private insurance coverage, Medicare or Medicaid coverage, Diagnosis Related Group (DRG) case mix group, and whether the patient arrived as a transfer, hospital teaching status, hospital urban location, hospital bed size, and hospital geographical region.

Table 6. Cost Estimate Sensitivity Analysis (Descriptive Data Proof)

	Total (N = 5,163,794) Mean (SD)	Advanced EHRs (N = 1,509,610) Mean (SD)	No Advanced EHRs (N = 3,654,184) Mean (SD)
Age, in years	48.3 (27.9)	45.9 (28.0)	49.3 (27.7)
Risk mortality	1.6 (0.9)	1.6 (0.9)	1.6 (0.9)
Risk severity	2.0 (0.9)	2.0 (0.9)	2.0 (0.9)
Cost per admission	$10,790 (17,857)	$10,203 (17,572)	$11,010 (17,993)
	N (%)	N (%)	N (%)
Medicaid	1,078,607 (20.9)	332,439 (22.0)	746,168 (20.4)
Medicare	1,899,951 (36.8)	4,979,650 (33.0)	1402301 (38.4)
Private insurance	1,717,720 (33.3)	529,941 (35.1)	1,187,779 (32.5)
Neonatal/maternal admit	1,177,819 (22.8)	364,631 (24.2)	813,188 (22.3)
Transfer into hospital	284,239 (5.5)	106,651 (7.1)	177,588 (4.9)
White	2,952,903 (57.2)	787,539 (52.2)	2,165,364 (59.3)
Black	587,325 (11.4)	206,575 (13.7)	380,750 (10.4)
Hispanic	623,272 (12.1)	171,195 (11.3)	452,077 (12.4)
Teaching hospital	2,525,001 (48.9)	970,582 (64.3)	1,554,419 (42.5)
Urban hospital	4,652,205 (90.1)	1,457,757 (96.6)	3,194,448 (87.4)
Small hospital	585,247 (11.3)	114,943 (7.6)	470,304 (12.9)
Medium hospital	1,239,321 (24.0)	386,845 (25.6)	852,476 (23.3)
Large hospital	3,339,226 (64.7)	1,007,822 (66.8)	2,331,404 (63.8)
Northeastern United States	1,405,749 (27.2)	573,844 (38.0)	831,905 (22.8)
Midwestern United States	668,842 (13.0)	303,385 (20.1)	365,457 (10.0)
Western United States	1,477,224 (28.6)	331,228 (21.9)	1,145,996 (31.4)
Southern United States	1,611,979 (31.2)	301,153 (20.0)	1,310,826 (35.8)

EHR indicates electronic health record.

From one end, IT ought to ensure that ethical practices involving personal information are upheld. This is important because once a culture is developed in which breaking policies is the norm; it is more challenging to change the culture. One of the final aspects of the privacy issue is that information may never be truly safe. Practitioners must know what is accessible, and how to keep tabs on potential issues that may arise at any time (Tripathi, 2012).

As one can see, a healthcare facility must comply with ethical practices in project management and EHR implementation. Compliance will ensure that in the future, ethical organizational, legal, privacy, and security implications do not occur. Pursuing the suggestions made in this section will provoke smaller and/or on-the-fence facilities to implement EHRs and reap its positive, ethical benefits.

Recommendations

As a project manager interested in implementing an EHR system, early planning and initiation within the bounds of what is known about available resources must be undergone. A recommendation "can be made to make the initiation and planning stages a solid foundation for the rest of the project," and it is hard to build on a careless base if awareness of requirements is lacking (Noblin et al., 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the planning stage, the project team must create a clear vision of the purpose of the EHR system. Everyone must agree on this vision. All those involved must share it because that will ensure that the process can run smoother. If the involved parties do not share the same line of vision, then the team risks conflict and unsuccessful, unethical implementation of the EHR system.

A final recommendation is to assess who the stakeholders are. By involving the stakeholders, the team can understand their vision and opinions about the project. It may not align exactly with each other, but there will be valuable insight into how to get the support needed to move forward on a project (Menachemi & Collum, 2011). Furthermore, involving the stakeholders will ensure that the produced system satisfies all their needs with quality.

In some respects, ethics in EHRs and healthcare IT is considered a messy matter. It is important to look at the situation without bias in order to collect all views. This collection can be achieved during the planning/implementation phases. If security is a concern, a plan of action should be created to handle it immediately (Waegemann, 2003). Security should be one of the topics of interest from the beginning of the project. It will not be beneficial if the team waits for something to happen before trying to prevent the ethical implications discussed in this study from arising.

Proactive ethics training is one of the best ways to combat issues with regards to ethics in the organization, legal, privacy, and security characteristics. It is important to ensure that all people involved are cognizant of potential legal issues, whether concrete as HIPAA or more ambiguous. Ethics education, along with basic workplace and out of workplace security education, can go a long way to prevent ethical issues and potentially illegal ones (Waegemann, 2003). An education on ethics will also further promote smaller facilities to embark on EHR implementation.

CONCLUSION

EHR systems are fraught with potential ethical issues. Some are combatable, while others are less so. It is clear that ethical issues with regards to EHRs are not going to be diminished. EHRs are in a crisis right now, especially with regards to their level of security, so is it crucial that we attempt tackling the ethical issues before they appear, instead of waiting until the last minute.

EHR systems will eventually yield positive results once security and ethical implications are eradicated. The real roadblock to success and defeating the ethical issues that are apparent is thinking that there is no potential to change how the system functions. There is much support, especially through government initiatives, for EHR systems. Some of the support comes from a team being motivated in the right direction. It may also include involving stakeholders and restoring trust into the system. Solutions for issues surrounding autonomy and informed consent are already possible—they just require implementation. When EHRs are given the chance to develop and be implemented, their impact on the healthcare industry will be astounding.

Chapter 74
Hierarchy Similarity Analyser–An Approach to Securely Share Electronic Health Records

Shalini Bhartiya
IITM, India

Deepti Mehrotra
Amity University, India

Anup Girdhar
Sedulity Groups, India

ABSTRACT

Health professionals need an access to various dimensions of Electronic Health Records (EHR). Depending on technical constraints, each organization defines its own access control schema exhibiting heterogeneity in organizational rules and policies. Achieving interoperability between such schemas often result in contradictory rules thereby exposing data to undue disclosures. Permitting interoperable sharing of EHRs and simultaneously restricting unauthorized access is the major objective of this paper. An Extensible Access Control Markup Language (XACML)-based framework, Hierarchy Similarity Analyser (HSA), is proposed which fine-grains access control policies of disparate healthcare organizations to achieve interoperable and secured sharing of EHR under set authorizations. The proposed framework is implemented and verified using automated Access Control Policy Testing (ACPT) tool developed by NIST. Experimental results identify the users receive secured and restricted access as per their authorizations and role hierarchy in the organization.

1. INTRODUCTION

The inclusion of electronic media in healthcare domain resulted in transformation of paper-based health records into Electronic Health Records (EHRs). These records are accessed from medical to non-medical users at the same time across multiple hospitals and other related organizations. These records possess a high level of sensitivity where the patient demands utmost care allowing only relevant and authorized access of the records. Rules and policies are defined with respect to the roles and responsibilities of health providers. It may differ from hospital to hospital. With the heterogeneity involved in the organizational structure and access policies, sharing EHR increases the chance of confidentiality leakages and security breaches. Organizations, hospitals in this context, experience various challenges and security issues (Bhartiya & Mehrotra, 2014; Bai et al., 2014) in making the data available to the intended users.

In spite of similar roles of the users, the two hospitals may exhibit dissimilarity in their organizational hierarchies. Hence, to enable cross- organizational sharing of data, well-defined standards or mechanisms should be developed. The objective is to logically identify similarities between user's roles and authorities and make two disparate organizations interoperable. For ex. comparing two doctors, one in government hospital and the other in private hospital, their work distribution may not be the same and hence, the set of access rules must differ in both cases. A possibility exists where an access to the resource should be permitted to one and denied to other. The case reflects a huge challenge in determining and setting their access rights and privileges for secured sharing of sensitive EHR in-spite of wide gap in their services.

Basically, sharing of EHR is dependent on how best the two systems can achieve interoperability. HL7 has been addressing interoperability problems in sharing or exchanging EHRs for over two decades now. It (HL7 Standards, 2015; HL7 Evolution, 2010) provides a framework for exchange and sharing of EHRs for seamless integration between disparate healthcare organizations. The Standard is broadly divided into two categories – Version 2 (V2) and Version 3 (V3). Fast Healthcare Interoperability Resources Specification (FHIR), Release 1 (HL7 FHIR, 2015) combines the best features of HL7's V2, V3 and CDA product lines. It is a standard for exchanging healthcare data electronically. It simplifies implementation without compromising information integrity. Integrity is complemented with confidentiality and availability of data.

Interoperable sharing of EHRs exhibits another challenge -maintaining the confidentiality and privacy of sensitive health information without compromising its availability to the health providers. NIST (NIST 800-53, 2013) in collaboration with the Office of the Director of National Intelligence (ODNI), the Department of Defense (DoD), and the Committee on National Security Systems (CNSS) is establishing a unified information security framework for the federal government. This framework is said to provide a strong base for mutual acceptance of authorization decisions and facilitate information sharing between disparate organizations.

An access control framework allocates the access rights and privileges on the resources. A typical deployment of an access control system is a combination of three logical components: an access control model (ACM), policies, and enforcement mechanisms. A logical access control system requires validating individual's roles and responsibilities for assigning the access rights on the data. As each system is autonomous specifying access control policies according to the user and resource hierarchy of the organization, collaborating such organizations often result in policy conflicts (Huang and Liu, 2009), matching of undefined attributes or rules, thus, imposing a threat to relevant and meaningful disclosure of the information. Support from industry standard access methods would enable the disparate EHR-systems to collaborate and expand access to the data for providing quality (de la Torre-Diez et al., 2012)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

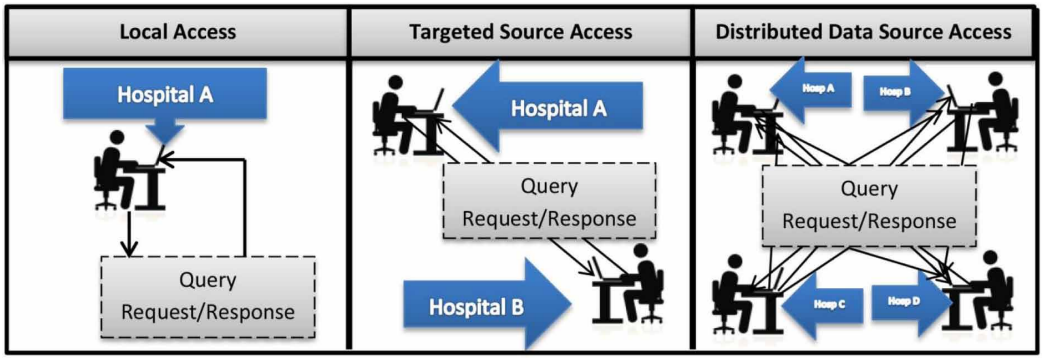
and timely care to the patient. The Standards and Interoperability (S&I) Data Access Framework (DAF) Initiative outlines the standards and profiles necessary for clinicians, providers and healthcare professionals to gain access to patient data within an organization and across organizations. DAF addresses three basic challenges-Who is accessing data, what and how the data is accessed and why the data is accessed?

Figure 1 identifies the different environments of information access requirements with respect to interoperable healthcare domain. DAF proposes to implement interoperable data access through a standard-based initiative delivered in two phases. Phase 1 would cater to the standard for local access via intra-organization query whereas phase 2 will focus on targeted access via inter-organization or distributed query. The standards selection is made keeping the modularity and substitutability into view. In order to enable the systems to interoperate, DAF specifies that organizations should implement consent requirements per their state, local, and institutional policies. However, there are no mandatory requirements for consent in DAF context. Moreover, access should be complemented with authorization control to provide a secure and reliable sharing (Parker & Wisley, 2009) of patient's health information with minimum or no change in the existing access control models. Hence, the aim of this study is to design an access control framework providing legitimate and only relevant access to EHR by deducing similarities between the roles of the users or health providers of disparate organizations.

Designing of ACM should strongly consider a comprehensive standards-based approach that enables current day interoperability capabilities and are cost efficient. Well-defined and standardized models should be encouraged, especially in cross-organizational environments. Due consideration should be given to functionality, interfaces, infrastructure, and IT support keeping in view the nature of users operating the system. A filtered mechanism must be employed for procuring the authorized access regardless of categorization of organizations, i.e. public, private or individual ownerships.

In this paper an ABAC based framework is proposed that integrates XACML policies by ranking each attribute on the basis of hierarchical distances between the user hierarchies of the healthcare organizations. The Hierarchy Similarity Analyser (HSA) algorithm generates security level (SL) that is assigned to users as per their positions in the organization hierarchy. SL is associated with the subject attribute on rules of access control policies. The policies are hence, fine-grained by associating authorizations based on Mandatory Access Control (MAC) rule. This allows a robust security control in limiting the amount of data to be accessible between two disparate health organizations. Lin et al. (2007) proposed a similarity-based policy filtering algorithm that identifies similar policies by calculating hierarchical distances between two or more attributes defined in the rule sets. Our framework uses a part of this al-

Figure 1. Data access between intra, inter and distributed hospitals



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

gorithm to calculate the similarity scores between two disparate user hierarchies. The similarity scores thus obtained are inputted to Hierarchy Similarity Analyser (HSA) that generates security level (SL) for each user in the given hierarchies. The SL obtains a clear relationship between the users with similar roles and similar or dissimilar responsibilities.

Access Control Policy Testing (ACPT) tool (Hwang et al., 2010) developed by NIST is used to verify the proposed framework. A comparative study by Li et al. (2015) reveals the significance and robustness of ACPT over other similar verification tools. ACPT bridges the gap between disparate policies by generating enforceable policies directly from policy models. The tool allows static as well as dynamic verification of the generated policies thereby helping in the identification and reduction of faults in the policies. Static verification is done through SMV (Symbolic Model Verification) model checker that checks given policy models to satisfy the user-specified properties. Dynamic verification is done by automatically generating and executing viable oracles through counterexample that illustrate semantic differences between the two policies. More specifically, each counterexample represents a request that evaluates to a different response when applied to the two policy versions.

This paper is divided into 5 sections. Section 1 details the problems in linking of heterogeneous health organizations with respect to access control policies that often contradict with each other arising confidentiality threats to sharable EHRs. Section 2 includes a literature review of related access control frameworks in other domains. Section 3 proposes the access control framework build on XACML structure. Section 4 deals with verification of the proposed framework using an automated tool ACPT. It takes up a case study to illustrate the working and testifying the framework. Section 5 concludes the results obtained justifying the viability of the proposed framework.

2. RELATED WORK

Various access models (Amini and Jalili, 2010; Hu et al., 2013; Thomas, 2007; Park & Lee, 2007; Karp et al., 2010; Hu & Kuhn, 2011; Miyagawa et al., 2014) have been proposed that promise to provide a well-integrated interoperable environment in their respective domain of study. Each of the model exhibit different architecture and features with respect to the access control policies.

The model proposed by Imine et al. (2009) deals with the latencies and resolves the policy conflict changes dynamically but allows any change to existing data-sets only at the administrator level. The users play a vital role in providing health services to the patient. Each user having any position in the organizational structure is equally crucial in the service-chain system of the organization. The organization experience frequent role-reversal of its users as per the demand and schedule. A domain-based approach (Wickramasuriya, 2004) to access control hides the sensitive data thereby acting as a filter at the object level. It establishes a security level on the domain of actors dynamically created and modified as per the need. Some organizations require reviewing the capabilities associated with subjects and their attributes defined through the access control policies. Access Control Lists work on the attribute of "identity" whereas RBAC works on the attribute of "role". The policies in ABAC expresses a complex Boolean rule set capable of evaluating many different attributes. The RBAC-based model (Power et al., 2011) captures the disparities of access control policies relying on specific constraint-checks to administer interoperability. With the advent of mobile-based (Rodrigues et al., 2013a) and cloud-based solutions (Fernández-Cardeñosa et al., 2012), access to EHR is not limited to closed environments. Ac-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

cess has to be complemented with assuring the security of data also. Analysis by Rodrigues et al. (2013b) identifies various confidentiality and privacy issues that should be considered by service providers for moving EHR between EHR-systems.

The constraints in health domain are subject to change with the dynamic creation of demand. It has to handle various contingencies where the system needs to change its behaviour and normal course of actions.

Also, demonstrating access control requirements compliance is difficult and costly due to the level of abstraction required between the requirements and RBAC model. A successful and secured collaboration may exist if the access rules are governed by well-defined authorizations. ABAC implementation can help in predetermining access authorizations. NIST Special Publication 800-53 provides guidance on stringent access controls, for ex. AC-3, AC-16 and many more for securing sensitive information when being processed, transmitted or stored on collaborative systems. The third control i.e. *Mandatory Access Control* (MAC) in the ***Access Enforcement*** family (AC-3 (3)), imposes constraints preventing a subject from passing information to another subject operating at a different sensitivity level, whereas, the fourth control, *Discretionary Access Control* (DAC) in the same family (AC-3 (4)), permits the subject to pass the information to any subject at the same sensitivity level. It is assumed that the problem can be sought through well-integrated access control policies (Hu & Kuhn, 2011) capable enough to dynamically inspect and resolve interoperable issues in sharing of data between heterogeneous systems.

3. DESIGNING OF PROPOSED FRAMEWORK

Lin et al. (2007) algorithm calculates the similarity score between matched and unmatched rules of various access control policies in homogeneous environment. The rules contain various attributes that are individually matched in each rule set. An overall similarity score is then obtained for all the rules belonging to one policy. Similar effort is repeated for all other policies that are probable candidates for collaboration. Finally, the scores are compared and the policies with higher scores are identified to satisfy successful and secured sharing of data by the legitimate users. Our previous work (Bhartiya and Mehrotra, in press) uses this approach to implement and verify the framework in homogeneous healthcare environment. This paper presents the proposed framework to deduce similarities between users in two disparate healthcare organizational hierarchies. Attribute-based access control (ABAC) implementation can reduce the risk of unauthorized access to the data due to its ability of implementing consistent policies and also update them easily to address changing threats. ABAC system is partially dependent on the organization's authorities for assigning attributes related to the allocation of resources (EHR) to the respective subjects (Users). As defined by NIST, "An access control method (ACM) where subject requests to perform operations on objects are granted or denied based on assigned attributes of the subject, assigned attributes of the object, environment conditions, and a set of policies that are specified in terms of those attributes and conditions".

The distribution and composition of ACM must be predetermined to avoid conflicts and other issues weakening the security of sensitive resource. For example, if a resource belonging to one organization is to be shared by other organizations, an unauthorized subject (user) in the organization with lesser restrictions should not have access permissions on it. Consistency in managing, maintaining and employing ACMs is needed to ensure interoperability and comprehensive security.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. XACML Environment

Access control framework consistent with ABAC is the Extensible Access Control Markup Language (XACML). The XACML model employs elements such as rules, policies, rule and policy-combining algorithms, attributes (subject, resource, action and environment conditions). XACML architecture includes functions such as Policy Decision Points (PDPs), Policy Enforcement Points (PEPs) and Policy Combining Points (PCPs) to control access. The description of each term is included in Table 1.

ABAC verifies and makes decision on the basis of attribute values assigned under each XACML element in the given rules or policies. Under this arrangement, policies can be created and managed without direct reference to users and resources, and users and resources can be established without reference to policy. In the context of sharing sensitive health information, of the patient, across hospitals, an access control framework (Figure 2) designed on ABAC approach is proposed. Each hospital has a unique categorization of health providers (doctors, nurses and other staff) vertically arranged in the order of their roles and responsibilities. The hierarchies may significantly differ from each other. Hence, these hierarchies need to be standardized in order to generate commonalities between them. A filter-based approach can then be applied to identify the relevant matching roles based on the similarities of hierarchical positions of the users in their respective hospitals. Identifying similarities between user attributes would ensure robust authorization, thereby, enhancing the availability complemented with confidentiality and privacy of health data. Table 2 describes the notations used in the framework.

Table 1. XACML terminologies

Term	Description
Subject	The entity (user) requesting to access the resource. The subject is sometimes referred to as a requestor
Subject Attributes	Characteristics or attributes of a subject such as name, designation, authority that distinguishes that person from all others
Object/Resource	Entity (data) to be protected from unauthorized use.
Privilege/Action	The authorized behavior of a subject as defined by an authority and embodied in policy or rules.
Environment Condition	Constraints set on the access rules and used as attributes at decision time to influence an access decision.
Policy and rules	A repository of privileges available to subjects from the perspective of the resource that needs protection.
Access control mechanism	Assemble authorization information, which may include information about the resource being protected, the subject requesting access, the policies governing access to the resource, and any contextual information needed to make a decision.
Policy Combining Point (PCP)	To combine disparate policies using rule-combining algorithm
Policy Evaluation Point (PEvP)	To verify the rules against set properties and environmental conditions
Policy Enforcement Point (PEP)	To enforce the decision using SLs and authorizations
Policy Decision Point (PDP)	To render a decision and generate matching rules

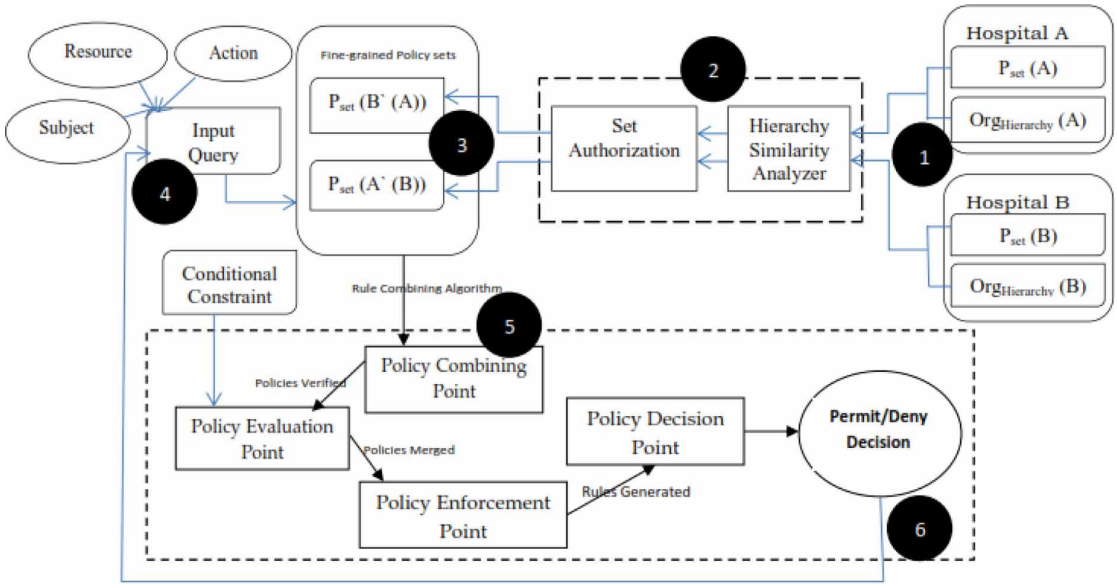
Table 2. Notations/terminologies for proposed framework

Notations	Description
HSA	Hierarchy Similarity Analyzer generates SL
SL	Security Level determining access rights in policy sets of disparate hospitals
P_{set} (A)	Policy set of hospital A
$Org_{Hierarchy}$ (A)	Organization Hierarchy of hospital A
P_{set} (B` (A))	Fine-grained policy set of hospital A with respect to hospital B
P_{set} (B)	Policy set of hospital B
$Org_{Hierarchy}$ (B)	Organization Hierarchy of hospital B
P_{set} (A` (B))	Fine-grained policy set of hospital B with respect to hospital A

Figure 2. Proposed framework for fine-graining XACML policies using HSA



3.2. Proposed Framework

The framework consists of the following six steps:

Step 1: Identify the policy set and organization hierarchies of the hospitals agreeing to share the data. Compare the position of each user in the given hierarchies and generate similarity scores based on hierarchical distances between them.

Step 2: Input the similarity scores to 'HSA' algorithm for generating unique values to be assigned as Security Level for each user. Input Security Level of each user to 'Set Authorization' algorithm and determine authorization in accordance with other user's security levels.

Step 3: Fine-grain the policy set of hospital A with respect to B and vice versa by assigning security level and authorization with the Subject attribute in applicable rules.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 4: Formulate the user request as input query and validate it against the refined policy-sets of hospital A and B.

Step 5: Apply selected rule combining algorithm to compare the rule-sets ***(Policy Combining point)*** and identify matching and non-matching rules based on the input query. Evaluate ***(Policy Evaluation Point)*** and obtain relevant rules that satisfy any pre-set conditional constraints in the policy set(s) of hospital A and B. Merge ***(Policy Enforcement Point)*** the obtained rules and enforce the validated privileges with each rule. Obtain a final decision ***(Policy Decision Point)*** and generate final rule-set that either permit or deny access to the requested data.

Step 6: Notify the decisions obtained to the input query and (if required) repeat the process with new query.

Designing solution to achieve interoperability without compromising security of EHR is highly complex and time-extensive task. This work is a small effort to bridge the interoperable gap and allow authorized access to data in healthcare domain. Heterogeneity in organizational structure and frequent change in user's roles and privileges is experienced in real-time study of healthcare environment. The proposed framework enables to reduce the heterogeneous distances between two structures and ensure authorized and relevant access to the data. Similarity score is calculated for each user attribute in the policy-sets. It lies between 0 and 1. A value near to 1 depicts high similarity between the selected user attributes thus increasing the chances of legitimate and authorized access to the required data. Also, similarity score for unmatched user attribute values is obtained by averaging their score with all the other attributes.

Figure 3. EHR hierarchy in healthcare domain

4. IMPLEMENTATION

4.2. Implementation Environment

Case of two independent healthcare organizations is discussed with respect to sharing of EHRs comprising of various health and personal details of the patient. EHR is categorized and composed in a hierarchy as shown in figure 3. Patient's clinical data comprise of diagnostic, prescriptions and other history details. Demographic data includes patient's personal information i.e. name, address, date of birth etc. It also stores the nominee's detail that is authorized to take decision and handle any contingencies for the patient. Financial data stores the billing and insurance claims of the patient.

4.2.1. Case 1

Environment: Healthcare organization H1 is a full-fledged government-aided hospital comprising of various facilities as per the specialization. It runs an OPD with an inflow of above 2000 patients daily. The user hierarchy for H1 is shown in figure 4(a). MS leads the hospital with each department being managed by respective HOD. A team of Sr. and Jr. Resident doctors handle the OPDs and are assisted by nurses and other technical and administrative staff. Patient is registered by the administrative staff before meeting with the doctor.

Administrative rights and Permissions: The doctor updates the patient's EHR with the history, diagnosis prescription and required laboratory tests details. MS can read record of any patient whereas the HODs can read the records of all the patients treated under their department. Sr. Resident can read and write the clinical details and read demographic details of specified patients. Jr. Resident can read and write the clinical details related to lab test duly approved by the Sr. Resident, but require no permission to write the history details of the patient. Nurses can read demographic and clinical details but have no access to lab details of the patient.

4.2.2. Case 2

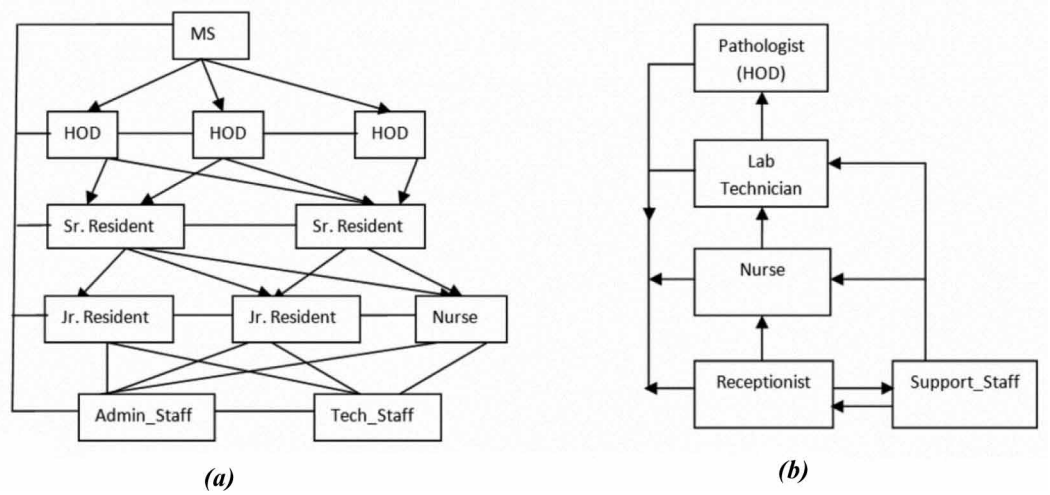
Environment: Another health organization H2 is an independent laboratory conducting various lab tests as prescribed by doctors. It registers various categories of patient i.e. independent or being referred by a doctor or a hospital. The user hierarchy of H2 is shown in figure 4(b). The lab comprise of a Pathologist (HOD), Lab technicians, nurses, receptionist and other administrative staff.

Administrative rights and Permissions: The receptionist records the required test and forwards the patient to the respective room. The nurse checks the basic vitals i.e. the BP, fasting/non-fasting, water intake etc. necessary for conducting the said test. Lab technician performs the test and the report is duly signed by the HOD before dispatching to the patient. The Lab technicians have a read access to the diagnostic details of the patient and write access for updating the test result obtained. The Lab technician need to take patient's or HOD's consent before accessing the diagnostic data. The test results must be verified by the HOD before writing into the patient's EHR. Patient has read permission on his/her test reports. The receptionist and the nurse are restricted to write in the patient's diagnostic section.

Figure 4(a) and 4(b) exhibit the organizational hierarchies of H1 and H2 with respect to users. The position and the responsibilities of HOD, nurses and other technicians vary in both the organizations. Sharing EHRs leads to policy-conflicts thereby resulting over or under exposure of data to the health

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. (a) User hierarchy in health organization H1; (b) User hierarchy in health organization H2



professionals. Thus, a balance between the user domain hierarchies of H1 and H2 needs to be established for secured sharing of the data.

Table 3 reveals the similarity score between the users positioned in these hierarchies (Step 1). Rows represent the similarity scores of H2 whereas columns represent the similarity scores of H1.The scores obtained identifies the similarities between each user-user pair of two different hierarchies. For ex. user hierarchy of H1 shows the HOD as a subset of MS whereas the same has a higher priority in H2. This signifies that some kind of hierarchical similarity exists between these attributes.

Using the hierarchical distances obtained in table 3, HSA assigns SL to each user in the respective category (step 2). The analyser expands the user's association with other users as well as itself. This is done to obtain the unique values as existence of two different security levels for the same association of rules is just not possible. It further enables establishing well-defined authorization on sharing of EHRs in disparate but interoperable healthcare environment. Table 4 shows the SLs assigned to each user thereby ascertaining the level of access permitted to the users specifically while integrating different EHR systems.

A merged set of users are defined for the sake of generality and verification of the proposed framework. The users are grouped into four categories, Doctor (includes Sr. Resident, Pathologist, HOD), Med_tech (includes nurse and Lab technician), admn_tech (includes receptionist, sample collector) and patient.

Table 3. Similarity Scores of user hierarchies in H1and H2

	H1					
H2		HOD	Sr. Resident	Jr. Resident	Nurse	Receptionist
	Pathologist	1	.87	.75	.62	.62
	Lab Tech	.87	1	.87	.75	.75
	Nurse	.75	.87	1	.87	.87
	Sample Collector	.62	.75	.87	1	1
	Receptionist	.62	.75	.87	1	1

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Security_Level (SL) obtained through HSA for each user-pair in H1 and H2

H2 / H1	Pathologist	Lab Tech	Sample Collector	HOD	Sr. Resident	Jr. Resident	Nurse	Receptionist
Pathologist	4	0	0	4	3	2	1	1
Lab Tech	0	4	0	3	4	3	2	2
Nurse	1	2	3	2	3	4	3	3
Sample Collector	0	0	4	1	2	3	4	4
Receptionist	1	2	3	1	2	3	4	4
HOD	4	3	2	4	0	3	2	1
Sr. Resident	3	4	3	0	4	0	3	2
Jr. Resident	2	3	4	0	0	4	4	3

4.2.3. Verification of HSA-Refined Policy Set

Enforcing robust controls and efficiently managing the arrangement of roles and their relationships concludes acceptable level of security mechanisms employed by the organization. The proposed framework need to be verified through properties and constraints as imposed in the real-world scenarios. Verification provides a logical reasoning of the suitability and compatibility of applied access control policies. Verification on merging of access control policies of H1 and H2 must identify and restrict irrelevant and unauthorized exposure of data. First Applicable Rule combining algorithm is executed by the simulator on the defined policies. It produces verification reports where if the property is true in the policy no test cases are generated. On the other hand, if the property is violated, counterexamples are generated.

Figure 5 and 6 enlist a sub-set of Med_Tech access policy defined for H1 and H2 respectively.

Med_Tech of H1 and H2 are permitted write access on Cl_test details. Read access is permitted to the Med_Tech of H2 only. Collaborating H1 and H2 generates permit/deny decisions on the basis of defined properties.

Property: *SPEC (Roles = Med_Tech) & (EHR = Cl_test) & (MLSDefaultAction = write) & (Patient_Consent = True) -> decision = Permit*

         <AttributeValue DataType="http://www.w3.org/2001/XMLSchema#boolean">True</AttributeValue>
      </Apply>       </Condition>      </Rule>

    <Rule RuleId="rule_7" Effect="Permit">
     <Target>         <Subject>
         <AttributeValue DataType="http://www.w3.org/2001/XMLSchema#string">Med_Tech</AttributeValue>
        </Subject>          <Resource>
          <AttributeValue DataType="http://www.w3.org/2001/XMLSchema#string">Cl_test</AttributeValue>
        </Resource>          <Action>
          <AttributeValue DataType="http://www.w3.org/2001/XMLSchema#string">read</AttributeValue>
        </Action>       </Target>             <Condition>       <Apply>
          <EnvironmentAttributeDesignator AttributeId="Patient_Consent" DataType="http://www.w3.org/2001/XMLSchema#boolean"/>
         <AttributeValue DataType="http://www.w3.org/2001/XMLSchema#boolean">True</AttributeValue>
      </Apply>       </Condition>      </Rule>
```

As mentioned, if the verification result identifies the property to be true in the policy, no test cases are generated. Figure 7 shows the NuSMV verification result where the said property is found to be true in both policies H1 and H2; therefore, no test cases are generated. The decision obtained permits Med_Tech of both the organizations to write the laboratory test details in patient's EHR.

Though Med_Tech, i.e. nurses and lab technicians, are permitted to write the laboratory details in the patient's EHR, it provides no restriction on the amount of data to be accessed by these users. Clinical tests vary from simple, regular health checkups to specific and sensitive tests. Each test report is differently sensitive and needs a security level for defining clear authorization and access permissions. The given policies lack to define authorization and control over the access on the amount of data to be shared.

Our framework fine-grains the policies of H1 and H2 by assigning a logistic security level on the given association of two or more users while sharing EHRs. The values in table 4 are assigned as SL to each user-pair of rules defined in H1 and H2 respectively (Step 3). Based on the SL and the data to be shared, the health organization allocates the authorization control on the access of the EHR. Fine-grained policies of H1 and H2 generates permit/deny decisions on the basis of defined properties.

Property: *SPEC (Roles = Med_Tech) & (Security_Level = 2) & (Authorization = Doctor) & (EHR = Cl_test) & (MLSDefaultAction = write) & (Patient_Consent = True) -> decision = Permit*

With respect to the previously defined property, there exist similar set of rules in policies of H1 and H2 as verified in figure 7. The property is redesigned and inputted as request to ACPT (Step 4). Figure 8 shows the NuSMV verification result where the said property is found to be false in H1 and true in H2 (Step 5). The specification identifies the policy conflicts existing in two policies. Though both policies permit a write access on the clinical test details of the patient, differ in context of authorizations and SLs. A counterexample hence generated shows the state of conflict and the possible decision allowing or denying access to the requested data (Step 6).

The property verification generates enormous test cases based on m-way factoring. 'm' here denotes to the number of attributes that are logically combined to obtain a valid decision. ACPT allows 2-way, 3-way and 4-way factoring. Table 3 shows a subset of the test cases generated using 3-way factoring to verify the said property on the refined set of access control policies of H1 and H2. The combination of SL, Authorization and Patient Consent is tested for accessing laboratory details by the medical technicians that include nurses and other lab technicians. The rules defined for these users differ in both organizations. For ex. Med_Tech of H2 is permitted a read access on the test details holding SL as 1 and authorization as that of doctor. It clearly contradicts with H1 where no such rule is defined. Another situation exists where the rules are defined in both policies but exhibit disparate combinations of attribute values. For ex. Med_Tech having SL as 2 is permitted an access on the test details if the authorization is of doctor. The rules do exist in H1 and H2 with a variation of patient's authorization instead of doctor's authorization in H1. Hence, the decision obtained reflects a permit in H2 and deny in H1. The verification result identifies such conflicts wherever exist in the rule sets as shown in table 5.

Collaboration of two or more health organizations entails a specific purpose of sharing. An authorization defined on the same set of access rules would vary between disparate collaborations. Our framework exhibits dynamism in assigning the authorizations over the access of data. The framework permits to assign a different authorization on the basis of defined properties even on the similar set of rules in two or more health organizations. Thus, our framework proves to strengthen the security policies in dynamic sharable interoperable healthcare environment.

5. CONCLUSION

Due to different administrative constraints prevalent in heterogeneous systems, achieving interoperability and security while sharing data becomes a challenging task. Each health organization defines an organizational hierarchy and assigns roles and responsibilities to the users on the basis of their qualification and experiences. The users are positioned in a hierarchy ranked according to their ranks and authorities, usually from top to bottom. The ranking and authorization may be differently handled by each organization. Thus, a need arises to determine agreeable access to the data covering the security needs of the

Table 5. Permit/deny decisions obtained on generated test cases to validate the defined property

Role	Resource	Security Level (SL)	Authorization	Patient Consent	Permission	Defined in H1	Defined in H2	Decision H1	Decision H2

organization and patient as well. To ensure authorized and timely availability of data, a well-integrated secured access control framework is proposed. The framework bridges the interoperability gap and ensures authorized access to the EHRs by balancing the disparities in user's roles and privileges identified in two or more healthcare organizations. Similarity score is calculated to rank the users according to their position in the organization hierarchy. Rule attributes defined in the respective access control policies of disparate organizations are refined by assigning security levels and authorizations to the users. The input query is matched with the refined rule-sets along with the conditional constraints and a justifiable subset of matching rules is obtained. The security level ascertains the sensitivity associated with the data and authorizations ensure only relevant and required access is provided to the users. This further mitigates the problem of gaining additional or full access to the data due to frequent shift of roles and responsibilities of health providers. Another issue very common in heterogeneous environment is the emergence of policy conflicts resulting in either unavailable or unauthorized disclosure of data. The framework is capable in revealing inherent policy-conflicts on merging of disparate policies. The verification tool concludes that such conflicts are traceable and can be resolved. Counter examples generated by the simulator gives an indication of how these conflicts can be resolved.

5.1. Future Scope

Disparities in user's roles and responsibilities have been handled in this work. It can be extended many other disparities categorized into semantic, syntactic, temporal constraints and further devise a solution to mitigate the interoperability and security issues. Apart from resolving identified conflicts, the framework must be able to handle other contingencies for uninterrupted but secured access to the EHRs in interoperable healthcare environment. Timely updating the framework to handling of guidelines issued by various federal agencies like Health Insurance Portability Accountability Act (HIPAA) (Final Rule, 2013) and following the standards such as HL7, DAF (DAF, 2015) can further strengthen its viability and reliability. As stated by NIST, dual authorization, i.e. approval of two authorized individuals is mandatory for permitting the request can be incorporated with very little effort in the current framework.

ABSTRACT

With the rapid increment in the clinical text, de-identification of patient Protected Health Information (PHI) has drawn significant attention in recent past. This aims for automatic identification and removal of the patient Protected Health Information from medical records. This paper proposes a supervised machine learning technique for solving the problem of patient data de- identification. In the current paper, we provide an insight into the de-identification task, its major challenges, techniques to address challenges, detailed analysis of the results and direction of future improvement. We extract several features by studying the properties of the datasets and the domain. We build our model based on the 2014 i2b2 (Informatics for Integrating Biology to the Bedside) de-identification challenge. Experiments show that the proposed system is highly accurate in de-identification of the medical records. The system achieves the final recall, precision and F-score of 95.69%, 99.31%, and 97.46%, respectively.

INTRODUCTION

With the start of the golden era in the medical interpretation, the vast amount of information in the clinical domain is increasing at a rapid rate. In the past decade, with the development of the health information technology and health data documentation, there has been progress in how heath care is performed (Berner et al., 2005).

With the widespread use of health information technology, there has been huge pace in the increment of clinical data in addition to the fast adoption of the Electronic Clinical Records and with the conversion of narrative data to the electronic form. The amount of information can be improved further with the minimization of the medical error. This requires the development of some sophisticated tools for Medical Language Processing (MLP). Most medical records are in the narrative forms which are formed as the result of transcription of dictations, direct entry by providers, or use of speech recognition applications. However, their use in this form is restricted to any organization or research, as medical records have a sufficient number of personal health information or protected health information (PHI). According to Health Insurance Portability and Accountability Act (HIPAA), 1996, the PHI terms need to be enclosed and protected. This has lead to de- identification problem. Paragraph 164.514 of the Administrative Simplification Regulations promulgated under the Health Insurance Portability and Accountability Act (HIPAA) states that for data to be treated as de-identified, it must clear one of two hurdles (HIPPA ACT 1996).

1. An expert must determine and document "that the risk is very small that the information could be used, alone or in combination with other reasonably available information, by an anticipated recipient to identify an individual who is a subject of the information."
2. Or, the data must be purged from a specified list of seventeen categories of possible identifiers relating to the patient or relatives, household members and employers, and any other information that may make it possible to identify the individual.

Studies showed that there was a significant drop in the patient consent request reducing the participation rate and also, this is quite infeasible for the huge population. Even, in the case when a patient provides the permission, documents must be tracked to stop any unauthorized disclosure. This emerging problem of consent, waiver, and tracking can be effectively handled if the patient personal health information is properly de-identified facilitating the clinical NLP research (Wolf & Bennett, 2006).

De-identification task is more specifically defined as the step where the private information is removed or replaced while keeping the record as it is (Stubbs et al., 2015). De-identification is a type of traditional named entity recognition (NER) problem, with the property of defining a term to be PHI type or not. The main aim of de-identification challenge as pointed out earlier is to remove the PHI terms maintaining data integrity as much as possible. Every record is enclosed in the RECORD_ tags and is provided a unique ID which is randomly generated. Figure 1 shows Sample Discharge Summary Excerpt; a sample discharge summary from the training dataset where the goal is to identify the PHI (private health information) terms. In this summary, some the PHI terms are doctors' name ("Dr. Do Little"), patient name ("John Doe") and hospital name ("ABHG", "SBHG"). A TEXT_ tag encloses the text of different records. Each PHI instance is enclosed within PHI_ tags and the PHI TYPE represents the category of the PHI term as shown in Figure 1.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

</RECORD>
```

As shown in Figure 1, the task is to enclose the PHI terms such as (“Dr. Do Little”, “John Doe”, “ABHG”, “SBHG”). This task can be seen as the typical sequence labeling task where for e.g. “Dr. Do Little” should be labeled as whole with Doctor. Here, we present an example where input forms the sequence of words and output is the label sequence and its corresponding de-identified sentence. “BIO” notation was followed to label the NE where “B” represents the beginning of label sequence, “I” denotes intermediate of label sequence and “O” represents others.

In the past few years, de-identification of the clinical record has become the booming research area. Sixth Message Understanding Conference (MUC) had defined the Named Entity Recognition (NER) problem with an objective to identify the relevant entities from the text. NER forms an important task in NLP. Similarly, in the medical domain, NER is very crucial in the identification of the clinical terms by which we can get insights to the problem, medication, procedure, and examination.

Major research works for entity extraction in the medical domain had used machine learning and rule-based concepts. MedLEE (Friedman et al., 1996) is one such system in clinical domain proposed by Carol Friedman et al. at Columbia University. Aronson (2001) developed MetaMap system at National Library of Medicine. Another system cTAKES (Savova et al., 2010), developed using Unstructured Information Management Architecture (UIMA) framework and OpenNLP, a widely accepted system.

Recently, the Medical Natural Language Processing Community had organized a number of challenges for NER task. The earliest shared task is organized by Center of Informatics for Integrating Biology and the Bedside (i2b2) in 2009 on medical name recognition (Uzuner et al., 2010). In 2010, i2b2 shared task was conducted with the aim to identify the medical problems, test entities and various treatments from

Table 1. Example of PDI task following BIO notation

Sentence	Mr.	John	D	Doe	is	xx-year-old	white	male
Named Identity	O	B-Doctor	I-Doctor	I-Doctor	O	O	O	O
De-Identified Sentence	Mr.	XYZ_Doctor			is	xx-year-old	White	male

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the clinical records (Uzuner et al., 2011). Since then, Conference and Labs of the Evaluation Forum (CLEF) had organized a challenge in 2013 with the aim of solving disorder mention recognition and normalization (Goeuriot et al., 2013). Very recently, i2b2 in 2014 (Stubbs et al., 2015) had organized a challenge for patient data de-identification problem and CUI (concept unique identifier) detection. Semantic Evaluation (SemEval) 2014 also came up with the disorder mention recognition and the normalization. With a large number of challenges organized almost every year, it had drawn the attention of many researchers to solve these real-life challenging problems.

Different approaches have been used to solve this problem ranging from machine learning techniques (Stubbs et al., 2015; Yang et al., 2015), rule-based system (Beckwith et al., 2006; Berman et al., 2003) to the hybrid system. Rule-based systems are designed over dictionaries with the rules that are designed manually to recognize the PHI terms from the text. Building a system using rules lacks generalization capability as well as it consumes more time and skill for developing rules. Rule-based systems are seen to provide good performance for the PHI terms those appear less often. This has lead to the development of some machine learning techniques for automatic extraction of PHI terms from the text which makes the process more generalized. The only drawback of machine learning based approach is the requirement of having large annotated corpus which can be developed manually.

Generally, the NER problem is the sequence labeling problem where the aim is to identify the proper output sequence of the entities. Thus, for the given input sequence of words, we need to obtain the best labeled- sequence. Researchers have primarily used supervised machine learning algorithms to solve this kind of medical NER problem. The algorithms used for extracting medical entities are Conditional Random Fields (CRFs) (Lafferty et al., 2001), Maximum Entropy (ME) (McCallum et al., 2000), and Structural Support Vector Machines (SSVMs) (Xue et al., 2008). Among these different classifiers, Conditional Random Field had drawn a huge attention for solving the sequence labeling task. Top best system (Yang et al., 2015) of de-identification task had used CRF as the underlying classifier because of the property of CRF to properly map the relationships between their surrounding tokens. Supervised machine learning techniques are able to capture the handcrafted features very effectively. Some of the prominent features which have been used are orthographic features that capture the word structures, syntactic features like Part of Speech (PoS), and semantic features as well as the discourse features. These features are typically used for solving any NER problems. Many other domain specific features could be generated for further improving the performance of the system.

In the current work, we develop a supervised machine learning based classification framework for solving the patient de-identification problem. The proposed method is evaluated on the i2b2 2014 dataset. It concerned identifying four different PHI categories, namely PATIENT, DOCTOR, HOSPITAL names and DATE from the medical records. Taking into account the effectiveness of applying CRF in solving the NER problem, CRF was adopted to train the model. Diverse features are extracted and CRF based model was trained using this huge collection of features. Several experiments were carried out with different cross folds. Results of the proposed system are shown for different cross-validation settings like 5,6,7,8,9,10 fold cross validations.

This task suffers from various challenges as similar to any NLP task. One such challenge is the ambiguity problem where we found that due to the lexical similarity PHI terms mostly overlap with the non-PHI terms. An example includes Brown (Doctor name) which is a PHI term vs. brown (Colour name) which is a non-PHI term. Another major challenge is the occurrence of some out-of-vocabulary PHI terms which are not present in the dictionaries. These words act like the foreign words which can be misspelled. Gazetteers list, dictionaries are the mostly used for solving any NER problem but the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

contribution of these types of words lowers the performance and creates some errors. Results obtained prove that the proposed system outperforms the existing systems in identifying four different PHI terms.

The remaining paper is organized as follows. Next immediate section discusses the background of de-identification task and its significance. This is followed by a section which provides the insight to the related work. Next section discussed the methodology adopted for the de-identification which is followed by the details of experiments and their analysis. Finally, we conclude in the last section.

BACKGROUND AND SIGNIFICANCE

Most of the works done in biomedical Natural Language Processing (NLP) domain can be distinguished into two different types on the basis of the text, biomedical text and clinical text (Meystre et al., 2010). Biomedical texts are the texts that appear in the journals, articles, posters etc. On the other hand, the clinical texts are mostly the texts written by the doctors in the form of prescriptions for the patients. This text comprises of the patient information like his/her name, age, gender, the procedure that was applied to him/her and what are his/her medical histories. These texts also provide insights to the findings made during procedure and the medication provided to them.

The clinical text is the whole range of narrative found in the patient records. These texts vary from the short-segment which gives the chief complaints to the long-text comprising of the history of the patients. There is another class of text which is discussed in the literature very often (Coorevits et al., 2013). While some of the texts are similar to that of biomedical texts for example internal research reports, the others appear to be like clinical texts for example patient notes. As these narratives are rarely exposed outside the organizations, there is a very sparse study on them.

There is one obvious question that what distinguishes clinical text from the biomedical text and why processing of these poses a challenge to the NLP society. Firstly, in the clinical texts, a large number of grammatical errors can be found which may have occurred at the telegraphic phrase. Other segments in clinical documents which create some problem are discharged summaries and the lab test reports. Moreover, clinical documents suffer from the problems like abbreviations and acronyms. These lexical structures are often overloaded i.e., there is a multiple rendering for the same word set. Literature shows that almost 33% of the times, acronyms are overloaded which makes it prone to the ambiguity problem (Liu et al., 2001). There is a huge problem due to the spelling mistake, which is observed most commonly in the notes lacking spelling support. US Veterans Administration (VA) has one of the largest EHR systems with only the basic text support. Even in their corpus, there are lots of abbreviations and acronym problem. Furthermore, the clinical data consists of different types of characters which appear anywhere within the text. Another problem that is raised is to change the unstructured narrative text into the structured; templates along with pseudo-tables are in general used in the method of conversion (Meystre et al., 2010). Template having a narrative structure for patient history or the discharge summary that is common among the medical society provides benefits to NLP. Explicit templates are formatted text with the fields specific to the institution are filled by the user. These different variations in template make this domain quite challenging.

There are many methodologies adopted to cover different types of questions related to clinical research domain (Dehghan et al., 2015), (Liu et al., 2015), (He et al., 2015). Although, the pharmaceutical industry covers the clinical trails and therapy but nowadays, these industries are spreading the horizon of solving the medication issues like drug interaction, disease prevention through the proper investigation of

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

diseases. These include the course of the disease and various other factors like, what were the different criteria for diagnosis, how the patient education affected his/her health and his/her surveillance. With the rapid and booming research interest in the clinical domain, the studies have also spread to obtain the role of different gene pathways in the identification of their relations in the development of diseases. Some clinical research focuses on improving the health care with lowering the health care cost, thus providing the benefits to the mass. As such, it is highly important to have a proper study of the clinical records in solving the major unsolved and challenging problems of the society with the NLP system.

De-identification task forms one such challenge which aims to identify the noun phrases or part of a noun phrase automatically from the text. In the traditional named entity recognition task, originated by the MUC challenge, the focus was to identify the person, organization, location names from the newspaper type electronic text. Generally, de-identification task is the task of identifying and enclosing patient personal health information like not just identifying the persons but also identifying the type of person (Patient, Doctor), Organizations (Hospital), Location (Streets, Country), ages, dates but not in the term of years. Apart from these, structures of the text too vary a lot. While in newswire or journalistic domain, lots of clues can be obtained from their titles, abstract and cases while in the patient records, due to its semi-structured form the task becomes quite challenging.

LITERATURE SURVEY

De-identification task is a type of the traditional Named Entity Recognition (NER) problem. Message Understanding Conference had been the center for the evaluation of NER system in several domains. MUC had organized several challenges to identify several named entities like person, location, organization, time, dates etc. For the MUC-6 NER task, a total of 15 teams participated in the challenge submitting 20 different systems. The best F-Measure value reported was 96.42% (Sundheim, 1997). In the MUC-7 challenge, 14 systems were submitted from 12 different teams obtaining the highest F-Measure value of 93.39% (Chinchor, 2001). National Institute of Standards and Technology (NIST) organized two different tasks, Information Extraction Named Entity task and the Automatic Content Extraction (ACE) tasks. Both of these tasks were evaluated on the newswire domain.

In the biomedical domain, Critical Assessment of Information Extraction Systems in Biology (BioCreAtIvE) (Hirschman et al.,2005), organized several biomedical challenges including the entity extraction task, where the task is to identify different entities like gene name, protein name from the given biomedical text derived from the PubMed, PMC. PubMed and PMC are huge repositories consisting of almost 3.5 million biomedical literature. For the evaluation, TREC Genomics Track was considered. The BioNLP 2009 challenge (Kim et al., 2009) focuses on event extraction primarily on the protein and gene event extractions. The same challenge was also focussed on BioNLP 11(Pyysalo et al., 2011) and BioNLP 13 shared task (Nedellec et al., 2013), where data was used from MEDLINE. Another task BioASQ was organized for entity extraction using data from PubMed. Several challenges have been organized for entity extraction. Recently, i2b2 had organized the task for the de-identification of the clinical terms in the years 2006 and 2014 (Stubbs et al., 2015). Here, the challenge was to identify the certain PHI terms.

In the 2006 shared task, a total of 889 patient records were used. This challenge got sixteen submissions from seven different teams. The challenge had used longitudinal records of each patient rather than the individual records. It was observed that longitudinal records contain more personal information of patients rather than an individual record. Completely identifying the patient information from individual

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

records is a problematic task. This makes the de-identification using the longitudinal records a more complicated task. The submitted systems identified the task as a token classification task (using Support Vector Machine) while some distinguished it as the sequence labeling task (using Hidden Markov Model, Conditional Random Field).

Wellner et al. (2007) in i2b2-2006 challenge built the best system based on CRF. They used some lexical and semantics features. They adapted two important NER systems, one based on the CRF, Carafe, and other Lingpipe, HMM-based implementation. The carafe was seen to be highly effective in capturing the PHI terms. Szarvas et al. (2007) adopted an iterative method for named-entity de-identification. They treat de-identification as a classification task and use machine learning based decision tree with local features and dictionaries. Aramaki et al. (2006) also used CRF as their classifier with the features such as local, external and global features. The global feature includes the features which capture position, the length of a sentence and also several tokens in the previous sentence. External features include the dictionary for location, person name, and dates. They performed two-phase learning wherein the first phase, they learned their system using local features and in the second phase, they include first phase features set in addition to the most frequent label. They identified that sentence feature is very informative in identifying dates, IDs and patient because of the appearance of this PHI in beginning of the records while the external feature was useful in identifying dates, locations, doctors and patients.

While many systems have used CRF based classifier, some submitted systems also used SVM. Hara (2006) developed a hybrid system making use of rules. The rules identified the patterns for the PHI terms such as phone numbers, IDs, and dates. They train SVM on the global and local features which were found to be very helpful in identifying the PHI terms such as a hospital, patient, location, doctors, and age. In addition to these features, their system included the section heading which is closed to the target, category of the sentence, the surface form of target, the root, PoS tag and orthography features. The system used two types of the ordered tree, dependency tree and "n-grams trees" making use of the Boosting Algorithm for Classification Trees (BACT). With this information and in addition of chunking technique, they identified the position and the text span of PHI terms such as a patient, doctor, location, and hospital. The results show that performance is degraded with the incorporation of sentence feature.

In 2014 patient de-identification task, machine learning technique was more prominent. According to the 2014 i2b2/UTHealth shared task, the challenge was to de-identify the data in a stricter way as compared to the HIPAA standards in the form of additional categories. The task was to identify the 25 PHI categories with the associated subcategories from the clinical records like professions, time and dates, facilities etc. These tasks also consider the longitudinal records. Yang et al. (2015) submitted the system in the i2b2-2014 challenge and they reported the accuracy of 93.60%. This was the best performing system. They developed a hybrid model which used both the machine learning and the rule-based technique to extract the PHI terms. They exploited the various features like linguistic features, syntactic feature and different word surface oriented features which were further improved by using the task-specific features. They also used the regular expression pattern to identify the PHI terms like date, ID.

The second best system (Dehghan et al., 2015) from Manchester used a combined system developed using the knowledge-based technique as well as the rule-based system. The rules were defined to obtain the orthographic features, different patterns. They used CRF as the underlined classifier to obtain the PHI terms. For some categories like PATIENT, DOCTOR, HOSPITAL, the initial annotation was extracted at the patient level and dictionary was created for the patient. At the last stage, the outputs of the rule-based system, as well as the CRF based model, were integrated on the basis of some rules. These systems were highly efficient in obtaining the PHI terms such as the DATE, DOCTORS, and PATIENT.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

System (Liu et al., 2015) from Harbin Institute of Technology Shenzhen Graduate School in i2b2 challenge used two different variations of the CRF. They define one CRF system working at the token level while another CRF system that works at the character level. They performed feature engineering and used the features such as bag-of-words, section relevant features, lexical features, semantic features. Apart from the two different CRF outputs, the third output was obtained by developing the rules using the Rule-based system. The final outputs of all the three systems were merged on the basis of the output overlapping. If there was no overlapping i.e., if all the three systems obtained the same PHI tag, then that tag was accepted else the tag was obtained on the basis of the preference. They give the first preference to the rule based system, then the character-level system and lastly to the token-level based CRF system.

Another submitted system from Harbin Institute of Technology (He et al., 2015) used OpenNLP system to pre-process their data, sentence splitting, and tokenizer. They trained their system using CRF making use of features such as lexical, syntactic and orthographic features. They did not use external features such as dictionaries to identify the terms. The system developed by Kaiser Permanente (Torii et al., 2014) adapted the MIST tool. They include some additional rules that used lexicon for Location and Profession and different regular expressions for the categories such as Phone Numbers, ZIP and Organization. In addition to MIST system, the team learned NER model using Stanford NER system. The system then merges the overlapped identified entities. They reported the F-Measure value of 92.21%.

Through the literature survey, we found that hybrid systems (both the rule-based system as well as the machine learning based) perform well when compared with the individual techniques. It is reported that among top ten ranked systems, seven systems have adopted the rule-based technique. MedEx (Xu et al., 2010) forms one such system proposed at Vanderbilt University that utilizes the biomedical dictionary to identify the important medical concepts.

Overall, the best systems report high recall and precision, often greater than 90%, and sometimes as high as 99%. Nevertheless, no study has evaluated the performance of automated de-identification for all PHI classes (Meystre et al., 2010). Only a handful of studies provide details on over-scrubbing (non-PHI wrongly identified as PHI) and none of them investigate the effect of de-identification on subsequent IE tasks. It is indeed possible that de-identification has an adverse effect on IE accuracy (Meystre et al., 2010). Over-scrubbing errors could overlap with useful information, for example, if a disease name is erroneously recognized as a person name, it will be removed and lost to subsequent IE applications. Second, NLP techniques such as part-of-speech tagging and parsing may be less effective on modified texts.

It can be concluded that though a lot of systems have evolved in the recent past, but still there is a need to develop a more accurate automated de-identification system.

METHODS

Supervised machine learning based classification frameworks have been developed to detect the PHI tokens from the medical records. Similar to any entity extraction technique, de-identification task is also considered to be the sequence labeling task. The proposed system architecture is divided into four different modules. The first module deals with the pre-processing of data. The second module represents the feature engineering part where features are generated. Training of the model through Conditional Random Field (CRF) is done in the third module. The fourth module represents the de-identification of the PHI terms. Detailed descriptions of the methodology adopted for the system are given below. Figure 2 represents the Proposed System Architecture.

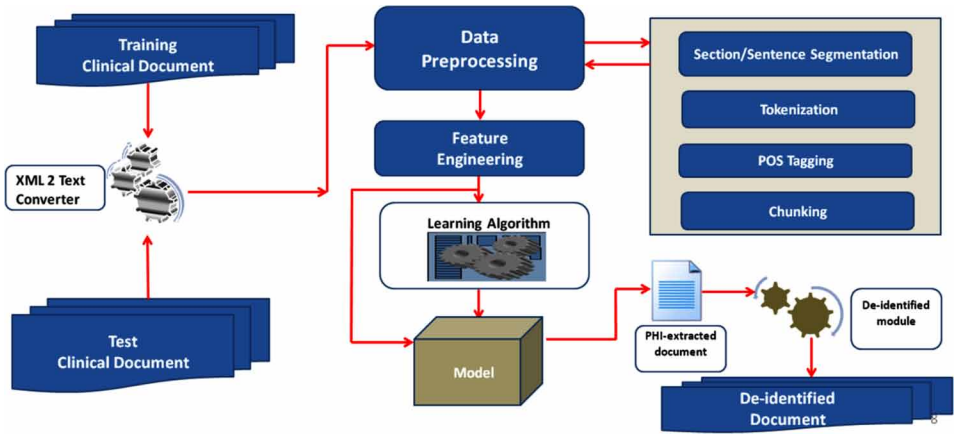
Figure 2. Proposed system architecture



Pre-Processing of the Medical Records

Datasets provided with the i2b2 de-identification challenge were untokenized; this necessitates the use of the pre-processing module for the process of tokenization. The pre-processing was performed in three different stages. The first stage of the pre-processing module deals with the sentence splitting. The second module focuses on the tokenization of the medical records. The last and final stages are used to identify the rules for tokens such that when they are divided, they should match some patterns.

Apart from this process, pre-processing steps also include shallow parsing and Part of Speech (PoS) tagging to obtain the word lemma, chunk and part-of-speech of the corresponding words. Additionally, we extracted some of the document- level features, for example obtaining the different sections (HISTORY OF PATIENT ILLNESS, MEDICATIONS etc.) and position of the sentence in the text (beginning of the text, end of the text) using some of the hand-crafted rules.

Feature Generation

This module focuses on developing some prominent features. The features were developed, such as the linguistic, syntactic features as well as word surface-oriented features in order to capture the semantics of the PHI terms. The features were further enhanced by embedding the feature set by the task-specific features. The list of the extracted features for the PHI recognition task is given below:

- **Token Features:** Some features are generated during the pre-processing step like word lemma, word chunk and the Part-of-Speech tag of the current word.
- **Bag-of-Word Feature:** It includes the unigrams, bigrams, trigrams of the target token within the window size of [-2, 2]. An *n*-gram is a contiguous sequence of *n* items from a given sequence of text or speech. An *n*-gram of size 1 is referred to as an unigram, size 2 is a bigram and size 3 is a trigram.
- **Contextual Features:** This feature is the combined feature which includes the lemma, chunk, POS tag of the surrounding tokens. We consider the window size of [-3, 3]. These features give the context knowledge for each word.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Combined POS-Token Feature:** The combination of POS tag within the context of [-1, 1] and the current token $\{w_0p_{-1}, w_0p_0, w_0p_1\}$ is formed, where w_0 represents the current word, and p_{-1}, p_0 and p_1 represent the previous POS tag, current POS tag and the next POS tags respectively.
- **Affixes:** This feature includes prefix and suffix of the word. It refers to the fixed length characters stripped either from the left most part or the rightmost part of the token. For example, the suffix and prefix of word 'health' are h, he, hea, heal and h, th, lth, alth respectively. Here, we set the length to size 4.
- **Sentence Information Feature:** This feature includes the structure of the sentence. It includes the information regarding length of the sentence, whether the sentence has any delimiters like '.', '?', '!', whether there is any bracket unmatched.
- **Orthographic Feature:** Several orthographic features were developed to capture the capitalization and digit information. These are very useful information to capture the entity extraction. Symbol such as the ',' is found to be very crucial in detecting the boundaries of the NEs. Table 2 lists some of the orthographic features with their examples in uses.
- **Word Normalization:** Two different variants of this feature were developed. The first feature is used to capture the words which are in plural form, verb, alphanumeric letters, hyphen, and digit. This feature actually converts the words to its root form. Another feature represents the orthographic construction of the words. This feature is termed as the word shape feature where each word is mapped to its respective class. Words are normalized by converting every uppercase character by 'A', lowercase character is changed to 'a' and every digit by '0'. For example, if the token is 'Medical-49', its normalized form would be 'Aaaaaaa-00'.
- **Word Class Feature:** This feature is generated motivated by the fact that similar entities reside within the similar class. This feature is the enhancement of the word normalization feature. After the word conversion, the squeezing operation is performed where the consecutive sequence of words is converted into the single character. For example for the word 'Medical-49', its word class form would be 'Aa-0'.
- **Section Feature:** This binary feature was generated after extracting the sections from the training set manually. Top 16 sections were extracted with their probabilities of carrying the relevant PHI terms. These sections were generated manually and form very effective feature in the identification of the PHI terms.
- **Gazetteer List:** For the identification of the PHI terms, task related term list helps in improving the performance of the system. These lists include the headings which give very strong remarks about the occurrence of the PHI terms. Example: 'Transcribed by', 'Dictated by'. These sections carry information about the occurrence of the DOCTOR name. Apart from this, the dictionary was used for the names like the common names across countries, full name and the abbreviation of the common US locations for e.g. "New York" and "NY". We used the list of names for the days, months.

In addition, some lexical clues were identified for each individual PHI category. These are the types of the trigger words that give an indication regarding the presence of the particular PHI terms for example 'Dr.', 'M.D' in the case of DOCTOR, 'Mr.', 'Mrs' in the case of the patient. These lexical clues are obtained from the neighboring contexts of the target PHI terms. These are filtered on the basis of occurrence and their importance with the target PHI categories.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Some of the orthographic features with their examples in uses

Feature	Example	Feature	Example
InitCap	David	CapMixAlpha	EpoR
InCap	mAb	DigitSpecial	12-4
DigitOnly	12,23	AlphaDigitAlpha	IL34S,EIB
DigitAlpha	28BC	CapLowAlpha	Srs, Ras, Epo
Hyphen	_	DigitCommaDigit	2,34
CapsAndDigits	28Houston	LowMixAlpha	mAB,mRNA
StopWord	at, on	AllCaps	DHC
AlphaDigit	s72	EndwithDot	Dr., Mr.

- **General Entity Information:** The Stanford Named Entity Recognizer (http://nlp.stanford.edu/software/CRF-NER.shtml) was used to obtain the named entity tag of the corresponding token.
- **Discourse Features:** This feature plays a very important role in the identification of the terms that are very much related to section headings and their positions of occurrence in the sentence. For example the strong contextual clues words like'CC:' and 'Dictated by'.

Classification: CRF Classifier

We trained our system using the Conditional Random Field algorithm. This algorithm is very popular in the domain of entity recognition because of its ability to tackle the sequence labeling task very efficiently. CRF is categorized under the class of statistical modeling. They are mainly applied for the structural prediction which is formed by the combination of classification and graphical modeling methods. CRF integrates the performance of the graphical models to compactly model multivariate data and classification methods to perform prediction using a large set of input features.

The CRF-classifier works on the Markov Assumption that given the observation sequence of the token x_1, x_2, x_3 .....x_n, the corresponding label-sequence y_1, y_2, y_3 .....y_n is predicted by the CRF. It maximizes the conditional probability for every *y* in the possible set of label sequence. Mathematically, CRF can be represented as

$$\exp\left(\sum_{j} \gamma_j t_j(y_{(i-1)}, y_i, x, i) + \sum_{k} \mu_k s_k(y_i, x, i)\right) \quad (1)$$

Here, $t_j(y_{(i-1)}, y_i, x, i)$ represents the transition feature function for the whole set of observation sequence. *i* and (*i*-1) denote the position of the labels in the label sequence. Here $s_k(y_i,x,i)$ represents the state feature function at the label position *i* and observation sequence. γ_j and μ_k are the parameters estimated from the training dataset. While defining the feature function, the real valued feature set of the observation is constructed as $b(x,i)$. It expresses empirical distribution characteristics of the training data in order to hold the model distribution.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are various other algorithms that can handle the sequence labeling task like Maximum Entropy Markov Model (MEMM) and Hidden Markov Model (HMM). The main advantage of CRF over HMM is that it is conditional in nature, which helps in relaxation of the independence assumption as needed by the HMM. Apart from that, CRF is very much efficient in handling the label bias problem. Label bias problem is due to the directed graphical model that is exhibited by MEMM and HMM. It was observed that CRF outperforms the other models in a number of tasks such as speech recognition, bioinformatics.

De-identification task targets to automatically extract the PHI terms with the proper boundary identification. As CRF being the better performer than other models, this work used CRF as an underline base classifier. The open source toolkit CRF++ was used to carry out our experiments. BIO notation was followed to label the PHI terms which occur in sequence. Here 'B' identifies the beginning of the PHI token, 'I' represents that the PHI token is within the sequence. 'O' is used to identify that token belongs to none of the PHI term categories.

For the classifier learning, whole feature set discussed in the previous section was used. CRF modeling is done by considering all the PHI categories through learning by the training phase and predicting the output of the model built during the test phase.

De-Identification of PHI Terms

In order to hide the patient personal information, de- identification of the PHI terms is highly necessary. A template was adopted through which we convert all PATIENT, HOSPITAL, DOCTOR names present into a generic format like XYZ_PATIENT, XYZ_HOSPITAL, XYZ_DOCTOR, respectively and all the dates into the format 00-00_DATE. Thus, capturing the information required without compromising the personal details. We represent this below in Figure 3 by considering the original document and the de-identified document. Figure 3 shows De-Identification Process.

Figure 3. De-identification process

DATASET AND EXPERIMENTS

Dataset

The 2014 i2b2 challenge dataset was used in the current paper, which was taken from the Research Patient Data Repository of Partners' Healthcare. A total of 1304 medical records basically of longitudinal nature were manually annotated. These records were obtained from 297 patients following the annotation guidelines. The dataset was divided into two parts where the first part consists of 790 records of 188 patients that were used as the training dataset and 514 records of 109 patients were test dataset.

i2b2-2014 challenge dataset compromises of 17,045 PHI relevant instances in the training dataset, while the test dataset consists of total 11,462 PHI instances. To ensure the patient confidentiality as much as possible, the challenge aims to identify HIPAA- PHI categories firstly with the added subcategories. They were annotated using seven main PHI categories with the twenty- five associated subcategories. While our experiments cover the seven main PHI categories, i2b2 challenge covers almost all HIPAA defined categories and subcategories. The list of categories, as well as subcategories that were needed to be identified, is as follows:

- NAME (subtypes: PATIENT, DOCTOR,USERNAME)
- PROFESSION
- LOCATION (subtypes: HOSPITAL, DEPARTMENT, ORGANIZATION, ROOM, STREET, CITY, STATE, COUNTRY, ZIP)
- AGE
- DATE
- CONTACT(subtypes: PHONE,FAX,EMAIL,URL,IPADDRESS)
- Ids(SUBTYPES: MEDICAL RECORD NUMBER, HEALTH PLAN NUMBER, SOCIAL SECURITY NUMBER, ACCOUNT NUMBER, VECHILE ID, DEVICE ID, LICENCE NUMBER, BIOMETRIC ID)

In this work, the aim was to identify four different PHI subtypes; PATIENT, DOCTOR, HOSPITAL name and DATE from the above-defined categories. The experiment was performed with only the training dataset.

Evaluation

The system was evaluated by using 10 fold cross-validation on the training data. For evaluating the classifier's performance, we have used the most popular evaluation metrics; recall, precision, and F-Measure. Recall also known as sensitivity is defined as the ratio of total number retrieved relevant documents to the number of relevant records. Precision represents the positive prediction and is the ratio of retrieved relevant records to the total number of documents.

Recall and precision are represented as follows

$$recall = \frac{Total\ number\ of\ correctly\ predicted\ NE}{Total\ number\ of\ actual\ NE\ present\ in\ the\ gold\ data} \tag{2}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$precision = \frac{Total\ number\ of\ correctly\ retrieved\ NE}{Total\ number\ of\ NE\ retrieved\ by\ the\ system} \tag{3}$$

F-Measure considers both the precision and recall. It is defined as the harmonic mean of recall and precision. We defined F-Measure value as follows:

$$f_{\alpha} = \frac{(1+\alpha^2)(recall * precision)}{\alpha^2 * precision + recall} \tag{4}$$

Here we set the value of α=1.

Experimental Results

Table 3. reports the extensive results of 10-fold cross validation: Recall, Precision and F-score values for individual entities. The system was developed using the handcrafted feature set trained on CRF. It was an interesting observation that with the set of whole features learned using CRF, the system performs quite well. The system was evaluated using 5,6,7,8,9,10 fold cross validation. Here, the performance of the proposed system with10 fold cross validation is reported.

Table 3 shows that overall system has achieved good recall values as compared to precision values. But there are some interesting observations regarding the recognition of individual entities. If the comparison is done on the performance among 3 important PHI terms; Hospital name, Doctor Name & Patient name then Doctor class is having the highest precision and recall values of 99.70% and 93.80% respectively. Precision and recall values for Date are quite good, but the performance can be further improved by introducing some more date based patterns. The recall value for the hospital is low as compared to all the PHI terms introduced here; the one possible reason behind this is to use abbreviation instead of full hospital names.

The report shows that the system is accurate in predicting the PHI terms with the high degree of precision. The detailed error analysis is performed on the obtained results.

Table 4 shows different error cases. Here, X or Y represents any class like PATIENT, DOCTOR, HOSPITAL, and DATE. “B_X” or “B_Y” represents the beginning of the token, “I_X” or “I_Y” represents the intermediate of the token and “O” denotes others.

Table 3. Results of 10-fold cross validation: Recall, precision & F-score values for individual entities

Class	Recall	Precision	F-Score
Overall	0.9569	0.9931	0.9746
Hospital	0.9056	0.9769	0.9399
Doctor	0.9380	0.9970	0.9666
Patient	0.9355	0.9831	0.9587
Date	0.9905	0.9984	0.9944

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Different error cases

Case	Actual Labels	Classified Labels
MISSED ENTITY	B_X I_X	O
ACTUAL ENTITY	B_X I_X	B_Y I_Y
WRONG BOUNDARY	B_X I_X	B_X O
OVER PREDICT	O	B_X I_X

Table 5 mentions about case 1: missed entity error. Here the system was unable to identify the entity. In the following e.g. 'DO' which in actual represents the Doctor name was predicted as others. The reason for the error is the short words or the abbreviated words. 'DO' is the abbreviated form of doctor name 'DO D LITTLE' which is missed by the system.

Table 6 presents the case 2: actual entity error. Here the entity was predicted but was not able to classify it in the proper class. For example in the following sentence, 'FOR' was captured as the B-DOCTOR while it should be others.

Table 7 represents the case 3: wrong boundary error. This case represents the boundary detection problem, where the system was able to capture the token properly but was not able to properly identify the boundary of the token. In the below example 'LITTLE' was not identified as the boundary of the system.

Table 8 represents the case 4: over predicted error. Last error occurred due to the over prediction where non-entity was categorized as the entity. For example here 'DO LITTLE' was categorized as the entity and was tagged by the DOCTOR. It might be because our system is unable to properly identify the context.

Table 5. CASE 1: Missed entity error

Words	DR.	DO	2	.	DO	D	LITTLE	,	M.D	.
Actual	O	B-DOCTOR	O	O	B-DOCTOR	I-DOCTOR	I-DOCTOR	O	O	O
Predicted	O	O	O	O	B-DOCTOR	I-DOCTOR	I-DOCTOR	O	O	O

Table 67. CASE 2: Actual entity error

Words	Dictating	For	DO	LITTLE	,	M.D	.
Actual	O	O	B-DOCTOR	I-DOCTOR	O	O	O
Predicted	O	B-DOCTOR	I-DOCTOR	I-DOCTOR	O	O	O

Table 7. CASE 3: Wrong boundary error

Words	HE	WILL	FOLLOW-UP	WITH	DR.	DO	LITTLE
Actual	O	O	O	O	O	B-DOCTOR	I-DOCTOR
Predicted	O	O	O	O	O	B-DOCTOR	O

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 8. CASE 4: Over predict error

Words	DO	LITTLE	THORACOSCOPIC	EXAM	BX	DRAINAGE	.
Actual	O	O	O	O	O	O	O
Predicted	B-DOCTOR	I-DOCTOR	O	O	O	O	O

From the confusion matrix presented in Table 3, it was identified that mainly case 1 type of the error was more dominated.

- DOCTOR was tagged as O where there are the following forms: < D1 > M.D., < D2 > M.D., < D3> M.D.
- Misclassification has occurred when Hospital name is written in short for example CMC, FIH, OLH, HGMC etc.
- Most of the misclassification errors occurred when the patient name was preceded by the Mr., Mrs., Ms.
- Dates of the forms like 11th of April, January 25, Veterans Day were not captured properly.

CONCLUSION

In this paper, a clinical de-identification system is developed that aims to identify the Protected Health Information and to classify them into the predefined categories present in the clinical records. The proposed approach for de-identification is purely based on a popular machine learning technique. A variety of domain independent features, semantic, lexical features were designed for the system to be domain adaptable. Various others features extracted from localization dictionaries were combined in order to further enhance the performance of the system. The proposed system achieves encouraging performance. The system obtained the overall F-Measure of 97.46%, in identifying PATIENT, HOSPITAL, DOCTOR names and DATE.

However, a lot of issues are yet to be resolved. One such issue is to resolve abbreviation problem which is identified as a non-PHI term. In addition, it would be interesting to observe the performance of the proposed system on other type of PHI mentions.

FUTURE WORK

In future, this work can be extended using deep neural network architecture to identify the PHI terms from the medical records. Another major challenge is to deal ambiguity and abbreviation problem to properly distinguish PHI terms with non-PHI terms which can be another future work.

KEY TERMS AND DEFINITIONS

Classification: Classification in the machine learning is defined as the supervised learning technique where problem is to identify the class of the new observation with the already developed observations through the labeled data.

Conditional Random Field (CRF): An undirected probabilistic graphic model categorized under statistical modeling method used for structured prediction in machine learning and pattern recognition.

Health Insurance Portability and Accountability Act (HIPAA): An act formulated in 1996 for the secure transmission and usability of the private health information electronically.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Machine Learning: A field of computer science that exploits the development of the algorithms for making a prediction on the data on the basis of its learning.

Medical Natural Language Processing: A domain of natural language processing that focuses on text mining of the medical records like clinical texts.

Named Entity Recognition (NER): An entity extraction task which aims to identify and retrieve the text carrying relevant information into some predefined categories.

Natural Language Processing (NLP): A domain of computer science, computational linguistics and artificial intelligence that focuses on computers understand to human languages or natural language.

Support Vector Machine (SVM): A supervised learning model used in the classification that learns from the data by developing a model that maximizes the error margin.

ABSTRACT

Geographic information systems (GIS) are useful informative systems for reducing the waiting time of diagnostic imaging examinations. ArcGIS software is used to develop a digital questionnaire which is used as a data collection tool. The information concerns the patients' personal information, type of examination required and medical history. Data is collected in real time and through GPS capabilities, the patients' exact coordinates are determined. GIS applications are used to create digital maps which display the average waiting time for performing imaging tests. Questionnaire data and interactive maps are uploaded to a digital platform. Through this application, it is possible to locate patients who actually need diagnostic imaging examinations in real time. Observing the location of patients on digital maps makes it easier to redirect them to the nearest health care units with the shortest waiting time. Data can also be acquired by mobile phones.

INTRODUCTION

In recent years the digitization of health services has greatly optimized the quality of the services provided. The continuous improvement of online applications helps users to deal with the rising health needs and contributes to cost savings. The use of digital media requires the handling and processing of large volumes of data. In the past, most data was stored in hard copy form, but nowadays, big data digital processing is considered to transform the way of living and working in most business areas. By digitizing, potential benefits occur that include early detection of diseases, effective prevention of healthcare fraud and prediction of financial outcomes (Raghupathi & Raghupathi, 2014). Big data analysis helps healthcare providers to develop cost-effective treatments and improve the quality of healthcare services. The release of big data enables health companies to develop innovative applications that help patients to improve their health status. Web-based applications use Informatics Technology (IT) to guide patients to the most effective treatment methods and thorough diagnosis.

Several review papers reveal the advantages of Geographic Information Systems (GIS) in healthcare services. GIS enable users to identify spatial inequalities inaccessibility of healthcare services (Neutens, 2015). They can be used to direct patients in neighboring healthcare services, in a very short time, especially when patients desire specific treatments (Masoodi & Rahimzadeh, 2015). The GIS analysis supports advanced calculations of disease distribution and environmental risk factors (Béland et al., 2014). Furthermore, the majority of review papers report positive results in integrating GIS applications and mobile applications (Nhavoto & Grönlund, 2014). Recent studies also reveal that GIS systems can easily be connected to mobile cloud computing systems for effectivebig data processing (Lo'ai et al., 2016).

The aim of this paper is to identify how mobile technologies and GIS applications can be used for estimating and reducing waiting time for diagnostic tests. The paper proposes a digital application that helps patients to choose the most appropriate hospital unit, in terms of the shortest waiting time, for performing diagnostic imaging examinations, by using their mobile phone. The whole process is done in real time and enables the processing and analysis of dynamic elements. The paper also aims to promote the knowledge and practice in the fields of management of technology in healthcare between health professionals and policy makers.

BACKGROUND

Recent studies focus on the benefits of Informatics Technology (IT) in the public sector. The most commonly used information systems that are used in the public sector are the Geographic Information Systems (GIS). GIS require a great investment in financial and human resources. They are mainly financed by public investors (Kurwakumire, 2014). In most cases, the implementation of GIS technology is used to test the efficiency of healthcare units and hospitals. They are used for analyzing and understanding the spatial dimension of health care (Topol, 2015). GIS tools enable the transformation of quantitative healthcare data to geographic objects. The process is known as geocoding and is used in data analysis (Yasobant et al., 2015). The use of GIS can solve many spatial-orientated management and planning problems (Jawad et al., 2013).

Besides all the significant benefits of using GIS mobile technologies, there are also some limitations. For example, great delays can be encountered when GIS applications access cloud services. There are also many challenges associated with GIS mobile applications and mainly is the privacy protection of

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

owner's data (Mehmood et al., 2015). Some papers reveal more limitations related to GIS processing of sociocultural data. In that case, the constraints refer to data exclusion and data incompatibility (Bagheri, 2014).

The spatial analysis tools enable the evaluation of accessibility in primary healthcare services (Craglia & Maheswaran, 2013). These systems provide sophisticated presentation capabilities, faster big data processing (Amirian et al., 2017), spatial analysis, retrieval and archiving. In several countries, such as Sri Lanka, GIS are used to evaluate the quality of healthcare services in the private sector that mainly provides therapeutic services rather than preventive (Govindaraj et al., 2014). Thus, they can be used to solve problems related to the identification of patients who require immediate diagnostic imaging examinations. They can also aggregate features related to patients' screening examinations and their medical history.

Thus, spatial modeling capabilities (Azevedo, 2016) allow the embedding of digital forms on interactive maps (Júnior et al., 2015). Users can answer key queries by using a geodatabase (Jankowska et al, 2016) that provides high-quality healthcare services. The use of GIS applications includes multidimensional information and concerns patients of different gender, age, level and health needs, as well as access to healthcare services. The spatial modeling of primary information allows the integration of digital questionnaires and interactive maps. Retrieving data in real time is enabled through the web - surveys (Mook et al., 2016) by using the capabilities of GPS and GIS tools. The whole application forms the basis of creating a digital platform for the management and control of the number and type of diagnostic tests. It also optimizes the efficiency of primary health care services using mobile phones, tablets and computers.

A MOBILE APPLICATION FOR PATIENTS' WAITING TIME CONTROL AND MANAGEMENT OF DIAGNOSTIC IMAGING EXAMINATIONS

The main terms that need to be clarified in this study are the following:

1. **Geographic Information Systems (GIS):** They include a database, consisting of observations with spatially distributed elements, processes and events defined in the space as points, lines or surfaces (Longley et al., 2015). They could be described as smart maps that simulate real world (Fradelos et al., 2014). GIS are used for depicting qualitative and quantitative data on maps by using raster or vector files. For example, GIS users can present the total healthcare expenditure of several hospitals on maps;
2. **Diagnostic Imaging Examinations** are the screening examinations that use:
    a. Ionizing radiation such as simple X-rays, mammographs, CT scan, bone densitometry for the diagnosis of osteoporosis (Heidari et al., 2015);
    b. γ-rays, such as bone scan;
    c. Non-ionizing radiation, such as magnetic resonance imaging (MRI) (Busong & Clarke, 2014) and ultrasound imaging (U/S);
    d. A micro camera equipped with a suitable light source used to illustrate the internal organs of the digestive system, such as gastroscopy, colonoscopy, bronchoscopy, etc.;
3. **Geodatabase:** It is defined as a database containing spatial data suitable for processing and analysis (Tsouhlaraki & Achilleos, 2015). A geodatabase is a store of spatial and attributive data. It supports all kinds of attribute data, geographical layers, satellite and aerial imagery (as raster and vector

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

data), land surface 3D modelling data, network systems, and field measurements (Ciampalini et al., 2015). The implementation of a geodatabase includes a collection of files or tables in order to make useful conclusions. For example, users create a geodatabase when they collect data associated with medical equipment. In that case, data is stored in shapefiles spatially distributed on maps. The total of these files is defined as a geodatabase;

4. **Survey 123:** Is a GIS application used for creating digital questionnaires. It is an intuitive form-centric data gathering tool that helps users to create, share and analyze surveys in real time. This application enables users to locate the exact coordinates of the participants in the questionnaire. All answers are saved in a database and can be shared among members of a group by using credentials. Survey 123 is supported by the Environmental Systems Research Institution (ESRI);
5. **Operations Dashboard for ArcGIS:** Is a web application that enables data visualization and analytics for real-time operational view of services and events. It offers analytics for real-time operational view of people, services, assets and events (ESRI, 2017a). For example, it can be used for dynamic monitoring of the activities of medical personnel, the exact position of medical equipment and the number of diagnostic imaging examinations performed in hospitals;
6. **Shapefile (.shp):** Is a spatial data format that can be read by a variety of programs (Löwenberg-Neto, 2014). A shapefile is a simple, nontopological format for storing the geometric location and attribute information of geographic features. Geographic features in a shapefile can be represented by points, lines, or polygons (areas).

METHODS

The proposed application is created in six different steps:

1st Step: Waiting time data for performing mammographs from 12 different Greek public hospitals of the 6th Health Region of Peloponnese was collected. Data were collected by telephone from the radiology departments of the public hospitals. Data were counted in days and was collected during 2017 (Table 1). Waiting time data must be updated monthly, in order to acquire the exact waiting time for each hospital unit. The type of the mammography system was also configured by telephone.

2nd Step: Waiting time data is converted to shapefiles and digitized. That means that all information data of Table 1 is uploaded on GIS platform and converted to symbols on a digital map. By clicking on these symbols, useful windows emerge. These windows contain waiting time data of Greek hospitals. The digital map is updated monthly.

3rd Step: At this point, the mobile application for waiting time control and management of diagnostic imaging examinations is created. The web application consists mainly of an anonymous digital questionnaire. The questionnaire was formed for patients' data collection by using Survey 123for ArcGIS. A variety of questions is digitizedin order to collect accurate patients' data (ESRI, 2017b). In order to create the web application, users choose the desired template and the type of questions (e.g. multiple choice questions) associated with patients. Survey 123enables users to perform a statistical analysis after patients have answered the questions. In that way, they can calculate the number and type of answers. The statistical analysis software supports GIS technologies. In that way, users can determine the exact location of patients who need a specific imaging examination (e.g. a digital mammography). The answers can be stored and shared among users. This application

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

is specially designed by ESRI to run on mobile phones and tablets too. Once the digital questionnaire is created, it is ready for downloading from Google Play Store. Patients download the Survey 123application and register to ESRI website, in order to run the application. By accepting the licenses and terms of the web application, they allow secure personal data processing and sharing of their location. Their location is determined by integrating GPS technology. Patients are asked to complete their gender, age, insurance provider, medical history and the type of the examinations needed. That is a real-time filling up procedure by patients' smartphone.

4thStep: GIS operational dashboard web application was used for directing patients to the nearest hospital units with the shortest waiting times for performing imaging examinations. Dashboards consist of elements, such as charts, maps, gauges, lists, and indicators. A dashboard occupies 100% of the application browser window. Elements can be stacked or grouped in various ways. There are progress and meter gauges that are used to show values moving forward or configure values that show the amount of a variable. The indicators are cards that are intended to count features or summarize the sum or the average of a variable. Dashboards also consist of details elements that show rows or features from a layer and can be toggled on and off. Thus, serial charts are integrated into the dashboard in order to show two or more series of data. That is an advantageous procedure, in case of statistical analysis of participants' answers in the electronic survey (ESRI, 2017b).

5th Step: The mobile data and the digital map created in the 2ndStep are uploaded to the operational dashboard platform. The online platform was installed on a computer unit in the DigiTHEA Lab in the University of Peloponnese. It acts as the central acquisition data system. At this point, users choose the refresh interval time of the operating background which is related to how many seconds are needed to receive the results of the questionnaire from different geographic regions. By modifying the type and color of the symbols, specific areas are blinking on the map. Each blinking symbol corresponds to a new patient's entry with a different type of desired imaging examinations. The central unit is responsible for data processing, analysis, saving and communication with all the participants.

6th Step: It consists of the pilot study of the mobile application. A sample of 12 members of the DigiTHEA Lab is used. Two of the members were located in the central data acquisition system in DigiTHEA Lab. Ten of them pretended to be the patients who requested diagnostic examinations by using their mobile phone. Their age was between 30 - 50 years old. All ten participants were in different places in Peloponnese at the same time. The digital application was tested regarding five different points (Table 2):

- **Speed Data Transmission:** The members of DigiTHEA Laboratory filled in the questionnaire and requested diagnostic examinations of different types. The time for filling in the questionnaire was calculated by using a stopwatch. Requested data was sent by the participants' mobile phone to the central acquisition data system. Most of the participants sent their data almost simultaneously;
- **Clarity of the Questions:** The participants were asked to comment on how clear were the questions (*Clear* corresponds to 100%, *Not Clear* to 0% and *Some Questions Were Clear* corresponds to 50%). The multiple choice questions enable the classification of all the answers in a table;
- **Data Upload:** All participants were asked to upload their medical prescription. The time of data upload was calculated by using a stopwatch;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Accuracy in Locating Patients' Exact Coordinates:** All participants were asked to use the GPS system of their mobile phone (successful tracking corresponds to 100% and failed tracking to 0%;
- **Accuracy in Redirecting Patients to the nearest Hospital Unit with The Shortest Waiting Time:** All participants were asked to comment on the accuracy of the directions given (accurate corresponds to 100%, not accurate corresponds to 0%).

The members who pretended to be patients were able to download and upload photos and pictures on the mobile application. These pictures were uploaded to the central data acquisition system. The participants who were located in the DigiTHEA Lab acquired all available data. They were able to locate the exact origin of all data acquired. That was accomplished because patients had turned the GPS system of their mobile phone on. Members of the DigiTHEA Lab could focus on specific symbols on the map and popup windows were displayed. The windows contained all available data. Data included the type of imaging examination required, average waiting time, contact details and location of the hospital unit, as well as the cost of the examinations. By choosing an appropriate color symbol, a particular cartographic environment was developed that enabled the grouping of quantitative and quality characteristics. The process of visual modelling of spatial data was also accelerated.

Table 1. The waiting data time for performing a different type of mammographies

Hospital	Waiting Time (Days)	Type of Mammography System
General Panarcadian Hospital of Tripolis	200	Digital
General Hospital of Messinia-Hospital Unit of Kalamata	36	Digital
General Hospital of Lakonia-Hospital Unit of Sparta	27	Film
General Hospital of Argolida-Hospital Unit of Argos	4	Film
General Hospital of Korinthos	25	Digitized
General Hospital of Arta	38	Digital
University Hospital of Patra	90	Digital
General Hospital of Ioannina ''Hatzikosta''	120	Digitized
University Hospital of Ioannina	360	Digital
General Hospital of Kefalonia	43	Film
General Hospital – Hospital Unit of Pyrgos	No more Mammographies until the end of 2017	Digitized
General Hospital of Patra – Hospital Unit 'Agios Andreas'		No
General Hospital of Aitoloakarnania – Hospital Unit of Agrinio		No
General Hospital of Preveza		No
General Hospital of Thesprotia – Hospital Unit of Filiates	Closed	Film
General Hospital of Corfu	Closed	Digitized
General Hospital of Lefkada		No
General Hospital of Lixouri		No

Table 2. The results of the five-point test per different categories

Participants	Time for Completing the Questionnaire (sec)	Questions (Clear: 100, not Clear: 0, Somewhere Clear: 20) (%)	Time of Data Upload (sec)	Accuracy in Patients' Location (%)	Accuracy in Redirecting Patients (%)
Participant 1	15	100	40	100	100
Participant 2	20	100	60	100	100
Participant 3	18	100	45	100	100
Participant 4	35	100	65	100	100
Participant 5	42	100	35	100	100
Participant 6	24	100	52	100	100
Participant 7	36	100	50	100	100
Participant 8	58	100	38	100	100
Participant 9	22	100	46	100	100
Participant 10	60	100	44	100	100
Average	33		47,5		

The central acquisition system could locate patients who needed immediate diagnostic imaging examinations. By studying the map with the waiting time data, members of DigiTHEA lab directed patients to the nearest hospital units with the shortest waiting time. The distance and zoom tools facilitated patients' redirection to the nearest hospital units. Members of the DigiTHEA Lab could communicate with patients through the available chat rooms provided by the system. Thus, the patients could give feedback and make their comments on the quality of healthcare services provided.

The designed digital platform functions as a pool of answers that is filled up in real time by the users. By selecting appropriate filters, the central acquisition data system can answer basic queries in a concise time (e.g. display all patients who desire a digital mammography). The system also provides ready queries added to the dynamic thematic background in the form of realistic widgets.

RESULTS

The results of the five points test per category are the following:

- **Speed Data Transmission:** The results show that all participants filled the questionnaire in less than 1 minute. The average time for filling in the questionnaire was 33 sec;
- **Clarity of the Questions:** 100% of the participants agreed that all the questions were entirely clear;
- **Time of Data Upload:** All participants uploaded their medical prescription in almost a few seconds. The central acquisition data system also achieved fast data processing in the DigiTHEA Lab. The average upload time was 47,5 sec. It is evident that the time of data upload was longer than the time of data transmission;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Accuracy in Locating Patients:** 100% of the participants successfully used the GPS system of their mobile phone. The central acquisition data system successfully managed to locate the participants' exact coordinates with no technical problems. The recording of all acquired patients' data was also successful;
- **Accuracy in Redirecting Patients:** The central acquisition data system provided the participants with exact orders, in order to redirect them to the nearest hospital units with the shortest waiting time.

The pilot study also reveals that:

- The radiology department in the University Hospital of Ioannina, the General Panarkadian Hospital of Tripolis and the General Hospital of Ioannina ('Hatzikosta') have the longest waiting time for performing mammographs (360, 200, 120 days accordingly). In the University Hospital of Ioannina, the average waiting time is almost one year which is the longest time in the 6th Health Region in Peloponnese. It is well mentioned that in case of emergency, in the University Hospital of Ioannina ('Hatzikosta'), the waiting time is reduced in 2 - 5 days;
- The radiology department in the General Hospital of Argolida - Hospital Unit of Argos has the shortest waiting time for performing mammographs (almost four days). It is well mentioned that this hospital unit has a filming mammography system;
- The average waiting time for performing mammographs in the majority of hospitals is almost one month;
- The majority of the radiology departments of the public hospitals in Peloponnese has a digital or digitized mammography system;
- The radiology department of the General Hospital of Argolida - Hospital Unit of Argos, the General Hospital of Laconia - Hospital Unit of Sparta, the General Hospital of Thesprotia - Hospital Unit of Filiates and the General Hospital of Kefalonia have a filming mammography system.

It is well mentioned that 5 Greek public hospitals in the 6th Health Region of Peloponnese do not have a mammography system in their radiology departments. These hospitals are the following:

- General Hospital of Patra - Hospital Unit 'Agios Andreas';
- General Hospital of Aitoloakarnania - Hospital Unit of Agrinio;
- General Hospital of Preveza;
- General Hospital of Lefkada; and
- General Hospital of Lixouri.

Patients who live in these regions are directed to the nearest hospital units equipped with a mammography system. The results of the pilot study show that 2 Greek public hospitals have a mammography system, but they do not perform mammographs because of a lack of personnel. These hospitals are the following:

- General Hospital of Corfu; and
- General Hospital of Thesprotia - Hospital Unit of Filiates.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, the General Hospital of Ilia - Hospital Unit of Pyrgos will start arranging new appointments for mammographs at the beginning of 2018. The main reason for not closing any more appointments was the high demand of diagnostic imaging examinations added to the lack of personnel.

DISCUSSION

Health policy makers face a compelling need to assess the comparative value between the cost and the income of diagnostic imaging examinations (Neumann et al., 2014). This issue is added to the increased need for reduced cost and shortest waiting time of screening tests. Patients' satisfaction represents their attitude towards care and is strongly associated with the waiting time for performing screening tests (Maseko et al., 2014).

Several studies focus on creating a measurement framework for reducing the waiting time of treatment and diagnosis (Gilbert et al., 2014). Thus, some studies emphasize on creating mobile applications used mainly for reducing the time of diagnosis (Laksanasopin et al., 2015). Some researchers argue that mobile applications are not as helpful as expected and many patients express negative views about them (Musiat et al., 2014). Although this is may be the case, most of the studies do not take into account the waiting time of performing diagnostic exams. They usually focus on reducing the treatment time.

The proposed application forms the basis for reducing the waiting time of screening tests. It promotes the rational management of the number and type of examinations. By using a mobile phone, a tablet or a computer, the patients can inform the central acquisition data system about the examinations needed (Wu et al., 2014). That is a real-time filling up procedure by patients' smartphone (Vij & Shankari, 2015). Patients' requests are forwarded to this center that suitably selects the hospital unit to be addressed to. In that way, the decongestion of healthcare units, namely of the laboratory hospital departments, is enhanced and the process of closing the appointments is accelerated (Chiuchisan et al., 2014). Health managers can easily record the exact number of all the diagnostic examinations performed in public hospitals and display the results on interactive maps. The results can be related to the total expenses, and income of the imaging examinations and the outcomes can be presented on 'smart' maps by using GIS tools (Huang, 2017). The integration of charts and report tables improves the cost-effective analysis (De La Torre - Díez, 2015).

The completion of the digital questionnaire can be done very quickly. Patients do not have to spend much time on arranging their appointments in the secretarial support departments. Within a short period, users can be informed about the patients' medical history and inform the diagnostic imaging departments accordingly. Patients' feedback on the proposed application will improve the quality of health care services. The mobile application will establish channels of communication between health policy - makers, health professionals and patients (Mumtaz et al., 2014).

Thus, the mobile application aims to reduce the waiting time of performing imaging examinations. Greek public hospitals do not provide any official information about the waiting time of performing a diagnostic examination (Economou et al., 2014). The telephone communication ensures the required waiting time data collection. It is clear that Greek public hospitals have not adopted an informatics system for waiting time control until now. Greek patients are discouraged from visiting the radiology departments of public hospitals for performing their diagnostic tests because of the long waiting times (Economou, et al., 2014). Doctors usually advise their patients to perform a digital mammography because of its low radiation and better sensitivity in early breast detection (Smith, 2015). That is the main reason why

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Greek public hospitals with a filming mammography system have shorter waiting times for performing a breast imaging test (e.g. the Hospital Unit of Argos). The second reason for the long waiting time is a lack of health professionals in most Greek Hospitals (Simou et al, 2015).

The economic austerity has caused many problems in the health sector. Recent surveys show that Greek patients who have cancer seem to be satisfied from the healthcare services provided in hospitals (Pini et al., 2014). In most cases, patients' satisfaction is related to the excellent behavior of the health professionals despite the lack of personnel. OECD (Organization for Economic Cooperation and Development) health statistics show that the majority of women in OECD countries have performed a breast cancer screening in 2012 - 2016. Data concern the number of women, 50 - 69 aged, who have performed bilateral mammography divided by the number of women of the same age, answering survey questions on mammography. Health data show that in Sweden in 2014, 90,4% of females, 50 - 69 aged, has performed a breast cancer screening. That is the high est percentage rate among all OECD countries in 2014. In Greece, in the same year, 59,6% of females, between 50 - 69 years old, have performed mammographs. It is clear that there is a growing demand for diagnostic imaging examinations in the majority of OECD countries. Thus, it is well mentioned that a small number of women between 50 - 69 years old in Latvia, Slovak Republic and Turkey have performed mammographs between 2012 -2016. In 2016, the available data show that the number of women in New Zealand, Slovenia and the United Kingdom who have performed mammographs is over 70% (71,5%, 76,8% and 75,4% accordingly).

As far as the Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) exams are concerned, Greece is among the OECD countries with the high estimated number of total CT and MRI exams per 1.000 inhabitants in 2012. In Greece, the average number of total CT exams is 181 per 1.000 inhabitants compared to 256,7 CT exams in the United States in the same year. The number of complete MRI exams per 1.000 inhabitants, in Greece, is 67,9% compared to the total number of MRI exams per 1.000 inhabitants, in the United States (104,8 in 2012).

Furthermore, in Greece, there hasn't been any official waiting list for surgery procedures yet. In most cases, the waiting time of performing mammographs in Greece is longer or almost equal to the waiting list of undertaking a hip replacement in the majority of OECD countries. The waiting list for undertaking a surgery procedure concern the waiting time for specialist assessment to treatment calculated in days. For example, the average waiting time of a hip replacement in Estonia is almost one year in 2016 that is equal to the average waiting time of performing a mammography in the University Hospital of Ioannina. The average waiting time of a hip replacement in Hungary, in 2016, is almost 120 days that is equal to the average waiting time of performing mammographs in the General Hospital of Ioannina ('Hatzikosta'). There is also a growing rise in the waiting time of a hip replacement in Poland in 2012 - 2016. The average increase is almost 20,5% in the same period (OECD, 2016).

CONCLUSION

The primary purpose of the proposed mobile application is to help patients perform diagnostic examinations in a concise time by choosing the nearest hospital unit. It is aimed to help policymakers adopt new guidelines for shortening the waiting times in the laboratory departments of public hospitals. The implementation of digital applications is a practical solution for the decongestion of public hospitals. By using

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

a mobile phone or a tablet, the access to primary health care services is enabled, and a communication channel between health professionals and policymakersis enabled. Thus, it will help health policymakers to create a digital file that contains the waiting time data of the different type of examinations.

The mobile application provides pervasive and timely access to patients' data for all medical professionals. They can retrieve the information needed, such as patients' medical history or pharmaceutical treatment, from the central data acquisition system in real time. They can also perform statistical analysis of the results of screening tests by using GIS tools. The web application enables medical staff to check patients' diagnostic exams in a concise time. Data acquired by the digital questionnaire are available for medical professionals and can be stored in digital files. In that way, the diagnosis and treatment will be accelerated, and patients' medical history can be secured. Medical professionals can organize their tasks more effectively and intuitively. Their working practice will also be improved because they will be able to organize their tasks more effectively and intuitively. The proposed application enables patients to be aware of the waiting time data in advance. Thus, less complaint will be made about the compliance of appointment.

The proposed mobile application combined with the operational dashboard platform is innovative because it allows real-time location of patients who want to perform diagnostic examinations. Existing systems do not allow the geographical patients' location, in addition, to a real-time monitoring of waiting time data. Existing mobile applications take into account the exact patients' coordinates, but they cannot provide dynamic monitoring of waiting time data. Furthermore, the proposed mobile application enables real-time statistical analysis of all the examinations needed in a territory. That is an ideal way of rational management and surveillance of all the examinations performed in hospital units.

The usability of the system ensures the simultaneous rational control of the number, cost and waiting time of imaging examinations. The patients are directed to the hospital units with the shortest waiting time for performing the desired exams. The proposed application provides fast spatial analysis and processing of a large volume of data by using a mobile phone. This kind of data is associated with patients' medical history, images of diagnostic exams (e.g. patients can upload a digital file of an X-ray), the type of examination needed, the cost of examinations and the waiting time data.

Through the proposed application, the assessment of healthcare services will be ensured in order to provide a healthcare system of high quality. The digital platform will provide the basis for the decongestion of hospital units from patients who perform imaging tests by classifying them in urgent and non-urgent cases. That will help saving costs and optimizing the efficiency of healthcare units. It is quite evident that Greek patients have to wait for a long time before performing a diagnostic imaging examination in public hospitals. The total income and expense of diagnostic imaging examinations can be recorded and saved in a database. The whole process is displayed on interactive maps that are easily accessed by health professionals.

The mobile application could be established in the Ministry of Health, and especially in the Greek Health Regions or any hospital units for pilot study. Although there are some cost limitations, ESRI offers plenty of open data and software that can be used to set this application with no charge.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

ABSTRACT

Researchers worldwide are increasingly looking to recruit research participants via social media (particularly @Facebook and @Twitter) because they appear to offer access to a wider range of research participants and afford inherently convenient tools for recruitment. In Australia, the National Statement on Ethical Conduct in Human Research, together with the federal Privacy law and a number of state-based privacy statutes, provide support and guidance for this novel approach. This article offers a preliminary analysis and discussion of this trend from an Australian perspective, illustrated by an enquiry into the ethical challenges posed by social media-based recruitment, conducted in an Australian university in 2015. Leximancer™ was used as an analytical tool and the content from social media sites used for a small number of research studies conducted up to 2015, taken in conjunction with the various national human research ethics guidelines, offered a means of understanding how ethical challenges of privacy and anonymity can be addressed for responsible social media-based research.

INTRODUCTION

The fundamental principle that people who take part in research projects should be willing and informed participants was articulated as a response to (predominantly medical and psychological) experiments undertaken during the 20th century where participants were anything but willing and informed. Human Research Ethics was designed to protect participants involved in medical research (see, for example, UNLV, 2016). The first attempt to codify the important issues for human participants in medical research was the Nuremberg Code of 1947 (BMJ, 1966a) which emerged from the Doctors' Trials immediately post-WWII. Subsequently, two additional sets of principles – the 1964 World Medical Association's Declaration of Helsinki (BMJ,1966b) and the 1979 U.S. Belmont Report (HHS.gov, 1979) – further clarified and extended the fundamentals of protecting human subjects of research.

Several countries, including the USA, UK, Australia, New Zealand and Canada have since developed their own national set of guidelines for ethical research. Over time, these have expanded from their original, somewhat narrow, focus on medical research to cover social science research; and continue to expand still further to include other fields.

The Australian approach to ethical oversight of research involving humans is centred around Human Research Ethics Committees (HRECs) (NHMRC, 2015). HRECs review research proposals involving human participants to ensure they are ethically acceptable and accord with relevant standards and guidelines. In undertaking this role, Australia's 250+ HRECs strive to ensure the projects they review comply with relevant standards, most importantly the *National Statement on Ethical Conduct in Human Research* (2007, most recently updated in 2018 via a system of rolling reviews). The *National Statement* informs all Human Research Ethics (HRE) in Australia and provides the fundamental guidelines with which all research ethics applications must comply – whether submitted by a university, a hospital, a government agency, a local council, or a not-for-profit organization (NHMRC, 2015).

Australian HRE is governed by both the national statement as well as by the NHMRC's research integrity guidelines, the *Australian Code for the Responsible Conduct of Research* (NHMRC, 2007), together with the federal Privacy Act 1988 and any relevant State privacy acts; plus additional guidelines on specialist issues, such as research involving Aboriginal and Torres Strait Islander (ATSI) participants or issues (Values and Ethics: Guidelines for Ethical Conduct in ATSI Health Research (NHMRC 2003) and Guidelines for Ethical Research in Australian Indigenous Studies (AIATSIS, revised 2/E 2012). Some overlap between research ethics and research integrity is unavoidable and a number of the research integrity requirements identified by the Australian Code (most notably management of research data, peer review and conflict of interest) are also covered by the National Statement and, consequently, incorporated into HRE application forms.

The national statement was originally published in 1999 by the National Health and Medical Research Council (NHMRC, 2015) and, following significant revisions to the entire document in 2007 and 2013, is now updated on a section by section basis to reflect current thinking. For example, Section 3 relating to research methods was reviewed during 2016-17, with an updated version of this Section published in mid-2018: "the draft chapters provide advice for both researchers and … HRECs addressing ethical considerations in the design, development, review and conduct of research (Chapter 3.1*)* [which now incorporates much of the material previously associated only with clinical trials] and ethical considerations specific to genomic research *(*Chapter 3.5*)*" (NHMRC, 2016).

One of the most significant changes in approach by the National Statement has been the expansion of its coverage. Originally focusing predominantly on bio-medical research, the National Statement

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

now also covers research in the social sciences, the arts and humanities; and more technical disciplines such as engineering and Information Technology. In addition to the complexities of expanded research domains, HRE is also facing a second type of complexity as the means of communicating with research participants moves inexorably online. While the addition of email as a communication medium was relatively easy to incorporate into existing HRE guidelines, the emergence of social media is proving far more challenging. The guiding principles of ethical conduct in research – academic merit and integrity; justice; beneficence; and respect (NHMRC, 2007) – are relatively well-understood by those reviewing 'traditional' research projects, but not nearly so straightforward for HRECs grappling with online research approaches and projects. A more nuanced understanding of how these principles apply in new and complex technology-mediated social spaces is required. Henderson, Johnson and Auld (2013) argue that when social media is involved, available guidelines for moral deliberations can be unclear – for example: who are the participants? who owns the data? what is private? and what are the consequences now and in the future?

This paper is organised as follows. Section 2 introduces the background to research ethics and social media (i.e. the historical context), recruitment via social networks, the notion of privacy, and related concerns regarding security as well as ownership of data. Section 3 details the research design and methodology used for the exemplary study. Methods of data collection, coding and analysis are presented. The section also introduces the text analytic tool used namely, Leximancer™. Section 4 presents the visualisation of data analysis using Leximancer™ and the discussion of emerging themes, drawing into a summary. Section 5 presents the conclusions from this study, together with a possible future outlook on social media's challenges to HRE, as well as recommendations for future research on this topic.

RESEARCH ETHICS AND SOCIAL MEDIA RECRUITMENT

The evolution of Information Communication Technologies and the Internet has had a significant impact on the recruitment of participants for research studies. The Internet supports research via two distinctly different approaches: as a tool for finding and accessing people and material (using search engines or online surveys); and as a location for meeting and interacting with people and groups. While these differing online uses are quite self-evident for the 'traditional' Internet, this dual usage is by no means intuitively obvious when considering social media.

Users of social media do not fit neatly into categories, as tools are increasingly embedded into social networking platforms (such as @Facebook or @Twitter), blurring the boundaries between recruiting activities and data collection activities over time (Buchanan, 2012). For example, @Facebook may be used as a *tool* for searching a person's profile, asking them to undertake an embedded survey or for connecting the person with others/groups of people existing on it.

Meeker (2017) in the latest Internet Trends Report, for example, states that @Facebook and @Google/Alphabet (as @Twitter is owned by @Google) now control 85% of the growth in online advertising and, as a consequence, the boundaries between Buchanan's formerly intuitive concepts of tool vs. location are increasingly difficult to identify for research using social media.

Nonetheless, researchers in Australia (and in other countries) cannot ignore the potential social media tools offer for research recruitment. According to Sensis (2017) the most recent survey of social media use in Australia indicates that:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- 79% of Australian Internet users are using social media sites, up from 69% in 2016;
- 59% of users access social media every day (or most days) and 35% check their social media accounts more than 5 times each day;
- 81% of social media users now access their accounts via smartphone (up from 72% a year previously) and 67% of this group access the Internet 5+ times a day
- 94% use @Facebook, 46% use @Instagram, 18% use @LinkedIn, 40% use Snapchat, 32% use @Twitter and 51% use YouTube;
- The average use spends 10 hours each week on @Facebook – a decline of around 2.5 hours per week since 2016 – but more time is now being spent on @Twitter, @Instagram and @LinkedIn;
- The percentage of users following businesses or brands via social media has declined from 1 in 3 to 1 in 4 over the past year across all age segments (except 30-39)
- Attitudes towards social media advertising have become more positive and likelihood to trust brands interacting positively with customers on social media has increased from52% to 64%

Recruitment via Social Networks

Researchers venturing into social media for research purposes need to pay meticulous attention to recruitment of participants (Buchanan, 2012). The crucial question in a recruitment medium where identity is not always clear may well be: Do you really know who your participants are? Is your apparently 18-year-old female participant actually a 55-year-old male? Or even a group of 12-year-old children sharing a single computer? How can you ensure participant privacy, confidentiality and anonymity in an online environment where 'sharing' is so popular and so widely used? Research participants must give informed consent, which is extremely difficult to ensure on social media. Buchanan (2012) argued that informed consent can be obtained via age verification and documentation, but other writers (see, for example, Miller-Merrell, 2012 or Gelinas, Pierce et al., 2017) note that such identification is exceedingly hard to guarantee.

A further concern is the representativeness of social media: Can social media represent the topic/issue under investigation? This really depends on whether the specific social medium being used for recruitment or study is typical of the user group in question. @Twitter is a particularly good example, with both academic and business commentators noting the platform's lack of representativeness (Mitchell & Guskin, 2013; Pack, 2015; Blank, 2016).

Finally, we need to consider issues of data sharing, storage, terms of service and end-user license agreements. When recruiting participants for a research project via social media the nature of the medium ensures that we will be sharing the collected data with other participants of the research. Will the social media channel itself cause a privacy violation? For example, a participant recruited via @Facebook may have consented to sharing their information contained on the specific page. However, the 'friends' of this person on @Facebook may well also have access to this data. In such cases, will @Facebook be able to protect the privacy of the participant? How anonymous is the person? The terms of service and end-user license agreements protect the researchers to some extent but do nothing to protect a participant under these circumstances. Traditional participant recruitment generally makes use of a 'push' strategy, where researchers know their potential targets. Even in the case of 'snowball sampling', participant groups tend to be controlled and recruiters have the ability to channel or restrict participant groups.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

By contrast, social media participant recruitment uses a 'pull' strategy. Potential participants are informed by means of an invitation and can talk to others, freely sharing information, without the researcher having any control or influence over this process. The responses to the participant invitation on social media are interactive rather than static, which may lead to unexpected outcomes. For example, if an invitation is sent out via @Facebook with participants posting responses and responding to posts made by others, subsequent posts may modify already-posted information. A tweet-based invitation may be re-tweeted with additional information added. Consequently, the information may become distorted, shared inaccurately and, as a result of interactivity, become transformed. And this inadvertent sharing may result in researchers losing control, with privacy and anonymity being compromised in the social media space.

The Notion of Privacy

One of the most relevant questions when recruiting via social media networks is the question of fairness to participants. In general, technology-mediated social media spaces are public and it is therefore reasonable to ask whether the space being used for research recruitment, participation and sharing information is perceived as private by its users. Specifically: are users of the space aware they are being observed and, if they are, would they still be happy to consent knowing their activities were being observed? In particular, are the inhabitants of the space expecting to be the subject of academic research? We argue that in many cases the participants are opting-in without much thought. If we take the example of a @Facebook-based invitation, the consequences of being observed do not occur to many participants.

In the case of an online research project, very few participants will truly be anonymous: IP addresses are usually traceable and online survey providers default to include them and 'tweets' may contain identifiers. Often, survey creators themselves are not familiar with the default settings on online survey tools such as *Qualtrics* or *SurveyMonkey*. In addition, the increasing inter-linking of social media and Big Data leads to ever-greater privacy concerns relating to research participants (Sula, 2016).

Informed consent is the fulcrum on which research balances, so that obtaining consent from adults online is crucial. In general, links from social networking sites to other, more reliable, sites could solve a number of privacy problems. For example: surveys using *Qualtrics* or *SurveyMonkey* can be accessed directly from advertisements in @Facebook, @Twitter or @LinkedIn; observable environments are easy to set up online; and in games environments, portals/tokens can be used. However, when the issue of informed consent relates to children or young people, there is no method of ensuring a participant's age or level of maturity. For example, are all @Facebook users really 15+ years old? It is often difficult to obtain parental consent and even harder to ensure participation of those who consented although it may be possible to access young people via their schools or their General Practitioner or some other relevant, formal relationship.

Security/Ownership of Data on Social Media

In Australia, Chapter 2 of the Australian Code (NHMRC, 2007) provides guidelines for ensuring security of data on social media sites. Relevant questions here include:

- How secure are your data in a social networking site? Can you access them as/when you need? Can anyone else access them at will?

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Can you depend on privacy / reliability claims from a social networking service, e.g. is your social network of choice always available?
- Can foreign governments access your data?

Social networking platforms are predominantly US-based, with real implications for research data (Hopewell, 2011). Any US-based data are subject to the Patriot Act, as well as to the less-well-known Foreign Intelligence and Surveillance Act. This means that data may be accessed by US Federal Law enforcement agencies, no matter who owns them. Australians storing data on US websites cannot claim protection under the Fourth Amendment of the US Constitution (which protects US citizens against unlawful search and seizure of property and information) because a 3rd-party provider stores their data. As well, inter-governmental treaties and agreements (e.g. the European Convention on Cybercrime) allow data stored in the US to be requisitioned by European law enforcement agencies without customer awareness, adding still further layers of government oversight.

The ownership of data on a social networking site is also crucial (Protalinksi, 2012). Who owns the data you create in a social networking site? Although it is not obvious to most users, @Facebook, in fact, claims the rights to any data collected from applications (including surveys) created. Jacquith (2009), explained this situation as follows. When anyone uses an application via @Facebook, it may ask for permission to access the @Facebook content and information, as well as content and information others have shared with you. While @Facebook claim to respect the privacy of the individual, the agreement with that application will control how it can use, store, transfer content and information. Therefore, when a @Facebook user publishes content or information using the public setting, that person is allowing everyone, including people who are not on @Facebook, to access and use the information or associate with the person.

This view that user data is the property of the social media site itself may well have been the root cause of recent scandals, such as that involving @Facebook's provision of user data to political campaigns – either directly for Barack Obama in 2008 and 2012, or via third-party Cambridge Analytica for Donald Trump in 2016 (see, for example, Pilkington & Michel, 2012; Urbain, 2018; Granville, 2018) – which have generated significant negative publicity for @Facebook during 2018. That political scandal has now widened into more general queries concerning @Facebook's access to and manipulation of other user data, such as health (Ostherr, 2018); and flow-on effects are starting to emerge for other major social media sites such as @Twitter and @Google's stable of products, as governments from Europe to the US to Canada and Australia question the data practices of the social media 'titans'(Browne, 2018; South China Morning Post, 2018). Under such conditions, one might well question whether Chapter 2 of the Australian Code can be actually followed.

Further complexities for Australian researchers exist in terms of the nation's strict privacy legislation and its implications for US-based social media sites. The 2014 changes to the federal *Privacy Act* mean that offshore data storage may place researchers in breach of certain Australian Privacy Principles (APPs 8 and/or 11.1 in this instance) of this Act, as those who send data overseas for storage are held responsible for any subsequent breaches or other dealings with those data, whether or not the researchers themselves have any influence over this process.

The research question was motivated and supported by the numerous questions raised in the previous sections: Is anonymity, privacy and security of participants recruited via social media (or linked methods) being protected in Australia? A study was undertaken in 2014 at University of Tasmania that

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

reviewed 18 months of ethics applications, at a time when social media use for recruitment, observation or research activity was still its infancy, with a view to understand researcher approaches and attitudes to this new environment. The study provided an early benchmark for ethical use of social media in research. The paper reports on the study findings and subsequently imbibing new knowledge from 2014 -18, adds an outlook.

RESEARCH DESIGN AND METHODOLOGY

For the initial phase of this project, we selected a set of ethics applications (n = 657) submitted over a period of 18 months to the University of Tasmania's Social Science Human Research Ethics Committee (SSHREC). Of these, 63 applications were found to have used social media as a tool to recruit applicants or, in a small number of cases, to gather data from participants once the project commenced.

Data Collection

The Project was formally reviewed / approved by the SSHREC's Deputy Chair to avoid a conflict of interest as one of the authors of this study was, at that time, the Chair of the SSHREC. Access to the server holding HRE data was formally approved in writing by the Research Operations Director and a research assistant (RA) with no other involvement in the study undertook the data retrieval and stripped out the fields relevant to the study, creating a fully-blinded dataset for the researchers. 657 applications submitted to the SSHREC between Jan 2013 – July 2014 were reviewed by the RA to identify those involving social media. Relevant, de-identified data from the 63 applications using social media to recruit participants / gather project data were then supplied by the RA to the researchers.

Data Coding

Data from the applications were coded into the following categories:

- Participant demographic 'class' (age, gender)
- Special selection issues (physical health, English ability)
- Privacy techniques (codes to replace login, secure storage, retention period)
- Recruitment approaches (invitation, snowball sampling, discussion boards)
- Social Media (@Facebook, @Instagram, @Twitter, @YouTube, @MySpace)
- Narratives for each element (if used).

Leximancer™: The Text Analytics Tool

Coded data were analysed using the *Leximancer*™ content analysis software to determine linkages and influences. This analytical software tool draws insights from qualitative data inputs by grouping related terms that are physically co-located in the text and are connected. The information is then displayed by means of a conceptual map which provides a 'bird's eye' view of the data and represents the main concepts and their relationships by forming thematic summaries (For example, see Figure 1).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Specifically, a concept is a group of related words (terms) that are linked together. The concepts begin with seed words (either automatically discovered by Leximancer™ or manually specified) for coding. When data are fed into Leximancer™ software, the analysis tool uses a process algorithm (known as knowledge discovery) and develops a list of concepts contained in the text and their relationships to one another. The outcome of this analysis process is in the form of a concept map. The (potentially iterative) learning process embedded in the tool evolves the concept seed definitions into a full thesaurus. Essentially, the tool automatically identifies concept seeds by looking for words which occur most frequently and groups them together. As the concept learning progresses, apart from adding highly relevant words to a concept, Leximancer™ may also add words that are negatively correlated with that concept (this rarely occurs). The aim of the concept learning process is to discover clusters of words which, taken together, maximise the relevance of other words.

A theme in this tool is a cluster of concepts bearing some common features or reflecting connectedness, as seen from their proximity on the visual concept map. The concept map is presented visually using coloured circles. However, the size of the circle (large/small) is irrelevant to the themes recognized. The circles are merely boundaries. Prevalence of a concept is determined by the number of concepts present in a theme, and this is given in the thematic report. The histogram bands produced for the thematic report are colour-coded (or heat mapped as hot or cold), to visually depict the prevalence of the theme. The colour is also carried through to the theme circle or boundary. The bar chart ranks the most appropriate themes relative to one another and, beneath that, the concepts which are visible within each theme are listed (for example, See Figure 2).

In *Leximancer*™, the term knowledge pathways refer to the strongest link between two concepts. As indicated in the visual analysis below, a black line on the concept cloud map indicates which other concepts might be bypassed to reach the concept themes. These pathways narrate stories that emerge from the textual analysis and focus on indirect connections between the concepts presented on the map. In the visual analysis, we present these pathways using the concept cloud view and knowledge pathways. The concept cloud view indicates the indirect connections that lead to the concept themes (or all the connections that are bypassed but are present to reach the destination theme).

The links between themes and the knowledge pathways generated from the concept maps are presented in the analytical discussion.

DATA VISUALISATION AND ANALYTICAL DISCUSSION

The researchers input the qualitative data obtained from the ethics applications into Leximancer™ to generate concept maps and thematic summaries (Figure 1).

The thematic summary shown in Figure 1 presents the main concepts and thematic summaries generated that are relevant and connected to the overall topic. Figure 2 represents the ranked concept list in order of relevance to themes. This figure shows three major concepts (data, participants and study) which were clearly inter-connected to all major themes.

Based on this preliminary analysis, we then classified the data into three main *concept themes* which capture the thematic summaries. These summaries reflect how the privacy of participants was protected in the research studies for which they were recruited.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Concept maps and thematic summaries

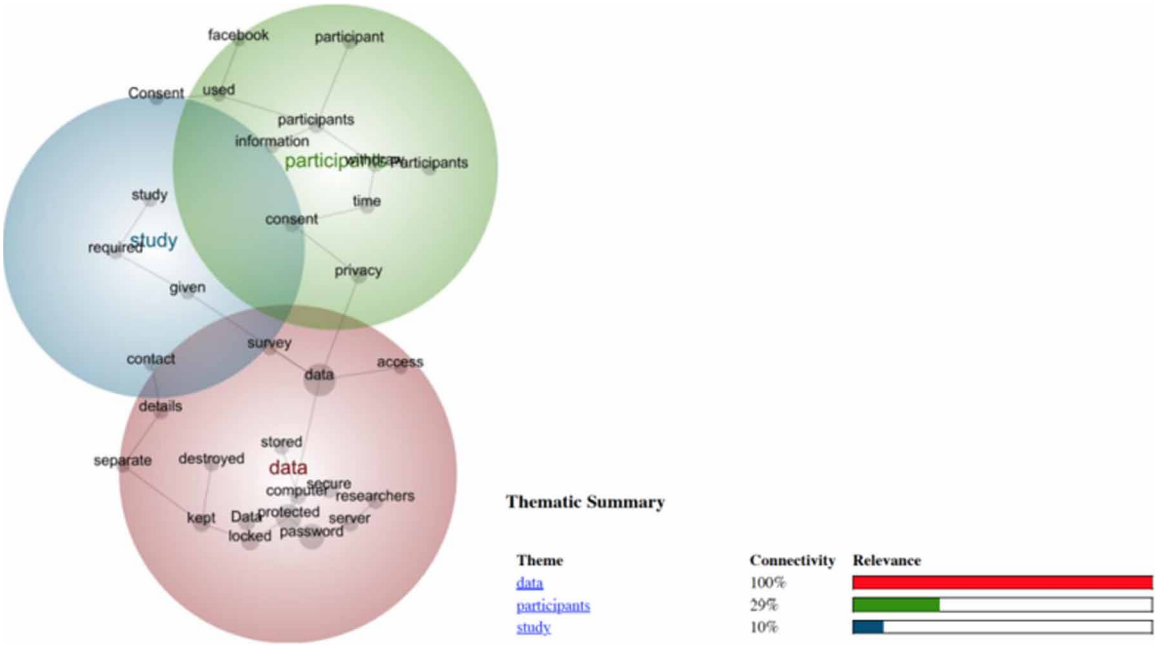

Figure 2. Ranked list of concepts and thematic summaries

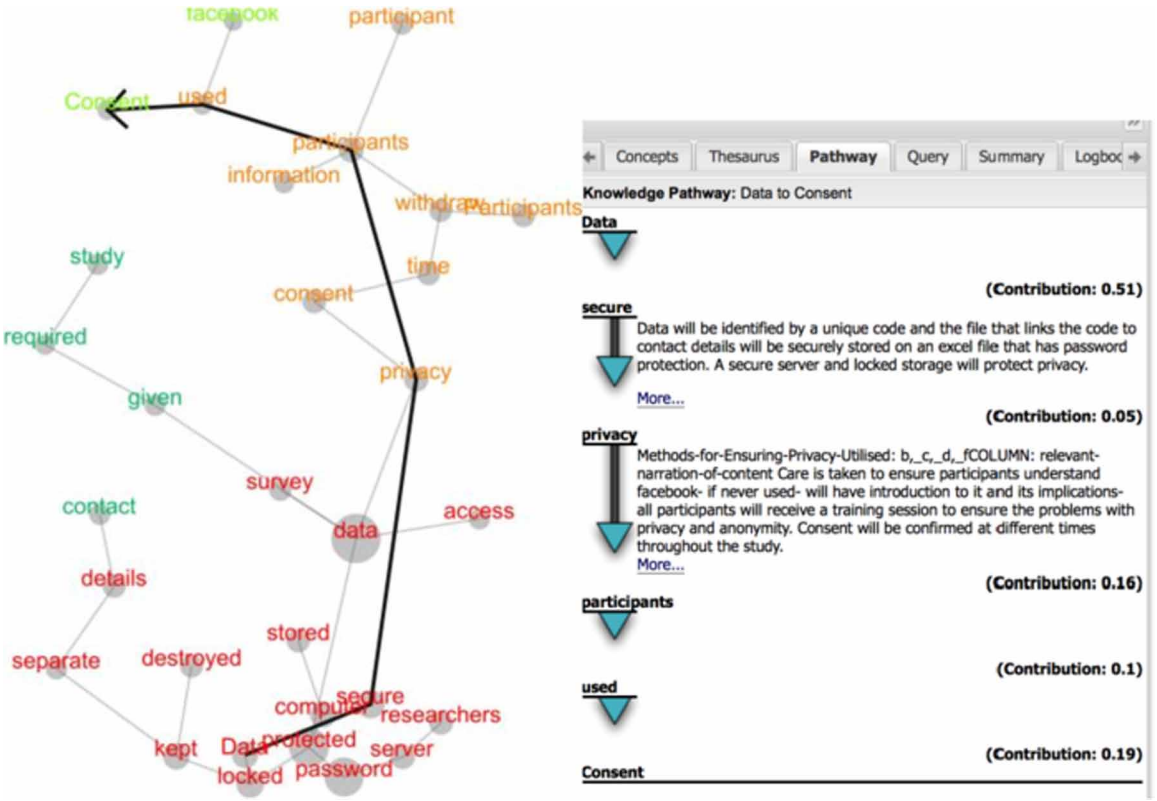


EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Concept Theme 1: Data

The theme named Data ranked the highest amongst the thematic summaries i.e. the prevalence of this theme and its linkage to other concepts emerged the strongest in the analysis (23% relevance). A key feature to note is that all research data is collected under conditions agreed to under HREC ethics approval. Data collection is based on informed consent during recruitment of research participants. This consent can be withdrawn (and therefore the participant's data can be removed) to protect privacy of participants until the publication of research involved. In practice, this meant that the collected data are extracted into word documents, anonymized, backed up into hard drives and locked in filing cabinets only accessible to investigators. Even data collected from blogs or posts (e.g. @Facebook) is protected, as the sharing of data ceases when a participant withdraws consent: even extracted/ anonymized data on word documents can be removed from the research data set. Paper copies of data are locked into a secure cabinet in the researchers' offices; electronic versions are kept on password protected computers exclusively. If any data are copied, there will be logs and records which can be deleted in case of withdrawal of consent.

Security of data is ensured by storage on secure servers within the research offices of the university, accessible only to research investigators listed on the ethics application. Data retained within the university are destroyed after 5 years (in the case of social research) and, in the case of projects where study outcomes had to be forwarded to partner organisations, only anonymized data were provided to government agencies (as per informed consent from the participants). In cases where a prize offer was provided to the participants for being part of the research the privacy and anonymity of data supplied were ensured by requiring participants wishing to be eligible for the prize to send a blank contact email to a designated 'prize' email address, thus separating the identity of the participant (their email) from the data provided for the study. In cases where questions in a survey could be regarded as intrusive, the survey design provided participants with the option not to answer. The data were, therefore, non-identifiable. Any access to the data is password-protected by University.

Clearly, this theme of data being anonymized and measured to protect the privacy of research participants emerged as a key theme in this research.

Concept Theme 2: Participants

While Data in particular protecting security and privacy is the key theme, the role and responsibility of participants is also highly relevant and prevalent (19%). Analysis of the Participant theme identified that the focus was on protecting privacy. The participants in the studies investigated were given the opportunity to protect their privacy through both direct and indirect methods. The participants themselves were encouraged to be involved in the process of protecting their own privacy. Prior to commencing data collection, research projects involving audio recordings, required participants consent to audio recording and, later, have the opportunity to review the transcript of their conversation. The notion of privacy was explicitly linked to eligibility criteria: if these criteria were not fulfilled, participation would not have been allowed. For example, the eligibility screening procedure warned participants that collection of data from those who, for example, disclosed illicit drug use (or any other activity which involved

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

researchers in a mandatory reporting process) would be placing themselves at risk (as required by the National Statement's Ch. 4.6).

Section 1.5 of the National Statement (NS) recommends that a summary of findings should always be provided to the participant group; and the results of the study showed that this was, indeed, occurring in all research project cases. Further, publications arising from project findings would not identify any individual participant: only de-identified and aggregated data were published.

For research projects in which @Facebook was used for recruitment, participants were provided information about @Facebook and its privacy implications; and a training session on protecting their privacy on social media (in this case, only @Facebook) was provided if they had not been regular users, or were new to @Facebook. Participants were informed that all data would be de-identified by the researchers. When @Facebook was used to invite participants, they were informed that participation was voluntary and that they could decline the invitation to take part in the project, without coercion, as required by section NS 2.2.

In addition to informed consent, participants were given the opportunity to use pseudonyms rather than their real names, to further increase their privacy. It was not necessary to obtain individual participant consent when accessing data relating to organisational social media: in this case, only a representative from the organisation was required to provide consent. However, even in this situation, privacy was protected as a software program anonymized social media data before the researchers accessed it.

Concept Theme 3: Consent

The *Consent* theme (11%) was the third most prevalent concept identified by the analysis. In particular, the notion of *informed consent* was highlighted in this theme. The research studies, analysed for this research, collected via electronic means a variety of information types, including: photos, recordings and written comments. Participants were therefore asked to provide consent in three different ways to reflect the nature of the data gathered. Consent forms for this data type included substantial information about privacy, rights and responsibilities. An information sheet was provided to all participants which detailed all ethical issues involved in sharing photos and other forms of information.

Further protection of participant privacy was provided by ensuring that 'screen names' (used in online forums) were only used when consent forms had been emailed to the researchers. If participants chose to withdraw from the study at a later stage, their responses would not be published, although their de-identified/anonymized responses would be used for analysis.

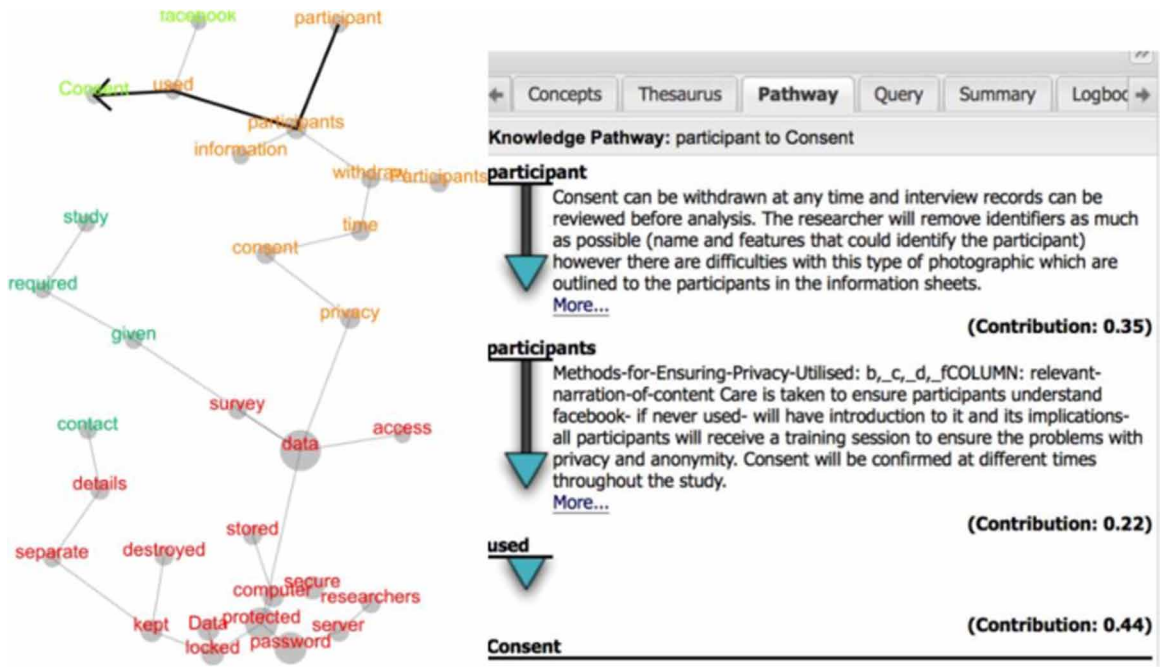
All participants had to sign consent forms (either electronically or physically) prior to participation and after being informed about privacy, rights and responsibilities. There was clear evidence in this emergent theme that informed consent was being obtained, ensuring privacy of participants.

Knowledge Pathways

In this section, we present the visualisation of Knowledge Pathways i.e. the strongest link between two concepts. The concept cloud view indicates the indirect connections that lead to the concept themes (or all the connections that are bypassed but are present to reach the destination theme).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. 'Data' to 'Participant' concept cloud and knowledge pathway



Pathway 1: Data to Participant

From the concept cloud shown in Figure 3, it can be seen that the black line connection between the strongest theme of 'Data' and that of 'Participants' is connected via secure and privacy concept pathways. As narrated in the knowledge pathway summary: the content can be scrolled past, privacy of participant's friends are preserved, cookies are deleted by using 'incognito' chrome session, logging out of profile in the presence of the participant. Data security is ensured by a unique code, together with the file that links the code to the contact details, which are securely stored in a password protected file.

The concepts of notions of privacy and security (both of data and participants) are apparent in this knowledge pathway connecting the two themes.

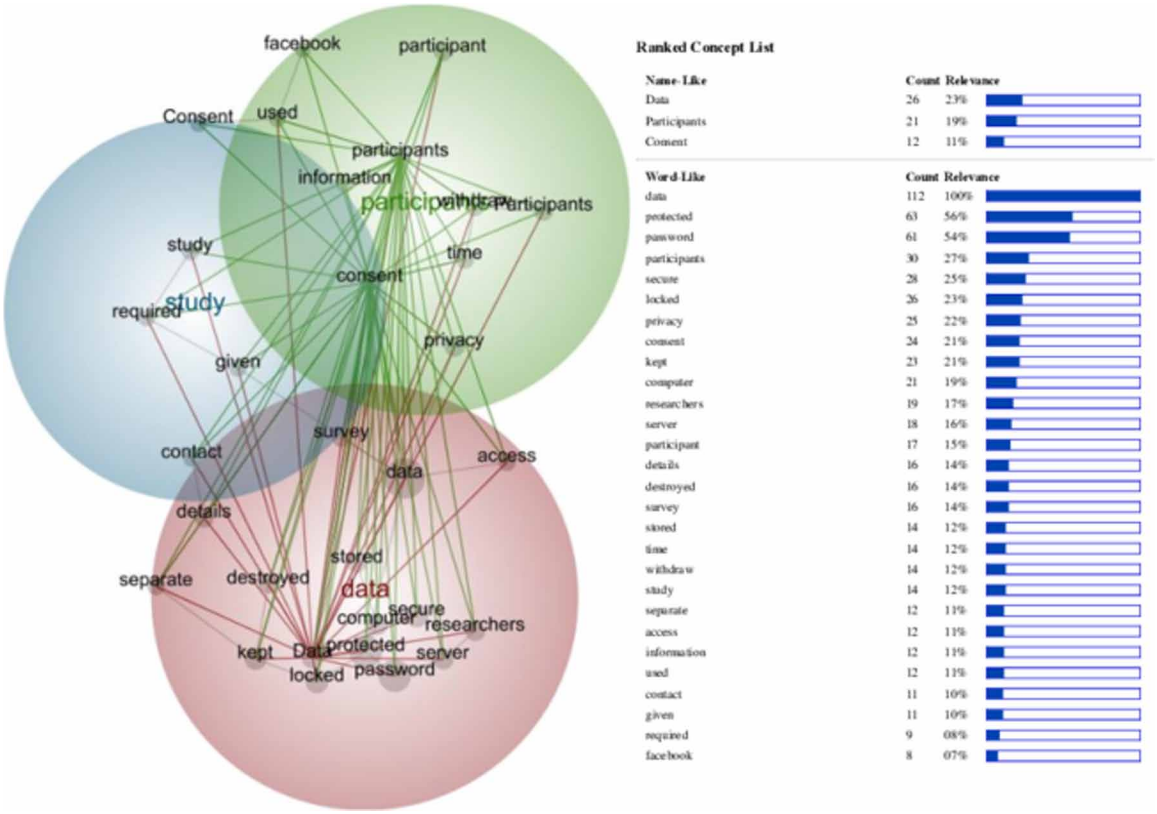
Pathway 2: Data to Consent

In this pathway, the notion of privacy between data and informed consent is examined. Security emerges as the strongest connection between the two themes. The notion of secure storage using passwords is a key element in facilitating informed consent. Specifically, participants are confident that the security of their data is ensured via a series of valid measures. At the same time, the researchers are ensuring privacy protection for participants by facilitating informed consent.

For example, see the commentary from *Knowledge Pathway: Privacy-Security*: '...relevant narration-of-content ... care is taken to ensure participants understand @Facebook – if ever used – will have an introduction to it and its implications – all participants will receive a training session to ensure the problems with privacy and anonymity...'

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. 'Data' to 'Consent' concept cloud and knowledge pathway



Therefore, there is a strong connection between enabling informed consent and protecting the data collected.

Pathway 3: Participant to Consent

The shortest pathway seems to exist between the participant and the consent themes, predominantly because consent can be withdrawn at any time by participants. The researchers also ensure that identifiers are removed, to the greatest extent possible. Researchers also ensure participants are well informed, trained and made responsible for their own consent. The emerging story here is that participants are able to be confident that their privacy is protected, and that they can withdraw consent at any point in time.

In each of the visual analyses and summaries, evidence of sound and ethical practices using a variety of approaches for the protection of data anonymity, security, and privacy was reflected. The approaches included:

- Informed Consent – which can be withdrawn up to publishing date of data – used exclusively;
- Interest generation - @Facebook was used to generate interest in the study. Applicants were given a separate online link to the actual survey for identification and recruitment; and

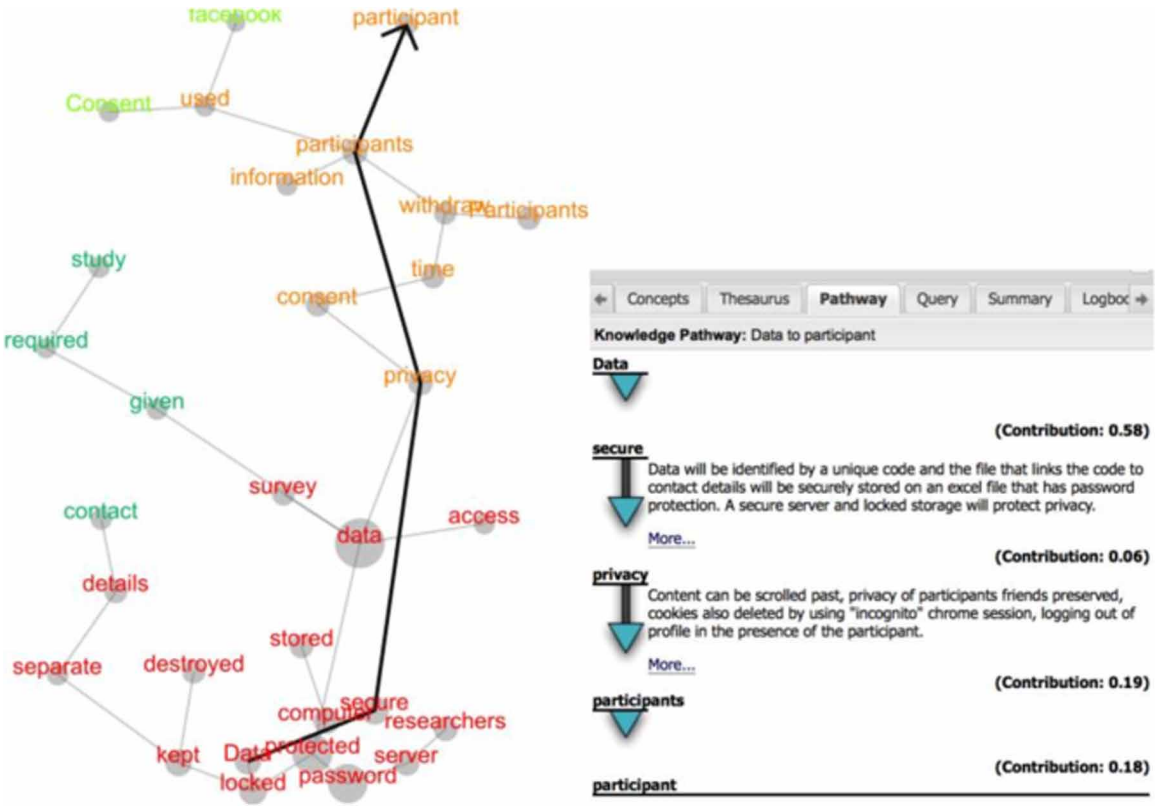
Figure 5. 'Participant' to 'Consent' concept and cloud knowledge pathway



- Online Surveys – using the @Facebook Messenger application and a specialised 'app' allowed tailored conversations between specific users. (No @Facebook-based surveys were included in the 63 applications reviewed)

As compared to a public post on @Facebook, a message and/or online survey via '@Facebook Messenger' can be considered personal for privacy purposes. In addition to the protection @Facebook Messenger offers, participants in this study were requested to remove the transcript of the @Facebook Messenger based online survey, after the responses were collected, to ensure that the privacy is fully protected.

All studies analyse the treated data (electronic and manual) in the same way. Data were transcribed, de-identified and retained securely for 5 years, after which they are destroyed. During this period, it was only possible for the researchers to re-identify data (for example in the case of a withdrawal of consent).

Addendum and Limitations

It should be noted that the ethics applications analysed as data for this research project were dated from early 2013 to mid-2014 (before and after the changes to the federal Privacy Law in Australia, which placed significant additional requirements on those storing data offshore). The number of ethics ap-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

plications involving social media recruitment approaches increased very rapidly (almost exponentially) over that period, supporting the general view of an upward trend in the use of social media for research recruitment and analysis.

At the time this research was conducted (in 2014), the system of ensuring anonymity, security and privacy of participants was apparently working for the Australian context. The privacy protection measures within the University combined with the federal Privacy Law were strong, and applicants were not relying on protection measures offered by @Facebook (the most popular social media site in Australia) or other social media providers. For example, arrangements were such that if a person is identified on @Facebook, they must re-identify themselves via an email link to be verified before recruitment can be completed (for this research study).

CONCLUSION AND OUTLOOK

This research project was conducted in 2014/15, at a time when privacy laws and statures were still evolving after the revisions to the federal Privacy Act. Since then, there has been a significantly increased uptake and saturation of smartphones in Australia. Most businesses have mobile applications and regularly undertake surveys, recruiting participants via social media. In this current scenario the question now arises for researchers (bound by the National Statement): would the same strategies apply for recruitment? No matter which approach is taken, researchers will need to ensure that data privacy and anonymity are being met in the ethical recruitment of participants: an issue which the @Facebook data privacy scandal makes immediate and urgent.

Contemporary researchers in Australia (such as Lunnay et al. (2015), conducted their research by recruiting participants through @Facebook. They cautioned qualitative researchers that ambiguity around the potential risks intrinsic to social media could hinder ethical conduct and discourage recruitment of participants through this medium. However, they also encouraged researchers that @Facebook recruitment is a practical research tool, adaptable for interacting with participants who already engage regularly with social media.

The North American research paper from Gelinas, Peirce et al. (2017) introduces a non-exceptionalism methodology for assessing social media recruitment, and these authors have identified 'respect for privacy' and 'investigator recruitment' as two key norms governing social media recruitment. According to this very recent, seminal work whether active or passive, social media recruitment has to be considered in the same way as traditional recruitment. The authors suggested that techniques should be normalised, while remaining sensitive to potentially novel aspects. They recommended mirroring physical-world methods explicitly, applying context-based ethical considerations and scrutiny; and then determining if social media recruitment differs from offline recruitment in ways that warrant a review. Their recommendations include two checklists to guide ethical recruitment of participants via social media. Allowing for some minor differences between the North American and Australian contexts, research using social media participation is today commonplace. Gelinas, Pierce et al. (2017) recommendations could be used as a guide where the recruitment of participants is achieved using social media.

We recommend that the recruitment of participants using social media extends both novel experience and convenience into the current Australian context still further, while the non-exceptionalist method – where traditional methods are mirrored when social media is used – could lead to a win-win situation. In

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Australia, the notion of privacy as guided by the National Statement is always translated into traditional recruitment approaches. Revisions to Chapter 3, published in 2018, includes further guidance on ethical online research approaches.

Our research findings made clear that the 'mirroring' recommended by Gelinas, Pierce et al. (2017) was already taking place, with participant privacy being well protected. Nonetheless, as social media-based recruitment becomes a norm for research, it is recommended that these checklists be used in addition to the National Health and Medical Research Council (NHMRC) of Australia guidelines, (both the National Statement and the Australian Code) contextualised to Australia in future. This method would ensure that the practical convenience of recruiting participants online is met with the notion of privacy still being protected – ensuring ethical research practices for the 21st century.

It would also be interesting to consider emerging research from other countries around the globe, and infer relevant insights into similar situation in Australia, and vice versa. We strongly recommend longitudinal and cross-country comparative studies in future to gain further insights.

ACKNOWLEDGMENT

The authors wish to thank the support of late Professor Ross Smith, for his feedback to enhance the quality of this paper. Dr Smith has rendered over 40 years to academia in Australia and this paper is his final contribution, before his death, in May 2019. The authors dedicate this paper to his eternal memory and invaluable contributions to academic research.

Chapter 78
Implications of Molecular Docking Assay for Bioremediation

Zarrin Basharat
Fatima Jinnah Women University, Pakistan

Monazza Bibi
Fatima Jinnah Women University, Pakistan

Azra Yasmin
Fatima Jinnah Women University, Pakistan

ABSTRACT

Bioremediation utilizes microbes to control environmental pollution, primarily through diverse enzymatic processes. With the incorporation of computation in biological experimentation, bioremediation has also been influenced by computational techniques. Molecular docking assay is one such pedestal of computational assisted bioremediation, which has been elaborated in this chapter. It helps in inferring whether the active site accommodate the pollutant molecules or not, depending on the stearic hindrance of the residues and nature of the active site pocket. The spotting of consequential active site residues and binding characteristics of compounds under study can conceivably be employed for site-directed mutagenic testing. From a vantage point, no one had expected such a remarkable usefulness of molecular docking assay for environmental research. Positive shades of low cost and efficiency, combined with eco-friendliness have made it a valuable method for analyzing biodegradative properties of enzymes responsible for pollution remediation.

INTRODUCTION

The world is facing an ever increasing menace of pollution due to industrialization and other anthropogenic activities. It is, therefore, at the foremost agenda of environmental scientists to find better, fast and eco-friendly solutions to mitigate pollution. Bioremediation is one such endeavor that exploits microbes to detoxify or degrade harmful contaminants in the environment. Bacterial enzymes are pollutant degradation workhorses that act to decontaminate environment. Molecular docking accelerates the procedure of choosing and improving enzymatic properties for a particular pollutant by quick computational scrutiny. The technique shows inordinate potential in its ability to predict enzyme adhesion and functionality in degrading or adsorbing the pollutant and presents a lucid picture of the relation and communication between pollutant and enzyme molecule. It helps in inferring whether the active site of certain enzymes accommodate the dye molecules or not, depending on the stearic hindrance of the residues and nature of the active site pocket. Protein-pollutant association is checked by assessing thousands of potential docking conformation poses. Picking poses that are reliable is an arduous task and one with lowest energy score is usually seen as the best match. Blind docking is attempted for proteins with unknown active site by entire protein surface scanning (Schnecke & Kuhn, 2000; Verdonk et al., 2005). Docking also provides information on mediator accommodation in the active site pocket to surmise about productive or non-favoured binding. The spotting of consequential active site residues and binding characteristics of compounds under study can conceivably be employed for site-directed mutagenic testing. These results then need to be tested in the lab experimentally and a critical evaluation of docking tools which gives better results might help define a set of rules and define a benchmark for such studies.

Molecular docking in remediation experienced a lag phase but now transitioned to alog phase in itsfrequency of application and attention of environmental scientists. It is now a noticeable area of research methodology assisting bioremediation studies. Bioinformatics boasts of numerous successful techniques developed for protein-ligand docking but shape complementarity and simulation approaches are most popular. In shape complementarity approach a matching procedure portrays the protein and the ligand as complementary surfaces (Meng, Shoichet, & Kuntz, 1992). In the simulative approach, interaction energies of ligand and protein are calculated (Feig, Onufriev, Lee, Im, Case, & Brooks, 2004). Knowledge derived information from docking assays for bioremediation is critical for a reliable evaluation of the state of the enzymatic micro-environment besides the transformations taking place inside enzyme, as well as for crafting strategies for sozotechnical measures aimed at environment clean up. This chapter discusses foundation of eco-analytical information for bioremediation, gained from molecular docking assay and provides information on some studies conducted until now. Finally the challenges and barriers to the molecular docking based bioremediation studies have also been analyzed and future perspective of such studies is also provided. The predictions are valuable for environmental chemists perusing metabolic intermediates, supervisory bodies/controllers endeavoring probable toxic products, microbiologists seeking to perceive microbial biodegradation, besides others having wide array of fascinations.

OVERVIEW

Molecular docking is a technique which calculates the preferred binding positioning of one molecule relative to the other, at a minimum energy conformation during complex formation (Lengauer & Rarey, 1996; Brooijmans & Kuntz, 2003). Docking can be carried out among protein and a small molecule,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

protein-protein, Protein-DNA, protein-RNA, protein-lipid, protein-sugar, polymer-ligand etc. where larger moiety is treated as a substrate and smaller one as the ligand. In case of protein-ligand interaction, which is the focus of this chapter, ligand generally fits inside cavity of the protein, which is usually predicted by a search algorithm (Westhead, Clark, & Murray, 1997; Gohlke, Hendlich, & Klebe, 2000; Brooijmans & Kuntz, 2003). This protein cavity turns active as a result of contact with substrates. It is formed of evolutionarily conserved residues and can thus, be traced on the basis of comparison with similar proteins (Lichtarge, Bourne, & Cohen, 1996). Many computational methods exist for identifying ligand-binding residues or active site prediction such as LIGSITE, SURFNET, CAST and PASS (Huang, 2009). After participation in the catalytic reaction, active site or catalytic site residue can be reused (Alberts et al., 2013). Some enzymes may have catalytic sites capable of binding effector molecule other than active site. These are called allosteric sites and occur mostly in proteins with more than one sub-unit and allow a range of interactions in addition to specific active site (Dedecker, 2000).

MECHANISM AND METHODS OF DOCKING

Protein-pollutant interaction study via docking is basically protein-ligand association modeling relative to bioremediation. Pollutants are treated flexible and allowed to adapt to a wide range of surface and pocket conformations. The complementary interaction region is also smaller and portrays reduced discrimination. The focus is therefore on the flexibility of the pollutant and modeling of weak associations accurately. 3D structure of the enzyme is first analyzed to identify active sites for fitting moiety of interest (Schechter, 2005). Experimentally obtained protein structures are the best source of information for protein-ligand docking studies. Availability of structural data information and steady increase in amount of publicly available structures with time, not only permits the investigation of novel protein-ligand docking parameters but also improve the understanding of already resolved as well as new targets. Structures relating a protein bound to diverse substrates or ligands could assist the knowledge discovery regarding ligand-induced conformation variations. New structures can be modeled using the already available structures (Basharat, 2015a). Standard computational methods are utilized forsolving protein structures based on the templates available in Protein Data Bank. More than 100,000 structures are currently present in the database and the number of sequences being deposited in NCBI alone is far greater than the number of these structures which means the number of protein sequences exceeds far greater than the number of structures and there is a huge gap, wealth of hidden information and demand for structure modeling. Steady progress has been made in this regard to model the protein structures based on available templates using the fold prediction and geometry calculation method called 'homology modeling'. *In silico* methods assist even the experimentally determined structures for geometry refining, estimation of binding energies, modeling the effect of mutations, predict the location of binding surfaces for new molecules.

Gap between sequence-to-structure ratio increases manifold in case of membrane proteins. This also signifies that the total numbers of residues are many times larger than the corresponding unique chains from the Protein Data Bank (Werner, Morris, Dastmalchi, & Church, 2012). *De novo* or *ab initio* modeling is employed in such a case for computational modeling of completely novel protein structures. These modeling approaches rely on physicochemical and thermodynamic properties of amino acid residues of the protein sequence and may not have direct linkage to the parameters of experimentally solved structures. Employing the scoring of energy function approach, it resorts to matching protein conformation at global minimum to least energy through an iterative procedure. *De novo* methods use knowledge based

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

scoring functions derived from experimental structures and their folds. Such methods are not template free *sensu stricto* and related to threading. *Ab initio* methods utilize force fields centered on first principles. This approach is template free and uses energy of the system for structure generation. Search space is large as all-atom model is used so this method works better in case of small sized proteins or peptides. The low-resolution structures obtained by computational approaches are further refined for docking studies through energy minimization and molecular dynamics (Werner et al., 2012). Protein structure assemblages are often implemented to obtain flexible models during protein-ligand docking. Structural conservation and catalytic site information is exploited for prediction of pollutant binding sites as catalytic residues and conformational changes in the active site region. Properly selected ensembles can improve docking performance considerably. Preprocessing of protein binding site ensembles may be carried out using dedicated webservers or databases like Astex Non-native Set (Verdonk, Mortenson, Hall, Hartshorn, & Murray, 2008), CoDNaS (Monzon, Juritz, Fornasari, & Parisi, 2013), Pocketome (An, Totrov, & Abagyan, 2005; Kufareva, Ilatovskiy, & Abagyan, 2012) and SIENA (Bietz & Rarey, 2016). The preparation of protein ensembles is quite intricate procedure due to unreliable annotation of many protein structures along with artifacts in structures. These impact the performance of ensemble employing applications. In case of missing or wrong information regarding binding site of a protein in the ensemble used for docking study, unintended bias may be introduced.

Ligand is usually obtained from a database source or drawn in a software or web interface (Exhaustive resource list available at http://www.click2drug.org/index.html) and saved. It is then processed and optimized before docking with the molecule. Missing residues and hydrogen atoms are added. Rotatable bonds are identified and partial atomic charges are calculated. As a ligand can move across six translational and rotational degrees of freedom, these movements are modeled. Initially both receptor and ligand molecules were treated as rigid bodies due to lack of computation power for solving the degrees of freedom. Maiden docking study of a protein and a small molecule (Kuntz, Blaney, Oatley, Langridge, & Ferrin, 1982) employed a negative receptor imageand six translational and rotational degrees of freedom. Spheres occupying the pockets and grooves on the receptor surface defined the prospective interaction sitesto clasp the ligand. Interactions were assessed by estimating the overlap as well as probablehydrogen bond formation between atoms in the protein-ligand complex. These types of rigid body calculations of protein-ligand studies have limitations as it does not account for induced fit ligand behavior (Brooijmans & Kuntz, 2013). With increment in computational power, algorithms and softwares were designed that could model interactions with one moiety as flexible and the other one as rigid (Leach, Shoichet, & Peishoff, 2006). Now, softwares exist for modeling the flexibility/degrees of freedom in both receptor molecule and ligand. The top results of active site accommodated ligands are judged on the basis of a statistical scoring function, which translates the unification energy into numerical value or the docking score (Leach et al., 2006). This is a critical step of docking, with correct prediction of the binding affinities/dissociation constant of a protein-ligand complex to separate true positives from false positives, a genuinely difficult task as its valuable outcome (Ambure & Roy, 2016; Yan & Wang, 2016). Complexes with least binding energies and maximum scores are then selected for further analysis. Calculation and scoring of interactions is a lot easier, less demanding and accurate in the gaseous phase as compared to that in the water phase due to small window of activity (Tirado-Rives & Jorgensen, 2006).

DOCKING ALGORITHMS AND SOFTWARES

For successful protein–ligand docking, speed and accuracy are the prime parameters. Development (Connolly, 1983) and usage of molecular surface calculations instead of explicit atom multi-configurations in docking have reduced the number of complexes and increased the speed of calculation (Jiang & Kim, 1991; Norel, Lin, Wolfson, & Nussinov, 1994). Ensuing this, grids to store physico-chemical properties of the receptor were integrated into docking procedures. Selected probe groups used were amino, methyl, and hydroxyl groups. The grids presented polar/nonpolar type of interactions, commonly preferred at each position in the binding site but presented difficulty in calculating energy. Later, tweaks in the algorithms led to hydrogen bonding, energy parameter and sophisticated scoring function calculation. This led to realistic scoring and the assessment of ligand flexibility in the active site during docking procedures. Ligand flexibility is usually calculated using systematic, stochastic, and deterministic search algorithms. Several algorithms use a sum of these approaches. Systematic search algorithms (Westhead et al., 1997) use grid values to calculate each degree of freedom with number of evaluations corresponding formal degrees of freedom. Cessation conditions are inserted to thwart the algorithm from sampling the space, identified to cause erroneous complex formation. Stochastic search algorithms check one degree of freedom at one time. Uncertainty of binding is rectified through independent runs. Examples include Monte Carlo methods and evolutionary algorithms. In deterministic searches, initial state leads to the next state, which is either equal or lower in energy to the previous state. These algorithms get trapped at local minima as they are unable to navigate across barriers. Different tactics are used to escalate their capacity to cross barriers or decrease the height of energy barriers. Examples include popular energy minimization and molecular dynamics simulation approaches. Other examples include Tabu search and Incremental construction etc. Some of these algorithms (Monte Carlo, Molecular dynamics and Genetic algorithms) are also applicable to receptor flexibility calculations (Brooijmans & Kuntz, 2013). For validation of the binding accuracy prediction of a protein with ligand, apart from the conventional root mean square deviation criteria, first principle, semi-empirical, empirical and knowledge-based methods exist and various softwares use these for calculating binding mode and affinities through estimation of parameters as van der Waals, electrostatic, hydrogen bond interactions etc (Kirchmair et al., 2012; Sliwoski, Kothiwale, Meiler, & Lowe, 2014). Classification and cataloguing of atom types, pairing this information with number of atom types and joint occurrence of specific class of atoms is essential part of knowledge based scoring functions. Free energy perturbation and thermodynamics incorporation are considered the high end procedures but computationally exhaustive. Molecular mechanics with Poisson Boltzmann surface area calculationapproach is also a recent popular method for free energy estimation of protein-ligand binding affinity (Weis, Katebzadeh, Söderhjelm, Nilsson, & Ryde, 2006; Liu, Liu, Zhu, Zhang, He, & Zhang, 2016). These approaches calculate the intermolecular, electrostatic, thermodynamic, stearic and solvent related forces or a combination of these forces. Algorithms/softwares for docking validation implement various amalgams of these forces for sieving out best results as neither of them is perfect in terms of precisionand broad applicability. Consensus scoring technique boosts the prospects of discovering accurately bound models by coalescing scores from several scoring functions (Huang, Grinter, & Zou, 2010).

More than fifty softwares are available for docking till to date, each varying in its approach or parameters but taking into account both these differing requirements. Speed of the fundamental steps has augmented due to availability of higher clock processing of modern computers along with the use of scoring grids. Latest developments in parallel computing domain have also enhanced the performance

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of docking algorithms and softwares considerably. Most popular of them are AutoDock (Huey, Morris, Olson, & Goodsell, 2007), Molegro Virtual Docker (Thomsen & Christensen, 2006), EADock (Grosdidier, Zoete, & Michielin, 2007), GOLD (Verdonk, Cole, Hartshorn, Murray, & Taylor, 2003; Joy, Nair, Hariharan, & Pillai, 2006), Flexx (Rarey, Kramer, Lengauer & Klebe, 1996; Kramer, Rarey, & Lengauer, 1999) etc. There are also dedicated web services available for docking like Molecular Docking Server (Bikadi & Hazai, 2009), SwissDock (Grosdidier, Zoete, & Michielin, 2011), PatchDock (Schneidman-Duhovny, Inbar, Nussinov, & Wolfson, 2005) etc for calculating geometry, site and energy of ligands interacting with proteins. The 3D pose of the bound pollutant-protein complex can be downloaded and visualized using different visualizing tools like PyMol, Rasmol etc which could help in inference of the best fit of ligand.

An increasing interest in human and animal enzyme interaction via molecular docking studies with pollutants is also of prime interest to environmental researchers working with occupational health hazard chemicals focused on bioaccumulation or toxicity property profiling of pollutants in human or animal bodies (Xie, Lü, & Chen, 2013; Zhou, Li, & Chen, 2013a; Liu, Chen, Jiang, & Song, 2014; Wang, Zhang, Cao, & Tang, 2014; Teng, Wang, Zou, Huang, & Du, 2015; Tripathi, Yasir, Gurjar, Bose, Dubey, & Shrivastava, 2015), Cytochrome P450 (Shimada et al., 2013; Zhou et al., 2013b; Shao, Chen, Li, & Zhao, 2014; Chushak, Chapleau, Frey, Mauzy, & Gearhart, 2015) and other xenobiotic degrading enzymes are of particular interest. Nanoparticle and polymer hazard has also been investigated through molecular docking assay for human and eco-toxicity bioindicator species (Lai et al, 2012; Hosseinzadeh, Moosavi-Movahedi, & Ghourchian, 2014; Liu et al., 2014; Yang, Hao, Li, Wei, Wang, & Liu, 2014; Ranjan, Dasgupta, Chinnappan, Ramalingam, & Kumar, 2015; Turabekova, Rasulev, Theodore, Jackman, Leszczynska, & Leszczynski, 2014). These are not being discussed in detail in this chapter as our focus is on bioremediation, and microbial enzyme docking investigation is best suited for such studies. Although, many of the enzymes in human and animal bodies also break down/detoxify the harmful pollutants but for environmental cleanup purpose, microbial enzymes are preferred owing to ease of availability and purification. Initiation and advancement of docking studies along the bioremediation line of research has been attempted by numerous researchers in the recent years (Table 1).

From the increasing number of studies including molecular docking for binding between pollutant and enzyme leading to degradation, it is evident that docking of protein-ligand is invaluable for studying the interactions of substrate and pollutants in bioremediation.

CASE STUDY: IBUPROFEN-COA LIGASE DOCKING

Sphyngomonas Ibu-2 has been reported to degrade ibuprofen [2-(4-Isobutylphenyl-Propionic acid)], an NSAID with an annual production of approximately 10 kilotonnes (Baumann & Baxendale, 2016), into catechols under aerobic conditions. CoA-ligase of *Sphyngomonas* sp. binds the said pharmaceutical and cleaves the acid side chain to yield isobutylcatechol metabolite (Murdoch & Hay, 2013). However, no report on the interaction of both these moieties exists. Here we describe a step by step method for protein-ligand study of this pollutant-enzyme interaction. The analysis shows that the CoA-ligase is capable of forming versatile conformations upon interaction with ibuprofen ligand. Modeling and abstraction played a noteworthy role in perceiving protein-ligand associations using computational *modus operandi*. Protein structural modeling and docking are helpful in inferring residues critical for interaction which might be mutated to obtain results of our interest. Detailed protocol and results are described as below:

Table 1. Comprehensive list of microbe-pollutant interaction studies carried out using molecular docking assay

Organism	Enzyme	Pollutant	Docking software	Reference
Pseudomonas sp.	Naphthalene dioxygenase	Indole, Naphthalene, Biphenyl	AutoDock program	Carredano, Karlsson, Kauppi, Choudhury, Parales, Parales, Lee, Gibson, Eklund, & Ramaswamy, 2000
Burkholderia sp.	Biphenyl dioxygenase	2,3′-Chlorobiphenyl, 3,4′-Chlorobiphenyl	Sybyl	Zielinski, Kahl, Hecht, & Hofer, 2003
Sphingomonas sp.	Naphthalene dioxygenase	Polyaromatic hydrocarbons (indole, naphthalene, biphenyl)	GRAMM	Librando & Forte, 2005
Rhizobium sp.	Haloalkanoic dioxygenase	Chloropropionic acid	AutoDock	Hamid, Hamid, Haziyamin, Wahab, & Huyop, 2006
Sinorhizobium meliloti, Pseudomonas diminuta	Amidohydrolase superfamily	Hydantoin, Paraoxon	DOCK	Hermann, Ghanem, Li, Raushel, Irwin, & Shoichet, 2006
Trametes versicolor, Bacillus subtilis	Laccase	Anthracene, Phenanthrene, Thiodicarb, Malathion, Captan, Atrazine, Remazol Red B, Chlorophenol	GOLD	Suresh, Kumar, Kumar, & Singh, 2008
Caldariomyces fumago	Chloroperoxidase	Limonene	GOLD	Aguila, Vazquez-Duhalt, Tinoco, Rivera, Pecchi, & Alderete, 2008
Pseudomonas sp.	Monooxygenase	Aromatic hydrocarbon	PyMol	Notomista, Cafaro, Bozza, & Di Donato, 2008
Coriolus versicolor, Pleurotus ostreatus, Pseudomonas sp.	Laccase, manganese peroxidase, lignin peroxidase	Polyaromatic hydrocarbon	FRED	Arun, Raja, Arthi, Ananthi, Kumar, & Eyini, 2008
Comamonas testosteroni	Biphenyl dioxygenase	Polychlorinated biphenyls	AutoDock 4.0	Baig & Manickam, 2009
Bacillus subtilis	Azoreductase	Azo dyes	PatchDock	Ramanathan, Shanthi, & Sethumadhavan, 2009
Sphingomonas paucimobills	Haloalkane dehalogenase	1,2,3-trichloropropane	Affinity	Zhao, Zheng, Zhang, Chu, & Sun, 2009
Rigidoporus lignosus	Laccases	2,5-xylidine	AutoDock version 3.5	Cambria, Di Marino, Falconi, Garavaglia, & Cambria, 2010
Comamonas testosteroni	Biphenyl-2,3-dioxygenase	Polychlorinated biphenyls	AutoDock	Baig & Manickam, 2010
Sphingomonas sp. CHY1	Ring-hydroxylating dioxygenase	Polyaromatic hydrocarbons	AutodockVina	Librando & Pappalardo, 2011
Burkholderia xenovorans, Pandoraea pnomenusa	Biphenyl dioxygenase	DDT	AutoDock4.2	L'Abbée, Tu, Barriault, & Sylvestre, 2011
Enterococcus faecalis	Azoreductase	Methyl red	AutodockVina	Feng, Kweon, Xu, Cerniglia, & Chen, 2012
Aeromonas hydrophila	Laccase	Aromatic/phenolic compounds	AutoDock	Singh, Mani, & Chaudhary, 2012

Sulfobacillus acidophilus	Barbiturase	Atrazine, Simazine, Hexazinone	PatchDock	Basharat & Yasmin, 2016b

Step 1: Modeling, Validation, and Optimization of Enzyme Structure

The structure of *Sphingomonas* sp. CoA ligase (Accession no: ABK92273) was modeled using I-TASSER as previously described (Basharat & Yasmin, 2015a; Basharat & Yasmin, 2016a, Basharat, Messaoudi, Ruba, & Yasmin, 2016a). Ten templates were used for threading based model generation of the structure. Fatty acyl CoA synthetase of *Mycobacterium tuberculosis* (PDB ID: 3R44) was the top template with a structural similarity of more than 30%.Best generated model had aC-score of 0.44 (good quality model lies between -5 to 2 range). Estimated TM-score was 0.77±0.10 with a RMSD of 6.5±3.9Å. The structure was corrected for errors and missing residues. Fitting of intermolecular parameters to structural and thermodynamic data along with energy minimization was carried out until a gradient of 0.05 was achieved. The 3D protein structure (Figure 1) was then tested qualitatively using ERRAT (http://services.mbi.ucla.edu/ERRAT/) and Rampage (http://mordred.bioc.cam.ac.uk/~rapper/rampage.php).

The structure had an overall quality factor of 78.19. Good resolution structures produce a value of over 95 and around 91 for 2.5-3 Å resolution structures. Since this is a homology model and equivalent to low resolution structure so the quality was considered fine. Structure passed the VERIFY3D (services.mbi.ucla.edu/Verify_3D) check as 90.51% of the residues had an average 3D-1D score of more than or equivalent to 0.2. According to the standard, more than 80% residues should have 3D-1D score more than or equivalent to 0.2. Ramachandran plot showed 79.2% of the residues were in favored region, 15.6% in allowed region and 5.1% in outliers.

Step 2: Ligand Procurement and Preparation

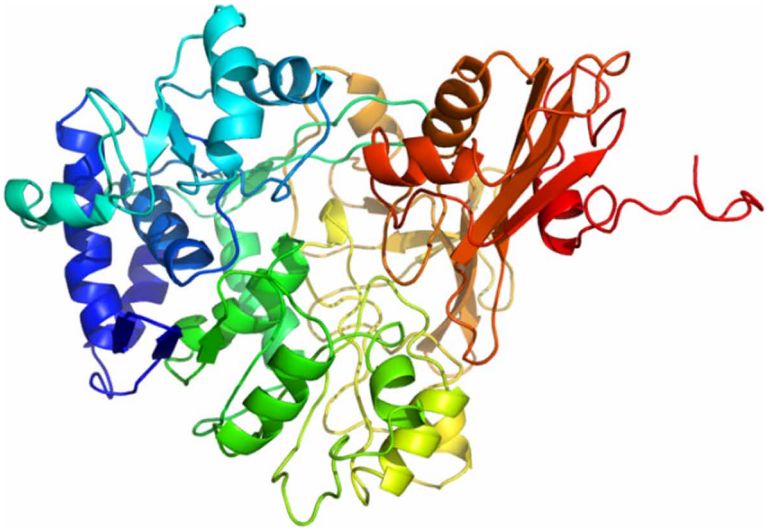
Ligand i.e. ibuprofen molecule was obtained from PubChem in 2D format and converted into 3D .pdb format using OpenBabel software. The ligand was optimized for pH 7, energy minimized using MMFF94 forcefield and saved for further analysis.

Step 3: Molecular Docking and Analysis

Docking was carried out using Molecular Operating Environmentsoftware.This software uses Monte Carlo simulated annealing process for docking, allowing conformational space sampling for ligand.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. 3D structure of the Sphyngomonas sp. ibuprofen-CoA ligase



Screening of everypossible binding site in the selected region of the target macromolecule was carried out. Docking interaction energy (U_{total}) of a given conformation is estimated from a set of energy grids centered in the macromolecule binding site using the formula parameters $U_{total} = U_{ele} + U_{vdw} + U_{ligand} + U_{solv}$ where U_{ele} is the electrostatic, U_{vdw} is the van der Waal interaction between protein-ligand complex. U_{ligand} is the conformation energy whereas U_{solv} represents the solvation energy. Among the generated poses, pose with lowest U_{total} is considered optimal. Ligase protein coordinates remained rigid during the docking process, while the flexible, mobile ligand relocated along the grid to trace most favorable binding orientation and conformation based on the interaction energy. The top ranking ten poses were retained in .mdb database format. These were then categorized according to increasing S-value i.e. final score indicating binding free energy. The complex with least S value was studied to evaluate the interactions of ligand with the active site residues of the ligase. Bonding interactions were evaluated via ligX option of Molecular Operating Environment. A value of -7.6335 was obtained for the optimal protein-ligand complex. 3D and 2D plot of the docked complex are shown in Figure 2 and Figure 3 respectively.

PERSPECTIVE

With increasing computation power, improved hardware and better simulations, we are achieving better insights and accurate prediction nearing natural chemical accuracy of interactions. This type of computational experimentation can help in unearthing the role of these residues and compounds in substrate specificity and activity, which in turn can be used for designing improved mutants and recombinants for degradation of noxious compounds (Prasad, Vindal, Narayana, Ramakrishna, Kunal, & Srinivas, 2012). Computational assessment of mutated protein residues in the structure is an inexpensive approach to assess alteration in functionality (Basharat & Yasmin, 2016c; Basharat, Zeb, & Yasmin, 2016b). This type of analysis attempted previously for laccase enzyme of *Bacillus licheniformis* using site-directed and random mutagenesis (Koschorreck, Schmid, & Urlacher, 2009) and can be extended for other enzymes

Figure 2. 3D view of the protein-ligand complex. Docked ibuprofen is clearly visible in the pocket of the CoA-ligase of Sphyngomonas sp

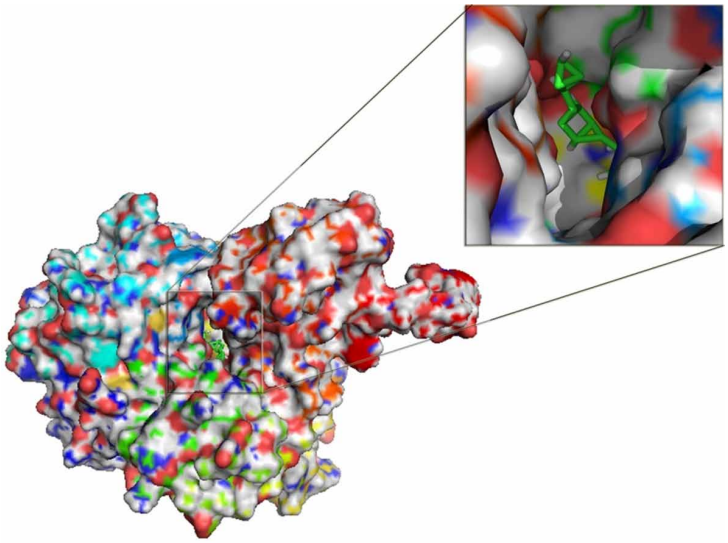

Figure 3. Molecular Operating Environment generated ligase CoA-ibuprofen interaction plot. It depicts 2D (flattened) spatial arrangement of ligand and CoA-ligase enzyme with respect to key interactions. The proximity contour shown by dashed lines. Trp210 donates electron to ibuprofen ligand OH group. The conformation of ligase-ibuprofen complex was energetically favored with the nucleophile and electrophile aptly positioned for catalysis

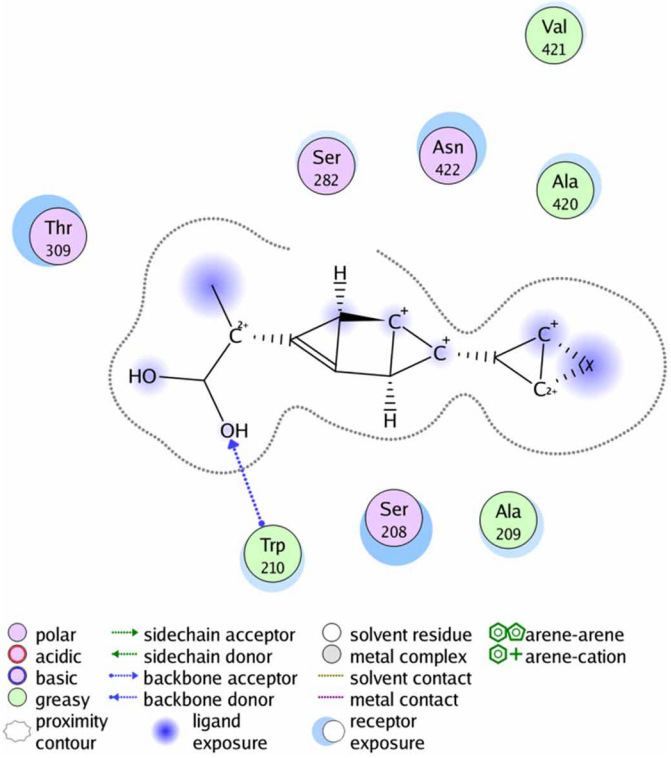

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

relevant to bioremediation. The existing algorithms and softwares are continually honed and perfected, as no one method functions fittingly for all protein systems.Paired occurrence of class of amino acids to more conjoined class of amino acids could help improve precision of scoring but is practically difficult to achieve due to scores of other undetermined parameters. Another challenge is the absence of a standard set of weighing coefficients for protein-ligand energy segment and forcefield scoring calculations. Presence of ions or co-factors in the pocket imposes parametrization difficulty in scoring as well. Evaluation of scoring functions is also a problem and each algorithm and software should be subject to CAPRI assessment for different datasets rather than simple root mean square deviation evaluation (for measuring quality of binding mode), before public release. Even though CAPRI (Janin, Henrick, Moult, Eyck, Sternberg, Vajda, Vakser, & Wodak, 2003; Méndez, Leplae, Lensink, & Wodak, 2005) exercises blind prediction feature that guarantees unbiased assessment but unrestricted usage of biological information like mutation dataand evolutionary analyses approach needs to be curtailed. Refined structural and binding datasets (including information of analogous pH and salt conditions) would be precious for parameter improvement. Systematic CASP-like ligand docking contests would do a good job of quality enhancement of algorithms.

Other challenges and barriers to the molecular docking include, but are not limited to issues like 'choosing the right approach', accuracy vs efficiency in assessing a particular algorithm, performance and prospective utility of a specific method over others in diverse situations etc. Throng of situations, factors, and data sets laid in front of the practitioner can confuse and the horde of pitfalls may render the docking approach less efficient. The shortcomings and technical traps of pollutant-enzyme docking methods could be avoided or reduced by knowledge based cautious approach which might make the practitioner aware and help make informed decisions which could limit probability of failure. Current scoring functions need to be trained rigorously on known and new datasets. In forcefield and knowledge based scoring methods, annexation of desolvation and entropic effects is indispensable for achieving precision.Scoring functions need to include fundamental compound measurements. Examples include transfer energies (for solvation and charges), dipoles/quadrupoles (for charge models), and pKa values for both small molecules and proteins (for solvation and binding energy). These can be calculated independently with softwares like DELPHI (Smith, Witham, Sarkar, Zhang, Li, Li, & Alexov, 2012; Sarkar, Witham, Zhang, Zhenirovskyy, Rocchia, & Alexov, 2013) but need to be integrated into the softwares and webservers.Such measurements are important as accurate scoring functions demands rigorous physical chemistry measurements for a wide variety of chemotypes.

Researchers have concentrated on pollutant binding to the protein, based upon structural knowledge of a known enzyme with degradation properties (Ajao, Kannan, Yakubu, Umoh. & Ameh, 2012; Basharat & Yasmin, 2016b). Conversely, designing a protein to bind a particular pollutant is also of interest to environmental scientists. It is intended for creating protein-based biosensors for pollutants. Computational design of pollutant-binding proteins is a perplexing inverse assessment of docking and scoring procedures, where experimental affinities are usually fed back into the algorithm development for refinement of complexes (Smith et al., 2016). Such protein design also entails a scoring function to rank and choose best conformations from the list of generated conformations. This would help in choosing relevant and active proteins to bioremediate/degrade pollutant.

Comparison between experimental and theoretical docking is not straightforward in biological entities but advent of combinatorial methods, growth in experimentally solved structures, theoretical advances, and improved computation power has definitely played a role in the success of docking studies and hopefully, will continue to do so in the near future. Computational efforts, particularly in combination with

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

relevant chemical strategies couldfurther boost efficiency and quality of docking. Molecular docking has been in use for more than three decades now and will continue to evolve and benefit the research community, including environmental scientists.

CONCLUSION

We need innovative real-time analytical methods capable of monitoring variations of priority pollutants in both time and location, integrated simulative models for perceiving and improving the breakdown mechanism, ultimately leading to better formulation of bioremediation strategies. To discover the substrate overtness of 3D available protein structure or a homology modeled enzyme and for gaining insight into the catalytic site, important residues and mechanism of the pollutant remediation-comprehensive information of enzyme structure complexed with substrate/pollutant is obligatory. For this purpose, computational molecular docking analysis is a boon and has been previously attempted for several noxious pollutants with enzymes. Although, several research groups have attempted to add to the scanty information on biodegradation analysis using docking assays but there is a need for more studies reporting and reproducing the conformations of protein-bound pollutants. The acquired information could aid in designing enzyme mutants for better accommodation of dye pollutants, especially for targeting at-once for a whole class of pollutants.

KEY TERMS AND DEFINITIONS

Ab initio: Method of estimation about biological features of a protein without any template structure or existing model.

Binding Mode: The positioning of ligand relative to the receptor and their coordination/conformation when bound/attached with each other.

De novo: Protein structure designed from the sequence alone.

Ligand: The molecule or entity which fits in/binds to the receptor. It might or might not be small in size compared to the receptor.

Pose: A specified position of ligand with respect to the receptor.

Ranking: Classification of poses based on scoring function.

Receptor: The molecule which acts as a receiving entity that might or might not be large in size as compared to the ligand.

Scoring: Evaluation of a pose through calculation of favorable interaction of parameters (such as hydrogen bonds, hydrophobic interactions).

Chapter 79
The Performance of Educational Institutions Through the Electronic Records Management Systems:
Factors Influencing Electronic Records Management System Adoption

Muaadh Mukred
National University of Malaysia (UKM), Malaysia

Zawiyah M. Yusof
National University of Malaysia (UKM), Malaysia

ABSTRACT

This article discusses the relationship between educational institutes that use ERMS and the performance of those institutions. This article uses a mixed explanatory method that incorporated quantitative and qualitative approaches. The quantitative method collected the responses from 364 participants. This was followed by a qualitative approach where experts were interviewed to verify the model. The results generated using the quantitative approach demonstrated that the quality of the system, information, and service as well as the security provided by the system had a significant positive relationship with the successful adoption of ERMS, which in turn improved performance. Moreover, the qualitative results that gathered through the experts confirmed the findings and contributed to enriching the understanding of the adoption of ERMS in educational institutions.

INTRODUCTION

Records management strives to control the records and documents related to business processes, transactions and decision making (Mohd & Chell, 2005) as it manages records over their lifecycle (Yusof & Chell, 2000). There are several benefits to using a records management system. In general, a records management system provides reliable information that allows an organization to operate effectively (Asogwa, 2012; Mukred & Yusof, 2015) while encouraging transparency and accountability (Mohd & Chell, 2005; Yusof & Chell, 2000). In organizations that are strictly regulated, such as those in the private sector, an effective records management system may be required by law (Wright, 2013). In a related study, Egwunyenga (2009) stated that records are important to educational institutions as they help these organizations achieve their educational objectives, but the principles used to manage records in these environments are inadequate. Other studies confirm that there are issues associated with the accuracy, reliability, and trustworthiness of managing records. To be considered a "record" information must be valid and authentic (Mohammad & Yusof, 2013). It must also be understandable, obtainable, and secured. Records are used because they can facilitate planning and help make decisions. An effective records management system allows an organization to adhere to any applicable legal requirements, efficiently retrieve information, and it creates the infrastructure for a secure information system (Baron, Thurston, & mcleod, 2016).

Currently, in institutions of higher education, such as universities, there is a growing demand for environments that focus on governance, audits, and risk management. An Electronic Records Management System (ERMS) can meet the need for effective recordkeeping by ensuring that institutions of higher education will be efficient, maintain their records, remain trustworthy, encourage audits, become more competitive while meeting their fiduciary obligations and preserve their transparency and accountability (Atulomah, 2011). ERMS is described as the electronic management of e-records and non e-records with the help of computer equipment and software on the basis of acknowledged premises and practices of records management (Akor & Udensi, 2013).

To ensure that the adoption of an ERMS is successful, there are several factors that must be examined before an appropriate model can be developed (Mukred & Yusof, 2017). For example, in a developing nation such as Yemen, one of the challenges that must be overcome is inertia (Larson, 2009; Mukred, Yusof, Asma'Mokhtar, & Manap, 2016). The aim of this paper is to propose a model for the adoption of ERMS to support the organizations performance in Professional Education (HPE) institutions using the Information System Success Model by DeLone and McLean and Technology Acceptance Model (TAM). One of the primary goals of this study is to contribute to the discussion regarding the growth of e-records. This study also attempted to help institutions of higher education adopt ERMS. Additionally, this study also hopes to redress the lack of information in the literature regarding the relationship between ERMS and the performance of institutions of higher education.

ERMS AND EDUCATIONAL INSTITUTIONS

In order for an institution of higher learning to take advantage of the benefits associated with ERMS, staff must know how to use it properly. Unfortunately, as shown by a survey conducted by (Ismail, 2009), both the academic or the administrative staff at Kolej Yayasan Melaka in Malaysia lacked the skills and knowledge needed to access records management. Consequently, this college does not retain

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

their students' records. Records are difficult to manage if the organization does not have policies and frameworks in place to handle the management of their records. Mohammad and Yusof (2013) pointed out that policies and frameworks act as a roadmap when implementing records management procedures. These two researchers conducted a study in Melaka and Negeri Sembilan that examined vocational collage that had adopted a records management system without first developing relevant policies or frameworks. In a similar study, Galala and Yusof (2013) revealed that public post-secondary schools in Libya lacked policies regarding electronic records. Universities in Africa were found to have staff that were unaware of the organization's policies and procedures for using their ERMS (Bigirimana, Jagero, & Chizema, 2015).

Modern institutions of higher learning would benefit greatly from making governance, audits, and risk management a priority. This means that ERMS must ensure that these institutions can keep and maintain good records, and thus achieve their governance goals, while preserving their history, instilling trust, enhance their competitiveness, meet fiduciary requirements, and demonstrate transparency and accountability (Baron et al., 2016; Ghering, Caruso, & Gift, 2010). According to (Adu & Ngulube, 2016), effective recordkeeping is a fundamental component of good governance and more studies are required to better understand the role played by recordkeeping. They recommended that universities in South Africa and Malawi should consider the role of recordkeeping when they develop alternative frameworks for managing their records and documents. (Adu & Ngulube, 2016) highlighted that digital preservation must support organizations and meet any standards governing digital preservation.

The current literature reveals that most educational institutions in the developing world struggle to manage their records and documents even though they have improved their systems of governance. Educational institutions would benefit from change to policy, digital record storage, records management units, the support of senior management, education and training of records management staff, and systems and procedures for the retrieval and distribution of records (Phiri, 2016). ERMS are used in the developing word but still barriers to their successful implementation remain (Baron et al., 2016). The move towards using ERMS in education is worldwide because it minimizes the gap between the supply and demand for education. Several countries are aware that investing in the adoption of innovations, such as ERMS, can improve the whole educational system (Cheon, Lee, Crooks, & Song, 2012). ERMS contributes to the provision of education improving the performance of an educational institute.

PREVIOUS WORKS ON THE ADOPTION OF ELECTRONIC RECORDS MANAGEMENT SYSTEM

ERMS are relatively new tools for records officers and archivists in the developing world (Asogwa, 2012; Mosweu, Bwalya, & Mutshewa, 2017; Mukred et al., 2016). Currently, there are few studies that examine the role between information systems and decision making (Atulomah, 2011; Mukred & Yusof, 2017; Mukred et al., 2016). One reason for the lack of studies may be that there is a lack of tools for measuring how information systems affect decision making processes. Instead a standard benchmark is used for comparison. Qualitative and qualitative methods are needed to measure the quality of decisions. This requirement was the reason this study examined the impact of ERMS on the performance of educational organizations. In the following sections, earlier studies regarding the technical factors that could affect the implementation of ERMS and the role played by ERMS in organizations' performance are examined.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Studies that investigate ERMS in institutions of higher learning are limited but that are several studies that examine ERMS in healthcare. The records relied on by healthcare providers are managed by Electronic Health Records (EHR). The concepts, methods, and management techniques used by EHR are applicable to other sectors. The degree to which information technology is proportional to the degree to which the adopter is convinced that the new technology would lessen their workloads (Phillips, Calantone, & Lee, 1994). The adoption of technology has been described as the acceptance of technology that would appear to offer the best course of action (Rogers, 2010) and thus it focuses on the initial motivation and intentions surrounding the use of innovative technologies (Proctor et al., 2011). The adoption of ERMS improves educational delivery services. The process begins when a potential adopter becomes aware of a technology and it ends when the adopter implements and uses the technology (Renaud & Van Biljon, 2008).

System Quality

An information system is measured by the quality of the system's output (Delone & McLean, 2003). The quality is connected to its software and data components, and it assesses the health of the technical aspects of a system (Gorla, 2011) and it has a significant effect on its effectiveness, which can be defined as the ability of a system to do what it was designed to do. A study conducted by Zheng, Zhao, and Stylianou (2013) looked at the effect of system quality. In their study, they defined quality as the ability of a system to manage processes without crashing and it tested the readiness of a system to engage in its processes. In a recent study by Coffman, Spetz, Grumbach, Fix, and Bindman (2014), a system quality model was developed to determine the availability of e-health records (EHRs) by certified nurse midwives, nurse practitioners, and physicians in California. Their study took place after California Medicare implemented an EHR system. The researchers used similar features to gauge the availability of healthcare providers and they found that nurse midwives, practitioners and physicians were more likely to practice in areas with fewer Medicare patients.

Information Quality

A review of the literature found that there were several definitions for the quality of information. (Gorla, 2011) suggested that the quality of information is related to its perceived value in the eyes of the user. Gorla stated that information is perceived as being of high quality if it meets its specifications as well as the expectations and requirements of the user. (Pérez-Mira, 2010) divided information into two categories when they identified information as required or obtained. Required information meets the aesthetic, cognitive, functional, and technical requirements of users. (Pérez-Mira, 2010) speculated that the quality of information will significantly influence the effectiveness of an information system. Several studies reviewed in this paper demonstrated the significant influence information quality had on the system (Ali & Money, 2005; Mercy Mlay Komba & Ngulube, 2014; Mercy Milay Komba & Ngulube, 2015). Given its importance, quality of the information must be considered when selecting and adopting an information system (Petter, DeLone, & McLean, 2013). The quality of the information is related to the accuracy and knowledge of the system overall and any new information it might generate. One way to ensure that system requirements for information quality can be satisfied is to obtain feedback from end users (Ali & Money, 2005).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Service Quality

The quality of service is another variable examined in this study. Service quality refers to the difference between normal service expectations and the actual performance from perspective of the user. Service quality centers on the types of services provided (Gorla, 2011). Al-Hudhaif (2010) based service quality on the accuracy and reliability of a service. Reliability was demonstrated to be one of the most important characteristics of a quality service. In a digital world, reliability will improve the trustworthiness of an organization because it reflects the consistency and credibility of the organization (Hsiao, Li, Chen, & Ko, 2009). The quality of the service provided by an ERMS depends on its ability to meet the needs of educational institutions. Good quality service will encourage users to adopt and use a system (Motaghian, Hassanzadeh, & Moghadam, 2013).

Security

Safeguarding the security of electronic records is critical. Security can be better protected by administrators when they support security management and adopt initiatives (McGinn et al., 2012). A focus on security can lead to the development of robust, superior systems. The user's perception of the security of a system will determine if they will adopt a system. A study conducted by Chhanabhai and Holt (2007) revealed that users quickly accept ERMS systems when its security is guaranteed. The security risks associated with the adoption of a system must be taken into consideration, especially since the standards and legislative requirements related to the security of electronic records have increased (Daglish & Archer, 2009). Further research is needed to explore these regulations and the role they play in implementing secure systems (Fernández-Alemán, Señor, Lozoya, & Toval, 2013). Several studies have investigated the influence of security on the adoption of technology. In one study, Wright (2013) found that data protection should be standard. Public Key Infrastructure is a possible solution as it authenticates and encrypts data and can be very effective when coupled with sufficient memory and processing capacities.

Intention to Adopt ERMS

The intention to adopt refers to a user's determination to accept a new technology (Seymour, Makanya, & Berrangé, 2007). In this study, the intention to adopt is defined as the intention of a user to adopt ERMS and their attitude towards ERMS. Gong, Xu, and Yu (2004) pointed out that attitude alone is not enough to determine if a user will adopt a technology as they discovered that other factors, such as behavioral intention, played a greater role. In a similar study, the quality of the output of a system was more important than intention when predicting if physicians would adopt internet based health applications (Chismar & Wiley-Patton, 2003). In the developing world, the intention to adopt ERMS is influenced by the quality of the system, information, and service. If barriers to accepting and using ERMS are to be lifted, then a greater understanding of the factors that influence attitudes and ultimate acceptance of a system is required (AlAwadhi & Morris, 2008; Mukred et al., 2016).

Adoption of ERMS

A need exists to examine the technologies adoption that would assist educational institutions in transforming themselves into global leaders in HPE institutions. Understanding such an adoption is required

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to diffuse and urge the technology adoption as this may improve learning and teaching. Without such understanding, technologies adoption may fail, their effectiveness may become obsolete and their sustainability will become negligible (Nachmias & Ram, 2009), and in the current progressive and dynamic world, this could mean universities' lagging behind and the loss of valuable resources. Additionally, the ultimate aim of effective management for electronic records within HPE and universities requires that their staff accept and use ERMS and as such, this study examines the attributes/characteristics that impact academic members/staff of HPE institutions adoption of ERMS and that contribute to their organizations' performance. Delone and McLean (2003) examined how the quality of a system, its information and service influences a user's attitudes towards the system and their satisfaction. They developed a model that is now widely used to measure the success of the adoption of an information system. Their model has been independently tested (Tona, Carlsson, & Eom, 2012). This study used an updated version of their model to examine the influence of intention on the adoption of ERMS.

Organization Performance

In measuring performance, two measures are generally considered: primary measures, which is the degree to which an operation fulfils its objectives and secondary measures, which is the degree to which the needs of customers have been met (Slack, 2015). A critical effective management parameter is the measurement of performance measurement; without measuring something, it is difficult to improve it. Therefore, this paper aims to identify and measure the impact of ERMS practices on organizational performance in order to improve it. Good records management improves the performance of an organization as well as its competitiveness (Tagbotor, Adzido, & Agbanu, 2015). The improved performance and competitiveness of an organization can be measured by better decision-making process, increased productivity, more sales and rising profits, reduced costs, enhanced customer safety, as well as the creation of employment and economic development. According to (Urbach & Ahlemann, 2010), decision making satisfaction directly and positively affected the quality of the system and information in DeLone and McLean's (1992) model.

Chae, Yoo, Kim, and Chae (2011) studied the relationship between hospital information systems, Electronic Medical Records (EMR), Clinical Decision Support Systems (CDSS), and the performance of a hospital. They also examined how management issues changed over time and during different stages of growth. They used a chi-square test to investigate the characteristics of the EMR-CDSS relationship and a t-test to evaluate the effects of both systems on the performance of the hospital. (Chae et al., 2011) found that there was a significant relationship between EMR and CDSS thus indicating that both factors improved hospital performance. Moreover, (Plantier et al., 2017) investigated the relationship between electronic medical records (EMR) adoption and organizational performance in French hospitals. The study concluded that EMR adoption directly affected the performance of the organization. The findings suggest that there should be an investment in EHRs for better organizational performances.

It is evident from the literature that studies addressing the factors influencing ERMS adoption in support of the organizations' performance (Smith, Bradley, Bichescu, & Tremblay, 2013); (Osakwe, 2013) are still few and far between, with an evident lack of framework that could guide in ERMS proper adoption, and in the system's role in the performance of HPE institutions. This calls for an urgent need to examine the organizations' performance through ERMS adoption. Exploration and investigation need to be carried out in order to put ERMS in place in educational setting to help in its decision-making process and organizations' performance.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

DEVELOPING ERMS ADOPTION MODEL

If universities are to become global educational leaders, they must identify those technologies that would help them meet their goals. Without this information, there is a risk that they may fail to adopt the right technology and become ineffective before becoming unsustainable and obsolete (Nachmias & Ram, 2009). The effective management of records in an educational institute means that staff must not only accept ERMS, but they must also use the system. Consequently, in this study, the attributes and characteristics of the staff and educators in institutes of higher learning and their effect on the adoption of ERMS was examined.

The literature points out the inability of institutions of higher learning to adopt ERMS. One of the primary goals of this study was to address the issues surrounding ERMS adoption and to develop an ERMS model that would facilitate organizations' performance. The model developed by this study was the result of analyzing the technical factors that impacted the adoption of the system by staff. DeLone and McLean's (2003) model was employed to evaluate the staff's intention to adopt ERMS and its relationship with organizations' performance. In other studies that looked at the adoption of ERMS, TAM, with or without modifications, was used to analyzed the adoption or acceptance of a ERMS (Gagnon et al., 2010; Gagnon et al., 2014; Morton & Wiedenbeck, 2010; Archer & Cocosila, 2011; Marcu, 2013; Terry, Brown, Denomme, Thind, & Stewart, 2012). Based on the success of previous studies, this study also used the TAM (1993) model to gauge how well the ERMS was adopted and its effect on the performance of an organization. Combining TAM with DeLone and McLean's (2003) model has been recommended (Cheok & Wong, 2015) to investigate organizational performance in an educational environment. The proposed model is illustrated in Figure 1.

The following hypothesis were tested in this study:

H1: The quality of the system positively influences the intention to adopt the ERMS.
H2: The quality of the information positively influences the intention to adopt ERMS.
H3: The quality of the service positively influences the intention to adopt ERMS.
H4: The security of the system positively influences the intention to adopt ERMS.
H5: The intention to adopt has a positive relationship with ERMS Adoption.
H6: The adoption of ERMS positively affects the performance of an organization.

Figure 1. The proposed model for ERMS adoption

METHODOLOGY

This study used an organized set of logical phases. Choosing between a quantitative, qualitative, or a combined approach depends on the research objectives (Creswell, 2013). Quantitative research approaches are best used with objective theories that can explore the relationships between variables. By contrast, qualitative research approaches are appropriate when the research objectives are concerned with individuals, groups of individuals, as well as social or human issues. In many studies related to information systems, neither a quantitative or qualitative approach, but combined approaches, are becoming more common because they can provide valuable information (Ngulube & Ngulube, 2015). Creswell (2013) described three different types of combined research methods. These methods are the explanatory, exploratory, and triangulation methods. The explanatory method conducts an initial quantitative study and then it uses a follow-up qualitative study. The exploratory mixed-method uses a quantitative study that relies on the results from an earlier qualitative study. The triangulation method, which is the most common approach, interprets data gathered using both qualitative and quantitative methods. The goal of the triangulation method is to confirm the results of a study using both quantitative and qualitative methods (Creswell, 2013).

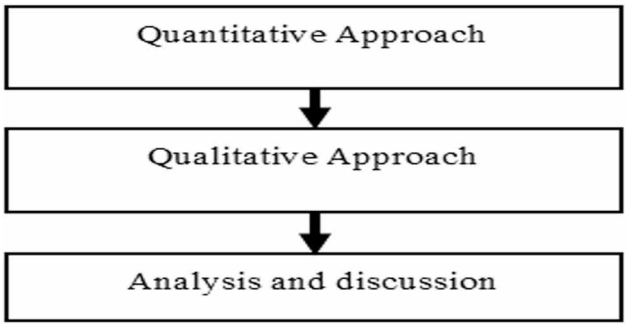
Harris and Brown (2010) noticed that in studies that used mixed methods, the structured questionnaires and semi-structured interviews produced confirmatory results. Likewise, (Ngulube & Ngulube, 2015) observed that mixed method allowed researchers to paint a comprehensive picture of a phenomenon and realize their research objectives. The clear picture and valuable insight provided by the data from studies that employ a mixed methodology allow for the development of more accurate theories (Ngulube & Ngulube, 2015). This study used an explanatory mixed method to collect data. First, quantitative data was gathered from 364 respondents working in either managerial or academic positions at the Ministry of Technical Education and Vocational Training (MTEVT) in Yemen. Myers (1997) asserted that in the social sciences, qualitative research techniques allow researchers to examine social and cultural phenomena. He stated that qualitative methods further our understanding of individuals and the social and cultural aspects of their environment. Qualitative studies are important because they provide insight into an individual's perceptions and behaviors through observations and questions (Glaser & Strauss, 2009). Collecting and analyzing qualitative data provides information about a phenomenon. In this study, qualitative data was used to better understand the role played by ERMS adoption in the performance of an organization. The most commonly used qualitative data collection methods are interviews, documentation, and observations (Myers, 1997). Interviews are typically used to gather data in qualitative studies and they may be combined with quantitative data collection methods to support the results. In this study, qualitative data was collected from the participants using interview methods.

The interview method is used to collect the experiences and perceptions of small group of interviewees (Brenner, Green, & Camilli, 2006). Typically, and interviewer asks the participants open ended questions about the topic being studied. The answers provided by the interviewees reflect their personal experiences and they are recorded (Creswell, 2013). The results of the interviews provided valuable information that is very different than the static data collected using quantitative methods. Additionally, interviews ensure the consistency of the quantitative results in studies that employ mixed methodologies. The explanatory approach starting with quantitative methods then qualitative methods is shown in Figure 2.

Figure 2 illustrates that the first step in the Explanatory Mixed Method is to take a quantitative approach. The data from the survey was used to observe the relationships between exogenous and endogenous constructs (Kline, 2015), predict and control phenomena, and determine the best concept (McNabb, 2015).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Explanatory mixed method



The data gathered using a quantitative approach is analyzed using mathematical procedures or statistics (Creswell, 2013). Qualitative data collection techniques should be related to the research objectives. In this study, this step included designing a questionnaire. Questionnaires are a common tool used by researchers thus it is important that any questionnaire used is effective. (Sekaran, 2006) recommended that particular attention should be paid to the wording of the questionnaire, how items are categorized, the scales and codes used to analyze the responses to the questionnaire, and the general appearance of the questionnaire. In this study, care was taken that the questionnaire protected the quality of the data, received enough responses, and that any anticipated biases were mitigated (Groves et al., 2011).

This study uses the online questionnaire format where emails were sent to clarify the purpose behind the research and to invite the participants to complete it. (Peytchev, Couper, McCabe, & Crawford, 2006) stated that online format surveys have several benefits over paper-based methods. For instance, an online survey takes two-thirds of the time taken to complete a traditional paper-based survey (Groves et al., 2011). The researcher does not have to wait to retrieve the paper questionnaires as data is automatically gathered. Online questionnaires also decrease the costs used and due to the automatic processing or responses, the results can be accessed in a timely manner (Schonlau, Ronald Jr, & Elliott, 2002). The questionnaire is divided into five sections with the contents as follows; the first section includes questions about the measurement of the information quality, system quality, service quality and security factors are contained; in the second section, the measurement of the behavioral intention factor are contained. The third section contained the questions regarding the adoption of ERMS and in the fourth section, the measurement of performance factors are contained. The respondents were requested to indicate their level of agreement to the items concerning the adoption of ERMS through a five-point Likert scale that ranged from strongly disagree depicted by 1 to strongly agree depicted by 5. Finally, the fifth question contains the participants' general information in terms of their demographic characteristics – these are entered into descriptive statistics to provide an insight into the study sample.

Studies that use mixed methodologies generally employ purposive sampling to collect qualitative data (Palinkas et al., 2015). In purposive sampling, units or cases are chosen for a reason rather than being selected at random. For example, participants may be selected for their knowledge or other characteristics. Identifying participants can ultimately help researchers better understand a phenomenon (Creswell, 2013). The standard for purposive sampling is that participants should be knowledgeable about the subject. Current studies of ERMS adoption that focus on developing countries highlight the importance of interviewing individuals from different levels of management because the definition of "success" depends on the subjective perspective of each individual (Heeks, 2006). An interview should begin by introduc-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing the topic being examined as well as the purpose and scope of the study. In this study, the questions asked during the interviews were related to validating the ERMS model. The data from the interviews was used to validate the model. Five experts were questioned during a semi-structured interview. The interviewer asked open-ended questions so that the experts could freely express their opinions. The interviewer also asked questions related to the factors that effected the successful adoption of ERMS. All the questions in the interviews helped the researcher comprehend the perceptions of the participants regarding the role of ERMS in organizations performance. The goals of the interviews were as follows:

1. Confirm that the factors highlighted in the literature were valid for ERMS and that the terminology could be translated into Arabic;
2. Determine if the study model was researchable;
3. Determine the importance of relevant factors;
4. Determine if other factors described by the practitioners were omitted by earlier studies;
5. Develop items from the design of the questionnaire.

Each interview session was conducted in a period lasting 35-55 minutes. The interview sessions were recorded, after which it was transcribed, and the transcripts were verified by a second person to determine inconsistencies. The highlighted minor inconsistencies were rectified by modifying the transcripts.

RESULTS AND DISCUSSION

Before the data can be analyzed, the constructs must be validated. Factor analysis is used to confirm exogenous, endogenous, and dependent variables. In addition to factor analysis, this study also confirmed the reliability of the items used to measure the constructs. An exploratory factor analysis (EFA) was undertaken using principal component analysis (PCA) with an orthogonal VARIMAX rotation to examine how well exogenous items completed the following five tasks:

1. The first task was to determine the number of factors that affected the exogenous, endogenous and dependent variables. If the factor had an eigenvalue greater than 1.0, it indicated that the factor had a measurable influence on a variable. By contrast, if the factor had an eigenvalue less than 1.0, it meant that that factor did not have a significant impact (Hair Jr, Hult, Ringle, & Sarstedt, 2016);
2. The second task used a Kaiser-Meyer-Olkin (KMO) value to measure sampling adequacy. The adequacy of a sample is confirmed if it had a value that exceeded 60% (Pallant, 2013);
3. In the third task, the correlation and partial correlation values were used to confirm that the size of each sample was adequate. A correlation value greater than 50% indicated that the size of the sample was adequate (Field, 2009);
4. The fourth task required that the significance communality, which indicated the significance of an item, was determined. Only factors with a communality percentage greater than 50% were considered significant (Tabachnick & Fidell, 2013).

In this study, structural equation modeling (SEM) was used to validate the model. The path coefficients were calculated using Smart PLS 2.0. Smart PLS 2.0 was also used to determine the significance of the path using a bootstrapping method. As recommended by (Hair Jr et al., 2016), a composite reli-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ability (CR) value greater than 0.7 indicates internal consistency and convergent validity (measured using Average Variance Extracted (AVE)) must be 0.5 or greater. Furthermore, the Cronbach's alpha value must be greater than 0.7 and factor loading should result in a value of at least 0.6. Table 1 sets out the results of the SEM analysis.

Table 1 shows that the values were sufficient (Hair Jr et al., 2016). The values for factor loading ranged from 0.748 to 0.928 and the Cronbach's alpha ranged from 0.828 to 0.906. The CR values ranged from 0.869 to 0.930 indicating that the model had good internal consistency. The AVE values were between 0. 571 and 0. 741. The path model is illustrated in Figure 3.

This study employed a DeLone and McLean IS model and TAME model and the results described the relationship between the exogenous, endogenous, and dependent variables. The results for each research hypotheses are summarized in Table 2.

As shown in Table 2, the quality of the system, information, and service and security determined the likelihood that an ERMS would be adopted. Because ERMS plays an important role in the decision-making processes of an educational institution and its performance, these organizations should ensure that the ERMS they adopt have the features (system, information, and service quality and security) that will encourage their employees to embrace its use. The findings indicated that the technical factors should be taken into consideration as a determinant of ERMS adoption in HPE sector and that it influences individuals and organization alike in different levels (operational, tactical, and strategic). Respondents stressed the crucial aspects of the system characteristics, including system quality, information quality and service quality in the system adoption as well as security. In addition, findings confirmed the positive impact of ERMS on organizations' performance. Once the statistical model was validated using SEM, the proposed model was further validated by five IS experts to confirm that the model would achieve its purpose. The five experts had experience in both academic, practical, and government settings. These experts validated the completeness of the model, the relationships between variables, correlations, and the strength of the relationships found in the proposed model. They also provided an explanation of the adoption model in institutions of higher learning.

The potential for bias originating from a single discipline was eliminated by selecting interview participants with different disciplinary backgrounds. As a result, the participants in the interviews included application integration managers, planning and coordination department managers, and business analysts.

Table 2. Summary of the results for the research hypotheses

Hypothesis		ß	Support	R^2
Intention to Adopt				0.339
H1	System Quality →Intention to Adopt ERMS	0.195	Supported	
H2	Information Quality →Intention to Adopt ERMS	0.225	Supported	
H3	Service Quality →Intention to Adopt ERMS	0.202	Supported	
H4	Security →Intention to Adopt ERMS	0.245	Supported	
Adoption				0.554
H5	Intention to Adopt → ERMS Adoption	0.745	Supported	
Organization's Performance				0.251
H6	ERMS Adoption → Organization's Performance	0.501	Supported	

The clarity of translated materials was confirmed by discussing the results in both Arabic and English with a professor with experience in IS. The results of the interviews revealed that the quality of the ERMS system was a reflection of the quality and accuracy of the information as described by Expert 1:

The most attractive advantage that promotes the ERMS use is that it provides quality information that satisfies the need of the decision makers in a timely manner. Your model is interesting owing to the clear and sufficient output information from the ERMS that is good evidence that information quality is a reflection of system quality.

Expert 2 described just how crucial quality information is to ERMS adoption:

The information quality factor in the model is crucial due to the dependence of decision making on the quality of available information.

Access to information technology requires appropriate infrastructure. If IT solutions such as ERMS are to work, access to them must be easy and reliable. The interview participants saw service quality as an important factor for adopting ERMS as expressed by Expert 3:

Service quality factor is important to enable employees and administrators to adopt the system. Your proposed model defines the system applicability even for future implementation.

The benefits of using ERMS include access to the records needed to make informed decisions as stated by Expert 4:

Information extracted from e-records through ERMS is vital for effective decision making.

Expert 3 made a similar statement:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

For easy decision-making, information has to be made available and this is made possible through extraction of information using ERMS.

As did Expert 5:

Information availability and system accessibility influence the ERMS adoption and implementing the system in HPE institution is important as this could play a significant role in evaluating OBE programs, and in enhancing the process of decision making. In other words, the ERMS enables time and cost saving.

The importance of ERMS to the managerial and academic activities of an educational institute was highlighted by Expert 1 who stated:

Electronic records management system is important for successful evaluation process in the outcome-based education. The system's adoption will help in saving cost, time and effort that will improve organizations' performance, from the academic viewpoint. From the viewpoint of administration, the system enables administrative processes depending on the system's generation of relevant information and will impact the organizations performance as well.

The findings were also supported by the experts, who confirmed that system factors (system, information, and service quality and security) play key roles in the adoption of ERMS in their HEP institutions. Similar result was reported by (Al Haderi, 2014); (Tzeng, Kuo, Talley, Chen, & Wang, 2015); (Mercy Milay Komba & Ngulube, 2015); (Sharma, 2015); (Ghazvini & Shukur, 2013); Compeau and Terry (2017). However, what makes this study unique is the proposal of an integrated model for those factors and their impact on the intention to adopt ERMS and the relationship between such adoption and organizations performance. The validation process included obtaining feedback from the experts through interviews (qualitative method) to support the results. The findings validated ERMS model as reliable and applicable in HPE institutions. The validity of the proposed model and the support on all the hypotheses are largely attributed to the involvement of experts.

CONCLUSION

One of the goals of this study was to identify the factors that would positively influence the adoption of ERMS in institutions of higher learning. This goal was met by developing the model shown in Figure 3. This model was assessed using SEM and Smart PLS statistical software. The results indicated that the model was valid. The model used in this study represents a theoretical breakthrough because it included variables associated with adopting innovations. An effective ERMS results in information that can help educational institutions make well informed decisions and improve their performance in a competitive marketplace. The results of this study confirm that ERMS significantly improves the performance of organizations. The completeness of the ERMS model used in this study was confirmed by a panel of experts because the model summarized the importance of those factors that increased the likelihood that an ERMS would be successfully adopted to the benefit of the organization. Furthermore, this study narrowed the gap in the literature related to the relationship between ERMS adoption and organizational performance by using both the DeLone and McLean IS Success Model and TAM model. The results

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

from this study also contribute to the literature regarding the validation of the DeLone and McLean and TAM model for institutions of higher learning in Yemen and other developing countries. Consequently, this study could shape future theory and empirical studies concerning ERMS, especially in cases where it is used to improve organizational performance. In addition, further research is called to build on the findings of this study, particularly to identify the other factors such as organizational and technological factors that might influence the adoption of ERMS.

ACKNOWLEDGMENT

We would like to thank Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia by giving the authors an opportunity to conduct this research. This research is funded by Universiti Kebangsaan Malaysia under Research Grant Code: GUP-2017-046

Chapter 80
Online Social Exergames for Seniors:
A Pillar of Gamification for Clinical Practice

ABSTRACT

The population is getting older, and the resources for care will be even more limited in the future than they are now. There is thus an aim for the society that the seniors can manage themselves as long as possible, while at the same time keeping a high quality of life. Physical activity is important to stay fit, and social contact is important for the quality of life. The aim of this chapter is to provide a state-of-the-art of online social exergames for seniors, providing glimpses of senior users' opinions and games limitations. The importance of the motivational techniques is emphasized, as well as the impact that the exergames have to seniors. It contributes to the book objectives focusing on current state and practice in health games for physical training and rehabilitation and the use of gamification, exploring future opportunities and uses of gamification in eHealth and discussing the respective challenges and limitations.

INTRODUCTION

An increase in the life expectancy and decrease in birth rate cause an ageing population and according to the UN reports the rate of population ageing in the 21st century will exceed that of the previous century. Older people (aged 60 years or over) increased from 9.2 per cent in 1990 to 11.7 per cent in 2013 and will continue to grow as a proportion of the world population, reaching 21.1 per cent by 2050. A continuous increase on the number of "oldest old" (aged 80 year or over) is expected, reaching 19 per cent in 2050 from 14 per cent in 2013 (United Nations - Department of Economic and Social Affairs Population Division, 2013).

Healthcare is costly and all countries face budget constraints, so spending more money is not the solution. Policy makers and health professionals believe that the solution lies in an active and healthy ageing (*White Paper: "Together for Health: A Strategic Approach for the EU 2008-2013"*, 2007). Services for each individual's whole-person need are emerging and should prolong the time elderly individuals can live autonomously and healthily (Berry & Bendapudi, 2007).

The use of information and communication technology (ICT) is an emerging field in active and healthy aging trying to create better conditions of life for the older adults and to strengthen the industrial opportunities. This includes the use of games for keeping seniors active and healthy in the form of exergames and gamified applications in combination with sensors and motion devices.

This new era of research gives rise to a multitude of challenges. Techniques, methods and strategies that are already applied in different domains are gathered in order to provide state-of-the-art games which will enhance the physical activity of seniors. Despite the fact that a lot of studies engage research on how a health game contribute to behaviour change, patients' self-management of care, and adherence to care, remain an open research field (Baranowski, Buday, Thompson, & Baranowski, 2008; Honka, Kaipainen, Hietala, & Saranummi, 2011; D. King, Greaves, Exeter, & Darzi, 2013; Strong, Tulu, Agu, & He, 2014) in order to be applied properly in the target group of seniors. Persuasive games and motivational strategies are starting to be applied in games for physical activity for seniors (Ellen Brox, Luque, Evertsen, & Hernandez, 2011; Kort, IJsselsteijn, Eggen, & Hoven, 2005), but complete frameworks which prove their effectiveness are still missing.

This Chapter is structured as follows. Initially an overview over games that are used by seniors for exercise are described. Mainly proprietary but also a few open-source games can be categorized in game types, providing the current trends. Many of those are normally not played online, although some offer online solutions too. Gamification is also being researched as a current trend in exergaming. The following section will identify the existing research that takes (or took) place through relevant EU and national projects. A review of those projects reveals the research gaps which need to be fulfilled in the future. An analysis of general requirements and an investigation into the different technology possibilities is following. The next section is focusing on the impact of exergames for seniors. This section strengthens the knowledge regarding improvements that exergames can have for seniors, thus providing the ground to build on. Physical activity can also improve the mental health and will be included in the key issues for possible positive contribution of exergames. The following section will focus on social aspects which have been proved to be an important factor of everyday life, especially for seniors. This section records the existing efforts on the inclusion of this aspect into the exergames. Motivation, on the other hand, is really important to keep the seniors to frequently play the exergames. Persuasive techniques that are used in exergaming are recorded and the connection with social aspects is emphasized. Last but not least future challenges and research questions will be presented in order to further boost the rapidly developing area of games in healthcare.

TRENDS OF EXERGAMES FOR SENIORS

Inactivity is the most common reason for loss of functional capabilities among elderly. Physical activity can effectively delay this process, and is one of the most important factors in promoting wellbeing among elderly (Goldspink, 2005; Taylor et al., 2004). However, adherence to exercise programs is a major obstacle. It requires large human resources to have long term effects (Teixeira, Carraca, Markland, Silva, & Ryan, 2012). It is in this light exergames are promising.

Exergames can be defined as "digital gaming systems with an interface that requires physical exertion to play" (Larsen, Schou, Lund, & Langberg, 2013). With exergames, one is thinking of digital devices that both record and instruct the users how to exercise correctly and motivate the users by giving feedback on their achievements to encourage them.

There are several types of exergames on the marked but they are not targeting seniors. Still some senior centres and nursing homes around the world have exergames as an offer for their users. It seems that mainly the two major proprietary game consoles are being used; namely Nintendo Wii and Kinect for Xbox by Microsoft. All home entertainment systems that have a way of registering users' physical activities can be used for exergames.

There is a multitude of games for all of these platforms, but in general they are targeted towards younger users. Some of the games are however also suitable for older users and are offered in the senior centres that use exergames. However speed, information overload, language, etc. make most of these games challenging for the seniors.

The Nintendo Wii mainly has two different controls used for elderly; a handheld remote or a balance board that register change in weight distribution. The remote is normally held in one hand, and several of the games can also be played while seated. There are also walking / jogging games that are played where the remote is supposed to be in a pocket, and it is possible to buy an extra remote ("nunchuck") to have one remote in each hand (used in for instance cycling games). Particularly bowling with the Wii remote has been considered suitable for elderly since it is turn based and one can play in one's own speed. But also several of the balance board games are suitable for seniors, and can be played with a chair as support and even a walking frame if the balance board fits underneath it. Touchdown's Dancetown Fitness System® was a dance mat for seniors with a frame to hold on to, but that has been discontinued.

The Kinect camera for Xbox offers a hands free gaming experience since there are no remotes or physical devices to be handled during gameplay. This could therefore be very suitable for seniors, and some of the games can also be played by elderly. However many current Kinect games are too fast or otherwise not suitable (for instance they require jumping).

Studies show that elderly seem to enjoy playing commercial Wii games (Chao, Scherer, Wu, Lucke, & Montgomery, 2013; Williams, Soiza, Jenkinson, & Stewart, 2010). Several studies also show that gameplay can be good for balance and rehabilitation (Billis et al., 2010; Chao et al., 2013; Jung, Li, Gladys, & Lee, 2009; Rendon et al., 2012; Theng, Dahlan, Akmal, & Myint, 2009; Williams et al., 2010; Wollersheim & Merkes, 2010). Another important aspect is socialising. Earlier studies show a larger psychological and physical well-being of seniors playing Nintendo Wii games compared to traditional board games due to the type of intervention with peers (Jung et al., 2009). There are however not many exergames that are designed for this age group, and particularly not commercially available. It is worth to note that the motions and interactions are all made for a healthy (and younger) audience (Anderson,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Annett, & Bischof, 2010; Chao et al., 2013), scores and progress measurements are too generic for rehabilitation use (Anderson et al., 2010), many of the games are difficult to play (Anderson et al., 2010) and many games are too fast (Theng et al., 2009; Wollersheim & Merkes, 2010).

Since Wii was on the marked before Kinect, there is much more literature about seniors and Wii play. However, since developing for Wii is hard, there are only a few games created for elderly on Wii like the Fit4All (Billis et al., 2010; E. I. Konstantinidis, Billis, Hlauschek, Panek, & Bamidis, 2010). In 2012 a study on motion sensors applied to exergames for elderly (Hors Fraile, Browne, Brox, & Evertsen, 2012) concluded that Kinect was a better option than Wii. Commercial Kinect is now being used for regular training for seniors, and studies on the use of Kinect for elderly have also started to emerge (Maggiorini, Ripamonti, & Zanon, 2012; Miyosawa, Yanagisawa, & Okuhara, 2013).

Another trend is to use accelerometers to register movements, for instance step-counters. There is however concern about the usefulness of this type of equipment for some of the elderly. Many elderly have gaits with hardly any leg movements, so step counters will not register movements correctly. Also wristbands that are growing in popularity are challenging for those using walking frames (Lauritzen, Muñoz, Luis Sevillano, & Civit, 2013).

Gamification

According to Wikipedia, Gamification is the use of game thinking and game mechanics in non-game contexts to engage users in solving problems. This is also used for physical exercise. McCAllum (McCallum, 2012) states that serious games and gamification refer to the way the experience has been designed. If it is an addition of game elements to an existing activity, it is gamification, but if it requires creating a whole new experience it is a game. Since most people walk, adding game elements to walking, for instance using a step counter can be considered gamification. There are many apps made for step counters, both dedicated step counters and phone apps, and many apps offer sharing of your effort online, for instance on Facebook. These can be considered gamification of walking, since it adds elements of competition and rewards (for instance likes of peers) to activities people already do. This also utilises peer pressure, since you share your walking – and scores – with others.

Gotsis, M. et al (Gotsis, Wang, Spruijt-Metz, Jordan-Marsh, & Valente, 2013) have tried out a web-based physical activity diary for adults, also with social gaming features, and they have positive results. When the diary adds feedback and rewards (even just stars on the screen) this can be considered gamification. (Stinson et al., 2013) designed and developed a smartphone-based pain diary app that would be engaging to adolescents with cancer through the gamification of pain assessment recordings. The gamification process involved adolescents playing the role of law-enforcement officers on a special investigative force that hunts down pain. Another example of a gamification can be found in the "Lifestyle Tool" intervention (Thorsteinsen, Vittersø, & Svendsen, 2014). A pilot test of an interactive, computer-tailored website physical activity intervention, with additional SMS text messages has gamified components: participants received points for completed activities; the test designed to increase the motivation for being physically active; and helping participants to set goals: social contract and competition. This study suggests that using gamification in physical activity interventions is a fun and engaging way to help people achieve behaviour change. The effect seems to drop off after some weeks though, but further research is needed (Thorsteinsen et al., 2014).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition gamification, applied with mHealth (mobile health) applications, is an encouraging implementation for incentivizing improved patient self-management according to (Miller, Cafazzo, & Seto, 2014). Some preliminary studies as reported by (Hamari, Koivisto, & Sarsa, 2014) indicate that gamification provides positive effects, but these effects are greatly dependent on both the context in which the gamification is being implemented and on the users using it.

Walking is an activity that elderly do, but the apps that exist are not elderly friendly. Within the GameUp project, to motivate the seniors, a gamification app was made; the users defined both individual and group goals, and there were game rewards when goals were reached. The step counter (Fitbit) also registered height differences, so one of the group goals was to climb a nearby mountain. Groups in two countries (Norway and Spain) could compare results. Both the common goals and the comparison with another group turned out to be motivational. Also an exerbiking game can be considered gamification for those who use it with stationary bikes they already have.

Gamification can be used to motivate elderly to continue to do what they do, or to do more of what they are able to do. Walking, even indoors, is one obvious activity, but also different kinds of housework can be beneficial. A roleplaying game called HabitRBG (habitrpg.com/) – gamify your life – offers users to define daily task, habits (good and bad) as well as to-do tasks. This game, or one using the same concept, can also be used for exercising.

Online Social Exergames for Seniors

Online social exergames for seniors could be defined as exergames that are played together with people that are not in the same room. Typically this requires that the participants are online at the same time, but there are also examples of turn-based games or games with other social elements (scorebords, common goals, etc) that do not have this requirement. Gamification could also be considered as another type of social online interaction. For instance gaining rewards for physical activities like going for a walk, vacuum-cleaning, etc.

Games can also be divided into collaborative and competitive games. In collaborating gameplay, two or more users must collaborate to solve a task. Multiplayer games are also often divided into Real Time Games and Turn Based Games (Schaefer, Enderes, Ritter, & Zitterbart, 2002). Typically the participants can do multiple moves/actions in Real Time Games and the game ends in a set time or when a particular goal is reached, for instance Wii tennis. In Turn Based Games, participants alternate in making moves. The advantage of turn based games is that all players do not have to be present at the same time, for instance Wii or Kinect Slalom. Wii Tennis on the other hand is an example of a turn-based game where both players have to be present simultaneusly.

Many games use mixed methods, for instance some turn based games are also supposed to be played together. Bowling is one such example, where players take turns, but they wait for each other and watch the other play.

The main purpose of motion games is the motions of the player – that is to make the players physically active. The elderly players get very involved in the exergames, but many commercial games can be a challenge for several reasons (Anderson et al., 2010; Theng et al., 2009; Wollersheim & Merkes, 2010). Some of these are speed, too much information at the time since elderly only manage to focus on what to do (correct movements to play the game and not additional information), colours and contrasts, etc. These points are especially important when dealing with elderly persons. Since the player has problems

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

focusing on things outside the gameplay (Ellen Brox et al., 2011; Gerling, Schild, & Masuch, 2010), it poses some challenges when integrating social elements. Online social exercise games for elderly therefore need very simple game interfaces.

The most common devices that are used for motion capturing or monitoring are shown in Table 1. Two of them are tracking the entire body, while the majority are using sensors to capture the movement of the parts of the body where the sensor is placed. New products coming mainly for smart TVs are able to identify the movement of the hand and it is possible to use it to perform some excersises. Each of the products have pros and cons and usually the choice is made according to the exergame or the gamified application.

Glimpses of Older Adults' Reaction to Online Social Exergames

Four senior colleagues (55+) at Norut were recruited to try a collaborative commercial Kinect game online called "1000 leaks". Only one out of the four had previously tried Kinect games. The trial was conducted in two rooms, and the chat function was on. The main aim of the trial was to see how the

Table 1. Existing products for motion tracking

Product	Body Part Tracking	Known Issues
PlayStation Eye camera	All the body	Development stop
Microsoft Kinect/ASUS/PrimeSense cameras	All the body	• Bad in daylight • Leg in camera
Nintendo Wii/Wii mote hand held remote	hand movement legs movement (depend on sensor placement)	
Wii Fit Balance Board	weight distribution	Does not track feet placement
Dance pads	feet placement	
PlayStation® Move hand hold remote	hand movement	
Open source Smartphones	Accelerometer (depend on sensor placement)	Short battery life
Android Smartphones	Accelerometer (depend on sensor placement)	Short battery life
Apple IOS Smartphones	Accelerometer (depend on sensor placement)	Short battery life
Apple iPhone 5	compass, accelerometer and gyroscope (depend on sensor placement)	• Tracks when phone is asleep, • Allows pedometer apps to run in the background, • Share results with friends nearby
Wearable sensors in health and fitness	(depend on sensor placement)	
Leap Motion's 3D gesture control	only hand and fingers	
Extreme Motion software with standard 2D camera	upper part of body	Good in near mode, good in daylight
PointGrab's software with standard 2D camera	hands	Connected with Smart TV platforms
Future Smart TV with cameras and gesture-recognition software	hands	Forthcoming technology

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

online gaming was received. Some early results showed that all found it fun, but those who had not played before found it a bit strange at first, and it was difficult to chat or listen to the other online players. It was also not so easy to understand that the other player was a real person in the next room. But all three who had not played before would like to play more. Despite the fact that the sample is really small, the results provide indicators for future research areas. This small trial empasizes the issue of the importance of integration of the social elements outside the gameplay, and encourages the users to talk, chat, or send messages/images between game sessions and also compare results.

A walking app based on Fitbit™ was developed in the GameUp project. This app both gave the users the possibility to define personal goals as well as offering groups of elderly to define group goals. This was tested in a senior centre where the elderly would have the fitbit at home for two weeks. It turned out that this was very motivational for the elderly, and some who could not go for a walk outdoors would rather walk much more inside their homes.

Effects and Barriers of Exergames for Seniors

Exergames for elderly have been the topic for multiple research projects. However, most of the projects have been isolated attempts at improving the situation, and most of them have been experiments with very few participants. The last couple of years, there have however been a couple of serious attempts at compiling the evidences of the effect of exergames in review articles.

The (Bleakley et al., 2013) review study is aiming to research the effect of computer games for elderly. The review looks at more than a thousand articles about "Interactive Computer Games" (ICG) for older adults (aged over 65) and excludes those that are related to rehabilitation after an injury. It ends up with a scoping review of twelve studies. The study concludes that there is "*preliminary evidence that ICG is a safe and effective medium to promote physical activity in an older population, and may be associated with a range of physical and cognitive benefits"*.It also concludes that, "*there was no evidence of an optimal exercise dose in terms of exercise type, duration, or intensity and, there were insufficient data to investigate potentially important subgroup effects based on age, gender, or baseline activity level"*. The authors in another study (Larsen et al., 2013) started to screen 1861 articles and ended up with 7 that fulfill their criteria which were randomized controlled trials about exergames for "healthy elderly". They concluded that all the included studies have low to medium methodological quality. Six out of the seven studies had positive results for the intervention. They are however too heterogeneous to make comparisons possible.

The typical trial size in exergame trials is between 20 and 40 participants. Several of the studies were able to prove that training is better than no training. The studied effect size is large enough to detect a difference with this sample sizes. However, very few of the studies where able to prove that exergames are better than traditional training. This might be caused by a lack of effect or that the studies are underpowered. It should also be noted that none of the studies had done pre-trial power tests. These tests are used to determine whether you have enough participants to detect a difference if such difference exists. Furthermore, there are no indications that exergames are worse than other training programs. In many of the studies there are also possible effects of exergames both in cost reductions and accessibility. Instead of studying the clinical effects, it is possible to aim the study at these aspects.

An important barrier to all these advancements could be the digital literacy and more specifically the gaming skills of seniors. It is common knowledge that the digital divide between seniors and younger adults is too wide (Olphert & Damodaran, 2013). When it comes to health-related ICT use (Wiklund

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Axelsson, Melander Wikman, Näslund, & Nyberg, 2013) health digital literacy is even lower. Nonprofit organisations (e.g. SeniorNet - http://www.seniornet.org/), municipalities, Universities of the Third Age, community information centers, ICT associations for seniors, and home teaching usually take the role of a tutor and provide basic computer-using knowledge to the seniors (Nguyen, Tapanainen, & Obi, 2014). To the best of our knowledge there are no researches showing who should teach gaming skills to seniors. But, based on the authors' experience and projects, gaming skills could be taught in senior centres, by visiting volunteers, by formal or informal carers or even by children or grandchildren. It could also be done in rehabilitation clinics if for instance exergames is being used there as part of the therapy. How it is done in each case will depend on the state of the person and how the elderly care is organised in that country or region.

Seniors with (mild) cognitive impairment are an important piece of the pie of potential users of the online exergames. The cognitive impairment of this group could act as a barrier to access the online exergames. However, even cognitively healthy elderly persons can have problems with technology. A person who cannot longer remember how to perform tasks she has done most of her life, will not be able to operate the equipment required for exergames. People with dementia go through many phases, and can master many things in the beginning, but nonetheless this target group will need help and support. However, physical and social activities are also important for people with cognitive problems. Simple games with activities, music and images from "back then" can maybe be used to activate persons in this group.

Game design targeting cognitive impaired seniors should consider the two major approaches which have been used successfully to train older adults directly in cognitive abilities:

1. Strategy training; and
2. Extended practice training.

For instance digital action games use general principles similar to those of extended practice training (Zelinski & Reyes, 2009). In addition, there is preliminary evidence that interactive computer games is a safe and effective exercise intervention for an older population, and may be associated with a range of physical and cognitive benefits (Bleakley et al., 2013; Zelinski & Reyes, 2009).

CURRENT AND PAST PROJECTS IN EXERGAMING FOR ELDERLY

The European Union is actively engaged in promoting active and healthy ageing (European Union, 2010) through law, initiatives and research funding. The Commission has proposed a Decision (1312/2013/EU, 2013) on the Strategic Innovation Agenda of the European Institute of Innovation and Technology (EIT) for 2014-2020 identifying "Innovation for healthy living and active ageing" as one of the priority themes for the EIT Knowledge and Innovation Communities (KICs) wave in 2014-2015. To this extent research grants are being continuously announced in the form of call for proposals towards active and healthy ageing. AMBIENT ASSISTED LIVING JOINT PROGRAMME (http://www.aal-europe.eu) is a funding activity that aims to create better condition of life for the older adults and to strengthen the industrial opportunities through the use of information and communication technology (ICT).

Similarly, strategies for active aging are presented and the needs for healthy and independent seniors are also defined in the rest of the developed countries (British Columbia. Ministry of Health, 2005). For example in the United States of America a report from the department of Health identifies the need

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to pursue health-promoting behaviours in older people and to meet the growing needs and demands of a rapidly aging nation (Centers for Disease Control and Prevention, 2013). In Australia development of strong public policy is the key issue to influence healthy ageing (Renehan et al., 2012). Also in the South-East Asia Region the (*Yogyakarta Declaration on Ageing and Health 2012*, 2012) sets out a number of policy commitments to be implemented in each member state. The Association of Southeast Asian Nations (ASEAN) Strategic Framework for Social Welfare and Development (2011 – 2015) (The ASEAN Secretariat, 2012) encompasses a number of initiatives to improve the lives of older people. The ASEAN has also recognised that the rapidly ageing population presents challenges to society to adapt social and economic policies.

There are numerous projects focusing on physical training and mobility of seniors, but less on the use of exergames, serious games and gamified applications in order to provide a motivational environment for senior users to keep exercising. There are several related projects since physical activity for the aging population of Europe is a theme that is receiving great attention due to its importance both for the target group and our societies. Table 2 is depicting EU co-funded projects targeting the improvement of physical activity of seniors by the use of exergames or gamified application and comparing them according to the type of game they are offering:exergames or games that have a game engine and that are controled with motion capture camera or other motion sensors; also whether the games are online and social. Whether they provide an administration portal for the carers of the elderly is also included.

Many of the projects in Table 2 are in addition using sensors such as acelometers, custom movement systems, heart rates, etc. The ELF@HOME system will comprise the wearable physical activity sensor(developed by EFL@HOME), biomedical sensors, a simple TV interface for fitness sessions and a computer vision system to analyse fitness exercises execution. All these components are connected to a service platform implementing the intelligence needed (Carús, García, García, Waterworth, & Erdt, 2014). To this extent, the PAMAP system aims to support out-of-hospital physical rehabilitation and physical activity monitoring services. The PAMAP system consists of the sensor network (accelerometers and heart rate monitor sensor) and a control unit that links the sensors and several different I/O devices. An interactive TV (i-TV) interface is used to enable patients to gain access to their health record and the details of the rehabilitation plan to be followed (Reiss, Stricker, & Lamprinos, 2012; Reiss & Stricker, 2011). Another project, FoSIBLE, was aiming to improve mental and physical well-being as one of its many goals by providing physical exercises based on different tracking and acceleration sensor technologies (Alaoui, Ting, & Lewkowicz, 2014).

Some gamified applications do not use any kind of sensors, but they create apps that encourage seniors to perform activity and provide useful information. The project DOSSy is targeting outdoor activities by developing an app for mobile devices. A hiking guide, high quality route information and basic safety system, which constantly checks the surrounding conditions (weather, daylight) for critical situations has been created ("DOSSy:Digital Outdoor and Safety System [project website]," 2012). The project MOBILE.OLD belongs to the same category. This project aims to provide a combined smartphone and TV-based service infrastructure with residential and outdoor services that will be delivered in a highly personalised and intuitive way and will advance the mobility of older persons (Karlhuber & Schürz, 2013). The MOB MOTIVATOR project aims to provide a comprehensive and engaging environment for promoting mobility and cognitive skills amongst elderly people, in both an indoor and an outdoor multiplayer gaming environment, which enables collaboration in an all-age social network ("momo: Mobility Motivator [project webpage]," 2012). Within the Is-Active project a gamebased app that make

use of an accelometer was developed. During the gamification of walking by using an app (people agree to walk at the same time, but not physically together), feedback is given about the score, pulse rate, and oxygen saturation for motivation and a safe exercising (Tabak & Marin-Perianu, R.S. Hermens, 2012).

The latest projects engage the use of games that have a game engine and are controlled with motion capture camera or motion controls. The iStoppFalls project developed an embedded system that can predict and prevent falls by monitoring mobility-related activities and other risk factors of falls in real-life. Beyond continuous fall risk monitoring, this enables tailoring individualized exercise programs coached by iStoppFalls. In addition, an Xbox/Kinect based fall preventive exergame facilitates real preventive exercise training and biomechanical modelling and optional heart rate data are used (Meurer & Wieching, 2012; Wieching et al., 2012). Within the FARSEEING project an exergame using motion capture camera was developed for seniors (Nawaz et al., 2014). The game has nature as a theme, and it is targeting to improve strength and balance and reduce the risk os falls. The Silvergame Project (according to the AALwebsite http://www.aal-europe.eu/projects/silver-game/) develops a platform for serious gaming to foster the social inclusion of elderly. It aims at making a prototype that will include three different modules on one central platform: a silver song club where people can sing together, a multimedia driving simulator for cognitive training and a dance and fitness application. In addition, Fit-TV in the Netherlands is using a Wii remote around a foot and films shown on a TV screen to let people cycle through a virtual landscape. They can use a stationary bike or a set of pedals placed in front of the chair of the user (Otten, 2012). The Long Lasting Memories (LLM) project developed a platform which comprised of three existing interoperable components that perform complementary and interactive tasks to provide the system's services: the Physical Training Component (PTC); the Cognitive Training Component (CTC) and the Independent Living Component (ILC). The PTC component is based on the Fit For All system developed by the Lab of Medical Informatics of the Aristotle University of Thessaloniki. Fit For All is a game platform that can help elderly people to exercise and maintain their physical status and well-being through exergames, using Wii Balance Board and Wii controls (P. D. Bamidis et al., 2011; P. Bamidis et al., 2011; E. I. Konstantinidis et al., 2010). Another example of an early prototype that uses Wii controls for exergames is the Join-In project. In this project the main aim was that the users should be able to join fun activities online, including exergames. A cycling app and early prototypes of 3D walking and exercising games for Kinect (E. Brox, Evertsen, Horst-Fraile, Browne, & Åsheim-Olsen, 2015) have been developed (Cantwell, Broin, Palmer, & Doyle, 2012; Johnsen, Burkow, & Vognild, 2012).

A few of the projects combine both gamified applications and exergames. For example the GameUp project developed a walking app to improve the endurance of the seniors who use a commercial step counter. Both individual and group common goals are provided to the seniors and insertion of the data into the app allow them to see their performance and whether the individual and team group goals are reached or not. Also, a physical exergame has been developed in order to improve balance, range of movement and strength. Capture of the user movements is done with a motion capture camera. To this extent, the Nettrim project has been analysing and further expanded one of the games developed in GameUp with social elements. Since Nettrim is a pre-project it aims to establish the basis for international research projects targeting elderly and physical activity (S. T. Konstantinidis, Fernández-Luque, Brox, & Kummervold, 2014).

The Rehabilitation Gaming System (RGS) developed a Virtual Reality (VR) tool for the rehabilitation of deficits that occur after brain lesions and has been successfully used for the rehabilitation of the upper extremities after stroke. The RGS uses a motion sensor camera to track body movements and Data

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

gloves to track finger movements and control games on a screen. The project does not refer directly to physical activity for all the seniors, but only for people after stroke, but it represents a good example of virtual reality tools used in physical activity (Cameirão, Badia, Oller, & Verschure, 2010). In the category of projects which are not only targeting seniors, but patients with stroke, the REWIRE project provides a set of mini-games shown on the TV screen, controlled by a motion capture camera, a balance board and a haptic device. Social aspects were implemented, providing communication through web 2.0 tools. (Massé, Paraschiv-Ionescu, Ženko, Džeroski, & Aminian, 2013; Wüest, Langenberg, & Bruin, 2013)

There are not many projects that have an online aspect of interaction between users within the game. Some of them are focusing on social interaction, but mainly through traditional communication technologies. The role of formal and informal carers is emphasized by half of the projects. The importance of monitoring and redefinition of the performed exercises is fostered through administration portals, where the carer could intervene and adjust the tension of the excersise and in some case also the type of the excersises according to the senior's personal needs.

Furthermore there are a few games that are targeting seniors. Some of them are already out on the market like the Dancetown Fitness System (http://www.popcitymedia.com/innovationnews/dancetown1212.aspx) which is a slow motion version of "Dance Dance Revolution". The game system comes with a frame to prevent the players from falling and provide the opportunity to level up into a steady paced dancing for those mastering the "oldies" level. Others are experimental platforms that are available for use, such as the KinectLabs (http://myweb.polyu.edu.hk/~kinelabs/) which offer coordinated upper limb, lower limb and trunk balance training tasks and also support multi-player mode, but they are still in prototype phase. On the other hand a few proprietary products have appeared such as FysioGaming (http://doctorkinetic.nl/en/fysiogaming/) but they are also in the first stage, without proper validation of their impact.

There are also research efforts for exergames or gamified application which include a robot or a robotic tool in order to motivate the seniors to perform their physical training (Dubowsky, Genot, Godding, Kozono, & Skwersky, 2000; Heller, Senior, & Wheat, 2014; Wada, Shibata, Saito, & Tanie, 2004). However, those exergames or gamified applications usually require more infrastructure than a motion detection sensor and they are mainly targeting rehbilitation of seniors (Novak, Nagle, & Riener, 2014; Tamura et al., 2004) rather than keeping the seniors active and healthy.

IMPACT OF EXERGAMES FOR ELDERLY

If everyone started to eat healthily, gained control over their weight, started to sleep a sufficient amount, managed their stress, stopped smoking, and limited their alcohol intake to a reasonable level, then 90% of all type-2 diabetes, 80% of all cardio-vascular diseases, and 70% of stroke cases would be prevented (Honka et al., 2011). It has also been shown that lack of physical and social activity, stress, poor diet, and poor sleep quality contribute along-side of the genes, to the onset and worsening of dementia (Hallberg, J., Casati, 2013). Many of the more common chronic diseases, such as cardio-vascular disease, type-2 diabetes, obesity, and dementia, are therefore dependant on staying active, both physically and socially. In some cases a healthy life-style change can completely relieve the symptoms of the disease, and perhaps even cure it. In other cases it is a matter of being able to live with the disease in such a way that the disease does not get worse, and so that the life-quality is maintained. Exergames for Elderly provide the necessary platform for people to meet and share a good and social time together, and to help motivate each other to stay physically active.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Physical activity is also good for the mental health (Rosenberg et al., 2010), and can help relieve stress. However it is also plain to see that physical exercise will be good for our bodies more generally (not just our brains) and as such can help to combat the many diseases that flourish because of our modern high-caloric sedentary life styles. We now have to worry about stress related diseases, cardiovascular disease, diabetes, metabolic syndrome and so on—diseases that were almost unheard of in earlier societies. Exercise does not only have a direct and even immediate positive impact on brain health, but it also gives us a release from stress and gives us a way to expend that enormous surplus of calories that many of us ingest on a daily basis.

Stress, worry and depression are other problems many elderly face. The problem of prolonged stress has become recognized within the medical community. One consequence of stress can even be physically damaged brains. Stress can literally kill neurons in extreme cases. But even if this does not happen, there is evidence of other sorts of damages. Stress can lead to compromised neurons in the hippocampus. That is they do not die, but their dendritic trees shrivel up. If the person suffers then the brain eventually also is likely to suffer.

Here we also couple our social life to stress. We are, at a very fundamental level, social beings. We not only have a need to be social, we are social primates as a fact of biology. Not surprisingly, it is becoming clear that having an active social life is a key factor for brain health and cognitive endurance. As other primates, we reduce anxiety and stress in social settings that are safe to us. Research indicates that those who maintain active social lives tend to be less likely to develop dementia. Many dangerous health conditions develop because of prolonged stress. It is when we are unable to turn of stress responses that our health suffers.

"Almost all stressed out people state social anxiety and relationship difficult as their primary causes of stress. Broadly, social anxiety comes from three major relationship categories – child-parent, marital, and career/professional" ("Stress and Relationships," 2013).

As stated in the previous section both physical and social activity can help relieve stress. These activities can therefore also contribute to a happier life. The relationship between happiness and health is also perceived by people. For example, a qualitative study reported in (Kaplan, Madden, Mijanovich, & Purcaro, 2013) showed that participants saw a strong causal relation between stress and unhealthy behaviors, including in particular eating and sleeping habits as well as smoking. On the contrary, happier individuals tend to take life-preserving measures. A study of over 300,000 individuals in the US has shown that happier people are significantly more likely to wear seatbelts, and that the effect persists even when taking into account many other variables such as gender, marital status, income, or exercise level (Goudie, Mukherjee Sr., De Neve, Oswald, & Wu, 2011).

Diener and Chan (Diener & Chan, 2011) provide a comprehensive overview of dozens of studies on the topic. What seems to emerge is the presence of a causal relation between positive affect and a reduced occurrence of certain diseases, specifically coronary diseases. The correlation appears to be weaker when negative affect is considered (that is, the search for a correlation between a higher negative affect and higher incidence of diseases is inconclusive). Furthermore, the authors observe that they are "not able to draw strong conclusion about which specific types of feelings are most related to health". Indeed, the interesting aspect in this area is that the number of (longitudinal) studies is very high, but the results are sometimes conflicting. Cohen and Pressman (Cohen & Pressman, 2006) provide a review of studies with a particular focus on elderly population. A very interesting finding in this case is that a correlation has been found between health and happiness in independently living older adults, but not for adults living in assisted living structures.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

One could argue that Exergames provide a great opportunity for people living independently at home to come together, either by attending a game session in person or by attending online from home, and exercise, and socialize, and hopefully have a good time and become happier. Besides being beneficial in its own right, happiness (and, specifically, frequent positive affect) could reduce the occurrence of certain deceases. Exergames is a facilitator, a methodology to achieve these positive effects and to help motivate elderly to perform these activities.

SOCIALISATION, MOTIVATION, AND PERSUASIVE TECHNIQUES

There are a lot of usability studies for exergames for senior users (Gerling et al., 2010; Ijsselsteijn, Nap, de Kort, & Poels, 2007; Pinelle, Wong, & Stach, 2008; Wüest et al., 2014), however the usability itself cannot be considered a sufficient motivation to use the game (Ijsselsteijn et al., 2007).

There is evidence that both physical activity, social contacts and cognitively stimulating activity may improve cognitive performance among elderly (Gallucci et al., 2009). There is also general consensus that all physical activity have considerable effect on the physical decline related to ageing, and that active ageing will have very positive effects both for the society and for the individual.

While it is hard to argue that socialisation directly leads to better physical health, socialisation is a strong motivating factor in following exercise programs. This might work by people being motivated by simply enjoying being together with other people, but they may also be motivated by others seeing them participate, or by not wanting them to see that they are not participating. The Nettrim and GameUp projects (S. T. Konstantinidis et al., 2014) try to closer examine all these sides of socialisation as a motivating factor, and by understanding them more closely, try to take advantage of this in designing motivating exergames.

Ijsselsteijn (Ijsselsteijn et al., 2007) identified four main areas for design opportunities for gaming targeting elderly including socializing with others within and outside their social network. Social interaction in games is being considered the main motivation for elderly users that also foster the intergeneration games (Khoo, Cheok, Nguyen, & Pan, 2008). A number of game projects showed that socialisation and communication (Lin, Mamykina, Lindtner, Delajoux, & Strub, 2006; Shim, Baecker, Birnholtz, & Moffatt, 2010; Toscos, Faber, Connelly, & Upoma, 2008) while playing or performing physical activity (Festinger, 1954) is more likely to achieve the desired goal. On the other hand, (Ellen Brox et al., 2011) stated that the social factor is really important regarding exergames for seniors, but seniors are sceptic, since they worried of the replacement of physical meetings with online ones. To this extent, (Gajadhar et al., 2010) show that online co-playing was deemed less rewarding than physical co-playing or when the seniors thought they were playing against a computer.

Persuasion can be summed up in the following buzzwords: behavioural change, attitude change, motivation, change in worldview and compliance (B J Fogg, 2003), and similarly, persuasion defined as the deliberate use of communication to change attitudes and behaviour of people. (Chatterjee & Price, 2009). To this extent, "Captology" an acronym based on the phrase: "Computers as Persuasive Technologies" is a term that coined by (B J Fogg, 2003), *"focuses on the design, research and analysis of interactive computing products created for the purpose of changing people's attitudes or behaviours"*. Persuasive technologies are part of people's everyday life (P. King & Tester, 1999) and they should not be left out from exergames for seniors, since in specific context persuasive technologies can play a positive role by convincing stimulating or motivating users to engage in health behaviours (Kort et al., 2005).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Designing and implementing persuasive technologies is not an easy task. According to (Bj J Fogg, 2009) many failures might occur before creating a successful product. Oinas-Kukkonen and Harjumaa proposed the Persuasive System Design (PSD) model, a framework for designing and evaluating persuasive systems, in which twenty-eight design guidelines were defined (Oinas-Kukkonen & Harjumaa, 2009). An eight-step design process in the early stages of persuasive technologies (mainly focusing on behaviour change) has been provided by (Bj J Fogg, 2009) to serve as best practices:

1. Choose a simple behaviour to target;
2. Choose a receptive audience (where possible);
3. Find what prevents the target behavior;
4. Choose a familiar technology channel;
5. Find relative examples of persuasive technology;
6. Imitate successful examples;
7. Test and iterate quickly;
8. Expand on success.

In addition persuasive strategies should be part of the design process to create persuasive technologies. Steps 3 to 6 could be analysed, identified and implemented easier through persuasive strategies, increasing the success of the final product. Persuasive strategies vary according to the users, the technology channel and the behaviour to target. A set of persuasive strategies for seniors increasing their physical activity through games identified by (Ellen Brox et al., 2011): display information to encourage people to be more active; record and display the user's past behaviour; use positive reinforcements to improve behaviours; Make an attractive and friendly user interface; provide information at opportune moments; use social influence.

Those strategies could be fulfilled by "personalizing", a strategy proposed by (P. King & Tester, 1999) as a general strategy. While all physical activities have positive health effects, there are few physical activities that are suited for all people. Activities need to be adjusted to the individual. At the same time, the motivating factors, needs to be individually adjusted. This individualized communication, is usually referred to as 'tailoring'. (Noar, Benac, & Harris, 2007)

Hawkins (Hawkins, Kreuter, Resnicow, Fishbein, & Dijkstra, 2008) divides tailoring strategies into personalization, feedback and content matching. Though the strategies are usually combined, they do constitute unique conceptual ideas. Personalization attempts to increase attention or motivation to process the conveyed messages through for instance techniques like 'identification', 'raising expectations' or 'contextualization'. Feedback presents to the individuals their own or their competitors/collaborators health status or their activities. Content matching tries to give the user relevant information on the behaviour of interest.

A MOTIVATIONAL FRAMEWORK: THE CASE OF THE GAMEUP AND NETRRIM PROJECTS

A framework was developed based on the existing aforementioned theories for motivation and persuasive technologies. Based on the input of the users performance a selection of predefined messages

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

were made and provided to the user screen at the appropriate time or game events. The Motivational Engine includes decision making techniques to select the appropriate motivational message regarding the timeframe of the game.

The exergame is an apple picking game (Figure 1) using a motion camera to capture the movements of the senior while catching the falling apples and placing them in the correct basket. The goal of the users is to catch as many apples as possible in a predefined time (different for each user). The game aims to improve the balance of the seniors.

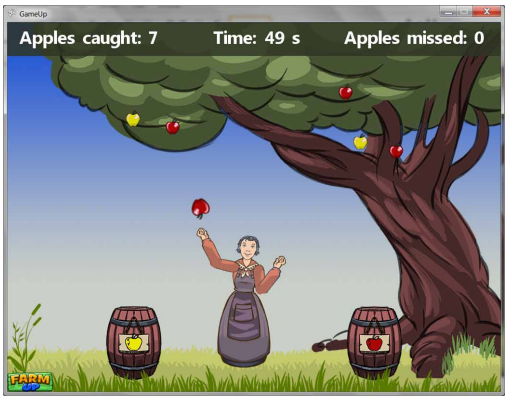
The framework gets both personal and team goals as input divided in 3 subcategories each.

For personal goals, the first category is the goal that the user is supposed to reach, the second is the current state of the user and the third is the results that are achieved by the user.

In addition the framework input also includes experts' predefined messages as input: "messages for personal progress" (during the game) and "messages for personal achievements" (at the end of the game). The messages for personal progress are positive and divided into 4 categories regarding the user performance: excellent progress; above average progress; average progress; and below average progress. As average progress either the average efforts of user record in the database or the average efforts of users with similar criteria (age, illnesses, abilities, etc.) could be defined. In the same way the positive messages for personal achievements are divided into 4 similar categories: excellent, above average, average and below average achievements. An average progress can be defined either as the average efforts of user recorded in the database to achieve the same goal or the average efforts of users recorded in the database to achieve the same goal with similar criteria (age, illnesses, abilities, etc.).

Two categories of output are provided by the framework. Firstly the "Personal Progress" category which is the feedback to the user during the game and this includes: a bar or a number that states the current progress of the game regarding the goal; a bar or a number that states the time that has passed and the remaining time; and predefined messages from experts. Secondly, the "Personal Achievements" category which is depicted after the end of the game and a combination of the following types of information could be depicted to the user: reach the goal message from experts; an image/video/animation represents how close to the goal the user is; the final score and the time spent.

Figure 1. The exergame: apple picking game



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

For Team goals the first category of input is the collaborative goal that the team is intent to reach, the second is the current state of the team goal and the third is the results of users that is achieved by the team.

The positive predefined messages from the experts as input to the framework are also divided into two categories: progress ("Messages for team progress") and achievements ("Messages for Team Achievements"), but there are also "Messages for personal progress within the team progress" and "Messages for personal achievements within the team achievements". All the messages are divided into 4 categories regarding the user and the team progress and achievements. Comparison of the team progress or achievements (average progress or average achievements) could be defined either as the average effort of teams recorded in the database or the average efforts of teams recorded in the database with similar criteria (age, illnesses, abilities, etc.) and similarly for the achievements. When it comes to "personal progress within the team goals", the messages are based on the average efforts of players compared with other members of the team or an average effort by players with similar criteria (age, illness, abilities, etc.) in the same team. The messages for "personal achievements within the team achievements" are defined respectively.

The output in this case includes the personal achievements, but also the team results. Two categories of output are provided by the framework for team goals, but personal goals could also have been used. In addition user contribution to the team is emphasized and positive messages are used. The "Team Progress" gives the feedback to the user about the progress of the team using: a bar or a number states the current progress of the team game regarding the goal; a bar or a number states the time that has passed and the remaining time; and predefined messages from experts are given. The "Team Achievements" category which is shown after the end of the game, depicts a combination of the following types of information: reached the team goal message from experts; an image/video/animation represents how close to the team goal the team is; the team's final score and the time; the user's final score and the time; and a comparison indicator for the user regarding the team.

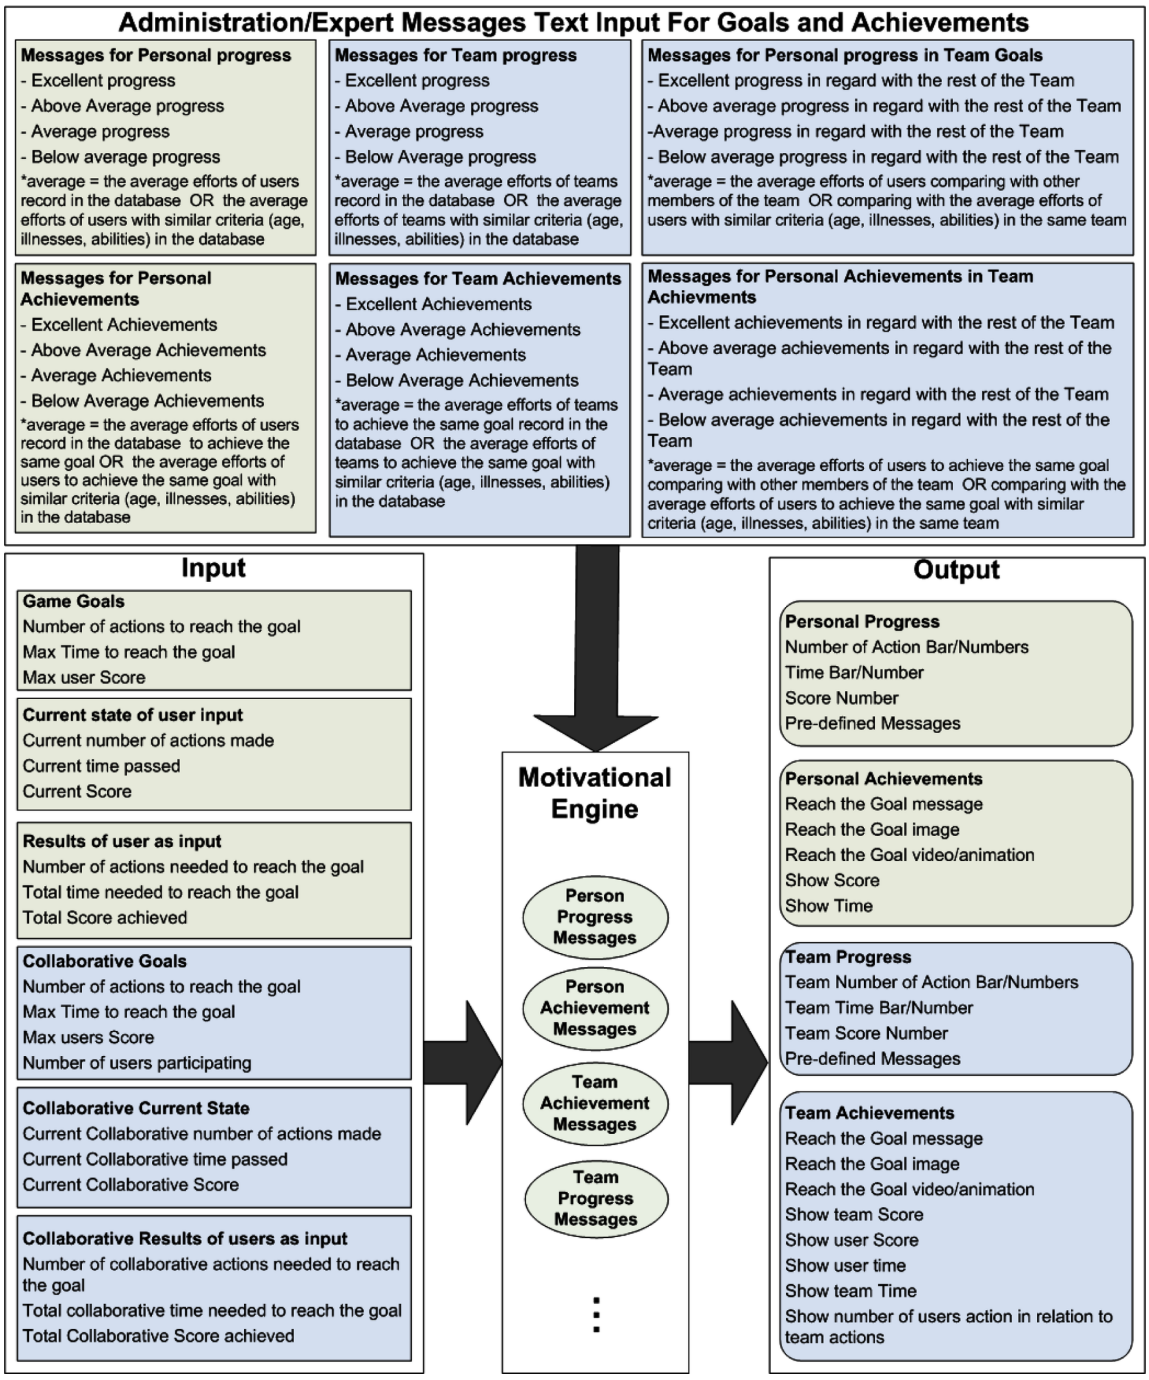
The "Motivational Engine" is responsible for suitable output by utilising appropriate algorithms on the input. Figure 2 shows an abstract of the architecture of the Motivational framework.

The motivational framework presented is following the persuasive strategies below and need an online game to be applied.

- *Display information to encourage people to be more active.* Both personal and team progress could be provided to the user in order for her to know her current state of progress. In addition, motivational messages encourage her to be more active.
- *Record and display the user's past behaviour.* The user's and the team's past behaviour is being recorded, displayed and compared with the latest one. The messages from experts are selected according to the user's past behaviour and performance.
- *Use positive reinforcements to improve behaviours.* The messages from the experts are all formed in a positive style in order to improve behaviour and performance. Even the messages for below average progress or achievement focus on next efforts of the user/team and guide them to increase the participation and performance.
- *Make an attractive and friendly user interface.* Despite the fact that the framework itself does not provide an interface, the elements (bars or numbers and messages) which it proposes can be used within an attractive and user-friendly interface without providing hazard to it.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Abstract architecture of the motivational framework



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- *Provide information at opportune moments.* The framework itself cannot determine when the output for progress will be presented, but gives the opportunity to be presented continuously, or at a chosen time. The achievements output should be presented after the end of the session or the game.
- *Use social influence.* The team goals and the team messages which can be set within this framework increase the social influence. Seniors interact with other seniors and try together to achieve a common goal. The element of comparison between seniors is minimized and is used as positive reinforcement to encourage seniors to be more active.
- *Personalization.* The goals set for each user are personalized according to her abilities. In addition, the goals set for each team are a sum of user goals according to each user's abilities. The comparison that takes place with other users/teams in order to provide a positive message is taking place either with the user's previous performance or with a user with similar criteria (age, illnesses, abilities, etc.).

Within the limitation of the aforementioned framework, the input of the experts is the most crucial. Positive messages should be tested and adjust to the seniors need in each different environment and game.

Socialisation has been proven to be an important factor of everyday life, especially for seniors. In this section existing efforts on the inclusion of this aspect into exergames have been described. Motivation on the other hand is really important so as to keep the seniors play the exergame frequently. Persuasive techniques that are used in exergaming are described and the connection with the social aspects emphasized. A motivational framework was presented as a case which implements the persuasive strategies for seniors found in literature.

FUTURE RESEARCH

To be able to provide exercise applications to a large number of elderly in a cost effective way, the logical choice is to provide them through a mobile platform, either on smart phones or on tablets. This can either be applications that use sensors in the phones/tablets, like movement or positioning, or it can be simple applications that only encourage the users to exercise and have means of communicating between users. This approach can however be challenging due to the screen size, and particularly phone screens will be too small for most gaming and gamification purposes. Also if Kinect is being used, a big screen is needed since the players have to be at a certain distance from the camera.

One aim for future trials could be to get new knowledge about what effect exergames could have for elderly, or to get knowledge about how exergames can be designed to improve any positive effects. Clinical protocols and standards should be formed and validated in order to measure the effect of exergames on seniors with clinical trials and provide the evidence that the clinical practice requires.

Most studies of exergames have a clinical effect component, even if in some cases they are just measuring whether the system is used – assuming all activity is positive. This is natural since the reason for using the games is to improve health and wellbeing. To use a standardised tool for testing effect, gives advantages in both reliability and validity. Within the field of exercises for elderly, there are several well tested tools for measuring effect.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In general these tools are considered to give more valid and reliable results, but the downside is that the tools usually require a physician to be together with the patient while performing the test. The alternative would be to use sensors and to rely on direct measures like step-counting, O2-consumption and heart rate. Changes in resting heart rate can for instance be used as a measurement of fitness.

It is also possible to design studies where the goal is not to get a better health effect than ordinary training. The study can be monitored for not having negative effects, while the real benefit might be in improved availability. Such a study can be performed by doing only an economic analysis of the alternate value.

Another approach is to assume that physical activity by definition will give health benefits, and instead of evaluating the health effect, you can monitor the use and/or compliance. In most cases this is significantly easier to measure than to measure the user's health status, though it might be harder to publish such studies in medical journals, since the clinical outcome is only measured through proxy. There are however journals within several other fields that are accepting such studies.

Instead of focusing on what effects it has on the user to use specific software, it is also possible to focus on how a specific piece of software can be improved to give better effects. At least two aspects are relevant for a study: How can the usability be improved, and how can the software be more motivating for the user.

Usability of software is a popular topic for many studies with a technological approach. There are multiple standardised tools for measuring usability, some of the most popular are:

- Software Usability Measurement Inventory (SUMI);
- Website Analysis and Measurement Inventory (WAMI);
- System Usability Scale (SUS);
- Questionnaire for User Interaction Satisfaction (QUIS);
- Usefulness, Satisfaction, and Ease of use Questionnaire (USE);
- Computer System Usability Questionnaire (CSUQ);
- Isometric Usability Inventory (IsoMetric).

What a future project should concentrate on will among other things depend on the participants. For instance testing of the physical effects of exergames requires that health care organisations are actively taking part, while testing of design and usability are more technical issues.

CONCLUSION

In this chapter the current trends of games for physical training that are used by seniors are described. Notions of exergames, gamified applications and online social games are analysed in order to provide a current state-of-the-art for a rapidly expanding research area, but also for new markets. In general exercise games for seniors are well accepted by them (Chao et al., 2013; Williams et al., 2010). However, there are a lot of design parameters that should be improved to match the usability needs of the seniors. Scores and progress measurements are too generic for rehabilitation use (Anderson et al., 2010), many of the games are difficult to play (Anderson et al., 2010) and many games are too fast (Theng et al., 2009; Wollersheim & Merkes, 2010).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The effect of games for physical activity for seniors has not yet been proven and existing research needs further expansion, but there are no indications that exergames are worse than other training programs. (Bleakley et al., 2013; Larsen et al., 2013; Webster & Celik, 2014) have registered a number of attempts to compile evidence of the effect of exergames for seniors. However these studies are not focusing on online social exergames for seniors. There is thus an urgent need of a definition of clinical evaluation frameworks in order to get the required evidence for the effects on the quality of life of seniors that arise from online exergames.

A big number of current and past projects reveal the intention of the society of further research for physical training of seniors through games. The existing projects use biomedical sensors (acelometers, custom movement systems, heart rates, etc.) and wearble sensors in order to capture the users' movements, while others just use a phone app to inform and motivate the users. The latest project advancements engage the use of games that have a game engine and are controlled with a motion capture camera or motion controls. A few of the projects combine both gamified applications and exergames. To this extent, online aspects of interaction between users and within the game are not common, but social interactions have been considered an important aspect, though so far they are mainly implemented through "traditional" communication technologies. The exergames for seniors need to be personalised and a lot of existing efforts through research project are focusing on that.

The technology is rapidly changing and the reseach for games for physical training of seniors is changing as well. New motion tracking devices are continusly appearing on the market and allow the creation of different results, covering different user needs. A sustainable game should be adaptive, and use the motion tracking device that really is needed, without overloading a senior user with uncomfortable sensors.

Exergames for seniors provide the necessary platform for people to meet and share a good and social time together, and to help them motivate themselves and each other to stay physically active. Despite the fact that exercising does not only have a direct and even immediate positive impact on brain health, it also gives us a release from stress and gives us a way to expend that enormous surplus of calories that many of us ingest on a daily basis. Furthermore exergames provide a great opportunity for people living independently at home to come together, either by attending a game session in person or by attending online from home, and have exercise, and socialize, and hopefully have a good time and become happier (Kaplan et al., 2013). The special needs of seniors should always be taken into account since online soacial games sometimes could be seen as a threat for inperson social interaction (Ellen Brox et al., 2011).

It is hard to argue that socialisation directly leads to better physical health, but socialisation is a strong motivating factor in exercise programs. In addition persuasive technologies can play a positive role by convincing stimulating or motivating users to engage in health behaviours. A persuasive strategy for seniors within games for physical training has started to be developed. The guidelines identified in the current chapter and a best practice of a generalized motivation framework is presented herein. Facilitators' input in that framework could limit the effectiveness if positive feedback is not taken into consideration. However, there is still a need for further research on motivational and persuasive strategies regarding social exergames for seniors and best practice guidelines in the form of a common standard are needed.

Exergames and mHealth applications for psysical training are on the starting line. Cost-effective solutions will likely emerge over the next years and further studies regarding clinical effects are needed. Usability should always be taken into consideration, especially the seniors' needs and abilities.

Having all that in mind, one could consider use of information and communication technologies (ICT) by seniors. Despite the fact that seniors increase their digital literacy in order to perform everyday transactions (e.g. bill payments, bank transactions, etc.), there is still a question regarding the similarity of those actions with the use of exergames and gamified applications for physical training.

The increase of "older" citizens in many countries will limit the resources for care in the future. The solution is believed to involve an active and healthy ageing. Seniors could prolong their independent living and health by personalized ICT services. The existing research reveals that the emerging area of games for keeping seniors active and healthy in the form of exergames and gamified application in combination with sensors and motion devices contributes to the solution of keeping the seniors healthy and active. Formal carers have started to experiment with the existing exergames with initial positive impact. Thus, online social exergames for seniors could acts as a pillar of gamification for clinical practice.

ACKNOWLEDGMENT

This work is partially supported by "Nettrim: Social online exercises for elderly" (http://nettrim.norut.no), a project co-funded under the Interreg IV A programme and co-funded by Troms Fylkeskommune (Troms fylkeskommune: RUP2013-0014 / Interreg IVA Nord 2013-0021) and by "GameUp: Game-based mobility training and motivation of senior citizens", a project co-funded by the AAL Joint Programme (REF. AAL-2011-4-090), the Research council of Norway, the Federal Department of Economic Affairs, Education and Research EAER - State Secretariat for Education, Research and Innovation SERI of Switzerland and the Ministering of Industry, Energy and Tourism of Spain. The authors would like to thank the participants in the studies and the partners of the projects.

Chapter 81
Exploring the Role of Service Quality and Knowledge for Mobile Health Services

ABSTRACT

The use of mobile technology-based services has made healthcare delivery more accessible and affordable in recent times. In fact, mobile health services today act as an effective means of providing healthcare knowledge to users directly from providers. However, the cynical behavior of users regarding this medium of healthcare services often encircles around the quality of such services. The aim of this paper is to examine the role of service quality and knowledge among other underlying factors that can influence future use intentions of m-Health services in the context of Bangladesh. The conceptual model of the study identifies that certain aspects of service qualities like reliability, privacy, responsiveness, empathy and information quality along with facilitating conditions, effort expectancy, performance expectancy and social influence plays an important role in capturing users' overall perceptions of mobile health services. Finally, the study highlights managerial implications, future research directions and limitations from the Bangladesh perspective.

INTRODUCTION

Information and communication technology (ICT) offers great potential for improving the quality of services provided along with the efficiency and effectiveness in health care sectors. In recent times, electronic health (e-Health) services truly serves as a tool with a huge potential for health care organizations to deliver quality and cost-effective care to geographically dispersed populations through the Internet (Jung, 2008}. However, a branch of e-Health services - mobile health (m-Health) has been constantly expanding over the last decade.

The m-Health services can be broadly defined as the use of mobile computing and communication technologies in health care and public health. This service application generally provides patient monitoring, sends text messages reminding patients to take needed medications and offers suggestions for maintaining health while pregnant, even in war-ravaged places. Current evidence suggests that the use of mobile technology can improve diagnosis and compliance with treatment guidelines, as well as patient information and can increase administrative efficiency (Rashidee, 2013}. In a broader sense, m-Health is not just improving health status rather it is the use of mobile technology to address health care challenges such as access, quality, affordability, behavioral norms, skill development in communication, supply management, information management and financial transactions through the exchange of information (Sultana, 2014}.

The m-Health services are a great initiative in health care sectors, since there are a number of patients who possess less knowledge and understanding of personal health problems but cannot afford time or money to visit doctors or medical centres on a regular basis (Nisha et al., 2015}. However, the benefits of m-Health services are often outweighed by the fact that many users are still skeptical of the quality of services that can be provided through such mediums. As such, it becomes imperative to examine the role of service quality and knowledge among other factors that can influence the acceptance, use, future prospect and necessity of m-Health services from the perspective of a developing country.

In the context of developing countries, technology may be well-perceived but when the content is sensitive like healthcare provisions, acceptance of the technology often depends upon the quality of the services and individual knowledge related to the service, among other factors. Therefore, the unified theory of acceptance and use of technology (UTAUT) model has been used for this paper. This study employed proposed constructs of system quality (system reliability, system efficiency, system privacy), information quality, interaction quality (responsiveness, assurance, empathy) and healthcare knowledge, to examine the factors that can influence users' intention to use m-Health services in Bangladesh. Moreover, this study has both theoretical and managerial implications. Theoretically, drawing upon relevant literature, this study aims to provide a model that is capable of understanding the determinants behind the future adoption of m-Health services among the people of Bangladesh. From a managerial perspective, the findings of this research should provide further insights into understanding and managing potential m-Health users, particularly hailing from the developing countries. This study can also assist various public and private hospitals and various telecommunication networks to consider the idea of providing m-Health services to the people of Bangladesh.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

LITERATURE REVIEW

This study argues that service quality and individual knowledge of health care plays a deterministic role in influencing the future use of m-Health services in the context of Bangladesh. As such, the current practice of m-Health services and its implications in Bangladesh, followed by the research platform of the study has been discussed to determine the gaps for the study.

A Budding Ground for Mobile Health Initiatives

Bangladesh is experiencing significant advances and development in health care sectors in recent years, since the government has started a new era in the health sector by introducing ICT for health service delivery. The government has developed a Health Management Information System (MIS) department under the Directorate General of Health Services (DGHS). The purpose of this department is to ensure the best use of ICT to build and maintain nationwide health information system of Bangladesh (DGHS, 2014}. This works as the backbone of the e-Health service network of Bangladesh and m-Health service is rendered using the national wide mobile phone network. The health professionals provide basic health advices and initial diagnosis when the service recipients' contacts through specialized 24/7 call centers. It has established free tele-consultation with government doctors, free SMS services for patient management and communication with staff, particularly for the needy people of the country. These cell phone numbers are circulated among the surrounding community. As such, people residing in the rural areas can contact with the health professionals through this network.

Additionally, web-camera has been installed in each sub-district, district, medical college and post-graduate institute hospitals in Bangladesh for providing telemedicine services using video conferencing platform. In recent times, there are few m-Health programmes that are operational in Bangladesh like m-Care, Aponjon and such others. These provide information and advice to pregnant mothers regarding health and nutrition related matters (Sultana, 2014}. In addition, the Mobile Alliance for Maternal Action (MAMA} Bangladesh program from D.Net with assistance from USAID and Johnson & Johnson provides voice messages to pregnant women to support the antennal, natal and post-natal information in Bengali (the native language of Bangladesh) (Reza, 2012}. Many mobile phone companies are also providing medical advice and prescriptions to millions of callers in their networks at nominal fees, alleviating some of the access and timeliness related challenges in the provision of healthcare services in Bangladesh (Rashidee, 2013}.

However, m-health service does not yet have a wide usage rate in Bangladesh. Across the entire country, m-Health services are being extensively adopted in the rural side of the country, which shows that the capital city of Dhaka is yet to adopt the use of such services. This paper, therefore, argues that factors like the service quality and necessary health care knowledge may influence the adoption and use of m-Health services among the dwellers of Dhaka city in Bangladesh.

Research Platform of the Study

Although a substantial section of the rural population uses m-Health applications today in Bangladesh, the urban people are still concerned about whether advice from an unknown hospital doctor should be considered. As such, evidence of quality of the m-Health services and use of individual knowledge of healthcare may bring about a change in the behavior of the urban people.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

One of the most important branches of information system research is to understand individual acceptance and use of information technology according to many literatures. The focus shifted towards technology acceptance and use, when the Technology Acceptance Model (TAM) was widely employed in many past studies (Davis, 1989; Davis et al., 1989}. Based on TAM synthesis of prior technology acceptance research, Venkatesh et al. (2003} developed the unified theory of acceptance and use of technology (UTAUT} model. The factors included in UTAUT (performance expectancy, effort expectancy, social influence and facilitating conditions) has been primarily used to predict the behavioral intention to use a technology and technology use in organizational contexts, moderated by individual difference variables like age, gender, experience and voluntariness (Venkatesh et al., 2012}.

In both organizational and non-organizational settings, UTAUT has repeatedly served as a baseline model to study a variety of technologies. However, given the number of technology devices, applications and services that are targeted at consumers in recent times, it became necessary to identify the factors that can influence consumer adoption and use of technologies (Stofega and Llamas, 2009}. This led to the introduction of the UTAUT2 model by Venkatesh et al. (2012}.

In UTAUT2, Venkatesh et al. (2012} adapted the four key constructs (i.e. performance expectancy, effort expectancy, social influence and facilitating conditions) that influence behavioral intention to use a technology and technology use from the original UTAUT model and customized it to fit the consumer context. Previous studies like Venkatesh et al. (2003} claim that the constructs of performance expectancy, effort expectancy and social influence determines the behavioral intention to use a technology, while behavioral intention and facilitating conditions influence the technology use in a particular context.

In addition, Venkatesh et al. (2012} further claimed that the addition of new constructs in a consumer context can contribute to the expansion of the theoretical horizons of the UTAUT model. Following the suit, this study has selected the original UTAUT and UTAUT2 model as a theoretical foundation to develop a proposed research model for the domain of healthcare from the consumers' perspective.

Proposed Constructs of Service Quality and Knowledge

Some recent studies like Sunyaev et al. (2014} and Hoque et al. (2015} argued that reliability, efficiency and privacy are the major dimensions of system quality that should be inspected in the context of sensitive mobile-based technologies like healthcare services. According to Hoque and Sorwar (2015}, users' perception of system reliability can be a major factor in capturing users' perceptions towards m-Health services in countries like Bangladesh, where mobile-based services are relatively new today. System efficiency, on the other hand, is the technical availability of the system, wherein accessibility, flexibility and response time are three major attributes. James et al. (2015} claimed that users with more positive impressions about accessibility, flexibility and response time are more willing to use m-Health services. The third dimension of system quality that has been explored in many studies is privacy. In the context of the adoption of technology-based services, privacy has always been considered as an important factor to gain reliance on the service platform as it protects personal information of the user (Ashrafi and Kuilboer, 2005; Guo et al., 2015}. Particularly, if it is customized mobile health services, these three factors of reliability, efficiency and privacy play a more significant role since health information requires confidentiality and maintenance of anonymity (Ren et al., 2010}.

Information quality is another additional construct that has been included in the proposed model of this study. This variable generally plays a critical role in building user satisfaction and customer loyalty for mobile healthcare services (Kumar et al., 2013}. According to Kahn et al. (2010}, information that is

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

provided to the patients over the mobile platform is mostly considered to be significant in such contexts. Therefore, it is very important that whatever information about healthcare services is provided should be complete, accurate and up-to-date (Fox, 2011}. Free et al. (2013} stated that more complete, accurate and up-to-date healthcare information will ultimately result into the enhancement of information quality. As such, this construct is deemed to be a crucial service quality that can influence the consumers to adapt the facilities of m-Health services.

Responsiveness, assurance and empathy are three other elements considered in this study and perceived under interaction quality of m-Health services. According to Yin et al. (2015}, interaction quality in the form of responsiveness, assurance and empathy affects user's loyalty indirectly and directly towards the use of mobile technology. Interaction quality is often vital in m-Health services, as people seek for customized attention with prompt consultancy in such matters (Nambisan, 2011}. Usually, the consumers seeking such services lack contextual emotional stability and hence timely responsiveness, accurate consultancy with emotional support and care tend to ease the conditional mindset at that context. Washington et al. (2015} claimed that relationship marketing has always played an important role in any service sector and so, empathy can lead to a strong relationship developed with the consumer base for such providers. Moreover, Xue et al. (2012} argued that by mentioning the name of the consultant providing the service in the delivered information and taking the accountability of credible consultancy, assurance can also be provided to the consumers. Even while delivering the service promptly over mobile devices, Huang et al. (2015} stated having the providers address the consumer with name and showing care with follow-up interactions, along with assurance and empathy the variable of responsiveness can be ensured as well.

Healthcare knowledge has been considered as an important factor in this study since healthcare is an area of which people are mostly sensitive. The probability of consumers seeking m-Health services is dependent on their prior knowledge on such. Gagnon et al. (2015} claimed that users lacking confidence about their relative knowledge related to healthcare are more likely to adopt this service. Townsend et al. (2015} further stated when knowledge is handy by other means, instead of seeking the service elsewhere consumers prefer using healthcare services over the mobile platform. On the other hand, Domínguez-Mayo et al. (2015} claimed that ensuring a basic healthcare knowledge among the citizen should be one of the major priorities of government for any developing economy. This is because such knowledge can facilitate the execution of m-Health services provided and ensures relatively quick relief, since consumers can relate their healthcare problems in a more proper way (Hasanain et al., 2015}.

RESEARCH MODEL AND HYPOTHESES

The purpose of this study is to examine the role of service quality and knowledge to determine the factors that can explain and predict users' intention to use m-Health services significantly in the context of Bangladesh. Along with the four key constructs (i.e. performance expectancy, effort expectancy, social influence and facilitating conditions) of the original model, four additional constructs, drawn from previous literature of m-Health services, has also been incorporated in this research model to make a significant theoretical contribution to the consumer context of the UTAUT model. The proposed research model used to address the influencing factors for healthcare technologies has been presented in Figure 1. In addition, all the variables hypothesized in this study and their likely relationships towards consumer acceptance and use of m-Health services in Bangladesh has been discussed next.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

System Quality

System quality is an overall measure of the information processing system itself. Even though system quality is sometimes perceived to be overlapped with factors that are closely related to service quality and ease of use, it has its own unique dimensions (Nelson et al., 2005}. The three most significant dimension of system quality are discussed below.

System Reliability

System reliability explains the accuracy of the technical functioning of the system and the truthfulness of service promises (Parasuraman et al., 2005}. According to Nelson et al. (2005}, it can be defined objectively as the technical availability of the system or the ability of the system to provide error free services. Thus, often consumers' perception of system reliability plays a vital role in defining consumers' adoption of m-Health services (Akter et al., 2010}. Particularly, for countries like Bangladesh where the concept of m-Health is relatively new, consumers' perception of reliability regarding m-Health is really questionable.

System Efficiency

From a consumer perspective, an efficient system is the one that is simple to use, structured properly, and requires minimum information to be input by individual (Parasuraman et al., 2005}. Therefore, how quickly consumers can reach the system when needed, how fast the system can be acclimatized to a variety of user needs and changing conditions and how quickly or timely the system responds to requests for information or action – all define system efficiency (Nelson et al., 2005}. This attribute usually has a strong influence on performance expectancy of m-Health services as they guide the perceptions of system quality and ultimately affect the usage intention of people.

System Privacy

Perceived privacy of consumer can be defined as the users' perception of protection against security threats and control of their personal health care information in an online environment (Lallmahmood, 2007}. It measures the degree to which the user believes the system is safe from intrusion and personal information is protected (Akter et al., 2010}. According to Angst and Agarwal (2009}, concern over privacy and security of personal health information is one of the reasons that held consumers from using m-Health services in developing countries like Bangladesh.

Hence, this study proposes the following hypotheses from the three characteristics of system quality:

H1A: System reliability positively influences performance expectancy of m-Health services.
H1B: System efficiency positively influences performance expectancy of m-Health services.
H1C: System privacy positively influences performance expectancy of m-Health services.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Information Quality

Lee and Chung (2009} suggest that information quality can significantly predict users' perception regarding the use of mobile based technology in sensitive areas like m-Health. Generally, the three most important indicators of information quality are completeness, accuracy and currency (Masrek et al., 2012}. Accuracy has been defined as the extent to which the information is correct, unambiguous, objective and meaningful or believable (Wand and Wang, 1996}. On the other hand, completeness refers to the extent to which all possible states relevant to the user population are available in the stored information, while currency can be defined as the degree to which the available information is up-to-date (Nelson et al., 2005}. As such, information quality can have a significantly positive effect on performance expectancy, which in turn can impact the behavioral intention of consumers towards m-Health. Thus, the study hypothesizes that:

H2: Information quality positively influences performance expectancy of m-Health services.

Interaction Quality

In this study, interaction quality has been perceived as a combination of three elements - responsiveness, assurance and empathy. Lin (2011} claims that interaction quality in the form of responsiveness, assurance and empathy affects users' loyalty indirectly and directly toward mobile internet technology. All these three factors are therefore discussed below.

Responsiveness

Responsiveness is the most important indicator of interaction quality (Lau et al., 2013}. It can be defined as the willingness to help users and to provide prompt services (Akter et al., 2010}. It can further be explained by the providers' ability to understand the users' problems and to provide precise services. Lau et al. (2013} found positive relationship between responsiveness and consumer loyalty. Based on this evidence, this study used responsiveness as a factor that will guide consumers regarding m-Health service adoption.

Assurance

Assurance measures knowledge, competency and courtesy of the provider that generate users' trust and confidence in the system (Akter et al., 2010}. It is the second most important factor of interaction quality that inspires consumer loyalty (Lau et al., 2013}. The service provider's ability to provide their promised and accurate healthcare services and their tendency of keeping commitments can only assure users regarding the adoption of mobile based technology. As past evidences from Lin (2011} and Lau et al. (2013} found positive relationship between assurance and consumers' acceptance of mobile technology, it has been perceived as an influencing factor for m-Health in this study.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Empathy

The final dimension of interaction quality is empathy that refers to the understanding ability of the users' needs and ability to provide personalized attention (Akter et al., 2010}. Consumers always appreciate a friendly and considerate environment. Hence, if the service provider shows genuine interest, enthusiasm and seriousness toward the users' healthcare needs, it will automatically lead consumers towards usage of m-Health services. In fact, Lau et al. (2013} found the highest correlation between empathy and customer satisfaction. This study thus proposes that empathy can positively influence performance expectancy, which can lead to the behavioral intention of consumers towards m-Health.

This study hypothesizes the following from the three characteristics of interaction quality:

H3A: Responsiveness positively influences performance expectancy of m-Health services.
H3B: Assurance positively influences performance expectancy of m-Health services.
H3C: Empathy positively influences performance expectancy of m-Health services.

Performance Expectancy

Burgess and Sargent (2007} and Wu et al. (2007} argue that the effect of performance expectancy is the most relevant factor for the adoption of internet-based technology. Performance expectancy generally depicts a users' view of the usefulness of adopting a technology (Venkatesh et al., 2003}. Sun et al. (2013} claim that in the context of m-Health services, the usefulness can only be captured by the extent to which it can help users to solve their health-related issues. If users believe that using m-Health services can help them to solve their problems, they are more likely to adopt this technology. Hence, the hypothesis is:

H4: Performance expectancy significantly affects individual intention to use m-Health services.

Effort Expectancy

Effort expectancy is considered to be directly related with the ease of using a particular technology (Phichitchaisopa and Naenna, 2013}. According to Venkatesh (1999}, all of these effort-oriented constructs act as more significant factors during the early stages of adopting a new technology. Several studies like Park et al. (2007}, Moores (2012} and Sun et al. (2013} claims that perceived ease of use or effort expectancy has considerable impacts on attitude towards the adoption of m-Health or any other healthcare related technology. As a result, the following hypothesis has been proposed:

H5: Effort expectancy significantly affects individual intention to use m-Health services.

Social Influence

Social influence refers to the degree to which an individual perceives that important others believe he or she should use the new system or technology (Venkatesh et al., 2003}. The idea behind social influence is that even though an individual may not be in favour of adopting a new technology, they intend to use it as he/she believes it will enhance his/her image among his/her family and peers (Venkatesh

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and Davis, 2000}. Researchers like Jung (2008} and Sun et al. (2013} empirically showed that there is a significant positive relationship between social influence and adoption of m-Health technology. Thus, the proposed hypothesis is:

H6: Social influence significantly affects individual intention to use m-Health services.

Facilitating Conditions

According to Venkatesh et al. (2003}, facilitating conditions refer to the resources and technical infrastructure that a user believes exists to support the adoption of a particular technology. In other words, facilitating conditions indicates the prospective conditions that may restrain or facilitate adopting a technology (Sun et al., 2013}. Venkatesh et al. (2012} claims that a consumer with a lower level of facilitating conditions can have a lower intention to use a particular technology. Moreover, Boontarig et al. (2012}, Phichitchaisopa and Naenna (2013} and Sun et al. (2013} showed that there is a positive significant relationship between facilitating conditions and healthcare technologies. Based on these findings, this study hypothesizes that:

H7: Facilitating conditions significantly affects individual intention to use m-Health services.

HealthCare Knowledge

Users' knowledge regarding healthcare can act as an important predictor of m-Health adoption. This is relatively a less investigated construct and was developed to measure the users' extent of knowledge and understanding of personal health problems (Wilson and Lankton, 2004}. Given all the resources and necessary infrastructure, people may tend to use internet-based health technologies to gain information regarding a health issue and increase their knowledge. This indicates that users who feel that they have relatively little knowledge about healthcare are more likely to adopt healthcare technologies. However, when Wilson and Lankton (2004} investigated this construct against the backdrop of e-Health technology they found it insignificant as a predictor of behavioral intention. To focus on this relationship further, this study hypothesizes that:

H8: Health care knowledge significantly affects individual intention to use m-Health services.

Behavioral Intention

Behavioural intention, which refers to the intention to use a system, is the major determinant of the actual behaviour. Researchers like Venkatesh and Zhang (2010} and Yu (2012} have repeatedly emphasized the strength of the construct of behavioural intention on usage behaviour. These past studies claim that individual behavior is predictable and can be influenced by individual intention that, in turn, can have a significant influence on technology usage. In the context of m-Health services, Jung (2008} and Sun et al. (2013} investigated and empirically proved that behavioural or adoption intention of the technology positively affects its usage. Following the lead, this study next hypothesizes that:

H9: Behavioral intention significantly affects individual behavior of using m-Health services.

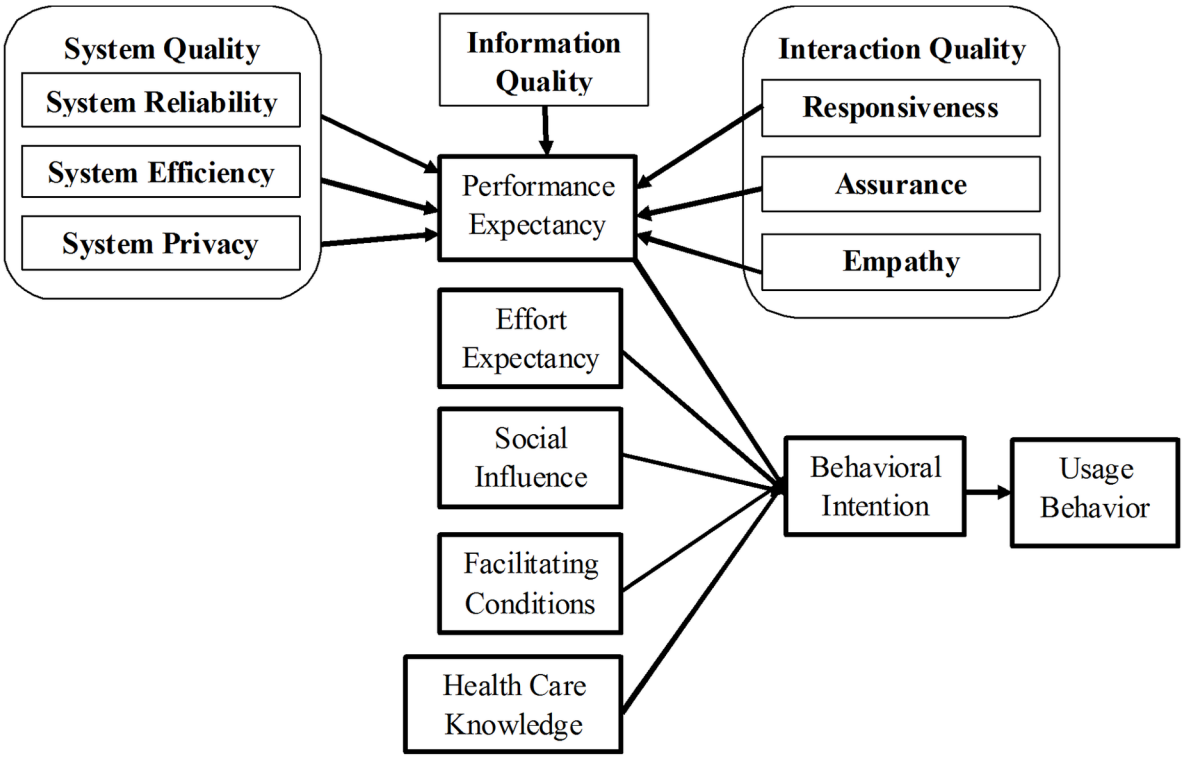
Figure 1. The proposed research structure



RESEARCH METHOD

Data Collection

The predominant existence of mobile health services in the rural areas has inadvertently raised the question as to why urban people still avoid the use of such services. In addition, the absence of city hospitals as the provider of m-Health services has made it imperative to examine the acceptance and use of m-Health services among the city dwellers of Bangladesh. As such, the population selected for this study only represented urban people who are currently exposed to the use of mobile phones and can thereby avail mobile health services in the future.

Data for this study was thus collected by conducting a survey through paper-based questionnaires on a sample of 1000 respondents in the capital city of Bangladesh – Dhaka. By using probability sampling and a stratified random sampling method, respondents were then selected for the sample. The use of this particular sampling method allowed us to avoid biasness in data and provided equal opportunity for all city dwellers who can be the potential users of mobile health services in Bangladesh.

Respondents were mostly educated and had English proficiency and so they were asked to self-administer the English version of the questionnaire. In other cases, the participants self-administered the Bengali version of the questionnaire or the research assistants themselves filled in the questionnaire based on the respondents' verbal responses.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Measurement

All the items used to measure the research variables of the survey were adapted from previous studies on information and technological advancements, e-Health services and m-Health services - with minor changes in wording to tailor them to the context of Bangladesh. This ensured the content validity of the questionnaire used to assess each constructs depicted in Figure 1.

The quantitative survey contained 42 statements in order to evaluate the original constructs of the UTAUT model and the eight new constructs proposed for the model, as listed in Table 1. The scales for the UTAUT constructs (performance expectancy, effort expectancy, social influence, facilitating conditions and behavioral intention) were adapted from Jung (2008}, Venkatesh and Zhang (2010} and Sun et al. (2013}. The scales for system quality (reliability, efficiency and privacy), information quality and interaction quality (responsiveness, assurance and empathy) were drawn from Nelson et al. (2005}, Lallmahamood (2007}, Jung (2008} and Lau et al. (2013}. On the other hand, the items used to assess health care knowledge were solely based on Wilson and Lankton (2004}. All these items were measured using a five-point Likert scale, ranging from "strongly disagree" to "strongly agree".

After a four-week survey, 927 completed and usable responses were obtained from the structured questionnaires. Table 2 represents the demographic information of respondents in terms of gender and age.

DATA ANALYSIS AND RESULTS

The research model was tested using the structural equation modeling (SEM) facilitates of SmartPLS (version 2.0). The method of partial least squares (PLS) was mainly chosen to conduct this analysis since a number of interaction terms have been included in the research model and PLS is capable of testing these effects [Chin et al., 2003}. As such, the measurement model was examined first to assess the reliability and validity of the constructs and then, the structural model was analyzed to examine the relationships hypothesized in the research model.

Measurement Model

Results from the measurement model are presented in Table 3 and Table 4 and it includes information about the reliability, validity, correlations and factor loadings. The composite reliabilities of the constructs ranged between 0.731 and 1.000, which exceeds the 0.7 cut-off value as recommended by Nunnally and Bernstein [1994}. The average variance extracted (AVE) was greater than 0.5 in all cases and greater than each square correlations, which indicates that the model has both convergent validity and discriminant validity [Fornell and Larcker, 1981}. Moreover, the internal consistency reliabilities (ICRs) of multi-item scales modeled with reflective indicators was 0.75 or greater, suggesting adequate reliability. The pattern of loadings and cross-loadings also supported internal consistency and discriminant validity, with some exceptions: one item from each construct of information quality, empathy (interaction quality), social influence, facilitating conditions, healthcare knowledge, and two items from system reliability (system quality) and system efficiency (system quality) were deleted due to their low loadings and high cross-loadings.

Table 1. Constructs and corresponding items

Constructs	Corresponding Items	Items Sources
System Reliability	[SR1} I believe m-Health services operate reliably [SR2} I believe m-Health services perform reliably [SR3} I believe the operation of m-Health services is dependable	Nelson et al. [2005}
System Efficiency	[SE1} I feel m-Health services make health information easy to access [SE2} I feel m-Health services provide health information in a timely fashion [SE3} I feel m-Health takes too long to respond to my healthcare problems	Nelson et al. [2005}
System Privacy	[SP1} I trust the ability of m-Health services to protect my privacy [SP2} I feel safe when I release health information to m-Health services [SP3} I feel matters on security has no influence in using m-Health services	Lallmahamood [2007}
Information Quality	[IQ1} I believe m-Health services provide complete information [IQ2} I believe m-Health services provide up-to-date information [IQ3} I believe m-Health services provide relevant information	Jung [2008}
Responsiveness	[R1} I think m-Health provides precise healthcare services [R2} I think m-Health has the ability to understand my healthcare needs [R3} I think m-Health services are helpful	Lau et al. [2013}
Assurance	[As1} I think m-Health provides healthcare services as promised [As2} I think m-Health provides accurate healthcare services [As3} I think m-Health services will keep their commitments	Lau et al. [2013}
Empathy	[E1} I think m-Health has the knowledge to solve my healthcare problems [E2} I think m-Health has the enthusiasm to understand my healthcare needs [E3} I think m-Health services will put my healthcare needs in the first place	Lau et al. [2013}
Performance Expectancy	[PE1} Using m-Health services will improve my life quality [PE2} Using m-Health services will make my life more convenient [PE3} Using m-Health services will make me more effective in my life [PE4} Overall, I find m-Health services to be useful in my life	Sun et al. [2013}
Effort Expectancy	[EE1} Learning to use m-Health services is easy for me [EE2} Becoming skillful at using m-Health services is easy for me [EE3} Interaction with m-Health services is easy for me [EE4} Overall, I think m-Health services are easy to use	Sun et al. [2013}
Social Influence	[SI1} People who are important to me think that I should use m-Health services [SI2} People who are familiar with me think that I should use m-Health services [SI3} People who influence me think that I should use m-Health services [SI4} Most people surrounding me use m-Health services	Jung [2008}, Sun et al. [2013}
Facilitating Conditions	[FC1} Using m-Health services suits my living environment [FC2} Using m-Health services fits into my working style [FC3} Using m-Health services is compatible with my life [FC4} Help is available if I have problems in using m-Health services	Venkatesh & Zhang [2010}
Health Care Knowledge	[HCK1} I am very knowledgeable regarding care for my health problems [HCK2} I understand my health problems and how to care for them	Wilson & Lankton [2004}
Behavioral Intention	[BI1} I prefer to use m-Health services [BI2} I intend to use m-Health services [BI3} I plan to use m-Health services	Sun et al. [2013}

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Demographic profile of respondents

Demographics	Frequency	Percentage (%)
Gender		
Male	546	58.9
Female	381	41.1
Age		
20 or below	158	17.0
21 – 30	476	51.3
31 – 40	145	15.6
41 – 50	94	10.1
Above 50	54	5.8

Structural Model

The path coefficients and significance levels in the structural model are presented in Figure 2. Among the three constructs of system quality, system reliability (0.240, $p<0.05$) and system privacy (0.120, $p<0.05$) showed significant and positive path towards performance expectancy, while system efficiency (0.084, $p>0.05$) reported an insignificant path. The factor of information quality (0.100, $p<0.05$) also displayed a significant and positive path towards performance expectancy. On the other hand, responsiveness (0.135, $p<0.05$) and empathy (0.072, $p<0.05$) under interaction quality had a significant and positive path towards performance expectancy, but assurance (0.070, $p>0.05$) showed an insignificant path.

Among other factors, facilitating conditions (0.235, $p<0.05$), effort expectancy (0.169, $p<0.05$), performance expectancy (0.155, $p<0.05$) and social influence (0.134, $p<0.05$) showed significant and positive paths to the behavioral intention of using mobile health services, in their order of influencing strength. However, the construct of healthcare knowledge (-0.024, $p>0.05$) reported an insignificant path towards the individual behavior of using mobile health services. Therefore, all hypotheses (except H1B, H3B and H8) dealing with behavioral intention to use mobile health services are supported. Subsequently, the hypothesized relationship between behavioral intention and usage (0.251, $p<0.05$) is found to be statistically significant, thereby supporting hypothesis H9.

FINDINGS AND IMPLICATIONS

This study has revealed quite a few understandings on the back stage possibilities of the potential usage of mobile health services among the urban population of Bangladesh. Some of the constructs representing service quality positively influences the performance expectancy while factors like facilitating conditions, effort expectancy, performance expectancy and social influence directly stimulates the usage of m-Health services. However, healthcare knowledge has been identified as an insignificant factor of behavioral intention in the context of Bangladesh. The inclined reasons behind such findings are quite obvious and most of such are shaped by the local culture and infrastructure of the country.

Facilitating conditions is found as the strongest direct determinant in influencing respondents' behavioral intention of m-Health services. This finding is consistent to Boontarig et al. [2012}, Phichitchaisopa and Naenna [2013}, Sun et al. [2013} and Nisha et al. [2015}. The penetration of mobile phones is a comparatively new concept in Bangladesh and particularly, when such devices are being used as a platform of commuting other errands such as receiving instant health care advices, ensuring facilitating conditions has a strong role to play. In perspective of Bangladesh, facilitating conditions generally tend to be wide availability of computers, strong mobile networks and fast internet services. Therefore, the first business implication is that, beyond offering ease-of-use and useful m-Health services, providers might emphasize on the compatibility between the offered services and the working/living styles of their target customers. That is, putting efforts in designing suitable services and infrastructures to meet specific needs of different customer segments. Both government and private sector hospitals and clinics have already started showing a lot of interests and concerns in this regard. As a matter of fact, entities like Medinova Telemedicine, eClinic24 (Chakaria Project), AMCARE and health services for expatriates in Singapore by TRCL, Breast Cancer Finding via mobile by Amader Gram, JBFH Telemedicine, all leading telecom companies of Bangladesh and many others have already set their foot targeting the rural segments and working on developing the infrastructure challenges. However, city hospitals need to work more towards the development of such conditions for the city dwellers. Strong and correct comprehension on available facilitating conditions is important to ensure to build the right perception in the mind of the target market by showing repeatedly that all they need is a mobile phone of any type and a mobile connection mainly to take the benefits of mobile health care services.

The study drills that most of the current and potential users of m-Health services tend to judge the importance of the service based on the required effort expectancy for it. Respondents who expect less effort input in the service consuming process, especially at the adoption stage like that of m-Health services in Bangladesh, are more likely to show positive attitude in embracing the service. This finding is consistent with the evidence provided by Moores [2012}, Sun et al. [2013} and Nisha et al. [2015}. By making sure that the target market perceives the efforts needed to avail these services as an ease, companies can net a positive attitude towards these services. Communications of the providers, particularly of the city hospitals, should focus more on the actual handiness of such services. To do this, the software platform of the m-Health service applications should be made more compatible and user-friendly for the ease of use of the urban population of Bangladesh.

Performance expectancy is the next most important construct according to the research findings of this study. Sustainable qualities of m-Health service such as saving time, receiving immediate and accurate healthcare advices, etc. play an important role in shaping behavior in terms of adopting such new technologies. Jimison and Sher [2008}, Holden and Karsh [2010} and Sun et al. [2013} have also found such similar results in their studies. The underlying cause behind such result is the novelty of such technology in the culture of Bangladesh, where most of the errands are preferred to be served in a traditional manner from physical locations. Take away for marketers from this finding is to ensure a lot of confidence among the users by highlighting the value propositions of such service with their importance in their daily life through the marketing mix of the companies. Clinching benefits such as the quality of system and of information, high responsiveness with empathy, ease of using m-Health services and the relative conveniences (outcomes) that are attached with such usages should be used as the major selling ideas of their communication campaigns to build a strong positive comprehension in the response process of the target market. The providers must also ensure a lot of empathy and a high level of responsiveness while providing the accurate information through the call center personnel to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the users. They must keep in mind that one negative case in terms of accurate and quick response with empathy may lead to decreasing brand equity and hence, hospitals and clinics should train the front liners accordingly. Developing a sustainable system which ensures privacy and efficiency to support the clinching benefits of m-Health services is additionally important to encourage the consumption of such services among the city dwellers of Bangladesh.

Since the culture of Bangladesh is mainly based on collectivism, this is the root cause behind the impact of the factor of social influence on behavioral intention towards m-Health services. Being consistent with the findings of Jung [2008} and Sun et al. [2013}, which argued that subjective norm was the most influential factor for technologically related services, this study identified social influence as a powerful factor that can affect the intention to use m-Health services in Bangladesh. Further analysis revealed that respondents are significantly influenced by peer groups and interpersonal world-of-mouth, which is also consistent to the findings of Venkatesh and Davis [2000}. Taking the above together, the business implication for the m-Health service providers is to create a buzz to get the benefit of social capita. Semiotics such as catchy jingle and slogans with positive testimonials might also help the providers to bag a positive viral response from the market. Creative publicity and sales promotional activities using a lot of support media, particularly targeting the city dwellers may lead to a viral word of mouth. Social media such as Facebook and You Tube may also be exploited to get the viral going in urban markets.

Alternatively, the construct of healthcare knowledge has been noted to have an insignificant role to play in terms of shaping behavioral intention for m-Health services in Bangladesh. As per the Human Development Report by UNDP (United Nations Development Programme), the HDI (Human Development Index) of Bangladesh is 0.558 with a positive growth. This indicates that the healthcare knowledge of general citizens is below the line and most of the people, particularly in rural areas, are unaware of basic healthcare processes which make Bangladesh a potential for m-Health service providers. Take away for marketers will be to capitalize this dependency and to develop better ways to provide m-Health services in order to support the growth of the HDI index of Bangladesh. Also, the busy lifestyle of the city dwellers in Bangladesh often adds to this dependency of people on online or mobile health care services, which is why city hospitals should think about introducing such services in the urban areas as well.

Once city hospitals manage to introduce such services for the urban population, they can even think of establishing criterions like experience and original certifications of doctors before including them in the panel of the medical team that involves in the provision of m-Health services. This will be instrumental in reducing the concerns of the urban population regarding whether to take advice from unknown hospital doctors. Furthermore, it can accelerate the acceptance and use of m-Health services in Bangladesh if the urban population can trust the quality of the doctors and therefore, the quality of m-Health services in turn.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

This study has several limitations like other empirical past studies. First, the conclusions drawn from this study are based solely on the urban population, specifically people residing in Dhaka city of Bangladesh. Future research can explore the behavioral intention of people of other major cities or even the rural areas of the country. Second, a longitudinal study can be adopted in future works to examine and compare the research model in different time periods, thereby providing a better insight into the adoption of m-Health services in Bangladesh. Moreover, the model has been generalized and is only

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tested in a very specific condition of healthcare mobile services in a single country. The application of a similar conceptual model to study the context of other developing countries in South Asia like India and Pakistan can add further value. Also, panel data can be gathered regarding m-Health services from different developing countries and compared to do a more constructive analysis. Finally, other than the factors used in this study, there can be various other variables that can influence the acceptance and use of m-Health services. Further research considering different constructs can enhance the understanding of precise determinants for m-Health services in Bangladesh.

Chapter 82
Effect of Power and Phase Synchronization in Multi-Trial Speech Imagery

ABSTRACT

Speech imagery is one form of mental imagery which refers to the imagining of speaking a word to oneself silently in the mind without any articulation movement. In this work, electroencephalography (EEG) signals were acquired while speaking and during the imagining of speaking consonant-vowel-consonant (CVC) words in multiple trials of different time frames. Relative powers were computed for each EEG frequency band. It has been observed that relative power of alpha and theta bands was dominant. Phase Locking Value (PLV), a functional brain connectivity parameter has been estimated to understand the phase synchronicity between two brain regions. PLV results show that the left hemispheric frontal and temporal electrodes has maximum phase lock in alpha and theta band during speech and speech imagery process. The combination of brain connectivity estimators and signal processing techniques will thus be a reliable framework for understanding the nature of speech imagery signals captured through EEG.

INTRODUCTION

Mental Imagery is a quasi-perceptual experience which is induced in an absence of external stimuli (Perrone-Bertolotti et al., 2014). Mental Imagery occurs in any of the sense forms- Visual imagery (mind's eye), Auditory imagery (mind's ear), Motor imagery (mind's muscle movement), Tactile imagery (mind's touch). Speech imagery is one form of mental imagery which refers to imagining of speaking a word or sentence to oneself silently in the mind without any articulation movement (Tian & Poeppel, 2012). Speech imagery is also referred to as articulation imagery. The auditory and kinesthetic response induced in speech imagery involves both motor and perceptual systems (Kosslyn, 1994). The speech perception and production of speech must depend upon each other to ensure a proper communication as well as the content of messages being conveyed (Liberman & Mattingly, 1985). Children with Autism disorder have an excellent mind voice like other healthy controls. But Autism children find it difficult to express their thought due to their speech impairment. The concept of speech imagery can be helpful in decoding the thought for such children. Speech imagery can also contribute for speech preparation that has to convey from the decoded thought.

Speech processing theories have predicted that multiple brain regions participate in speech and language comprehension, which includes frontal and temporal lobes of left hemisphere. Broca's area found in the left inferior frontal gyrus and Wernicke's area located in the left posterior superior temporal gyrus are cortical areas specialized for production and comprehension, of human language respectively (Poeppel & Hickok, 2007; Price, 2011). Neuroscientists have followed conventional brain imaging techniques such as fMRI (Dogil et al., 2002) and electrophysiological measures such as EEG (Callan et al., 2000) to study the neuronal activation in these brain regions during speech production from healthy and speech impaired participants.

Electroencephalography (EEG), a non-invasive electrophysiological technique, is used in analyzing the neuronal excitations in different regions of the brain and to understand their functional cooperation while performing a task (Teplan, 2002). EEG signals contain useful information and this information can be analyzed in time domain, frequency domain and time-frequency domain. Transforms like Discrete Fourier Transform (DFT) and Fast Fourier Transform (FFT) can be used for converting a time domain signal into frequency domain in order to analyze the signal information in each frequency band over a wide range of frequencies related to the task. EEG signals have five sub-band frequencies such as Delta band (05.-3Hz), Theta band (4- 8Hz), Alpha band (8-12Hz), Beta band (13-30Hz) and Gamma band. (> 30 Hz) (NeuroSky, 2009). Valipour et al. has used FFT technique for the spectral analysis of alpha band during open and closed eyes (Valipour et al., 2013). Power Spectrum Densities (PSD) describes the power distribution of the signal as a function of frequency of a periodic signal. Saa et al. has analyzed the power spectral density during motor imagery for classifying the imaginary motor movements (Delgado, Saa & Gutierrez, 2010). (Rojas et al., 2016) has analyzed the EEG signal during imagined speech of Spanish vowels using digital signal processing techniques such as Filters, FFT and statistical analysis based on ANOVA test and has reported that by using signal processing it is possible to recognize the Spanish vowels from imagined speech. In general EEG signals are nonlinear and non-stationary. EEG data contains artifacts due to the surrounding noise. The amplitude of artifacts is quite large compared to the task related EEG signal. Artifacts due to eye blinks (electrooculography-EOG) and muscle movements (electromyography-EMG) has to be removed in order to analyze the signal for interpreting correct results. Independent Component Analysis (ICA) techniques have been used to remove the above-mentioned artifacts. There are many source separation algorithms designed for ICA. These techniques attempt to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

unmix the EEG signals into some number of underlying components that would result in clean EEG by nullifying the weight of unwanted components (Nolan et al., 2010; Jung et al., 2000).

Research in the domain of extracting significant information about brain connectivity from EEG recordings has been found to be active and still new findings are continuously reported. Cognitive researchers working in the field of neuroscience are actively involved in the estimation of brain connectivity of electrophysiological signals. In the study of brain connectivity, the central issue of determining directionality of the interactions among neural signals is of great interest because it allows revealing pathways of information flow within the nervous system. The brain connectivity can be defined in terms of anatomical connectivity (physical connections linking brain regions), functional connectivity (statistical dependence in spatially remote brain activity) and effective connectivity (the causal influence of one brain region on another i.e., directional relationships) (Friston, 2011; Greenblatt, 2012). The prevalence of brain connectivity estimators is useful in quantifying the frequency synchronization between the different regions of the brain. Various studies have been proposed in order to estimate functional synchronization and connectivity from EEG signals (Sakkalis, 2011). In recent research brain connectivity has been analyzed while imagining of speaking for similar and dissimilar sounds (Sandhya & Kavitha, 2015; Sandhya et al., 2015). Phase synchronization measures such as Phase Locking Value (PLV) is a functional connectivity parameter through which the phase coupling between two time series signals can be estimated using PLV (Lachaux et al., 1999). The whole brain functional connectivity has been investigated using Phase Locking Value for resting state signals (Schmidt et al., 2014).

In this work, EEG signals were acquired from healthy subjects while speaking and imagining of speaking Consonant-Vowel-Consonant (CVC) words using multiple trials in different time frames. Artifacts from the EEG signal were removed using ICA. Absolute powers were computed using FFT in each frequency band during the tasks for all the trials. Relative spectral power has been derived from absolute power values for each frequency band. This relative power analysis will be useful in contributing an effective EEG data analysis during speech imagery process. The EEG bands that will be dominant during speech and speech imagery can be recognized using this power spectral analysis which can be further extended to analyze the neuronal correlations during speech imagery tasks. The phase synchronization between two time series signals were estimated using PLV for multiple trials using CVC words. PLV will not only provide information about the dominating lobes of the brain during the speech imagery task but also about the connectivity among them.

METHODOLOGY

EEG signals were recorded in a sound proof room as per the guidelines of Institutional Ethics Committee of Department of Biomedical Engineering, SSN College of engineering, India. Two right-handed subjects participated in this work. All subjects were men and native Indians, between the mean age group of 19 and 22 (20.5 ± 2.12).

EEG Acquisition

EEG signals were acquired using EMOTIV EPOC, a 14 electrode wireless EEG acquisition device. Figure 1 shows EEG recording setup for a representative participant using EMOTIV EPOC. EEG signals were transferred to the system via Bluetooth. Signals from fronto-polar (AF3 and AF4), frontal (F3, F7,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. EEG recording set up

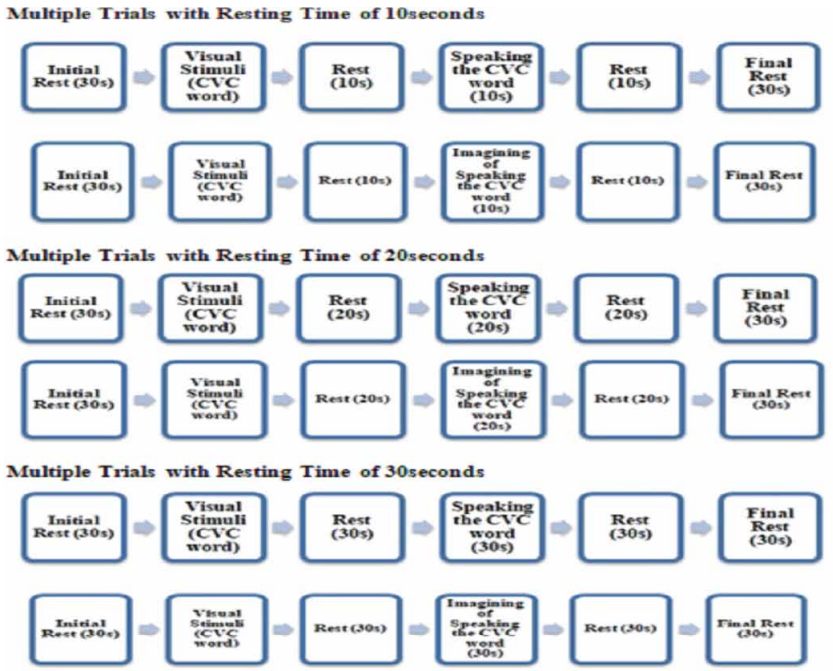
F4, F8), fronto-central (FC5 and FC6), temporal (T7, T8, P7, P8) and occipital (O1 and O2) lobes were acquired with a sampling rate of 128 Hz. These electrode locations are named according to standard 10-20 electrode placement system. The reference electrodes were chosen to be P3 and P4. EEG signals from EMOTIV EPOC were acquired within the in-built range of 0.001 to 43 Hz. Though the signals were acquired from all 14 electrodes, the region of interest related to speech and speech imagery are frontal and temporal lobes. So, the electrodes (F7, FC5, T7, P7) with respect to Broca's and Wernicke's regions located in left frontal and left temporal regions were analyzed exclusively, as these regions are responsible for speech production and speech comprehension.

Experimental Protocol

For each vowel in the vowel set 'a', 'e', 'i', 'o', 'u' one CVC word has been chosen. The chosen words are *'Can', 'Let', 'Did', 'Jog', 'Sun'*. These words were shown as visual stimuli to the subjects. The subjects were asked to speak the word and imagine of speaking the word silently in the mind without any articulation movement. An initial rest period of thirty seconds was provided to the subject on beginning of each trial and similarly a final rest period of 30seconds was given at the end of each trial. Different time frames were used while switching between speech and speech imagery process. The resting time for each protocol has been increased before and after the task with a time period of 10seconds, 20seconds and 30seconds respectively. Similarly, the task time with respect to speaking and imagining of speaking were also increased gradually with the time periods as mentioned above. Three sessions were carried out for each word. In the first session, subject was made to feel comfortable, and training had been given to understand the protocol. For the second session, subject was asked to speak the CVC word for five times. In the third session the subject was asked to imagine of speaking the CVC word for five times. This protocol of three different time frames was employed to test the difference in brain connectivity's as the brain was allowed to settle and switch over between speaking and imagining of speaking processes under varying time intervals. Five trials for each CVC word for every resting time of 10s, 20s and 30s.15 trials for one CVC word. For speech process the total number of trials is 75 (15*5 CVC word = 75) and similarly for speech imagery process the total of number of trials is 75 (15*5 CVC word = 75). The size of the EEG data for each CVC word in single trial with respect to 10s is (2 subjects* 14 channels * 900 samples), 20s (2subjects * 14 channels* 1800 samples) and 30s (2subjects* 14 channels * 3000 samples). Figure 2 shows the experimental protocol for speech and speech imagery process involving different time periods.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Experimental protocols for speech and speech imagery process involving different time periods



EEG Preprocessing

The acquired EEG signals were filtered between the frequency ranges of 0.5 Hz to 40 Hz using an IIR Band-Pass Chebychev filter for both speech and speech imagery signals (Subramanian et al., 2017). In order to remove the artifacts due to eye blinks and muscle movements the signals were further decomposed using Independent Component Analysis (ICA). ICA method is used for separating a multivariate signal into additive subcomponents. Each component is statistically independent from each other and non-Gaussian. A fast and stable non-linear ICA decomposition algorithm was implemented for automatic rejection of components related to artifacts (Delorme & Makeig 2004). After ICA decomposition, these signals were further filtered using smoothing filter. In this work moving average technique has been implemented for obtaining the smoothed signal. This method creates a series of averages of different subsets of the full data set and can be classified as a type of finite impulse response. Ultimately, the moving average function can be viewed as a low-pass filter (Azami et al., 2012). Using IIR band-pass chebyshev filter, the signals were segmented into EEG sub-band frequencies. The prominent EEG frequencies were found to be Delta (1-3 Hz), Theta (4-8Hz), Alpha (8 to 13 Hz), Beta (13 to 30 Hz) and Gamma (30 to 40 Hz). Power spectral density and relative powers were analyzed in each frequency band for EEG signals in multiple trials.

Power Spectral Density (PSD) and Relative Power

The frequency domain analysis was carried out using Fast Fourier Transform (FFT) in order to calculate the absolute power (μV^2 /Hz) and relative power (%). For a signal *x(t),* Fourier transform of the signal *x(t)* is given by *X(f).* The power spectral density is expressed as the square of the absolute values of FFT

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the signal (i.e) power present in the signal as a function of frequency (i.e.) $|X(f)|^2=S_X(f)$. The absolute power of a band is the integral of all power values within the frequency range (Wang et al., 2016) (i.e.) The absolute spectral power is defined as the band of frequencies from f_0 Hz to f_1 Hz to the total power delivered at the output of a band-pass filter that passes all frequencies from f_0 Hz to f_1 Hz and stops other frequencies.

Absolute Spectral Power is given by:

$$\int_{-f_1}^{-f_0} S_X\left(f\right)df + \int_{f_0}^{f_1} S_X\left(f\right)df \tag{1}$$

Relative power measures the ratio of the total power in the band to the total power in the signal (i.e.) ratio of absolute power in each frequency band to the absolute power summed over the five frequency bands (Delta, Theta, Alpha, Beta, Gamma) (Yuvaraj et al., 2014).

Relative Spectral Power is given by:

$$\frac{\int_{-f_1}^{-f_0} S_X\left(f\right)df + \int_{f_0}^{f_1} S_X\left(f\right)df}{\int_{-\infty}^{\infty} S_X\left(f\right)df} \tag{2}$$

In this work relative power were analyzed in each frequency band for the multi trial speech and speech imagery EEG signals. Relative spectral powers were analyzed exclusively for the signals originated from the electrodes F7, FC5, T7 and P7. These electrodes were located near Broca's and Wernicke's area respectively.

Phase Locking Value (PLV)

Lachaux et al. (1999) demonstrated a practical method for the quantification of transient phase locking between two neuro electric signals. Phase Locking Value (PLV) is a phase synchronization measure used for bi-variate process. For each EEG electrode the phase time course is given by ϕ. The difference between two phase time course ($\Delta\phi$) quantifies the locking between the phases of given two electrodes. If the EEG signals of two electrodes rises and falls together during the given cognitive task then there is more synchronization (i.e) enhanced connectivity is observed between the given two electrodes and $\Delta\phi$ will be constant between trials. If de-synchronization or decreased connectivity is observed between two electrodes then $\Delta\phi$ will be random. PLV ranges between 0 and 1. PLV of 0 represents that two electrodes are not coupled whereas if PLV is 1 it indicates that one signal follows the other synchronously and the two electrodes have a strong connectivity. Phase Locking Value (PLV) for a single trial is given by:

$$PLV\left(t,f\right) = \frac{1}{N}\left|\sum_{n=1}^{N}\exp\left(j\left\{\Delta\Phi_n\left(t,f\right)\right\}\right)\right| \tag{3}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

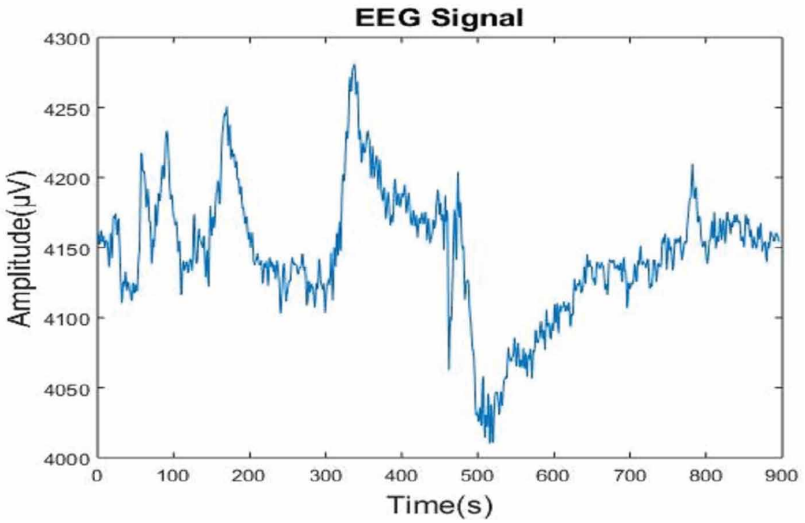
where N is the number of samples, $\Delta\Phi_n(t,f) = \Phi_1(t,f) - \Phi_2(t,f)$ is the instantaneous phase difference. In case of multiple trials N is the number of trials and PLV was computed over multiple trials at every instance of time. In this work, PLV has been computed between various electrodes for each EEG frequency sub-bands while speaking and imagining of speaking the given CVC words. Importance was given to inter-hemisphere and intra-hemisphere frontal and temporal lobe electrodes due to their close proximity to the Broca's area and Wernicke's area.

RESULTS AND DISCUSSION

Relative Power Analysis While Speaking the CVC Word

Frontal and fronto-central electrodes (F3, F7, FC5, F4, F8, FC6) with respect to left and right hemisphere of the brain were analyzed individually during speaking of the CVC word *'can'*. F7 and FC5 electrodes are located near Broca's area of left frontal lobe which is responsible for speech production. The signal analysis for F7 electrode has been discussed in detail for understanding the nature of the signal while speaking the representative CVC word. Similarly, other frontal electrodes were also analyzed with the same procedure. Figure 3 shows the F7 electrode EEG signal while speaking the CVC word *'can'* with a resting time of 10 seconds. It can be observed from Figure 3 that amplitude ranges are very high. The signals recorded using Emotiv Epoc device was transmitted via Bluetooth and hence the amplitude ranges are very high. DC level of the signal occurs at approximately 4200 μV, negative voltages are transmitted as positive values less than the average level, and positive voltages are transmitted as positive values greater than the average. Before performing any kind of analysis such as FFT, it is necessary to apply some kind of DC offset removal.. The simplest method is to normalize the signal by subtracting the average from the entire data channel. The normalized signal is further filtered using bandpass chebyshev filter in a frequency range of 0.5 Hz to 40 Hz.

Figure 3. EEG signal-F7 electrode



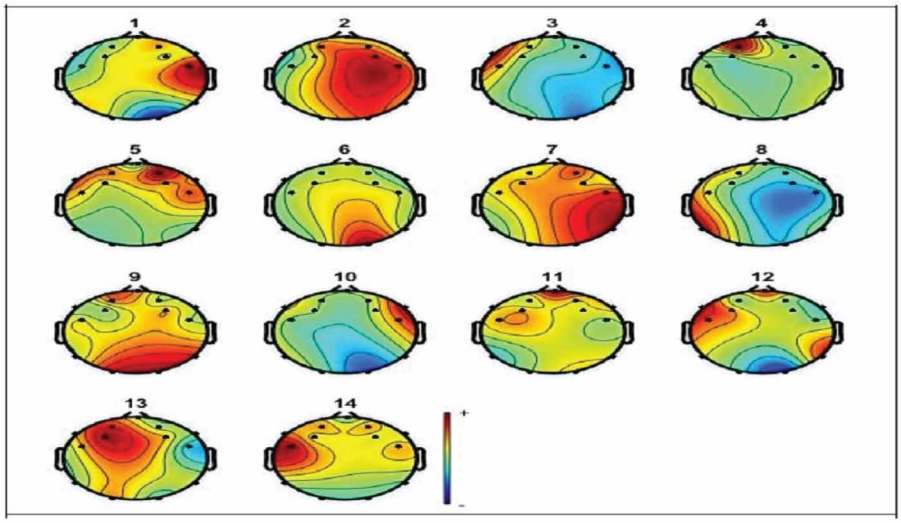
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

EEG signals are often affected by artifacts due to the surrounding sources such as background noise. Removal of artifacts is a major step in preprocessing stage. In order to remove these artifacts, the filtered EEG signals were decomposed using ICA. The output of ICA decomposition is a data activation matrix. The channel data are arranged in a matrix of *n* channels (rows) by *t* time points (columns). Each row in the matrix represents the time course activity of one component that is spatially filtered from the channel data. The scale of each component activity time course uses arbitrary units of the original data. Components with eye and muscle artifacts were rejected based on the power spectrum. Components with smoothly decreasing EEG spectrum were considered to be a typical artifact. ICA obtained from EEG signal while speaking the CVC word *'can'* is shown in Figure 4. Red colour indicates maximum synchronous activity (maximum range of the scale) and blue colour indicates non-synchronous activity (negative range of scale) and the less active components are represented in mid-range of the scale (i.e.) mix of yellow and green colour. From Figure 4 it has been observed that ICA components with respect to IC2, IC4, IC7, IC11, IC12 and IC13 were showing synchronous activity during speaking of the CVC word *'can'*. Similarly, ICA components with respect to IC1, IC3, IC5, IC6, IC8 and IC10 were showing a non-synchronous activity. ICA components IC9 and IC14 were showing a mild activity. After the rejection of ICA components related to artifacts, a total of 12 components were selected for further analysis.

After ICA decomposition, the signal has been further filtered using smoothing filter. The main function of the smoothing filter is to capture the important patterns in data and also used for filtering out unnecessary noise. The smoothed signal was obtained using moving average technique. Signals were further segmented into EEG frequency bands such as delta, theta, alpha, beta and gamma bands using band-pass chebyshev filter and their corresponding power spectral densities were estimated in each frequency band using FFT. The prominent EEG frequencies are Delta (1-3 Hz), Theta (4-8Hz), Alpha (8 to 13 Hz), Beta (13 to 30 Hz) and Gamma (30 to 40 Hz).

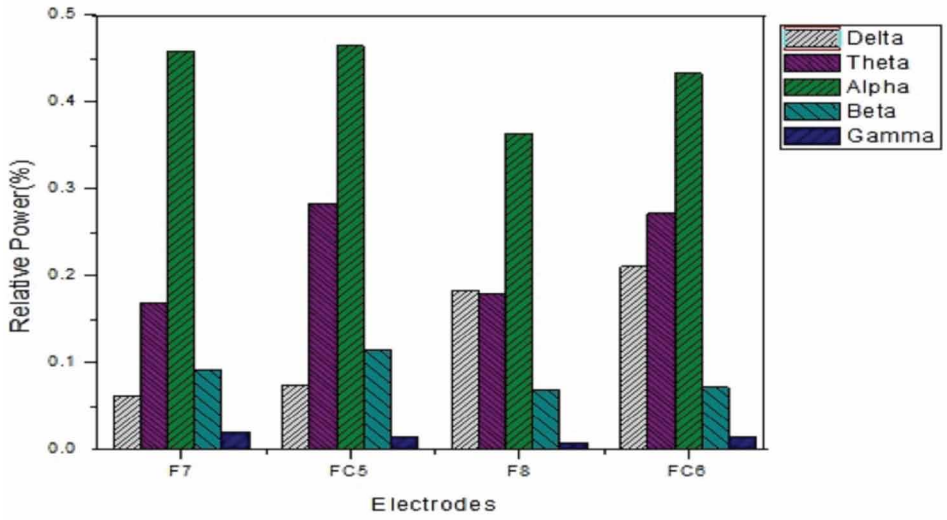
Based on the absolute power for each band, the relative power has been computed for electrodes with respect to frontal electrodes in left and right hemisphere of the brain. Figure 5 shows the relative power for frontal electrodes (F7, FC5, F8, and FC6) while speaking the CVC word *'can'* in a time period of 10

Figure 4. ICA components obtained from EEG signal while speaking the CVC word 'can'



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Relative power of frontal electrodes during speech process



seconds. From Figure 5 it was observed that relative power of alpha bands were found to be high for F7 and FC5 electrode. It was also observed that relative power of delta, theta, beta and gamma bands were low compared to alpha bands during speech task. It was also observed that right hemisphere electrodes (F8, FC6) were found to have a lower relative power compared to the left hemisphere electrodes (F7, FC5).

Relative Power Analysis While Imagining of Speaking the CVC Word

Temporal electrodes (T7, T8, P7, P8) with respect to left and right hemisphere of the brain were analyzed individually during imagining of speaking the CVC word *'can.'* T7 electrode was chosen for speech imagery analysis as this electrode is located near the Wernicke's area of temporal lobe. Wernicke's area is responsible for thinking and speech perception. The signal analysis for T7 electrode has been discussed in detail for understanding the nature of the signal while imagining of speaking the representative word. Similarly, for other temporal electrodes were also analyzed with the same procedure. As discussed for the analysis of speech EEG signals in previous sections, the same procedure will be followed for speech imagery signals. The filtered EEG signals were decomposed using ICA in order to remove the artifacts. The smoothed signals were further segmented into EEG frequency bands such as delta, theta, alpha, beta and gamma bands using band-pass chebyshev filter and their corresponding power spectral densities were estimated in each frequency band using FFT. Based on the absolute power for each band, the relative power has been computed for electrodes with respect to temporal electrodes in left and right hemisphere of the brain. Figure 6 shows the relative power for temporal electrodes (T7, T8, P7, P8) while imagining of speaking the CVC word *'can'* in a time period of 10 seconds. T7 and P7 electrode is located near Wernicke's area of left temporal lobe. From Figure 6 it was observed that relative power of theta band were found to be higher for T7 and P7 electrode while imagining of speaking the CVC word *'can'*. It was also observed that relative power of delta, alpha, beta and gamma bands were low compared to theta band during speech imagery task. It was also observed that right hemisphere electrodes (T8, P8) were found to have a lower relative power values compared to the left hemisphere electrodes (T7, P7).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Relative power for temporal electrodes during speech imagery process

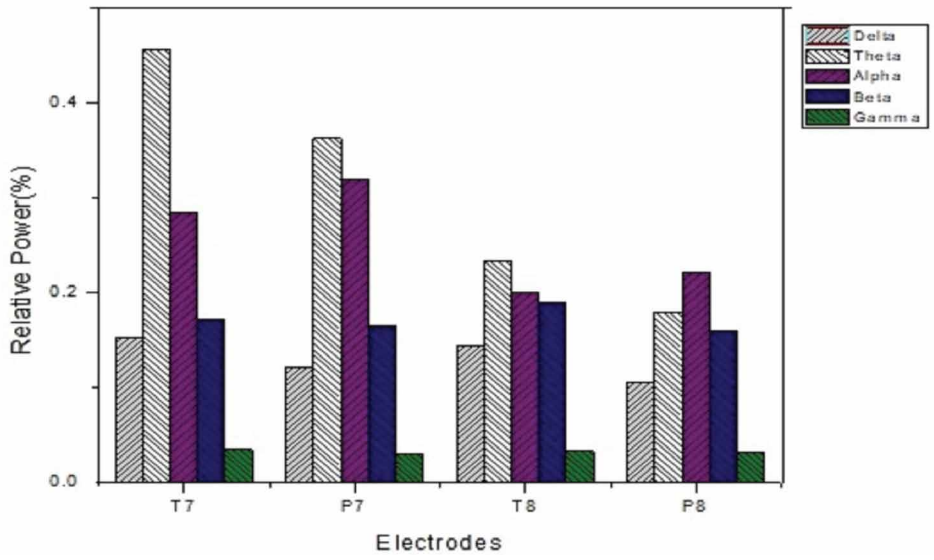


Figure 7 shows the averaged relative power of F7 electrode in 10 seconds, 20 seconds and 30 seconds of alpha band while speaking the CVC word *'can'*. Figure 8 shows the averaged relative power of T7 electrode in 10 seconds, 20 seconds and 30 seconds of theta band while imagining of speaking the CVC word *'can'*. In each trial it was evident that alpha and theta were found to have a high relative power value while speaking and imagining of speaking a CVC word. From Figure 7 and Figure 8 it has also been observed that, relative power value was progressively increasing with the increasing resting time period for speech and speech imagery protocols. It was also observed that right hemisphere electrodes (F4, F8, FC6, T8,P8) were found to have a lower relative power values compared to the left hemisphere electrodes (F3, F7, FC5, T7, P7).

PLV Analysis for Speech Imagery Process Involving CVC Words in Multiple Trials

PLV has been estimated for frontal (F7, F3, F4, F8), fronto-central (FC5, FC6), temporal electrodes (T7, T8, P7, P8) while speaking the CVC word in multiple trials. A 10*10 matrix were obtained for the frontal, fronto-central and temporal electrode combinations. These matrixes were obtained for all five sub-band EEG frequencies (delta, theta, alpha, beta and gamma). PLV has been estimated during speaking of a CVC word with respect to 10s resting time, 20s resting time and 30s resting time individually for each EEG bands. In all cases it has been found that alpha band was dominant band compared to other bands. Figure 9 shows the averaged PLV connectivity during speaking of the CVC word *'Can'* in alpha band with resting time of 10s with respect to lateral, medial, coronal and axial view of the brain in multiple trials. The electrodes are represented in terms of Brodmann areas. Frontal electrodes are represented as F7-47L, F8-47R, F3-8L, F4-8R (47 L&R-Inferior Prefrontal Gyrus, 8 L&R-Frontal Eye Field with respect to left and right hemisphere of the brain). Similarly fronto-central electrodes are represented as FC5-45L, FC6-45R (45 L &R-Broca's area of left and right hemisphere) followed temporal electrodes

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Average relative power for speech process in alpha band under three different resting time periods for F7 electrode

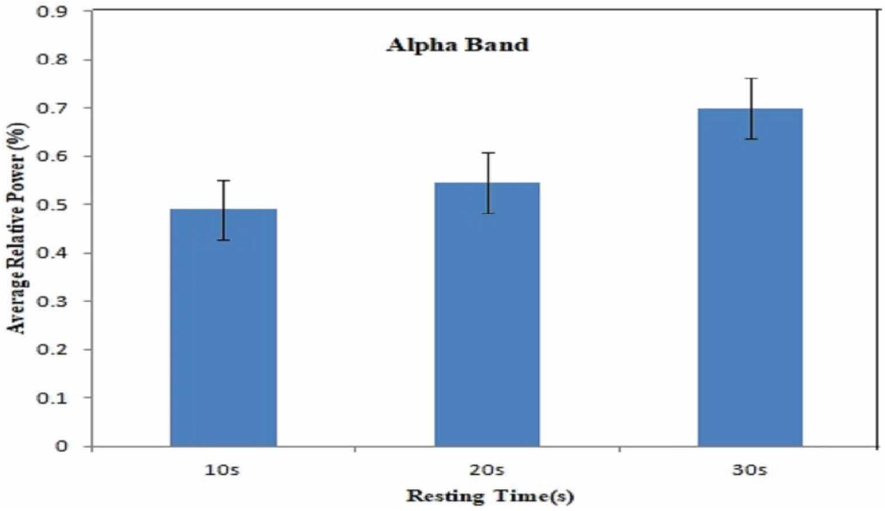

Figure 8. Average relative power for speech imagery process in theta band under three different resting time periods forT7 electrode

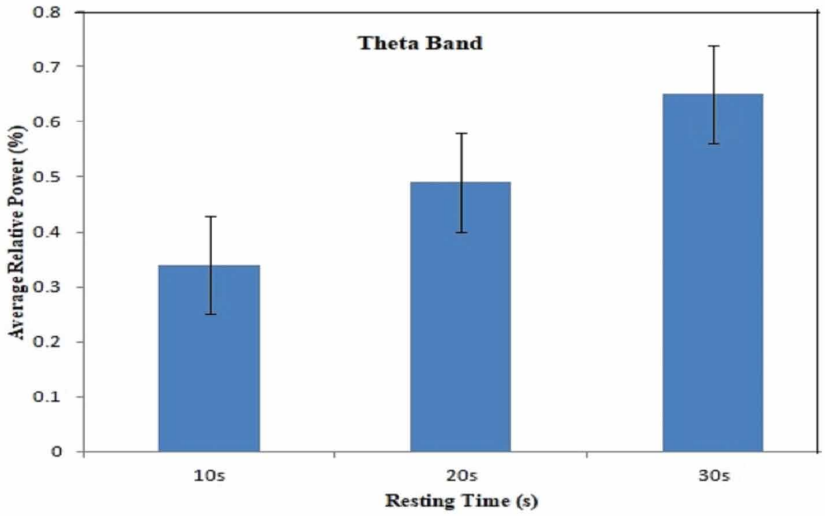
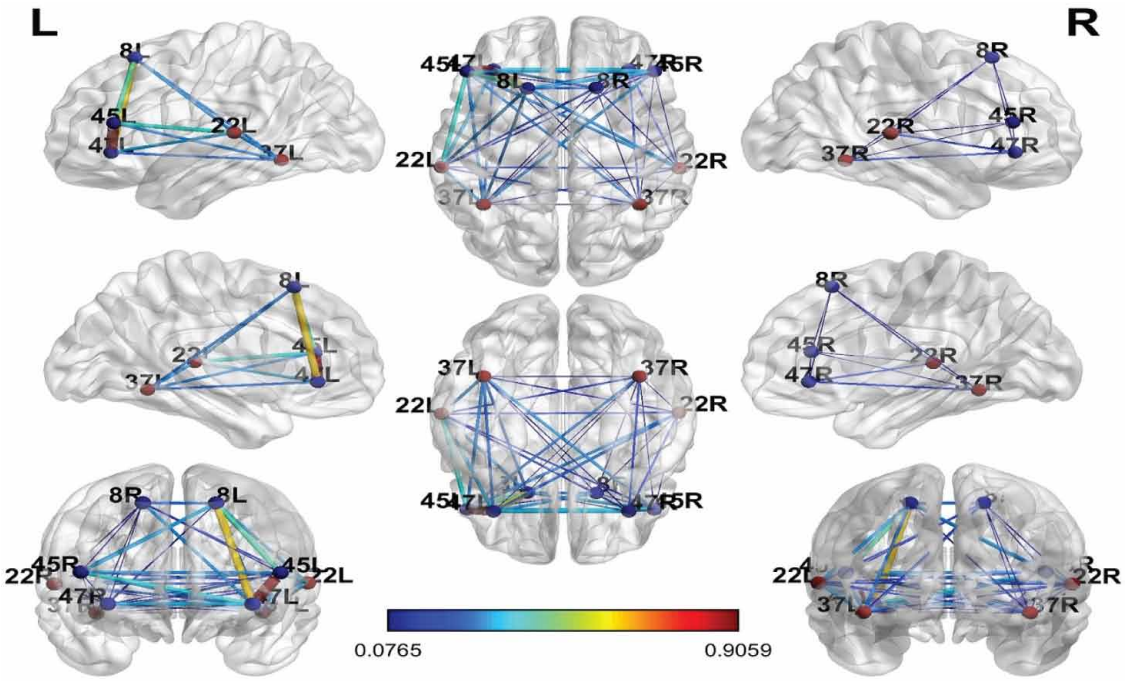


as T7-22L, T8-22R, P7-37L, P8-37R (22 L&R- Wernicke's area of left and right hemisphere, 37 L&R-Fusiform Gyrus of left and right hemisphere of the brain). From Figure 9 it was observed that the left hemisphere electrodes with respect to frontal and fronto-central electrode combination (F7 with FC5) showed maximum phase lock value which indicates that the difference between these two electrodes quantifies the locking (i.e) both the signals phases are locked and one signal follows the other perfectly (rise and fall time of both the electrodes were in phase). Scale ranges from blue to maroon color. Blue indicates the PLV value of 0.1 and below. Maroon color indicates higher PLV connectivity between the electrodes of value 0.9 and above.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Average PLV connectivity during speaking of the CVC word with resting time of 10s in multiple trials



The connectivity matrix of averaged PLV in multiple trials is shown in Figure 10. From Figure 10, the connectivity between F7 with FC5 was found to be 0.9 which was the highest compared to other electrode combinations. The inter hemispheric electrode combinations showed a lower connectivity during speaking of the CVC word *'Can'*. Scale ranges from blue to yellow color. Blue indicates lower connectivity and yellow indicates higher connectivity between the electrodes. Lower connectivity can be observed between F7 with P8 and F3 with P8 electrode combinations. The connectivity between pairs of temporal electrodes were low compared to that of frontal and frontal-central electrode combinations which proves that Broca's area were active during speech production.

Figure 11 shows the averaged PLV connectivity during speaking of the CVC word *'Can'* in alpha band with resting time of 20s with respect to lateral, medial, coronal and axial view of the brain in multiple trials. From Figure 11 it was evident that the left hemisphere electrodes with respect to frontal and fronto-central electrode combination (F7 with FC5) showed a high phase lock value compared to other electrode combinations. PLV was found to be increasing in frontal and fronto central electrodes when the resting time of the task is increased from 10s to 20s.

Figure 12 shows the averaged PLV connectivity during speaking of the CVC word *'Can'* in alpha band with resting time of 30s with respect to lateral, medial, coronal and axial view of the brain in multiple trials. From Figure 12 it was evident that the left hemisphere electrodes with respect to frontal and fronto-central electrode combination (F7 with FC5) showed a maximum phase lock value compared to other electrode combinations. PLV was found to be increasing in frontal and fronto central electrodes when the resting time of the task is increased from 20s to 30s which is evident that the electrode F7 and FC5 signals are more active while speaking a CVC word when the resting time of the task is increased.

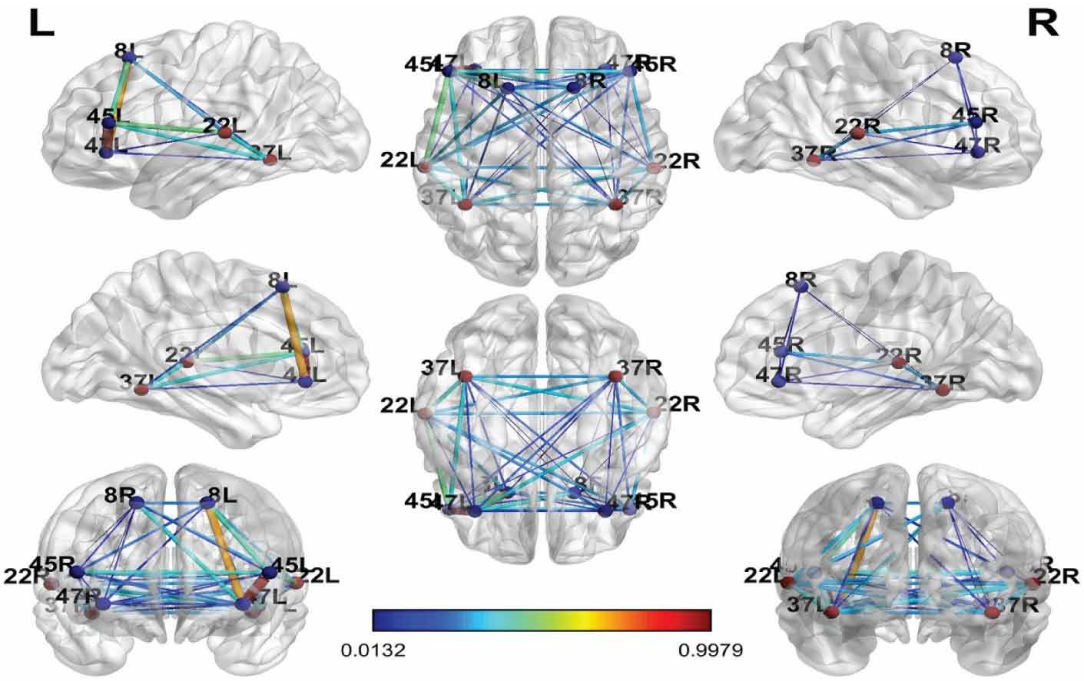
Figure 12. Average PLV connectivity during speaking of the CVC word with resting time of 30s in multiple trials



PLV Analysis for Speech Imagery Process Involving CVC Words -Single and Multiple Trials

PLV has been estimated for frontal (F7, F3, F4, F8), fronto-central (FC5, FC6), temporal electrodes (T7, T8, P7, P8) while imagining of speaking a CVC word in multiple trials. A 10*10 matrix were obtained for the frontal, fronto-central and temporal electrode combinations. PLV has been computed while imagining of speaking a CVC word with respect to 10s resting time, 20s resting time and 30s resting time individually in multiple trials for each EEG bands.

In all cases it has been found that theta band was the dominant band compared to other bands. Figure 13 shows the averaged PLV connectivity during imagining of speaking of the CVC word *'Can'* in theta band with resting time of 10s with respect to lateral, medial, coronal and axial view of the brain in multiple trials. The electrodes are represented in terms of Brodmann'areas. Frontal electrodes are represented as F7-47L, F8-47R, F3-8L, F4-8R (47 L&R-Inferior Prefrontal Gyrus, 8 L&R-Frontal Eye Field with respect to left and right hemisphere of the brain). Similarly, fronto-central electrodes are represented as FC5-45L, FC6-45R (45 L &R-Broca's area of left and right hemisphere) followed temporal electrodes as T7-22L, T8-22R, P7-37L, P8-37R (22 L&R- Wernicke's area of left and right hemisphere, 37 L&R-Fusiform Gyrus of left and right hemisphere of the brain).

From Figure 13 it was observed that the left hemisphere electrodes with respect to temporal electrode combination (T7 with P7) showed maximum phase lock value which indicates that the difference between these two electrodes quantifies the locking (i.e.) both the signals phases are locked and one signal follows the other perfectly (rise and fall time of both the electrodes were in phase). Scale ranges from blue

lower connectivity during imagining of speaking the CVC word *'Can'*. Scale ranges from blue to yellow color. Blue indicates lower connectivity and yellow indicates higher connectivity between the electrodes. Lower connectivity can be observed between frontal electrode combinations. The connectivity between temporal electrodes was high compared to that of frontal and frontal-central electrode combinations which prove that Wernicke's area was active during speech imagery process.

Figure 15 shows the averaged PLV connectivity during imagining of speaking of the CVC word *'Can'* in theta band with resting time of 20s with respect to lateral, medial, coronal and axial view of the brain in multiple trials. From Figure 15 it was evident that the left hemisphere electrodes with respect to temporal electrode combination (T7 with P7) showed a high phase lock value compared to other electrode combinations. PLV was found to be increasing in temporal electrodes when the resting time of the task is increased from 10s to 20s.

Figure 16 shows the PLV connectivity during imagining of speaking of the CVC word *'Can'* in theta band with resting time of 30s with respect to lateral, medial, coronal and axial view of the brain in multiple trials. From Figure 16 it was evident that the left hemisphere electrodes with respect to temporal combination (T7 with P7) showed a maximum phase lock value compared to other electrode combinations. PLV was found to be increasing in temporal electrodes when the resting time of the task is increased from 20s to 30s which is evident that the electrodes T7 and P7 signals are more active while imagining of speaking a CVC word when the resting time of the task is increased.

CONCLUSION

Fast Fourier transform has been used in this paper to analyze signals in the frequency domain for speech and speech imagery. It extracts the information present in the frequencies of a particular band and the amount of computation is reduced compared to other transforms. Power spectrum densities of each frequency band were derived based on the absolute values of FFT. Relative power for each inter and intra hemispheric frontal and temporal electrodes in each frequency band were analyzed exclusively. It was observed that relative power of theta band was dominant during speech imagery process and relative power of alpha was active during speech process. It was also observed that the relative power value was found to be increasing with the increasing resting time period involving different protocols. Functional brain connectivity parameters such as Phase Locking Value have been estimated for speech and speech imagery processes involving CVC words in multiple trials of different time periods in units of ten. PLV reveal the degree of synchronicity between two regions of the brain when a task is performed. It was observed that PLV of left hemispheric frontal electrode combination (F7 with FC5) (> 0.85) showed maximum phase lock value in alpha band during speech process which indicates that the difference between these two electrodes quantifies the locking (i.e.) both the signals phases are locked and one signal follows the other perfectly. Similarly, PLV has been computed for speech imagery process using CVC words in multiple trials. It was inferred that left hemispheric temporal electrode combination (T7 with P7) showed maximum phase lock value in theta band (>0.9) during speech imagery process. PLV values were found to increase progressively with the increasing resting time in units of ten. Results confirmed that left frontal electrodes were active during speaking of a CVC word and left temporal electrodes were

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

active during imagining of speaking a CVC word. This work can be extended by including Consonant-Vowel-Consonant –Consonant (CVCC) words for each vowel, and also by including different brain connectivity parameters for analysis. Therefore, through these adaptive signal processing methods and brain connectivity estimators, future scope of this work can be used to develop a control scheme for speech prostheses for the production of words in speech impaired people using speech imagery process.

Chapter 83
Nursing Students' Perception of Medical Information Protection in Hospitals

Hyeon-Cheol Jeong
Sahmyook University, Korea

ABSTRACT

The purpose of this article is to investigate the perception of medical information protection. The subjects were 281 students from 2 nursing students from September 1, 2015 to October 20, 2015. A total of 28 self - administered questionnaires were used. As a result, the perception of medical information protection behavior was 3.39 ± 0.51. In the fourth grade, the 'privacy protection' category was low (p = .007) and the 'communication' category was high (p = .045). In case of having experience in practice, 'privacy protection' category (p = .010) and 'medical information management' category (p = .041) were low and 'communication' (p = .021) was high. In the 'communication' category, the perception score was high when the medical information protection law (p = .001) and the nurses' code of ethics (p = .040) were known. When the subject completed 'medical security education' (p = .004), the perception was high. In conclusion, it is necessary for schools and medical institutions to develop nursing education programs for their educational environment and role.

1. INTRODUCTION

In the early 1990s, the order communication system (OCS) was introduced; later on, in the late 1990s, the picture archiving communication System (PACS), which is based on the hospital information system (HIS), was introduced on a large scale. Medical informatization became more systematic in the 2000s, with many hospitals introducing electronic medical record (EMR) systems that make it possible to input, save, and exchange patient information (Suh & Lee, 2014).

EMR is the input, organizing, and archiving of the patient's medical care, surgery, and examination records based on computerization in the form of promised codes. As a result of examining the EMR

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

system for medical institutions in Korea in 2010, the rate of introduction of EMR reached 37.2%, and the rate of introduction of tertiary medical institutions was 50.2%, which is higher than the rate of introduction of US medical institutions (Jin & Choi, 2012).

In the medical environment, informatization converts the existing analog medical information into digital and creates a medical information network to improve the quality and efficiency of medical service (Shick, 1998). Such medical information includes personal information (eg, location, family, assets, social life, sex life, personality and daily habits) and very sensitive content (eg, injuries, illnesses, and treatment records) as well as the patient's health status.

Therefore, if medical information is exposed to a third party, it might violate the fundamental rights of privacy and freedom stipulated in the Constitution. Additionally, it might violate human's most fundamental rights, such as that of human dignity and values, and the right to pursue happiness. In particular, EMRs can easily be copied and sent to others. For this reason, if they are leaked and any modified and fabricated information is reproduced, the concerned individuals' privacy is likely to be violated much more than when dealing with conventional paper-based information. Therefore, it seems important to treat EMRs very carefully (Kim, 1998; Jeun, 2013; Koskosas & Asimopoulos, 2011).

Nurses, who care for patients 24 hours per day at hospitals and can easily access patients' personal information, are often in the most critical position for protecting patients' medical information. Nursing university students, as future nurses, are also highly involved in protecting patients' medical information during their period of clinical practice (Jung & Jung, 2011). Nevertheless, what nursing university students are taught about protection of patients' personal information differs widely depending on their school; there is not, at present, any standardization of such education. During their clinical practice courses, these students are given an ID allowing them to access patients' personal information, and thus the protection of such information is dependent on each student's personal ethics (Kim, Jeong & Song, 2013).

Despite the rapid informatization of the medical environment, there does not appear to be much education or research on nursing university students' own actions to protect patients' medical information. Therefore, this study attempts to identify students' perception of how to protect patients' medical information, and thereby provides fundamental material for developing an education program for students to protect patients' information in this rapidly changing medical environment.

2. STUDY METHOD

2.1. Study Design

This is a descriptive survey study on nursing university students' perceptions of the protection and management of patient information.

2.2. Study Subjects

The study subjects were students from the nursing departments of two universities in Seoul. The minimum sample size was determined to be 210 subjects using the G*power 3.1.5 program, according to an α of .05, a power of .95, and an effect size (F) of 0.5. A total of 350 questionnaires were distributed, with consideration of non-participation, and 294 copies (84%) were collected. Of these collected copies, 13 with insincere answers were excluded. Finally, 281 copies were used for data analysis.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.3. Study Tools

The questionnaire used in this study was developed with reference to the questionnaire developed by Jung & Jung (2011), which was used to study nursing university students' protective actions concerning patients' medical information, as well as the 4th revision of the Korean Code of Nursing Ethics and the 1st revision of the Korean Ethical Guidelines of Nursing of the Korean Nurses Association. In particular, drawing on Article 10 (Privacy Protection), Article 11 (Confidentiality), and Article 12 (Management Responsibilities of Medical Records) in Chapter 3 (Ethics for Patients) of the Korean Code of Nursing Ethics, we modified and supplemented the styles and content adequacy.

Given that the subjects of this study were nursing students, we conducted the pilot test with five students at the nursing department and two new nurses. Based on the pilot subjects' ratings of the adequacy of the phrasing, understanding of the content, and time to complete the questionnaire, we selected 28 questions for further testing. The content validity of these questions was examined by three professors from the nursing department and two head nurses with a Ph.D. degree who were working at the university hospital. They determined that all 28 questions were valid (CVI = 0.9 or more). As a result, all questions were incorporated into the questionnaire without any changes.

This questionnaire comprises 28 questions in four categories to measure the degree of perception of patient information protection ("privacy protection," 4 questions; "confidentiality," 8 questions; "medical information management," 9 questions; and "communication," 7 questions). In this questionnaire, each question is rated on a 5-point Likert scale. Higher scores indicate a more positive perception of the protective actions of a patient's medical information.

When Jeong developed the original measurement tool, its reliability (Cronbach's α) was .90 (Jung & Jung, 2011). In this study, the Cronbach's α was .91.

2.4. Data Collection Period and Method

We collected data from Sep. 1 to Oct. 20, 2015. Before data collection, the researcher was given permission from the dean of each nursing department and explained the purpose of the study to subjects. All data were collected when subjects did not have a class. The students who determined to participate were given a self-administered questionnaire, and each questionnaire copy was collected by a student representative. The questionnaire contained an introduction to the researcher and described the purpose of this study, as well as a written explanation that the questionnaire would not be used for anything other than the stated study purpose, that participants could withdraw their participation at any time.

2.5. Data Analysis

For data analysis, SPSS Statistics (Ver. 21) was used:

1. Subjects' perception of the actions for protecting patients' medical information was analyzed using descriptive statistics, including minimum and maximum values, means, and standard deviations;
2. Differences in subjects' perceptions according to their general characteristics were analyzed using t-tests;
3. The correlations between the categories of perception of actions to protect patients' medical information were analyzed using Pearson's correlation coefficients.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. STUDY RESULTS

3.1. Characteristics of Study Subjects

The general characteristics of the study subjects are presented in Table 1. Their average age was 21.4 years, and most were senior students (at 41.6%).

The majority (59.4%) had experienced hospital practice and were aware (66.5%) of the Medical Information Protection Act. Furthermore, 84.0% were aware of the Korean Code of Nursing Ethics developed by the Korean Nurses Association. However, 32.4% did not have a medical information security education. Regarding education on the protection of patients' personal information, the largest proportion (29.1%) had received such education in their fundamental nursing education class.

3.2. Perception About the Protection of Medical Information

Table 2 shows the results of analyzing the perception level of medical information protection for patients. The total score for this perception questionnaire was 3.39 ± 0.51 (5-point scale). With regard to category, confidentiality (4.20 ± 0.58) and communication (4.20 ± 0.65) had the highest scores.

3.3. Scores of Questions on Protective Actions for Patients' Medical Information

Table 3 shows the scores for each question of the questionnaire on perceptions of protective actions for patients' medical information, grouped by category.

Table 1. General characteristics of subjects (N = 281)

Characteristics	Classification	n or Mean	% or ±SD
Age		21.4	±2.17
Grade	1	51	18.1
	2	64	22.8
	3	49	17.4
	4	117	41.6
Hospital practice experience	Yes	167	59.4
	No	114	40.6
Are you aware of the Medical Information Protection Act?	Yes	187	66.5
	No	94	33.5
Are you aware of the Korean Code of Nursing Ethics?	Yes	236	84.0
	No	45	16.0
Received education on medical information security	No	129	32.4
	In fundamental nursing class	116	29.1
	In total nursing education	62	15.6
	In hospital education	91	22.9

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Perception about the protection of medical information

Category	Min	Max	Mean	±SD
Privacy protection	1.00	5.00	3.37	.79
Confidentiality	2.38	5.00	4.20	.58
Medical information management	2.22	5.00	4.18	.64
Communication	1.86	5.00	4.20	.65
Total			3.99	.51

Regarding the perceptions for each question, Q6 (*"When presenting a case study in an academic meeting or to others after practice, a nursing student must not reveal a patient's personal information"*) had the highest score, at 4.50 ± 0.79, followed by Q25 (*"Nursing students must not give a patient's information to any person not related to the patient's treatment on the phone";* 4.48 ± 0.79) and Q24 ("*Nursing students must not disclose a patient's medical information obtained during practice in a private place"*; 4.46 ± 0.84).

In contrast, Q4 ("*When a nurse educates a patient about being discharged from the hospital, nursing students must prevent people other than the patient from listening to their conversation*") had the lowest score, or 2.97 ± 0.97.

3.4. Differences in Perception According to General Characteristics

Table 4 shows the differences in subjects' scores on the perception questionnaire according to their general characteristics.

In the categories of privacy protection and communication, perception score significantly differed according to school year. Senior students had significantly lower scores for privacy protection ($F = 4.107$, $p = .007$), but significantly higher scores for communication ($F = 2.725$, $p = .045$). In the case of having experience in hospital practice, 'privacy protection' (-2.61, $p = .010$) and medical information management (-2.05, $p = .041$) were statistically significantly lower. However, 'communication' (2.32, $p = .021$) was significantly higher.

The scores in the 'Communication' area were significantly higher when 'Medical Information Protection Act (3.40, $p = .001$)' and 'Nurse Code of Ethics (2.07, $p = .040$)' were known. In addition, when the subject completed 'medical security education' (-2.92, $p = .004$), the score in the 'communication' area was high.

4. DISCUSSION

Regarding the average scores of nursing university students' perceptions on the protection of patients' personal information, three of the four categories in the questionnaire had scores over 4.18 (out of 5). This result (4.11 point) is similar to that found in Lee's study (Lee & Park 2005), which was conducted with 289 nurses, but is lower than that found in (at 4.39) in Jung's (2011) study, which was conducted with nursing students using a 25-item questionnaire. Furthermore, the total mean score of the perception questionnaire was relatively high (at around 4 points). If a patient's personal medical information is

Table 3. Scores of questions on perceptions of protective actions concerning patients' medical information

	Questions	Scores	
		M	±SD
Privacy protection Protection	Q1 When a nurse checks a patient's health, the nursing student must prevent people other than the patient from listening to their conversation.	3.50	.93
	Q2 When medical staff talk about the patient's medical treatment in a hospital room, the nursing student must prevent people other than the patient from listening to their conversation.	3.38	1.06
	Q3 When a nurse tells a patient the results of an examination, the nursing student must prevent people other than the patient from listening to their conversation.	3.60	.98
	Q4 When a nurse educates a patient about being discharged from the hospital, the nursing student must prevent people other than the patient from listening to their conversation	2.97	.97
Confidentiality	Q5 To use a patient's medical information for research purposes, a nursing student must obtain the patient's agreement.	4.31	.94
	Q6 When presenting a case study in an academic meeting or to others after practice, a nursing student must not open a patient's personal information.	4.50	.79
	Q7* When a case study report is posted on the Internet, all types of information, including personal identity can be viewed.	4.35	1.12
	Q8 In order to record a patient's conversation, a nursing student must receive the patient's written agreement.	4.31	.86
	Q9 Nursing students must not tolerate a situation where a different colleague student records or photographs nursing care or treatment.	3.99	1.05
	Q10 Nursing students must not inform a patient's guardian of the patient's medical information without obtaining the patient's agreement.	3.76	1.06
	Q11 Nursing students must not disclose a patient's information without their agreement, even when the information is required for a lawsuit.	4.16	.92
	Q12 Nursing students must not talk about what they observe to people other than medical staff.	4.20	.89
Medical information management	Q13 When viewing data on a medical information system, nursing students must only view the minimal range of data directly related to the patient they are caring for.	3.85	1.04
	Q14 During practice, nursing students must not take a list of patients or medical records received by the nurse outside of the hospital ward.	4.24	.97
	Q15 Nursing students must help in preventing other people from looking at a patient's medical information.	4.29	.84
	Q16 To access the medical information system, nursing students must use their assigned ID or password.	4.36	.82
	Q17 Immediately after viewing data on the medical information system, the nursing student should log out.	4.37	.81
	Q18* Nursing students should share their own ID and password with others.	3.70	1.38
	Q19 Nursing students should not photograph medical information (EMR, PACS, or OCS) without receiving the written agreement of a patient.	4.23	.98
	Q20 Nursing students should not search for the medical information of their colleagues or celebrities for purposes other than actual practice.	4.33	.90
	Q21 Nursing students should reject any request of writing or modifying medical information untruthfully.	4.29	.93

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

leaked, it is highly likely to violate that patient's privacy. Therefore, it is essential, rather than optional, to protect patients' medical information. Given that, when planning an educational program, educational institutions must take into account the scores of each category found in this study and provide tailored education that contributes to accomplishing a final goal (5 points). Fortunately, medical institutions involved in nursing students' clinical practice often make some effort to protect patients' personal information (Jeong, 2016).

With regard to nursing students' perceptions by category, the communication category had the highest score. This result is similar to that of a previous study [7, 8, 9]. The high score in the communication category is perhaps because it includes questions relating to a high risk of personal information leakage, including Q24 ("Nursing students should not disclose a patient's medical information obtained during practice in a private place"), Q22 ("Nursing students should not talk about a patient in an elevator or corridor"), and Q23 ("When with other students, a nursing student should not talk about what they hear when medical staff are transferring patients' information between them"). Additionally, it might be because students about to engage in clinical practice receive intensive education on this topic at nursing school. Therefore, the repeated education seems to bring about its effect.

The differences in perceptions were analyzed according to study subjects' characteristics. The results showed that junior and senior students tended to have higher perception scores than did sophomore students. This is perhaps because, with every subsequent school year, students are likely to receive repeated education about patients' personal information protection, either at school or during their clinical practice at a medical institution, which in turn influences their perception. Particularly, subjects who had previous experience of clinical practice, who were aware of the Medical Information Protection Act and Korean Code of Nursing Ethics, and who had received education on medical security had significantly higher scores in the communication category compared with other categories. Therefore, this study proposes that schools and medical institutions should attempt to discuss effective education strategies in consideration of their own educational environments and develop a systematic educational program that improves students' perception of protecting medical information.

5. CONCLUSION

In order to improve the perception of nursing students about the protection of patients' personal information, it is necessary for schools and medical institutions to establish educational strategies in accordance with their environment. It is also important to realize the importance of personal information, to develop sustainable and systematic education programs.

Chapter 84
Information Security Standards in Healthcare Activities

José Gaivéo
Polytechnic Institute of Setubal, Portugal

ABSTRACT

Information is mandatory in healthcare activities and in all that are related to it. In this same sense, people that deal with those information requires attention because patient´s information could be exposed. The use of directions stated by information security standards might allow a proactive attitude in the face of the diversity of threats that as the potential to explore the vulnerabilities of organizational assets. This article intends to recognize information threats and vulnerabilities that could be explored, using information security international standards to support the activities needed to assume information safeguard. Another intention is the establishment of a basis of references in information security to define a level of risk classification to build a referential to the potential that a given threat has to exploit the vulnerabilities of informational assets, preventing damages to personal and organizational property, and also activity continuity, assuming information as the main resource.

INTRODUCTION

Nowadays, information, one of the great challenges of societies, implies profound changes in the vast majority of institutions, not only in its functioning but also in people.

The quantity and diversity of information that is currently available and easily accessible by the emergence of an information society brings new and hard challenges. This type of society deals essentially with information and need people with appropriate skills and competencies to deal with it, using all available resources to assure that information is adequately used and, consequently, protected.

Facing the current context of social and economic globalization, in which a society based on the use of information emerges, it is important to use appropriate technologies and systems to serve institutions. This information systems and information and communication technologies (ICT) support can and should be used to conduct institutional development based on information.

As can be noted, information has seen growth in its importance within the institutions, being essential ensuring its widespread use. In this sense, the institutions, given the challenges and implications that arise from the modernization necessary to their development, require that its employees, experts or not, have the right skills for the use of information systems and ICT to support information needs.

Thus, security of information systems and ICTs is only a part of information security in an organization. Of course, the security of information systems and ICTs is important in the organizational context, mainly because information systems and ICTs are pertinent to support information acquisition, supporting, storing and sharing according to organization needs.

Nevertheless, taking simply information systems and ICT into consideration, information safeguard covers only a part of the whole problem, what implies that the approach to the security of organizational assets must be focused on whole organization, which means that security measures should attend to it.

In this sense, the people awareness and training about security are subjects that must be taken into account. This is so relevant as the potential impact of information on information systems and ICT usage, and also in the activities related to information about patient's health.

Because patient's data must remain confidential, organizations shall adopt information security policies to provide the appropriate protection. Those policies could use directives provided by information security international standards as ISO/IEC 27x family, in order to establish procedures and rules that correspond to organizational business needs.

With this paper, through the assumption that information is an important organizational asset, and that is of particular importance in the healthcare sector, is intended to make the appropriate recommendations for the establishment of a framework to support the establishment and implementation of information security policies that provide the adequate protection of information.

In this circumstance, also, by the nature of the asset information, consider the role of people who deal with this information and provide them with the necessary awareness of this problem, as well as with the education and training suited to each concrete context.

We must also, in addition to the identification and valuation of such assets, identify threats and vulnerabilities that can affect the assets, in order to assess the risk and, consequently, to its management.

Still intend to characterize what is meant by information security and their supports, getting to know the legal and regulatory framework to ensure compliance of security measures, with international information security standards, such as ISO/IEC 27x family, to support the main activities related to these objectives.

BACKGROUND

In a sector where main activities are conducted by people, as healthcare, the foremost resource relates to information about patient's life. In this sense, information needs to be adequately protected against misuse and disclosure of any kind.

Few years ago, health patient's data were essentially supported by paper, and the major problems was their handling and storage, this contributes to several difficulties in its usage. Nowadays, despite people are more awarded about information systems and ICT usage implications, data and information remain without appropriate attention related to their security.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Many of these challenges involve structural changes in organizations as a factor of sustainability of the information society in the current context of globalization of markets and societies. Those changes can, and should, involve profound changes in the structure of institutions requesting membership, and the conscious and active participation of all stakeholders.

However, it should be observed, those information supports cannot be assumed as a panacea for all problems in institutions, but must be understood in its essence as enhancers of competencies of people and its capacity for the use for the benefit of institutions.

On the other hand, this new attitude embodies a clear perception of the relevance of information to the organization and the assumption of the need to provide their protection according to their criticality in line with the objectives and strategy. Protect information and systems that support their sharing internally and with the various partners emerges as a key strategic objective, in the context where the credibility of the institutions is a critical success factor in their activity.

Think about information security implies, besides to think about information as an organizational asset, to think about the security of their main supports in today organizations, namely information systems and ICTs. This attitude that must be assumed as critical to business success.

Thinking about how to solve those simple problems, allows us to note that potential solutions aren't as easier like initially seeming to be. Mainly because there are two main issues that could affect any possible solution; a) people, due the ways they use information, and b) the information themselves. Those issues are factors that tend to increase the vulnerabilities, and consequently the threats that could explore those vulnerabilities.

Organizational Assets and Security

Organizations are composed of people, and the technologies can help people to perform their activities. However, the use of technologies as competitive advantage depends on how they are used, and also how people and information are understood as organizational resources.

Sharing information can affect power relations within the organization, implying that the success of the information systems depends of organizational decision-makers, not excluding, however, that also depend on end-users.

Being the information a resource, it is necessary to ensure their possession, where the protection of information requires the availability of adequate resources, a fact which by itself needs more resources, implying an increase in costs.

Information is usually defined as something that has value to an organization and that requires adequate protection, regardless of the form or medium of storing, processing, and/or transmission, but could be also defined as a business asset that is essential to an organization and consequently needs to be suitably protected (International Organization for Standardization, 2014). This vision is reinforced by Workman, Phelps, and Gathegi (2013) that presents information as data interpreted in a specific context.

However, in a sector like healthcare, information is not only about patients, but also about all participants i.e. include, besides patients, collaborators, stakeholders, competitors and regulators.

One of the aspects that highlights to the need for information security, today is the greater availability of information and the ways of use. this has increased problems brought to organizations and people, making the need for information security in a mandatory factor; especially in organizations where information is an asset essential to business.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nevertheless, in a general definition, information security is seen as the preservation of confidentiality, integrity and availability of information, something that Whitman and Mattord (2010) mentions as "the key concepts of information security, which are mainly referred as CIA triangle" (p.8).

In this position, confidentiality is to ensure that information is only accessed by those authorized to do so. Integrity is about not modifying the information ensuring its accuracy and credibility. Availability is to ensure that authorized persons have access to information and associated services whenever necessary (Smith, 2013). To do this, according to Whitman and Mattord (2010); confidentiality implies, among other measures, to classify information, security documentation and apply security policies, while integrity involves to take care about information entering, storing and sharing, and finally, availability relates with the information format that allow their usage without interference or obstruction.

Complementarily, Smith (2013) assumes that security process has six phases: identify assets; analyze the risk of attacks; establish security policies; implement defenses; monitor defenses; and, recover from attacks. The author also notes that "defense is a security measure intended to protect the assets from the threat agents" (p.12).

The realization of that objective is achieved through the definition and implementation of information security policies that must provide the management's commitment and appropriate support of critical activities to information security, where security policy is the set of good practices that the organization must follow and thus the expression of organizational strategy.

Information security develops through an information security management system (ISMS), which includes the collation of business assets (people, equipment, buildings, auxiliary material and information, among others) that are identified as essential for the normal development of the business by providing their management in accordance with the stipulations of the standards and policies existing in the organization.

The ISMS is a part of the general system for the management (includes organizational structure, policies, planned activities, responsibilities, practices, procedures, processes and resources), based on the approach to business risk, to establish, implement, operate, monitor, review, maintain, and improve an organization information security to achieve business objectives (International Organization for Standardization, 2014).

According these points of view, it's important to know and understand legal and regulatory framework to adequately develop an information security strategy that looks to information protection in healthcare sector. In this subject matter, because information is related with patients, it's important to know who can see and use that information, in what circumstances and what for.

Legal Framework

In terms of supporting legislation, it is transverse in most countries the existence of laws for the protection of personal data. Some examples are:

- Personal Information Protection and Electronic Documents Act of 2000 (PIPEDA) – Canada;
- Federal Information Security Management Act of 2002 (FISMA) – United States of America;
- Data Protection Act 1998 – United Kingdom;
- Data Protection Act of 1978 (revised in 2004) – France;
- Data Protection Directive of 1998 – European Union;
- Federal Data Protection Act of 2001 – Germany.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In a general way, countries adopt several laws and regulations that complement those and allow states, institutions, enterprises and people to perform tasks to provide information security.

Some of these countries understand the importance and sensitivity of the information on this sector in particular and adopted specific laws/regulations to provide a more objective and greater protection of that information. In this context must be referred the Health Insurance Portability and Accountability Act (HIPAA, Public Law 104-191), which was approved by the Senate and House of Representatives of the United States of America, by 1996.

Later, in 2003, related with this same law, was approved a security rule (referred to as HIPAA Security Rule) that constitute the security standards for a reliable information on health (Scholl *et al*, 2008).

In addition to ensure the portability of health insurance, HIPAA sets a number of requirements relating to security and privacy of patient information (HIPAA, 1996).

Although this seems only relevant to the health care industry, any organization that transmits and store patients' health information, including information on employee benefits and claims, is subject to the rules of HIPAA.

The main purpose of this Rule is to ensure that the health information of anyone is adequately protected, while the flow of health information required to a) provide and promote healthcare and b) high quality to protect public health and welfare is also protected.

To do so, Whitman and Mattord (2010) reminds the five fundamental principles of HIPAA, which are:

- Control of medical information by patients;
- Use medical information with boundaries;
- Privacy of private information accountable;
- Balance responsibility for the use of medical information;
- Security of health information.

This rule searches for a compromise that allows important uses of information, while protecting the privacy of individuals seeking health care. The design of the principles must obey to the indispensability of being flexible and comprehensible in order to cover a variety of uses and discoveries that need to be addressed.

To achieving that, HIPAA restricts the access to private health information without documented consent, giving patients the right to know who as access to their information.

Countries have not their information security regulation in the healthcare sector, being frequent the adoption of several HIPAA procedures to sustain most of their needs in this area.

Regulatory Framework

Although there are many rules about information security, which fall into a wide range of aspects associated with implementing information security policies and support systems, some are part of internationally recognized standards such as ISO/IEC 27x series, which assumes the security as a management process by providing framework guidelines to safeguard organizational information.

Because the ISO/IEC 27x series standard assumes the information security issues as a management process, it is important to make use of a common and consensual definition of information security provided by these standards as the preservation of the confidentiality, integrity, and availability of information (International Organization for Standardization, 2014).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In this subject matter an international standard on security area as ISO/IEC 27002, known as the code of best practices for information security, provides some guidelines for controls related to mobility of information and with devices in transit throughout the organization.

Those guidelines of controls, used to sustain risk assessment performed according to ISO/IEC 27001 through the application of ISO/IEC 27005 or ISO 31000 risk management models, allow the implementation of security measures to protect information assets and their supports.

The previous reality reinforces the relevance of a standard like ISO 27799, which applies ISO/IEC 27002 concepts, to be used as the main base to provide a key reference to deal with the multiplicity of security issues that emerges from an enlargement of the amplitude provided by information on social and organizational activities in healthcare sector.

Usually, ISO 27799 applies their controls additionally to those provided by ISO/IEC 27002, attending to the specificity of issues related with healthcare matters, i.e., the guidance provided by ISO/IEC 27002 must be considered in addition to the guidance provided by ISO 27799.

Using a standard like ISO/IEC 27001: 2013 (Information security management systems – Requirements) helps to establish an ISMS that intends to support the protection of the organizational information and other business assets that are fundamental to organizational activities.

The ISO/IEC 27001 specifies requirements for establishing, implementing, maintaining and improving the ISMS in the context of the business of the organization (International Organization for Standardization, 2013a).

The standard is organized into seven distinct but complementary chapters (International Organization for Standardization, 2013a), has the following:

- Context of organization;
- Leadership;
- Planning;
- Support;
- Operation;
- Performance evaluation;
- Improvement.

Based on those chapters, the ISO/IEC 27001 provides a set of steps to assure a security program:

- Set the ISMS and its scope;
- Set the information security policy;
- Define roles and responsibilities;
- Develop an appreciation of the security risks;
- Manage the identification of risks;
- Select the controls to be implemented;
- Prepare the appropriate documentation, including a statement of applicability;
- Provide information security motorization and evaluation;
- Establish the needed improvement;
- Assure compliance.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The structure of this standard has in attention an implementation approach that could be understood as being based on PDCA (Plan-Do-Check-Act), also known as *The Deming Cycle*, comprising the following aspects:

- Plan - Establish the ISMS;
- Do - Implement and Operate the ISMS;
- Check - Monitor and Review the ISMS;
- Act - Maintain and Improve the ISMS.

The ISO/IEC 27002:2013 (Code of practice for information security controls) presents the set of good practices that organizations must follow to perform information security management, providing a list of controls that may be used in the framework of ISO/IEC 27001.

This standard has 114 security controls framed in 14 security control clauses (International Organization for Standardization, 2013b); each one organized in main security categories that group the controls, which is as follow:

- Information security policies;
- Organization of information security;
- Human Resource security;
- Asset management;
- Access control;
- Cryptography;
- Physical and environmental security;
- Operations security;
- Communications security;
- Systems acquisition, development and maintenance;
- Supplier relationships;
- Information security incident management;
- Information security aspects of business continuity management;
- Compliance.

The order that the clauses are presented in this standard has nothing to do with its importance, but with the circumstances of the application according to organizational security needs, leading to every organization that uses this standard can identify the applicable clauses their relevance and application to individual business processes.

The primary purpose of information security is, in accordance with this standard, to protect the information from a variety of threats, ensuring business continuity through the minimization of damage to the business for security incidents, seeking to maximize the return on investments and business opportunities.

This cycle includes the assessment of risks, implement controls for dealing with risks, monitor and review the risks, and maintain and improve the system of risk controls.

Harmonized with the stipulations in the main reference standards with regard to information security, in particular ISO/IEC 27002 and ISO/IEC 27001, the ISO/IEC 27005: 2011 (Information Security Risk Management) presents a set of guidelines that aim to enable a more efficient risk management in organizations, considering all aspects of risk management cycle of an ISMS. In the same topic, ISO 31000:2009

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Risk management) presents an approach that provides a wider risk assessment due to a focus to whole organization. Nevertheless, assuming that both standards could be used, ISO/IEC 27001expressly refers that the information security risk assessment and treatment processes must follow ISO 31000 principles and generic guidelines, however, this recommendation didn't imply the exclusivity of use.

In this sense, the ISO/IEC 27005 was especially developed to be used as a tool for business managers and information security professionals directly or indirectly involved with the development, implementation, operation, management, maintenance, revision and/or organizational continuous improvement of the ISMS, and should be implemented according to an approach by processes (International Organization for Standardization, 2011).

The structure of ISO/IEC 27005 is divided into 4 groups of guidelines that allowing in particular:

- The framework of the concept of risk to information security on an organizational context;
- The process of analysis and assessment of risk in the organization;
- The process of risk treatment and management, also as regards decision-making on the part of organizational management;
- Continued activities for risk management within the organization's ISMS.

While ISO/IEC 27005 is focused on risk management to information security, ISO 31000 relates to risk management to organization and provides principles and generic guidelines that can be applied to the complete lifecycle of an organization.

The structure of ISO 31000 is divided into two major directives: Framework and Processes. The framework focuses on the risk management and on organizational context, while Processes focuses on risk assessment and risk treatment and monitoring (International Organization for Standardization, 2009).

This standard presents a framework for risk management that uses the same principles of PDCA cycle to design, implement, monitor, review and continual improvement of the framework.

By 2008 was published the first edition of ISO 27799 (Health informatics – Information security management in health using ISO/IEC 27002), that provides guidance to healthcare organizations and other custodians of personal health information, on how to best protect the confidentiality, integrity and availability of such information by implementing ISO/IEC 27002 (International Organization for Standardization, 2008). Due to the extensive application of ISO/IEC 27002 for health informatics security management through several countries, namely Australia, Canada, France, United Kingdom, etc. this standard, the ISO 27799, complements the more generic standards as ISO/IEC 27002 or ISO/IEC 27001, applying, besides ISO/IEC 27002 controls, the PDCA model that supersedes those family of standards related with information security to continuously maintain the information security program.

This statement allows the application of same perspectives and studies, the majority of them based in ISO/IEC 27002 for instance, to information, and also to their supports, related with healthcare activities. The application of ISO/IEC 27002 controls – framed by ISO 27799, due its relevance and implantation in most organizations, constitutes an added value factor to a sector, like healthcare, where information protection isn't a major preoccupation, but something that must be done.

The standard ISO 27799 (2008) has the following chapters:

- Health information security;
- Practical action plan for implementing ISO/IEC 27002;
- Healthcare implications of ISO/IEC 27002.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, this standard provides a set of steps to implement a health information security program:

- Management commitment to implementing ISO/IEC 27002;
- Establish the ISMS (phase Plan of PDCA model);
- Implement and operate the ISMS (phase Do of PDCA model);
- Monitor and review the ISMS (phase Check of PDCA model);
- Maintain and improve the ISMS (phase Act of PDCA model);
- Appliance of guidance found in ISO/IEC 27002 to healthcare issues.

Nowadays, the actual version of this standard, dated from 2008, is under a review process to align with the new versions of ISO/IEC 27001 and 27002, published in 2013, with the expectations that will be published in 2016. In this sense, should be noted that there aren't expectations of huge changes between versions that imply substantial alterations in the practices to be adopted within healthcare sector related to information security.

In addition, should be considered the suitability of incorporating the recommendations made by the standard ISO/IEC 27005 (International Organization for Standardization, 2008a), particularly when the ISO 27799, in annex A, takes into account aspects relating to threats to the confidentiality, integrity and availability of health information assets, enabling an objective approach to the treatment of risk regarding information security.

The issues referenced by annex A of ISO 27799, in articulation with ISO/IEC 27002, are: Masquerade by insiders; Masquerade by service providers; Masquerade by outsiders; Unauthorized use of a health information application; Introduction of damaging or disruptive software; Misuse of system resources; Communications infiltration; Communications interception; Repudiation; Connection failure; Embedding of malicious code; Accidental misrouting; Technical failure of the host, storage facility or network infrastructure; Environmental support failure; System or network software failure; Application software failure; Operator error; Maintenance error; User error; Staff shortage; Theft by insiders; Theft by outsiders; Willful damage by insiders; Willful damage by outsiders; Terrorism.

INFORMATION SECURITY ISSUES

The problems inherent in the management of data (sorting, handling, storage, availability) and the management of information (production, sharing, and utilization) must, given the importance they possess now, be a constant organizational decision-makers concern.

In this matters, could be followed some recommendations made by Gaiveo (2011) that refer the importance of a proactive approach to information security requiring, from managers and people, new attitudes and a larger mutual aid that goes further than what were the usual day to day activities, particularly using the provided identification of ISO/IEC 27002 controls related with people and with information supports, which could be applied according to organization needs.

Security-related issues have increased relevance when there are large volumes of data or a large number of potential users, particularly when the shapes and tools for accessing these data are diverse and available.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Breaks in security arise habitually following the occurrence of disasters that may manifest themselves in various forms; may be natural (earthquakes, fires, floods, lightning) or unnatural (technological, manifesting itself in failures of systems, and human, appearing distinctly as undue access, theft, and/or sabotage).

The success of security measures depends on the organizational commitment of decision-makers and the involvement of people in pursuing its objectives, particularly when there is an information society where organizations depend on their information to fulfill their business strategies.

It should, however, be noted that the optimal solution to a problem of this kind must pass by a security policy that involves the whole organization in all its aspects. This does not preclude, that there may exist, it is even desirable, a classification on the basis of the levels of the criticality of the organizational information.

This way, and articulate with the legislation which provides the accounting framework for public administration and the diverse normative applicable, it is important to carry out a regulatory framework for information security. That framework must seek to establish the appropriate mechanisms for safe and effective use of accounting information arising from the activity of the institutions. This could be done by assuming reference standards that are able for performances of excellence to the development of an information society more inclusive in all aspects, involving the public and private sectors in a partnership of national development.

Besides to the usual threats and vulnerabilities (and consequently risks) that any information is subject, this type of information is often the target of greatest attention, requiring the strengthening of preventive measures and a greater awareness of their protection.

In this sense must, therefore, be established a set of aspects to consider as deserving of special attention, namely: people, vulnerabilities, threats, attacks, risks.

From this, emerges the need of understanding security concepts like vulnerabilities, threats, and risk, as well the people involvement and responsibilities in security matters, and even security requirements to support information security policies definition according to specific needs of the healthcare sector.

Involvement and Responsibility of Individuals

Nowadays, the main challenges are related to people and with the ways that they act in societies, organizations, considering personal, social or institutional relations. Moreover, considering information as the main asset of organizations elicits the need to strengthen the protection of information and consequently assure information security according to legal and normative framing, in order to provide their appropriate usage to support business activities.

In the current social context, all organizational functions play an essential role in the activities of business, no matter if are functions directly related to the business, or if are supporting functions only.

Compete with the demands of new markets and customers is not possible without the involvement of all organizational levels as a unified structure that should function in an integrated and coherent way.

The information has come to impose its presence on all organizational levels, becoming a feature of extreme relevance for most of the organizational functions.

Commonly referred as the weakest link in matters affecting the security of information systems and technologies that support the flow of information, people represent an important organizational resource.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

How people react to change their behavior to using ICT, particularly those affecting their everyday activities, largely depends on the dissatisfaction at several levels, whether for reasons of adaptation and organizational culture or even incompetence, conducting to not acceptance of the rules.

In this context, financial and accounting functions use information which, by its relevance and criticality, must be protected to ensure its confidentiality, integrity, and availability. This observation implies the existence of an information security policy that is appropriate to ensure the privacy of such information.

In an organization, successful information security results from a balance between three distinct issues: organization objectives; risks; and, security measures costs (Smith, 2013).

Another aspect to consider relatively to the involvement of people is linked to the so-called "social engineering," that combines technical skills with the attitude of pretending to be someone that the attacker is not to harm or damage organizational assets (Smith, 2013).

The involvement of people in institutional activities soon reveals the importance of its appropriate framework for these activities and their attitudes towards the information they use. These visions are corroborated by Whitman and Mattord (2010), to whom "people are the most critical link in the information security program" (p.15), what allows the assumption that is crucial the raising of awareness of information security and potential organizational impacts arising from these situations.

On the other hand, it is equally important to provide adequate training on the organizational strand, looking for a greater involvement of people in the use of organizational resources to enhance their performance.

The pursuit of these objectives relating to the persons, as for the most of the activities related to organizational security, obliged to a clear and unambiguous commitment of top management, thus making clear an involvement at all organizational levels in the activities essential to the development of institutional activities.

The involvement of people in these activities is crucial to the success of the safety objectives defined for the organization mainly due to the fact that, in the contexts referenced, people and information have become fundamental assets in business organizations by allowing them to respond adequately and timely to the new requirements of the information society.

Then, according to Dark (2006), considering people as the first line of defense in terms of security, organizations need to provide awareness raising, education, and training in this area.

The role of people assumes new scopes, including the use of information and guarantee information security of business, boosting its full use by the organization in accordance with the needs identified in the conduct of its business activities.

This is so much serious when attacks come from internal sources, mainly because inside attackers have special access to valuable assets, i.e. they have almost direct access to the resources needed to perpetrate the attacks (Smith, 2013).

The need to ensure the confidentiality and reliability of the information were always constant since the dawn of humanity, which varied according to the way of sharing such information (including its acquisition and treatment).

The universe of general sharing of the information available was initially very low (the family). With the human evolution, gradually extending to the present day, the sharing of information is quite unlimited by the access to existing technologies and the capacity for its use.

Emerges thus strengthened the indispensability of assume people's relevance in the context of information security, and simultaneously encourage a greater awareness of this type of problem. Because

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

people are frequently referred as the weakest link in any security matter, is crucial that, according to Merkow and Breithaupt (2014) "that a security program address user education, awareness, and training on policies and procedures that affect them" (p.72).

Vulnerabilities, Threats and Security Risks

There is often confusion between fundamental concepts in information security (vulnerabilities, threats, risks) that matter to specify and to frame.

Organizations face some difficulties when trying to define what information should be protected and what level this protection must achieve. Is the definition of the risk associated with the likelihood and potential damage that allows support options necessary for the framing of the definition of security policies and ISMS.

Vulnerability can be seen as a weakness or flaw in a system that exposes information assets to attack or damage (Whitman & Mattord, 2011), or, according to Smith (2013), "as a weakness in the boundary that protects the assets from the threat agents" (p.12), which allows to assume that vulnerabilities are weaknesses in the systems, which can be exploited by the threat materializing. In the same sense, Workman *et al.* (2013) assume that "vulnerabilities represent the potential to exploit systems and information" (p.55).

As examples of vulnerabilities can refer:

- **Related to People:** Absences; death; insanity; competencies; only one; ethics; errors; sensitivity; communication;
- **Related to Equipment:** Malfunction; power failures; portability; depreciation;
- **Related to Information:** Portability; format; limited life; single; legal compliance.

Threats are events that can lead to potential damage and cause undesirable effects

The source of threats could be internal or external and are linked to the vulnerabilities of a system, what means that the exposures of those vulnerabilities are strongly linked with the threatening agents (Workman *et al.*, 2013).

Whereas the likelihood that a given threat exploiting a given vulnerability successfully is estimated by the opportunity and motivation of the source of the threat or by methods which lead to this exploitation, while the impact of a successful exploitation is estimated by examining the effects of exploitation may have on confidentiality, integrity and availability of the system and the data it processes (Bowen *et al.*, 2006).

Risk may also be defined as the potential of a threat to harm or damage people or assets (Workman *et al.*, 2013), as the negative impact of performance on a vulnerability considering the likelihood and the impact this occurrence (Stoneburner *et al.*, 2002), or as the probability that a particular threat to exploit a particular vulnerability (Peltier, 2010), or even the potential situation that threat the assets (Smith, 2013).

Risk can then be defined as potential losses incurred by a business, as a result of an unwanted event that can turn into losses in business or even interruption.

Risk, in a formal sense, corresponds to "danger; the possibility of being in danger", however, in terms of business, has two aspects that must be specified. The first part is directly related to the business and essentially depends on customers and competitors. The other strand relates to business support tools and activities that are related specifically to information, i.e. with its safety in relation to the risks which could affect it.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The difficulty to fully understand the concept of risk is inherent in the uncertainty, and, according to Workman *et al.* (2013) occurs when a known or unknown vulnerability is associated to a corresponding threat.

In risk determination, Merkow and Breithaupt (2014) consider that are two main factors to attend, being firstly the consequences of losing an asset and secondly the likelihood of that occurrence. According to the same authors, both factors must be identified and graduated, also giving an example (p.26) that frames likelihood between "rare" and "almost certain", and consequences between "insignificant" and "catastrophic."

Usually, the risk is the product of three factors: Threat, Vulnerability, and Value of the asset. In this sense, Merkow and Breithaupt (2014) note that "a risk is real when there is a presence of a threat, a vulnerability that the attacker can exploit, and a high likelihood that the attacker will carry out the threat" (p.72).

Risk management is defined as coordinated activities to direct and control an organization with concern to risk (International Organization for Standardization, 2009), which is achieved through the application of management policies, procedures, and practices.

The management of risk can be understood as the main security management issue (Workman *et al.*, 2013), in which context the risk management process is the assessment of information security risks, being this appreciation required to understand the security requirements of the business information, and risks to the organization's business assets.

The appreciation of the risk must identify, quantify and prioritize risks against acceptance criteria of risk and the relevant objectives for the organization, and the results obtained used to guide and determine priorities and appropriate management actions for the management of information security risks as also to support the implementation of selected controls that provide protection against these risks (International Organization for Standardization, 2013b). It is still referred the need of the valuation of risk that includes a systematic approach to estimating the magnitude of risk (risk analysis), and the process of comparing the risk estimated by the criterion of risk, to determine the relevance of risk (risk assessment).

In this context, Workman *et al.* (2013) refers "risk assessment as an ongoing process of identifying risks and threats" and risk management as "the ongoing process of implementing measures according to the costs and benefits associated with risks and security countermeasures" (p.105) incorporating also strategies and measures to recover from attacks.

From Smith (2013) perspective, risk assessment process has two separate activities, one corresponding to the identification of risks, i.e., how they arise and attack the assets, and the other related with the prioritization of risk by looking for the likelihood of occurrence and impact on the assets. To the author, those activities are performed through "five steps: Identify assets; Identify threat agents and attacks; Estimate the likelihood of attacks; Estimate the impact of attacks; and, Calculate the relative significance of attacks" (p.19).

According to ISO/IEC 27002 (International Organization for Standardization, 2013b), the valuation of risk (or risk assessment) includes a diverse set of activities and actions, among which are:

- Identification of the assets;
- Identification of legal and business requirements that are relevant to the identification of the assets;
- Valuation of assets identified, taking into account the legal and business requirements that are identified, and the impact of the loss of confidentiality, integrity and availability;
- Identification of vulnerabilities and significant threats to the assets identified;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Evaluation of the likelihood of occurrence of a vulnerability or threat;
- Calculation of the risk, namely its potential impact estimation.

The risk management process will comprise a number of aspects to monitor, in particular (International Organization for Standardization, 2013b):

- Avoid the risk;
- Transfer the risk;
- Reduce the vulnerabilities;
- Reduce the threats;
- Reduce possible risks;
- Detect unexpected events, react and recover;
- Accept the risk (residual).

Relatively to the processing of risk, organizations must decide in advance the criteria for determining when the risks are acceptable or not (International Organization for Standardization, 2013b). After that, for each of the identified risks following the appreciation of the risk, it is necessary to make decisions about the treatment of risk.

As a component of risk management, risk mitigation starts, according to Workman *et al.* (2013), with the identification of assets and this valuation. Those assets include systems software and information that must be evaluated to reflect their relevance to business activities.

Identification and Specification of Security Requirements

Acquire, select, store and share data depends mainly from the technological capabilities available and usable by the organization and also from people's capacities to use organizational resources to manage information. In this sense, produce, manage and share information depends crucially on the adequacy of the available technologies and human resources capacity in their use for the benefit of the organization. Already the creation and sharing of knowledge depend on the skills of human resources at the service of the organization.

If the development of new technologies facilitates the access to information, enabling a broader diffusion by all business partners, people involvement is a critical success factor to increase the accomplishment of information usage in business activities.

However, the success of information sharing is directly associated with the capacity of information support to respond to the organization's needs.

Information flows, supported by information systems, traverse not only the value-chain of the organization but also those of its partners, imposing the adequate skills and competencies to deal with it in order to increase the creation of value for all stakeholders that are involved. Thus, sharing information is not only within organizations but also among business partners.

Have data to produce information relevant to support activity and provide this information when it is needed and in the proper format, requires technological support, but also human resources with the necessary skills and knowledge.

The identification of security needs depends firstly on the intrinsic characteristics of each organization, but also of the resources involved, in particular of persons in its various organizational levels.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This situation implies, however, identifying and classifying assets to protect, so as to enable the measurement of the effectiveness of options set to ensure the protection of these assets, and take the necessary measures to avoid or minimize potential threats to which they may become subject.

A clear specification of fundamental assets for organizational activities constitutes the basis for the establishment of adequate security policies to the reality of each organization.

Showing a perspective in the context of the necessary resources for developing and implementing security policies, Weaver, Weaver, and Farwood (2013) classify assets into four types:

- **Physical:** Equipment and buildings of the organization;
- **Data:** Databases, personal records, customer information and other data stored;
- **Application Software:** Server programs, security programs and other applications used in communications of organizational activities;
- **Personal:** People who work in your organization, customers, business partners and subcontractors that contribute to the organization.

Whereas this engaging, Peltier (2010) refer that, in order to be effective, the analysis process should be accepted as an integral part of the business process of the organization, stating that the risk analysis should seek the organization's business needs and establish safeguards to address these needs.

The identification of information assets to protect, the specification and characterization of the vulnerabilities that those assets are exposed, as well as also the identification of potential threats that could exploit those vulnerabilities, are fundamental aspects of an assessment of the risks that such assets are subject.

In this situation, the selection and characterization of the relative weights of each component is an essential factor for the adequate perception of the organizations regarding the relevance and impact of each threat.

Any approach to information security needs to deal with uncertain, and the culture and organizational environment, situation that leads to a real understanding of the particularities of each institution, mainly because: asset identification and classification, identification of threats/vulnerabilities, and risk assessment are specific, i.e. there have not an identical solution for all, by that, these activities shall be made according to the specificity of each organization.

That assumption reinforces the need of having guidance to fulfill information security requirements, essentially when ISO 27799 identifies threats to health information assets but didn't present asset classification, vulnerabilities likelihood, neither risks assessment. According to those issues; this is a situation that makes difficult their full applicability to a large part of information security policies.

A possible solution is provided by ISO/IEC 27005 that shows same examples that could be applied to information security in the healthcare sector, providing a risk assessment that is a crucial aspect in the context of information security, enabling a proper guiding of the resources given to assets that must be protected.

However, also, ISO 31000 could be applied to provide a must wide-ranging approach to risk assessment that involves all organization, and all its activities, instead of the simply emphasis in information security.

In this context is not important what standard is selected to apply, because both can be used to support security requirements and both can be applied to all type of organizations, no matter what dimension they have.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Definition of Information Security Policies

According to Merkow and Breithaupt (2014), information security measures try to address at least one of three goals- that are considered the basis of all security programs. These are: "Protect the confidentially of data; Preserve the integrity of data; and Promote the availability of data for authorized use" (p.20).

Information security can generally be understood as the set of measures that constitute security policy, by which the organization must determine which assets may be materially affected, i.e. define what the value of an asset is.

In this context, the policy is a "set of organizational guidelines that dictates certain behavior within organizations" (Whitman & Mattord, 2010, p.14), a situation that puts the focus of the information security in people and their attitudes when dealing with information. On the other side, Smith (2013) refer to information policies as security requirements, i.e., as the description of the protection that organizations need.

The information security policy, in accordance with the codes of good practice, is supported by a document that should be known by all employees of the organization (International Organization for Standardization, 2013b). This document shall contain:

- The commitment of management;
- The definition of what is meant by information security;
- The description of policies;
- The definition of responsibilities for information security;
- References to support documentation.

Another perspective on security policy refers to it as a high-level plan that outlines the objectives of these procedures, defining the details of implementation policies, i.e. providing a description of security in general (Barman, 2002).

In this sense, assuming a policy as a high-level declaration that should be as brief and concise as possible, there must be no doubt about the intention of this policy.

To meet the security requirements specified for an organization, a good policy must:

- Be easy to understand;
- Be applicable;
- Be amenable to implementation;
- Be proactive;
- Avoid absolute terms;
- Meet business objectives.

On the other hand, it is important to consider the aspects linked to security checks, considering the legal implications and best practice to use.

Relatively to controls with legislative implications, can be identified the following (International Organization for Standardization 2013b):

- Intellectual property rights;
- Safeguarding of organizational records;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Protection and privacy of data of personal information.

In regard to the control of good practice, the following deserve special relevance (International Organization for Standardization 2013b):

- Information security policy document;
- Allocation of responsibilities in information security risks;
- Training and education in information security;
- Reporting of security incidents;
- Business continuity management.

In this context, before security policies being written, it is necessary to determine the general objectives, namely what business activities should be protected, or whether such protection should serve only the data flows or the information systems, where the first step is to determine what should be protected and why (Barman, 2002).

The information security policy is supported by a document that should be known by all employees of the organization, and it specifies the management commitment, what organization understands as information security, what are the policies, who are responsible for information security, and also related documentation, as referred by International Organization for Standardization (2013b).

Solutions and Recommendations

The understanding of the relevance of information in the development and performance of organizations depends, in essence, of the understandings that the key decision-makers have about it and of their articulation with the organizational culture.

If we consider that the organization is competing in a global environment where information is acquiring greater relevance, the decision about choosing among the panoply of information at the disposal of organizations can make a difference in terms of performance, because the value creation depends more on the use of information than on the information systems and ICT that support it.

The economic and social consequences resulting from unemployment and low training on the use of nowadays tools (mainly based in information systems and ICT), may be proved catastrophic for the development of organizations and society, many times contributing to widen the gap between the more developed countries with stronger economies.

This results in a reduced ability to withstand competition from global enterprises and major inequalities that are brought by the emergence of a society that is based on the information.

The permanent learning depends in large degree of all involved and interested in their own processes and their adequacy to the culture and organizational goals.

The connection of people to organizations relates closely with the ability that they have to meet the needs and desires of human capital. There are thus not only implied compensation issues, a factor often seen as the only one relevant to limit individual performances, but also social situations and self-esteem, seeking the development of people in all its aspects.

The organizational culture and the organization's ability to respond to the people aspirations constitute the foundations of connection that is needed between people and organizations, with the search for balance between needs.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Human resources or people have only to do with the framing in various areas of analysis. Human resource if the scope is restricted to working relationships, people if is considered a broader social and professional environment.

In a matter of security, particularly in information security, people are the final component but are indeed the most important one. This statement assumes a wider relevance, because people are present in every activity related with healthcare; as end-user of information systems and ICT, as patients, as medical or administrative staff, or even as suppliers of equipment or medicines, essentially because all of them deal with information.

In this sense, Wallin and Xu (2008) states that "information is a valuable asset in the information society, particularly in the healthcare sector where access to patient information is one of the most important factors for safety and quality" (p.13), referring that patient information, being sensitive, must be classified as confidential.

It is also important to take care about those that deal with patient's information during their normal activities, essentially because people deal with huge amount of information that must be confidential, integer and available.

The sensitivity of information that remains available, by information systems and ICT usage, and is frequently accessible by people in organizations, implies a proper approach to the measures that must be taken to protect it. To control accesses and handling only by authorized user when needed, it´s important, according Gaiveo (2011), to understand the relations that occur between information, people and security.

When the amount of personal health information is growing in all segments of healthcare (Wallin & Xu, 2008), it is important to assume that the need for support the creation, store and exchange of that information is an organizational imperative. By that, one of the main problems with healthcare become information systems that are currently used, is the storage of information in different formats, because some are open and other proprietary.

This diversity of formats is a serious impediment to sharing of information between all those involved, and may even become a critical factor in the protection of shared information due to vulnerabilities that originate the necessary integration between different systems.

Being "the main purpose of information security in healthcare is mainly to achieve two important aims: high-leveled patient safety and patient privacy" (Wallin & Xu, 2008, p.14), it's important to achieve a high level of patient safety in order to provide him/her with the best care as possible, using in the appropriate ways their information.

The needs of organizations in the establishment of an information security policy can be mitigated by the use of international standards for safety of information previously submitted, whereas a set of complementary activities is:

- **Identify and Classify Assets:** Achieved by using Annex B (Identification and valuation of assets and impact assessment) of ISO/IEC 27005 (International Organization for Standardization, 20011), that specify assets in primary and supporting. Primary assets are: Business processes & activities, and Information, while supporting assets are: Hardware (desktops, tablets, etc.), Software (applications, system, etc.), Network (switches, bridges, etc.), Personnel (end users, developers, helpdesk staff, etc.), Site, and Organization's structure;
- **Identify and Typify Threats:** Provided by Annex A (Threats to health information security) of ISO 27799 (International Organization for Standardization, 2008), but shouldn't be restricted to it, being a good option take into account threats source, in a similar way that is done in ISO/IEC 27005

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in their Annex C (Examples of typical threats), that presents threats by type, namely: Physical damage, Natural events, Loss of essential services, Disturbance due to radiation, Compromise of information, Technical failures, Unauthorised actions, and Compromise of functions;

- **Identify Vulnerabilities that Could Be Explored by Threats:** Done by applying Annex D (Vulnerabilities and methods for vulnerability assessment) of ISO/IEC 27005 (International Organization for Standardization, 2011), that presents vulnerabilities and threats that could explore each one. The examples of vulnerabilities versus threats are presented by type as: Hardware, Software, Network, Personnel, Site, and Organization;
- **Establish a Risk Assessment:** Through the Annex E (Information security risk assessment approaches) of ISO/IEC 27005 (International Organization for Standardization, 2011). With the aim of make the risk assessment according to the likelihood of occurrence of threat and ease of exploitation, taking into account the value of assets and business impact, in order to rank the threats by measuring the risks;
- **Planning and Implementing a Security Policy:** What should be done by applying ISO 27799 (International Organization for Standardization, 2008) guidelines, the same that are provided by ISO/IEC 27002, but within the specification of healthcare information security issues.

Besides that, controls presented by ISO 27799 contain modifications related with healthcare comparatively to ISO/IEC 27002 controls. Being necessary that, in addition to following the guidance given by ISO/IEC 27002, health organizations should follow the specific controls and implementation guidance provided by ISO 27799.

From that, emerges that those standards, and the appropriated application of their annexes, constitutes a fundamental resource that, jointly with ISO/IEC 27001, and also with ISO/IEC 27002, are fundamental to any information security program that intends to implement an ISMS.

CONCLUSION

In fact, no matter what experience people have about security or even what kind of security policies are in place; what seems to be undeniable is that information and its support require new attitudes and approaches to deal with the new contexts that are on the top of common preoccupations.

This need to ensure the security of business information is something that often is not the target of attention of organizational leaders. When the information it is assumed as an important organizational resource, business information can make the difference in the acquisition of competitive advantages and boosting the development of organizations.

All this context makes obvious the role of individuals in the performance of organizations, particularly when of those depends on the proper use of resources to respond appropriately to new business requirements. Before the biggest competitive demands that organizations face, where the information seems to emerge as a feature of considerable value and indispensable in the various organizational environments, people provide the skills and knowledge appropriate to the acquisition of competitive advantages for organizations.

The attraction of attention to the various organizational requirements in terms of business activities, is only achievable if the attention is given to the various kinds of information that the organizations utilize in their day-to-day routine; while ensuring their confidentiality, integrity, and availability according to the specific needs of the organization.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Moreover, supporting information flows within the organization and between this organization and its business partners; the information systems and ICT should be the target of similar attention of organizational leaders, including the safety aspects considered in terms of policies definition and their implementation in the organization.

Note that security concerns must be considered in a holistic manner, in order to incorporate into the organizational culture, looking for so that all actors in the organizational activities are sensitized about their relevance to the activities developed by the organization.

In this context, the creation of a climate of confidence is crucial to the pursuit of such activities. Essentially on the assumption of a responsible environment involving, as stakeholders, all participants in organizational activities, regardless of their placement are internal or external to the organization.

Any solution adopted by organizations in these areas will involve people as active parties, ensuring that the information security policies correspond to the needs of different stakeholders respecting the organizational culture and the applicable legislation. This strand is indeed a fundamental angle in the success of security measures to be adopted by organizations, seeking thus to avoid overrunning of the controls that are implemented according to specified requirements.

Together with this, organizations should apply the recommendations contained in the information security standards such as ISO/IEC 27002, to be used simultaneously with the other standards of series ISO/IEC 27000, that should be applied in conjunction with specific standards such as ISO 27799 in the context of information security in the healthcare sector.

These recommendations, jointly with the identification of potential threats that can take advantage of vulnerabilities in terms of information security, should allow the implementation of security policies, but also the raising of people awareness about the problem of information security, ensuring the protection of information in an appropriate manner to the needs of people and organizations.

Chapter 85
The Politics of Establishing ICT Governance for Large-Scale Healthcare Information Infrastructures

Gro-Hilde Ulriksen
University Hospital North Norway, Norway

Rune Pedersen
University Hospital North Norway, Norway

Gunnar Ellingsen
Arctic University of Norway, Norway

ABSTRACT

In Norway, the focus on interoperability and communication across healthcare practices has increased the need to connect ICT portfolios at different levels of healthcare, into large-scale information infrastructures (II). Governing healthcare practices is exceptionally complex, due to the diverging goals and policies of the heterogeneous actors involved. Establish well-functioning ICT governance organizations to handle these large infrastructures is therefore important. Using information infrastructure theory, and governance literature from the IS field, this paper contributes with empirical insight to the longitudinal and political process of establishing ICT governance in a healthcare context, reporting from one of Norway's largest health ICT projects, situated in the North Norway Regional Health Authority in 2012–2016. Our focus was on the following research questions: How does organizational politics shape the process of establishing an ICT governance organization in a heterogeneous healthcare environment, and what does it take to establish such ICT governance organization?

INTRODUCTION

Standardization of technology and work processes, to reach seamless integrations and semantic interoperability in Norwegian healthcare, has gained increased focus over the last years. The growing need for inter-organizational collaboration (Croteau, Bergeron, 2009; Dahlberg & Helin, 2014) and communication has raised the need for regional information and communication technology (ICT) portfolio. The role of the EPR systems, moving from local information storage systems, to large-scale user-centered work tools, has been particularly important. Consequently, the ICT portfolios have expanded in size and complexity. Hence, well-functioning ICT governance organizations at different levels of healthcare practices has gained increased focus. ICT governance include how to design and implement effective organizations by creating flexible ICT and information system (IS) structures and processes (Patel, 2002). The overall goal is for governance organizations to ensure successful deliverance of healthcare services (Beratarbide & Kelsey, 2009). There are increasing evidence related to establishing a connection between well-organized governance of health care organizations, and improved organizational performance (Tabish, 2012). However, hospitals and health systems struggle with matters of governance, particularly related to care standardization, and quality improvement (Tabish, 2012).

When making an effort to regionalize and standardize ICT portfolios, ICT governance organizations are important for maintaining the regional focus and handling challenges along the way. Traditionally ICT governance organizations were run in a top-down manner (Weill & Ross, 2004), this has however rarely proven efficient or successful for heterogeneous healthcare practices (Constantinides & Barrett, 2014; McGinnis, 1999). Therefore, a pressing need for shifting to a more bottom-up governance structure, focusing on the dynamic interactions between technical and social elements in ICT design (Constantinides & Barrett, 2014) has raised. Given the increased ambitions of information sharing, healthcare is characterized as institutions with different goals and policies, different ICT portfolios in play, and, stakeholders with different interests. Hence, it is necessary to look at the complexity of ICT governance, and the challenges of governing ICT portfolios at regional levels of healthcare. Introducing inter-organizational governance is an attempt to overcome the lack of interoperability and standards in healthcare (Dahlberg & Helin, 2014).

The contribution of this paper is to provide empirical insight to the longitudinal and political process of establishing an ICT governance organization within a healthcare context. Based on this, we ask the following research questions: How does organizational politics shape the process of establishing an ICT governance organization in a heterogeneous healthcare environment, and what does it take to establish such ICT governance organization?

We have gathered our empirical data, by following the steps of a regional initiative in the North Norwegian Health Authority. In 2012, this health region completed a large tender, and decided to regionalize their new ICT portfolio. To carry out these changes they established a regional project (dubbed BigProject), to run from 2012-2016. BigProject was one of the largest ICT investments in Norwegian healthcare, and the main goal of the project was to establish a regional ICT portfolio as a foundation for regionally standardized patient pathways, decision support, and integrations between clinical ICT systems (Christensen & Ellingsen, 2013). A regionalization, including standardizing EPR workpractice, was necessary requirements for reaching such goals, and for enabling the Health Authorities to better administrate and compare the hospitals in the region. In addition, the BigProject worked in close collaboration with the largest EPR vendor in Norway, on developing a more structured and interoperable EPR system, in order to communicate across heterogeneous healthcare practices (Nasjonal-IKT, 2012).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The data was collected by using a qualitative interpretive method (Klein & Myers, 1999; Walsham, 1995), including open-ended interviews, document studies, and participation in meetings and workshops. Through this approach, we aimed to emphasize various viewpoints of the process in order to achieve a deeper understanding of the challenges detected.

Theoretically, we applied information infrastructure theory; see (G. C. Bowker & Star, 2000; Hanseth & Lyytinen, 2010; Hanseth & Monteiro, 1998; Hanseth, Monteiro, & Hatling, 1996; Star & Ruhleder, 1996) frequently used to characterize and analyze large-scale integrated information systems portfolios (Garrod, 1998; Meum, Monteiro, & Ellingsen, 2011), and the interconnection between users and technology in heterogeneous healthcare practices (Hanseth & Lyytinen, 2010; Hanseth & Monteiro, 1998). We also used ICT governance literature from the information systems field; see (Beratarbide & Kelsey, 2009; Brown, 1997; De Haes & Van Grembergen, 2005; Simonsson & Johnson, 2005).

The rest of the paper organized as follows. First, the theoretical framework is introduced. Next, we present and elaborate on the method. Further, the case, including the BigProject and the new EPR is describe. We then present a discussion, emphasizing on different governance perspectives, and methods of structuring an ICT governance organization, aimed at managing large-scale information infrastructures. Last, we conclude the paper.

THEORY

The goals of integrated care, evidence-based treatment and standardized patient pathways have led healthcare organizations to invest heavily in integrated ICT systems (Chantler, Clarke, & Granger, 2006; Chiasson, Reddy, Kaplan, & Davidson, 2007; LeRouge, Mantzana, & Vance Wilson, 2007). Accordingly, we are not dealing with just one system, but instead with a portfolio of interconnected systems across institutional, departmental, and professional boundaries. As a way of conceptualizing this idea, the notion of information infrastructure (II) is particularly useful (G. Bowker, Timmermans, & Star, 1996; Ellingsen, Monteiro, & Munkvold, 2007; Star & Ruhleder, 1996; Timmermans & Berg, 2003). From a technical viewpoint, assembling an II involves designing, implementing, integrating, and controlling increasingly heterogeneous ICT capabilities (Tabish, 2012). Socially, creating an II requires organizing, and connecting heterogeneous actors with diverging interests, in ways that allow II to grow and evolve. Furthermore, IIs are heterogeneous, and open to an unlimited number of participants, such as users, vendors, and technical components (Hanseth & Lyytinen, 2010; Hanseth & Monteiro, 1998), which is important for use in a healthcare setting. A particularly important concept is the installed base (Hanseth & Monteiro, 1998), which implies that an II never develops from scratch, but emerges and evolves from an existing installed base. When developing new EPR systems, considering the old portfolios and practices in Health Trusts is important. For the different parts of an II to communicate, standards are core elements (Hanseth & Lyytinen, 2010). Standards ensure high-quality care through best practices development (Timmermans & Berg, 2003), increased efficiency, as well as ensuring seamless patient trajectories over organizational borders (Pedersen, Meum, & Ellingsen, 2012).

A pressing question is how and to what degree an II in general and standards in particular can be managed at different levels of healthcare. In the II literature, several authors; see (Edwards, Bowker, Jackson, & Williams, 2009; Karasti, Baker, & Millerand, 2010; Pipek & Wulf, 2009), have used the notion of infrastructuring, in order to emphasize the proactive engagement with large ICT portfolios. These insights are relevant for understanding the mechanisms for change; however, there has been less

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

focus on the more formal governance of organizational structures and configurations of II's. There is an increased need to establish ICT governance organizations that make decisions, as well as monitor results, and performances (Beratarbide & Kelsey, 2009), at different healthcare levels. Our focus in this paper is on interorganizational ICT governance at a regional level.

Most information systems had in-house ICT governance until the mid-1990s. Therefore, ICT governance has often been applied from an internal perspective (Boynton, Jacobs, & Zmud, 1992; Brown, 1997; Brown & Magill, 1994; Sambamurthy & Zmud, 1999). It is thus challenging to establish regional interorganizational ICT governance. ICT governance specifies the decision rights and accountability framework to encourage desirable behavior in ICT usage (Weill & Ross, 2005). We adhere to the following definition of ICT governance: "The preparation for, making, and implementation of decisions regarding goals, processes, people, and technology, on a tactical and strategic level of the IT organization" (Simonsson & Johnson, 2005). Stars and Ruhleder (1996) stated that the configuration mechanisms of governance are typically a mixture of various structures, processes, and relational aspects (Star & Ruhleder, 1996). Implementing ICT governance contributes to ensure successful delivery of healthcare according to Beratarbide & Kelsey (2009). The overall goal of an ICT governance organization is "to assure the stakeholders that things will go as expected, and ensure the successful delivery of healthcare services" (Beratarbide & Kelsey, 2009). Many ICT-related management frameworks, methodologies, and standards are used today; see (Beratarbide & Kelsey, 2009; Van Grembergen, De Haes, & Guldentops, 2004). None forms a complete ICT governance framework, but all have a role in assisting organizations towards more effectively managing and governing their information and related technologies (Beratarbide & Kelsey, 2009), as well as identifying ICT governance weaknesses.

Previously, a top-down approach with a clear ICT governance structure defining necessary decisions, and who should make them, was frequently used (Weill & Ross, 2004). Management studies promoted this design based on pre-defined models of work practices see, for instance, (Ashkenas, Ulrich, Jick, & Steve, 2002; Davenport, 1993). However, such strong controlling ICT governance for defining and making decisions (Weill & Ross, 2004), has been ineffective, and even impossible to apply to II in healthcare (Constantinides & Barrett, 2014). Several actors on the clinical and technical sides of healthcare need to be included in such governance. Due to the constant growth in complexity and deviation from original intentions, an II is impossible to govern completely in a top-down fashion (Croteau & Bergeron, 2009; Hanseth & Lyytinen, 2010).

In interorganizational contexts (such as in our case), Van Grembergen et al. (2004) suggest that ICT governance should include cooperation mechanisms to improve coordination of stakeholders with different ICT backgrounds (management and governance histories), and competence (ICT assets and resources) (Dahlberg & Helin, 2014). This because interorganizational relationships mature dynamically, and collaboratively, over various states (Croteau & Bergeron, 2009). The purpose of such governance is to ensure that organizations like Health Trusts have structures, processes, and mechanisms for collaboration, resolving disagreements, and organizing work on the interorganizational and organizational levels (Dahlberg & Helin, 2014). Improved quality and more interoperable health information is necessary, but very challenging to match with ICT governance principles and benefits in large scale interorganizational IIs.

However, despite establishing cooperation mechanisms, the size and scope of an II may be a serious challenge to ICT governance. Heterogeneous stakeholders have different goals and strategies for reaching them, resulting in frequent tension. This is particularly evident in a healthcare context. As a result, regionalization processes may be extremely challenging to accomplish. An obvious challenge is the tension between standardization and flexibility, recognized by Hanseth et al. (1996). However, flexibility

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

is necessary at the local level of a healthcare II, which enable users to work efficiently. In contrast, the regional perspective emphasizes a need for standardization, and the ability to compare different units as a part of running a more efficient and cost-effective healthcare services. In this regard, Constantinides and Barrett (2014) suggest a polycentric governance approach in which different stakeholders are engaged in dynamic and adaptive governance processes (Constantinides & Barrett, 2014).

Polycentric governance includes organizing a number of governing units at diverging levels, instead of one monocentric governance unit (McGinnis, 1999). In such governance model, there is a distribution of decision-making across organizational layers, and among a broad range of stakeholders, where each layer deals with associated subjects at a gradually larger scale and less-detailed level (McGinnis, 1999). This way, different actors in an II (such as a Health Trust) participate in ICT governance by controlling parts of an ICT portfolio. Consequently, this may lead to a smoother regionalization process in which the actors do not need to give up all local control. One key advantage of polycentric governance is the possibility of creating general formed rules that can later be adapted to specific local needs (McGinnis, 1999).

However, this model does not represent a "fast track to salvation;" it requires that actors spend extensive time and energy on negotiating and compromising on acceptable collaborative solutions (Latour, 2005). Even in cases where a common forum is established, it may be impossible to agree on governance structures acceptable to all parties, because of the heterogeneity of interests and resources involved in healthcare IIs (West, 2007). In order to grasp the challenges of governing information infrastructures, it is crucial to understand the various interests and associated mechanisms and how they play out over time (West, 2007).

METHOD

This study is positioned within a qualitative interpretive paradigm (Klein & Myers, 1999). It contributes to a longitudinal qualitative study connected to a large-scale EPR project in the Northern Norway Regional Health Authority. Analysis of longitudinal research is a continuous and iterative process, with an ever-changing intensity, focusing on developing and increasing the understanding of a phenomenon, by exploring diverse viewpoints within a specific context (Klein & Myers, 1999; Walsham, 1995).

This North Norwegian Health region consists of five Health Trusts including 11 hospitals. The regional EPR project (BigProject) has 25 employees and 5 sub-projects, of which two focuses on ERP. We interviewed participants from Health Trusts, local and regional management organizations, Regional Health Authorities, and BigProject to establish different viewpoints of the regional processes. Since regional standards had not yet been implemented in the Health Trusts, interviewing physicians and other end-users was not required at this point. Their perspectives will be more important to enlighten after completing the implementations of standards in 2015–2016.

The fieldwork builds on the first author's role, working in the standardization of practice project for two years, in addition to participating in workshops, discussions, and meetings in this project, and also the development of the new EPR. The data collection includes 11 open-ended interviews conducted in 2014–2015. Except from one, all the actors asked agreed to be interviewed. The interviews lasted 60–120 minutes each. The interview guide was semi-structured with questions related to the standardization of practice projects. This included pros and cons of standardization, why regionalization is important, and what regional challenges remain after the projects are finished. There were also questions concerning challenges with establishing and organizing a regional ICT governance organization.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Overview of interviewed participants

Informant	Time	Background
Four informants from BigProject	60–90 min	Laboratory, nursing, health secretary, technical
Three informants from regional ICT management	60–120 min	Technical, nursing.
Two local project leaders from Health Trusts	60 min	Nursing, occupational therapy
Leader from the local governance organization, UNN	60 min	Nursing
Leader from a Regional Health Authority	90 min	Economy

Refer to Table 1. The first author transcribed the interviews, and analyzed, and categorized the text into main issues in collaboration with the other authors. We used the hermeneutic circle, moving from understanding parts of the process to understanding the whole process (Klein & Myers, 1999). The challenges of organizing a regional governance organization, and how to deal with tension between different actors, were some main issues. Then we discussed and reflected on these subjects in relation to the context, the theory, and the research questions. In addition, we supplemented the data analysis with project documents and reports to acquire the best possible outline of the processes.

CASE

The Regional Strategy

After a prolonged bid for tender process in 2011, the North Norwegian Health Authority decided to invest in new clinical ICT systems for all their 11 hospitals, and at the same time regionalize the ICT portfolio. As a result, the Health Region established BigProject for the 2012–2016 period. With a cost likely to exceed €100 million (Christensen & Ellingsen, 2013), this project constitutes one of the largest and most ambitious ICT projects in Norwegian healthcare. The goals of the project were to establish

- Standardized clinical pathways
- "Best practice" standards for EPR workpractice and procedures across the Health Region
- Clinical decision support
- Regional integrations and interoperability between clinical systems

A crucial part of the project was contributing to developing a new EPR system (NewArena), using a completely new architecture with a user-centered configuration, and structured clinical content. As the hospitals in the Health Region already had an up-and-running EPR system (ClassicEPR), a crucial part of this project was to establish a strategy for a smooth transition between ClassicEPR and NewArena. In the next sections, we elaborate in more detail on these efforts.

In this process, BigProject had the primary responsibility for handling the major activities. However, the existing regional ICT management organization was also ascribed a crucial role. Their 250 employees were responsible for delivering ICT services, as well as running and maintaining the technical parts of the ICT portfolio in the Health Region. The regional ICT management collaborated closely with various

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

sized local ICT organizations in the different Health Trusts. In addition, both BigProject and the regional ICT management collaborated with a regional clinical ICT advisory board, established for handling the clinical content of the ICT portfolio at a regional level. The advisory board had representatives from all the five Health Trusts in the region, and met about once a month to provide strategic recommendations for the Regional Health Authorities. The advisory board acted as decision-makers for regional ICT issues, and thus represented a temporary de facto regional ICT governance organization. Even so, it was a common understanding in the Health Region to replace the advisory board with a permanent regional governance organization, which worked on a daily basis, when this organization was established.

Developing New EPR

In 2012, BigVendor started developing NewEPR based on openEHR architecture. OpenEHR built on standardized information models, open source components, and highly structured clinical content, including archetypes as core components (Beale & Heard, 2008). Archetypes are structured data elements of clinical concepts, envisioned to ensure technology-independent interoperability, easy reuse of information, and efficient decision support (Chen, Georgii-Hemming, & Åhlfeldt, 2009). Experienced clinicians are responsible for defining the archetypes, this way the clinical personnel control what content to structure, as well as how and when to do it. It is possible to build the entire internal structure of schemes, processes and decision support in the EPR, by organizing all data in archetypes, and combining them to form templates. There is a call for close regional collaboration, to maintain and build the clinical content, including patient pathways and archetypes for NewArena. The goal is to have a new EPR system working across institutional borders capable to follow the patients' entire trajectories (Pedersen et al., 2012).

To support this organizationally, the University Hospital North Norway (UNN) established a regional archetype governance organization in 2013 with 10 employees. This unit will support clinical users in creating and maintaining the archetypes at various levels (locally, regionally or nationally). The regional archetype governance will be organized at an overall regional level in the new governance organization, independent of clinical applications like EPR, radiology and laboratory.

The Health Authority needed to decide on a strategy to combine ClassicEPR with NewArena, since NewArena is developed and implemented in modules over at least five years while ClassicEPR is still operative. This made it necessary to be able to manage two different EPR systems simultaneously, as well as ensure that users could switch seamlessly between the systems. Therefore, the regional ICT management implemented a technical solution, to ensure that the old and new systems can interact seamlessly. "A context sync is installed, to make the switch between NewArena and Classic EPR seamless for system users. However, switching between two systems increases the risk of user errors, and technical complications" (representative from regional ICT management). This change is technically demanding, as well as challenging, for users, as attention to what platform they are working on is required to accomplish their work (Christensen & Ellingsen, 2014). After implementing more modules of NewArena, some functionalities will be in ClassicEPR and others in NewArena. In addition, both technology and use are very different between ClassicEPR and NewArena. An example described by Christensen and Ellingsen (2014) from the first pilot of NewArena illustrates this: The new system had structured data based on archetypes, but Classic EPR did not support structured text. Physicians created archetype-based documents in NewArena to plan operations. Then they sent these documents to ClassicEPR, and secretaries included the documents in the surgery-planning module. Structured data registered in NewArena then

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

became free-text documents, and the benefits of using archetypes disappeared completely (Christensen & Ellingsen, 2014). This indicated the risk of users not receiving any actual benefits of NewArena, until there are several modules implemented.

NewArena also calls for a close engagement related to user's practice, and more request for ICT support and governance closer to the end-users. This relates to the goal of designing clinical decision support and patient pathways, and the need to keep them constantly updated. However, this is an impossible task for the existing ICT management organization to provide, due to its regional role, and thus its distance from users. "The distance between the clinics and the regional governance organization is too far. It is cumbersome to get hold of the right person to solve a problem" (local project leader). To make this work, there is a need for a regional governance organization. In the first pilot of NewArena, the testing related to the surgery outpatient clinic confirmed that users would require close follow-up related to make the new functionalities useful for them.

The Standardization of Practice Project

To prepare organizationally for the new system, and attain the Regional Health Authority's goals of higher quality, efficiency and interoperability, regional standards and routines for EPR usage had to be established. Standards are important for a large II such as a Health Region to work optimally. Big Project's standardization of practice project was therefore initiated in 2012. The goal was to "increase quality and safety in patient treatment, through standardizing clinical practice related to EPR usage across the region" (Nilsen, 2013). More than 500 system users from all 11 hospitals in the region participated in mapping EPR usage and establishing regional standards in 2012–2013. The project identified existing work practices (the installed base) at all hospitals, and used a best practice principles to standardize work routines and procedures. In addition to system users, the EPR vendor, and both regional and local ICT management organizations participated in this process. The implementation of the regional standards will be completed in 2015–2016, including areas such as organizational configurations, journal structure, access control, laboratory work, and workflow (Nilsen, 2014). A consequence of the regional standards are extensive changes to the different hospitals' work practices. For example, after implementing the standards, a new form of access control will be required to use the EPR system. Today, there are great variations related to what users at the different hospitals can access automatically. For some, this new admission control will provide them with automatic access to less of the EPR than they have today. Another change is that all hospitals must register equivalent activities at the same organizational level, making information easier to compare at the regional level. Consequently, the organizational structuring of the hospitals has to be altered.

"Establishing the regional standards is a success, leading to better collaboration within the Health Region than ever before" (project leader, BigProject). However, for some standards it has been difficult to agree. One example relates to registration. The regional standard states: "Registration is connected to the patient's illness (Nilsen, 2014)." This means connecting all practice to a specialized field, such as ear, nose, and throat, or neurology. A project leader in BigProject states: "At a small hospital, activity registration can no longer be connected to the clinician doing the job, but rather the illness of the patient." Following the regional standard, all activities are registered at a regional level, since all hospitals in one Trust share the departments and sections connected to different specialized fields. This way, the Health Authorities improved their overview of activities related to each field. However, the hospitals themselves no longer have the same local overview. Local hospitals do not see the benefits of changing

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

their registration practice leaving them with less local control of their data. There have been several attempts trying to reach an agreement on this matter, without any luck so far. Similar challenges are likely to appear after implementing the standards, and the users' experience how their workdays are affected. Project leaders in the BigProject underline the need for a regional governance organization, to form a strategy for handling such issues, as well as others related to aberrations, modifying existing, or forming new standards. Without a governance organization, they fear that the regional structures will fall apart after BigProject is completed. "Regional decisions have already been effectuated, and there is a risk of them dissolving without the necessary regional governance in place" (project leader, BigProject).

Consequently, there is an increased need for a well-structured regional interorganizational ICT governance organization to follow up on the results of the standardization of practice project, and prepare for NewArena. Working out an overall goal for regional ICT management, including what to do and how to get there, is necessary. "It may take several years and the process may need to be done in steps, but to move forward, we need to have a strategy stating what the region wants this organization to encompass" (project leader, BigProject).

Establishing a New Regional Governance Organization

When the Health Region in 2011 decided to regionalize the ICT portfolio and established BigProject, they also started working on forming a regional ICT governance organization. However, it was difficult to negotiate the nature, form, and location of such organization, preferably having the authority to enforce standards on the various Health Trusts, as well as strategically manage a large ICT portfolio.

The experiences and lessons learned with the regional ICT management, was that this organization could not sufficiently support clinical practice, thus be responsible for regional ICT governance. There is a clear difference between ICT governance and ICT management. ICT management focuses mainly on suppling ICT services in addition to products, as well as managing ICT operations (De Haes & Van Grembergen, 2005). ICT governance is much broader, concentrating on performing along with transforming ICT to meet present besides future demands of the business and the customers.

Today, all Health Trusts, especially the largest one, have well-functioning local ICT management organizations, due to the need for user support and governance close to the workers. The local ICT management at the University Hospital also emerged as a de facto organization for clinical ICT management, preparing for the future clinical governance of NewArena, as well as being a key player preparing UNN for developing as well as piloting the new EPR system. "My guess is regional functional governance is placed in the biggest Health Trust, they already have an established organization for governing both NewArena and ClassicEPR" (leader, BigProject). Giving up local control and ICT management for a newly established regional ICT governance organization, did not seem like a tempting offer. However, even if the users agreed on the need for local clinical governance (i.e., the local ICT organization), the actual content of this organization was far from clear. At one point, this resulted in a territorial dispute between the local ICT governance at UNN, and regional ICT management. The regional ICT organization locked out the local ICT management from the administration tool in ClassicEPR (user management, access, role definitions etc.), with the argument that this was a technical issue. The local ICT management, however, claimed this tool was part of the clinical ICT governance, and demanded continued access. They also supported their claim by implicitly referring to the regional ICT management's managing role: "It is the Health Trust that own the system and decides who gets access to what" (leader, local ICT governance). This indicated a strong need for a regional ICT governance organization to handle similar issues in the future.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

After discussing several suggestions without reaching an agreement, UNN was in 2013 pointed out to complete a proposal for organizing regional ICT governance. In their proposal from 2014, they suggested a fragmented governance model in which each Health Trust were responsible for governing separate areas of the ICT portfolio on behalf of the others, meaning that one Health Trust would govern the EPR; one the laboratories, another radiology and so on. This model was established, based on the regional discussions: "Many discussions relates to establishing one small governance unit in each Health Trust, or one regional governance unit" (leader, local ICT governance organization). The solution presented by UNN distributed governance competence and local control across the Health Trusts. The Health Authorities piloted this solution for radiology in 2014–2015. After an evaluation, they will decide whether to apply this model to the rest of the regional ICT portfolio. This model is in many ways comparable to a polycentric governance model. Governance is spread out in the organization instead of assembled in one unit (McGinnis, 1999).

The informants were skeptic of applying such fragmented model to EPR governance, since the EPR is very complex, and has many integrations and interconnections with the rest of the ICT portfolio. It is necessary to include a large group of technical and clinical personnel to handle EPR governance, and a group working specifically with archetypes and NewArena. How to organize this and how to separate EPR related clinical content, is complicated to work out. "The systems are so closely interconnected, especially the EPR and the laboratory, that even if the Health Trust agrees to split their governance this seems impossible without compromising the interoperability" (project leader, BigProject). Even with all the skepticism, this model made it possible to define who was responsible for different clinical governance areas. "It seems like the best solution the region is able to agree on for the time being" (representative, Regional Health Authority). A fragmented governance model was at least a starting point for regional collaboration on governing an interorganizational ICT portfolio. In addition, establishing and updating regional patient pathways across Health Trusts, primary care and other institutional boundaries have to be extensive parts of the regional ICT governance.

DISCUSSION

De Haes and Van Grembergen (2005) states that ICT governance contains a mixture of various structures, processes, and relational mechanisms (De Haes & Van Grembergen, 2005). We agree, but we emphasize that governing an evolving II should be less concerned with creating uniform organizational structures for generating order, and focus more on a process for handling diverging political interests, managing tensions, as well as complex interdependences. This case has illustrated that establishing a uniform interorganizational governance regime is a formidable, if not impossible, task. Taking into account previous research on complex II (Bowker et al., 1996; Hanseth & Lyytinen, 2010; Hanseth & Monteiro, 1998; Star & Ruhleder, 1996), the current outcome is far from surprising. Modern IIs have become increasingly more interconnected and interdependent. At the same time, ICT systems, and in particular EPRs have been increasingly included in local practice. Thus, the infrastructure must serve regional as well as local interests simultaneously. In this case study, this is expressed by tailoring NewArena to the clinical practice through the new openEHR architecture. At the same time, the Regional Health Authority aims at standardizing practices across the Health Trusts in the region.

The two perspectives of the regional portfolio call for different sorts of governance: NewArena requires a governance regime grounded in local practice with high competence on how the new technology af-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

fects the clinician's daily work. Thus, consider how the first pilot of NewArena at the surgery outpatient clinic identified that users would need close follow-up engaging with the new functionalities. In contrast, Big Project's standardization of practice calls for a more authoritative governance regime. The regional standards and routines must be implemented in clinical practice; in addition, someone have to make sure that the users adhere to the standards for the standards to continue to evolve alongside clinical practice. At this point, the regional ICT advisory board and the regional ICT management organization are not equipped to handle such a governance task on a permanent basis, since they are management, not governance, organizations. There is a need for a more powerful interorganizational governance organization operating at an overall level on a daily basis, to support successful delivery of healthcare.

In addition, governing an II also implies taking into account and building on the existing ICT portfolio, the installed base (Hanseth & Monteiro, 1998; Nasjonal-IKT, 2012). The BigProject leaders have considered the existing system with their current strategy to plan for years of interplay between ClassicEPR and NewArena. This enables seamless integration of NewArena, by replacing ClassicEPR in a stepwise manner avoiding a "Big Bang" implementation. Operating the two EPR solutions simultaneously however, has created challenges, such as the example from Christensen and Ellingsen (2014) in which a process moved from NewArena back to Classic EPR resulting in an outcome that is the same as today; thus, no improvements in NewArena are detected for users. The benefits for users may not be noticeable until replacing most, or all parts of the old system.

From a governance perspective, a key point is that the interplay between the old and new portfolios require thorough technical insight. Simultaneously, such a technical perspective relates closely to clinical practice, since technical and clinical decisions affect each other. Consequently, governing an II implies understanding and including different interrelated areas, where each part requires a unique governance regime. The three governance perspectives introduced in this paper, the local, the regional, and the technical, are interconnected. Changing one area of the infrastructure may result in unpredicted changes to other areas (Vikkelsø, 2005). These interactions may cause tensions in addition to conflicts of interest. For example, pushing too heavily on a regional perspective and standardization, may have unforeseen effects on local flexibility. An example is how physicians at small hospitals lost local overview and authority of their patient data, when the standardization of practice project implemented regional standards. Consequently, things that are very useful from a regional perspective, becomes a liability for local practice. Accordingly, based on the preliminary results, there are indications that regional ambition has been pushed a step too far, as the different Health Trusts could not agree on how to organize a governance organization able to serve all the various needs. Given New Arena's heavy influence on future work practice (decision support, patient pathways, structured EPR content, etc.), it is not surprising that the Health Trusts sought highly competent local ICT governance close to clinical practice, instead of relating to a newly established regional ICT governance organization.

A strategy for solving the local and regional challenges has been to divide the governance into smaller domains such as EPR, radiology, laboratory, etc., where each domain is anchored in one of the Health Trusts instead of at the regional level. This solution is similar to a polycentric governance model, with multiple governing units, several overlapping arenas of authority and responsibility (Constantinides & Barrett, 2014). To some degree, this may solve the local/regional tension within the specific area in question. A key challenge with the fragmented governance structure suggested is defining the boundaries, then the areas of responsibility between the different units. Thus, several independent organizational units end up controlling areas of the same system, and the ICT management organization that delivers technical solutions have to collaborate with several Health Trusts. In addition, some parts of the ICT

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

portfolio, such as EPRs and laboratories, are so closely connected that separating them may seem impractical if not impossible. Another challenge may relate to two governance organizations disagreeing on a topic. Who decides the outcome? These borders are not clear-cut (as we have pointed out), and require cumbersome negotiation between areas of responsibility, thus making governance a complex task to handle. Such fragmented governance models have been impossible to agree on in the past, according to McGinnis (1999). Even in cases where a common forum was established, it has been impossible to agree on governance structures acceptable to all parties, since heterogeneous interests and resources are involved in a large scale II.

One of the goals of NewArena is to operate across institutional borders, to follow a patient's entire trajectory gathering all necessary patient information in one place. The fragmented governance solution suggested, made embracing NewArena extra complex. Governance of NewArena demands a regional focus on clinical content independent of system vendors, leading to an increased need for regional ICT governance. There is a call for close regional collaboration to maintain and model the clinical content, including archetypes and templates. It is necessary to take into account the goals of the new system, when the interorganizational ICT governance organization is established. This indicates that trying out the suggested polycentric governance model will potentially create room for endless negotiations plus a constant need for compromises. If choosing this model, a key success factor is to define clearly, who makes the final decisions when the different governance organizations disagree. If not, it will be damaging for the whole II, and it will be challenging to assure the stakeholders that things will go as expected. In addition, it is necessary to make an overall strategy securing the appropriate handling of all necessary areas of interorganizational governance.

CONCLUSION

Given the increased ambitions of information sharing, standardization, and interoperability, to ensure successful delivery of healthcare, it is crucially important to establish a well-functioning II. A key factor for success is establishing an ICT governance organization. We have discussed several challenges of how and to what degree an II in general and ICT portfolios in particular, can be managed, by focusing on organizational structures as well as processes on how to formally govern II's. We emphasized the longitudinal and political process of establishing an interorganizational ICT governance in a heterogeneous healthcare context.

The goal is for the EPR systems to evolve from today's information storage systems to interoperable user-centered work tools. Standardization of technology and work processes, as well as interorganizational governance collaboration is necessary to reach such goals. The regional ICT governance organization must operate on a daily basis; make decisions, as well as monitoring results and performance on different healthcare levels. In addition, standards must evolve alongside the EPR to be useful.

For such ICT governance organization to succeed the Health Authorities and the Health Trusts have to define an overall strategy for what they want to include in this organization. Interorganizational ICT governance has to include different aspects of governing the regional ICT portfolio, including local, regional, and technical aspects, plus the ongoing tensions among them. Regionalizing an ICT portfolio is challenging, even if representatives from Health Trusts, ICT management organizations and vendors participate in the process, the standards established might not always fit local needs. Therefore, a strategy

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

for handling regional disagreements, besides evaluating requirements for revising and adding standards, is also important to work out. In addition, it is necessary to define the structure of such ICT governance organization.

The fragmented governance model suggested for the North Norwegian Health Region is similar to a polycentric governance structure, which offers opportunities for organizing several governing units at diverging scales instead of one monocentric governance unit. This is an attempt to get a step closer to regional collaboration, and seems to be as far as the Health Trusts are ready to go at this point. Using this model, they keep some local control of their ICT portfolio. A fragmented governance solution demands close collaboration, and clearly defined borders between the different actors. This implies that a polycentric ICT governance structure may be an acceptable but challenging solution for a loosely connected II as a Health Region.

Chapter 86
Inhibitors of Physicians' Use of Mandatory Hospital Information Systems (HIS)

Heiko Gewald
Neu-Ulm University of Applied Sciences, Germany

Corinna Gewald
Neu-Ulm University of Applied Sciences, Germany

ABSTRACT

Physicians' use of information systems continues to be a highly relevant area of information systems research. Although numerous studies have investigated the relationship between hospital physicians and hospital information systems (HIS), a comprehensive framework for assessing the factors which inhibit the use of HIS has yet to be developed. To advance these efforts, this exploratory research takes a qualitative approach to investigate HIS use inhibitors based on interviews with 48 informants and observations from over 40 hours of workplace shadowing in two German hospitals. The findings show that focusing solely on the user does not lead to successful system deployment in hospitals. Rather, the road to success needs to take a combined approach focusing on the user, the process and the system. If these three building blocks are well aligned, correspond with the organizational context and are supported by strong leadership, medical personnel are much more satisfied with the HIS, which results in more effective use.

1. INTRODUCTION

Information technology (IT) is used widely in hospitals in developed economies all over the world. Although it seems to be logical to employ hospital information systems (HIS) and it is "…no matter of if, but of when…" (Wiggins, Peterson, & Moss, 2015) they will be employed, anecdotal evidence and discussions with practitioners often give the impression that HIS are not performing up to expectations: Proof that these systems provide a sustainable and measurable positive impact on patients and the healthcare industry is still outstanding.

Numerous authors, such as Buntin, Burke, Hoaglin, and Blumenthal (2011) and Denis (2009), have discussed the expected positive benefits from HIS, including improvements in the quality of care, a decline in healthcare delivery costs, and the avoidance of unnecessary procedures. However, critical voices, such as Ash, Berg, and Coiera (2004) or Koppel (2016), also associate serious negative outcomes like unnecessary mortality and redundant expenditures with the use of HIS. Despite the lack of proof of benefits, hospitals in developed economies continue to invest large amounts of money in their IT systems. Actual figures are hard to get and vary depending on sources. According to a report by the European Commission, most European hospitals spent around 2.5 to 3% of their operating budget on IT services (Buddrus, 2013; European Commission, 2013). This investment is significant and not likely to decrease in the near future (IDC, 2015).

Considering the expected benefits of HIS and the investments into IT, one wonders why healthcare systems around the world have difficulties living up to expectations (Davino, 2011). This poses the question whether HIS is able to provide the promised benefits (Kellermann & Jones, 2013). The answer to this question is influenced by multiple factors and is thus highly complex. Inspired by personal experience and anecdotal evidence, this research aims to shed light on this question by assessing the role of the user. Medical personnel's acceptance of HIS has been identified as an important prerequisite for successful healthcare delivery (Tulu, Burkhard, & Horan, 2006; Walter & Lopez, 2008) and the anticipated benefits of a HIS will only materialize if users use the IT as designated (Engelbert & Graeml, 2015). As Abouzahra et al. put it: "…the benefits of HIS can only be reached if [the HIS] are used in practice." (Abouzahra, Guenter, & Tan, 2015, p.14).

Due to their central role in healthcare delivery, medical personnel is often considered a major obstacle to successful IS deployment in hospitals (Boonstra, Versluis, & Vos, 2014; Paré, Sicotte, & Jacques, 2006). As Lowenhaupt put it: "Physicians' adoption [of HIS] has long been considered 'the holy grail' of clinical information systems: critically important, but elusive…" (Lowenhaupt, 2004, p. 12). This leads to the guiding hypotheses of this study that physicians and HIS are not well matched. Buntin's 2011 literature review identifies initial quantitative support for this hypothesis.

This paper delves deeper into this hypothesis, addressing the research question: What are the key factors that inhibit physicians from having a positive attitude towards hospital information systems in a mandatory use setting?

HIS are mandatory use systems, especially when used to document patient-related information. In a mandatory-use setting, whether a user likes or dislikes the IS does not determine whether or not he or she will use the IS. However, research and practice show that there are different levels of system interaction "…ranging from use to effective use…" (Burton-Jones & Grange, 2012, p.632). It seems obvious that a positive attitude towards the system is a vital building block to "more effective use" of the HIS. This research aims to provide further insights into why physician users of HIS do not always like working with the system and, more specifically, why physicians tend to not always use the systems as designed by system engineers for the mandatory-use hospital setting.

Numerous papers and several literature reviews (Abouzahra et al., 2015; Boonstra & Broekhuis, 2010; Boonstra et al., 2014; Buntin et al., 2011) identify a large body of research into the enablers but mainly inhibitors of hospital medical personnel HIS usage. Unfortunately, Boonstra et al. (2014, p.16) concludes that "…the literature is diffuse, and articles seldom build on earlier ones to increase the theoretical knowledge…" In light of this observation, this exploratory research investigates the root cause of the problem: the interaction between users and systems in the context of clinical work. Although numerous studies have already been conducted on the issue, there is still no comprehensive understanding and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

literally all papers call for further research into this issue. Instead of performing a further quantitative study, we build on available knowledge and conduct qualitative research to get at the root of the problem. Following a semi-structured interview guideline developed based on previously identified inhibitors of physicians' use of HIS, we held 48 interviews of physician users of HIS and shadowed such users for over 40 hours in two hospitals in Germany. The interviews and observations were coded, sorted and compiled to create a reference framework.

This paper is organized as follows: After reviewing the literature on IT adoption and usage in hospitals, we outline our research method. We then discuss our findings and derive the proposed framework. Finally, we discuss the limitations of our research, suggest further research and draw our conclusions.

2. LITERATURE REVIEW

Over the years, countless studies have tried to explain physician`s (non-)adoption of HIS. This section defines the relevant terms and discusses three major issues affecting the relationship between physicians and HIS in hospitals:

1. **Concepts of Usage:** The types of behavior physicians have displayed towards HIS
2. **Mandatory Use:** User behavior in environments where no choice can be made whether or not to use a system, i.e. where usage is not voluntary.
3. **Known Inhibitors:** Findings of previous research what inhibits users from using HIS.

2.1. Definitions

The term HIS is often interpreted differently. For this research, it is defined as the IT system(s) used by hospital physicians to document patient-related information. This is typically the electronic medical record; however, it can also be the general hospital information system (like the ERP for industrial firms) or another specialized system. The definition excludes function-specific medical IT systems such as x-ray machines, heart catheters etc. which are used for diagnostic purposes only (although the data may feed into other administrative systems). Our definition limits HIS to hospital-internal systems and excludes inter-organizational systems such as health information exchanges or electronic health records.

2.2. Concepts of Usage

2.2.1. Adoption, Acceptance, and Intention-to-Use

Numerous studies have investigated the interaction between users and systems in healthcare (see literature reviews by Boonstra and Broekhuis (2010), Holden and Karsh (2010), and Shaikh and Karjaluoto (2015)). The most popular objects of study are the electronic medical record (EMR) and HIS in general. Several popular IS adoption models have been utilized (such as TAM, TAM2, UTAUT and SCT), adapted to the healthcare context and sometimes extended to include specific constructs. Some researchers argue that specific traits of the physician's occupation (like the construct "perceived threat to professional autonomy" proposed by Walter and Lopez (2008). However, we have not found a study that sufficiently explains why physicians do not show the same adoption behavior as users in other industries.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

All the papers dealing with either adoption, acceptance, or intention-to-use (see Venkatesh and Davis (2000) for an in-depth discussion of these terms) share an inherent assumption that the use is, to some degree, free to choose whether or not to use the system. This is not the case for HIS in a hospital environment. Laws, policies and regulations dictate that healthcare providers must document their work extensively (Tulu et al., 2006). This means that if a hospital switches from a paper-based to electronic medical record keeping, physicians do not have a choice whether to use the system. They must use it, whether they like it or not.

2.2.2. Resistance

Scholars have observed that users often resist new IS implementations. This type of resistance is defined as "…opposition of a user to change associated with a new IS implementation…" (Kim & Kankanhalli, 2009, p.567). Users show active, passive, overt, or covert negative behavioral responses to avoid using a system (Laumer & Eckhardt, 2012). Several studies of resistance to IS implementation in general (Hirschheim & Newman, 1988; Kim & Kankanhalli, 2009; Lapointe & Rivard, 2005; Laumer & Eckhardt, 2012; Laumer, Maier, Eckhardt, & Weitzel, 2015) and of resistance to IS implementation in hospitals (Bhattacherjee & Hikmet, 2007; Doolin, 2004) highlight the importance of including the user in the implementation process, since changes to their work processes will impact them directly (Liu & Cheng, 2015). These studies find that resistance is a typical reaction to changes before or during the implementation of a new system. In the case of physician users of HIS, the vast majority of medical personnel in hospitals use systems that have already been implemented, so the concept of resistance is restricted to rather specific circumstances.

2.2.3. Continuous Use

To distinguish between first-time and ongoing use of an implemented system IS usage scholars have established the concept of "continuous use". Unfortunately, as pointed out by Gebauer et al. (2013), considerable research (e.g. Bhattacherjee, 2001; Karahanna, Straub, & Chervany, 1999) regards continuous use to be grounded in the same theoretical approaches used to explain initial IT adoption (i.e. TAM, UTAUT, TRA, TPB etc.). These theories use "intention to use" as a dependent variable, which is being increasingly questioned as the link between behavioral intention and actual usage is not as strong as often expected (Limayem, Hirt, & Cheung, 2007) especially in self-reporting research settings (Wu & Du, 2012).

Due to their focus on the intention construct, continuous use theories assume voluntary use of the system under observation. Logically, the few continuous use studies undertaken in the healthcare context focused on non-mandatory use systems (e.g. Tulu et al. (2006).

2.3. Mandatory Use

In summary, studies on adoption, resistance or continuous use do not help explain the behavior of hospital medical personnel using an existing system in compliance with hospital and statutory healthcare provision rules and regulations. It is mandatory that medical personnel use the HIS. In this case, the end-user has no choice whether or not to use the system (Melone, 1990). Management made that decision for all end-users by deciding to implement the system (Vehring, Riemer, & Stefan, 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Previous research shows that user behavior differs depending on whether system use is voluntary or mandatory (Gallivan, 2001). However, there is far less research into mandatory system use (Chan et al., 2010). Even though it is common in the business environment to require employees to use certain IS (Brown, Massey, Montoya-Weiss, & Burkman, 2002), research on the specific user behavior towards mandated use is scarce (Laumer, Maier, Eckhardt, & Weitzel, 2014).

Despite some discussion about whether system use can be really mandatory or whether a degree of voluntarism is always involved (DeLone & McLean, 2002; Vehring et al., 2011), scholars agree that the quality and intensity of use directly affects the degree to which system benefits are realized, even in required-use settings: "…even when use is required, variability in the quality and intensity of this use is likely to have a significant impact on the realization of the system benefits…" (DeLone & McLean, 2002, p. 5). This is due to the fact that even in mandatory settings the extent of system use varies by user (Burton-Jones & Grange, 2012; Melone, 1990).

Thus, theoretical models focusing on "intention to use" as a dependent variable are not as strong in mandatory context. While there will be variance in terms of use and workarounds, the mandatory-use setting per definition excludes user choice.

The question thus remains: What factors influence the degree of IS usage and what factors create positive or negative attitudes toward IS usage in a mandatory-use setting?

2.4. Inhibitors of HIS use

Table 1 below summarizes the factors identified by IS usage scholars which encourage or hinder physicians' use of HIS (Holden & Karsh, 2010). We added additional information in brackets to further clarify the original descriptions. Please note that Boonstra et al. (2014), Boonstra and Broekhuis (2010), Buntin et al. (2011), and Holden and Karsh (2010) are literature reviews. If these are stated as source they represent a secondary and not a primary reference.

3. RESEARCH METHOD

As discussed in more detail in the introduction, in order to get at the root question of what inhibits physicians from using an implemented HIS in a mandatory-use hospital setting, we conducted exploratory research using qualitative methods. Using identified inhibitors of physician's HIS use, we developed a semi-structured interview guideline and interviewed physicians in two hospitals in Germany and shadowed physicians to deepen our findings. The findings were coded, sorted and compiled to create a reference framework.

3.1. Research Objects

This study addresses the behavior of hospital medical personnel towards an information system provided by the hospital. We did not analyze the hospital as an organization which may benefit from HIS through improved cost-effectiveness or an improved doctor-patient relationship (geared towards a team approach instead of a 1:1 relation). Since organizational behavior is driven by different motives than individual behavior, we excluded this lens.

Table 1. Inhibitors of physicians' HIS use

	Inhibitor	Source(s)
1	Lack of interoperability [the system is insufficiently connected with other HIS systems]	Kellermann and Jones (2013) Lærum, Ellingsen, and Faxvaag (2001)
2	Insufficient ease-of-use, system too complex [difficult to find information, insufficient GUI, etc.]	Kellermann and Jones (2013) Boonstra and Broekhuis (2010)
3	Insufficient efficiency within the system [too many clicks required, sign-on to multiple systems, etc.]	Boonstra et al. (2014)
4	Insufficient integration with other clinical processes [coding, billing, cross-departmental consultations, etc.]	Kellermann and Jones (2013)
5	Professionals need to adapt their working customs [change management issue]	Liu and Cheng (2015) Lærum et al. (2001) Shachak and Reis (2009) Wakefield et al. (2007)
6	Technology does not fit to professionals' needs / work procedures [system does not support the required functionality]	Villalba-Mora, Casas, Lupiañez-Villanueva, and Maghiros (2015) Heisy-Grove and Patel (2014) Boonstra et al. (2014) Tulu et al. (2006)
7	Threat to physicians' professional autonomy	Walter and Lopez (2008) Lowenhaupt (2004) Walter and Lopez (2008) Weeger and Gewald (2015) Chau and Hu (2002)
8	Negative impacts on physician-patient relationship	Shachak and Reis (2009)
9	Patient privacy and information security concerns	Thomas (2008) Gold, McLaughlin, Devers, Berenson, and Bovbjerg (2012) Villalba-Mora et al. (2015) Heisy-Grove and Patel (2014) Chau and Hu (2002)
10	Network effect [it only makes sense to use the system if all members of the department use it, otherwise the data is incomplete]	Kralewski et al. (2008)
11	Leaders are not using the system [lack of leadership support/involvement, role model]	Boonstra et al. (2014)
12	Lack of IT infrastructure [insufficient hardware]	Villalba-Mora et al. (2015) Lærum et al. (2001)
13	Insufficient speed / response times [waiting for system responses]	Boonstra et al. (2014) L. Wu, Li, and Fu (2011)
14	Lack of IT support / technical assistance	Heisy-Grove and Patel (2014) Boonstra and Broekhuis (2010) Boonstra et al. (2014)
15	Lack of integration with existing systems [non HIS-systems such as administrative backend etc.]	Villalba-Mora et al. (2015)
16	Lack of user's IT skills	Villalba-Mora et al. (2015) Boonstra and Broekhuis (2010)
17	Lack of knowledge and training on the system	Villalba-Mora et al. (2015) Boonstra et al. (2014)
18	Lack of system reliability [system outages]	Boonstra et al. (2014) L. Wu et al. (2011)

Table 1. Continued

	Inhibitor	Source(s)
19	System vendor is not responsive to change requests [resulting in user frustration]	Boonstra et al. (2014)
20	Patient data in the HIS may not be complete [mistrust in data completeness]	Lærum et al. (2001)
21	HIS provides individual's data for performance review [fear of misuse of transparency generated through HIS]	Liu and Cheng (2015)

We also excluded individual physicians working in private and small practice because their behavior is driven by different motives than hospital physicians. For example, if a physician owns her or his own practice, then his or her behavior toward IS is more likely to be driven by cost considerations (Boonstra & Broekhuis, 2010) such as the cost of licensing, implementing and maintaining the information systems. Financial incentives (e.g. those awarded in conjunction with the HITECH act in the US or the introduction of DRG in Germany) also play a significant role in their behavior towards information system (Heisy-Grove & Patel, 2014). However, those physicians working in a hospital are not usually motivated by these considerations.

We collected our data from June to July 2015. In order to capture a broad range of opinions in alignment with the exploratory character of this study, users from different departments, in different roles, and using different systems were selected. In all, we interviewed 48 informants. Their demographics are summarized in Table 2 below.

Data was collected at two hospitals in Germany: Hospital A is a large university medical center, ranking among the 10 largest hospitals in Germany. The hospital comprises of several different clinics which are departments led by a head physician who has both medical and management responsibilities. Hospital A has a very complex and heterogeneous IT landscape. In many cases, the clinics have their own IT departments. Hospital A has a unified administrative back office system (which also provides medical record functionality) complemented with several different HIS systems in different clinics. Several clinics use paper-based medical records or a mix between electronic and paper-based records. Also, there is a variety of different electronic medical records in use at different stages of implementation. Hospital B is a medium-sized specialized clinic which provides a uniform HIS system for all physicians. However, the hospital still relies to a large extend on paper-based medical records.

Table 2. Interview partner demographics

Department	Interviewees	Age		Sex	
Intensive care	11	20-29	9%	Female	48%
Surgery	5	30-39	43%	Male	52%
Internal med	8	40-49	28%		
Orthopedics	13	50-59	17%		
Neurology	8	60+	3%		
Anesthesia	3				
Sum	**48**

3.2. Semi-Structured Interviews

Our semi-structured interview guideline consisted of three sections:

1. **"Who are you and what do you do?":** Demographic data of the interviewee and specification of her/his workplace and/or specific tasks/role(s).
2. **"Do you like the HIS?"** Enablers and inhibitors identified in previous research with special consideration of the inhibiting factors.
3. **"How do you use the HIS in your work?":** Description of the way the interviewee uses the system as part of her/his daily working routines.

The interviewers collected complete demographic information (Section 1) either directly from the informant or through secondary sources. Section 2 was an open discussion and the interviewer drew specific attention to the inhibitors listed above. Given the open question format to address issues, interviewees often picked the most pressing issues and talked about these for some time. Towards the last third of the interview, the interviewer addressed Section 3 to gain an understanding of the way the physician uses the HIS to perform her/his daily tasks.

3.3. Workplace Shadowing

A common problem in social sciences is the disparity between self-reported behavior and actual observable actions. To mitigate this effect, we chose to not only rely on interviews, but rather to also shadow physicians. The team spent over 40 hours accompanying physicians on their ward rounds, observing their general work and team meetings. Our main goal was to observe directly how the physician interacts with the system.

3.4. Data Analysis

We interpreted the data collected as recommended by Miles, Huberman, and Saldana (2013): All notes taken during the interviews were reviewed, clarified as necessary and coded. Open coding was guided by associating the key phrases to either one of the known enablers/inhibitors (section 2.4), or by associating it to a new concept. Following open coding, axial coding was performed to ensure all important aspects had been identified. Two researchers coded the data independently and all disputes were discussed until a unanimous agreement was reached.

The resulting data table lists the major categories and associated concepts, which was the basis for developing a framework to structure the findings.

4. DISCUSSION OF FINDINGS

Our findings underscore that physicians are not generally technophobe, as we had suspected at the outset. They value technology but not for the sake of technology itself but on a much more rational level (in line with Lowenhaupt (2004): Technology is valued most when it is useful to complete a task or process in a more efficient or effective way compared to a given alternative. This "alternative" is usually not a

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

different system, but a workaround (e.g. writing paper notes instead of entering the data directly into the system) or delegating interaction with the system (e.g. by asking a team member to enter data) (cf. Ash et al. (2004).

We found evidence which supports both (semi-)rational and emotional arguments for the way physicians interact with the provided HIS. The main categories resulting from our coding are illustrated in Figure 1 below.

Our interpretation of the interview data and our observations indicate a clear relationship between user, process and system - all influencing each other respectively. Leadership and organization also play an important role. These categories and their relationships are discussed in the following sections.

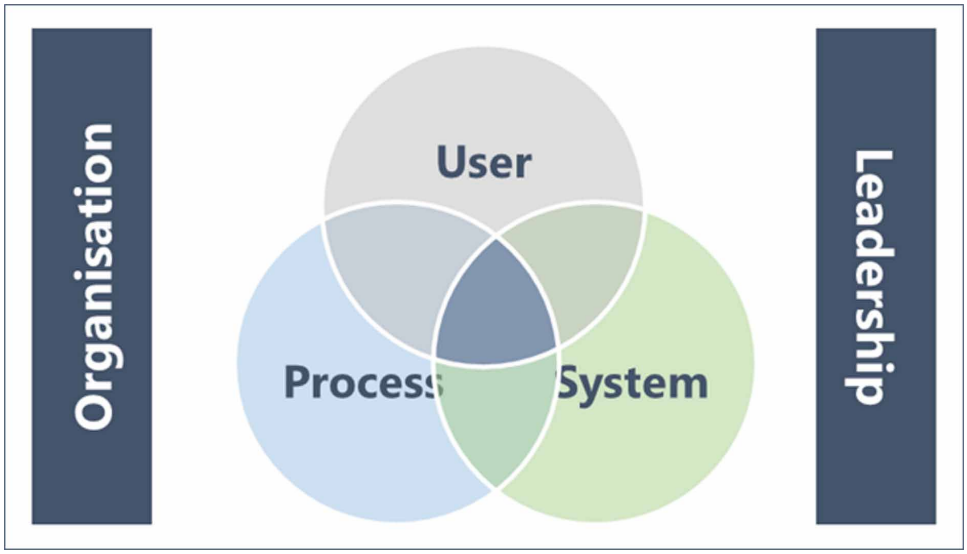
4.1. User - Process – System

Our sample represents a wide range of HIS users: those who are happy with the HIS and those who openly dislike it. In line with the findings of Chau and Hu (2002), we see that physicians usually show a positive attitude towards the HIS when it closely matches their established work behavior, i.e. they perceive a good fit between user, system and process. Also, we noticed, that physicians' attitudes are strongly influenced by the mindset and behavior of their superiors (see Section 4.2).

4.1.1. User

The issues in the category "user" relate predominantly to knowledge and skills, but also to personal efficiency and professional autonomy. We observed that the users were happy with the HIS when they believed the HIS would enable them to get their work done faster or better (i.e. be more efficient and/or effective). The principle enablers were better exchange of/access to information, being able to read all entries [issue of bad handwriting on paper files] and decision support. Although the informants had

Figure 1. Framework of Findings



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

different attitudes towards IT in general, no one refused to work with the system. Some felt that their work is increasingly becoming too IT-focused ("At some point in time we all will have to study computer sciences to do our job…" [N04]).

The physicians interviewed assessed the impact of the HIS on the patient-physician relationship differently depending in part on her/his specialization. Physicians who have more physical interaction with the patient (e.g. in orthopedics) considered the HIS less helpful. In general, physicians appreciated patients' positive perceptions of their use of advanced technology ("I like working with the system. It shows our patients that we are up to date… [with technology]" [N05]). Several informants complained about the HIS lagging behind hardware and software developments like smartphones, tablets and apps. A general perception was that "My work as a doctor is not valued when the IT I am given does not meet my needs…" [P19]. This ties into other recent research, which indicates that physicians tend to perceive IT gadgets as status symbols (Weber, Gewald, Weeger, & Haase, 2016).

The effect of training was considerable. Physicians who attended system training sessions were more comfortable using the system and observably faster and more knowledgeable about the system's functionality. Physicians acknowledge that training is helpful ("It was very hard to use the system in the beginning, but the training helped a lot to make the most out of it…" [P07]), however previous research also observes a strong tendency for physicians to not attend training sessions (Weber & Gewald, 2014).

Several physicians also identified over-transparency (e.g. with regard to performance reviews or lawsuits) stemming from built-in activity tracking and timestamps as a potential inhibitor.

4.1.2. Process

Our findings in the category "process" focus on the intersection of healthcare delivery and HIS use (diagnosis, consultation, prescriptions, etc.)

Our findings underscore that HIS has the greatest potential to benefit physicians if used as designed. When information is entered in a timely and accurate fashion, some important tasks, such as writing the doctor's letter, can be completed very quickly: "We continuously update our doctor's letters as part of our documentation and so in the end they are done very quickly." [P13]. However, this also requires all necessary systems to be integrated: "Writing doctor's letters is the task we like to postpone most because it takes so much time to retrieve all information needed from the system." [P04]. However, some informants mentioned information overload ("I don't want all the information automatically thrown at me. As a doctor, I want to think and make my own decisions." [P10] and others have a general mistrust in the information provided by the system ("With all that copying and pasting one cannot trust the information in the system all the time." [P14]). Hence, system integration and data integrity seem to be a key requirement for successful working processes.

Established work habits can be a major inhibitor to system use. We observed that physicians are rarely willing to adapt their working procedures to fit the system. They rather want the system to reflect their individual (or departmental) working habits. This poses a problem to off-the-shelf software which typically has a limited range of customizability. Even when software can be customized, history (especially in the manufacturing sector, see SAP implementations in the mid 1980ies) has shown that heavy customization leads to system incompatibilities and update problems over time. Individually developed software would resolve this problem, but high maintenance costs are prohibitive for most hospitals.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

System: A major "system" critique associated with the actual HIS and its deployment was that the graphical user interface (GUI) was frequently regarded as too complex or "*not made for doctors*" [P05]. This ties into the "process" findings about established working habits. Some physicians also complained about multiple logons to different systems (as opposed to a single sign on) or the need to press too many buttons before being able to retrieve information (Observation [P02]).

A recurring infrastructure critique was long response times (subjective observation during workplace shadowing) and system outages/crashes. Although concerns with IT security and data privacy were frequently reported in previous research, these issues were not mentioned by our informants.

4.1.3. Interrelationships Among User, Process and System

These three categories appear to be tightly coupled. As we know from the concept of Task-Technology-Fit (Goodhue & Thompson, 1995), a system is accepted most readily when the technology provided fits the task the user needs to perform. In the case of our research, we observe that physicians do not oppose the HIS provided per se, but struggle with the GUI, (perceived) long response times and incomplete or not easily accessible information. Some of these factors can be addressed by training and investment in IT-infrastructure, but an off-the-shelf software almost certainly will not support all established working processes in all hospitals. So in order to support physicians efficiently, the systems need to change (improve GUI, implement single sign on, improve data integration) the processes need to change (adapt clinical processes to a standard model which can be supported by a commercial software) and the users need to change (attend training sessions).

These three factors are so closely interconnected that addressing just one of them appears to be an inviable path forward.

4.2. Leadership

Our interviews and observations also offer important "leadership" insights into how medical and administrative managers influence the user-process-system framework. In a hospital context, we distinguish between medical management (leadership exerted by the medical superiors, e.g. the head physician) and administrative management, i.e. the hospital administration.

4.2.1. Medical Management

In hospitals, the medical management generally fulfills the administrative and the medical management role because the head physician bears overall responsibility for her/his department, including medical, organizational and financial responsibility. This distinguishes the healthcare context from other industries where managers often do not have direct operational responsibility. In hospitals, the head of the surgery department usually carries out most difficult procedures personally, whereas the head of engineering typically does not maintain engines in the automotive industry. This has important implications for research. Our findings clearly substantiate the important role superiors play in forming attitudes and behavior towards HIS in their departments. Whenever the head physician was skeptical of HIS, e.g. "Technology is necessary these days but paper is faster and more efficient [P01]", this attitude was common across the department. This applies to positive mindsets as well. The strong impact of medical management

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

towards HIS derives from the double role of medical and managerial responsibility. The department head greatly influences working procedures, has a (if not THE) leading role in the HIS selection process, and decides how much budget will be spent on system development, such as new functionalities and integration with other systems.

4.2.2. Administrative Management

Hospital administration traditionally has a difficult role to play vis-à-vis medical directors because they are financially responsible for the hospital but have no say medically. This makes it difficult to assert overall leadership in the absence of direct supervision. As a result of the lack of supervision, different departments sometimes deploy different HIS for the same purpose. This is costly and greatly hinders integration and standardization efforts. However, it is difficult for the hospital administration to influence individual departments' selection of an HIS if the selection is made on the basis of medical procedures.

4.2.3. Influence of Leadership on User-Process-System

Our findings show that leadership on all levels plays an important role. For example, in units where the medical management (head physician) is a strong supporter of HIS, the attitude of the physicians in the unit towards the system was much more positive than in other units. This is not surprising because the head physician bears ultimate responsibility for all actions across the entire department and thus strongly influences working practices.

When medical management encourages the physicians in his or her unit to use the system, they are much more satisfied with the system. If administrative management (especially together with medical management) fosters consolidation, integration and in some instances standardization of systems, the benefit for all users of the HIS increases. The physicians we interviewed in the hospital with a unified HIS were generally more satisfied with the system than the physicians we interviewed where the IT landscape was diverse.

If management has a shared vision of HIS use and makes an effort to make this vision a practical reality, the overall outcome is rewarding because it directly influences the user-process-system construct.

4.3. Organization

The main issue raised by the physicians related to the "organization" of work within the hospital was the low level of integration with other departments. Due to the division of administrative and medical leadership described above, the hospital lacked a coherent system and process integration structure, resulting in a complex IT landscape consisting of several different HIS systems and heterogeneous working procedures: "I have to put the request for a counsel into the system, print and sign it, fax the request to the other department and then call them every time to make sure they got the information" [P22].

Many physicians also commented that the IT department was too distant from the medical profession and that they found it difficult to communicate and interact with IT personnel. This observation relates to previous IS research into IT/business alignment which shows that hospitals with good alignment perform better than hospitals with isolated departments (Weeger, 2017).

As illustrated, the organizational factor indirectly but strongly impacts the user-process-system construct. Aligning the organization well leads to overall performance improvements.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.4. Summary

In summary, our interviews and workplace shadowing showed that physicians are willing to work with systems when these systems help them do their job more efficiently. We observe that the better the user-process-system construct is aligned, the better the physicians interact with the system and the better the results are. We also observed that strong and coordinated leadership enables good use of IT and that organizational alignment positively influences system use.

Our resulting framework consists of an inner model (user-process-system) of cross-influential factors and an outer model (leadership and organization) which directly influence the inner model.

5. IMPLICATIONS

Our findings show that different IS research strands are required to explain use of a mandatory HIS by hospital physicians, including Task-Technology-Fit and business/IT alignment. We do not consider our understanding of the issues to be refined enough to merit large-scale quantitative research assessing enablers and inhibitors and recommend further research building on our framework which certainly needs to be refined when deeper understanding is available.

From a practical perspective, our study identified several issues frequently overlooked in HIS system implementation. As in other industries, hospitals are in need of Business Process Reengineering. Physicians' use of a HIS is less likely to be improved by buying a (new) system than through a combined effort of system customization and adapted working habits, which requires significant change management effort. Additionally, more focus should be put on GUI development and IT topics which directly impact users, such as response times and multiple logon requirements. Although it may never be possible to satisfy all users, such efforts can increase user satisfaction.

6. LIMITATIONS AND FURTHER RESEARCH

This qualitative study provides deeper insights into hospital physicians' use of mandatory HIS system and aims to identify major use inhibitors. Since we only interviewed 48 physicians at 2 hospitals over a short timeframe in Germany, our results are not widely generalizable.

However, future research can nonetheless benefit from our research by identifying a basis for comparisons across different hospitals, organizational structures, etc. We encourage IS usage scholars to test our findings in other settings.

7. CONCLUSION

We conducted an exploratory study into the major inhibitors of hospital medical personnel using the mandatory HIS system(s) the hospital provides. Our findings show that in addition to the traditional focus areas of information systems research "user, process and system", leadership and organizational setting also influence user behavior. We find that despite a generally positive attitude towards the system on the part of physicians, effective use was inhibited primarily by insufficient support of the working procedures caused by:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Insufficient systems integration and/or inadequate systems deployed by the hospital,
2. Traditional work processes that do not match the systems in place, and
3. Physicians' reluctance to adapt their work processes.

ACKNOWLEDGMENT

Chapter 87
Using Key Performance Indicators to Reduce Perceived Perioperative Complexity and Improve Patient Workflow

Jim Ryan
Auburn University at Montgomery, USA

Barbara Doster
University of Alabama, USA

Sandra Daily
Duke Medical Center, USA

Carmen Lewis
Troy University, USA

ABSTRACT

This study examines the development and use of balanced scorecard metrics as key performance indicators within each stage of the perioperative process to enable business process management across the entire process to gauge performance and target improvement opportunities. The identification of existing limitations, potential capabilities, and the subsequent contextual understanding are contributing factors toward perioperative improvement. This paper identifies how dynamic technological activities of analysis, evaluation, and synthesis applied to internal and external organizational data can highlight complex relationships within integrated hospital processes to address root causes rather than symptoms and ultimately yield improved capabilities. This case study investigates how integrated information systems can identify, qualify, and quantify perioperative performance indicators to measure improvement based on a 157-month longitudinal study of a large, 1,157 registered-bed teaching hospital. The theoretical and practical implications and/or limitations of this study's results are also discussed with respect to practitioners and researchers alike.

INTRODUCTION

The current focus of healthcare administration in the United States has shifted toward performance monitoring and improving clinical outcomes to meet regulatory and reimbursement requirements due to the American Recovery and Reinvestment Act of 2009, the Health Information Technology for Economic and Clinical Health Act, the Affordable Care Act, and the Joint Commission on Accreditation of Healthcare Organizations (TJC) / Centers for Medicare & Medicaid Services (CMS) core measures (Blumenthal, 2012). Meeting these performance and reporting challenges require leveraging information systems (IS) and technologies (IT) (PwC, 2012). Consequently, the current widespread IS/IT adoption across United States healthcare also necessitates the need for value realization (Jones et al., 2014). To this end, this study investigates how key performance indicators (KPIs) across a hospital's entire perioperative process can identify and ultimately achieve improved patient workflow via business process management (BPM).

A hospital's perioperative process is complex (Fowler et al., 2008), involving multiple interconnected sub-processes that provide surgical care for inpatients and outpatients during pre-assessment, pre-operative, intra-operative, post-operative, and central sterile supply (CSS) activities. Furthermore, the perioperative process yields patient end-state goals (Silverman & Rosenbaum, 2009) where: (1) a correct diagnosis for surgical intervention is identified with noted co-morbidities and patient consent; (2) a patient undergoes the surgical procedure; (3) a patient exhibits minimal exacerbation of existing disorders; (4) a patient avoids new morbidities; and (5) a patient experiences prompt procedure recovery. Meeting perioperative patient end-state goals also avoids hospital-acquired-conditions and hospital-acquired-infections (HACs/HAIs) connected with negative financial incentives (CMS, 2015; Waters et al., 2015; NQF, 2008). However, perioperative sub-processes are sequential, where sub-process activity sequence paces the efficiency and effectiveness of subsequent sub-process activities and risks achievement of patient end-state goals. Consequently, the perioperative process is tightly coupled to patient safety, patient quality of care, patient flow, and stakeholders' satisfaction (i.e., patient, physician/surgeon, nurse, perioperative staff, and hospital administration).

This case study identifies complex perioperative dynamics within and across the entire process that is nested in the hospital environment and reflected via sub-process scorecard metrics. This research investigates how traditional BPM practices are applicable to reduce perioperative complexity, measure process performance, target areas for improvement, and subsequently yield improved patient workflow. This study associates particular perioperative sub-processes with individual patient end-state goals, specifically highlights multiple balanced scorecard metrics from each perioperative sub-process, and explains how the metrics are applicable as KPIs. The investigation method covers a longitudinal study of an integrated clinical scheduling information system (CSIS) within an academic medical center. The implementation of agile, integrated IS and subsequent contextual understanding of perioperative sub-process data prescribed opportunities for measured improvements. Specifically, developing and implementing perioperative sub-process metrics as KPIs, grounded in internal and external best-practices, provides the framework for targeting opportunities and evoking improvement. The combined assessment of sub-process KPIs also provide change dynamics for evaluation and improvement to the overall perioperative process.

The following sections review previous literature on KPIs, BPM, as well as perioperative scorecards and dashboards. Following the literature review, we present our methodology, case study background, observed effects, and summary discussion. By identifying a holistic framework for analysis, evaluation, and synthesis of sub-process KPIs with established benchmarks, this paper prescribes an a priori envi-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ronment to support perioperative sub-process measurement and improvement through the identification of specific sub-process root causes rather than overall process symptoms. The conclusion also addresses study implications and limitations.

LITERATURE REVIEW

Integrated IS offer continuity through information sharing, synergy, and improvement (Karimi, 1988). Likewise, integrated IS and IT provide measurement and subsequent accountability for healthcare quality and cost, creating a dichotomy (e.g., quality versus cost) that represents the foundation for healthcare improvement (Dougherty & Conway, 2008). Within the perioperative process, patient end-state goals are the focus of work. However, United States hospitals currently face increasing pressure to provide objective evidence of organizational quality, efficiency, and effectiveness (Blumenthal, 2012; PwC, 2012). To this end, a BPM approach (Jeston & Nelis, 2008; Turban et al., 2008) borrowed from the manufacturing industry provides a framework to measure performance and target improvement.

The perioperative process is typically the primary source of hospital admissions, averaging between 55 to 65 percent of overall hospital margins (Peters & Blasco, 2004). Likewise, total hospital supply costs are variable with the largest cost category being the perioperative process (e.g., 33 percent) (Macario et al., 1995). Nonetheless, the perioperative process has many core sub-processes nested within the hospital environment that yield overall clinical performance. Furthermore, managing and optimizing quality, efficient, and cost-effective perioperative sub-processes to yield improved clinical outcomes are critical success factors (CSFs), both operationally and financially. To meet these demands, administrators and medical professionals must focus technology-enhanced practices that yield high quality of care and patient safety, coupled with increased efficiency and cost effectiveness. Measured utilization of these practices is not a result from any lack of research as an extensive body of knowledge exists concerning the application of these approaches in healthcare (Doebbeling et al., 2012; Albanese et al., 2010; Eckerson, 2010; and Tarantino, 2003). However, the literature suggests that such management practices and interventions can yield positive results with significant variations in success.

Key Performance Indicators

Early in the IT literature, Ackoff (1967) proposed IS design to include feedback control to avoid management misinformation. Similarly, information before and after intervention is an integral part of process improvement, which encourages bottom-up communication at the day-to-day operations level and requires process data comparisons to control metrics. Consequently, organizations define data metrics as KPIs to assist management in monitoring CSFs for organizational action via business processes (Munroe & Wheeler, 1980; Rockart, 1979; Zani, 1970). To this end, KPIs focus on organizational priorities that create long-term value for stakeholders (Baker, 2015). Likewise, performance metrics are essential requirements for BPM. However, doubt exists as to whether perioperative management can meet these demands (Catalona & Fickenscher, 2007), in part due to perceived perioperative complexity as a barrier (Fowler et al., 2008).

Operational and tactical KPIs identified in evaluating a hospital's perioperative process typically focus on intra-operative metrics (Doebbeling et al., 2012; Wright et al., 2010; Peters & Blasco 2004; Tarantino, 2003; and Kanich & Byrd, 1996) from the operating room (OR) like: (1) monitoring the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

percentage of surgical cases that start on-time (OTS), (2) OR turnaround time (TAT) between cases, (3) OR suite utilization (UTIL), and (4) labor hours per patient care hours or units-of-service (UOS) expended. However, OR schedules are tightly coupled to individual OR suites, patients, and surgeons where incomplete perioperative sub-process tasks upstream impact intra-operative KPIs. For example, incomplete pre-assessment or pre-operative tasks as well as unavailable CSS supplies/instruments/devices can delay a scheduled case as well as the subsequent scheduled cases in the particular OR suite or for the particular surgeon. Consequently, intra-operative inefficiencies and delays in turn impact post-operative activities downstream. Within the perioperative sub-processes, symptoms downstream can be more noticeable than actual root causes upstream, which supports having KPIs within all the perioperative sub-processes to gauge performance independently to identify problems and root causes rather than symptoms. Addressing problems and root causes supports continuous improvement.

Perioperative sub-process KPIs are often closely associated with multiple hospital CSFs. For example, OR TAT and a flexible work environment are CSFs for physician satisfaction (Wright et al., 2010; Macario, 2006; and Tarantino, 2003), which in turn is a CSF for hospital margin. Conversely, poor operational and tactical KPIs like OTS and OR TAT affect strategic CSFs of patient safety, patient quality of care, surgeon/staff/patient satisfaction, and hospital margin (Marjamaa et al., 2008; Peters & Blasco, 2004). Likewise, inefficient and ineffective reprocessing of instruments/devices within the CSS sub-process yields poor OR TAT KPIs (Duro, 2015) as well as places strategic CSFs at risk. This study takes a holistic view and identifies KPIs across all the perioperative sub-processes.

Business Process Management

This study uses the BPM definition provided by Jeston and Nelis (2008, p. 10) as "the achievement of an organization's objectives through the improvement, management, and control of essential business processes." The authors further elaborate that process management and analysis is integral to BPM, where there is no finish line for improvement. Hence, this study views BPM as an organizational commitment to consistent and iterative process performance improvement that meets organizational objectives.

Continuous process improvement (CPI) is a systematic approach toward understanding process capability, customer's needs, and sources of observed variation. Tenner and DeToro (1997) views CPI as an organizational response to an acute crisis, a chronic problem, and/or an internal driver. Incremental improvement gains occur via iterative cycles of analysis, evaluation, and synthesis or plan-do-study-act (Walton, 1986) to minimize observed variation. Doubt can exist as to whether the incremental improvement addresses symptoms versus causes; whether the improvement effort is sustainable year after year; and/or whether management is in control of the process (Jeston & Nelis, 2008).

Business analytics is the body of knowledge identified with technology solutions that incorporate performance management, definition and delivery of business metrics, as well as data visualization and data mining (Turban et al., 2008). Business analytics within BPM focus on the effective use of organizational data and information to drive positive business action (Tenner & DeToro, 1997). The effective use of business analytics demands knowledge and skills from subject matter experts and knowledge workers. Similarly, Wears and Berg (2005) concur that IS and/or IT only yield high-quality healthcare when the use patterns are tailored to knowledge workers and their environment.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perioperative Scorecards and Dashboards

The terms scorecard and dashboard are frequently used synonymously to describe a visual display mechanism that conveys performance information at a glance (Baker, 2015). Dashboards and scorecards are comprised almost entirely of KPIs, which collectively embody the corporate strategy tailored to each individual in the organization by role and level (Eckerson, 2006). Using scorecards and dashboards for purposes such as strategic, tactical, and day-to-day operations, coupled with internal and external best-practice benchmarks, provide the framework for targeting opportunities and measuring improvement. Drawing a distinction between the two, dashboards monitor process performance via charts or tables while scorecards focus on target or goal attainment using graphics (Baker, 2015; Wilbanks & Langford, 2014).

The KPI data presented in scorecards or dashboards provides the opportunity to monitor performance for process improvement or gather data for timely information in support of decision making. KPI data granularity within the scorecard or dashboard must be high enough to support drill down capabilities for knowledge discovery via online analytical processing or data mining to support analysis, evaluation, and synthesis activities associated with possible decisions (Karami, 2013). Overall, scorecards and dashboards can play a pivotal role in converting data and information into actionable knowledge (Baker, 2015; Wilbanks & Langford, 2014; Eckerson, 2006).

RESEARCH METHODOLOGY

The objective of this study is to examine KPIs across all perioperative sub-processes for use in traditional BPM practices that provides a framework to target and measure improvement as well as maintain perioperative patient end-state goals. To this end, case research is particularly appropriate (Weber, 2004; Eisenhardt, 1989). Paré (2001) recommended using a positivist case study methodology to build and test theories in IS research. A positivist approach in case research allows focus and analysis of the associated qualitative problems and environmental complexity (Yin, 2003). Hence, our study took an in-depth positivist approach to case research.

Our research site (e.g. University Hospital) is an academic medical center, licensed for 1,157 beds and located in the southeastern United States. University Hospital is a Level 1 Trauma Center, with a robotics program across eight surgical specialties as well as a Women's/Infant facility. University Hospital's recognition includes Magnet since 2002 and a Top 100 Hospital by U.S. News and World Report since 2005. Concentrating on one research site facilitated the research investigation and allowed collection of longitudinal data. This research spans activities from August 2003 through September 2016, with particular historical data since 1993. During the 157-month study, we conducted field research and collected data via multiple sources including interviews, field surveys, site observations, field notes, archival records, and document reviews.

CASE BACKGROUND

University Hospital Perioperative Services (UHPS) is the University Hospital department designated to coordinate and manage perioperative patient care across pre-admissions via the pre-operative assessment consultation and treatment (PACT) clinic, admissions, surgical preparations (PRE-OP), central sterile

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

supply (CSS), OR surgery and endoscopy, and post anesthesia care units (PACU). The workflow through CSS reprocesses all reusable surgical instruments/devices and moves supplies to pre-assessment, pre-operative, intra-operative, and post-operative activities. The following sections highlight tools, events, and outcomes that have shaped the UHPS BPM approach.

CSIS Implementation

UHPS implemented a new, agile CSIS in 2003, after using its prior CSIS for 10 years. The new CSIS supports OLAP tools, a proprietary structured query language, and both operational and managerial data stores (e.g., operational data store and separate data mart). Flexible routing templates or surgical preference cards (SPCs) allow standardization of surgical care supplies-instruments-devices or customization for surgeon specific procedures. Since the CSIS implementation, over 7,750 generic and custom SPC configurations facilitate the surgical specialty services (SSS) represented in Table 1. Similarly, the agile CSIS data mart serves as the central repository for perioperative data used to report KPIs with a business intelligence layer to support data visualization and dashboards.

November 2004

University Hospital opened a new diagnostic and surgical facility (i.e., North Pavilion) in November 2004. UHPS relocated CSS onto one floor (i.e., 3rd) with Pre-OP, ORs, and PACU on each of the two floors above CSS (i.e., 5th and 7th). The North Pavilion campus expanded UHPS to cover an additional floor and nine ORs (i.e., 33% capacity increase), providing 40 state-of-the-art OR suites with standard-

Table 1. Current CSIS SPCs

ized and surgical specialty equipment. Within six weeks of occupancy, an intra-operative KPI reflected chaos. Surgical case OTS plunged to 18% during December 2004. Having only 18% OTS is unacceptable in a highly competitive hospital industry, as 82% of scheduled surgeries experience delays and risk patient care and safety.

In January 2005, UHPS expressed concerns before a quickly convened meeting of C-level officers with top nursing, surgeons, and anesthesia representatives. The meeting yielded a hybrid management structure and governance in the formation of a multidisciplinary executive team, chartered and empowered to evoke change. The executive team consisted of perioperative stakeholders (i.e., surgeons, anesthesiologists, nurses, and UHPS). The executive team's charter was to focus on patient care and safety, attack difficult questions, and remove inefficiencies. No issue was off-limits.

Perioperative Process Improvements and Expansion

University Hospital's executive team launched a process improvement effort in 2005 to address the perioperative crisis. This CPI effort resulted in the executive team enlisting numerous task forces to address specific perioperative process problems and opportunities, which became the foundation for their BPM approach (Ryan et al., 2008). Since 2005, UHPS has focused data-driven analysis of KPIs to gauge process variance, identify improvement opportunities, and yield process improvement (Ryan et al., 2014). Using this systematic BPM approach, University Hospital's improvement efforts have targeted various perioperative sub-processes to achieve a balanced workflow (Ryan et al., 2016) at the North Pavilion campus. The results achieved through UHPS's BPM approach encouraged University Hospital administration to expand UHPS management responsibilities into other University Hospital facilities.

In 2009, UHPS expanded its management beyond the initial 32 general ORs (GENOR) and 8 cardiovascular OR suites (CVOR) within the North Pavilion campus to the other campuses of University Hospital Health System (UHHS) facilities to include 16 OR suites at the Highland campus (HHOR) and 8 endoscopy labs at the TK Clinic campus. In 2011, UHPS also created and assumed management of a pre-operative assessment, consultation, and treatment (PACT) clinic to screen pre-operative patient flow into UHHS ORs (Ryan et al., 2012). Two additional general ORs have been equipped since 2013 at the North Pavilion campus to bring UHPS management to 58 ORs and 11 endoscopy labs.

OBSERVED EFFECTS

The identification and definition of perioperative KPIs has been an iterative evolution since 2005. Consistently, the focus was data-driven improvements, with process control measures collected through the CSIS and benchmarked to external industry standards or prior months' metrics. While reviewing what could have been done better early in the CPI efforts, UHPS recognized the need to involve more perioperative stakeholders in improvement efforts and not just end-result to-do lists. Consequently, the executive team launched an initiative in 2008 to begin performance reporting for CMS and TJC. The perioperative BPM effort established balanced scorecard (Kaplan & Norton, 1996) measures (e.g. quality of process, satisfaction of customer, or financial) and a means to disseminate the process feedback to perioperative stakeholders at strategic, tactical, and operational levels. The BPM approach was expanded in FY2010 to reinforce UHHS strategy across all core hospital processes (Ryan et al., 2014).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In FY2014, the BPM task force (e.g., surgeons, anesthesiologists, nurses, and UHPS administration) was charged to create actionable information to support operational, tactical, or strategic initiatives across the perioperative process. The cross-disciplinary effort identified KPIs upstream and downstream of the ORs to include all perioperative sub-processes. The following sections detail the resulting KPIs, with each KPI classified by a Kaplan and Norton (1996) balanced scorecard (e.g. BSC) metric category of F-financial, Q-quality of process, or S-satisfaction of customer. A sampling of sub-process KPIs also illustrate the CSIS business intelligence layer capabilities for data visualization and performance dashboards.

Pre-Assessment KPIs

Pre-operative integrated evaluations communicate and document practitioner-patient awareness to avoid conflicts and identify potential OR specific risks (Silverman & Rosenbaum, 2009). To this end, University Hospital's PACT clinic manages pre-admission patient flow into UHHS ORs where all surgical patients receive a scheduled PACT evaluation prior to their surgical procedure. Prior to implementing the PACT clinic in 2011, missed pre-assessment activities contributed to 18% of intra-operative OTS delays.

The pre-assessment sub-process assists with a patient's end-state goal of (1) identifying a correct diagnosis for surgical intervention with noted co-morbidities and patient consent. When a patient arrives for a PACT evaluation, the surgeon documents a focused assessment of the patient and confirms surgery consent. The surgeon may also order testing (i.e. Stress, EKG, Imaging/X-ray, and/or Lab) as well as a cardiac/medical consultation as needed. Documentation of existing HACs or HAIs prior to the patient's admission also disassociates UHHS with potential negative financial incentives (Waters et al., 2015; NQF, 2008) for the pre-existing HACs or HAIs. During the PACT evaluation, a PRE-OP nurse also verifies CSIS inclusion of pre-assessment patient documentation across eight categories: 1) surgery consent; 2) medication reconciliation; 3) medical history / physical exam (H&P); 4) surgical procedure history; 5) patient allergies; 6) problem listing; 7) pre-surgical physician orders; and 8) scheduled procedure / patient education.

Table 2 details the current UHHS recommended pre-assessment KPIs. The five pre-assessment sub-process KPIs are quantitative metrics derived from the CSIS operational data store per the following calculations. % of Patients Seen is the number of PACT patients divided by the number of scheduled out-patient and same-day-surgery cases that should yield 100%. % of Patient Walk-ins is the number of PACT walk-ins divided by the number of PACT visits where the metric should be 5% or less. % of No Shows is the number of no show appointments divided by the total appointment slots and the target is 1% or less. Missing Documentation is a ratio of the total missing documents per category (e.g. 8 total

Table 2. Pre-assessment Sub-process KPIs

Pre-assessment KPIs	BSC	Best Practice
% of Patients Seen	Q	100%
% of Patient Walk-ins	F	5% or less
% of No Shows	F	1% or less
Missing Documentation	Q	0 or none
PACT Length of Stay (LOS)	S	45 min.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

categories) divided by the number of PACT evaluations, where the target is none. *PACT LOS* is the average elapsed minutes for a patient's PACT evaluation and the target is 45 minutes. PACT pre-assessment metrics are analyzed, evaluated, and discussed to minimize future occurrences.

Pre-Operative KPIs

During pre-operative activities, PRE-OP nurses prepare patients for their surgical procedures per physician orders and provide acute patient care after anesthesia. PRE-OP is queue or staging area upstream from intra-operative, with a finite number of areas/beds to prepare patients for surgical procedures. The pre-operative sub-process assists patient's end-state goals of (1) identifying a correct diagnosis for surgical intervention with noted co-morbidities and patient consent, (3) patient exhibits minimal exacerbation of existing disorders, and (4) patient avoids new morbidities. Table 3 details the current UHHS recommended pre-operative KPIs.

The four pre-operative sub-process KPIs are quantitative derivations from the CSIS per the following calculations. *Patient-Arrival-to-Admission* is the patient UHHS arrival time prior to PRE-OP entry and the target timeframe is 2 to 3 hours. *% Patients w/o PACT Eval* is the number patients not seen in PACT prior to PRE-OP, divided by the number of PRE-OP patients, where the target is 5% or less. *PRE-OP Delays* are delay minutes tallied by reason and the average minutes per reason is targeted to be five minutes or less. *PRE-OP LOS* is the elapsed minutes a patient stays in PRE-OP prior to moving to an OR suite and the target average is 35 minutes per patient. All patient experiences of excessive Patient-Arrival-to-Admission time, arriving without a PACT evaluation, PRE-OP delay, or excessive PRE-OP LOS time are analyzed, evaluated, and discussed to avoid future occurrence.

Intra-Operative KPIs

When a patient arrives in an OR suite, an OR nurse begins documenting all people, time, and activities encountered while the patient is present, as required by TJC and CMS, as well as all medication, blood, tissue, and supply usage via the CSIS surgical case. Other CSIS intra-operative documentation includes quality issues for patient longitudinal outcomes, retained object counts, and robotic usage. The final intra-operative CSIS documentation occurs after the patient's surgical case completion when OR staff document the UOS time spent on the OR suite clean up and setup for the next scheduled surgical patient. The intra-operative sub-process assists UHHS in meeting a patient's end-state goals of (2) a patient undergoes the surgical procedure; (3) a patient exhibits minimal exacerbation of existing disorders; and (4) a patient avoids new morbidities.

Table 3. Pre-operative Sub-process KPIs

Pre-operative KPIs	BSC	Best Practice
Patient-Arrival-to-Admission	Q	2 to 3 hours
% Patients w/o PACT Eval	F	5% or less
PRE-OP Delays (By reason)	Q	5 min. or less
PRE-OP Length of Stay (LOS)	S	35 min.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4 details the current UHHS recommended intra-operative KPIs documented via the CSIS during a patient's surgical or endoscopy procedure. The fifteen intra-operative KPIs are derived from the CSIS operational data store per the following calculations. *Prime Time Room Utilization* (e.g. UTIL) is the sum of the time duration to perform each surgical procedure (i.e. "OR In" to "OR Out"), plus the total turnaround time, divided by the prime time available to GENOR and CVOR suites (i.e. 7AM-5PM Mondays to Fridays except 8AM-5PM on Tuesdays) or to HHOR suites (i.e. 7AM-3PM Mondays to Fridays except 8AM-3PM on Tuesdays), with OR availability decreasing on holidays and weekends. The best practice target for Prime Time Room Utilization is 80%. *Modified Block Utilization* is the sum of the time duration to perform each surgical procedure (i.e. preparation of the patient in the OR, anesthesia induction, and emergence) plus the total turnover time, divided by the modified block time scheduled where the target is 75 to 80%. *Block Run-Over Utilization* is the sum of the time duration of surgical procedure performed in 2 hour increments after the assigned prime time block for GENOR and CVOR (i.e., 5PM – 7 PM and 7 PM – 9 PM) or HHOR (i.e., 3 PM – 5 PM and 5 PM – 7 PM) divided by the hours available based on scheduled ORs during those time increments. The Block Run-Over Utilization target is none, with an exception for emergency surgeries. These utilization metrics gauge the use of OR time by specific SSS and surgeons as well as providing the basis for projecting future OR time allotments back to the specific SSS or surgeon.

First Case of the Day On-time Starts (FCOTS) is the percentage of first cases scheduled as of 6 AM day of surgery with an in-room start time (i.e., wheels in) that is either early or not more than 5 minutes after the scheduled start time with a cut off time of 7:30 AM Mondays to Fridays except 8:30 AM on Tuesdays. The target for *FCOTS* is 90% +/- 5 minutes and 95% within 15 minutes. *Subsequent On-time Starts* (e.g. *OTS*) is the percentage of "Prime Time" non-first cases where patient-in-room start time is within 15 minutes of the estimated scheduled procedure start time and the best practice target is 80%

Table 4. Intra-operative Sub-process KPIs

Intra-operative KPIs	BSC	Best Practice
Prime Time Room Utilization	F	80%
Modified Block Utilization	F	75% - 80%
Block Run-Over Utilization	F	None
First Case of the Day On-time Starts	S	90% +/- 5 min. or 95% in 15 min.
Subsequent On-time Starts	S	80% in 15 min.
OR Turnaround Time	F	25-30 min.
In Room to Cut Time	Q	20 – 30 min.
Close to Out of Room Time	Q	12-17 min.
Surgeon RVU Gap	F	30 - 40%
Accurate Case Duration Est.	Q	80%
Day of Surgery Cancel Rate	F	Less than 2%
Day of Surgery Add-ons	Q	Less than 10%
% of Cases with Delays	S	Less than 5%
Average Minutes per Delay	S	5 – 15 min.
Total Minutes Lost to Delays	F	None

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

within 15 minutes. *OR Turnaround Time* (e.g. *TAT*) is the minutes elapsed between the prior patient exiting the room and the succeeding patient entering the room, with the best practice target of 25 to 30 minutes. *FCOTS*, *OTS*, and *TAT* reflect the performance of patient workflow based on the OR schedule and subsequent intra-operative sub-process, communication, and teamwork.

In Room to Cut Time is the elapsed minutes from when a patient enters the room (i.e. wheels in) till the patient's cut-procedure-start time, where the target is 20 to 30 minutes. *Close to Out of Room Time* is the elapsed minutes between the patient's close-procedure-stop time till the patient leaves the OR (i.e. wheels out), where the target is 12 to 17 minutes. *Surgeon RVU Gap* is the minutes elapsed between the prior patient-closed-procedure-stop time and the surgeon's succeeding patient's cut-procedure-start, divided by the prior case time (e.g. cut-procedure-starts to close-procedure-stop). The best practice for Surgeon RVU Gap is 30 to 40%. The first two OR time metrics reflect the total time a patient is in the OR by zones—waiting to start, procedure time, and waiting to exit. Excessive wait times before or after a procedure are reviewed by UHPS administration. Likewise, the Surgeon RVU Gap is a surgical time efficiency measure provided to the surgeon and SSS.

Accurate Case Duration Est. is the percentage of cases where patient-in-room duration (e.g. wheels-in to wheels-out) is within 15 minutes of the estimated in-room duration (i.e. total scheduled surgical time), where the best practice target is 80%. *Day of Surgery Cancel Rate* is a percentage of scheduled cases cancelled after 7PM on the day prior for any reason, divided by the number of scheduled cases for the day of surgery, where the target is less than 2%. *Day of Surgery Add-ons* is a percentage of cases scheduled after 7PM on the day prior, divided by the number of scheduled cases for the day, where the target is less than 10%. These metrics gauge modified block scheduling process (Ryan, et al., 2011) performance and adherence by specific surgeon and SSS.

% of Cases with Delays is a percentage of case delays to cases performed by a surgeon or SSS, where the best practice target is less than 5%. *Average Minutes per Delay* is the elapsed minutes associated with particular SSS delays divided by the number of delays for a SSS, where the target is 5 to 15 minutes. *Total Minutes Lost to Delays* is the number of elapsed minutes associated with delays for a particular SSS, where the best practice target is none. All delayed surgical cases are analyzed, evaluated, and discussed for future delay avoidance.

Post-Operative KPIs

The post-operative sub-process assists in meeting a patient's end-state goals of (3) a patient exhibits minimal exacerbation of existing disorders; (4) a patient avoids new morbidities; and (5) a patient experiences prompt procedure recovery. PACU nurses receive surgical patients from the OR and continue acute care per physician's orders until patient recovery. The PACU has a finite number of acute care beds that accommodate surgical intensive care patients. As surgical patients recover from anesthesia, the need for acute care lessens and patients move to PACU Phase-II ambulatory patient care via the CSIS, leaving acute care patients in acute care beds. Inpatients (IP) recover from anesthesia to be discharged or outpatients (OP) recover to be moved to a hospital bed.

Table 5 details the current UHHS recommended post-operative KPIs documented via the CSIS during a patient's PACU visit. The five post-operative sub-process KPIs are derived per the following calculations. *Bed-Assigned to Ready-to-Move* is for inpatients only and represents the average minutes between the two times, where the target is 15 minutes. *Ready-to-Move to Occupy-Bed* is for inpatients only and represents the average minutes between the two times, where the target is 15 minutes. *Ready-*

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Post-operative Sub-process KPIs

Post-operative KPIs	BSC	Best Practice
Bed-Assigned to Ready-to-Move	Q	15 min. for IP
Ready-to-Move to Occupy-Bed	Q	15 min. for IP
Ready-to-Sign-Out to Sign-Out	Q	5 min. for both
# of Patient Holds in PACU	F	None
PACU Length of Stay (LOS)	S	60 min. – IP or 45 min. - OP

to-Sign-Out to Sign-Out is for both inpatients and outpatients, representing the average minutes between the two times and the target for both is 5 minutes. *# of Patient Holds in PACU* is the number of patient holds in PACU by Patient Type and average elapsed minutes, where the target is none. *PACU LOS* is the average minutes from patient arrival in PACU to discharge from PACU, where the target is 60 minutes for inpatients and 45 minutes for outpatients. PACU KPIs measure how long an inpatient or outpatient spends in PACU, waits to be moved, and denotes patients held in PACU. All excessive times and PACU holds are analyzed, evaluated, and discussed for future resolution.

Central Sterile Supply KPIs

The workflow through CSS moves sterile supplies/instruments/devices to ORs and soiled materials back on all three OR campuses via separate CSS facilities. Prior to a patient's arrival in each OR, CSS delivers a prepared case cart (i.e. up to 8-hours in advance) containing supplies/instruments/devices for the patient's specific surgical procedure per the CSIS SPC pick list and then reprocesses used and un-used case cart contents after the surgical case completion. The CSS sub-process assists the patient's end-state goals of (3) a patient exhibits minimal exacerbation of existing disorders and (4) a patient avoids new morbidities. Likewise, CSS KPIs assist UHHS to avoid HACs and HAIs as well as associated potential negative financial incentives (Waters et al., 2015; NQF, 2008).

Table 6 details the current UHHS recommended KPIs documented during the CSS sub-process. The six CSS KPIs are quantitative and derived per the following calculations. *Immediate Use Steam Sterilization (e.g. IUSS) Usage Rate* is the number of IUSS occurrences divided by the number of surgical procedures, where the target is less than 2%. *Damaged Tray Rate* is the incident total of all trays (e.g., trays of instruments) not meeting surgeon and staff expectations including tracking of wet trays (i.e., sterilized instruments contaminated with retained water), divided by the total trays processed, where the target is none. *Preventive Maintenance (e.g. PM) Plan Adherence Rate* is the percentage of trays receiving the PM review per the contracted number of sets to be reviewed, where the target is 100%. I*nstrument Trays > 25 Lbs.* is the number of tray sets, including vendor trays (e.g., instruments on loan from vendors), exceeding the 25 pound weight limit, where the target is none. *Vendor Tray Management Non-Compliance (e.g. NC) Rate* is the number of incidents that the vendor tray management process was not met, where the target is none. *Surgeon Preference Card (e.g. SPC) Update Review* is the number of surgical preference cards signed off by the SSS surgeons every 6 months divided by the number of SSS SPCs, where the target is 100%. These operational and tactical metrics impact strategic CSFs of patient safety, patient quality of care, employee satisfaction, and hospital margin.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. CSS Sub-process KPIs

Central Sterile Supply KPIs	BSC	Best Practice
IUSS Usage Rate	Q	Less than 2%
Damaged Tray Rate	Q	None
PM Plan Adherence Rate	Q	100%
Instrument Trays > 25 Lbs.	F	None
Vendor Tray Mgt. NC Rate	S	None
SPC Update Review	F	100%

KPI DATA VISUALIZATION

Figures 1, 2, and 3 are examples of data visualization for pre-assessment, intra-operative, and CSS sub-process KPIs. KPI filters are depicted on the left side of each figure. Figure 1 takes each of the 8 KPI categories of PACT *Missing Documents* required for complete documentation and uses line graphs to illustrate the magnitude of the top three missing document frequency counts above 30% for medical reconciliation, problem lists, and surgical procedure history. Figure 1 also shows the bottom five categories that were 15% or less. Figure 2 takes the *Prime Time Utilization* KPI and displays it as a stacked bar graph and a pie chart, along with a bar chart of modified block minutes assigned to each SSS. Lastly, Figure 3 displays *IUSS* KPIs via line graphs and *Tray Set* KPIs via bar charts. All of the perioperative sub-process KPI data residing in the CSIS data mart can be visualized like these examples.

Intra-Operative Performance Dashboard

Before FY2016, UHPS tallied perioperative BSC measures into electronic dashboards and pushed the results out to stakeholders (Ryan et al., 2014). As of FY2016, KPI data visualizations and dashboards are pulled on-demand by stakeholders. Figure 4 below depicts a dashboard query of intra-operative metrics. For a given time period, location, OR room, or SSS, the dashboard query will visualize intra-operative KPIs of *FCOTS* and *OTS*. Complete cases have been UHPS verified and the *Add-on Case* gauge reflects the criticality of 25% add-on case volume to resource capacities. *Case Cancelled on DOS* is a Pareto chart identifying surgeons who have the most cases cancelled on days which specific surgeries were scheduled to occur. The *Patients entering PACU* graph depicts cumulative peak volume times of patients entering PACU over a 24-hour frequency. Lastly, the *Number of Cases with Late Starts* is a Pareto chart identifying surgeons with the highest frequency of surgical cases that did not start on-time.

SUMMARY AND DISCUSSION

Perioperative stakeholders pull KPI data visualizations and dashboards on demand as needed. The 35 perioperative KPIs represent distinct perioperative sub-process perspectives from which stakeholders can gauge, visualize, and measure performance while providing the opportunity to drill down to potential problem root causes within a given sub-process rather than being limited to visibility of associated symptoms elsewhere in the process. In regards to a BSC approach (Kaplan & Norton, 1996), 13 of the

Figure 3. Central Sterile Supply KPIs

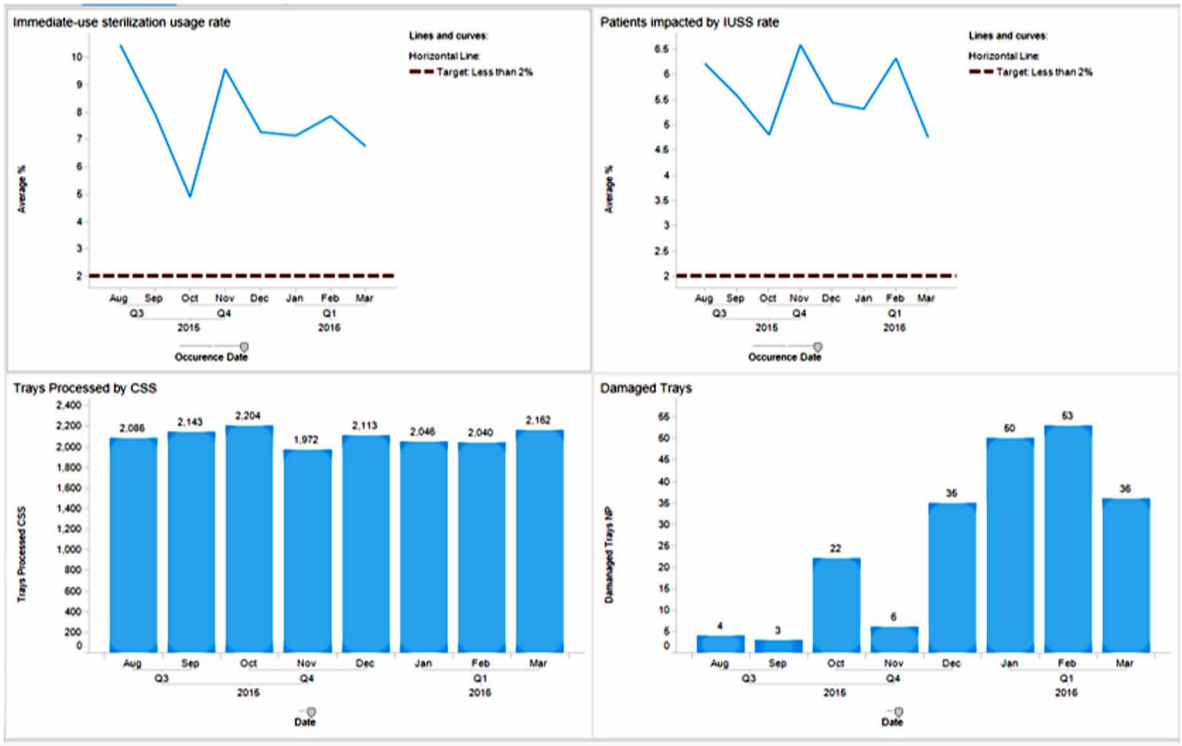

Figure 4. Intra-operative Performance Dashboard

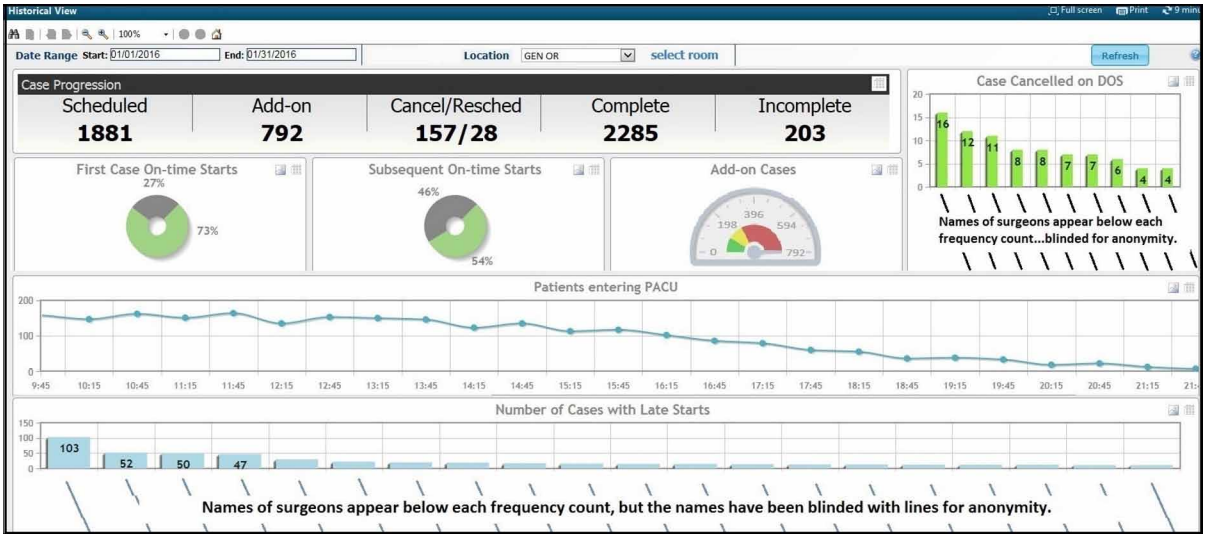

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

KPIs reflect financial perspectives (e.g., 37.1%), 14 reflect quality of the process (e.g., 40%), and 8 reflect satisfaction of the customer (e.g., 22.9%). Similarly, all 35 KPIs provide a learning perspective to evaluate each perioperative sub-process as well as identify how each KPIs in each sub-process support specific patient end-state goals. Furthermore, breaking down perceived perioperative complexity (Fowler et al., 2008) into component sub-processes demonstrates a proven approach to understanding complexity by reducing the perspective of the phenomenon into smaller more manageable, comprehendible, and explainable units (e.g., sub-processes).

The BPM taskforce's charge to create actionable information to support initiatives at the operational, tactical, and strategic levels requires a periodic iterative review of KPIs due to anticipated improved understanding of specific sub-process relationships. Improved sub-process understanding will drive the need to revise existing KPIs to better reflect the improved comprehension. Hence, periodic KPI reviews and revisions provide continuous improvement opportunities for each sub-process and the overall perioperative process workflow.

To demonstrate increased perioperative patient flow, the GENOR (i.e., North Pavilion campus without CVOR) surgical volume increased by 11.69% between FY2006 (18,921 cases) to FY2014 (21,133 cases). Figure 5 reflects UHHS increased patient volume over FY2014, FY2015, and FY2016, with increasing patient flow across inpatient and observation (10.37%), emergency department (11.76%), surgical procedures (5.95%) as well as labor and delivery (5.16%).

CONCLUSION

This study highlights balanced scorecard metrics from each perioperative sub-process (e.g. pre-assessment, pre-operative, intra-operative, post-operative, and ancillary CSS activities), demonstrates how the metrics are applicable as KPIs, and defines how each perioperative sub-process supports specific patient end-state goals. Empowered individuals, integrated IS, and a holistic framework for analysis, evaluation, and synthesis of sub-process measures prescribed an a priori environment for replication and use. Moreover, BPM practices were adaptable to explain overall perioperative complexity and improvement efforts within the perioperative sub-processes. The cycle of analysis, evaluation, and synthesis also reinforced communication and stimulated individual as well as collective organizational learning.

Our case study contributes to the healthcare IT literature by examining how continuous improvement is applicable to BPM practices via establishing KPIs as well as the management of perioperative sub-processes nested within the hospital environment. This paper also fills a gap in the literature by identifying sub-process KPIs to help explain perioperative complexity and how process metrics as data are both a performance measure and management tool.

This study was limited to a single case, where future research should broaden the focus to address this issue along with others that the authors may have inadvertently overlooked. The case examples presented in this study can serve as momentum for BPM via KPI identification and use in healthcare methodology, comprehension, and extension. The study's results should be viewed as exploratory and in need of further confirmation. Researchers may choose to further or expand the investigation, while practitioners may apply the findings to create their own version of BPM through KPI identification and use within the hospital environment.

Chapter 88
Building Intelligent Systems for Paying Healthcare Providers and Using Social Media to Detect Fraudulent Claims

Jack S. Cook
The College at Brockport, USA

M. Pamela Neely
The College at Brockport, USA

ABSTRACT

Using an interpretive case study approach, this paper describes the data quality problems in a regional health insurance (RHI) company. Within this company, two interpretive cases examine different processes of the healthcare supply chain and their integration with a business intelligence system. Specifically, the first case examines RHI's provider enrollment and credentialing process, and the second case examines the processes within the special investigations unit (SIU) for investigating and detecting fraud. The second case examines DIQ issues and how social media can be used to acquire evidence to support a fraud case. In addition, the second case utilized lean six sigma to streamline internal processes. A data and information quality (DIQ) assessment of these processes demonstrates how a framework, referred to as PGOT, can identify improvement opportunities within any information intensive environment. This paper provides recommendations for DIQ and social media best practices, and illustrates these best practices within this real-world context of healthcare.

INTRODUCTION

Organizations rely on data for a multitude of applications: customer service and relationship management, decision making, and regulatory compliance. There is currently a push specifically in healthcare to be smarter about its management of key performance outcomes, as well as to actively investigate fraud

and potential fraud. Organizations are beginning to search for methods to deliver information to decision makers in more intelligent ways. A desire to lower costs and improve patient outcomes is driving this need for more intelligent data. Therefore, one option is to use business intelligence (BI) and/or collective intelligence (CI) to form the heart of any system that delivers organizationally sustaining data to providers and payers so they can make decisions that positively impact patient and service outcomes, and lower costs.

The challenge is to convince administrators, clerical staff, clinicians and physicians to buy-in to the importance of integrating previously disparate data to create a real-time view of the relationship between a patient, the provider, and the payer or payers. This article focuses on BI and CI systems that support healthcare, and the data and information quality (DIQ) issues that are inherent in any environment that is information intensive. These systems have tremendous potential to impact healthcare, from multiple perspectives – patients, providers and payers. From a patient's perspective, BI can provide clinicians treatment and immunization recommendations that are preventative in nature, improving both diagnostic accuracy and better implemented care plans. Billing is critical in today's healthcare environment; providers transmit claims to multiple payers, and payment denials are common. BI dramatically improves data and information quality. Therefore, from the provider's perspective, IT professionals can streamline the complex billing process using BI. From a payer's perspective, a better connection to providers and a more intelligent way to enroll and credential them will reduce claims adjustments and disputes. CI has the ability to systematize the discovery of fraud – both provider fraud and member fraud.

This article provides a brief literature review of healthcare, business intelligence (BI), and collective intelligence (CI), as well as data and information quality (DIQ), followed by a brief summary of fraud prevention, deterrence, detection and response. The article then examines two cases that make the point that BI and CI are reasonable approaches to managing key healthcare performance outcomes, including early detection of fraud. The first case details the process that a payer performs to enroll and credential a healthcare provider. The second case examines a special investigations unit's process for determining if fraud has occurred, independent of whether it was committed by a provider or member. The objective in this second case was to streamline the process by utilizing lean six sigma to eliminate waste and explore fraud red flags using social media so that more investigations, using the same resources, can be processed within a given time period. We conclude with recommendations for using BI and CI most effectively in a healthcare setting.

LITERATURE REVIEW

Healthcare

As defined by the U.S. Department of Health and Human Services, a healthcare provider is "a provider of services as defined in §1861(u) of the Act (Social Security Act), a provider of medical or health services as defined in §1861(s) of the Act, and any other person or organization who furnishes, bills, or is paid for healthcare services or supplies in the normal course of business." (U.S. Department of Health and Human Services, 2001) Until recently, healthcare providers were paid when sick people sought treatment. Quality and outcomes were not rewarded, but rather providers were paid based on how much was done to treat the patient. In the future, healthcare providers will be given financial incentives to keep people well, and quality, not treatment, will matter a great deal. This shift from volume to value will require a rethinking of treatment plans and a shift towards preventative care.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Business Intelligence (BI)

Traditionally, BI has been described as supporting human intelligence with "technologies, applications and processes for gathering, storing, accessing and analyzing data to help users make better decisions" (Wixom & Watson, 2010, p. 14). BI is used in many industries, including healthcare (Olinsky & Schumacher, 2010; Sillup, Klimberg, & McSweeney, 2010).

Wixom and Watson (2010) contend that BI is about getting the data in (via a data warehouse or data mart) and getting the information out (using organizational specific tools to meet decision making purposes). They provide a model of a BI-based organization that includes the traditional data warehouse elements and data integration coupled with analytical tools that have historically been of the online analytical processing (OLAP) and decision support type. These historical tools are now under the umbrella of BI technologies and applications, and are not listed separately. Additionally, and equally as important, the model includes processes related to metadata, data quality and governance. The recognition of these processes as important to the BI environment reinforces the need for practitioners to evaluate BI as a system, not simply a technology.

An important aspect of BI is the ability to analyze data and return information that can be used in decision making. Related to BI is the field of big data analytics. As data has become more abundant, there is a need for new technologies and techniques to analyze this data effectively (Chen, Chiang, & Storey, 2012). Another challenge in healthcare is the abundance of free text that is not easily analyzed. Doctors' notes, prescription information, and notes attached to test results can all be found in the typical healthcare system. New technologies in text analytics are necessary to adequately mine the data to affect decision making (Chen et al., 2012).

Chang (2014) introduces the concept of Business Intelligence as a Service (BIaaS) in the Cloud. He implements the approach using two financial based scenarios; risk and pricing for financial analysis and stock market analysis. This approach harnesses the power of the Cloud and allows for more complex models and improved accuracy of predictions. Taken together, the structure of BI is morphing and becoming an even more powerful tool.

Social Media

This term refers to much more than just Facebook. The wealth of user-created information on the web (Web 2.0) has led to the ability to share virtually anything with anyone. The various categories of social media enable end users to interact with each other in the virtual worlds, sharing opinions, discussions, pictures, videos, and factual information. The various parties may or may not know each other in the face-to-face world. Thus, social media has broadened the opportunities to meet and collaborate with people from around the world. It has also opened up the possibilities of employers learning more about employees than has previously been possible. However, the large amount of data generated by social media will need new tools in order to truly harness the power of all of this data. Chang (2016) describes a Social Cloud that allows companies to learn how people react to products and services. Because the tool permits the use of multiple APIs, this is a good first step in designing systems that will capture data that may be related to fraud.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Collective Intelligence (CI)

CI is the shared or group intelligence that emerges from consensus decision making. These group decision outcomes depend on rules, such as majority rule or quorum rule (Hastie and Kameda, 2005). Multiple medical/healthcare related studies use collective intelligence to show that group decisions are consistently better than individual decisions (Wolf, et al, 2015; Engel, 2014; Henandez-Chan et al, 2012; Jane Budge et al, 2015, Kurvers et al, 2015). Crowdsourcing and social media support CI, and the collective behavior of a group of individuals online in terms of their social media usage can provide evidence of fraudulent behavior on the part of one or more members in the group.

Data Quality Management (DQM)

Weber, Otto and Osterle, (2009) define DQM as quality-oriented management of data as an asset, that is, the planning, provisioning, organization, usage, and disposal of data that supports both decision-making and operational business processes, as well as the design of the appropriate context, with the aim to improve data quality on a sustained basis. The management of DIQ is also referred to as data governance.

The quality of data and information is dependent on how it is used, also known as fitness-for-use (Neely & Cook, 2011). It is difficult to trust your business intelligence system when DIQ is poor, and processes are ill conceived. Within healthcare, a reduced number of denials for claim payment and increased patient care (Leape et al., 1993) can result from improved DIQ because the system can notify providers of immunization and care plans automatically. This should result in better patient satisfaction. Fewer adjustments to the claims processing system (Romano Mj, 2011), decreased time to enroll providers, and reduced labor with respect to enrolling providers will result in better provider satisfaction and an increase in revenues in general (Rauscher & Wheeler, 2008).

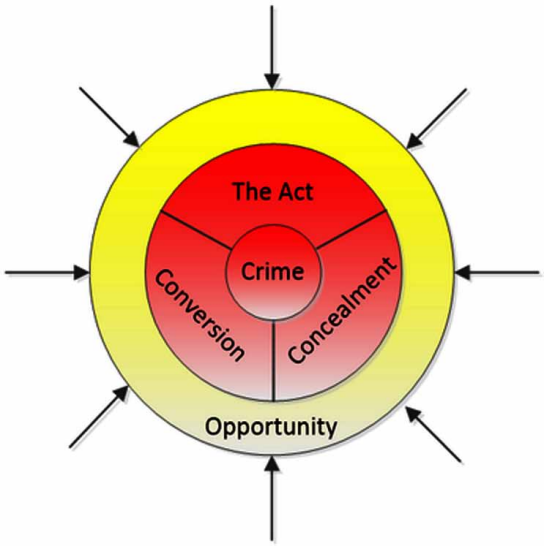
DIQ in healthcare will continue to be of the utmost importance, for patient safety and satisfaction as well as the financial health of the system. Given the unique nature of the payment system in healthcare, it is critical that systems facilitate providers being paid. Getting paid from sometimes multiple payers, when payers have the ability to deny payment for a multitude of reasons, is much more challenging than in almost any other industry.

Fraud Management

Fraud prevention, deterrence, detection and response has been extensively studied in the literature (Bonchi et al, 1999; Debreceny et al, 2005; Fawcett & Provost, 1997). In particular, fraud is prevalent in healthcare (Bosler, 2015; Bourquard & Kirsch, 2015; Delancy & Gorton, 2015; Simborg, 2014). As seen in Figure 1, fraud consists of the criminal act, conversion, and concealment, assuming the opportunity to commit the crime exists in the first place. In Figure 1, the larger circle represents an opportunity for someone to commit a fraud. The larger the opportunity, the more likely it is that someone will commit a crime. If no opportunity exists, then no crime can be committed. The arrows pointing in towards the opportunity circle represent the actions taken by the company to close the "hole", represented by increased security measures, surveillance, and utilizing social media to name a few. Given the opportunity, the fraudster will commit the criminal act, conceal it from the organization, and eventually convert it to a form (primarily money) where it can be used by the fraudster.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The crime



Dorminey et al (2008) explores the topic from the perspective of the fraud triangle as well as a meta-model of white collar crime. When the fraud triangle was developed, it was seen as an employee/employer relationship and occurred within the context of the work environment. Often these people were crisis fraudsters, and this was the type that was originally envisioned when the original fraud triangle was proposed. This person has pressure, rationalizes their action and has the opportunity to commit the fraud.

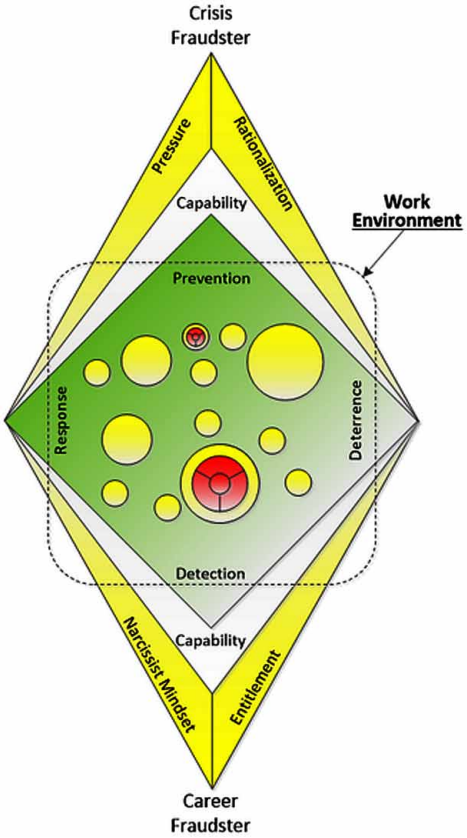
We have extended this work by identifying two different types of fraudsters, with differing motivations – crisis fraudster and the career fraudster. The fraud compass (as seen in Figure 2) shows that both types of fraudsters need to possess the capabilities necessary to commit the criminal act. Also, our model shows the relationship between the crime (fraud) and the work environment. As online resources, especially social media, have become more prevalent, the work environment has expanded from the physical space to the virtual space. As one work environment becomes too challenging to defraud, the career fraudster moves to another company, committing frauds in each position they hold. They have a narcissistic mindset and a feeling of entitlement, which is very different from what was envisioned by the fraud triangle. Until they are prosecuted and convicted, they will continue to seek opportunities to commit fraud. In order for fraud to occur, both types of fraudsters must have the capability to commit the fraud and an opportunity. Luckily, companies can limit the opportunities through better use of BI, CI, and social media to identify fraudulent acts earlier.

Interplay between DIQ, CI and BI

Quality can be dramatically improved; for example, medical errors account for the deaths of at least 200,000 people in the U.S. even though the US healthcare system has traditionally been known for high quality (Harmon, 2009). BI systems could help to alleviate many of the errors found in healthcare systems. For example, diagnostic errors could be mitigated with BI by utilizing data mining techniques to look for cause and effect of lifestyle factors. These lifestyle factors could guide the diagnostician towards additional testing, ultimately resulting in a correct diagnosis.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Fraud compass



By using decision-support tools or BI, these systems can increase the adherence to protocol-based systems. However, these systems can be costly and there is a need to study the return on investment. Bardhan and Thouin (2012) show that the use of electronic health record systems (EHRs) can positively impact the treatment for heart attacks, heart failures and pneumonia. Furthermore, using financial management systems can result in lower operating expenses. On the other hand, Romano (2011) studied clinical decision making systems (CDS) and did not find a correlation between visits with and without a CDS on the quality of care. Linder et al. (2007) had a similar finding. Their study examined EHR use and ambulatory care quality and found no significant association. According to Giannangelo and Fenton (2008), in order for the EHRs to be effective, there must be a standard of codification and it must be used consistently to ensure that data is correct and reliable. This codification, particularly within the financial portion of the system, can lead to more effective revenue cycle management (RCM).

RCM is the collection of methods used to manage claims payment processing and revenue generation. Unlike the standard business-to-business or business-to-consumer model, whereby an invoice or request for payment is generated and the payment is made, a significant proportion of the revenue in healthcare is derived from non-patient payment (e.g., a third party), resulting in multiple streams of payments that must be managed. RCM is a frequent component of BI, allowing managers to increase the speed and amount of patient revenue collection (Rauscher & Wheeler, 2008).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is potential for social media and crowdsourcing to support collective intelligence, thus allowing early detection of fraud. The BI system can automatically scan social media sites, allowing auditors additional support for decision making, effectively providing a larger sample of data and providing the majority rule components of collective intelligence (Bardhan and Thouin 2012).

A properly implemented business intelligence system can play a vital role in ensuring quality throughout the data and information lifecycle. Thus, this article examines the connections between these three very important and mutually dependent areas of practice, BI, CI, and DIQ, in such a data-rich environment as healthcare. The PGOT framework, discussed next, provides an excellent mechanism for evaluating opportunities for improving quality.

DATA AND INFORMATION QUALITY FRAMEWORK – PGOT

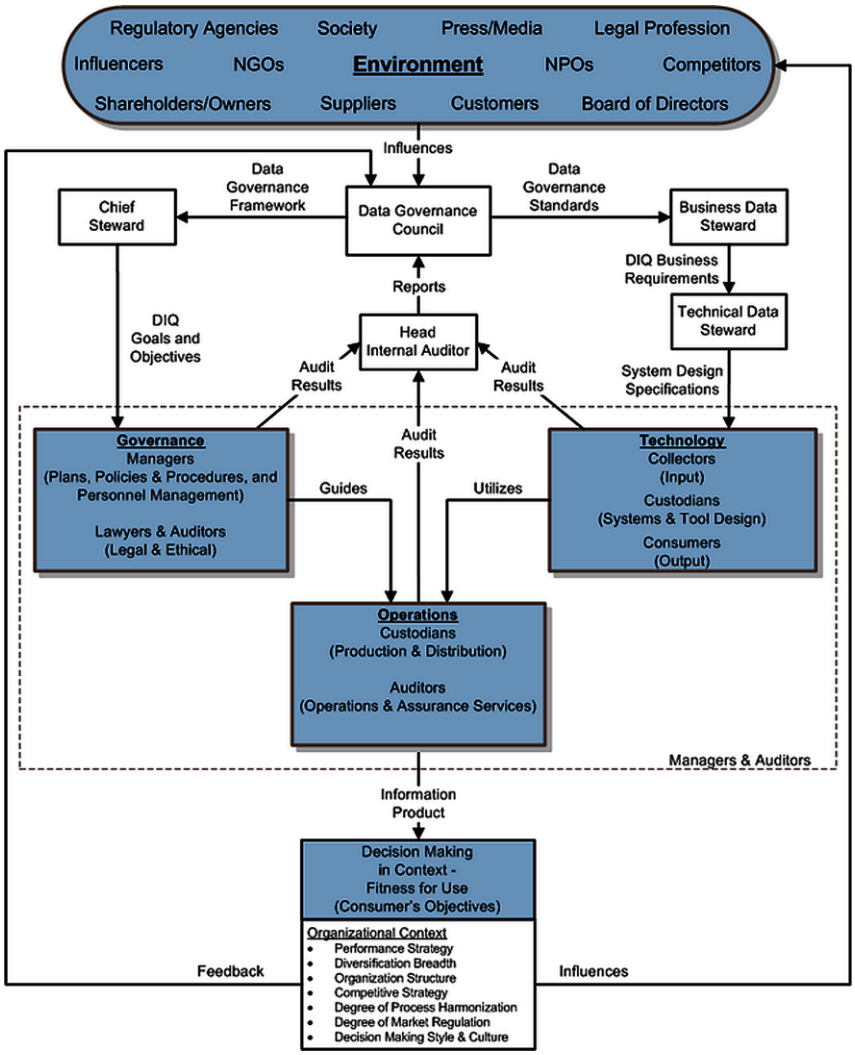
As evidenced by frameworks such as COBIT (Boritz, 2005), IT governance has been at the forefront of management concerns for a number of years. Increasingly, the challenge is to govern not only the systems, but also the data residing in the systems (Maguire, 2008). As indicated earlier, DIQ is dependent on how the data is used. Thus, acceptable quality in one instance may be unacceptable in another. For example, prescription information may be entered into a system for a patient. The data is accurate, but incomplete. The system has not captured the fact that the patient is seeing a specialist who has prescribed other medications that negatively interact with what the primary care physician has prescribed. Proper data governance, across all care providers, could help to alleviate this problem.

Compared with the extensive research literature on IT governance, academic interest and research on data governance and its relationship to business intelligence is still in its infancy. As introduced in Neely and Cook (2011), the PGOT (***p***eople, ***g***overnance, ***o***perations, and ***t***echnology) framework provides a foundation for evaluating the quality of data and information. Figure 3 presents an enhanced version of the PGOT with an increased emphasis on the people within the system. The governance plan, operational efficiency and technical competency of the systems continue to be a driving force in the overall quality of the data and information. Based on the contingency theory of organizational design, the underlying assumption of the PGOT framework is that there is no universal design applicable to all organizations for data and information quality, and healthcare is no exception. It is the contextual factors in healthcare that impact the contribution of data governance in enhancing IT governance and organizational performance. This framework focuses on long-term data and information quality improvement and error prevention, rather than correction. In the two cases discussed later, business intelligence systems are the mechanism by which DIQ is improved. The usefulness of a BI system is directly correlated to the quality of the data that it contains and the information it produces.

It is impossible to ensure "perfect" data quality on all dimensions given that the quality of data and information is dependent on its use; that is, decision making in context. The role of the data governance council, and by extension the chief data steward, business data steward and technical data steward, is to ensure the data and information is of sufficient quality to best meet the demands of most decision makers. The business data steward must define the business requirements and expectations, and trust the technical data steward to work with developers to build a system that meets data and information quality-related business requirements. In addition, the chief data steward must design and implement plans, policies and procedures that comply with legal and ethical requirements and meets the needs of data consumers. The chief data steward would also design and implement plans for using social media to detect potential fraud.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. DIQ in context: PGOT research framework



Although perfect data is impossible, there are multiple feedback loops illustrated throughout the framework, many of them resulting from data quality audits, to help in the identification of opportunities to continuously improve DIQ and detect fraud. Therefore, the ability to audit the data and information quality from an operational, technical, and compliance perspective is vital to DQM. As a result, the BI system should have embedded continuous auditing controls, and metrics from such audits should be frequently analyzed for system usability and reliability.

The roles of the people who influence, manage and use the BI system with an emphasis on the data governance system will be illustrated later in the second case. The PGOT framework will be used to focus attention on DIQ within the BI system, specifically when investigating fraud. The next section briefly describes the healthcare environment and this is followed by a description of two case studies, illustrating how a methodical approach to examining DIQ can help to improve the quality and usefulness of the BI system, and ultimately positively impact healthcare financials.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

BETTER MANAGING COSTS AND MEDICAL OUTCOMES USING DIQ, CI AND BI

Medicare and Medicaid continue to ratchet down provider payments, and this is not expected to change. Fee for service is becoming less prevalent, while value-added and bundled services, referred to within the industry as episodic payments, will increase. Many payers already pay a lump sum for maternity. Physician procedural income will decline while their employment and integration with healthcare facilities will increase. As a result, hospitals, physicians and other healthcare providers will either find a way to deliver healthcare for less money or go out of business. The fundamental challenge of healthcare reform is to simultaneously improve the quality of care while lowering its costs. Although profitability is a dirty word in healthcare, without it, healthcare will not have the funds needed to provide better care for patients, whether it is acquiring the latest technology or hiring adequate staff to treat patients.

Case 1: Provider Relations

This case involves a regional health insurance company and a large, independent provider group. This regional health insurance company, referred to here as RHI, is located in the United States and is a nonprofit health insurer. It has provided health insurance for over eight decades and currently serves approximately two million members. The provider group represents almost 1,000 specialists and primary care providers. It assists in negotiating payment rates with third parties, and facilitates credentialing its providers. The specialist and primary care provider (SPCP) group will be referred to here as the SPCP group for short.

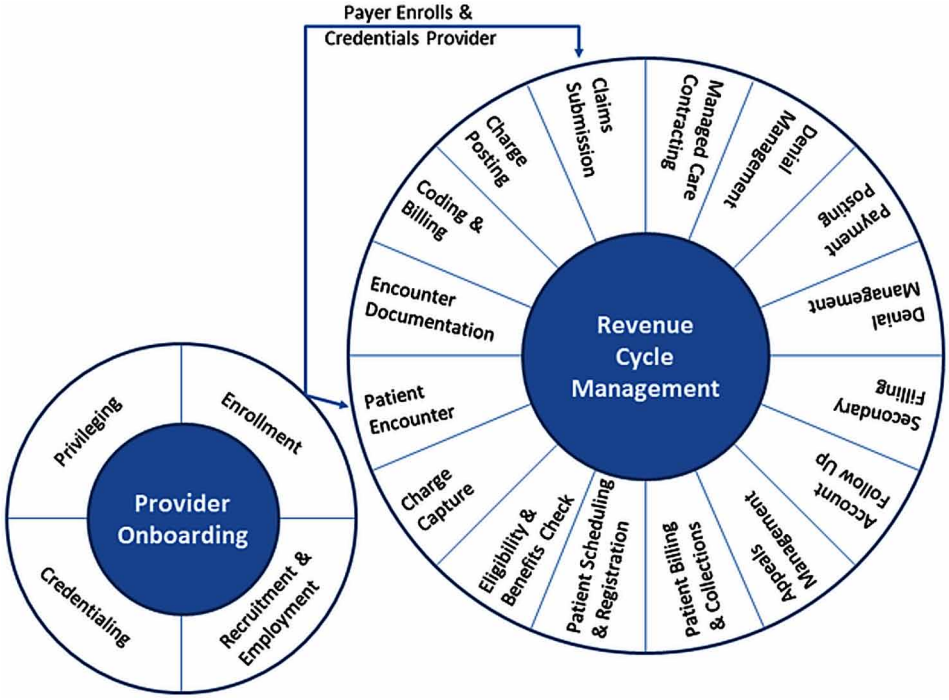
As seen in Figure 4, there is a relationship between the provider's onboarding process (i.e., the process whereby a physician or specialist is authorized by the organization to treat patients) and revenue cycle management. This relationship ultimately dictates when a provider will be paid for services rendered. A provider must first be credentialed by both the healthcare organization and the payer to ensure that that they have the necessary qualifications to practice medicine. Privileging is the process of determining what services a provider may offer patients. Once credentialing and privileging are complete, the provider is enrolled. From a payer's perspective, a claim that is submitted must come from an enrolled provider. Otherwise, the claim is denied, and if the provider should have indeed been paid and was not due to the payer's inefficient credentialing process, additional work will need to be completed to retroactively pay the claim. From both the provider's and payer's perspective, decreasing the time for credentialing is imperative. It is this problem that formed the impetus of the project.

SPCP group has many providers, in many different locations, with differing rates depending on the service(s) rendered. Keeping provider data current is challenging for RHI. SPCP requests monthly additions and updates to provider information. The SPCP group submits these changes to RHI in three ways: (1) carve-out list, (2) all employee list and (3) modifications based on a printed copy of the provider database. A carve out list is a list of medical services that are separated from a contract and paid under a different arrangement. Reports have overlaps in information and many people touch these reports before the department ultimately responsible for handling provider file maintenance receives them. For example, sometimes, the duplicate requests found on these three reports are inconsistent. Properly maintaining the provider file is important since the provider record drives the reimbursement the provider receives.

As a result of a poor process, the following impacts were felt by both RHI and the SPCP group: (1) system updates lagged well behind requests for updates due to the many "touches", (2) reimbursements to the providers were not timely nor accurate due to lag time mentioned in the first point, (3) inaccurate and untimely reimbursements result in almost 10,000 adjustments per year, (4) credentialing had to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Revenue management and provider enrollment cycles



perform duplicative tasks in order to complete their new provider process in a timely manner and (5) the SPCP group was very dissatisfied. This dissatisfaction led to the group withholding repayment of over $1 million in overpayments to induce RHI to reduce the time it took to make updates and to increase the accuracy of the provider file database itself.

The provider file data management (PFDM) department loads and maintains the provider information in all RHI systems. As mentioned before, the provider record drives provider reimbursement. PFDM processes service requests from SPCP, resulting in three main activities: the creation of new provider records, punching through the carve-out list, and making demographic updates. The analysis of the service request process requires that all three activities are examined.

The primary objective of this process improvement project was to reduce the time it takes to react to requests for changes from SPCP. Specifically, it addressed reducing the times associated with three activities: the creation of new provider records, punching through the carve-out list, and making demographic updates. The primary objective of the new provider creation process was to reduce the time it takes to create a new provider record from its current baseline of 55 calendar days to seven calendar days. The primary objective for punching through the carve-list was to reduce the time it takes from its current baseline of 40 calendar days to seven calendar days. Lastly, the primary objective for updating provider demographics was to reduce the time it takes from its current baseline of 50 calendar days to ten calendar days. Secondary, but important, benefits included reduced time to research the provider record requests and reduce the number of claim payment adjustment – resulting in an increase in SPCP's satisfaction.

By implementing a business intelligence system, the data was cleansed, multiple handoffs were eliminated, cycle time targets were met, and greater customer satisfaction was achieved. Specifically, the BI tool proactively identifies providers who were either (1) in the process of being credentialed, who had

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

not yet been approved, but that had started submitting claims, and (2) providers who were submitting claims but who had either not sent their credential application or that the application had been misplaced by RHI. In the first case, the BI tool was used to put a hold on all incoming claims, and sent an exception notice to the PFDM department indicating they needed to expedite the credentialing process. This substantially reduced the 10,000 adjustments per year. In addition, the BI tool was integrated with an existing credentialing database so better tracking of the approval process was available. The creation of the BI tool (and other improvements) allowed the company to exceed its stated objectives, improve SPCP's satisfaction, and decrease its costs. Next, we turn our attention to the Special Investigations Unit of RHI.

Case 2: Special Investigations Unit (SIU)

Increasing a Fraud Department's Ability to Detect Fraudulent Claims

Healthcare fraud and abuse affects everyone by increasing healthcare costs and healthcare coverage premiums. To combat fraud and abuse, the RHI's Special Investigations Unit (SIU) proactively seeks to detect and investigate potential healthcare fraud and abuse. SIU was experiencing an increase in the backlog of investigative leads. Under the leadership of its director, the department had a stated objective of "reducing the average investigation time (AIT) it takes for an investigator to complete an investigation by eliminating waste." To accomplish this objective, a two-pronged approach was pursued: (1) decrease the time for internal investigative procedures for assessing provider fraud, and (2) decrease the time for external investigations of member fraud. The first part involved a lean six sigma approach to streamline operations, and the second part involved active use of social media by investigators to seek out information on relationships and evidence that might indicate fraudulent behavior, coupled with the use of data analytics to connect fraudulent claims over time.

Fraud encountered by the company can be broken into two types – those frauds committed by providers and those acts committed by members. Common fraud schemes providers pursue include (1) billing for services that were never provided, (2) billing for services more expensive than those that were actually provided, (3) performing medically unnecessary services solely to receive insurance payments, (4) misrepresenting non-covered treatments as medically necessary covered treatments to receive payment, and (5) altering claims. Common frauds committed by members or individuals include (1) adding someone who is not eligible for insurance coverage or lending an ID card to family or friends, (2) submitting a fraudulent worker's compensation claim, and (3) submitting a fraudulent medical claim associated with staged accidents.

In Figure 5, the current state of the SIU's process is diagrammed. This process, though complete, would be more powerful with the addition of social media monitoring and a better BI tool to identify leads. The BI system would provide additional leads to be investigated, with supporting data already fed into the pre-audit review and internal audit procedures. Social media also supports CI, as multiple sources could report the same or similar relationships and red flags, allowing decision makers to come to quicker agreement. Overall, an effective system could be made more efficient with the addition of both BI and social media monitoring. Later in this section, mathematical equations will be used to show how BI and social media changes the balance of the equations so it is more costly for fraudsters to commit the crime.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Special investigations unit's current state

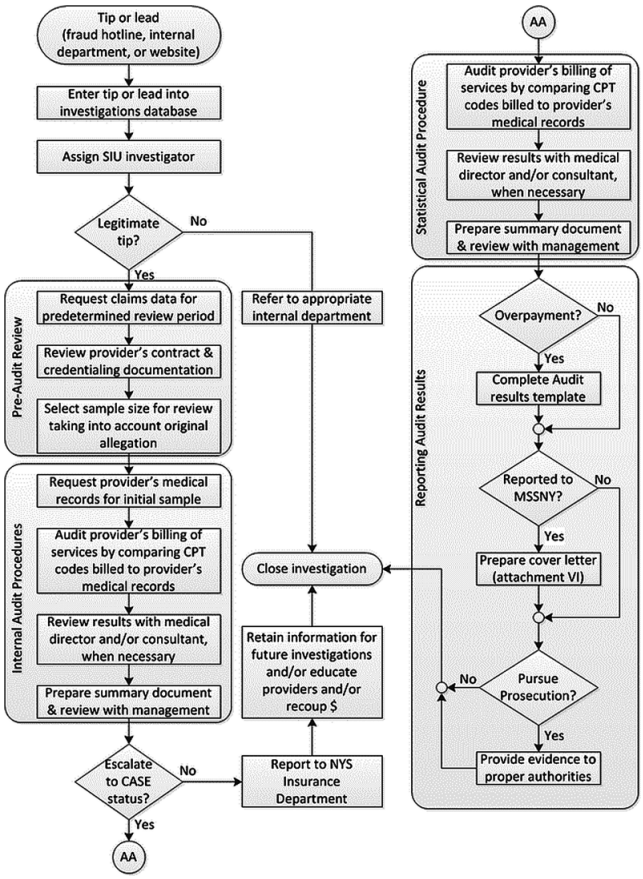


Figure 6 illustrates how the PGOT is used in a healthcare setting, with an emphasis on the people component of the model. A system implies components that work together, within a specific environment. In the healthcare realm the environment is broad and includes actors along the entire supply chain. These actors within the PGOT provide a framework to utilize collective intelligence. By definition, collective intelligence requires a consensus for any given action. By framing the actions within the governance, operations and technology components of the PGOT, the people can develop and implement policies and procedures for fraud investigation, operationalize the special investigations process and design the system for monitoring and reacting to the leads.

In stage 1 (decreasing the time for internal investigative procedures), when the team was gathered, it quickly surfaced that investigators were regularly and frequently answering calls from members concerning customer service issues that had nothing to do with fraud. In fact, what had happened was that customer service had eliminated their telephone number from the "Explanation of Benefits", leaving the fraud hotline number as the only number on the document. Members with legitimate customer service questions called the only number they had available – the fraud hotline. And that is exactly what happened – investigators were on the phones with members they should never have talked to in the first place. As a result of identifying this wasteful practice, the fraud hotline was relocated to the customer service department resulting in an improved member experience, increased satisfaction and quality, reduced wasted time, and decreased costs.

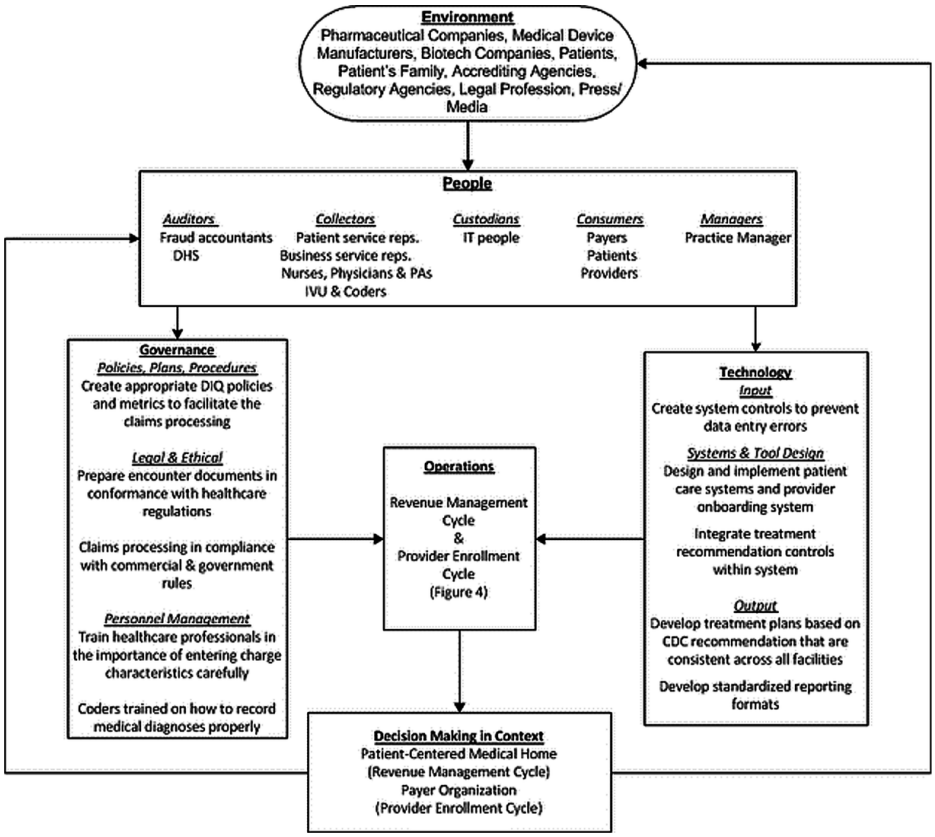
Figure 6. Roles with data governance



Next, we examine the financials of fraud from the fraudster's perspective, and the impact of actions by the payer on the costs. From this discussion, it will be clear that the development of BI and CI tools change the attractiveness of committing fraud, while only mildly increasing costs for payers.

Fraudster's and Company's Financial Perspective on Fraud

From the fraudster's perspective, the expected fraud cost (EFC) is a function of the cost of the criminal act (A), the cost of converting (if necessary) the misappropriated asset into something of value (C_1), and the cost of concealing the crime (C_2). To be clear, by definition, EFC consists of the costs associated with the fraudulent act itself, and not of the ramifications of being caught. The challenge in preventing healthcare fraud is that the expected cost of committing fraud for the fraudster is so small relative to the rewards one receives. For example, the conversion cost in healthcare fraud is practically zero since the fraudster receives money, and the sheer volume of claims in the system helps conceal the fraud itself. Therefore, very little effort is required by the fraudster, other than committing the act itself, to benefit from it. Equation (1) expresses these costs mathematically:

$$EFC\left(A, C_1, C_2\right) = A\left(P, D_1, D_2\right) + C_1 + C_2 \tag{1}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The cost associated with being caught is explicitly addressed elsewhere in this analysis (see equation (2)). The cost of committing the fraudulent act (A), measured monetarily, is a function, among other things, of the prevention (P), deterrence (D_1), and detection (D_2) controls in place to stop such fraud from occurring. An example of A(P, D_1, D_2) is the cost associated with staging an accident in such a way that it is not obvious to investigators that it was staged. The more scrutiny individual accidents are given by investigators, the more effort criminals must put into staging it. The same holds true of providers who purposely code claims improperly in order to receive greater reimbursement dollars. Prevention, deterrence, and detection measures are designed to drive up the cost of committing the fraudulent act (e.g., A(P, D_1, D_2)) from the fraudster's perspective and the use of BI tools and social media monitoring are inexpensive ways to drive up a fraudster's cost. In general, the greater the controls, the greater the cost to the fraudster for planning and executing the commission of the crime.

In healthcare, prevention methods implemented by payers could include investigating whether a provider has any red flags concerning fraud before credentialing them. Another inexpensive preventative measure is sharing policies, plans, and protocols concerning fraud online with providers and members. Deterrence involves creating an ethical culture – consistent communication about the costs and punishments associated with fraudulent behavior, communicating a clear definition of what constitutes fraud, training healthcare professionals in the importance of accurately recording diagnoses, and training coders on how to record medical diagnoses properly. Detection mechanisms are also inexpensive ways to get good leads. These controls include tip hotlines, and fraud auditing.

The cost of converting what was misappropriated into something of value to the fraudster (measured monetarily) is almost always zero with health insurance fraud since the fraudster receives a check from the insurance company; therefore, the time depositing the check is all that is involved in the conversion process. In other industries, say where the misappropriated asset is inventory, the fraudster must spend time searching for a buyer for the inventory to convert the asset into cash. The cost of concealing the fraud, once again measured monetarily, depends on the circumstances surrounding the fraudulent act. At the very least, the fraudster has to consider the lost opportunity given their time could have been spent doing other, more productive things.

The expected fraud penalties (EFP) is a function of the probability (Pr) that the company's detection mechanisms (D_2) discovers the fraud, multiplied by the punishment cost (based on the company's response (R) and the value of the misappropriated asset (MA)), plus the negative emotional costs (E^-). The punishment costs (PC) include all formal and informal costs arising from punishment and lawsuits such as fines, lost income, and legal fees. Equation (2) expresses these costs mathematically:

$$EFP\left(E^{-}, D_2, R, MA\right) = E^{-} + \Pr\left(D_2\right) * PC\left(R, MA\right) \tag{2}$$

The negative emotional costs include guilt, anxiety, and fear to name a few; these costs are high(er) with crisis fraudsters, and low to nonexistent with career fraudsters. In terms of healthcare insurance fraud, most fraudsters are career fraudsters, and therefore are not burdened by the negative emotional costs that a crisis fraudster experiences.

The expected financial reward (EFR) received by the fraudster consists of two components: the positive emotional value (E+) from the criminal act itself, and the value from misappropriating the asset (MA), and if necessary, converting that asset into something else of value to the fraudster. The positive emotional value includes the thrill of danger, retribution, and sense of accomplishment to name a few;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

this value is high(er) for career fraudsters, and low to nonexistent with crisis fraudsters. No stand-alone equation is shown for EFR, but rather it is embedded within Equation (3).

The expected net profit (or loss) that a fraudster would receive if they committed the fraud repeatedly is denoted by ENP, and it equals the expected financial reward (EFR), minus both the expected fraud cost (EFC) and the expected fraud penalties (EFP). Equation (3) expresses these costs mathematically:

$$ENP = EFR\left(MA, E^{+}\right) - EFC\left(A, C_1, C_2\right) - EFP\left(E^{-}, D_2, R, MA\right) \tag{3}$$

Most of us would admit to having broken the law at some point in our lives; when was the last time you exceeded the speed limit or jaywalked? If you break the speed limit because you are late to work, then you are a "crisis" lawbreaker. On the other hand, if you regularly speed, run red lights, and do not yield to pedestrians, then you are a "career" lawbreaker. Each of us has a temptation threshold; this threshold is a function of many things, but an obvious parameter is our current income (prior to committing the fraud) and our moral compass. Therefore, even though all of us have different thresholds (and some individuals may claim their threshold is infinity), people follow this basic rule:

$$If\ \ ENP \geq temptation\ threshold,\ \ then\ commit\ the\ fraud;\ \ else,\ \ don't \tag{4}$$

The purpose of implementing BI tools and monitoring social media is to decrease the expected net profit to a value below the fraudster's temptation threshold. See Table 1 for a summary of the terms discussed above from the fraudster's perspective. Next, we will examine costs from the company's perspective, and then discuss how BI and social media can disrupt the cost equations.

The purpose of prevention, deterrence, detection, and response is to make sure that the cost equation is such that ENP is small enough that someone contemplating committing a fraud is not tempted to do so (assuming they are a rational decision maker and have a "normal" threshold). The use of business intelligence systems and social media increases the controls associated with prevention, deterrence, and detection at minimal costs, and hence, makes fraud less attractive.

If the company had no fraud strategy at all, then a certain percentage of the total assets (TA) would be misappropriated. The expected savings from having a fraud strategy (ESS) represents the difference between the estimated percentage of those assets that would have been stolen if no fraud strategy existed (L_{ns}) and the estimated percentage of those that actually were stolen as estimated by last period's losses given a strategy is in place and being executed (L_{ws}). Equation (5) expresses this relationship mathematically:

$$ESS\left(L_{ns}, L_{ws}, TA\right) = \left(L_{ns} - L_{ws}\right) * TA \tag{5}$$

The cost of a company's fraud strategy (CFS) is equal to the sum of the prevention, deterrence, detection, and response costs in a given time frame. The first three cost components of CFS were discussed earlier. Response (R) includes following the fraud response plan, gathering and presenting evidence, recommending punishments, and recovery of losses; these costs are denoted by C(R). Equation (6) expresses these costs mathematically:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Financials from the Fraudster's perspective

Acronym	Phrase	Description
A (P, D_1, D_2)	Cost of the Criminal Act	Cost of committing the fraudulent act is a function, among other things, of the prevention (P), deterrence (D_1), and detection (D_2) controls in place to stop such fraud
C_1	Conversion Costs	Cost of converting what was misappropriated into something of value to the fraudster (measured monetarily)
C_2	Concealment Costs	Cost of concealing the fraud (measured monetarily)
E^-	Negative Emotional Costs	These costs include guilt, anxiety, and fear to name a few
E^+	Positive Emotional Value	This value includes the thrill of danger, retribution, and sense of accomplishment to name a few
MA	Value of Misappropriated Asset	Value of misappropriated asset (e.g., time or more specifically labor costs, inventory, information) stolen by fraudster
PC	Punishment Costs	All formal and informal costs arising from punishment and lawsuits such as fines, lost income, and legal fees
EFR (MA, E^+)	Expected Financial Reward	Expected financial reward received by the fraudster from misappropriating the asset, and if necessary, converting that asset into something else of value to the fraudster, plus any positive emotional value experienced
EFC (A, C_1, C_2)	Expected Fraud Cost	Function of the cost of the criminal act (A), the cost of converting the misappropriated asset into something of value (C_1), and the cost of concealing the crime (C_2)
EFP (E^-, D_2, R, MA)	Expected Fraud Penalties	A function of the probability (Pr) that the company's detection mechanisms (D_2) discovers the fraud multiplied by the punishment cost (based on the company's response (R) and the value of the misappropriated asset (MA)) plus the negative emotional costs (E^-)
ENP	Expected Net Profit	The expected net profit (or loss) that a fraudster would receive if they committed the fraud repeatedly; it equals the expected financial reward (EFR) minus both the expected fraud cost (EFC) and the expected fraud penalties (EFP)

$$CFS\left(P, D_1, D_2, R\right) = C\left(P\right) + C\left(D_1\right) + C\left(D_2\right) + C\left(R\right) \tag{6}$$

The expected net financial impact (NFI) on the company of having a fraud strategy in place and implementing it is equal to the expected savings from having a fraud strategy (ESS), minus the cost of implementing the company's fraud strategy (CFS). Equation (7) expresses this relationship mathematically:

$$NFI = ESS\left(L_{ns}, L_{ws}, TA\right) - CFS\left(P, D_1, D_2, R\right) \tag{7}$$

Without a fraud strategy, fraud skyrockets. Therefore, ENP and NFI are related. The fraud strategy pursued by a company impacts both the EFC and EFP, which determines the ENP. And the average size of ENP impacts the need for a fraud strategy (and its associated costs). Change the fraud strategy (and NFI), and you change the behavior of the fraudster (and their ENP):

$$If\ NFI > risk\ threshold\left(\$\right),\ then\ execute\ a\ fraud\ strategy;\ else,\ don't \tag{8}$$

We have presented these equations so the reader can understand how the costs incurred by the fraudster are impacted by or a function of the controls put in place by the company (see Table 2).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Financials from company's perspective

Acronym	Phrase	Description
P	Prevention	Preventative controls include creating an anti-fraud policy, fraud audit plan and response protocol, and a fraud response plan; the costs of putting in place preventative controls is denoted by C(P)
D_1	Deterrence	Deterrence involves creating an ethical culture; the costs of putting in place deterrence mechanisms is denoted by $C(D_1)$
D_2	Detection	Detection mechanisms include tip hotlines, and fraud auditing; the costs of mechanisms designed to uncover fraud is denoted by $C(D_2)$
R	Response	Response includes following the fraud response plan, gathering and presenting evidence, recommending punishments, and recovery of losses; these costs is denoted by C(R)
CFS (P, D_1, D_2, R)	Cost of Fraud Strategy	The cost of a company's fraud strategy is equal to the sum of the prevention, deterrence, detection, and response costs in a given time frame.
L_{ns}	Loss Factor (no strategy)	Estimated percentage of assets that would be misappropriated without a fraud strategy in place
L_{ws}	Loss Factor (with strategy)	Estimated percentage of assets that would be misappropriated even though the company has a fraud strategy in place and implements it
TA	Total Assets	Sum of the value of all assets that the company cares to protect from fraud and respond to if misappropriated
ESS (L_{ns}, L_{ws}, TA)	Expected Savings from (Fraud) Strategy	If the company had no fraud strategy, then a certain percentage of assets would be misappropriated; the expected savings from having a fraud strategy represents the difference between those assets that would have been stolen if no fraud strategy existed and those that actually were (as estimated by last period's losses)
NFI	Net Financial Impact	Expected net financial impact on the company of having a fraud strategy in place and implementing it; it equals the expected savings from fraud strategy, minus the cost of the company's fraud strategy

Figure 7 shows the relationship between the work environment and the social environment. By using social media, the company is able to quickly and cost effectively look for red flags and relationships among claimants or providers that might indicate fraud exists. Next, we examine some very specific recommendations for action to improve process performance with minimal costs.

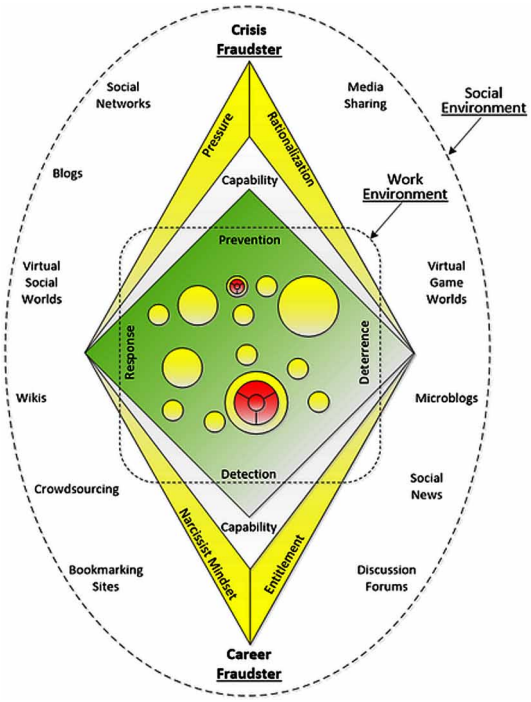
RECOMMENDATIONS AND MODEL VALIDATION

BI systems have the potential to decrease costs in the healthcare industry by improving DIQ. Such systems provide information that will enable better patient care and help healthcare organizations survive with expedited (but smaller) payments, and decreasing fraud. However, these benefits will only accrue if the data that drives the information is of high quality and is appropriate for the decisions being made.

The PGOT framework, with its focus on the systemic effects of DIQ, can provide structure to the development and use of a BI system in healthcare. Thoughtful consideration of the implications of policies and procedures with respect to DIQ, appointing appropriate people in key roles such as Chief Data Steward and a Governance Council, and ensuring that systems are operationally and technically aligned with the DIQ goals, can help ensure that the BI systems can provide the information needed by payers to efficiently credential and process claims, and investigate frauds.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Fraud compass with social media impact



As seen in both cases, one of the difficulties facing healthcare is the potential time involved in performing processes, whether credentialing or investigating fraud. Given the size and scope of current healthcare organizations, it is common to find long, drawn out processes. Figure 6 illustrates how the PGOT can be applied to healthcare, specifically with respect to fraud investigation, a key driver for ensuring the financial success of the health insurance organization. By examining the BI system with respect to DIQ systemically, we can help ensure that the organization as a whole is running at optimal efficiency. For example, DIQ governance in healthcare can facilitate claims processing, credentialing, and special investigations. As indicated earlier, the healthcare industry does not deal with one payer and one payee, but rather multiple payers and payees. As seen in Figure 4, the revenue cycle management can only be enabled if the providers are successfully enrolled in the system with the right credentials and privileges. Without providers, there would be nothing to bill for. Without billing, the healthcare organization would not be able to support itself.

Thus, our recommendation is that a multi-step approach be followed:

1. Create a high-level context diagram that shows the system connections to the environment and closely examine the roles of people as they apply to the process (see Figures 4 and 6 for examples);
2. Create a process flow chart that shows the stakeholders, activities and system data flows in question (see Figure 5);
3. Align the PGOT framework (Figure 3) to the process flow chart to identify areas of concern (Figure 5);
4. Implement interventions to close the gap between the "as is" and the "to be";

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. For special investigations, use social media to investigate relationships and red flags (see Figure 7);
6. Track DIQ and process performance, continuing to make adjustments as needed.

IS design research emphasizes new method development over the use and evaluation of existing methods (Moody, 2003). There is a real lack of empirical research validating methods in practice, and a need to apply methods by practitioners within real organizational contexts. There are inherent problems evaluating any methodology or design technique given typically no theory, hypothesis, experimental design or data analysis exists to apply traditional evaluation criteria (Weber 1997). There are many more IS design methods published in the research literature than what has been implemented or even tested in practice. (Fitzgerald, 1991) persuasively makes the case that usage is an important pragmatic measure of the "success" of a method, and should be considered when evaluating research.

Moody (2003) combined the Technology Acceptance Model (TAM) from the IS literature, and Methodological Pragmatism from the philosophy of science to construct an approach for evaluating IS design methods. There are two dimensions of success: Actual efficacy which is defined as whether the method improves tasks performance, and adoption in practice of the method regardless of whether the method improves performance or not. This method evaluation model developed by Moody (2003) validates our model since our approach both improved task performance (i.e., actual efficacy) and was adopted in practice. With this methodical approach to examining the problem and solution, with a careful examination of the DIQ issues along the way, the BI system can be implemented to take full advantage of the power that it holds.

CONTRIBUTIONS TO THE LITERATURE

This paper contributes to the literature in healthcare, fraud management, and business intelligence. A new model of fraud is proposed: the fraud compass. Using this model and the PGOT model introduced in Neely and Cook (2011), we demonstrate how social media can be used in the early detection of fraud. Additionally, the PGOT model is implemented in a specific environment, showing that the model can move from the general to the specific. The development of mathematical models to support fraud management are discussed. Further research is needed to test the applicability of these mathematical models of fraud in other settings. Finally, practitioner recommendations are presented, with an overarching goal of improving healthcare processes, through diagrams and implementation. Future research can focus on implementing the PGOT in other domains, exploring the relevance of the fraud compass and developing experiments to test the validity of the mathematical models.

CONCLUSION

This paper describes two case studies in the healthcare industry. By weaving the elements of the PGOT framework throughout the narrative, several opportunities for improvement were suggested and discussed. This led to recommendations for best practices. This paper adds to the theoretical literature by operationalizing a theoretical model and showing the interconnections within an overall DIQ system. It adds to the practical literature by offering specific recommendations for practice. DIQ is obviously

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

an important issue in healthcare. It affects the ability of providers and business managers at all levels to make decisions. Within the healthcare industry there are many opportunities for improved decision making, which can directly impact medical outcomes and the bottom line.

There are many organizational systems including transaction processing systems (TPS), management information systems (MIS), enterprise resource planning systems (ERP) and business intelligence (BI) systems. As discussed in the literature review, BI is not just a technology. It is the system which collects, stores, and analyzes business data to support decision making. Key components of this system include source systems, the data warehouse and associated metadata, and the analytical tools such as data mining and general statistical analysis. Moving data from the sources to the data warehouse requires data integration which is both a technology and a process. Metadata, data quality and data governance processes ensure that data moves through the system efficiently and effectively (Wixom & Watson, 2010). Integrating DIQ methodologies into the BI system will help to ensure that the system addresses the end user needs. The descriptions of the cases in this article show how this can be accomplished. CI can support fraud investigation, through the use of social media monitoring. Taken together, DIQ, BI and CI will improve all aspects of the healthcare system, with the two case studies showing examples of where these techniques can be used.

Chapter 89
Forensic Investigation of Digital Crimes in Healthcare Applications

Nourhene Ellouze

Noureddine Boudriga
University of Carthage, Tunisia

ABSTRACT

Healthcare applications are increasingly being used due to the safety and convenience brought to patients' life and healthcare professionals, respectively. Nevertheless, the use of weak authentication techniques and vulnerable communication protocols makes these applications threatened by specific classes of security attacks and e-crimes. The latter threaten the privacy, the safety and even the life of the persons using these applications, due to the fact that they handle sensitive information and implement complex and critical features. This chapter focuses on postmortem investigation of crimes on healthcare applications. After classifying crimes targeting healthcare applications, the requirements for the design of appropriate postmortem investigation system, are discussed. A literature review of proposals related to the investigation of crimes in healthcare applications together with a discussion of the advanced issues are also provided in this chapter.

INTRODUCTION

The advances in Information and Communications Technologies have led to the release of a wide set of healthcare applications, including, but are not limited to, remote monitoring of patients in hospitals, real time detection of emergency situations threatening chronically ill patients, and continuous monitoring of

elderly people. Healthcare applications are increasingly being used owing to the great efficiency and quality of service they offer to elderly persons, patients, and healthcare professionals. They have contributed to the enhancement of patients' autonomy, and the improvement of clinical treatment and remote health surveillance through the development and implementation of several technologies and equipment like, Wireless Sensor Networks (WSN), Implantable Medical Devices (IMDs), and cloud services.

Healthcare applications exhibit significant security weaknesses including the use of weak authentication techniques and the lack of appropriate security mechanisms. These weaknesses make them unprotected and subject to several criminal attacks threatening the safety and the privacy of patients, especially as these applications handle sensitive medical data and provide life-sustaining functions. Among the most common crimes targeting healthcare applications, we cite the unauthorized access to the medical records. Such type of attacks may induce serious threats on the privacy of the victims through the disclosure of their medical records, or even may threaten their life through the malicious modification of their medical records to make further medical prescription by physicians erroneous. In this context, the design of a system for postmortem investigation of criminal incidents threatening healthcare systems is becoming a key requirement.

A set of challenging issues should be addressed during the design of a postmortem investigation system tailored to healthcare applications. The first challenge is related to the storage of the huge amount of evidential traces that can be provided by healthcare systems, as these traces require an unlimited storage space when collected over a long period of time. The second challenge is related to the integrity and the trustworthiness of the provided evidence, especially as healthcare systems are connected to open environments (e.g., internet) through vulnerable communications protocols. The third is related to the complexity of medical evidence collection and processing, especially as healthcare systems implement different technologies and equipment that may provide heterogeneous evidence. The fourth challenge is related to the need that an investigation on healthcare digital crimes collects and analyzes two types evidence collected from the IT system under investigation. The first type contains information related to authentication, access, sensitive events execution, while the second type contains the medical information related to the victim health status.

Several research works have focused on the identification of criminal attacks targeting healthcare applications, and the development of security techniques protecting them from security attacks. Other research works focused on the development of secure audit and accounting tailored to healthcare applications to prepare for a postmortem investigation. A set of postmortem investigation techniques were also proposed in the literature to address medical and physical crimes. An overview of these research works will be provided in this chapter.

The remaining part of this chapter is organized as follows. The next section provides an overview of e-health systems. In Section 2, we identify and classify crimes targeting healthcare systems. Section 3 discusses the main requirements for the design of postmortem investigation of e-crimes on healthcare applications. In Section 4, we review the literature related to the design of techniques and methodologies for the checking of audit logs and the analysis of incidents on Wireless Body Area networks. We also discuss in this section digital investigation scope and techniques considering attacks on Implantable Medical Devices. Section 5 reviews investigation techniques tailored to physical crimes. In Section 6, we discuss advanced issued related to the investigation of criminal attacks on healthcare applications.

SECTION 1: OVERVIEW OF E-HEALTH SYSTEMS

E-health systems refer to the systems providing healthcare services (e.g., diagnosis, treatment, monitoring) using Information and Communication Technologies (ICTs). These systems can largely serve patients safety by making healthcare services more efficient and improving the work of healthcare professionals (e.g., physicians and caregivers). There are several types of healthcare applications such as remote monitoring of patients, and real time detection of emergency situations which can improve the quality of life of elderly and chronically ill persons, as they reduce the amount of travelling (e.g., to book diagnosis appointments) and avoid hospitalization. In the remaining part of this section, an overview of healthcare applications will be provided.

Generic Architecture of E-Health Systems

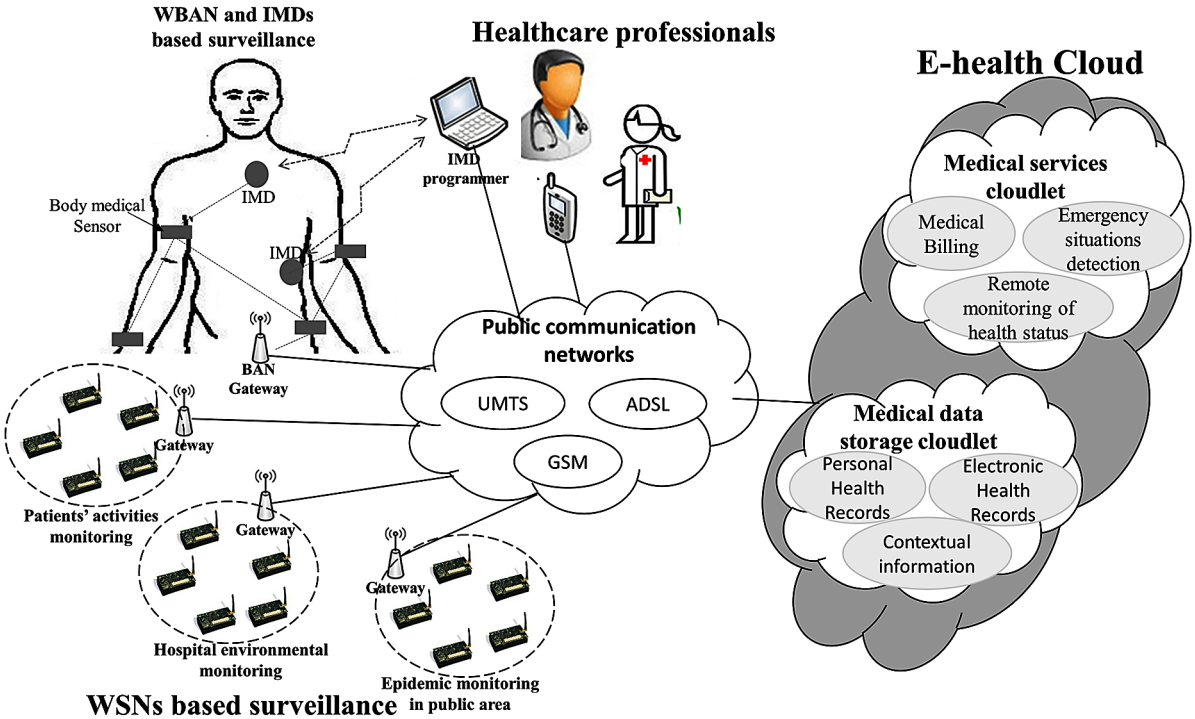
Typically, e-health systems involve three principal stakeholders: a) the healthcare service providers, which are responsible of managing and providing healthcare services; b) the patient, who represents the person eligible for the provided healthcare services; and c) the healthcare professionals (e.g., physicians and caregivers) which use e-health systems to perform their healthcare functions, such as the remote diagnosis of patients.

Several architectures of e-health systems were proposed in the literature. They vary according to the type of the designed healthcare applications, the provided services, and the implemented technologies. In the sequel, we provide a generic architecture of e-health systems that is able to implement the majority of applications and technologies. Figure 1 illustrates the generic architecture of an e-health system which mainly integrates the following described components.

- **Wireless Sensor Network (WSN):** Consists of a set of environmental sensor nodes including, but are not limited to video cameras, gas, pressure, temperature, humidity, and locations sensors. These nodes are typically deployed around the monitored person (e.g., home, hospital) to provide rich contextual information about him and identify the environmental conditions where he is located. Nodes of the same network communicate through a multi-hop wireless technology (e.g., ZigBee) to forward the sensed data to the sink node or the gateway.
- **Wireless Body Area Network (WBAN):** Represents a specific type of Wireless Sensor Network, which consists of a set of medical sensor nodes (e.g., physiological, cardiac, and glucose sensors) that are deployed on the body of a person to monitor its vital signs. These nodes can be interconnected through a wireless network by means of different technologies, such as IEEE 802.15.4. Body medical nodes belonging to the same WBAN cooperate together to forward the performed measurements to the BAN gateway, which will be in charge of transmitting these data through a public communication network to be stored in the corresponding medical data storage cloud/cloudlet.
- **Implantable Medical Device (IMD):** Is a medical device that is surgically implanted inside the body of a patient who suffers from chronic ailments, such as cardiac arrhythmia, diabetes, and Parkinson's disease. Such a device is in charge of measuring the vital signs of the patient (e.g., heart rate, glucose level, or blood pressure) and applying specific medical therapeutic functions when abnormal physiological conditions appear. Because they are surgically implanted, IMDs require a wireless connection to allow healthcare professionals to collect of data stored in them (e.g.,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Generic architecture of e-health systems



the history of the patient's vital signs and the history of responses undertaken by the IMD), monitor in real time the patient's vital signs, adjust the therapy configuration, and update the device firmware. To this end, IMDs can be wirelessly configured using an external programmer through the 402-405 MHz Medical Implant Communication Service (Savci et al., 2005) band. Thanks to the integration of IEEE 802.15.4 and 6LoWPAN (Hui & Culler, 2008) technologies, future IMDs would also be wirelessly connected to the public communication network (Astorga et al., 2014) through a BAN gateway.

- **Gateway:** Ensures the adaptation layer between the Internet Protocol (IP) stack's link, and Wireless Body Area and Sensor networks, so that IP packets could be sent and received over these networks. A gateway is in charge of forwarding the data received from WBANs or WSNs through the public communication network to the medical data storage cloudlet to be stored. It is also responsible of transmitting the data requests received from healthcare professionals to the corresponding entity (i.e., WSNs or WBAN).
- **Public Communication Networks:** They ensure the interconnection between the WSNs (as well as the WBAN) part of the e-health system, the healthcare professionals, and different used cloudlets. Several IP and packet switched and cellular networks can be used to offer a fixed or mobile broadband access. The selection of the communication technologies to be used depends on the specific requirements regarding the quality of service and security to be provided. In healthcare applications, where medical equipment need to transfer patients' medical using wireless communication, while reducing communication interference, prioritizing access to the wireless channel by remote medical equipment, protect medical services from unavailability and harmful interferences, cognitive radio networks can be provided as a solution for e-health applications in hospitals.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **E-Health Cloud:** There are several types of clouds which are designed to provide a large scale of services and applications. Among the most common types of cloud services, we cite: Cloud Storage as a Service (StaaS) and Cloud Software as a Service (SaaS). StaaS ensures an infinite remote storage of data and allows users to access them any time from any place. It also allows cloud applications to share data between them and scale beyond their limited servers. SaaS makes available a set of applications running on a cloud infrastructure and accessible to the user through a thin client interface without requiring to manage or control the underlying cloud infrastructure (e.g., network, storage, and operating systems).

As depicted in Figure 1, two main types of interaction scenarios may be distinguished: regular and emergency. While communication in the first scenario is periodically performed by the e-health system, the second scenario is only used in emergency situations (when the healthcare professionals notice a deterioration of the health status of the patient, and need to get a real-time data information to identify the actual health status of the patient).

In the regular scenario, the WBAN and the deployed WSNs collect periodically a set of medical and contextual information. After that, the collected information is forwarded by the gateways of these networks to the medical data storage cloud/cloudlets through public communication networks. After being stored in the medical data storage cloud/cloudlet, these data will be accessible to the healthcare professionals. Generally, healthcare professionals use third-party applications to get access to/analyze the data related to the supervised patients.

In the emergency scenario, which is triggered by the detection of bad health parameters, the healthcare professionals need to collect instantaneous information about the patients' health status, and be able to remotely order immediate medication, intervention, or emergency ambulance transportation. All the emergency requests exchanged with the different healthcare professionals and the WSNs/WBANs should be timely transmitted via the communication system, while ensuring a high level of quality of service to control the end-to-end delay and network throughput. Therefore, at least two levels of quality need to be provisioned by the network depending in the interaction scenario: regular, or emergency.

Wireless Sensor Networks for Healthcare

Thanks to the continuous monitoring of the vital functions that can be offered by sensor nodes, WSNs for healthcare applications have the potential to offer a set of benefits to patients, healthcare professionals, and the society. First, they provide a continuous long-term monitoring of chronically ill patients, confirm the adherence of these patients to treatment guidelines, and monitor the effects of drug therapy. Second, they provide a real time feedback of the health status of patients. Third, they allow the early detection of life-threatening and emergency situations, so that a proactive reaction could be undertaken by the medical staff. Fourth, WSNs for healthcare applications allow the collection of context aware information (e.g., location, motions, and activities) which are useful to identify unusual patterns of the monitored persons. Fifth, they provide the early detection of serious external threats on patients' safety such as air pollution and presence of virus, as they are able to perform a continuous monitoring of a wide set of environmental and physiological parameters. Because of the benefits offered by WSNs for healthcare, a set of WSN based healthcare applications was proposed in the literature. Among these applications, we cite:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Tracking and monitoring of patients inside hospitals;
2. Monitoring the physiological parameters of chronically ill persons; and
3. Surveillance of the behavior and activities of children and elderly peoples.

A set of prototypes of WSN based healthcare systems was also designed to monitor the health status of patients and transmit his/her physiological data. Among them, we cite:

1. Medical Emergency Detection in Sensor Network (Ko et al., 2010) system. Such a system ensures the monitoring of the physiological parameters of patients inside hospitals;
2. Medical Ad hoc Sensor Network (Hu et al., 2008) system which is in charge of ensuring the real-time surveillance of patients who suffer from heart diseases; and
3. A body area network based system (Felisberto et al., 2015) for the recognition of human activities and the detection of harmful events.

Several issues should be addressed during the design of WSNs for healthcare applications. One of the principal issues is the preservation of power consumption, since sensor nodes use a battery with limited lifetime whose replacement is a burdensome task. To this end, it is required to extend the availability of sensor nodes by minimizing to the maximum possible the energy overhead induced by the implemented algorithms. Privacy and security are also among the critical issues that should be addressed. In fact, the unauthorized collection and use of the sensitive data collected by sensor nodes can cause life threatening risks to the proprietary patient.

Implantable Medical Devices for Healthcare

Implantable Medical Devices (IMDs) are increasingly being used by chronically ill patients, due to the benefits, the life-sustaining, and the therapeutic functions they offered. In fact, they have improved the quality of life of patients by making it possible the continuous control of their health status and the automatic delivery of therapy when abnormal physiological conditions appear. Pacemakers, for example, are implanted in the heart tissue of a patient to regulate its heart rhythm through the delivery of electric shocks.

A generic architecture of an IMD mainly integrates:

1. A set of sensing devices to measure the physiological parameters useful to identify the health status of the patient;
2. A processing unit to manage the functionalities of the device;
3. A stimulator to deliver the required therapy;
4. A memory to store the collected measurements and therapy settings;
5. A transceiver to enable the wireless communication with the programmer used by physicians; and
6. A battery which is in charge of powering the device components.

The principal issues of IMDs are the preservation of energy consumption and the guarantee of the privacy and the security of the patients carrying them. In fact, an IMD should remain operational as long as possible, despite the fact that it uses a limited battery whose replacement requires a surgical intervention. In addition, due to the use of wireless communication, IMDs are threatened by a set of se-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

curity attacks, where most of them could be a serious source of death of patients carrying these devices. For instance, since an IMD automatically reacts to treat the detected cardiac anomalies, with respect to therapy settings which is generally adjusted by authorized physicians, a malicious modification of these settings may lead to a future inappropriate reaction, and thus harming the health status of the patient.

Cloud Based Services for Healthcare

Cloud computing can be considered as a promising paradigm for the enhancement of healthcare services. First, it allows coping with the limited storage of the traditional local healthcare servers, as it provides an infinite storage of medical data. Second, it ensures a continuous availability and sharing of e-health data that are managed by different healthcare providers. Third, it allows providing virtualized healthcare services (generally using a third-party application) independently of the geographic locations of the involved healthcare professionals. In fact, when medical data are stored in cloud, there is no need to perform clinical tasks in the same hospital where these data are generated. Fourth, it offers a set of benefits regarding data management like scalability, Quality of Service (QoS), cost effectiveness, and ease of access.

Cloud Storage as a Service (StaaS) is among the existing cloud computing types. It provides several services, including the storage of Electronic Health Records (EHRs) and Personal Health Records (PHRs) which represent the digital version of the health information of a patient, such as medical history, medication and allergies, and vital signs. The migration of the EHRs and PHRs to the cloud offers several advantages. First, it is possible to ensure an infinite storage of data. Second, thanks to the use of cloud storage, healthcare services will be able to interoperate between them to improve the quality of healthcare services through sharing information across healthcare organizations. In fact, the patients' EHR can be distributed at various locations due to the fact that a patient may be examined by many healthcare professionals of different specialties (e.g., primary care physicians, specialists, and therapists) and register with a set of different health insurance companies according to the insurances types. Third, the use of cloud storage relieves healthcare professionals and organizations from the infrastructure management tasks.

Typically, healthcare services generate and manage sensitive personal data (e.g., medical records) that have strict confidential, privacy and security concerns. In this context, the security of cloud based services for healthcare is a challenging issue that should be addressed during their development. For instance, a long term storage of healthcare data in a cloudlet belonging to a third party organization requires robust security solutions that ensure secure access controls, audit controls, authentication, and storage privacy, in order to avoid exposing theses data to unauthorized entities and security threats (e.g., disclosure, theft). Trustworthiness of cloud environment is another security issue which depends on the cloud deployment model (e.g., private, public). Private clouds seem to be trusted and more secure than public clouds, due to the fact that the security control of the physical infrastructure and the access to data is mitigated to the owner of the private cloud. Nevertheless, the owner of the private cloud needs to call for security expertise to handle the security of the cloud infrastructure, which is a heavy and expensive task. In the other side, the organization owning the public cloud infrastructure is responsible of enforcing a sufficient security policy that guarantees the protection of data in public clouds. The use of public cloud by a healthcare provider may therefore introduce additional security risks and threats, especially as security depends on the degree of trustworthiness to the provided security mechanisms in the public cloud.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

A wide set of healthcare applications was proposed in the literature. These applications can be classified with respect to the services they offer to the patients. In this context, we distinguish three classes. The first, denoted by "emergency detection and response", groups the healthcare applications that are in charge ensuring a real time surveillance of specific types of parameters (e.g., physiological, movement) allowing to proactively detect emergency situations, locate patients, and provide them with the necessary health support (e.g., alert generation toward doctors which can issue remote prescriptions, or order sending ambulance to the patient's location). The second class, "disease and safety surveillance", includes healthcare applications that are designed for the surveillance of patients and elderly persons who suffer from chronic illness and need a continuous monitoring of their health status, or need to be monitored during a recovery period after a surgery or an acute event. The third class, "medication and assistance in prescription solution", groups healthcare applications, which are in charge of managing and processing the stored electronic medical records to identify the patient's disease and assist physicians in remotely delivering the appropriate healthcare prescription.

Table 1 classifies a set of references related to healthcare applications, with respect to five criteria, namely the monitored parameters, the area of surveillance, and the provided quality of service.

SECTION 2: DIGITAL CRIMES TARGETING HEALTHCARE SYSTEMS

As emerging healthcare systems rely on mobile networks and internet to provide and improve healthcare services (e.g., remote monitoring of patients, storage and sharing of medical records), they become unprotected and vulnerable to a set of security threats due to the lack of appropriate security mechanisms. A Compromised security of such type of systems could disrupt the critical functions they perform and expose the patients to privacy and life threats. Recent research works have demonstrated that healthcare systems are targeted by several types of digital crimes that can be classified according to their goals and their impact on the patients. Four classes of crimes are described hereinafter.

Table 1. Classification of healthcare applications

Application Classes	References	Monitored Parameters	The Area of Surveillance	Quality of Service
Emergency detection and response	(Ko et al., 2010)	Physiological parameters	Hospital	Optimized rate control protocols
	(Felisberto et al., 2015)	Movement Parameters	Home	-
	(Almadani et al., 2015)	Health status parameters	Ambulance	Real time transmission
Disease and safety surveillance	(Chen et al., 2014)	ECG	Home	-
	(Al-Qurishi et al., 2015).	Multimedia and medical Information	Home	-
	(Aquino-Santos et al., 2013)	ECG	-	-
Medication and assistance in prescription solution	(Kaur & Chana, 2014)	Health data	Home	Resource elasticity mechanisms
	(Maia et al., 2014)	Vital signs of patients	Home	-

Crimes Threatening the Privacy of Patients

As healthcare applications have significant security weaknesses, several attacks ranging from eavesdropping to location tracking could be executed to discover and disclose the personal information of the victim patient. Using the discovered information, a set of crimes targeting the patients' privacy may be performed. Below, we present some examples.

Eavesdropping attack can be performed by simply snooping on the radio communication and analyzing the intercepted traffic. If the latter contains sensitive information about persons, such an attack may threaten their privacy. For instance, we consider the case of WBAN based health monitoring application. When executing an eavesdropping attack on the traffic exchanged between wearable sensor nodes and the BAN gateway, an adversary would be able to discover a set of health information (in the form of values of some physiological parameters). This can be achieved through the analysis of the intercepted traffic, if the latter contain clear text data. However, when the exchanged traffic is secured using the same cryptographic keys for a long period of time, the adversary can execute some attacks in persistent mode (e.g., brute-force attacks) to discover the used encryption keys, and therefore he will be able to decrypt the intercepted traffic. One of the criminal consequences of eavesdropping attack is the disclosure of the discovered health information which may cause significant harms to the victim, especially if these data information show the presence of chronic illnesses or other types of serious diseases. For example, a person may fail physical exams for employment (e.g., a footballer) due to the diffusion of its health information showing the presence of chronic diseases. The disclosure of health information can also cause financial harms to the victim, if for instance, his/her personal health information, which exhibits a chronic illness (e.g., cardiac arrhythmia), is disclosed and forwarded to the insurance organization which provides to him the healthcare coverage. If such a situation happens, the health insurance premium cost will be increased.

Fingerprint and Timing-based Snooping attack (Srinivasan et al., 2008) is one of the side channel attacks that can also threaten the privacy of persons who use WSN based e-health system. Such an attack can be performed by simply eavesdropping and analyzing the wireless transmission of the traffic of the sensor nodes which are deployed in home to collect contextual information. Even if all wireless communication between sensor nodes and the gateway are fully encrypted, the execution of this attack remains possible. In fact, its execution requires only the identification of timestamp and the fingerprint (in the form of a set of features of a Radio Frequency waveform that are particular to unique transmitter) of each radio message. An adversary, who performs fingerprint and timing-based snooping attack, would be able to infer the private activities of a person (e.g., cooking, showering, or sleeping). Nevertheless, the tracking of the persons' private activities in his/her home constitutes a significant invasion of privacy, which can reveal many things about his/her life, and thus can prepare for several serious harms. For instance, an adversary can post the daily activities of the victim on a social site. This would make the victim in embarrassing position, especially if he is a famous person (e.g., actor or politician).

Crimes Targeting the System Availability

Crimes targeting the availability of healthcare systems are those that are intended to eliminate the system capacity of performing the expected functions, so that the threatened medical systems would not be able to react properly during emergency situations. These crimes can be typically achieved by disrupting the performance of the deployed network or by altering the functionality of the system components. Below, we detail some examples of crimes targeting the availability of e-health systems.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Jamming is defined as the continuous emission of high power interference to disrupt the wireless communication between two communicating entities. When executed, this attack may disrupt the availability of the system, affecting the instantaneous response of the system, which is needed to ensure the patients safety. Typically, when executed on e-health monitoring applications, jamming attack can target the traffic exchanged between sensor nodes belonging to the same network or between the wireless network (e.g., WSN or WBAN) and the gateway to prevent the collected data from being transmitted to the gateway, and thus from being forwarded to the analysis center. Nevertheless, if the jammed traffic contains information showing the detection of an emergency situation, the system could not trigger the appropriate reaction to such situation. By the way of example, we consider a Home Care Monitoring System (Magaña-Espinoza et al., 2014) which allows monitoring the heart rate of patients in their home and triggering alerts to physicians or family members when detecting emergency situations (i.e., rapid physiological changes due to falls or occurrence of some types of fatal arrhythmias like tachycardia). By executing jamming attack on the messages exchanged between the nodes monitoring the patient and the gateway, the sensed data could not be delivered to the gateway, so that it may become impossible to detect the occurrence of emergency situations, and thus it will be impossible to generate instantaneous alerts towards the involved physicians.

Sensor worm attack (Tan et al., 2011) can also be classified among the security attacks threatening the availability of WSNs for healthcare applications. Such an attack consists in discovering and exploiting software vulnerabilities of sensor nodes. It can be executed as follows. The adversary discovers exploitable software vulnerabilities (this may be achieved through the analysis of the libraries of the popular operating systems running on sensor nodes). Then, he exploits the vulnerabilities of the implemented software update mechanisms to inject a malicious program into the firmware of the sensor node. For example, when sensor nodes implement an over-the air-programming mechanism to update the healthcare applications, the adversary can exploit the self-programming routines in the bootloader to inject a malicious program into these sensor nodes. Typically, the injected malicious codes allow tampering the logic of sensor nodes and altering the expected sensing and processing functions they implement. For instance, when performing counterfeit software updates of medical sensors belonging to healthcare WBANs, these nodes would not able to accurately measure and collect physiological parameters.

Crimes Targeting the Life of Patients

As discussed in the previous section, Implantable medical devices are autonomous medical devices. They are wirelessly accessible through an external programmer. Nevertheless, because of the use of insecure and vulnerable communication protocols, IMDs are threatened by a set of security attacks, where most of them could be a serious source of crimes targeting the life of patients carrying them. In the sequel, we detail some of these security attacks.

Battery depletion attack can exhaust the battery of IMDs by flooding these devices with a large amount of bogus encrypted traffic. In fact, for security purposes, an IMD is required to verify the authenticity of every received message using cryptographic computations before proceeding with acceptance or rejection. By receiving a huge amount of encrypted messages, the IMD consumes a lot of energy, due to the intensive execution of the implemented cryptographic algorithms. Consequently, its battery may be depleted, as it has a limited lifespan. When the battery depletion attack targets some types of IMDs, such as defibrillators, the consequences of the battery depletion attack may be fatal. In fact, the defibrillators

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

could not perform the implemented life-sustaining functions including the detection of arrhythmias and the delivery of therapies. In (Hei et al., 2010), it was shown that a depletion attack on an Implantable Cardiac Defibrillator (ICD) can be easily launched by an adversary who uses a radio software platform to conduct a reverse-engineering of the communication protocol used by the ICD and execute the attack.

Exposing some types of IMDs, such as pacemakers, to electromagnetic interference (EMI) can be also classified among fatal attacks threatening patients carrying these devices. The use of EMI within a frequency spectrum being detected by the sensing circuitry of the pacemaker, can affect the pacemaker functioning in different ways. When exposing the pacemaker to a magnetic field that is within the heart rate range, the pacemaker will stop the delivery of the stimulating pulses that regulate the heart's rhythm. Consequently, patients will be susceptible to lightheadedness, syncope, or even death according to the duration of the EMI and the cardiac rhythms. Otherwise, when the pacemaker is exposed to a strong magnetic field, it contiguously delivers stimulating pulses at a fixed rate (which can be rapid or low rate pacing) regardless the real heart's rhythm. This can threaten the safety of the patient, since a very rapid pacing can induce the occurrence of ventricular fibrillation, which is one of the fatal arrhythmia.

Another fatal security attack consists in using a relay node to repetitively replay old messages which are typically exchanged between an implanted device or sensor node, and a remote controller. The reception of old messages that contains old values of the sensed physiological parameters leads the remote controller to order the delivery of erroneous treatment (e.g., mistreatment or overtreatment) which can endanger the health status or even the life of the patient. For instance, insulin delivery systems are vulnerable to replay attack (Li et al., 2011), due to the weakness of protection against replay attack (every packet showing a counter different to the one received in the last packet is accepted). In fact, by replaying in an altering fashion two intercepted packets, an outdated glucose level can be reported to the insulin pump. Moreover, the replay of an old message to the insulin pump showing high blood glucose level will cause the delivery of an overdose of insulin.

Crimes Targeting Medical Records

Medical records of a patient may refer to Personal Health Information (PHI), Electronic Medical Record (EMR), or Electronic Health Record (EHR). Typically, these records include very sensitive data that should be properly protected against security and privacy threats, since their unauthorized alteration or disclosure can induce serious consequences to the victim ranging from financial to life threatening harms. Nevertheless, due to the complexity of the architecture of e-health systems managing these records and the lack of security solutions that ensure end to end protection of medical records (during transmission, storage, and access), medical records are threatened by a set of security attacks.

The use of unsecure end-user systems to access to medical records makes them vulnerable. End-user systems (e.g., personal computers or Smartphone) are generally used by an authorized patient or physician to retrieve or update medical records. However, access to medical records using end-user systems is sometimes performed using weakly protected operating systems, or even weak authentication techniques that are implemented by third party applications for securing access to medical records. As discussed in the work of Dmitrienko et al. (2013), an adversary may exploit the vulnerabilities of the software running on the end-user system to get unauthorized access to medical records, by inducing this victim user to install malicious software (e.g., malware) or faked third party applications. When the victim user uses a fake third party application to log, the credential he enters will be sent to the adversary.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Medical identity theft is one of the serious consequences of unauthorized access to medical records. It presents one of the vicious new kinds of crimes threatening medical records. Medical identity theft is defined as the fraudulent use of personal health information to obtain medical services or goods such as prescription drugs, medical treatment, or Medicare reimbursement. It often aims to alter or inject false medical records (e.g., false diagnosis, falsified medical history) to make healthcare professionals unable to provide the appropriate treatments. Medical identity theft can also lead to a fraudulent acquisition of medical services, inducing an important financial loss to the victim.

SECTION 3: REQUIREMENTS AND CHALLENGING ISSUES FOR A POSTMORTEM INVESTIGATION OF HEALTHCARE CRIMES

A postmortem digital investigation system of healthcare crimes should at least fulfill the following requirements.

Ubiquity and Diversity of Collected Evidence

To be investigable, a healthcare system should provide a variety of accurate ubiquitous evidence. In fact, due to the diversity of the implemented technologies and services in healthcare systems, a postmortem investigation of these systems should address the investigation of the entire system components including networks, databases, embedded sensor nodes, and medical devices. To this end, the following types of evidence should be at least available:

1. Evidential traces collected from sensor nodes. These traces could help identifying the source of the malicious nodes, and the malicious forged/exchanged information, which are used to prepare for the crime execution;
2. Evidence data provided by wireless access devices (e.g., gateways or access points). Typically, these data contain traces related to the sensitive activities (e.g., authentication, database update) performed by remote users. They can help identifying potential crimes on networked healthcare systems;
3. Digital traces collected from autonomous medical devices, capable of automatically ordering/delivering therapy (e.g., Implantable Medical Devices). This type of evidence would allow identifying inappropriate functionalities performed by these devices and representing the root of the incident damages;
4. Database evidence traces (e.g., EHR, contextual information, physiological parameters) which include the data collected by healthcare devices. They could allow identifying potential crimes targeting the life of patients, since they would be useful to determine how and when the health of the victim was deteriorated;
5. Digital evidential traces related to the third-party applications. The latter traces may be useful in some circumstances (e.g., when the involved third-party application is malicious or indirectly used to facilitate the execution of the crime), since they would allow identifying the potential attacks exploiting these applications and determining their objectives;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

6. Evidential traces provided by physical authentications devices (e.g., smart cards). In fact, since these devices are used to authenticate users, they store various information including authentication keys, and some user-generated sensitive activities. Such type of information would be useful to determine the behavior of the user carrying the physical authentication device; and
7. Evidential traces provided by virtual infrastructures. Since in some cases, a virtual infrastructure (e.g., virtual cloud instance) can be the place where the incident happened or originated, it can provide useful information for forensic investigation.

Hypothetical Investigation Tolerant to Data Incompleteness

Typically, an investigated system cannot totally detect and record all executed events. To this end, evidential data provided to the investigator may be incomplete. In some circumstances, investigators may also be faced to new types of security attacks targeting the system under investigation. Moreover, the implemented library of attacks can also exhibit the absence of some security attacks targeting the investigated system. Nevertheless, to enable the reconstruction of potential crime scenarios, the postmortem investigation system should be tolerant to the incompleteness of the provided information related to evidential traces, investigator knowledge, and the library of attacks. To do this, such a system should allow hypothesizing missing events and generating hypothetical actions when needed.

Accuracy and Correctness of the Postmortem Investigation System

Because of the diversity of the collected evidence and the complexity of crime scenarios, the results of postmortem investigation may become prone to errors. To cope with this, postmortem investigation should be based on formal techniques and methodologies. The latter are time-saving and able to automatically infer provable potential crime scenarios starting from the collected evidence, and provide accurate and relevant results, even with a huge amount of evidential data.

Trustworthy and Evidentiary Aspect of Evidence

In order to enable an efficient postmortem investigation, the trustworthy and integrity of the provided evidential traces are stringent requirements. Moreover, once gathered, digital evidence should fulfill the same legal requirements. They should be:

1. **Complete:** Contain enough information allowing proving or disproving the occurrence of the crime;
2. **Reliable:** Have not been changed after their creation and they are collected using reliable techniques from a physically protected device that ensures at least tamper proof evidence;
3. **Believable:** Convincing to juries; and
4. **Admissible:** Collected using procedures that are conform to the common law and legislative rules.

To this end, it becomes crucial to protect the evidential traces against security attacks, especially from anti-forensic attacks which are intended to alter the generated evidence to hide information related to the executed attack, and mislead the investigator. The use of tamper-evident mechanisms in e-health system could be a promising solution. In fact, such a mechanism could allow tracking and recording all actions (e.g., removal, modification) that may be performed on the digital traces, so that the integrity of these

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

traces can be checked before postmortem analysis. Moreover, it is also required to implement a security solution, which allows the protection of e-health systems against security attacks and the provision of a secure environment for the measurement, the collection, and the storage of the evidential traces.

Aggregation of the Pathologists and Healthcare Providers' Efforts, and Digital Forensic Investigators Efforts

As digital crimes on healthcare applications may affect the life of patients, a postmortem investigation of crimes on healthcare systems requires fitting together the efforts and the decisions of healthcare experts (e.g., physicians, pathologists) and digital forensic investigators. In fact, when a digital crime was conducted on a healthcare system and led to the deterioration of the health status of the victim, digital investigators can only demonstrate its occurrence and reconstruct plausible crime scenarios starting from the collected digital evidence. On the other side, healthcare experts can only prove that the inappropriate functioning of the healthcare system induced the deterioration of the patient health status. Nevertheless, none of them (i.e., healthcare experts and investigators) could prove or disprove whether the death is a consequence of a digital crime, unless the causality between them is identified. This can only be achieved by conducting a collaborative postmortem analysis between forensic investigators and healthcare experts. Nevertheless, to provide accurate results, forensic investigators and healthcare experts need to make accessible and share between them the collected evidential data and the obtained results. The development of forensic as a service cloud-based solution can be a promising for the collaborative postmortem investigation. In fact, such a service would allow benefiting from the expertise of investigators, as it makes collaborative investigation available anytime at any place. In addition, it can also help constructing a large library of investigated crimes scenarios, which can be useful to improve the efficiency and the productivity of the forensic experts. A postmortem investigation can also benefit from the storage as a service, as it allows coping with the storage limitation of the provided evidential data. In fact, such a service can provide an infinite storage space of evidential data. Moreover, it could also allow sharing evidential data across the involved investigators.

SECTION 4: AUDITING AND INVESTIGATING CRIMES ON E-HEALTH SYSTEMS

E-health systems provide convenience and efficiency to elderly and chronically ill persons through the healthcare services they implement. Nevertheless, as discussed in Section 2, healthcare systems are vulnerable to a set of digital crimes, which can threaten the privacy, the safety, and even the life of persons using these systems. To cope with this, it becomes crucial to develop forensic readiness e-health systems that enable the secure auditing and the postmortem investigation of crimes on these systems. In the context of digital crimes targeting healthcare systems, a pre-mortem investigation could not be applied because of the need of the presence of forensic pathologists to collect the medical evidence. The latter are essential for the reconstruction of medical scenarios.

The existing postmortem investigation approaches (Carrier & Spafford, 2006) tailored to general types of digital systems cannot be applied directly to investigate digital crimes on e-health systems, for the following reasons. First, contrary to the general types of digital systems, where a crime affects only the hardware of software assets, crimes on e-health systems affect these types of assets as well as the patient. The consequences of these crimes are more serious, as they affect the health status of the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

patient and may even cause its death. Second, when reconstructing the potential executed scenarios, the classical digital investigation techniques assume that the consequence of an action (malicious or legitimate) part of the scenario is deterministic. This is not the case for the investigation of several types of healthcare crimes. In fact, the consequences of an action may vary (i.e., is probabilistic) depending on the behavior, the health status, and the physiological state of the patient. Third, conducting an investigation of digital crimes on e-health systems requires the collaboration of forensic pathologists and digital investigation experts. The forensic pathologists will be in charge of examining the status of the victims and determining the cause of death and/or injuries, while the forensic digital investigation experts will be in charge of examining digital evidence and reconstructing the scenarios of attacks (e.g., illegal modification of sensors configuration), determining the source of the attack, and identifying the types of exploited vulnerabilities. Proving that an illegal modification of the e-health system is the root cause of an unsuitable medication that leads to the death cannot be done unless the conclusions derived by the two types of experts are correlated together. Fourth, a healthcare attack could take a long time to impact the patient. For example, an illegal modification of the electronic healthcare records a patient may lead to an unsuitable medical several months or years after. Reconstructing the whole scenarios and finding the traces related to the illegal modification, requires storing the evidential data for a very long time. Such a feature, introduces additional challenges related to the long-term secure storage of evidence.

Several research works were proposed in the literature to address the secure auditing and the postmortem investigation of digital crimes on e-health systems. In the sequel, we provide an overview the most important ones of these research works.

Auditing the Health Information Exchange

Health Information Exchanges (HIEs) systems refer to distributed systems ensuring the sharing of medical records between healthcare institutions. As discussed in Section 2, the inappropriate sharing of medical records, which are highly sensitive data, could threaten the privacy and the safety of patients. It is therefore essential to implement techniques and mechanisms, which allow providing secure accountability and auditing of the exchanges of these sensitive data, especially as evidential traces (i.e., audit data) could be useful to conduct postmortem investigation of crimes on e-health systems. These techniques will be in charge of monitoring the exchanges and the sharing of health information, and logging sensitive action executed on e-healthcare systems, including access, share, and transfer of healthcare records. To allow tracing the entire sharing path of a patient's health records, the logged data should contain a wide set of information, including, but are not limited to, the identities of the entities (e.g., the physician, the hospital) involved in the creation of the health record, the timestamp of these records, and the identities of the entities updating them.

To improve the accountability of actions executed in e-health systems and enable the identification of data breach, Mashima and Ahamad (2012) developed a patient-centric scheme allowing the establishment of robust information accountability in electronic health record (EHR) sharing systems. The proposed system introduces the use of a secure metadata, namely "accountability tag", which is attached to each copy of EHR record. An accountability tag implements a cryptographically-verifiable evidence of the involved entities (e.g., the repository that creates the copy of the healthcare record, the sharing source, and the sharing destination). Thanks to the use of accountability tags, the proposed scheme offers the benefit of patients' awareness to the access and the sharing of EHR in the e-healthcare system, so that a patient can determine whether sharing is appropriate and even identifies the involved entities when

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

detecting a suspicious disclosure or sharing of its healthcare data. Accountability tags are managed by a trusted agent, namely "patient-centric monitoring agent". They are verified and logged each time the "Accountable Update" or the "Accountable Usage" protocol is executed, so that the monitoring agent will be able to reconstruct the sharing path and identify the involved entities. Accountable Update protocol is initiated when a health record is created or updated. In fact, when the record issuer creates or updates a health record, he attaches his digital signature, which is encrypted using the public key of the monitoring agent, to the created record. After that, he sends them to the repository which will be in charge of obtaining the proof of patient's authorization through the monitoring agent. After accepting the creation or the update of the record, the repository generates and sends verifiable receipts to the monitoring agent and the record issuer. The Accountable Usage protocol is executed when the consumer receives the healthcare record. Since the consumer needs to decrypt the received signature, he sends a verification request to the monitoring agent. The latter logs this action, decrypts the signature, and creates a non transitive signature using Universal Designated Verifier Signature scheme (Steinfeld et al., 2003). Such a signature can be only verified by the specific consumer. After that, the monitoring agent sends back the generated signature along with a transaction proof to the consumer which verifies this signature using the issuer's public key.

For the sake of privacy preservation, Oh et al. (2014) proposed a Health Information Exchange (HIE) audit system which allows limiting the amount of accessible logs' information to only those that are required to provide evidence for audits process. This system implements together the use of Hierarchical Identity Based Encryption (HIBE) algorithm, which is an encryption algorithm ensuring the encryption of the data stored on audit logs, and a logic-based audit algorithm, which is able to handle the incompleteness of the available logs and generate formal explanations using only the available decrypted information. The proposed audit system uses two types of logs: internal Audit Trail and Node Authentication (ATNA) logs, which represent standard audit logs providing infrastructure for HIE audits, and external audit logs which include supplementary information (e.g., patient registration, medical billing) retrieved from healthcare organizations to enhance the results of HIE audits. The audit system mainly integrates four components: the audit data processor (ADP), the audit agent, the audit algorithm, and the auditor viewer. The ADP is in charge of encrypting external audit logs using HIBE algorithms, aggregating ATNA logs and external logs together, and making them available to the audit agent. When receiving a set of accesses of audit interest from the auditor through the auditor viewer, the audit agent transmits audit logs together with the policy and the requested access of interest to the audit algorithm, which will be in charge of verifying whether the requested access of interest complies with the policy. Since audit logs are encrypted, the audit algorithm may not be able to decide about compliance or violation. To this end, starting from the residual policy, the audit agent identifies the minimum data information required for audits, requests the corresponding decryption keys from the ADP, decrypts these data information, and then makes them available to the audit algorithm. Based on the available decrypted data, the audit algorithm generates the formal explanations for accesses and then sends them to the auditor viewer, which will be in charge of translating these explanations in human readable information. After that, it returns them to the viewer. When detecting incompliance, the auditor sends a notification to the involved healthcare organizations.

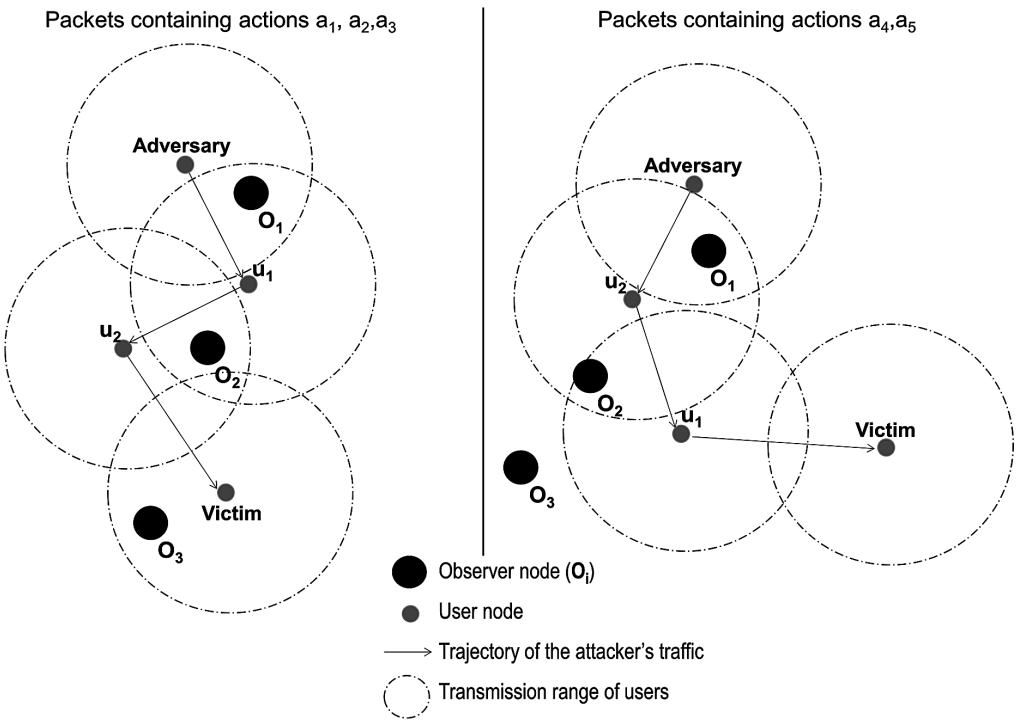
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Forensics in Wireless Medical Body Area Networks

As detailed in Section 2, wireless medical Body Area Networks (BANs) are vulnerable to specific classes of security attacks that can be exploited to perform crimes threatening the privacy and the safety of patients who use them. In this context, it becomes crucial to address forensic investigation of security attacks on wireless medical BANs. Several research works investigated the possibility of using wireless medical BANs for healthcare applications. Nevertheless, to the best of our knowledge, there is no postmortem investigation system proposed in the literature, which is tailored to wireless Medical BANs. The work of Cusack and Kyaw (2012) discussed only the need of developing a forensically ready and secure wireless Medical BANs based systems, which allows investigating events after their occurrence. However, it is possible to customize the forensic systems, proposed in the literature to investigate security attacks on Mobile Ad hoc and Sensor Networks (MASNets), to the investigation of healthcare security attacks and crimes in wireless medical BANs, especially as wireless medical BANs are specific classes of MASNets.

Since Mobile Ad hoc Sensor Networks (MASNets) are typically characterized by the absence of infrastructures and the mobility of nodes, techniques and mechanisms developed for the investigation of attacks on wired networks cannot be efficient to investigate attacks on MANets. In fact, as attacks targeting such type of networks are generally mobile, traditional evidence collection techniques for wired networks could not allow tracing and tracking mobile attacks. To cope with this, a digital investigation in MASNets needs to implement new techniques allowing a distributed supervision of the network, so that it becomes possible to collect digital evidence from different locations in the network and the victim system. In this context, Rekhis and Boudriga (2011) developed a new architecture and evidence collection

Figure 2. Variation of the network topology during an attack scenario



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

technique in MANets which ensures an efficient collection of mobility-based information. In addition to the user nodes (i.e., mobile devices of patients) which are randomly distributed over the network, the proposed technique integrates the use of a set of mobile trusted nodes, namely observers, which are responsible of supervising the mobile networks. As depicted in Figure 2, observer nodes, denoted by $\{O_i, i \in [1,n]\}$ where is the number of observers, are distributed over the network in a way that they form an observation network allowing the supervision of every pair of communicating user nodes, denoted by u_i. Each deployed observer is responsible of monitoring the traffic exchanged within its transmission range, storing the observable parts of the detected datagrams and actions as network evidential traces, and forwarding them to the node in charge of investigation (selected among the observer nodes).

Because of the mobility of observer nodes and the scheduling algorithm they implement to minimize energy consumption, an observer node will not be able to detect all the datagrams sent by the attacker. In fact, the observer node may go out of the attacker transmission range or change its state to inactive, so that some of the attacker datagrams will be invisible. Nevertheless, datagrams, which are invisible to a given observer, can be visible to another, and thus observer nodes can generate redundant or/and complementary evidential traces which need to be merged and aggregated by the node in charge of investigation before reconstructing the occurred scenario. An example of nodes mobility and topology variation during an attack scenario is depicted in Figure 2. During the occurrence of the attack scenario, user nodes as well as observer nodes change their positions, where two paths are used to forward the datagrams sent by the adversary to the victim node. While the first path (Adversary $\rightarrow u_1 \rightarrow u_2 \rightarrow$ victim) is used to forward packets containing actions a_1, a_2, and a_3, the second path (Adversary $\rightarrow u_2 \rightarrow u_1 \rightarrow$ victim) is used to forward packets containing actions a_4, and a_5. Observer nodes take two different positions during the execution of the attack scenario. In the first position, O_1 is under the coverage of adversary and u_1 nodes, O_2 is under the coverage of u_1 and u_2 nodes, and O_3 is under the coverage of the victim node. In this position, all observers O_1, O_2, and O_3 detect the datagrams containing the actions a_1, a_2, and a_3. In the second positions, while O_1 and O_2 detect the datagrams containing the actions a_4, and a_5, since they are under the transmission coverage of adversary and u_2, and u_2 and u_1, respectively, O_3 cannot detect any packet.

Network evidence could not provide sufficient information related to some type of attack scenarios targeting MANets. In fact, attack scenarios may include some suspicious events compromising the target system, which are unobservable at the network level (e.g., a set of actions are executed locally on the target system, in response to a remote actions executed over the network) or invisible to the developed network security solution used the observers (e.g., actions are encrypted). To cope with this, Rekhis and Boudriga (2011 proposed to use and aggregate system evidence, in addition to network evidence, for conducting a postmortem investigation on MASNets. Note that, sstem evidences represent the evidential digital traces generated by the security solution that the system implements. They provide a set of information related to the observable parts of executed actions and a description of the related consequent system states.

The huge amounts of evidence that may be generated by the implemented security and network solutions can make their analysis and the generation of attack scenarios complex and prone to errors. Such a limitation can be handled through the development of a formal methodology managing evidence and ensuring an automatic reconstruction of possible attack scenario. In this context, the methodology for investigation of security attacks proposed in the work of Rekhis and Boudriga (2011) implements an inference system that integrates network and system evidence and copes with the incompleteness and duplication of the information to generate the possible and provable attack scenarios. The proposed methodology is organized into four principal steps described as follows. During the first step, the node

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in charge of investigation will be in charge of collecting the available evidence from the victim system and the observer nodes deployed in the network under investigation. The network evidence should be also filtered to include only the digital traces related to the attack under investigation. In the second step, an aggregation of the collected network evidence is performed. This can be achieved through the execution of a set of inference rules allowing the generation of merged and optimal network evidence. Heuristics, which are based on information appended by nodes during the generation of their observations, are also implemented to retain plausible sequences. The third step consists in the generation of the set of possible attack scenarios based on the provided network and system evidence. The fourth step consists in determining the provable actions and scenarios among the generated possible attack scenarios. All of the previous detailed steps are automatically performed through the execution of a specific set of inference rules, which allows aggregating the generated network evidence, inferring possible attack scenarios, and generating provable actions and scenarios.

In the case when the fourth step fails to determine a provable attack scenario, investigators are expected to select from the potential evidence a plausible attack scenario. Three techniques can be used. In the first technique, the set of information, which profiles the attacker, is extracted from every possible attack scenario. Based on the collected information, the scenario showing the most malicious profile will be selected as the plausible attack scenario. In the second technique, the set of information, which indicates the estimated degree of damage of every attacked system resource, is extracted from every generated possible attack scenario. The scenario showing the highest degree of system damage will be considered as the most plausible attack scenario. In the third technique, every action in a possible attack scenario is labeled by the probability value of its occurrence from the state in which it is enabled. According to the probability values, the plausible attack scenario will be selected.

The inference conducted in this research is a sort of data mining by which the investigator can access to a knowledge base describing known attacks on systems, and the description of the investigated system, detect interesting dependencies in a very noisy data, and infer more elaborated scenarios involving the execution of several actions that argument the content of the collected evidence. The use of data mining for the purpose of investigation is developed in other chapters of the same book.

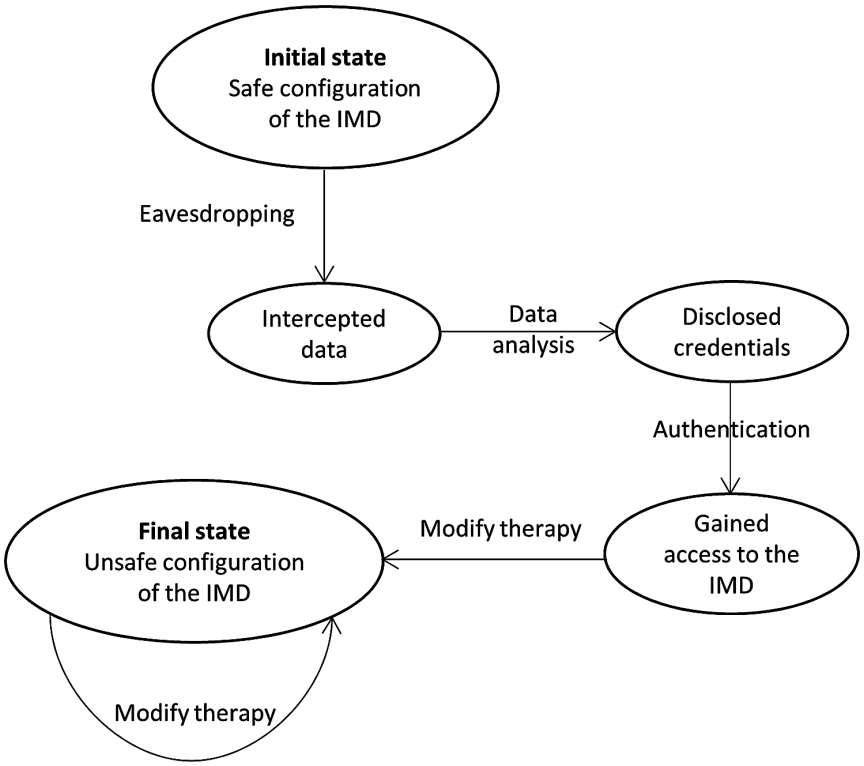
Digital Investigation of Criminal Attacks on Implantable Medical Devices

As discussed in Section 2, IMDs are vulnerable to a set of attacks threatening the life of patients carrying them. Some of these attack scenarios are illustrated in the graph depicted in Figure 3. Every node in the graph specifies the state of the IMD, which can be secure (safe configuration) or unsecure (safe configuration). Every arrow in this graph represents an elementary attack action (e.g., eavesdropping, modify therapy, data analysis). An example of a lethal attack scenario depicted in this figure is described as follows. An attacker intercepts the traffic exchanged between the IMD and an authorized programmer (A_1: eavesdropping), and analyzes the intercepted data to disclose the credentials used for authentication (A_2: data analysis). Having identified the credentials, the attacker authenticates himself to the IMD and gets a privileged access to the IMD (A_3: authentication). After that, he modifies the therapy settings (A_4: modify therapy), so that the IMD configuration becomes unsafe. A further reaction of the IMD in the case of heart arrhythmia, would be inappropriate, and could harm the health of the patient.

In this context, the design of a postmortem investigation system of lethal attacks on cardiac IMDs becomes crucial. This system would enable the identification and the reconstruction of potential attack scenarios source of death of the victim. Such a system should combine together medical and technical

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Examples of lethal attack scenarios targeting IMDs



notices. While the technical investigator conducts forensic analysis to prove or disprove the occurrence of malicious attacks, the medical expert performs forensic analysis to prove that the IMD malfunction is the source of death of the victim.

Typically, cardiac IMDs (e.g., pacemakers and cardiac defibrillators) provide a set of digital traces such as, the history of electromyogram and the history of the delivered therapy. These traces could be useful to conduct a forensic investigation. In fact, starting from these traces, pathologists can derive some conclusions about the primary cause of death. Nevertheless, these traces are insufficient to provide accurate investigation results. They need to be extended to include the sensitive events that may be executed on the IMD. Moreover, they should be authenticated and secured against tampering and forging. In addition, since a cardiac IMD may provide a huge amount of evidential traces, it becomes necessary to develop appropriate mathematical and formal analysis techniques for postmortem investigation allowing the automatic generation of results (i.e., potential scenarios). In this context, Ellouze et al. (2014) proposed a postmortem investigation system of lethal security incidents on cardiac IMDs. Such a system allows the generation of potential attack scenarios source of the death of the patient carrying a cardiac IMD. It reconciles in the same framework the conclusions derived by forensic medical experts and technical investigators.

The proposed system defines two types of evidence: medical and technical. Medical evidence refers to the medical experts (e.g., pathologists) findings during a forensic analysis of the victim's body and IMD. Typically, medical evidence include:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. The history of the electromyogram (EMG) of the patient over the period of time preceding the death;
2. The set of therapies (i.e., electric shocks) delivered by the IMD, as a series of time stamped reactions along with the value of electric shocks;
3. The clinical observations which are derived during autopsy; and
4. The information collected from the medical record of the victim.

Technical evidence present the set of sensitive events executed on the IMD. They are typically stored in IMD logs as a series of time stamped events. They include:

1. Access information which help differentiating between sessions of remote connection;
2. Evidential traces related to the updates of IMD configuration and therapy settings;
3. Evidential data showing the occurred sensitive actions (e.g., the update of the IMD firmware); and
4. Information of the traffic exchanged between the IMD and remote devices. Such information is useful for the identification of some security attacks (e.g., battery depletion).

As the results of postmortem investigation mainly rely on the correctness and the trustworthy of the provided evidence, Ellouze et al. (2014) proposed an in depth security solution, which allows securing cardiac IMDs against security attacks and protecting the provided evidence from tampering to ensure their integrity. The proposed solution implements two security layers. The first layer is responsible for the protection of the cardiac IMD against security attacks (e.g., unauthorized access). It implements a mutual authentication protocol together with a security protocol ensuring a secure encrypted exchange between the IMD and the authorized programmer. The second layer is responsible of the protection of IMD logs against tampering and removal. It can only be executed by remote users who have been successfully authenticated in the first layer. The second layer implements also a biometric authentication protocol (Ellouze et al., 2013) allowing the verification of the physical proximity of the remote user. In fact, only authorized physicians, who are able to provide the biometric key computed over the electrocardiogram collected from the patient body, can get access to modify or delete records in IMD logs.

The proposed postmortem investigation system implements a three-step methodology. The first step consists in the medical investigation, which is responsible of the automatic generation of potential medical scenarios source of the death of the victim based on an inference engine executed in backward chaining starting from the victim death. This step is conducted based on the medical evidence collected from the cardiac IMD under investigation and a library of inference rules, which describe the causal relations between the different types of arrhythmias and the reactions undertaken by the cardiac IMD. Typically, an inference rule of this library takes the following form to state that the successive occurrence of *Ev* for n times induces the successive occurrence of *Ev* m times within a period of time T, where n and m are positive non-zero integers, and *Ev* and *Ev*' are a conjunction and/or disjunction of simple events (e.g., *Ev* is conjunction of two simple events: an arrhythmias and an instantaneous reaction undertaken by the IMD; and *Ev*' is a subsequent arrhythmia). Events included in inference rules can be classified into: a) observable events, which are the events detected by the IMD and included in the provided medical evidence. Examples of observable events include the delivery of electric shocks and the occurrence of ventricular fibrillation; and b) unobservable events, which are the events that cannot be detected by the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

IMD, so that they are not included in the medical evidence. Starting from the last observed event in the medical evidence (i.e., death), inference rules are executed in backward chaining to reconstruct a tree of potential medical scenarios, whose root node is the death event.

In the second step, which refers to the technical investigation, investigators are in charge of reconstructing the potential attacks scenarios. Starting from the library of attacks, they combine elementary actions to construct attack scenarios that provide the same collected evidence when executed. Typically, an attack scenario, say S, takes the following form $S = \langle s_0, A_1, s_1, \ldots, A_n, s_n \rangle$, where s_0 is the initial system state, $A_i (i \in [1,n])$ are the elementary actions of the scenarios, which can be legitimate or malicious, and $s_i (i \in [0,n])$ represent the description of the intermediate system states. An intermediate system state s_i is generated unless an action A_i is enabled at state s_{i-1} and is executed from it. With respect to the monitoring and security supervision mechanism implemented on the IMD, an action or a state can be visible (i.e., its value is included in the available evidence) or invisible (i.e., none information regarding its occurrence can be determined from the evidence). To support the automatic reconstruction of potential attack scenarios, a Model Checking based algorithm is executed in forward chaining. Such an algorithm is in charge of executing possible actions from the library, to generate a graph of technical scenarios satisfying the provided evidence.

After the generation of potential medical scenarios and potential technical scenarios, a correlation between these two types of scenarios is performed during the third step. This correlation allows proving whether the malicious actions in the technical scenarios of attacks caused the absence of reactions or the execution of inappropriate reactions identified in the medical scenarios. Correlation of the generated scenarios is performed in three sub-steps. The first sub-step consists in the deeply analysis of the potential medical scenario to check whether there are suspicious IMD reactions (e.g., delivery of unsuitable therapy) in the potential medical scenarios, and identify their related parameters. In the second sub-step, malicious actions threatening the IMD security are identified through the examination of the generated potential technical scenarios. A correlation is conducted in the third sub-step to check whether there is a causal relation between one of the identified suspicious IMD reactions and the determined malicious actions.

An example of a lethal attack on cardiac IMD is described as follows. An attacker, who gained an unauthorized access to the IMD, altered the thresholds associated to the detection of some arrhythmias, so that the IMD becomes unable to appropriately detect and treat the occurred arrhythmias. This inadequate configuration of the IMD has led to the occurrence of fatal arrhythmias causing the victim death. To investigate this lethal attack, the three-step methodology is performed as follows. During the first step, pathologists generate the medical scenario leading to the victim death. For instance, starting from the available EMG history and the IMD response traces, pathologists prove that the occurrence of successive events of a fatal arrhythmia (e.g., ventricular fibrillation) has induced the death of the victim as follows. They demonstrate that:

1. The IMD inappropriately detected the occurred arrhythmia events, for example it detected Sinus-Tachycardia (ST) events as Ventricular Fibrillation (VF) events. To this end, it delivered the therapy suitable for VF rather than ST;
2. The delivery of successive inappropriate therapies have led to the occurrence of VF events whose intensity grew from an event to another; and
3. The IMD was unable to handle the occurrence of VF events and deliver the suitable therapy, since it reached the maximum number of electric shocks it can deliver.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the second step, starting from the available technical evidence and the library, which contains simple attacks targeting IMDs, technical investigators reconstruct attack scenarios, which induced the inappropriate detection of arrhythmias. For instance, they prove that the inappropriate detection of the IMD occurred further a remote attack executed on the IMD, which altered the thresholds associated to the detection of some arrhythmias (e.g., Sinus-Tachycardia). In the third step, the correlation of two types of generated scenarios (medical and technical) showed that the alteration of IMD settings (i.e., thresholds associated to the detection of some arrhythmias) makes the IMD unable to deliver the therapy suitable to the occurred arrhythmias, which led to the victim death.

SECTION 5: COMPUTER AIDED PHYSICAL CRIMES INVESTIGATION

A set of research works were proposed in the literature took interest to the development of theoretical approaches for the investigation of physical health crime scenes. In the sequel, we detail the most important ones of these approaches.

Modeling Crime Scenarios Using Assumption Based Truth Maintenance System (ATMS)

In order to improve the criminal investigation process and assist investigators, a decision support system (DSS) was proposed in the work of Keppens and Schafer (2006). The proposed system implements a knowledge driven methodology together with an abductive diagnosis approach. The principal component of the proposed architecture is an Assumption based Truth Maintenance System (ATMS), which is an inference mechanism allowing the reconstruction of all possible scenarios that can provide a set of explanations for the available evidence and support some hypotheses. Possible scenarios are generated starting from an initial set of inputs (facts and evidence) using a knowledge base. The constructed possible scenarios are then grouped in the form of a data structure, namely the scenario space. In order to analyze the scenario space, users can generate a set of standard queries which are translated into a specification of ATMS nodes of interest through the query analyzer. Answers related to the received queries are computed through the extraction of the relevant parts from the scenario space, transformed in a user understandable format by the report generator, and then sent back to users.

According to the proposed DSS, a scenario consists of a set of events, states, and causal relations between these events and states. It is constructed using a knowledge base, which integrates the use of three principal constructs. The first construct is the property definitions, which allow describing the involved types of events and states. The second construct is a set of causal rules, called scenario fragments. An example of a causal rule is as follows.

```
if {
suffers(P, C),
cause-of-death(C, P),
medical-examiner(E)
} assuming {
determine(E,cause-of-death(P)),
correct-diagnosis(E,cause-of-death(P))
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

```
} then {
cod-report(E, P, C)
}
```

This rule states that: a) if there is a person *P* who suffers from ailment or injury (denoted by *C)*, *C* is the cause of death of the person *P*, and there exists a medical examiner, denoted by *E*; and b) assuming that *E* determines the cause of death of *P* and performs the correct diagnosis; then a piece of evidence is generated in the form of a report which indicates that according to *E*, *C* is the cause of death of *P*.

The third construct consists of a set of inconsistencies, which allows identifying the combination of events, and states that are impossible and inconsistent with one another. An example of inconsistency is as follows.

```
inconsistent {
suicide-action(hanging, P),
is-hanged(P)}
```

This inconsistency states that a person P cannot kill himself (i.e., suicide) and be hanged by another person in the same time.

The proposed decision support system (Keppens and Schafer, 2006) implements two types of inference mechanisms. The first type is a backward chaining inference mechanism. It infers plausible scenarios, which explains the available evidence, starting from the available evidence and until reaching the initial state of the system. The second type is a forward chaining inference mechanism. It is executed starting from the initial system state and until reaching the available evidence. It allows the generation of new plausible scenarios, in addition to those created during the backward chaining phase.

Modeling Crime Scenarios in a Bayesian Network (BN)

A Bayesian network (BN) is a probabilistic graphical model that encodes probabilistic relationships among a collection of relevant variables. For instance, in the medical field, BN may allow representing the relationships between the occurred cardiac arrhythmias and the death of a patient. It can be also used to compute the probabilities of the occurrence of the death event. In this context, the use of a Bayesian network (BN) can be a promising solution for the modeling plausible crime scenarios and the proof of the communication between investigators and judges in legal cases (e.g., crime on e-health system). Nevertheless, the identification of relevant variables, during the construction of such a network, is not always easily feasible. To this end, a formal foundation for evidential reasoning, which allows the automatic construction of a Bayesian network, can be used to enable the development of a software tool, which allows assisting investigators and judges during the investigation of crimes on healthcare systems.

Vlek et al. (2013) proposed a formal evidential reasoning approach, which allows modeling plausible crime scenarios for a legal case in a single Bayesian Network and connecting them to the provided evidence. The proposed approach integrates four main steps described as follows. The first step consists in formulating all the relevant scenarios and identifying the guilt hypotheses that could be supported by each specified scenario. It may exist relevant scenarios which do not support any guilt hypothesizes. Guilt hypothesis should be formulated in such a way they are either equal, or mutually exclusive. During the second step, a set of scenarios idiom are generated and represented in the graph under construction

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

starting from the relevant scenarios (formulated in the first step). This can be achieved as follows. For every state or event in the formulated relevant scenario, a binary node is included in the graph under construction. Then, an arrow is drawn between dependent events or states, since the absence of an arrow between two nodes, representing events or/and states, means that they are independent from each other. After that, a set of binary scenario nodes are also included to represent every scenario formulated in the first step, and an arrow is drawn from each scenario node to all state and event nodes in that scenario. To represent the supported guilt hypothesis, a set of binary nodes are added, and a set of arrows are drawn from every scenario node to the guilt hypothesis it supports. In the third step, in order to merge the generated idiom scenarios in one Bayesian Network, the same guilt hypothesis nodes are replaced by one node, which will be connected to the different scenarios supporting this guilt hypothesis. After merging the scenarios idioms, a verification of the existence of other dependencies between nodes should be performed, in order to be modeled with arrows. Moreover, if there are nodes describing equal states, events or evidence, they are replaced by one node. Nevertheless, if there are nodes, in two different scenarios, describing conflicting states, events or evidence that cannot occur simultaneously, a constraint node is included to present the identified constraint. Finally, the fourth step consists in adding the relevant evidential nodes to the Bayesian network under construction. A binary evidential node representing each piece of evidence, collected during the investigation process, is included. These included evidential nodes are also connected to the event or state node in the scenario it supports. The resulting graph (i.e., the Bayesian network) will be connected, representing all idiom scenarios of a legal case.

Automated Inference of Past Criminal Action Instances in Digital Investigations

Because of the technological evolution, and the intensive use of digital equipment by persons to access to diverse types of services, the amount of digital evidence that should be handled during postmortem investigation is continuing to increase. In this context, James and Gladyshev (2015) proposed a signature analysis model allowing the automatic provision of data to knowledge acquisition for the involved digital investigators. The proposed model ensures the automated approximation and reconstruction of past action instances within a compromised digital system. It integrates the use of signature-based methods to provide a formal description of the different categories of signatures. In this work, a signature is expressed as follows $S=\{T_i,\theta,cm\}$, where: T_i represents the set of objects time stamps associated to an action instance, θ is the object update threshold related to the action instance, and cm defines the update consistency checking function which is specific to the category of object update patterns. Three principal time stamp-related update patterns are defined in the work of James and Gladyshev (2015). Below, we detail each pattern.

The first time stamp-update pattern, namely Core object update, defines the update pattern of Core object time stamps as follows. Core object time stamps represent the set of time stamps, denoted by Score, which are always updated to be equal to the value of the clock of the system each time a specific action is executed. This definition means that when observing a trace in a Core set, it can be noticed that an action instance might have occurred. In fact, an artifact observed in a Core set can be related to only single action. Moreover, due to the fact that time stamps belonging to Score are always updated, each time stamp should be within a certain time range of each other that is identified according to the object update threshold of the action, denoted by θ. Let us consider the example of a configuration file of a Program X that is modified each time the Program X is closed, thus the modification time stamp of this file is a Core trace for the action "Close Program X". Starting from the definition of the first pattern,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

an object time stamp update consistency function, namely CoreTest, was developed. Such a function is in charge of checking whether each object update conforms to the Core signature category based on the object update threshold and the TraceStates array that includes the values of time stamps of all objects specified in the signature. According to this function, if the difference between the recent timestamp value and the oldest time stamp value of the TraceStates array is lower than the object update threshold, the Core traces are considered as consistent, otherwise, they are inconsistent.

The second time stamp-update pattern, namely Supporting object update, defines the update pattern of Supporting object time stamps as follows. The supporting object time stamps represent the set of time stamps, denoted by $S_{support}$, which are irregularly (i.e., not always) updated each time a single particular action instance is executed, and they can only be updated by a single specific action. Similarly, to Core signatures, the detection of a trace in a supporting signature means that an action instance must have occurred, since an artifact observed in a supporting signature can be related to a single action. For example, an irregular update of time stamp may be figured when a file is cached in memory after the first execution of the first action instance. In fact, it may happen that the subsequent action instances accessed the file data cached in memory rather than the file disk, so that the trace related to this update would be unobservable on the disk, since the original file's meta-data on disk was not updated. Starting from the definition of the second pattern, an object time stamp update consistency function, called SupportTest, was derived. Such a function is in charge of testing whether each object update conforms to the supporting signature category based on the object update threshold θ and the TraceStates array that includes the values of time stamps of all objects specified in the signature. If an object update conforms to the supporting update category, and if each trace has been updated within the threshold θ, the action execution time can be defined to be approximately equal or shortly lower than the oldest time stamp in the TraceStates array. In the case where there exists a time stamp updated outside of θ from another related object time stamp, then it can be noticed that a separate instance of the same action must have happened.

The third time stamp-update pattern, namely Shared object update, defines the update pattern of Shared object time stamps as follows. Shared object time stamps represent the set of time stamps, denoted by Shared, which may be always or irregularly updated on the occurrence of each execution of multiple actions. Differently to the Core signatures and the Supporting signatures, more than one action can be associated to a trace in a Shared signature, so that the only information that can be derived from the observation of a trace in a Shared signature is that at least one of the actions associated to this trace must be executed. The access time stamp of a .dll file (.dll represents the file extension of a Dynamic-link library) can be considered as an example of a Shared object time stamp, since more than one action may induce the .dll file to be accessed. The conclusion that may be derived when only analyzing this file (without any additional information) is that each action, which is able to induce the .dll file to be accessed, has the same occurrence likelihood. An object time stamp update consistency function, called SharedTest, was derived from the definition of the Shared object update pattern. This function allows testing whether each object update conforms to the Shared object update category, and determining the actions associated to the trace. If an object update conforms to the Shared update category, and if each trace has been updated within the threshold θ, then the action execution time can be defined to be approximately equal or shortly lower than the oldest time stamp in the TraceStates array. In the case when there exists a time stamp updated outside θ from another object time stamp, then it can be noticed that a separate instance of the same action must have happened, because objects are irregularly updated. Since multiple actions can be associated to a trace, additional information are also required to enable the identification of the action causing the trace.

SECTION 6: ADVANCED ISSUES

Several approaches were developed in the literature to conduct a digital investigation on compromised digital system. Several issues were addressed by these ranging from the need to generate provable results, address scalability, and provide resilience to anti-forensic attack. However, the whole majority of these approaches are not directly applicable to investigate healthcare attacks. In fact, contrary to general types of digital attacks which affect only the target system, crimes on e-health systems could firstly affect the medical devices, and then spread to the patient. A healthcare investigation would therefore require the cooperation between at least two types of experts: forensic pathologists and digital security investigators. Moreover, a healthcare attack can be conducted with a long-term interest (a modification of electronic healthcare records could lead to an unsuitable medication that will be prescribed a long time after), Techniques for the long-term secure storage of evidence need to be developed. As a medical attack on a healthcare system can affect people, its impact will vary from a patient to another, introducing an uncertainty in the attack consequence. Such an uncertainty needs to be handled by the existing investigation techniques.

Despite some advances in the development of frameworks for the forensic investigation of digital crimes in healthcare applications, several issues remain unsolved.

The first issue is related to the development of forensic readiness. We have shown in the previous sections of this chapter the importance of the risk associated to attacks on wireless medical systems, and their consequence on the patients and practitioners' safety, privacy, and legal liability. To make attacks on medical systems investigable, the complete healthcare system should be made forensically ready so that a complete and successful investigation can be conducted, or a root cause analysis can be performed when the security incident occurs. Developing the forensic readiness aspects in healthcare requires setting technical and non-technical measures to maximize the ability of collecting and securing evidences. These measures include, but are not limited to:

1. The collection of evidence legally while minimizing at the maximal possible any interference with the business process of the healthcare system;
2. The definition of the healthcare system usage scenarios that require a collection of evidence;
3. The identification of the potential sources of digital evidence, including the different wireless access networks used by patients and healthcare professionals, the various used cloud infrastructures and services, and the diverse access equipment;
4. The maximization of the capabilities of collecting evidence from the healthcare system in a way that keeps them authentic, secure, and admissible in courts of laws;
5. Training the technical staff to conduct future digital investigation; and
6. Developing the procedures to facilitate the postmortem analysis.

All of these mechanisms should be made possible, and capable to cope with the voluminous aspects of the collected medical data, the huge number of intervening persons, the diversity of the access equipment, the distributed aspects of healthcare systems and applications, the heterogeneity of the evidence to be collected, and the complexity of healthcare investigation.

The second aspect is related to the need to maximize the ability of a healthcare crime investigation system to cope with anti-forensic attacks. These attacks target the availability and usefulness of digital evidences to the healthcare forensic investigation process. The evidence can be compromised by hiding,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

destroying, or forging them. An attacker can conduct a successful crime and later alter the generated traces to make it non investigable. Aware of these types of attacks, the developed frameworks for the investigation of healthcare crimes should develop new techniques to first detect anti-forensic attacks, and also to conceal their effect on the compromised evidence. Once the anti-forensic attacks are identified, it becomes possible to proceed with the scenarios reconstruction, and the crime identification. Several issues make these actions challenging. First, the anti-forensic attacks are difficult to detect as most of them do not leave traces on their execution. Wiping an evidence file to completely hide the original content, for example, is not only difficult to detect, but also impossible to recover. Second, several classes of ant-forensic attacks exist (e.g., address anonymization, multimedia steganography, data hiding in slack space), making it necessary to develop the required formalism to model them within libraries of attacks, useable during an investigation. Third, the protection from anti-forensic attacks requires the development of novel tamper-evident technologies to make unauthorized access to the device storing the evidence easily detected. Additional levels of protection are also required to identify the potential tampers and their gained level of knowledge, determine the techniques and methods used to attempt to gain access, control access to the evidence, and reduce to the maximum possible the cost associated to the tamper evident features and the detection of tampering.

The third issue is related to the need to cope with the resources scarcity of the wireless healthcare systems, especially as they are showing an extensive use of small and tiny devices for the purpose of sensing, monitoring, identification, and on-demand information exchange. While several approaches attempted to overcome the limitation of resources and the transient unavailability of the collection devices, by using virtualization and cloud computing technologies, an extensive work still needs to be developed. The aim is not only to virtualize the storage space and the processing resources, but also to virtualize all the types of sensors used by the healthcare solution, in order to decrease the number of required sensors, increase the accuracy of the sensed data by taking profit from the redundancy of sensors, increase the network lifetime and the continuous delivery and availability of services, collect complex data starting from diverse physical sensors, and decouple the physical sensors resources from the developed sensing application. The new expected types of cloud sensors for healthcare applications should also meet the requirements in terms of quality of service, security, and energy preservation.

The last issue is related to the need to cope with the increasing need of energy. In fact, the prominent need to make investigation in healthcare be proactive instead of postmortem, makes it necessary to develop novel techniques for the continuous collection and delivery of evidence, and the instantaneous reaction to potential digital crimes. These techniques will certainly increase the consumption of energy from the battery of medical equipment (wearable or mobile sensors), making it necessary to optimize the used algorithms to reduce their consumption of energy, or to find alternative sources of power. One of the potential used solutions is to use highly sophisticated batteries and power management systems, which will certainly increase the cost of the healthcare solution. Another, alternative and highly cheaper solution consists in using power harvesting or energy scavenging techniques to power the different tiny and autonomous sensors from many external sources such as solar power, thermal energy, and Radio Frequency energy. The ongoing and future research development should work on eliminating the battery from the energy-sensitive medical equipment and get rid of the weakest component in these devices. In some devices, such as pacemakers, the use of energy harvesting techniques would avoid doing surgical intervention by physicians to replace the patient's pacemaker each time its battery is depleted.

CONCLUSION

In this chapter, we took interest in the postmortem investigation of digital crimes on healthcare applications. Firstly, we provided an overview of healthcare systems' architectures together with a detailed description of the involved components and their functions. We also reviewed and classified the most important types of healthcare applications proposed in the literature. Then, we identified and described a representative set of digital healthcare crimes. These crimes have been organized into four classes based on their goals and their impact on the patients' safety and privacy. We also discussed the impact of these crimes on the availability and the accuracy of the provided healthcare services. After identifying digital crimes on healthcare applications, we discussed the main requirements that should be fulfilled during the design of a postmortem investigation system tailored to these applications. A literature review of research works related to the use of theoretical techniques for the investigation of digital crimes on healthcare applications, and also the investigation of physical health crime scenes, was provided. Finally, we discussed a set of advanced issues that should be addressed during the design of an efficient postmortem investigation system capable of providing accurate results.

KEY TERMS AND DEFINITIONS

Attack Scenario: A series of malicious and legitimate actions executed on a digital system to harm its security. At some step in the scenario, a malicious action is executed to transform the system state from safe to unsafe (these states are already defined in a security policy).

Digital Crimes: Encompass all offences against the secrecy, integrity, and availability of electronic data and digital systems. When executed, they could lead to a set of serious threats ranging from economic to life threats.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Digital Forensic Investigation: The process of a postmortem analysis of a compromised system, to identify and retrieve digital evidence, understand the incident, identify attackers, and reconstruct potential attack. To conduct a forensic investigation, scientific methods can be used to prove/disapprove a claim about the incident in a court of law.

E-Health Systems: Healthcare systems which integrate the use of information and communications technologies to provide medical services to patients. Thanks to the integration of these technologies, a wide set of e-health applications, which improve the quality of life of high risk patients, were developed.

Implantable Medical Devices: A specific class of digital devices (e.g., pacemakers, defibrillators, insulin pumps), which are surgically implanted into a human's body, and used to treat chronic ailments (cardiac arrhythmia, diabetes, Parkinson).

Lethal Attacks: Security attacks that generally target medical devices and e-health systems. When executed, these attacks seriously harm the health status of the victim patient and lead to its death.

Physical Healthcare Crimes: Encompass all violations against the person's bodies. They generally cause serious physical damage (e.g., abuse, homicide) to the bodies of victim persons.

Chapter 90
Bidirectional Spreading Activation Method for Finding Human Diseases Relatedness Using Well-Formed Disease Ontology

Said Fathalla
University of Bonn, Germany & Alexandria University, Egypt

Yaman M. Khalid Kannot
Arab Academy for Science, Egypt

ABSTRACT

The successful application of semantic web in medical informatics and the fast expanding of biomedical knowledge have prompted to the requirement for a standardized representation of knowledge and an efficient algorithm for querying this extensive information. Spreading activation algorithm is suitable to work on incomplete and large datasets. This article presents a method called SAOO (Spreading Activation over Ontology) which identifies the relatedness between two human diseases by applying spreading activation algorithm based on bidirectional search technique over large disease ontology. The proposed methodology is divided into two phases: Semantic matching and Disease relatedness detection. In Semantic Matching, semantically identify diseases in user's query in the ontology. In the Disease Relatedness Detection, URIs of the diseases are passed to the relatedness detector which returns the set of diseases that may connect them. The proposed method improves the non-semantic medical systems by considering semantic domain knowledge to infer diseases relatedness.

1. INTRODUCTION

Usually, computers were used to perform tasks with none sort of intelligence or semantics thus there is a necessity to make computers as intelligent as human (Antoniou & Van Harmelen, 2004). The defect of non-Semantic applications is painted by the statement "lack of semantics" particularly when the talk is concerning information retrieval. The semantic web's goal is to extend automation in processing web-based data and to enhance the interoperability of web-based information systems (Payne, Terry & Lassila, 2004). The semantic web gives the meaning of knowledge making software systems can perform intelligent tasks instead of users (Berners-Lee, Hendler & Lassila, 2001) using a semantic knowledgebase called Ontology. Ontologies is a repository in which information are organized and used in semantic-based applications (Shadbolt, Berners-Lee & Hall, 2006). Below a group of definitions that may be used as a basis for mathematical formulation of the term ontology and its components (Fonseca, Davis & Câmara, 2003):

Definition 1: A term is a triple $\tau = [\eta, \delta, A]$, $\tau \in T$, where η is a string of characters containing the name of the term, δ is a string of characters containing its definition and A is a set of attribute domains A1, A2, ..., An, each associated to a value set Vi.

Definition 2: A relation $\varphi: T \rightarrow T$, $\varphi \in \Phi$: is a function from T to T such that for every term $\tau 1 \in T$, there is a term $\tau 1 = \varphi(\tau 1)$, $\tau 2 \in T$.

Definition 3: A semantic relation σ between two concepts is one of the relations among the set of semantic relations $\Sigma = \{$Hypernym, Hyponymy (is-a), Meronomy (part-of), Synonymy$\}$. In linguistics, a hyponym is a word whose semantics is enclosed inside that of another word which called its hyperonym or its hypernym. In other words, a hyponym has the same a type-of relationship with its hypernym. For instance, dog, cat and cow are all hyponyms of Mammals (their hypernym); that, in turn, could be a hyponym of animal (Fromkin, Rodman & Hyams, 2013).

Ontologies are often used in many systems as a semantic knowledgebase (Oberle, 2014). In the field of health informatics, ontology is used for the representing and organizing medical vocabularies. Collins and Loftus (1975) discussed in their research that the Spreading Activation (SA) runs on semantic networks (Anderson et al., 1983) and is used for information retrieval process (Burnset et al., 1981). It runs on a graph structure that comprises of a set of nodes connected by edges. The concepts are nodes which have an activation value and the relations between them are represented by edges between these nodes. An activation value is assigned to each node in the graph and then the algorithm spreads to the nodes with the higher activation value. The algorithm runs in a set of iterations and terminates when a stopping condition is reached.

The main objective of this work is to identify whether two human diseases are related to each other or not. If so, identify the set of diseases that connecting them. Finding a relatedness between diseases is important because the doctor can treat patient not only based on the symptoms they suffer from but treat the real cause of this disease which may be related to another disease that causes these symptoms therefore, the doctor can treat the cause disease not the symptoms.

This paper is organized as follows. Section 1 gives a brief overview of semantic web and ontologies. Section 2 reviews the literature. Section 3 describes the ontology for SAOO. Section 4 introduces the methodology of the proposed work. Section 5 illustrates the methodology by showing a running example. Section 6 describes the prototype used to implement the methodology. Finally, Section 7 presents conclusions and future work.

2. LITERATURE REVIEW

There is a considerable amount of literature on biomedical knowledge management and medical decision making. Biomedical knowledge available in the web is increasing considerably as most of the biomedical research papers are published online. Identifying named text features in user's query is a crucial procedure for efficient text analysis and matching. Semantic matching is a technique used to identify information which is semantically matched information in structured data. Many diverse solutions of match have been proposed so far. Some examples of individual approaches addressing the matching problem can be found in (Dhamankar et al., 2004) and (Do & Rahm, 2002). In their cutting-edge paper of 2004, Kanavos, Theodoridis and Tsakalidis (2014) proposed a metasearch engine over PubMed1. It provides accurate clustering of results according to their specific topic using a biomedical ontology, named MeSH[2] in addition to RxNorm[3] that is a US-specific terminology in medicine that semantically links clinical drugs vocabularies and support the interoperation between them. Ngo, Cao and Le (2010) proposed an ontology-based model for semantic annotation and searching using a vector space model. It takes advantage of ontological features of both named entities and WordNet vocabularies, and develops a spreading activation algorithm for query expansion. As anticipated, their experiments demonstrate that the proposed model is better than the solely keyword-based model and also better than the ones using only WordNet or named entities. In addition, it merges various ontologies to improve the semantic search process. De Maio et al. (2011) proposed a project named ODINO which uses a fuzzy knowledge approach for disease diagnosis that supports medical decision making. Medical knowledge is defined according with physician experts and represent relations between medical disease and its symptomatology. ODINO has three main features which are faceted search of diseases through taxonomy constraints, disease catalogue browsing and preliminary medical diagnosis.

Many efforts have been made to represent medical information as a semantic knowledgebase for further processing by semantic applications. Despite the existence of many medical ontologies, it is important reuse and integration of ontologies is to establish suitable mappings between their concepts. In recent years there has been growing interest in ontology matching and integration (Shvaiko and Euzenat, 2013; Euzenat, 2011). Shvaiko and Euzenat (2013) surveyed the state of the art of ontology matching and addressed some important challenges for ontology matching. In addition, they analyzed the results of recent ontology matching evaluations. Below some of the famous medical-related ontologies will be listed:

- Disease Ontology (DO)[4] is a biomedical resource of standardized common and rare disease concepts with stable identifiers organized by disease etiology;
- Vaccine Ontology (VO)[5] has been developed through collaboration with vaccine researchers and many national and international centers and programs. VO is represented in the Web Ontology Language (OWL) and edited using the Protégé-OWL. Currently VO contains more than 2000 terms and relationships (He et al., 2009);
- The Infectious Disease Ontology (IDO)[6] ontologies are designed as a set of interoperable ontologies that will together provide coverage of the infectious disease domain. At the core of the set is a general Infectious Disease Ontology (IDO-Core) of entities relevant to both biomedical and clinical aspects of most infectious diseases;
- The Ontology for Biomedical Investigations (OBI)[7] is an integrated ontology for the description of life-science and clinical investigations;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The Ontology for General Medical Science (OGMS)[8] is based on the papers toward an ontological treatment of disease and diagnosis and on carcinomas and other pathological entities. OGMS was previously called the Clinical Phenotype Ontology.

3. THE ONTOLOGY FOR SAOO

The semantic web uses the resource description format data model (RDF) to describe data models, including concepts and relationships between them. The main purpose of developing ontology is to use it as a semantic knowledge base representation for identifying concepts in a specific domain and discover concepts semantics and the relationships between them (Fathalla, Hassan & Kholief, 2013). The authors of Köhler (2013) and Croft (2014) discuss in their research that the human disease data is a cornerstone of biomedical research therefore there's an enormous need for a consistent representation of human disease for robust data analysis (Colomb, 2007; LePendu et al., 2011). Creating a biomedical knowledgebase in the form of ontologies creates a rigid knowledgebase for semantic annotation of biomedical data through defined concepts and relations connecting them (Hoehndorf, Dumontier & Gkoutos, 2012).

The disease ontology (DO) used in this work has been developed as a standardized ontology for human disease. The objective of DO is to provide the biomedical community with convenient, reusable and robust knowledgebase of human disease concepts, phenotype characteristics and related medical vocabulary disease concepts. It is a collaborative effort of researchers at Northwestern University, Center for Genetic Medicine and the University of Maryland School of Medicine, Institute for Genome Sciences. DO does not include progression (early, late, metastasis, stages) or manifestations (transient, acute, chronic) of disease as part of the definition of disease (Kibbe et al., 2014). The human disease ontology is concentrate on representing predominant and rare disease concepts captured across biomedical resources with the mission of providing a disease interface between data resources through ongoing support of disease terminology needs. Major enhancements to the DO database since 2012 has been made including: the content of DO has had 192 revisions, including the addition of 760 terms and 32% of all terms now include definitions, improved data structure, new areas of community based efforts, new community partners and a switch to web ontology language (OWL). The current version of the DO website (version 1.0) provides a comprehensive resource to perform full-text searching on the DO as well as exploring and visualizing relationships between terms. The Disease Ontology database has been updated to the latest ontology as of 02-03-2017. The DO project has had a considerable influence on the development of biomedical resources, as evidenced by 291 Google Scholar citations to DO's paper in 2012 (Schriml et al., 2012). Table 1 shows the number of classes, properties, triples and the number of imported ontologies.

4. METHODOLOGY

The methodology of the proposed work is divided into two phases: Semantic matching and Disease relatedness detection as shown in Figure 1. In Semantic matching phase, semantically search for the user submitted diseases to identify whether these diseases are exist in the ontology using concepts that are semantically related to query concepts or not. The output of this phase is whether the diseases are found in the ontology or not. In case of found, the URIs of both diseases are retrieved. In the Disease related-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Do's statistics

Type	Local	Imported	Inferred	Total
Number of Triples	187957	89224	2390	279453
AnnotationProperty	25	0	0	25
Class	8720	25030	0	33750
DatatypeProperty	1	0	0	1
ObjectProperty	0	1	0	1
Ontology	1	5	0	6

ness detection phase, the URI for each disease is passed to the relatedness detector to find whether they are related or not. If they are related, the algorithm returns the set of diseases that connect them in the path from the first to the second.

4.1. Semantic Matching

The main objective of this phase is to identify diseases in the ontology which is semantically related diseases in the submitted query. It is assumed that, when searching for a concept, it is also important to get synonyms of that concept. For example, the synonyms of the disease "Hyperuricemia" are "Hyperuricaemia" and "Uricacidemia" therefore, diseases describing these concepts are also retrieved as well. The matching process is performed by in the following proposed algorithm:

```
Input: Ontology O, String disease1, String disease2
Output: URI of both diseases when matched, null if not.
α←false
β←false
For each (Resource R in O) do
α = Semantic_Matching (R, disease1)
If (α≠false) then
URI [0] = Resource.getURI(R);
Else
Print ("Disease 1 not found")
Return null
End if
β = semantic_matching (R, disease2)
If (β≠false) then
URI [1] = Resource.getURI(R);
Else
Print ("Disease 2 not found")
Return null
End if
End for
```

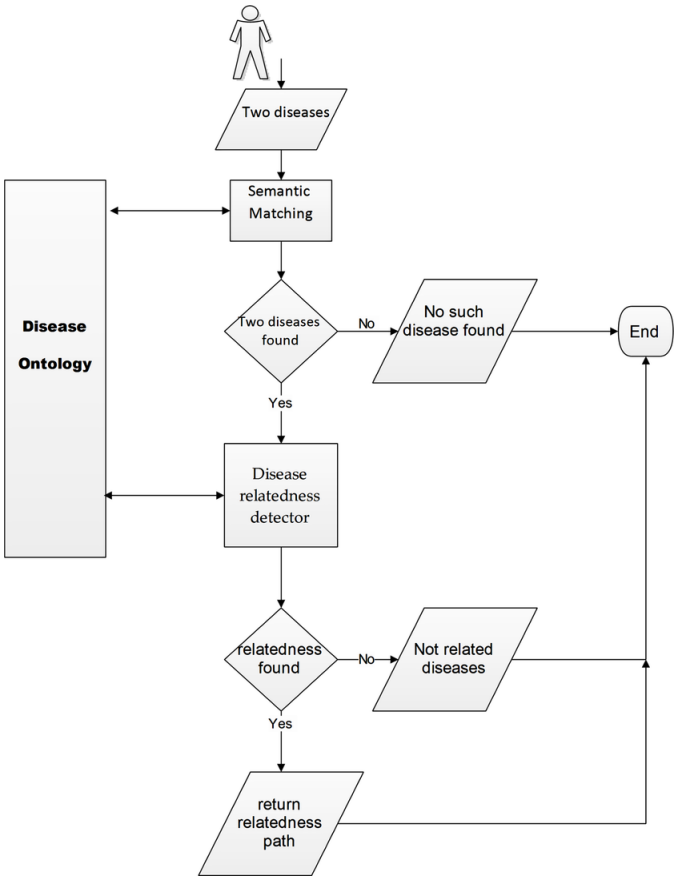
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The matched algorithm iterates through ontology resources and performs semantic matching between this disease and that resource. When matched, sets a flag α to true and then repeat this process for the second disease. Otherwise, the disease is not found in the ontology and returns null. Semantic matching conducts more analysis in matching process. This analysis may comprise term normalization; phrase analysis, word sense disambiguation, and the matching may be performed on phrase level and word sense level (Li & Xu, 2014).

4.2. Disease Relatedness Detection

In disease relatedness detection phase, the two diseases relatedness is detected by using bidirectional spreading activation on ontology graph. The idea of a bidirectional search is to cut back the search time by looking out forward from the beginning and backward from the goal at the same time. When the two search frontiers meet, the algorithm will reconstruct one path that extends from the beginning state through the frontier intersection to the goal. The merit of bidirectional search is its speed and it requires less memory (Poole & Mackworth, 2010).

Figure 1. Semantic matching process



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. RUNNING EXAMPLE

As a running example in this paper, a query includes two diseases ("Joubert syndrome with orofaciodigital defect" and "Meckel syndrome") will be used as a user submitted query. The results of relatedness detection may consist of a set of different diseases. As shown in Figure 2, the relatedness between "Joubert syndrome with orofaciodigital defect" and "Meckel syndrome" diseases are detected by the intersection nodes "Ciliopathy". The algorithm runs in the following steps:

1. Begin with two initial nodes "Joubert syndrome with orofaciodigital defect" and "Meckel syndrome" (marked in light gray);
2. The first cycle of activation process will active one more node from each of the starting node which is Joubert syndrome (from node 1) and Ciliopathy (from node 2);
3. The second cycle of activation process will active Ciliopathy and genetic disease diseases from the first and second path respectively;
4. The algorithm detects an intersection node Ciliopathy and stops.

The whole spreading process is summarized in Table 2.

6. EXPERIMENT

In this section, SAOO prototype is presented. This prototype exemplifies how spreading activation is used over ontology. SAOO automatically processes user's query in the following steps:

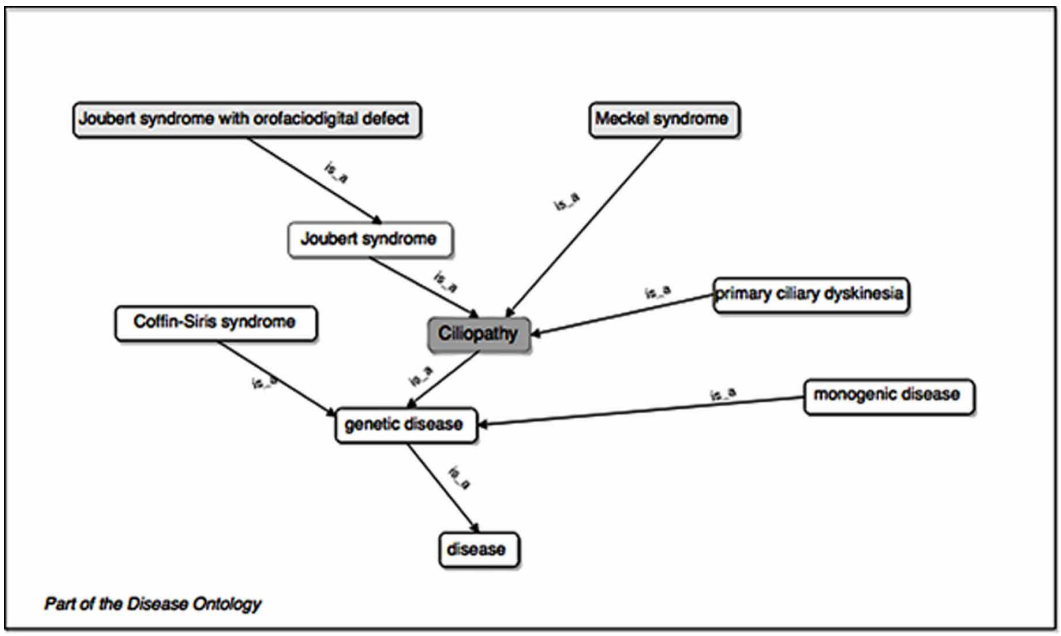
1. **User Input:** User submits the two diseases as a string;
2. **Query Preprocessing Including:** See the following:
   a. **Intelligent Tokenization and Stop List Elimination:** Tokenize the query string, by breaking it down into understandable segments. Usually a token is defined as an alpha-numeric string that separated by white space or punctuation. Then, eliminating all stop words. Those terms have little value in describing user's intention. A stop word list typically consists of those word classes that do not contain important significance to be used in the query, such as articles (an, a), conjunctions (and, thus), interjections (oh, but), prepositions (at, on), pronouns (he, she), and forms of the "to be" verb (is, are);
   b. **Stemming:** Stemming removes word suffixes: both inflectional suffixes (-s, -es, -ed) and derivational suffixes (*-able, -aciousness, -ability*) are stemmed;

Table 2. Summarization of the spreading process

1st Initial Node	Joubert syndrome with orofaciodigital defect
2nd Initial Node	Meckel syndrome
Path from node 1	Joubert syndrome- Ciliopathy
Path from node 2	Ciliopathy
Intersection	Ciliopathy

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The relatedness path between "joubert syndrome with orofaciodigital defect" and "meckel syndrome" diseases



3. **Formulate Semantic Query:** Take the preprocessed query string and formulate a semantic query using SPARQL and executes it against the ontology which performs the semantic matching process based on the inference rules (Fathalla, Hassan & El-Sayed, 2012). By incorporating these rules, semantically matched diseases could be found using Jena reasoners (Jena, 2015). These rules have been divided into three types: Transitive Rules, Symmetric Rules and Co-Reflexive Rules. In mathematical notation, these rules types defined in Table 3 (De Oliveira & Rodrigues, 2004). As an example of symmetric rule, if the disease "Hyperuricemia" is related to the disease "Hyperuricaemia" via hasSynonym property, then, it could be inferred that "Hyperuricaemia" must also be related to "Hyperuricemia" via hasSynonym property. In other words, if "Hyperuricemia" is a synonym of "Hyperuricaemia", then "Hyperuricaemia" must be a synonym of "Hyperuricemia". As an example of transitive rule, if a disease "Heart failure" has a synonym "Weak heart" and "Weak heart" itself has a synonym "CHF" then it could be inferred that "Heart failure" has synonym "CHF". Jena inference system is designed to permit a various inference engines or reasoners to be plugged into Jena. Such engines are able to infer logical consequences from a set of asserted facts or axioms together with any optional ontology information, axioms and rules associated with the reasoner. The main use of this technique is to support the use of languages which allow additional facts to be inferred from instance data and class descriptions such as RDFS and OWL. Available predefined reasoners included in the Jena distribution are (Jena, 2013):

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Inference rules types

Rule Type	Mathematical Notation
Transitive	$\forall a,b,c \in X: (aRb \wedge bRc) \Rightarrow aRc$
Symmetric	$\forall a,b \in X: aRb \Rightarrow bRa$
Co-reflexive	$\forall a,b \in X: aRb \Rightarrow b=a$

a. **Transitive Reasoner:** Provides support for storing and traversing property chains or transitivity axioms. This implements just the transitive and reflexive properties;
b. **RDFS Rule Reasoner:** Implements a configurable subset of the RDFS entailments;
c. **Generic Rule Reasoner:** This type of reasoners is very important because it supports user defined rules. Also, forward chaining, backward chaining and hybrid execution strategies are supported;

4. **Disease Relatedness Detection:** The diseases relatedness is detected by using bidirectional Spreading Activation on ontology graph if the diseases haven been found in the matching process.

7. CONCLUSION

This paper proposes a new method named SAOO (Spreading Activation over Ontology) in order to detect the relatedness between two human diseases by applying spreading activation algorithm based on bidirectional search technique over a well-formed disease ontology called DO. The main objective of this method is to identify whether two human diseases are related to each other or not. Moreover, identify related diseases that may connect them in a common path. The importance of the relatedness is that the doctor can treat patient not only based on the symptoms they suffer from but treat the real cause of this disease which may be related to another disease that causes these symptoms. Therefore, the doctor can treat the cause disease not the symptoms. The proposed method enhances the non-Semantic medical systems by considering semantic domain knowledge to infer diseases relatedness. For future work, authors are planning to find the relatedness between more than two diseases using multiple-goal search algorithms and provide the relatedness graph between them not only a simple path. In addition, a relatedness set is returned to the user which is a subset of the power set of the set of input diseases. In other words, which of these diseases is related to the others?

ABSTRACT

This article describes how machine learning (ML) algorithms are very useful for analysis of data and finding some meaningful information out of them, which could be used in various other applications. In the last few years, an explosive growth has been seen in the dimension and structure of data. There are several difficulties faced by conventional ML algorithms while dealing with such highly voluminous and unstructured big data. The modern ML tools are designed and used to deal with all sorts of complexities of data. Deep learning (DL) is one of the modern ML tools which are commonly used to find the hidden structure and cohesion among these large data sets by giving proper training in parallel platforms with intelligent optimization techniques to further analyze and interpret the data for future prediction and classification. This article focuses on the use of DL tools and software which are used in past couple of years in various areas and especially in the area of healthcare applications.

INTRODUCTION

Machine learning (ML) is a field of study which learns the behaviour of functional relationship among data without considering the detail underlying characteristics present in them. These techniques are applied to derive the functional attributes of underlying data which do not contain precise definition about them. In real cases, the datasets which are available do not have a precise definition and functional co-relation. So, ML algorithms are used appropriately for these types of data which are capable to infer the useful features of the data and their functional co-relationship so that they can be used in the problems of classification, clustering and prediction etc. Deep learning (DL) is a field of study under the umbrella of Machine learning (ML) which is constituted on the algorithms inspired by the structure and utility of human brain. This study is coherent to artificial neural network (ANN) and can be called as advanced ANN having higher set of problem solving capability and utility. DL refers to a special type of ANN which is constituted by multiple numbers of hidden layers. The hidden layers are responsible for handling nonlinearity and complexity of underlying data. These are mainly useful for giving training to network exhibiting complex co relational functions and behaviour and are mostly suitable for large data sets. Due to this reason these are very successfully applied to big data domain. In this contemporary era, data is highly scalable and growing exponentially. There is a parallel growth in data reproduction, availability and access and abundance high speed computers. So, the need of the hour is to develop high speed large neural network which are scalable enough to deal with plethora amount of big data. The input to the conventional shallow learning algorithms are known features from the data, but DL algorithms possess the potential to extract the representative feature available from the raw data whose sources are social media, transactional data, business houses, etc.

In most application of data like classification, clustering and prediction the common work flows for machine algorithms are built on some basic steps like: (i) data cleaning (ii) pre-processing (iii) training which build the learning model and (iv)testing which will evaluate the built model. For these problems the input space contains a set of input data sample x_i ($i = 1, 2, ..., n$; where n is the number of input instances which is a vector of 'm' dimension where m is the number of features) and output y_i . In supervised algorithms the artificial model learns to derive a mapping function $f(x) = y$ from a priory known pair of (x_i, y_i). After the model is duly trained on the basis of known input-output pairs (x_i, y_i), it is evaluated against the unknown samples to infer the target output which is called as testing.

In the case of unsupervised model, the model has to explore the pattern exhibiting in input x_i to find out y_i. In the training phase output y_i is not provided to the model, it has to find itself. Clustering and principal component analysis are some of the examples of unsupervised learning.

Deriving feature sets x_i to build an input dataset is very time consuming and problem specific. These are less available and difficult to create for every problem. This is the reason for unsuitability of supervised and unsupervised algorithm in all problems. But deducting the principal feature from a data set is directly associated with the performance of a learning algorithm. If features are correctly fetched from the data, then learning will take less time and the model shows higher level of accuracy. In the other hand for high dimensional data containing big data components, it is almost impossible to find out all the informative and relevant features from the raw data. This is a major limitation behind using conventional machine learning algorithms in big data possessing high dimensional feature data. This limitation is overcome by the emergence of deep neural network (Bengio et al., 2013; LeCun et al., 2015). Deep neural network contains many layers containing more than one hidden layer (Oliveira et al., 2016). The input layer takes the high dimensional raw data and extracts the relevant representive

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

features from them. These abstract features are regenerated in subsequent hidden layers to incorporate the complex and nonlinear functions exhibited in high dimensional big data. The potential of deep learning algorithms to handle high dimensional raw data make them popular in the field of data analysis to deal with data having components like volume, variety, veracity, versatility of data (Aye & Thein, 2015).

BACKGROUND

Apart from health care, the application domains of DL are in various sphere such as: speech and audio processing, natural language processing, acoustic modelling, speech synthesis, language modelling, object recognition, computer vision, etc. (LeCun et al., 2015). Some specific task may include colorization of black and white images, classification of objects in still photographs, auto generation of handwriting, automatic system for gaming, generation of appropriate captions for images etc. In last couple of years DL has been widely used in the area of public health care and life science (NVIDIA corp. (2016). The data analyst from NVIDIA has recently disclosed in a report about the estimation of possession of AI components is 80% in applications by the year 2020. They have discussed about the recent advancement of medicine world and pointed the role of DL in bringing transformation in medicine world. Some of the focused areas in health care which indulge DL are discussed below.

Mining Clinical Data for Faster Treatment

The medical records of a patient which may include prescription details, medical images, MRI scans and clinical test reports are the useful information for a doctor. Maintain all these data for all the patient is a cumbersome job. Extracting useful information on time will help the doctor for diagnosis and detection of a disease. In these cases, GPU accelerated DL tools can be used to process these data and finding relevant information of a patient data for quicker treatment.

Quicker Diagnosis Process

Doctors rely greatly on medical images like MRIs, CT Scans, X-Ray reports, Ultra sound reports, ECG signals to detect and diagnose some diseases. Sometime these data are hard to analyse and consume a lot of time. In this case DL can be used as an automatic tool to analyze the data, which can further help the medical practitioners to make the diagnosis process faster.

Prescribing Personalized Medicines

The genomic data are responsible for causing disease in living body. Identifying and studying the genomic data causing disease is very difficult. Because genomic data are voluminous and extracting genetic parameters from huge genomic data are computation intensive jobs and require faster processing. DL can be employed to handle voluminous genetic data to do processing on these to mine information of disease causing genetic materials. So that personal medicines can be prescribed to individual patient according to the genetic structure and analysis. A GPU accelerated project taken over by a class of researchers from University of Toronto are working on a project named as" genetic interpretation engine". Their work is focused on identifying cancer causing genes present in individual patient.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Helping Disabled People

Visually impaired people face a lot of difficulties while doing routine tasks such as road crossing, recognising people, reading tags and labels of different products. For this segment of people wearable devices are being developed containing embedded prior programmed chips. DL algorithms with the help of other techniques like image processing, computer vision is employed as embedded programs to perceive and understand the surroundings and transform these perceptions to words so that the blind people can get help to know their surrounding and accomplish the task.

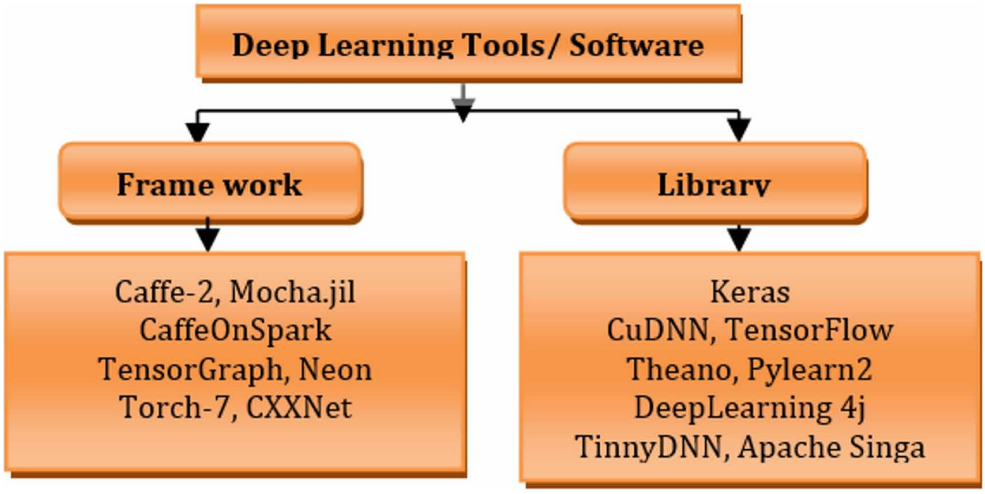
Prediction of Pharmacological Properties of Drugs

Experimental gene expression data collected from human cells are applied as input data for studying the functional changes by using chemical and drugs. These study focuses on the reaction of different newly designed drugs by exploiting them to gene expression data. These types of data are voluminous and hard to compute with conventional methods. Deep neural network is used in these cases to forecast properties of drugs on various diseases (Mamoshina et al., 2016).

OBJECTIVE OF PRESENT WORK

Different types of DL architectures are: Deep neural network; Deep Auto-encoder; Deep Belief network; Deep Boltzmann machine; recurrent neural network; convolution neural network. Among these the widely used is deep neural network. The available software to implement and deploy DL models do not support all mentioned types. Some tools are specific, and some are generic. Some have fixed architecture, and some have customizable modules. The deployment of DL models can be done through two parts: (i) Frame work or (ii) Library. These are responsible for model different layers as a building block of the network and the architecture of the network is fully dependent on the problem domain. Figure 1 presents the available DL libraries and framework.

Figure 1. List of DL framework and libraries



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

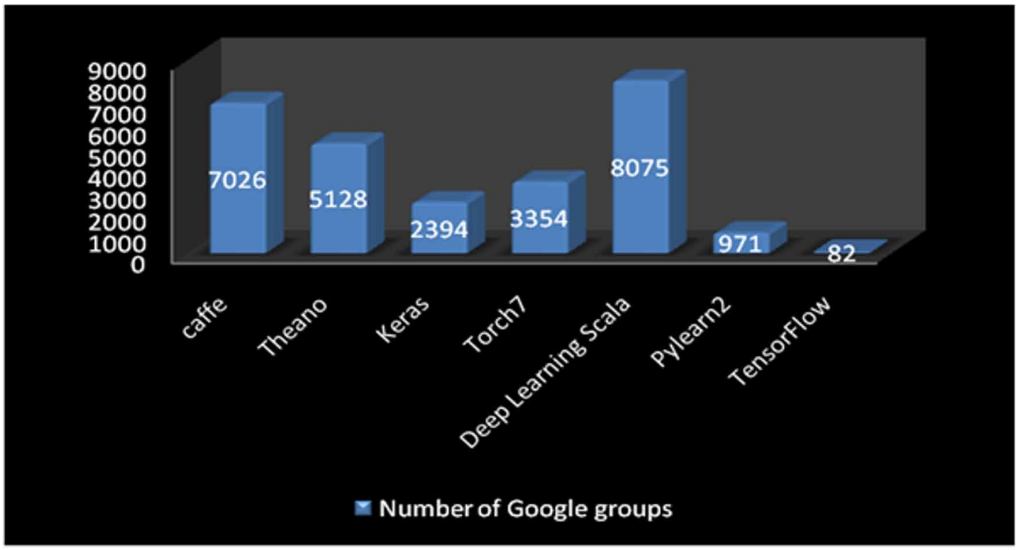
The present work focuses on analysis of the deep learning tools being used and can be applied in the field of health care system. The parameters like their make, platform, execution environment, interface support, application domain, implementation details, distributiveness, parallel environment support are the main points which are investigated in this paper. The limitations of these tools are studied and depicted. The results are taken from studied literatures from reputed article, industry white papers and product documentations.

Some of widely accepted tools found in literature survey are depicted below. The statistics of some of these tools' popularity is quantized by number of Google groups using these tools are shown in Figure 2.

Caffe

This is a deep learning framework which is developed by Berkly AI Research which is meant to facilitate a complete package for training, testing, adjusting the deep learning model parameters (CenterBerkeley, 2016). It supports modularity, so extension over new version would be easy. It has a clear isolation between representation and execution layer. So, switching between CPU and GPU is very easy and it just needs to call a function. Python and Matlab languages can be employed to create networks and for data classification, thereby supporting interface to bind these. It provides pre-trained reference models which help new researchers to quick start with it. In caffe through configuration file, network architectural parameters are set, and the network can be trained and tested through command line. This helps users not to write detail coding to configure and deploy the model. This tool is widely used for image recognition and computer vision task. It is applicable in medical image analysis. Some limitations of caffe include, it is not well designed for recurrent network; customization can be made with C++ only (Jia et al., 2014).

Figure 2. The number of google groups working with DL software (as on 14-05-2017)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Theano

Theano is built on a set of python library, is a declarative programming model aiming to provide research support in deep learning. Its native code is C++ and Python and innovated by University of Montreal. The core part of machine learning application's execution is doing complex matrix operations. It provides a rich library to solve this mathematical expression with the help an intelligent compiler which uses heuristics to optimize the expressions and swiftly handle multidimensional arrays. It also has the support of GPU devices which run the expressions faster and with a higher degree of accuracy. It can be customized according to user application need. One drawback of Thiano is that, the compilation time is more while dealing with larger datasets. Because the network model is produced as a computational graph and reconverted to native code through the optimized compiler (Universite de Montreal, 2016).

Pylearn2

It is a library constituting of machine learning libraries built up in LISA at University de Montreal. Since this is created for researchers, it is having its own target users. The users must have expertise on machine learning algorithms to understand the code walk through. It can execute symbolic expressions directly. It is built on top of Theano. This library was aiming to be utilized for academic and scientific use. But it is a customizable module thus can be applied for any real data mining task like classification, prediction etc. The only limitation is that customization modules must be written in C++ (Goodfellow et al., 2013).

CaffeOn Spark

It integrates the features of DL framework Caffe and big data framework apache spark and apache hadoop. It is an open source framework that can create a distributed DL network with a cluster of CPU and GPU servers [Andy Feng, Jun Shi and Mridul Jain]. Unlike some other DL framework need an isolated cluster for deep learning, which requires large datasets to be migrated among cluster nodes which is leading to increase system latency and latency, here the cluster is built not separately and is embedded in Spark application program, by which unwanted data migration among cluster nodes can be prevented (Kim et al., 2016).

NVIDIA cuDNN[]

cuDNN a collection of primitives to implement standard routines of deep neural network to create, train and evaluate the network. It is a GPU accelerated framework which provides support to create software applications build on created neural network models. It contains number of tensor transformation functions which are helpful for repetitive computation done in ML algorithms. It can be integrated with caffe and Baidu (Chetlur, 2014).

keras

It is a Python library to implement deep learning which makes use of either Thiano or TensorFlow as backend. It runs in python 2.7 or 3.5 versions. This can be used to design deep learning models both for research and development. It is an open source tool. The main guiding principle on which it is built

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

is modularity and extensibility. Its native is Python and no other language is supported. It is used as a binary and multiclass classifier. It can also be used for regression analysis (Franois Chollet, 2016).

Deep Learning 4j

Deep learning 4j java based open source library for creating and deploying deep neural network. It works in the company of Spark and Hadoop. Its native is Java having Apache 2.0 license, so all JVM languages such as Scala or Closurie are compatible with it. This is written in C++. It can be integrated with Haddop and Spark and can execute on various other backends. It gives a plug-and-play solution instead of building configuration. A part of Deep learning 4j, ND4j is a vectorization tool containing a rich matrix library to do core machine learning tasks. This tool can be used to create recurrent network and supports reinforcement learning. Unlike other tools it is solely built for commercial use in business house. This framework is distributed and supports multi-threaded programming model, thus is capable to run in parallel environment. It is a complete package to provide all sorts of application to model a deep neural network possessing smart n-dimensional array class (Skymind, 2016).

Mocha.jil

It is a DL library developed at MIT for a new programming language Julia, especially designed to do scientific and numerical computation. Its native code is Julia and can interface with Julia only. It can work with Julia backend, but it supports GPU backend and can be integrated with Nvidia libraries like cuDNN. It is highly modular and can be easily extended. It does not require configuration file for describing network architecture. Network architecture can be directly written by Julia code. It contains some pre-trained models to do a quick start. The only difficulty with this is it is compatible with Julia only (Ravi et al., 2017).

Torch7

Torch7 (MIT, 2015) was first built up in the University of New York. Its foundation is on a special scripting language called LuaJIT. Lua is chosen because it can easily be integrated with C language. By placing appropriately, the existing modules the deep Networks could be formulated. As based on a scripting language the model is not required to be compiled. This makes it suitable for quick prototyping if compared to Theano (Collobert, 2011). This one is used in facebook AI lab and Google deepmind. A possible downside of this tool is that the user has to be familiar with the LuaJIT scripting language. Also, LuaJIT is not good at creating custom recurrent networks.

TensorFlow

Like Theano, TensorFlow is also an open source library. It is designed to do numerical computation by using data flow graphs as in case of neural network. It was innovated by the researchers of the Google Brain Team at Google's Machine Intelligence laboratory. Unlike Thiano, TensorFlow is based on distributed computing, so well fit to work with many GPUs and CPUs in clusters. It has an inherent support for heterogeneous and parallel computation (Google, 2016). This tool is developed in C++ and has

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

python compatibility. One demerit of TensorFlow is that, pre-trained model is not available in a large proportion. It is used in handling biological data in bioinformatics to solve different problems like gene selection, prediction etc. (Rampasek, 2016).

TensorGraph

It is an easier and simpler framework for creating any graphical model based on TensorFlow. It contains three types of nodes: StartNode which takes input for the graph, HiddenNode for creating the hidden layers and EndNode used for generating the outputs of the model (Xu, 2013).

Tinny-dnn

It is a header file written in C++ containing some deep learning library. It can be easily integrated with any compatible application to build network. The network can be trained and tested by using suitable methods. It contains several activation functions such as tanh, sigmoid, softmax, leaky relu etc. (Angelova, 2015).

MXNET

MXNET is rapid, and compact distributed deep learning framework basing on MShadow. MShadow is a lightweight CPU/GPU Matrix Template Library in C++/CUDA. The goal of mshadow is to provide device invariant and simple matrix library for ML work. It Supports CPU/GPU/Multi-GPU and distributed system. It is a lightweight and highly modular C++/CUDA neural network toolkit, which can interface with Python and Matlab for training and prediction (Chen et al., 2015).

Neon

This is an open source python based framework developed at Intel, used to create DL models. It is used to develop convolution network with multi-GPU support. It does optimization at assembler level and data loading level. It has rich visualizations library to well understand DL process. It involves object oriented approach for implementing DL constructs such as layers, learning rules, activation functions etc. It can be used multi-layer perceptrons, recurrent neural networks and auto encoders. It is included with pre-trained examples for image captioning and sentiment analysis work (Nervana Systems, 2016).

RESULT AND DISCUSSION

The analysis and investigations done throughout the above studies are presented in Table 1, Table 2 and Table 3. Table 1 gives a comparative analysis of DL software and their characteristics details. Table 2 gives the common areas in health care system which uses DL software. It also focuses some specific application areas for which solution domain uses machine learning and deep learning algorithms along with the input data used for the problem. The prime areas are health informatics (Simonyan et al., 2014) Bioinformatics (Ravi et al., 2017; Chrimes, et al., 2017), public healthcare and Medical imaging. Table 3 gives brief comparison about the tools along with some inferred observations regarding their pros and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

cons and the areas of application. It can be observed from the literature that, the use of DL in health care domain and other is increased exponentially in recent past. Most of the popular tools use Python as the interfacing language. The commercial available tools are less. One of the examples is Deep learning 4j. Most of the tools are open source and can be customizable for research and scientific applications. With the increase of structure and volume of data, the tools are also evolving. There are certain limitations existing for using DL in health care can be noted here (Chen et al., 2014):

- The field of DL is new to researchers and scientist. There are many questions still lying with DL to be answered.
- For training deep, neural network a large amount of training data is required. This is causing a major problem to use DL with the present health care system. Because the electronic data keeping system is yet to be achieved in this sector.
- The visualization of DL technique is still remains a black box for many researchers.

Table 1. Comparison of DL software

Software	Developed & Maintained By	Open source	Native Code	Support Interface	Nvidia cuDNN Support	Presence of preexisting training model
Caffe	Berkley AI Research Lab	Yes	C++	MATLAB, Python	Yes	Yes
Theano	University of Montreal	Yes	Python	Python	Yes	Yes
Pylearn2	LISA at University de Montreal	Yes	Python	Python	Yes	Yes
CaffeOn Spark	Yahoo Research Lab	No	Not available (NA)	Apache Hadoop, Spark, Scala	Yes	NA
cuDNN	Nvidia	Yes	C	Can be integrated with other existing DL models	Yes	NA
MXNet	DMLC Group	Yes	C++	R, Python, Julia, and C++	Yes	Yes
Keras	François Chollet	Yes	Python	Python	Yes	Yes
Mocha-jil	MIT	Yes	Julia	Julia	Yes	Yes, but very few
Deep learning 4j	SkyMind	Yes	Java	Java	Yes	Yes
Torch7	Ronan Collobert et al.	Yes	Lua	Lua, LuaJIT, C	Yes	
TensorFlow	Google	Yes	C++	Python	Yes	No
TensorGraph	Google	Yes	NA	Python	Yes	No
TinnyDNN	Tiaga Nomi	Yes	C++	C++ supporting languages	NA	No
Neon	Intel Nervana	Yes	Python	Python	Yes	Yes

Table 2. Summary of areas and application in health care with input

Area	Input Data	Applications
Clinical Informatics	Digital clinical data, Medical records	Disease prediction Human health monitoring Early Notification on abnormality
Public Healthcare	Geospatial images Social media personal data captured from smart phone Text data	Air Pollution detection Lifestyle disease controller Demographic information prediction Detection of Infectious diseases epidemics
Medical Imaging	MRI/CITI Scan reports X-Ray images Endoscopy pictures	Neural cells classification Healthy/unhealthy tissue classification Tumor detection Blood hemorrhage detection Cell clustering
Bioinformatics	DNA Samples Gene sequence Microarray Data	Drug designing Cancer diagnosis Gene classification Gene selection

Table 3. DL software with their pros and cons

Software	Programming Model	Suitable for	Pros & Cons
Caffe	Declarative	Image recognition Computer vision Speech recognition	**Pros** User does not have to write detail code. Pre-trained models are present to do a quick start **Cons** Cannot be used to create recurrent network Customization can be made only through C++.
Theano	Declarative	Numerical computation	**Pros** Good for tensor based mathematical expressions Compiler can optimize expressions **Cons** Compilation time is more for larger datasets
Pylearn2	Declarative	Classification Prediction	**Pros** Quicker computation **Cons** Customization can be made only through C++. User should have good knowledge on DL to understand the code execution.
Keras	Emparative	Prediction Image classification Large scale image recognition Feature extraction	**Pros** Easily extendible **Cons** Only interface is Python
Deep learning 4j	Object oriented programming	Object recognition in Social networks for Photo tagging	**Pros** Can import neural net models from Tensorflow, caffe, Torch and Theano. It is distributed Complete package suitable for commercial use
Torch7	Emparative	Used in Facebook AI research IBM Research lab	**Pros** Easily integrated with C No Compilation is needed **Cons** User has to be familiar with LuaJIT
TensorFlow	Emparative	Image classification Drug Designing Information Retrieval	**Pros** Distributed and inherently paralle **Cons** No pre-trained libraries
Neon	Object oriented	Image captioning Sentiment analysis	**Pros** Optimization at assembler and data loading level Rich graphical & visualization properties

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

Nvidia cited that use of ML algorithm in health will change the dimension of current health care system. Earlier data were limited in size. So, for mining information from data and using the same results to let a machine to estimate and predict something can be established by using simple neural networks having different learning rules. With the explosive increase of data, its dimension and structural composition are changing. The complexity and nonlinearity has been changed.

So, present models are not able to compute these data. DL came into picture few years ago. Their architecture of having more intermediate computing layers is designed to handle the complexities and nonlinearity of big data. Some widely used tools like Caffe, Thiano, Deep learning 4j, Tensor Flow are discussed in the study by taking into consideration, some of their technical specifications, their strength and weakness (Min et al., 2016; Deng & Yu, 2014; Poonia et al., 2016; Schmidhuber et al., 2015). The health-related application areas are discussed along with the specific problem, which are using DL tools and techniques. Most of the tools are designed in the view of scientific and academic use. Full-fledged commercial tools are yet to come. Maximum of the available tools are open source and can be customizable according to requirement. As the technique is its early stage, some concrete hypothetical theories are yet to be evolved.

Chapter 92
Real Time Analysis Based on Intelligent Applications of Big Data and IoT in Smart Health Care Systems

Mamata Rath
C.V. Raman College of Engineering, India

ABSTRACT

Currently, there is an expanding interest for additional medical data from patients about their healthcare choices and related decisions, and they further need investment in their basic health issues. Big data provides patients presumptuous data to help them settle on the best choice and align with their medicinal treatment plan. One of the very advanced concepts related to the synthesis of big data sets to reveal the hidden pattern in them is big data analytics. It involves demanding techniques to mine and extract relevant data that includes the actions of piercing a database, effectively mine the data, query and inspect the data and is committed to enhance the technical execution of various task segments. The capacity to synthesize a lot of data can enable an association to manage data that can influence the business. In this way, the primary goal of big data analytics is to help business relationships to have enhanced comprehension of data, and subsequently, settle on proficient and very much educated decisions. Big data analytics empowers data diggers and researchers to examine an extensive volume of data that may not be outfit utilizing customary apparatuses. Big data analytics require advances and statistical instruments that can change a lot of organized, unstructured, and semi-organized data into more reasonable data and metadata designed for explanatory procedures. There is tremendous positive potential concerning the application of big data in human health care services and many related major applications are still in their developmental stages. The deployment of big data in health service demonstrates enhancing health care results and controlling the expenses of common people due to treatment, as proven by some developing use cases. Keeping in view such powerful processing capacity of big data analytics in various technical fields of modern civilization related to health care, the current research article presents a comprehensive study and investigation on big data analytics and its application in multiple sectors of society with significance in health care applications.

1. INTRODUCTION

The use of big data in data analysis and synthesis have been utilized as a part of explanatory instruments must find examples, patterns, and relationships over an assortment of time skylines. In the wake of breaking down the data, these instruments envision the discoveries in tables, diagrams, and spatial outlines for proficient decision making. Along these lines, big data investigation is a genuine test for some applications due to data unpredictability and the adaptability of basic calculations that help such procedures acquiring supportive data from big data investigation is a basic issue that requires adaptable logical calculations and strategies to return all around planned outcomes, though current methods and calculations are wasteful to deal with big data analytics (Rath et al., 2019). In this manner, huge framework and extra applications are important to help data parallelism. In addition, data sources, for example, rapid data stream got from various data sources, have diverse configurations, which makes coordinating different hotspots for analytics arrangements basic. Subsequently, the test is centered around the execution of current calculations utilized as a part of big data investigation, which isn't rising directly with the fast increment in computational assets.

In general, when the term "big data," is coined people instantly consider large data volumes. On the off chance that these were the main purpose behind health care services to receive the better approach for putting away data, they could oversee without, in light of the fact that the majority of them could contain what they have in a strong social database (Sun et al., 2012). In 2001, Doug Laney portrayed the "3 Vs" of large and complex data as "Volume, Velocity and Variety." While medicinal services could profit by every one of the three, the accentuation ought to be on assortment. This is a pattern experienced by human services, as well as by all enterprises. Figure 1 shows Big data applications in various fields.

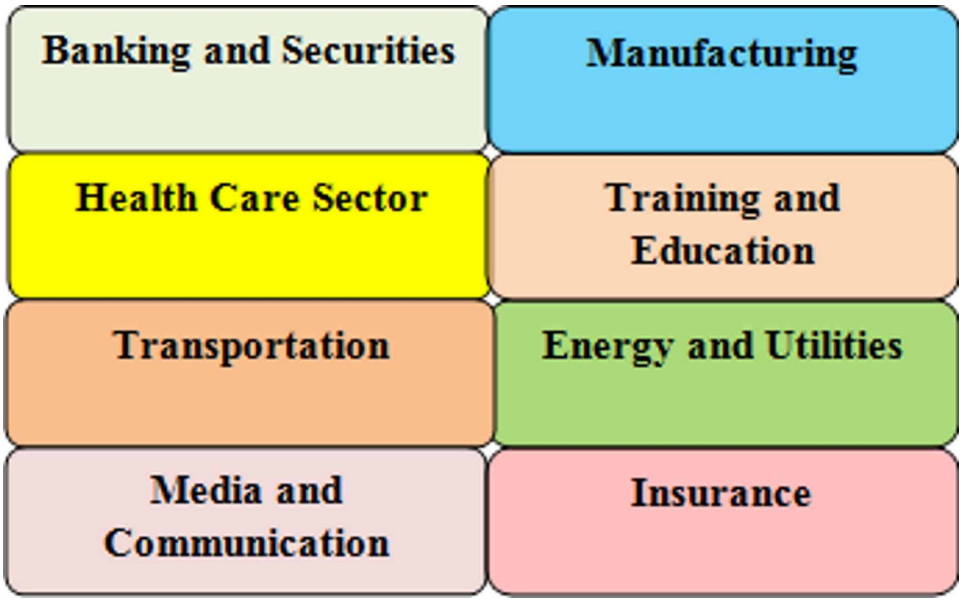
Aside from traditional patient data contained in content, there are different pictures and sounds recorded, from x-beams and ultrasounds, to Doppler and MRI imaging. A few specialists very much want that their discussions with patients be recorded for the patient's advantage (Qiu et al., 2015). This gathering of conflicting information is for the most part unstructured and can't be requested in the flawless tables and segments of a social database. This is the place big databases, as Hadoop, score. Be that as it may, it is one thing to store big data and very another to recover it seriously. Data researchers who can plan techniques to extricate important information from the non-consecutive and apparently irregular big databases are currently popular (Rath et al., 2018).

These techniques are challenging and hard to solve, however the IT business is beginning to convey activities that make significant data extraction less demanding. There is additionally a move to a half breed database structure, where data is put away in both a social and a "No SQL" database. Where social insurance elements have handled this obstacle, the outcome is an all-encompassing perspective of the patient, which expels a portion of the unpredictability of finding for the medicinal professional and makes life less difficult for the patient (Archenna et al., 2015). It likewise opens the path for the move to machine-to-machine (M2M) correspondence and the utilization of computerized reasoning to filter through and investigate data transmitted from the sensors gathering it (Rath et al., 2017). The future guarantee is examination that will screen health more than ever however there are likewise further issues that should be tended to, for example, data protection and security. Figure.1. Big data applications in various fields.

For analysis of major type of business process, Big Data helps in transforming major selling practice by improved techniques and accurate analysis of presented data. As shown in Figure 1 some of such process are Banking and Security, (Khan et al., 2014) Media and communication, Health Care Sector,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Big data applications in various fields



Manufacturing, Training and Education, Insurance, Transportation, Energy and utilities. Using big data analytics in all these fields improves the quality of the process and results improved output. The organisation of the paper has been done as follows. The Second section describes the Literature Review. Section 3 presents Big Data Applications in Modern Technology, Section 4 presents Monitoring and Controlling Health Care using Big Data Analytics and at last Section 5 concludes the paper.

2. LITERATURE REVIEW

Though there are many dangerous impacts of high radiations on health, radio signals on vision and many other such impact on health system, still the speed of progress in technology in social systems is impossibly fast. IBM Watson's electronic concept (Lomotey et al., 2017) accumulates atrocious measures of information, its impact and plans the best treatment elective for patients by checking terrifically vital medicinal examinations, and significant learning computations will do substantially more. Propelled tattoos can check the critical prosperity parameters and basic signs to disclose to us when there's short remark care of through our mobile phones (Vippalapalli et al., 2016). Expanded reality devices, for instance, Holocene from Microsoft can broaden propelled scenes on what we see and prepare masters for troublesome methodologies. Medicinal administrations advancement just doesn't stop stunning (Finlay et al., 2016). In 2013, there were bits of prattle about new organizations transforming adherence control by inserting microchips into calm compartments to allow specialists to check whether and when patients take them. Devices that allow holographic data input yet just misrepresented, toy-like contraptions have ended up being open. Without broad associations placing assets into them, they will have far to go before standard choice. A phenomenal case is L'Oréal, the excellence mind items association putting into a wearable sensor that fills the wearer in with respect to whether first experience with the Sun accomplishes dangerous levels (Pusala et al., 2016).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The present expansion and development in the field of Internet of Things (IoT) are giving surprising potential (Farahani et al., 2018) in the course of the novel era of healthcare. The visualization of the healthcare is expansively supported, as it progresses the perfection of life and health of people, including a few health controls. The perpetual increment of the multifaceted IoT devices in health is comprehensively tried by difficulties, for example, controlling the IoT terminal hubs utilized for health observing, continuous information handling and shrewd choice and occasion administration. In the choice of the most modern decade, there has been an expanding passion for huge information look into, particularly for health administrations applications (Rath et al., 2016). The requisition of the distributed computing and the Internet of Things (IoT) worldview in the healthcare field can convey a few chances to therapeutic IT, and specialists trust that it can essentially enhance healthcare administrations and add to its ceaseless and orderly advancement in a major information condition, for example, Industry 4.0 applications. In any case, the expected assets to oversee such information in a cloud-IoT condition are as yet a major test. In like manner, (Elhoseny et al., 2018) proposes another model to streamline virtual machines choice (VMs) in cloud-IoT health administrations applications to productively deal with a major measure of information in incorporated industry 4.0. Industry 4.0 applications require to process and examine huge information, which originate from various sources, for example, sensor information, without human mediation. The proposed demonstrate plans to improve the execution of the healthcare frameworks by lessening the partners' demand execution time, streamlining the required stockpiling of patients' huge information and giving an ongoing information recovery component for those applications.

Real time information can likewise be fused into big data. Ongoing big data has numerous preferences. For instance, any mistakes or investigate in an association can be recognized quickly and the operational issue can be survived. This will spare time, cost and increment the efficiency. The administrations additionally can be additionally enhanced as the continuous gives the most recent data on the topic. For example, it will give the total data on the patients and in the meantime ready to oversee therapeutic intercession immediately. In healthcare, big data is likewise utilized in prescient examination which is to distinguish and address the restorative issues previously it is turning into an unmanageable issue (Rath et al., 2014). Healthcare experts can lessen the hazard and beat the issue with the data got from the big data. Aside from that, big data is additionally ready to help recognize fakes in healthcare particularly on protection claims. Fake, irregularity and false claims can be hailed. This will encourage insurance agencies to avert misfortunes.

Big data can likewise profit healthcare through data administration, electronic therapeutic records and data examination. The big data will discover and distinguish the correct populace or target gathering. Big data comprises of assorted gathering of populace and certain gathering can be recognized for chance appraisal and screenings. The presence of big data will likewise permit advancement or change of a program or intercession to focus on the health issue (Khalifa et al., 2016). It will empower clinical preliminaries to be started instantly. Big data will give a clearer picture on the sort of populace and in addition their restorative issue. The example of the dispersion or malady data will permit fast advancement of mediation program and additionally focusing on the influenced bunch as ahead of schedule as conceivable Data development of pharmaceutical businesses were gotten from patients, caregivers, retailers and Research and Development.

The inclination of universal frameworks is supported by the improvement and dynamic selection of the Internet of Things (IoT) devices and their empowering advancements. IoT has been appeared to have critical potential in high-chance Environment, Health, and Safety (EHS) enterprises. In these businesses, human lives are in question and IoT-based applications are prepared to offer protected, dependable, and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

effective arrangements because of their capacity to work at a fine granular level and give rich low-level data. (Thibaud et al., 2018) audits existing distributed research on IoT-based applications in high-hazard EHS businesses with particular prominence on healthcare industry, nourishment inventory network (FSC), mining and vitality enterprises (oil and gas and atomic), insightful transportation (e.g., associated vehicles), and building and foundation administration for crisis reaction tasks until 2016.Web of Things (WoT) offers a consistent stage to interface individuals and items to each other for improving and making our lives simpler. This vision conveys us from form based unified plans to a more circulated condition offering a tremendous measure of utilizations, for example, intelligent wearable devices, smart home, perceptive versatility, and savvy urban areas. Farahani et al. (2018) talks about material ness of IoT in healthcare and prescription by displaying an all-encompassing design of IoT eHealth biological community. Healthcare is ending up progressively hard to oversee because of inadequate and less compelling healthcare administrations to meet the expanding requests of rising maturing populace with constant ailments. This requires a progress from the center driven treatment to understanding driven healthcare where every operator, for example, clinic, patient, and administrations are flawlessly associated with each other. This patient-driven IoT eHealth biological community needs a multi-layer design: (1) device, (2) mist figuring and (3) cloud to engage treatment of complex information regarding its assortment, speed, and inertness. This mist driven IoT design is trailed by different case cases of administrations and applications that are actualized on those layers. Those illustrations run from versatile health, helped living, e-drug, inserts, early cautioning frameworks, to populace checking in keen urban communities.

Over the most recent couple of years, the m-health care (mobile health care) applications in context of Internet of Things (IoT) have given multi-dimensional highlights and ongoing administrations. These applications give a stage to a huge number of individuals to get health refreshes routinely for a healthier way of life. Enlistment of IoT devices in the healthcare condition have renewed numerous highlights of these applications. The huge information created by IoT devices (Rath et al., 2015) in healthcare space is broke down on the cloud rather than exclusively depending on restricted capacity and calculation assets of handheld devices. In respect to this unique situation, a cloud-driven IoT based M-healthcare checking illness diagnosing system is proposed which predicts the potential ailment with its level of seriousness. Key wordings are characterized to produce client situated health estimations by investigating the idea of computational sciences. The structural model for brilliant understudy healthcare is intended for application situation. The outcomes are registered subsequent to preparing the health estimations in a particular setting. (Verma et al., 2018) deliberate understudy point of view health information is created utilizing UCI dataset and medicinal sensors to anticipate the understudy with various illness seriousness. Finding plans are connected utilizing different best in class order calculations and the outcomes are registered in light of precision, affectability, specificity, and F-measure. Exploratory outcomes demonstrate that the proposed technique beats the benchmark strategies for illness forecast.

3. BIG DATA ANALYTICS IN HEALTH CARE USING MODERN TECHNOLOGY

With the assistance of big data, the immense measure of data can be put away deliberately. Presently specialists and other human services professionals can settle on educated choices as they approach an extensive variety of data. Obviously, the data produced will develop significantly, and more up to date frameworks will have the capacity to process it rapidly and cost adequately. Tumor is quickly devastating people over the world. Big data can battle disease all the more successfully. Social insurance suppliers

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

will have upgraded capacity to recognize and analyze illnesses in their beginning periods, doling out more efficacious treatments in view of a patient's hereditary cosmetics, and manage sedate measurements to limit symptoms and enhance adequacy. It will likewise give awesome help to parallelization and help in mapping the 3 billion DNA base sets. The utilization of big data makes it less demanding for healing facility staff to work all the more effectively. Sensors are utilized other than understanding beds to ceaselessly screen pulse, pulse and respiratory rate. Any adjustment in design is immediately alarmed to specialists and social insurance chairmen.

New prospects for health care checking is induced by the expansion of Internet of Things (IoT) and Big data, and in addition the universal idea of little wearable bio sensors (Jeste et al., 2016) Numerous defy presently can't seem to be routed to make a tried and true and adaptable framework for health care checking Big data investigation on IoT based Health care framework is proposed and it utilizes IoT based health care observing framework that contains "Web of health sensor things". These things create gigantic volumes of data that couldn't be dealt with by the doctor. The Physicians imperative concern is that they have to settle on basic choices about their patient's health from these gigantic volumes of health data. He/she needs to isolate the data around one specific patient from the surge of health care data landing from the monstrous number of patients. Intel Galileo Gen 2 is going about as IoT operator and is utilized to convey the health data of patients into the Cloud. The could deal with the expanding volume of health data, ingeniously share the data crosswise over healthcare frameworks and give feasibility to Big data examination. Ongoing alarming of patient health data is a critical exercise in Big data which is essential in the proposed work. The Big health sensor data are investigated utilizing the Hadoop system.

Big data could encourage the pharmaceutical organizations to recognize new potential and viable medications and convey it to the clients all the more rapidly. Issues with Big Data, there is an enormous test in big data as far as data assurance, gathering and sharing of health data and data utilization. Big data examination with the utilization of refined innovations can possibly change the data storehouses and settle on educated choices. Issues, for example, protection, security, gauges and administration to be tended to. Data, for example, nano particulate treatment on growth treatment could be likewise be fused in big data to give a diagram and best treatment for disease particularly when nanotechnology is imperative in tranquilize conveyance in tumour treatment. Security Since the big data contained subject's close to home data and their health history, it is critical for the database to be shielded from hacking, digital burglary and phishing, where the stolen data can be sold for a colossal aggregate. Aside from the health data and individual data from the health framework which can be hacked or stolen, other big data in other business associations, for example, broadcast communications companies, banks or monetary organization are additionally powerless without the information of the customers. Before big data can be executed, it is important to guarantee that the organization, security, security of the big data (Rath et al., 2018) is all around ensured. Insurance health data by means of transmission security, multilayer confirmation, utilizing against infection programming, firewalls, data encryption are without a doubt fundamental. As the data turns out to be more local and worldwide, it turns out to be more convoluted and have more genuine effect on security, guidelines, dialect and phrasing (Rath et al., 2018). The availability of the healthcare data should be reliably inspected and observed. Data Classification Big data is a monstrous, less organized and heterogeneous. In that capacity there is a need to distinguish and order the data with the goal that it very well may be utilized successfully. Nonetheless, it is relentless to look for a particular data in the big data. The big data additionally required to be contextualized or pooled together with the goal that it will turn out to be more important to particular people or gatherings. Data Modelling Although big data is astounding for demonstrating and simulation, there is a need to recognize,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

structure and pool the correct important data with the goal that it very well may be utilized to display the issues, which later can be utilized for intercession. Without the correct organized data, it is trying to break down and envision the yield and to extricate particular data or data.

The intensity of machine learning has been enormously perceived in changing different ventures and health care applications (Mertz et al., 2018). The reason that Amazon, Netflix, and Google have changed their enterprises and have inserted learning all through each part of what they do. AEGLE enterprise (Wang et al., 2017) focuses to construct an imaginative ICT arrangement tending to the entire data esteem chain for health in view of: distributed computing empowering dynamic asset portion, HPC frameworks for computational speeding up and propelled perception techniques. analysis of the tended to Big Data health situations and the key empowering advances, and data security and administrative issues has been completed which are to be incorporated into AEGLE's bio analytical community, empowering propelled health-care expository administrations, while additionally advancing related research exercises.

Basic Health Care IT Computing Systems such as life sustained devices, Health checking systems, data processing systems that give purpose of caring solution and direction to care groups are a key segment of a lifesaving exertion in Healthcare. The high trends of mobility, social, cloud joined with far reaching increment and modernity of malware, has made new difficulties and the point in time location strategies at the clinics are never again compelling and represent a major danger to the basic care systems. To keep up the accessibility and honesty of these basic care systems, new versatile, learning security safeguard systems are required that not just gains from the activity entering the healing facility, yet in addition proactively gains from the movement around the world. Cisco's Cloud web security (CWS) (Rogers et al., 2017) gives industry-driving security and control for the dispersed attempt by ensuring clients all over, whenever through Cisco overall danger knowledge, propelled risk barrier abilities, and wandering client assurance. It uses the huge information to perform conduct investigation, irregularity location, avoidance obstruction, quick Detection administrations utilizing stream based, signature based, conduct based, and full bundle catch models to distinguish dangers. A specialized audit takes a gander at how huge Data Analytics is utilized as a part of blend with other security capacities to proactively distinguish dangers and anticipate far reaching harm to social insurance basic resources.

3.1. Interfacing the Physical World to the Internet of Things (IoT)

It takes into account the advancement of a wide assortment of utilizations. Things can be sought, overseen, examined, and even incorporated into collective amusements. Enterprises, health care, and urban areas are misusing IoT information driven systems to make these associations more productive, in this way, enhancing the lives of residents. For making IoT a reality, information created by sensors, advanced mobile phones, watches, and different wearable should be coordinated; additionally, the importance of IoT information ought to be expressly spoken to. Nonetheless, the Big Data nature of IoT information forces challenges that should be tended to keep in care the end goal to give versatile and productive IoT information driven foundations. These issues have been taken care of and focussed on the problems of portraying the significance of IoT spilling information utilizing philosophy and incorporating this information in a learning chart (Hossain et al., 2017). DESERT, a SPARQL inquiry motor has been planned to influence ready to on-Demand factoriz and Semantically To advance stReam information (DESERT) in a learning diagram. Coming about learning charts show the semantics or significance of combined information as far as elements that fulfill the SPARQL inquiries and connections among those substances; in this manner, just information required for question noting is incorporated into the learning diagram. It

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

assesses the consequences of DESERT on SRBench a benchmark of Streaming RDF information. The trial comes about recommend that DESERT takes into consideration accelerating question execution while the extent of the learning charts remains generally low.

One of the biggest obstacles obstructing to utilize big data in social insurance is the manner by which restorative data is spread crosswise over numerous sources represented by various states, clinics, and authoritative offices. Combination of these data sources (Panda et al., 2017) would require building up another foundation where all data suppliers team up with each other. Similarly, critical is actualizing new data examination instruments and procedures. Social insurance needs to get up to speed with different ventures that have effectively moved from standard relapse-based techniques to more future-arranged like prescient investigation, machine learning, and chart examination.

3.2. System Used for Alert in Real Time Applications

Data security and patient secrecy is an additional hazard. One of the benefits of paper and siloed electronic records is that they are not hackable. At the point when human services associations consider versatile application advancement to help IoT equipment, they should likewise guarantee that weakness is held within proper limits. Regardless of these dangers, wearable, sensors and portable applications are propelling the wildernesses of medicinal learning at a consistently expanding rate – particularly in battling and anticipating perilous sicknesses and immune system diseases. The odds of creating tumor in one's lifetime are evaluated to be as high as one out of two (for US guys). In any case, the industry is making fast walks in battling and keeping these malignancies. Different cases of big data in human services share one pivotal usefulness – constant alarming. In doctor's facilities, Clinical Decision Support (CDS) programming breaks down restorative data on the spot, furnishing health experts with guidance as they settle on prescriptive choices. Be that as it may, specialists need patients to avoid healing centers to maintain a strategic distance from expensive in-house medicines. Individual examination equipment, as of now drifting as business intelligence popular expressions a year ago, can possibly turn out to be a piece of another medicinal services.

3.3. Electronic Health Records (EHRs)

It's the most across the board use of big data in human services. Each patient has his own advanced record which incorporates socioeconomics, restorative history, hyper sensitivities, research facility test comes about and so on. Records are shared by means of secure information frameworks and are accessible for social insurance suppliers from both open and private area. Each record is included one modifiable document, which implies that specialists can execute changes after some time with no printed material and no peril of data replication.

EHRs can likewise trigger admonitions and updates when a patient ought to get another lab test or track medicines to check whether a patient has been following specialists' requests. In spite of the fact that EHR are an awesome thought, numerous nations still battle to completely execute them. U.S. has made a noteworthy jump with 94% of healing centers receiving EHRs as indicated by this HITECH research, yet the EU still lingers behind. Notwithstanding, an aggressive mandate drafted by European Commission should transform it: by 2020 brought together European health record framework ought to end up a reality.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As a case study, Kaiser Permanente is driving the path in the U.S. and could give a model to the EU to take after. They've completely executed a framework called Health Connect that offers data over the majority of their offices and makes it less demanding to utilize EHRs. A McKinsey cover big data in human services expresses that "The incorporated framework has enhanced results in cardiovascular infection and accomplished an expected $1 billion in investment funds from lessened office visits and lab tests." In any case, there are some sublime occurrences where medicinal services doesn't fall behind, for example, EHRs (particularly in the US). So, regardless of whether these administrations are not some tea, you are a potential patient, thus you should think about new social insurance (Patel et al., 2017) investigation applications. In addition, it's great to investigate now and again and perceive how different ventures adapt to big data.

One of the key data sets is 10 years of clinic confirmation records, which data researchers crunched utilizing "time arrangement examination" systems. These examinations enabled the researchers to see significant examples in confirmation rates. At that point, they could utilize machine figuring out how to locate the most exact calculations that anticipated future affirmations patterns. Summing up the result of this work, Forbes states: "The outcome is an internet browser-based interface intended to be utilized by specialists, attendants and clinic organization staff – untrained in data science – to figure visit and confirmation rates for the following 15 days. Additional staff can be drafted in when high quantities of guests are normal, prompting decreased sitting tight circumstances for patients and better nature of care."

3.4. The Utilization of Sensors to Monitor Activities

One of the key components adding to this war on tumor is the capacity to accumulate large volumes of patient data amid clinical preliminaries, utilizing sensors as opposed to overviews and meetings. Patients with different myeloma, an exceptionally agonizing blood growth, are to be observed through a blend of wearable and cell phones, with data transferred to a cloud stage. These patients are not being observed for their reaction to drugs, but instead for their personal satisfaction. Their rest examples and general portability are estimated to show signs of improvement comprehension of how the illness and ensuing treatments affect their everyday lives. Such research can likewise be utilized to advise and help health experts. Specialists of today need to remain over improvements in the adequacy of medications. A stage that both orders oncology research and keeps specialists educated enhances malignancy treatment on two fronts. Medicinal services are a segment in which IoT and big data will assume an undeniably fundamental part. While big data isn't at present required from a volume or speed point of view, this will change when data from billions of sensors should be put away and investigated. Table 1. Shows the description of some important contribution of Big Data associated with other technology in smart applications of society that are studied and analysed in this research work.

3.5. Precision of Medication

The Precision Medicine Initiative calls for restorative specialists to apply research and brought together data to advance customized quiet care. President Obama has a dream to set up a national patient databank to encourage customized treatment and advance genome research. Indeed, even without a national databank, healing centers can apply similar standards to give customized mind utilizing big data investigation to associate patient data put away in EMRs to national patterns and other data sources. Prescient investigation, for instance, can advance precaution nurture coronary illness and heftiness.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Description of some important contribution of Big Data associated with other technology

Literature / Author	Year	Details of Related Application
F. Zuhra et al.	2017	Use of WBSN (Wireless Body sensor Network and Protocols in detection of body anomalies
B. Farahani et al.	2018	Fog Computing approach and IoT based e-Health care system
M. Hossain et al.	2017	Internet of Things (IoT) Based Health Prescription Assistance software for health diagnosis
A. Harbouche et al.	2017	Use of WBN (Wireless Body Sensor Network) for health care and correct monitoring system
T. Adame et al.	2018	A Hybrid monitoring system for smart health care using RFID and Wireless Sensor Network
J. Lloret et al.	2017	Improved Protocol for efficient and smart nonstop e-health controlling & monitoring
O. Olayinka et al.	2017	Big data knowledge Implementation in Global Health Education System
B. Knoppers et al.	2017	Rules related to Ethics and Systems in big data health care Analysis
M. Pramaink et al.	2017	Big data enabled health paradigm and issues in smart city Health Applications

3.6. Proof Based Prescription

Cookbook drug has been the standard, utilizing a similar battery of tests to analyze by decision out the reason for ailment. With confirm based prescription, specialists connect side effects to limit the determinations. Beth Israel Deaconess Medical Center in Boston, for instance, is utilizing persistent data from two million patients to give data focuses to diagnosing through a cell phone application. Keeping in mind the end goal to encourage investigation, doctor notes are being encoded to institutionalize references; for instance, "hypertension" and "raised circulatory strain" are coded similarly to make data accessible.

Perceptive investigation likewise advances quality care and patient wellbeing. In the emergency unit, illustration, patients are inclined to a sudden downturn because of sepsis or different diseases. Sepsis alone has a 40 percent death rate and is hard to distinguish for early treatment. The University of California, Davis, has utilized EMR data investigation to make a calculation to give an early cautioning of sepsis contamination. In another illustration, the University of Iowa Hospitals and Clinics has utilized prescient examination to diminish postoperative disease following colon medical procedure by 58 percent. Similarly, as examination can be utilized for prescient administer to singular patients, similar techniques can be utilized as a part of the study of disease transmission. Duke University, for instance, is mapping EMRs to geographic information framework data so as to distinguish human services slants in particular geographic territories. By mapping the correct data sets, it's conceivable to anticipate particular illnesses, for example, flu that will raise in particular regions, making it less demanding to strategize diagnostics and plan for stocking serums and antibodies. The National Institutes of Health has been taking a shot at comparable systems for quite a while to anticipate malady episodes.

3.7. Reduced Rate of Hospital Re-Admissions

Readmission rates are a ceaseless issue for doctor's facilities, particularly with patients who return inside 30 long periods of treatment. Big data investigation of EMRs uncovers slants that feature those patients prone to require extra treatment to forestall readmission. At a Texas healing center, for instance, EMR investigation prompted a drop in the readmission rate of cardiovascular patients from 26.2 percent to 21.2 percent by recognizing high-chance patients. Commentators stress that patient records are a practical objective for digital hoodlums, on the grounds that they yield individual information that is significantly

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

more important than charge card data, for example, Social Security numbers, Medicare information and solution information. Advocates call attention to that big data investigation can really be a significant resource in anchoring therapeutic records by distinguishing changes in arrange activity or conduct that demonstrates a digital assault. Restorative protection is mind boggling and tormented with questioned and fake cases. Big data examination streamlines the efficiency of medicinal protection guarantees by uncovering claim slants and streamlining claims preparing. Patients show signs of improvement returns on their protection cases, and parental figures get instalment speedier.

These are only a couple of the ways that big data investigation is having an effect in social insurance. Anyplace there is a data-driven process, big data investigation can be connected to enhance persistent care and health focus tasks. Furthermore, new innovation, for example, radio frequency recognizable proof (RFID) chips—is conveying more data for potential examination. New data sources give new chances to big data investigation, and it's up to arrangement suppliers to demonstrate to human services experts generally accepted methods to open the intensity of that data with new examination.

3.8. Customary Patient Checking Using IoT

The Internet-of-Things (IoT) has supposed control over the business range, and its applications fluctuate broadly from farming and social insurance to transportation. A hospital condition can be extremely upsetting, particularly for senior people and youngsters. With the consistently expanding total populace, the regular patient-physical checkup has lost its viability. Thus, keen medicinal services turn out to be critical. Savvy social insurance can be actualized at all levels, beginning from temperature checking for children to following essential signs in the elderly (Sunderavadivel et al., 2018). The intricacy and cost of execution shifts in light of the required exactness of the individual equipment, functionalities, and complexity of the application for which they are utilized. Savvy medicinal services likewise fall under vertical territories, for example, expansive scale combination, inserted framework, enormous information, machine learning, distributed computing, and computerized reasoning.

Data technology has progressed amid the most recent five decades to the phase where its effect is being felt by the general public in each administration that it gets from media, business, health care, shopper devices, vitality and power, and transportation domains. Amid this course of human-technology collaboration tremendous measure of data and learning exchange happens straightforwardly between specialist co-ops and their customers, and in addition by implication between customers. Since human propensity is to "investigate" its past with a specific end goal to foresee the "future", monitoring this powerfully gushing voluminous heterogeneous data, called Big Data (BD), and examining it for significant revelation of learning that prompts esteem included business turns into a critical research action. It is in this setting research in Big Data (BD) figuring has developed. Important choices can be construct just with respect to huge information disclosure, which thus requires a decent comprehension of the attributes of the aggregated data, a fitting grouping of this enormous gathering, and a proficient investigation of it. Health care part is a basic framework since its administrations influence the lives of humans and the absence of administration coherence might be unfortunate to the economy and human lives. The huge measure of data gathered by this part from its customers is organized into Electronic Health Records (EHR) which is BD and is utilized alongside pharmaceutical and administrative data in giving health administrations. More BD is produced while controlling administrations and estimating their effects on customers subsequent to regulating the administrations. Literature (Pusala et al., 2016) explores the sorts and features of Health Care BD (HBD), its attributes, and give a characterization of it.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. MONITORING AND CONTROLLING HEALTH CARE USING BIG DATA ANALYTICS

Indeed, in the past plan, medicinal services suppliers had no immediate motivating force to impart persistent information to each other, which had made it harder to use the intensity of big data. Since a greater amount of them are getting paid in light of patient results, they have a money related motivation to share data that can be utilized to enhance the lives of patients while cutting expenses for insurance agencies. At long last, doctor choices are ending up increasingly confirm based, implying that they depend on large swathes of research and clinical data instead of exclusively their tutoring and expert feeling. As in numerous different enterprises, data social occasion and administration is getting bigger, and experts require help in the issue. This new treatment state of mind implies there is a more noteworthy interest for big data investigation in human services offices than any time in recent memory, and the ascent of SaaS business intelligence apparatuses is additionally noting that need.

4.1. Electronic Health Records

Doctors sharing EHRs (Electronic Health Records) can total and break down data for patterns that can decrease human services costs. Sharing data amongst doctors and social insurance suppliers as they inspect patients can decrease copy tests and enhance understanding consideration. Most EHR data is siloed, to a great extent for security and administrative consistence reasons, however finding a protected path to mine patient data can enhance the nature of care while lessening costs.

Consider the intensity of examining patterns in doctor's facility mind. For instance, concentrating investigation of medicinal instruments in a pediatric ward can detach conceivable newborn child disease drifts prior. Or then again consider the instance of one doctor's facility that could diminish post-agent staph contamination: by utilizing big data, the organization could establish that one specialist was recommending post-agent anti-microbials that were less powerful against disease. Table 2 displays the descriptions of various research related to big data in health care.

4.2. Public Health Research With Controlled Information

The therapeutic calling is suffocating in data. Therapeutic workplaces and healing centers submit data about restorative conditions and inoculations, however without big data, those data are good for nothing. Utilizing investigation standardizes crude patient data to fill holes in general health records that can influence controls and in addition giving better care. Utilizing proof-based medication, the specialist can coordinate side effects to a bigger patient database so as to go to a precise finding quicker and all the more effectively. Where big data assumes a part is absorbing information from various sources and normalizing the data, so one record that portrays "hypertension" maps to another that depicts "elevated blood pressure."

4.3. Reducing Hospital Re-Admit With Better Medicinal Practice

Hospital costs are rising very high somewhat due to high readmission rates inside 30 long stretches of patient discharge. Utilizing big data examination so as to distinguish in danger patients in light of previous history, outline information, and patient patterns, healing centers can recognize in danger patients

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Descriptions of various research related to big data in health care and other related applications

Literature	Year	Research Related to Big Data
L. Cui et al.	2016	Big data use for SDN and SDN based Big data
Y. Demchenko et al.	2014	Online education instructional model using big data curriculum
M. Khan et al.	2014	Value extraction and understanding of big data

C. Lee et al.	2014	Handover optimization in using big data analytics

and give the essential care to lessen readmission rates. Insurers like UnitedHealthcare are utilizing big data examination keeping in mind the end goal to recognize therapeutic extortion and fraud. The organization utilizes investigation on discourse to-content records from calls to the call focus to recognize potential fraudsters. The insurance agency additionally utilizes big data keeping in mind the end goal to anticipate which kinds of treatment designs will probably succeed.

As medicinal practices develop, obliging more specialists and more patients turns out to be additionally testing. Consider Westmed Medical Group in Westchester County, New York. This training developed from 16 doctors in 1996 to 250 doctors today observing 250,000 patients, with yearly income of $285 million. As the training develops, it should be more effective keeping in mind the end goal to succeed. Utilizing big data, the training could break down in excess of 2,200 procedures and methodology. Accordingly, the training could streamline work process, move clinical undertakings from specialists to medical caretakers, lessen pointless testing, and enhance persistent fulfillment. Like any business, big data made it obvious where procedures could be progressed.

The above issues are not many that are drastically affecting medicinal services. The more data that are accessible to doctors and clinic overseers, the less demanding it is to distinguish patterns, standardize persistent data, and recognize bottlenecks in understanding consideration. Restorative experts can apply big data investigation similarly they are connected in some other business. The main distinction is that the stakes are higher and the bits of knowledge from big data may enable spare to people's lives. For those with unending medical problems or perilous ailments, the line of pros and methodology can appear to be perpetual. Besides, each time another specialist or facility is gone to, the patient is required

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to fill in long and convoluted structures – particularly if a medicinal protection is included. It's presently evident that the business needs to experience some significant changes, beginning with data administration. In the course of the most recent decade, clinics, medicinal practices, therapeutic plans and research offices have been digitizing their data with an end goal to distribution center it successfully. They are presently beginning to swing to counselling firms to embrace big data as an answer for data stockpiling.

As it were, medicinal services costs are considerably higher than they ought to be, and they have been ascending for as long as 20 years. Plainly, we need some brilliant, data-driven reasoning here. What's more, current motivating forces are changing too: numerous insurance agencies are changing from charge for-benefit designs (which compensate utilizing costly and, in some cases, superfluous medicines and treating large measures of patients rapidly) to plans that organize persistent results. As the writers of the famous Freakonomics books have contended, money related impetuses matter – and motivating forces that organize patient's health over treating large measures of patients are something to be thankful for.

5. CONCLUSION

The influence of health care administrations using big data has been developing significantly faster than many similar technologies. progressions in health care informatics, digitalizing health records, and telemedicine has brought about fast development of health care data science. These days, there is a consistently relocation of people to urban zones. Health care benefit is a standout amongst the most difficult perspectives that is incredibly influenced by the huge flood of individuals to downtown areas. Thus, urban areas around the globe are putting vigorously in advanced change with an end goal to give healthier bio analytical systems to individuals. A standout amongst the most encouraging regions where big data can be connected to roll out an improvement is medicinal services. Medicinal services investigation can possibly decrease expenses of treatment, foresee flare-ups of scourges, keep away from preventable ailments and enhance the personal satisfaction all in all. Normal human life expectancy is expanding along total populace, which postures new difficulties to the present treatment conveyance techniques. Medicinal services experts, much the same as business people, are now equipped with reservoir of data and they can search for best procedures to utilize these useful datasets. The above article addresses the applications of big data in human service sector significantly in health care with an analytical review that includes role of big data in human service and medicinal sector.

Chapter 93
The Impact of Healthcare Information Technology on Patient Outcomes

Edward T. Chen
University of Massachusetts Lowell, USA

ABSTRACT

The purpose of this article is to review the existing literature on health information technology (HIT), specifically electronic health records (EHR) and life-long patient records, in order to provide a broad assessment of the current state of this technology in the United States. Relevant literature was reviewed to determine whether key hypotheses were validated. Areas for additional research and development were identified, and a potential path forward was proposed. HIT adoption is a worthwhile effort in the United States, and it is possible for us to enact an interoperable central records system within our current fee-for-service healthcare system. Wide scale adoption will require subsidies and regulatory involvement at the state level, but professional networks may be exploited to speed the rate of adoption. A four-tier architecture with autonomic security systems, properly validated, can provide the infrastructure necessary.

INTRODUCTION

There can be no doubt that one's health is a major factor in quality of life. According to the World Health Organization (WHO), in their online World Bank Statistics, 9.7% of the world's total gross domestic (GDP) product was spent on healthcare in 2014. That equates to trillions of dollars spent annually on the direct delivery of healthcare from skilled health workers. This includes in-patient hospital care, out-patient preventative care, diagnosis and treatment, laboratory testing and imaging, emergency medical services and long-term care. The range of conditions is wide and disparate – everything from acute illness to chronic conditions, prenatal to end of life, physical and mental health. There is no facet of our life that does not, in some way, interact with the healthcare industry at one point or another.

Yet, this important industry does not always deliver the standard of care it ought to. In the United States, annual spending exceeds $2.7 Trillion. This is the highest percentage of GDP for any nation on Earth, and yet our quality of care is ranked 37th in the world by the WHO. Clearly, there is a disconnection between our spending and outcomes (The World Bank, 2017).

The advancement of information technology in health care is pivotal to the guidelines set in the Patient Protection and Affordable Care Act. As health care organizations have become clinically data driven, the need for information systems and IT is imperative (Vo & Bhaskar, 2012). Analysts in IT departments at hospitals play the role in maintaining and implementing systems. Clinical staff members, such as nurses and physicians, play the role of end users and require the skills needed to effectively operate these systems and forms of technology in order to carry out their clinical duties (Najaftorkaman, Ghapanchi, Talaei-Khoei, & Ray, 2015). Key developments in IT include the transformation of the medical record from paper to digital, the use of mobile devices, and the emergence of integrated health care systems that have the capacity for handling the many complexities that the industry has to offer.

Equally impacted are all U.S. employers who offer health insurance to their employees and the dependents of their employees. While employers attempt to contain the trend of health insurance expense, information systems are needed to pinpoint conditions that prove to be the most costly and implement benefit redesign plans to reduce costs and promote wellness. Employers also keep their staff productive by keeping them healthy. In the same light, information systems help employees examine disease management programs that are geared towards steering employees to engage in healthy behavior and seek preventive care regularly. If health care was once described as being technically challenged when compared with other industries, that notion is being put to rest by the progression of IT in the industry (Vo & Bhaskar, 2012).

A potential bridge to creating a level of care commensurate with our spending is the use of integrated health information technology (HIT). It is theorized that increased use of HIT will reduce medical errors, streamline operations, and reduce overall costs while improving healthcare outcomes. In 2009, the US committed to a set of policies called the Health Information Technology for Economics and Clinical Health (HITECH) Act, aimed at spurring widespread use of Electronic Health Records (HER) and a level of interoperability among individual facilities and care providers (Adler-Milstein & Jha, 2014). Related to this Act, President Barak Obama committed $20 billion to computerizing medical records. Yet, adoption of EMR in the United States remains slow, with only 30% of hospitals across the country participating in the Health Information Exchange as of 2012.

This paper will explore the literature documenting the benefits of HIT. Case studies from other countries provide useful insights into the actual validity of theorized and purported benefits. We will explore two such cases. The risks of implementing HIT will be discussed, along with some of the mitigating approaches that can be used to reduce the risk. Finally, we will look more closely at the implementation barriers that have kept this technology from having more impact on our healthcare system.

STUDIES ON PATIENT OUTCOMES

The Patient Protection and Affordable Care Act (PPACA) was signed by President Barack Obama on March 3, 2010 and upheld by Congress on June 28, 2012. The act mandates that all Americans are required to be insured with health coverage or pay a penalty to the government beginning in 2014. Another

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

provision includes the expansion of Medicaid to adults whose incomes are at a defined rate at or below the federal poverty limit. Furthermore, the act seeks to decrease the cost of health care (Nussbaum, Tirrell, Wechsler, & Randall, 2010; Rosenbaum, & Margulies, 2011).

Exchanges have been established in the majority of the states either on their own or with the assistance of the Federal Government. The exchanges represent online marketplaces where participants can shop for health insurance plans. The exchanges also provide online resources that allow users to determine their eligibility for a federal subsidy (Carey & Appleby, 2013; Najaftorkaman, et al., 2015).

There are two primary claims regarding the potential benefits of implementing HIT. The first is that implementing HIT will increase the quality of outcomes in healthcare delivery. A major potential benefit is the reduced likelihood of healthcare mistakes, which can have severe and far-reaching impacts. According to Fichman, Kohli and Krishnan (2011), medical errors are a leading cause of adverse events that are expensive, increase patient stays, decrease patient outcomes, cost human lives, and can even affect public health. Aron et al. (2011) explored the potential relationship between HIT and procedural and interpretive medical errors across three primary healthcare processes – sensing, controlling and monitoring. They found that HIT could overcome interpretive errors when complemented by professional training that enables users to exploit automation. The impact on procedural errors was less clear. Although it was found that in some cases technology might increase the likelihood of those types of errors, a record of behavior could reinforce positive behavioral and procedural actions. This study also found that HIT can have a positive impact on public health outcomes, such as outbreaks of severe acute respiratory syndrome (SARS), when the technology has the ability to adapt to connect and disconnect key players as needed by the developing situation.

STUDIES ON FINANCIAL BENEFITS

The second proposed benefit is reduced medical spending. Section 3022 of the PPACA introduces a Medicare Shared Savings Program for the Accountable Care Organization (ACO). An Accountable Care Organization is a health care provider that aims at delivering high service quality care and reducing the cost of care. In doing so, the ACO can expect to achieve an incentive in the form of shared Medicare savings (Berwick, 2011).

The ACO model depends greatly on Health Information Technology (HIT). HIT has evolved in the health care industry more and more as data becomes the centerpiece of delivering high service quality care, cost analysis and payment reform. The ACO concept links care and payment risk across multiple organizations and physicians. In order for the model to survive, data sharing will be crucial. The delivery and storage of this data is where technical resources come into play. The ACO portrays a team concept where multiple entities collaborate to achieve financial incentive while providing the best possible care. In order to do so, a patient's Electronic Health Record (EHR) must be electronically maintained and available across all clinical professionals involved. The EHR concept is at the early stages of development in health care and currently represents limited data sharing capabilities. It is evident that Accountable Care Organizations will be required to invest in IT interfaces that track the patients across the entire episode of care (Bitton & Filer, 2012). Clinical data is at the forefront of the ACO model. As organizations adopt the concept, they will require sophisticated IT resources to share data internally and externally with other acute and post-acute care facilities.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

A study by Park et al. (2015) of a pilot HIT program in South Korea examined acceptance and use of HIT by health professionals, while also examining the outcomes in terms of financial and health impacts. This study followed a 3-year pilot project funded by the Ministry of Health and Welfare in South Korea. Seoul National University Bundang Hospital (SNUBH) deployed a HIT system in 2009 that exchanged information - including demographic data, health status, medications, diagnoses, complaints, laboratory results, diagnostic imaging, treatments, care plans, histories and summaries – between SNUBH and referring local clinics and physician practices. This study permitted patients to opt into the study, after which point the hospital physicians would be able to see a special button on the display screen indicating that the patient was a study participant. System logs confirmed that physicians clicked the button and accessed the exchange information at over 99% of first encounters. This indicates a high physician interest in this additional data.

Their investigation compares a group of patients participating in the health information exchange (HIE) with a group of patients who opted out of the pilot program. Clear difference in the charges for various tests and in the length of hospitalization can be observed. Total charges were reduced significantly. These indicators have a clear impact on cost, however the physicians surveyed for this and a previous study by the same researchers indicated that perceived benefits in cost reductions were viewed as far less than the perceived benefits in patient outcomes and quality of care.

The researchers point out that there are several limitations to these findings. First, the cases involved simple referrals between providers and the hospital. Cases in which multiple providers interact simultaneously have yet to be examined. Second, this study did not attempt to measure direct quality of care indicators, which the researchers believe could lead to an underestimation of the benefits of HIT. Third, there were no significant workflow changes as part of the introduction of the HIT. Workflow issues have to be considered, but were not as part of this trial. Some of the benefits could certainly have been related to workflow modifications attendant to HIT adoption. Finally, the researchers warned about limitations on the type of health system studied and the potential generality of the findings. They caution strongly that South Korea has a fee-for-service mechanism, with limited policy initiatives to contain healthcare cost. This certainly impacts the ability to extrapolate results to other locations with centralized health care or significant cost-saving incentives. However, this warning actually implies a strong correlation between the U.S. system and that of South Korea. The system in the United States is a fee-for-service system, and while the debate around health insurance has been vigorous and produced some level of regulation, the discussion of costs for medical services has had far less traction. In this way, it would appear that a study of South Korea's HIT is at least reasonably applicable to HIT in the U.S.

APPLICATIONS OF HIT

Future uses of HIT have been proposed that require additional consideration. One proposed by Fichman, Kohli and Krishnan (2011) is the potential for evidence-based medicine (EBM). EBM promises the ability to make healthcare decisions based on strong, empirical evidence rather than basing decisions on personal habits, tangible and intangible incentives, or medical traditions that could be of various and questionable value. EBM adoption is limited by several factors. One is the lack of information available about the actual efficacy of various treatments. Digital storage of health information could give researchers opportunity to investigate links between treatments and outcomes to arrive at better analyses

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and tools. Another is the time it takes for newly discovered medical information to circulate through the medical community. HIT could facilitate distributing that information to providers or integrating it into automated tools.

Another possibility proposed by Fichman, Kohli and Krishnan (2011) is that of personalized medicine. Personalized medicine uses specific details about a patient's unique physiological makeup to allow earlier and more accurate diagnoses and treatment. Genetic information can be included, identifying risk factors and potential treatments that have been linked to certain genetic traits.

POTENTIAL RISKS AND MITIGATION FACTORS

The most significant risk to HIT implementation, especially implementation of a national registry, is security of private information. According to Chen and Lambright (2016), healthcare information systems (HIS) lag other industries in the development of adequate cyber security, but the information stored in an HIS is of great value to hackers. Their paper states that the healthcare sector reports 340% more information security incidents than other sectors, with 81% of healthcare organizations reporting cyberattacks in the two years between 2014 and 2016. Yet a 2015 industry survey showed only 53% of providers and 66% of insurers report being prepared to defend against a cyberattack.

This perceived risk affects the willingness of patients to participate in this technology. Fichman, Kohli and Krishnan (2011) advise that patients perceive a higher risk of compromise than actually exists, which is quite telling when one considers the actual risk of compromise as explored by Chen and Lambright (2016). Willingness to disclose is critical to this effort, because the effectiveness of treatment and the impact on public policy can be significant. Unless and until security concerns are adequately addressed, any attempt to implement a national health database would be met with skepticism and resistance, undermining the entire effort.

A NOVEL SECURITY MODEL

Chen and Lambright (2016) present an interesting model for potentially securing this sensitive information. Their model presents an autonomic security monitoring system. This system constantly would imbue the registry with a certain level of ability to self protect in much the same way that the human body uses the autonomic nervous system to monitor functions and maintain homeostasis without direct, conscious involvement. Their Autonomic Security Management Framework (ASMF) would contain elements of risk assessment, prevention mechanisms, early warning and detection and limited response actions.

They base this framework on a three-tier architecture whose three tiers are a web tier, an application tier, and a data tier for storing and retrieving information. In this model, the data tier collects data from relevant participants and store the data in repositories. The web tier provides server-based applications for use by providers and patients. The application tier contains mobile web applications that communicate and transfer data and information between the other two tiers. The researchers identified five prevalent attacks that healthcare systems would be susceptible to and identified approaches for each attack. The first attack is scanning attacks, in which hackers would scan devices in the network in order to gather network information that can be used to launch more sophisticated attacks on the system as a whole. The second is spoofing, in which adversaries could impersonate authentic system users to gain access

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

either by masquerading passively as part of the system or masquerading actively as validated system users. The third is injection attack, in which hackers may exploit vulnerabilities in the data tier to insert untrusted data. They could inject malicious information or commands in order to reduce the security of the overall system. Fourth are broken authentication and session management attacks. These attacks exploit vulnerabilities to assume the identity of a valid system user. The fifth type of attack is denial of service or DOS. These attacks make the system unavailable by overwhelming it with bogus requests that overwhelm system resources, blocking legitimate uses.

To counteract these attacks, the authors relied on the use of Risk assessment, intrusion Estimations, intrusion Detection, and intrusion Response (REDR) modules. Risk assessment is divided into five steps. The first step is to characterize HIS, in order to create a "normal region" that represents secure system performance according to relevant metrics like CPU Time, Memory Utilization and I/O Read/Write Rate. Step two is to identify threats and vulnerabilities, from which a protection requirement is generated. From that protection requirement, a comprehensive baseline and system controls are selected and implemented in steps three and four. Step five is to assess and report on the performance of the system. The intrusion estimation module contains system sensors that constantly monitor selected features. Historical values are used to project future values, which are then combined with system models and used to deploy early warnings when measurements fall outside expected normal or predicated parameters. This scan can also execute appropriate mechanisms to respond to attacks as they occur, without waiting for controllers to respond. The intrusion detection module is a data analysis module that analyzes real-time information to detect anomalous system behavior. This must be upgraded frequently to identify attacks sooner and uses live forensic analysis tools to learn unknown attack signatures. New attacks could be automatically detected and added to the catalog of known attacks for future detection. The intrusion response system gives the HIS the ability to self-protect, mitigating impacts of attacks and returning system parameters back to normal. Dynamic response systems allow autonomic management of the system, allowing the HIS to execute lower ranked responses without human intervention.

The researchers were able to design a prototype system with two demilitarized zones that applied the previously discussed REDR model. Users of the system would be able to send requests for information via the Internet, with known malicious requests filtered by the firewall. Only legitimate users and more sophisticated attacks would be capable of violating this barrier. The intrusion estimation model monitors for known and unknown attacks that bypass the firewall, and the intrusion detection model activates prevention mechanisms. Once new attacks are detected, the intrusion response module can autonomously select protection and mitigation mechanisms. A second firewall is added within the ASMF to filter out any internal attacks or illegitimate requests.

This theorized system represents a cost-effective automated method for detecting and responding to low-level, unsophisticated attacks. It is theorized that coupling this method with other complimentary approaches, like honeypots to prevent denial of service attacks, will make HIS more reliable and safe, protecting large volumes of very private and sensitive data. The researchers plan to create an HIS testbed in order to further explore this option.

Chioreanu et al. (2014) propose a hybrid cloud system, with a public and private cloud for storing sensitive information. This particular model proposes using secure communication networks and encrypted certificate pairs to protect sensitive data. Creating a separate administrator for the public cloud and the private cloud, with access restricted to appropriate users, provides additional security. However, this system was modeled on a very small scale – only hosting the documents of a single department within one hospital – and was not tested against malicious attacks. It relies on very simple protection

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

mechanisms, a private network and encryption keys, and the more involved security functions are handled by a system administrator. The use of cloud computing provides greater computing power in a virtual environment which can reduce the reliance on data centers that create a single point of vulnerability.

RELIABILITY OF HIT

Another potential problem that must be addressed is reliability. Gawanmeh et al. (2015) investigated the reliability of current HIS. They examined the different verification models that can be used to identify internal errors that can cause expensive and even dangerous adverse events. This includes not only record-keeping and data management systems, but also wearable technology and remote devices, such as radiation therapy devices and pacemakers. The authors examined studies of HIS that used simulation to verify system performance. Many of these simulations were used to examine performance factors related to scheduling, patient flow, and physician loading as a means of streamlining appointment scheduling. A number of simulations were also used to evaluate security requirements. Authentication, confidentiality, integrity, and privacy are factors that have been tested using simulation. Simulation has also been used to test the performance properties of various medical devices, such as pacemakers and electrocardiographs. Formal methods that use mathematical models to analyze systems are highly recommended for safety critical systems, and when they are automated they can assess complex systems successfully. They have been used for verification of such aspects as efficiency, security, reliability, computer aided diagnosis, medical devices, access policies, and electrocardiogram algorithms. Several research groups have found, in different cases, that developing software using formal methods of verification produces more reliable applications than other methods (Flemming & Huebner, 2013; Newell, 2011; Yusof, Papazafeiropoulou, Paul, & Stergioulas, 2008). Formal methods have also been used to assess trust metrics and survivability. Semiformal methods are based on formal methods but allow for informal semantics. These methods have been used recently in testing HIS, but this is a newer development that has less proof of concept and fewer case studies to confirm their results.

Gawanmeh et al. (2015) concluded, from their literature review, that healthcare systems should not be limited to one particular type of verification, but that multiple methods should be used due to the complexity of these systems and their many components. In particular, they concluded that test case generation would often require informal or semiformal methods due to their lack of source data. Overall systems may be subjected to probabilistic verification because workflow transitions occur with certain probabilities. No standard method for verifying trust could be established, while multiple methods could be used to verify privacy. They encouraged strong data verification, because there is a particularly high risk of missing, incomplete or inaccurate information in HIS. For applications involving large volumes of data, such as cloud-based assessment of complex records like genomic data and medical image processing, formal methods were recommended as potentially enhancing trust.

ISSUES OF IMPLEMENTATION

Barbarito et al. (2012) examined the effects of interoperability standards on regional healthcare in Lombardy, Italy. Over a period of 10 years, the Lombardy Region has set up the Regional Social and Healthcare Information System (SISS, from the Italian acronym) that connects all healthcare providers

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in a region of about 10 million citizens. The approach was twofold – first was to push all hospitals to accept the Health Level 7 (HL7) standard for their individual records and second, to provide a technical infrastructure for interoperability that each individual location could freely and easily access. The Italian healthcare system is a single-payer centralized system in which regional governments cover the expenditures for their citizens. The "Local Healthcare Units" (ASL in the Italian acronym) manage services for a specific geographic area within the region. Each patient refers to a general practitioner (GP) who is chosen from a local unit close to the patient's residence. Pharmacists, GPs, hospital physicians, specialists, nurses, office personnel, and the Regional Call Center personnel use the SISS. At the end of 1970, clinical and administrative data for all living residents were collected on a monthly basis. In 1982 central registries for patients and GPs were created. The unified SISS project was started in 1999. In 2010 the region introduced a lifelong personal health record (PHR) that collected all available documentation of a single citizen, with the goal of making this information available to all providers regardless of the location where a document was produced.

Information flows within single units were standardized and synchronized to the central registry, but by creating middleware that translated standard documents from each location to the central standard. The interoperability specifications were designed in a top-down approach, and any developer must adopt their technology to these specifications in order to implement a system. The system uses a three-level architecture. The Central Registry of Clinical Data does not store individual clinical electronic documents (CED), but rather indexes them according to standard messages sent by the hospitals where the CEDs are generated. A connective infrastructure, the Extranet, is the intermediate level between the central domain (first level) and local practitioners (third level). It is a virtual private network (VPN) with encryption software that provides communication between the different actors. Individual documents are the property of the patient, who can hide specific files or types of files if desired. Individual physicians query the central registry through the Extranet, and then send a request to the front office of the facility holding the specific CED desired, who then returns an electronic copy of the record. A separate process is used for booking appointments. A patient calls the Regional Call Center and a worker at the call center queries the central database to find available appointments, then presents the available appointments to the patient who selects on to confirm. Orders (for treatment, tests, or medications) are communicated from the provider to the facility in similar fashion. If a patient is admitted to a hospital, the change is broadcast to the central repository and visible to all providers. All of the indexed documents are arranged chronologically to create a complete, lifelong PHR, unless a patient indicates that it is to remain hidden. However, hidden documents remain on the local repository.

Workers are identified through personal smart cards, and these cards store user profiles that set the level of access and permissions each user has. The citizen also has a personal health smartcard, which is used for identification and to verify right to access care. It can also be used to book appointments and consult the PHR.

At present, this system functionally connects 10 million citizens and 73,000 healthcare professionals. It manages 4.7 million pharmacological prescriptions and 1.7 million laboratory exams per, 490,000 lab reports, 180,000 radiological reports, 180,000 first aid reports, and 58,000 discharge summaries on a monthly basis. The implementation has been long, and delays were encountered in training developers and testing systems. Healthcare workers required proper training. Many had trouble adapting to carrying their smart-cards with them at all times. However, the decision to use middleware to translate individual records into a standard format avoided pushing a single standard on all of the individual locations and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

making major workflow changes that would have caused problems and frustration among providers and patients. Also, adopting mandatory goals (such as 90% of CEDs digitally signed) for hospital administrators and creating incentive payments went a long way in overcome resistance to change.

Clearly, this study cannot be generalized to the U.S. system without consideration for the different healthcare systems found in each country. The U.S. has a fee-for-service private payer system, while Italy uses a centralized single-payer system. However, this study demonstrates that creating such a system is possible. That is a significant finding – namely that the complexity of healthcare does not rule out the possibility of creating a central and interoperable system for sharing medical records. Particularly significant for the United States is the decision to treat individuals PHR as their property. Once this distinction is made, it is easy to see why providers or treatment centers would be required to make these documents available to any person the individual designates. In fact, the American healthcare system already requires portability of a patient's information freely between providers in the Health Insurance Portability And Accountability (HIPAA) act of 1996 (U.S. Department of Health and Human Services, 2017). The creation of a central interoperability platform is merely a tool to facilitate this already mandated exchange.

Peng, Dey and Lahiri (2014) pointed out that, although there is a great deal of legislative and financial investment in the technology, HIS adoption in the United States lags far behind adoption rates in other developed nations. In the first quarter of 2013, the Healthcare Information and Management Systems Society (HIMSS) reported that one in eight providers still lacked a clinical data repository (CDR), which is the most basic building block of an EHR system, while a large percentage of providers who do have a CDR system have yet to implement other related systems.

Human Barriers to Adoption

Peter Orszag (2008) on behalf of the Congressional Budget Office, published a report on the causes behind this hesitance, which highlights multiple problems. Firstly, the savings from HIT are largely experienced by patients and insurance companies, giving providers little incentive to adopt the technology. Secondly, the possible improvements in quality of care are unlikely to yield any tangible rewards for providers, as they are not likely to be compensated in any way for them. Thirdly, adopting a completely interoperable, national EHR system will increase portability of records, making it easier for patients to move to a competing provider. Fourthly, since so few providers have adopted the technology, there is no pressure on hospitals to follow suit. The lack of standardization adds to the uncertainty and confusion of participating in this new effort. Concerns about implementation, patient privacy, security, loss of control over patient records, and the risk of other unintended consequences further inhibit participation.

Fichman, Kohli and Krishnan (2011) also point out that the healthcare industry is heavily influenced by regulations and competition. In most European countries, a single payer (public) system has the ability to subsidize, exert pressure on, and even directly require providers to share information. It is difficult to induce providers to participate in a PHR system without subsidizing them. Because there is a risk that patients whose records are easily transferred will transfer providers more frequently. Additionally, they mention the hierarchical nature of healthcare. Peng, Dey and Lahiri (2014) explore this in great detail. They examine implementation as a knowledge transfer problem. In their analysis, they find that knowledge transfer in the social network made up of healthcare providers has a great potential to push adoption forward in the U.S. They determined that some hospitals are more inclined to be receptive to knowledge related to HIT and EHR, owing to an existing familiarity and comfort with electronic systems

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in general. By placing these providers in networks with providers who have yet to adopt HIT systems, they can act as mentors to encourage and guide them in the process, disseminating their knowledge. Groups similar to the Mayo Clinic, the Geisinger Health System, and Kaiser Permanente are models for the sort of provider network that can effectively promote adoption of HIT systems. This effect is stronger and more influential. They are respected as mentors in the medical community. These healthcare networks can spur initial adoption. They are pushing it to the point at which the contagion effect will take over. The contagion effect is that point at which a new technology becomes so common that everyone must adopt it or be left behind. The contagion effect can only be useful once the technology has reached a fair level of adoption. They argue that a continuum exists in which knowledge transfer coupled with incentives, guides early adoption but the contagion effect eventually replaces it as the primary force.

These conclusions appear to be supported by the findings of Adler-Milstein and Jha (2011). They found that for-profit hospitals were less likely to participate in a state HIE than non-profit providers. Hospitals with a dominant market share were more likely to participate than those with a more vulnerable market position. Hospitals that were part of a centralized system, similar to the network groups mentioned in the Peng, Dey and Lahiri study (2014), were also more likely to participate. Those states that had the highest rates of adoption were those that provided financial incentives and regulatory requirements for participation. However, one state with high participation, Maryland, was also credited with creating a central infrastructure that supported adoption.

System Maturity as Barriers to Implementation

Another potential barrier to implementation is uncertainty regarding the maturity of these systems. Peng, Dey and Lahiri (2014) mention that a sense of uncertainty about the technology causes reluctance on the part of providers. Carvalho, Rocha and Abreu (2016) attempt to provide a framework for assessing HIT maturity in their literature review. They reviewed 14 maturity models of HIT developed by various entities including health care companies, research organizations, and academic experts. All fell within one of two general approaches: assessing individual system components in highly specialized models or comprehensively examining hospital information system as a whole. Most did not disclose their design process. Many failed to name explicit characteristics for each stage of maturity. Many used overlapping factors, but gave them different and terminology, and failed to apply weights to these factors. Most models assessed maturity and provided a path of improvement, but not all had a systemic process to move from one level of maturity to the next. The researchers concluded that no sufficient model yet exists with a broad enough scope that covers all areas and subsystems of a healthcare organization, while giving proper weight to varying factors based on relative importance that is supported by rigorous validation methods. In the absence of a maturity model that meets these criteria, it will be difficult to provide proper assurance to new adopters of HIT systems.

DISCUSSION

The matter of adopting HIT, specifically EHRs in the form of a central, interoperable national system, can be addressed as a series of hypotheses that require validation. If these hypothesis can be proven, there is sufficient cause and capacity to pursue a system of this type.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 1: Health Information Systems provide benefits that make them valuable to providers and patients.

The list of theorized benefits is attractive – decreased cost and increased reliability, accessibility, and quality of care with fewer adverse events. The case study from South Korea demonstrates that financial benefits definitely exist, in the form of reducing the length of hospital stays and the frequency of medical testing. This study was unable to capture the attendant cost savings from administrative efficiencies, workflow improvements, reduced effects and reduced litigation from those events, but the researchers assert that the pilot system produced cost savings in these areas that increased the overall financial benefits of the system. The study did not explore reliability, accessibility and quality of care. However, surveys of healthcare providers provided a relevant insight. In the pilot program, almost all physicians accessed the data contained in the electronic record when it was made available to them, indicating that this data was useful to and valued by providers. Physicians surveyed also indicated that they believed the quality benefits of the EHR system outweighed the financial benefits, which suggests that the quality effects could be quite significant. Related work by Aron et al. (2011) indicated that automating medical sensing functions reduce the occurrence of procedural and interpretive errors. But this study does not explore the full benefits of an EHR system – only the impacts of automated sensing. Hypothesis one is well supported by the available literature.

Hypothesis 2: Large-scale adoption of an interoperable regional or national Health Information System is possible.

The staggering complexity of the healthcare industry makes the implementation of a single system for managing healthcare information difficult. There are many different players, each interacting with different types of information, and many of the players already have paper systems for record-keeping, or a form of EHR that is unique to their practice or facility. Attempting to dictate a single standard for record-keeping across all facilities would be time-consuming and burdensome. Existing records would need to be translated to the new format and workflows would require significant changes. Also, the amount of data would be immense. Compiling it in a central storage facility would require massive resources at great expense. Such a single data repository would also be a single point of failure. Any compromise or problem at such a repository would cause major problems throughout the system. The case study from the Lombardy region of Italy, however, presents a unique alternative. Their three-tier architecture uses central indexing to locate files stored at their point of origin, and file contents are indexed in a single language which allow information to be recalled in a standardized manner without requiring that files be changed to a single standard format. This reduces the amount of effort to implement the system, removes burdensome workflow changes, and avoids the need for a central repository by leaving the original data in its place. The example given is from a single-payer health system. The underlying concept is flexible and adaptable and its structure is not impacted by financial factors. The only significant modification would be considering the role of insurance contracts in arranging care, as certain insurance carriers only contract with certain providers and that would have to be factored in to any appointments made. Similarly, insurers have individual lists of approved medications that must be considered when writing or filling prescriptions. However, these pieces of information can be treated as fields that require additional indices in the system. The flexibility of the design permits for them to be

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

considered. The current system in Lombardy serves 10 million people. There would still be a need to scale the system in size to meet the needs of America's population of 323 million, the proof of concept system is large enough to be considered relevant. This case study serves as support of this hypothesis.

Hypothesis 3: A central Electronic Health Record system can be successfully secured against electronic attacks.

The work by Chen and Lambright (2016) present a framework that gives the system a level of autonomic protection that can protect against low-level security threats, leaving IS personnel free to dedicate their time and energy to more sophisticated attacks. This theoretical system was designed around a three-tier architecture very similar to what was adopted in the Lombardy region and previously accepted as a support of hypothesis two. However, this design is theoretical and has not yet been tested or verified in the field. The current state of healthcare information security is marked by shortfalls in protections and a large number of successful attacks. However, the proposed autonomic system, coupled with the inherent protections of a distributed storage system as described in the Lombardy region, do have the potential to meet this requirement. This hypothesis remains unproven until the ASMF system designed by Chen and Lambert (2016) can be verified and appropriate validation of the entire system is conducted.

At this point, two of the three hypotheses are supported with valid cases and the final one is considered yet unproven. The third hypothesis could be considered confirmed once adequate validation of the proposed security system is carried out. This makes a discussion of implementation strategy for next steps and additional research opportunities worthwhile.

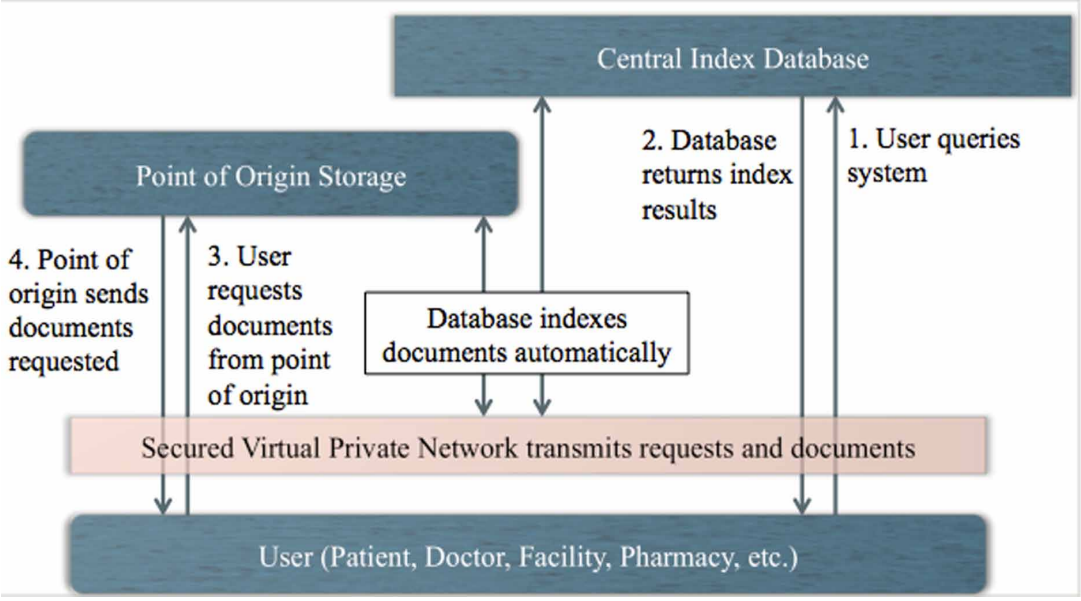
POTENTIAL SYSTEM

We would like to recommend a system similar to that of the Lombardy region, in which data is maintained at its point of origin and accessed through a central index using a query system that permits practitioners to see all entries in a longitudinal patient record. The proposed system differs from the Lombardy system, though. In the proposed system, it has four tiers instead of three. This is because the Lombardy system groups point of origin record sources in with the system users. Although there is overlap between the document sources and the system users, we believe it will be better to separate the two into separate tiers. This will permit additional protections, such as encryption or firewalls, to be enacted around the individual storage sites to further protect them from catastrophic compromise. A diagram of the proposed system is given below. This system would have minimal impacts on workflow, but would require 100% enactment of EHR at all facilities and providers. We have not yet accomplished this goal, but applying knowledge theory through establishing regional or state provider networks to create effective mentoring relationships will be useful. Additionally, as demonstrated by multiple researchers, financial and regulatory incentives will be necessary to overcome the initial financial risks and investments. Once sufficient number of providers have adopted this technology, the contagion effect will capture late adopters, as they are forced to adopt or be left out in the cold.

Sufficient security appears to be attainable, but it will require that the healthcare industry become more serious about their efforts to secure their data against attack. Currently, the industry lags others in giving sufficient attention to this problem. The problem of adoption and the issue of security appear to go hand in hand – as providers have doubts about their ability to secure an electronic system. They are

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Proposed Four-Tier Healthcare Information Exchange System



reluctant to adopt such a system. As fewer providers adopt electronic systems, there is less pressure on the industry to develop effective controls. This is a significant area of further research and development (see Figure 1).

CONCLUSION

As mentioned already, the proposed security system requires verification and validation. Chen and Lambright (2016) articulate plans to validate their model. Additional security verification will be required as the ASMF system develops and is integrated into the overall EHR system. Carvalho et al. (2016) identified various forms of verification and their most appropriate uses. Their work suggests that security testing should use formal, rather than informal or semi-formal, validation methods. Validation of the overall system can be subjected to various methods of validation depending on the individual component of the system to be tested.

No single maturity model exists for assessing the level of development of any potential system. None of the various maturity models that do exist are clear or robust enough, nor do they provide a clear path to developing HIS technology from one level of maturity to the next. A single, clear, actionable maturity model must be developed with clear metrics that are well understood throughout the healthcare industry and among the developers creating HIS. Until this model is developed, it will be difficult to convince potential users to adopt a proposed system.

Another significant gap in the existing body of research is confirmation of the theorized benefits to healthcare outcomes. Hypothesis one was accepted as valid primarily on the weight of financial benefits demonstrated in South Korea. This study could not capture actual benefits to patient health and well-being. Since South Korea's pilot program is a reasonable model for predicting U.S. outcomes, owing to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the similarity of their health system to our own, it would be particularly useful to return to the SNUBH pilot program with a set of metrics aimed at capturing quality of care. Of particular interest would be any reductions in adverse effects or medical malpractice incidents, as well as other measurable factors like time to diagnosis, time to treatment, treatment efficacy, and missed nursing care. It would also be useful to capture ancillary financial benefits, such as administrative cost reductions.

Pursuing these additional research opportunities would allow us to develop a robust national HIS as the basis for implementing more advanced uses of this technology. Until a national, or at least regional, central EHR can be implemented, the information provided by wearable devices and home health monitoring will not be put to effective use. Similarly, personalized medicine and automated diagnostic tools cannot function in a fragmented system that may not provide complete data for individual patients. Research into developing strong algorithms for these technologies can occur alongside the research necessary to develop EHR interoperability.

Chapter 94
Role of Bioinformatics in Nanotechnology: An Initiation towards Personalized Medicine

Harishchander Anandaram
Sathyabama University, India

ABSTRACT

Recent advancements in bio-computing and nano-technology accelerated the discovery of novel biomarkers in the emerging field of personalized medicine. Personalized medicine deals with disease detection and therapy from the molecular profile of each individual. Personalized medicine is also called as predictive medicine that uses genetic/molecular information to predict disease development, progression, and clinical outcome. In this chapter, we discuss the advantages of using nanotechnology to understand biological systems with an example of the biomarker discovery of cancer. Recent developments in bio computing served as the base for the identification of multiplexed probes in a nano particle. Together we have correlated the bio molecular signatures with clinical outcomes and we have also addressed an emerging field called bio-nano-informatics to suggest an individual therapy for cancer and other diseases.

INTRODUCTION

The nature of self-organization is a key feature of biological system and this feature provides a broader vision for the development of nanotechnology. Molecular diagnosis for identifying human diseases has witnessed an exponential growth in the last two decades and it laid the path for developing advanced technologies for molecular diagnosis and therapy (Ginsburg & McCarthy, 2001). Revolution in molecular diagnosis and therapy was based on discovering novel biomarkers for predicting disease behavior (Little et al., 2008; Jain et al., 2002). Molecular profiling and diagnostics deals with characterizing histological lesions which is heterogeneous in cellular and molecular level of a human disease (Allison et al., 2008). Current technologies like RT-PCR (real time-polymerase chain reaction) and gene microarrays were not

designed for handling this kind of heterogeneity because they require a constructive preparation of cells and tissue specimen into a homogeneous solution, leading to a loss of valuable information regarding the 3D cellular environment and tissue morphology (Hepper et al., 1984; Liu et al., 2004).The development of nano technology has provided an additional opportunity for integrating morphological and molecular information, which is also followed by observing the correlation between the molecular and cellular changes in disease behavior. Specifically, bi conjugated quantum dots (QDs) have been used to quantify multiple biomarkers in cancer cells and tissue specimens (Steeg, 2008; Wu et al., 2008; Ferrari, 2005; Wang et al., 2008). Nanotechnology can be used for molecular imaging and therapy to improve the efficacy and toxicity profiles of chemotherapeutic agents (Nie et al., 2007; Chan & Nie, 1998; Alivisatos et al., 2004; Michal et al., 2005; Gao et al., 2005). At present, a major challenge in biomedical nanotechnology is to understand the mechanism of interaction between nano particles and biological regimens (blood, cells and organs) under *in vivo* physiological condition. However, the ultimate task is to overcome the inherent limitation to ensure the delivery of nano particles to diseased sites or organs (Gao et al., 2003; Xing et al., 2006; Xing et al., 2007; Yezhelyev et al., 2007; Ghazani et al., 2006). Another challenge is to generate critical studies for linking biomarkers with disease behaviors, such as rate of tumor progression and response of patient to radiation or drug therapy (Sinha et al., 2006; Davis et al., 2008; Jain, 1999; Jain, 2001; Jain, 1998). Finally, we insist on the integration of biomarkers and bio computing with nanotechnology for analyzing a high-throughput data of multiplexed molecular profiles in specimens of cells and tissues.

BIOMARKERS AND THEIR APPLICATIONS

Bio molecular markers can be an altered or mutant gene, RNA, proteins, lipids, carbohydrates and small metabolites, which can be correlated with a biological behavior and its clinical outcome (Wang et al. 2007; Liotta et al. 2000). Most of the biomarkers are discovered on the basis of molecular profiling studies of association or correlation between a molecular signature and disease behavior. Initially, a study was conducted by Gloub *et al.* for classifying tumors on the basis of patterns in gene expression had reported. This study had provided a novel insight into tumor pathology by analyzing the stage and grade of tumor along with the understanding of clinical course and response to treatment (Petricoin et al., 2002; Negm et al., 2002; Ludwig & Weistein, 2005; Golub et al., 1999; Ross et al., 2000). Gene expression studies illustrate the fact that "Molecular signatures of each tumor are inflammatory factors of the original lesion with heterogeneity" (Alizadeh et al., 2000).

The first clinical correlation of gene expression patterns with clinical outcome was reported for the diffusion of B-cell lymphoma (Perou et al., 2000), which is a clinically proven disease with heterogeneity. Whereas, more number of patients had responded well to therapy and survived for a longer period. Hence, it was understood that the variability in a disease progression could be correlated with a specific pattern of a gene expression. Based on this concept, specific molecular portraits were analyzed for the tumor of each individual patient and later, the clinical study was validated by Perou et al. by using an array of clinical samples (Bittner et al., 2000, Dhanasekaran et al., 2001) and it served as the foundation for the discovery of specific expression patterns with the in prostrate, breast, liver and lung cancers (Paik et. al., 2004; Chen et al., 2007; Beer et al., 2002). Biomarkers are divided into predictive, prognostic and therapeutic markers. Prognostic biomarkers predict the natural course of an individual cancer. So, at present it possible to distinguish the indolent and aggressive tumors.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Predictive biomarkers are used to assess the probability of patients benefit in a particular treatment (Hoshida et al., 2008; Hynes & Lane, 2005). For example, breast cancer patients with a normal level of expression of HER2 gene responds well to drug Herceptin, whereas breast cancer patients with up regulated level of HER2 gene responds well to drug tamoxifen (Osborne, 1998; Eisen et al., 1998). Pharmacodynamic biomarkers are used for measuring the short-time treatment effect of a drug in treating tumor (Geraci et al., 2008). In case of clinical applications, biomarkers should be validated by techniques of multiplexed nanotechnology (for proteins) or by RT-PCR (for nucleic acids) (De Souto et al., 2008). Further, we discuss the advantage of using bioinformatics tools for initiating biomarker discovery.

Bioinformatics Tools for Biomarker Research

In earlier days, biomarkers were analyzed on the basis of microarray data using bioinformatics tools with unsupervised learning algorithms (Rehrauer et al., 2007). For example, **Eisen** et al., 1998 had developed a software with several methods of unsupervised clustering and the recent development is a web based application (Rehrauer et al., 2007). Similar methods were used for analyzing the gene expression data from the clinical samples of various patients for identifying the different subtypes of cancer (Pirooznia et al., 2008). Recently, supervised learning methods are used in bioinformatics software for analyzing microarray data in different clinical conditions. For example, MAGMA and ILOOP (Interoven loop) are the two web based applications which is used for analyzing two-channel microarrays (Tarraga et al., 2008; Rainer et al., 2006). ILOOP interface assists the experimental design of a microarray (two-channel) and MAGMA incorporates the normalization procedures in statistics into an application for usability and reproducibility (Gentleman et al., 2004). Most of the web based applications follow a common pipeline of data mining principles. Similarly, GEPAS (Gene Expression Profile Analysis Suite) includes function with steps including data normalization, feature selection and class prediction. In addition to that, CARMA (Comprehensive R and bioconducter-based web) and Gene pattern are recent tools which are being used for microarray analysis (Reich et al. 2006; Michiels et al., 2005; TGO Consortium, 2000; Zeeberg et al., 2003). It was well established that biomarkers are resulted from microarray data analysis on the basis of selection algorithms (Zeeberg et al., 2005; Beissbarth et al., 2004; Carbon et al., 2009; Maere et al., 2005). Apart from sampling algorithms, other databases like Gene Ontology (GO) had given a platform for the evolution of packages like GoMiner, GOStat, AmiGO, BiNGO and GOEAST (Zheng et al., 2008; Frijters et al., 2008; Edgar et al., 2002; Parkinson et al., 2006; Brazma et al., 2001). There was also similar application for searching medline abstracts with specific keywords to display a network structure of GO data (Stokes et al., 2008).

Due to an increase in the accumulation of gene expression data, there is a need for automated packages to mine gene expression data from large repositories like Gene Expression Omnibus (GEO) and Array Express (Ivliev et al. 2008; Zhu et al. 2008; Ochs et al. 2008).There were certain packages constructed for automation but those packages contain certain overlaps in predicting gene expression and hence certain web based applications like Microarray Retriever, GEOmetadb and Array Mining (Hull et al., 2006; Phan et al., 2009; Fogel, 2008). Despite the availability of software, there are challenges in normalization and quality control over gene expression data (Irizarry et al., 2003; Li, 2008; Stokes et al., 2007). Further, there is also a need for translating the list of gene symbols from a feature selection application before the application of a particular GO. Gene Trial Express and Taverna were the workflow application for feature selection (Shei et al., 2006). Another web based bioinformatics resource for biomarker identification was developed by Phan et al. and he named it as omni BioMarker. In this software, biomarkers are

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

identified from several steps which include normalization, feature selection, biological interpretation, validation and clinical prediction. Since there is no single path for biomarker identification, we require unique parameters to address the clinical significance of biomarker.

Clinical Validation of Biomarkers

A study of small set of biomarkers was conducted for the purpose of molecular diagnosis with nanoparticles that are conjugated to antibodies for and targeted therapy (Hernandez et al., 2003; Mora et al., 2005). In particular, multiplexed QD probes can be used to profile a selected panel of biomarker in typical specimen of clinical tissue (Marquez et al., 2005). The use of five to ten protein biomarkers could have a significant impact on disease diagnosis and individualized treatment (Hicks et al., 2001). In this study, four QD-antibody conjugates have been used to recognize and detect four tumor antigens (i.e.) E3 ubiquitin ligase mdm-2, tumor-suppressor p53, zinc-finger transcription factor EGR-1 and cyclin-dependent kinase inhibitor p21/CDN1A. These markers are known to be important in prostate cancer diagnosis and it has been correlated with tumor behavior (Konecny et al., 2003). It is important to note that tumor classification with antigens which are expressed at low levels which can be subjective and therefore it require an experienced observer for identifying a considerable variation. In contrast, quantitative QD measurements allow accurate and user-independent determination of tumor antigens from lowest level of gene expression (Xiao et al. 2004). Thus, the quantitative nature of QD-based molecular profiling could simplify and standardize categorization of antigens of low abundance on intact cells and tissue specimens. This study was proved to be vital for the management of breast cancer. Since the likely benefit of hormonal therapies and trastuzumab is reflected on the quantity of hormone or HER2 receptors (Douglas et al., 2007; Yan et al., 2003; Rothemund et. al., 2004; Chworos et al., 2004).

Integration of Bioinformatics in DNA Nanotechnology and Synthetic Biology

In order to construct an artificial system from biological molecules such as DNA or RNA by the process of self-assembly, there is a requirement to understand the genetic mechanisms behind the action of bio molecules with the help of a high performance computing system. Hence bioinformatics plays a vital role in the integration of synthetic bio systems by the components of nucleic acids (Jaeger & Chworos, 2006; Ponchon & Dardel, 2007; Dittmer et al., 2004; Qian et al., 2005). DNA nanotechnology was established more than 25 years ago by Nadrian Seeman. It is based on the precisely predictable events of molecular recognition between DNA strands with their complementary sequences. In first inception, DNA molecules were used to construct an increasing complex of supra molecular structures ranges from three-dimensional objects (3D) over two-dimensional (2D) lattices (Wilson & Szostak, 1999; Garibotti et al., 2007) to an arbitrary pattern of 2D (Rackham & Chin 2005). From the perspective of synthetic biology, it is particularly interesting to consider the RNA based nanostructures also because of its vital role in the process of transcription. In nature, RNA is rarely used as a structural element. Nevertheless, Jaeger and co-workers could demonstrate a variety of RNA assemblies (Chin, 2006, Seeman, 2005). RNA nano construction process is slightly difficult because of the degradation of RNA. However, recent work suggests that the process of degradation can be avoided by incorporating the structures of tRNA into the RNA transcripts (Bath & Turberfield, 2007; Mao, 1999). In the current era of science, nucleic acid based nano assembly represent the “bottom up” strategy in to capture a part of complexity found in biological self-organization. DNA nano construction is used for finding a DNA sequence which as-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

sembles itself into a structure with a desired thermal equilibrium and annealing process is used to direct the assembly. Some biologists work in contrast to the direct assembly of bio molecules because they believe that most of the complex structures in biological systems are inherently present in the state of non-equilibrium. For an example, cytoskeleton is composed of protein filaments in dynamic equilibrium and the process is constant by the assembly and disassembly of ATP or GTP molecules. In order to explain further, building of complex structures needs the control over the order of assembly in both spatial and temporal arrangements. A biological example for this condition is the complex intracellular rearrangements preceding the cell division or development of multi cellular organisms.

DNA nano devices are proved to be versatile in analyzing machine like assemblies with mechanical properties. Most of these devices are composed of a single or multiple strands of DNA and the molecule can be folded to a designed structure. These devices can change their confirmation by the addition of a strand with respect to the type of nucleic acid and the conformational changes and recently, DNA nano devices has enhanced their versatility by the adaptation of functional nucleic acids (Yurke et al., 2000). In order to achieve the process of self-assembly; the system is subjected to be in non-equilibrium based thermodynamic system with molecular control over the circuits (Yan et al., 2002) and it was stated that the evolutionary process of nucleic acid must be incorporated into the bio based artificial structures (Shin & Pierce, 2004). According to Garibotti et al., the spirit of synthetic biology is the idea of "translation machinery" for nanotechnology. In contrast to the conventional approach by the application of chemicals the artificial translation machinery was developed by Garibotti et al. and mostly they cannot be used to produce an *in vivo* based artificial materials and this lead to the possibility of using the modified ribosomal systems developed by Chin and co-workers (Sherman & Seeman, 2004; Bath et al., 2005; Venkataraman et al., 2007).

Integration of Biological Mechanisms in Computers

Recently, DNA-based molecular recognition has been used to realize various assemblies of machine-likeliness with the property of information-processing and this model is slightly different from nano construction (Adleman, 1994; Ezziane, 2006). These devices are composed of single or multiple strands of DNA, which folds itself into a particular structure and in most of the cases, the structure is designed rationally. The conformation of the devices can be switched between several structures by the addition of DNA or RNA strands or by incorporating a small change in buffer conditions. In this method, the devices can act as simple sensors for the sequences of nucleic acid or the environmental factors which are subjected to the device functioning. The conformational changes can also be utilized to induce the mechanical motion of the device (Yan, 2003; Rothemund et al., 2004; Szostak et al., 2001) and it was also found that the device has the functionality of translational movement (Pohorille & Deamer, 2002; Dittmer & Simmel, 2004; Dittmer et al. 2005; Zhong & Seeman 2006). Finally, the adaptation of functional nucleic acids for DNA nano devices has considerably enhanced their versatility and aptamers were utilized as an autonomous molecular device for computing.

The original work on DNA based computing with an introduction to nanotechnology was initiated by Adleman (Famulok et al., 2001) and certain examples were demonstrated for the processing of DNA based information (Ponchon & Dardel, 2007).DNA model was used for the utilization of certain algorithms to incorporate the process of self-assembly to produce supra molecular patterns (Yingling & Shapiro, 2007; Simmel, 2007) and finally the concept of DNA nanotechnology and DNA computing can be adapted to design novel strategies for the control of transcription and translation. Due to their

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

compatibility in programmable structures, RNA-based devices and control circuits should also be of considerable as the interest for developing the components of artificial cells (Mandal & Breaker, 2004; Sudarsan et al., 2006).

Implementation of DNA Nano Devices

Implementation of an artificial nano device follows the bottom up approach of biological nanotechnology because it utilizes the existing machinery of living organisms on the basis of their metabolism. In *case of an* In vivo operation in a synthetic molecular device may represent a faster road to success. In vivo implementation of molecular devices based on nuclic acids (DNA or RNA) can be achieved in two very different ways *i.e.* (i) Chemical modification of nanodevices, followed by packaging and delivery or (ii) Transfection of cells with artificial genes containing the blueprint for the working of those nanodevices. For example, several DNA based nanomechnical devices were operated using certain effector molecules of RNA *in vitro* (Isaacs et al., 2004; Bayer & Smolke, 2005; Hannon, 2002) and the *in vivo* assembly of such structures has not yet been attempted. In order to achieve an *in vivo* assembly, nanodevices should favour the intramolecular folding of single strands. An another example, we consider the "intramers" (Elbashir et al. 2001;). These intramers are intracellular RNA aptamers, which are produced from an expression system which was genetically engineered to transfer the foreign molecules into live cells. Intramers had been demonstrated to be useful for the *in vivo* targeting of the disease-related proteins. A similar approach is also achieveable for another RNA-based nanodevice. In case of the production of an *in vivo* based nanostructure of RNA, the tRNA-technique may be of great use (He and Hannon, 2004). However, it may not be straight forward approach to transfer the DNA-based assay of *in vitro* technology to an RNA-based assay of *in vivo* system. Currently, certain computational tools are being developed to support RNA-based nano construction (Rinaudo et al., 2007). Recently Simmel et.al gave an overview of the potential in vivo applications of DNA-based nanodevices and they have also addressed the challenges involved in the process implementation (Bansal et al., 2010**).**

Implementation of DNA Nanotechnology in Artificial Ribo Regulators

In the final era of pre genomics and the initial era of post genomics, "riboswitches" have been found to play an important role in the regulation of gene expression in bacteria (Szostak et al., 2001). Ribo switches are natural structures of RNA aptamer and it is being incorporated into the transcripts of mRNA. The transcripts may adopt one of the alternative conformations on the basis of the presence or absence of aptamers. Depending on the conformation, transcription may be terminated or translation of mRNA into protein may be inhibited. In this way, riboswitches exert the control over genes during the process of transcription or translation. It has been shown that, cells perform complex tasks such as logical computations using the circuits of a riboswitch (Pohorille & Deamer, 2002). However, switchable structures made from nucleic acids (DNA and RNA) serve as a central topic in the area of DNA nanotechnology and coupling these switches to gene regulation has been attempted in a variety of different ways. In this case, the construction of artificial riboswitches represents a fusion of ideas from DNA nanotechnology and synthetic biology. In fact, certain artificial ribo regulators were recently devised and implemented in prokaryotic (Forster and Church 2006) and eukaryotic (Seeman, 1982) cells. For example, Isaacs et al. had

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

constructed a part of self-complementary based mRNA molecules, which has the tendency to fold back onto them in such a way that the ribosome binding site was blocked and hence the process of translation was inhibited. This strategy for post-transcriptional regulation had been found in natural ribo switches.

Implementation of DNA Nanotechnology in In Vivo Computing

Another class of a regulatory RNA are termed as microRNAs, which serve as major components in the machinery of natural RNA interference (RNAi) (Chen & Seeman, 1991). In case of RNAi, the process of gene silencing process is triggered by the presence of double-stranded RNA molecules, which are cleaved by the enzyme Dicer into short RNA duplexes termed as short interfering RNAs (siRNA). One of the RNA strands contained in the siRNA duplex is bound by the so-called RNA-induced silencing complex, which induces a site-specific degradation of mRNAs containing a complementary sequence. Excitingly, this natural process of RNAi can be used to knock down genes by the synthetic molecules of siRNA (Shih et al. 2004). Shortly, after the discovery of RNAi, it was also found that the endogenous molecules of regulatory RNA exist and those molecules were currently found to be the microRNAs (Goodman et al., 2005). Recently, Benenson and colleagues utilized the RNAi process to perform logical computations *in vivo* (Gates and Hinkley, 2004). To this end, the computation was implemented into genes, whose expression was regulated by natural microRNAs. When a logical combination of several endogenous molecular inputs was present *in vivo*, the expression was only observed in the reporter gene (coding for a fluorescent protein). Hence, the fluorescence of the modified organisms represents their current logical state which was later termed as the "molecular state." Apart from computing, microRNAs are the prime candidates for coupling artificial DNA or RNA-based nano devices for the processing of life in *in vivo*.

Applications of Bioinformatics and Nanotechnology in Understanding Biological Systems

There are numerous applications to study biological systems by the approach of either Bioinformatics or Nanotechnology but the combination of both approaches have a limited number of a few applications which are very effective and they are (i) Positive feedback gene amplifier (Gates et al., 2005) and (ii) Programmable structure (Gogonea et al., 2001).

Positive Feedback Gene Amplifier

In general, a positive feedback gene amplifier uses the mechanism of a positive feedback to regulate gene circuits by inducing a response to generate binary outputs. Positive feedback method has an advantage over other methods because of the non-requirement of an external factor. At present most of the gene amplifiers of positive feedback uses the mechanism of an auto inducer-independent variant of the quorum-sensing regulator (LuxR). In order to test the potency of the gene amplifier with the mechanism of positive feedback, a case study was conducted by amplifying the output of a one-component of a tetracycline sensor and two-component of the aspartate sensor. In both cases, the positive feedback module amplified the response to their respective inducers on the basis of their dynamic range and sensitivity. In order to construct a circuit of positive feedback, there is a requirement for a transcriptional activator that did not interfere with the regulation of a native gene. In addition to that, there should not

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

be an exogenous inducer to suppress the activator molecule. Based on various studies in the past, an engineered design was made by the three constitutively active variants of LuxR were made to test their suitability in designing an amplifier.

Programmable Structure

Incorporation of nucleic acid based nano devices and computers into a natural or a synthetic biological system is a straight forward approach. In the beginning stage biological cells produce an RNA nano device by transcription. In the next stage, the regulatory mechanisms of genes can be used to control the time of production of nanodevices by a naturally occuring RNA (For e.g., microRNA or RNA) that transcribed from artificial control genes can be used to drive them. Finally, the concepts of DNA nanotechnology and DNA computing can be adapted to devise certain novel strategies for the control of transcription and translation among genes.

FUTURE PROSPECTIVE AND FURTHER CHALLENGES

While addressing the future prospective of biomarker research, there exists a variety of research direction which is particularly promising in biomedical applications but it requires an additional effort for success. The initial direction of research is to design and develop nanoparticles with only one or multiple functionalities. For applications in cancer and other medical conditions, relevant nano particles were used in therapy. Nano particles could also be designed to have novel properties and applications. For example, binary nano particles with two functionalities could be developed for molecular imaging and targeted therapy. Bio conjugated QDs, which have both targeting and imaging functions, could be used for targeted tumor imaging and applications related to molecular profiling. Conversely, ternary nano particles that combine three functions could be designed for simultaneous imaging and targeted therapy. Another direction of research will address the panel of optimizing biomarker using bioinformatics and quantitative molecular profiling with the help of nanotechnology. For example, bio conjugated nano particle probes are used for predicting cancer behavior. The key hypotheses that will need to be tested are that a panel of tumor markers will allow more accurate correlations than relying on single tumor markers. The most important research direction is to investigate the distribution nano particle in ADMET system.

CONCLUSION

Bioinformatics and nano technology aims at the analysis and construction of artificial molecular structures and machines from biomolecules by utilizing the principles of self-assembly and self-organization. In fact, Nuclic acid (DNA and RNA) molecules have been successfully witnessed to realize a wide range of supramolecular structures, nanomechanical devices and molecular computers. Incorporating the potential of “simple” molecular self-assembly and many other properties of biological systems would be desirable for technological systems. For example, environmental responsiveness, robustness, fault tolerance, self-healing, self-reproduction, evolvability, growth and differentiation were some of these properties can probably be realized in compartmentalized nonequilibrium systems containing the networks of complex molecular interactions. Recently, there have been a lot of effort for integrating the components

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

developed on the basis of DNA nanotechnology into larger networks. The genetic nature of its building materials i.e. DNA and RNA, makes DNA nanotechnology compatible with genetic processes. Genes may be used to produce RNA structures.

Gene regulation may be used to control nanodevices or to feed molecular computers and in turn the DNA or RNA switches may be used for unconventional processes of gene regulation. Integration of DNA or RNA-based systems is possible both *in vitro* and *in vivo*. *In vitro*, there have been efforts to incorporate the synthetic gene networks within the artificial cell-like compartments but there are also efforts to directly operate the nucleic acid devices in live cells. Here the utilization of ribo regulators and RNAi processes seems to be promising. In either case, stochastic effects are expected to play an important role in systems behavior and there is a demand for the stable operation of artificial biosystems in small compartments.

The research trends surveyed in this area indicate the fact that a part of the current efforts in DNA nanotechnology and DNA computing will be absorbed in the future prospective of synthetic biology. But the relationship between nanotechnology and synthetic biology is mutual. Current trend of DNA nanotechnology offers the components and concepts for synthetic biology. On the other hand, synthetic biology could be the ultimate "bio nanotechnology" in future.

ACKNOWLEDGMENT

The authors thank the management of Sathyabama University for providing the computational facilities to complete this book chapter.

KEY TERMS WITH DEFINITIONS

ATP: Adenosine Tri Phosphate.

Biomarkers: Characteristic biological properties that can be detected and measured in various parts of the body.

Bio-Nano-Informatics: A branch of science which deals with the application of nano technology and information technology to understand biology.

CARMA: Comprehensive R and bioconducter-based web portal.

GEO: Gene Expression omnibus.

GO: Gene Onthology.

In vivo: within the living.

QD: Quantum Dots.

RNA: Ribonucleic acid.

RT-PCR: Real Time Polymerase Chain Reaction.

Chapter 95
Overview of Cellular Computing–Basic Principles and Applications

Amit Das
University of Kalyani, India

Rakhi Dasgupta
University of Kalyani, India

Angshuman Bagchi
University of Kalyani, India

ABSTRACT

Computers, due to their raw speed and massive computing power, have been highly used by biologists to expedite life science research whereas several computational algorithms like artificial neural network, genetic algorithm and many similar ones have been inspired by the behaviors of several biological or cellular entities. However till date both these disciplines i.e. life sciences and computer sciences have mostly progressed separately while recent studies are increasingly highlighting the impact of each discipline on the other. The chapter describes several features of biological systems which could be used for further optimizations of computer programs or could be engineered to harness necessary computational capabilities in lieu of traditional silico chip systems. We also highlight underlying challenges and avenues of implementations of cellular computing.

INTRODUCTION

Computers, especially the modern day desktops and workstations, owing to their massive processing power and speed, have been traditionally used for deeper understanding of several biological phenomena. Techniques essential for high through put processing of genetic (gene sequencing), transcriptomic (micro-array), proteomic (mass spectroscopy) and imaging (microscopy and diagnostic techniques like CT-Scan,

PET, MRI etc.) data, heavily rely on traditional silicon chip based computing systems (Kuznetsov et al., 2013). However at the heart of every computer, lies a processor which ultimately understands Boolean logic and rely on direct or modified form of Von Neumann architecture. This basic simplistic core of a computer also resembles the behavior of an individual cell which responds to certain input parameters (signals) through the generation of an output based on certain sets of logic. This common feature between a computer and a cell gives rise to a relatively new field of study, termed as 'Cellular Computing' (CC) which focuses on harnessing the power and characteristics of biological entities like cells for the purpose of computation rather than using traditional in-silico network analogy based methods for better understanding of complex systems (Sipper, 1999; C Teuscher, 2012). In case of CC, the word 'computation' does not necessarily restrict its meaning to 'adding numbers' only, rather it is used to describe achievable outcomes through direct or engineered (or synthetic) exploitation of bio-molecular / cellular logic sets which have been evolutionarily selected.

The two following example will provide better understanding of the analogy between computer and cellular logic processing system and a couple of the advantages of CC:

1. The bacterial growth scenario:

Logics like IF/ELSE or AND/OR are a common part of almost every kind of algorithm and rarely requires any introduction. Now it is remarkable to highlight that even the miniature scale cellular biological entity i.e. a bacteria is always responding to its surrounding environment based on such logics and that too is related to its primary aim which is bacterial growth and division (Figure 1). For example IF nutrition is present in the surrounding medium, then continue growth ELSE suspend growth and prepare for tough situation. So it is clear that, without going into any underlying biological pathway details, it is possible to find to similarity between a cell (or bacteria) and a computer. To make a little complex scenario lets add one more factor in the bacterial growth scenario i.e. the temperature. IF nutrition is present in surroundings AND temperature is favorable, continue growth ELSE suspend growth (Figure 1).

The underlying molecular details of this bacterial sensing and growth regulation are also an outcome of series of events of such logic and thereby can be specifically categorized as 'Molecular Computing' which although related but for the better understanding of the readers are discussed in details in a separate chapter and thereby carefully kept outside the scope of this chapter.

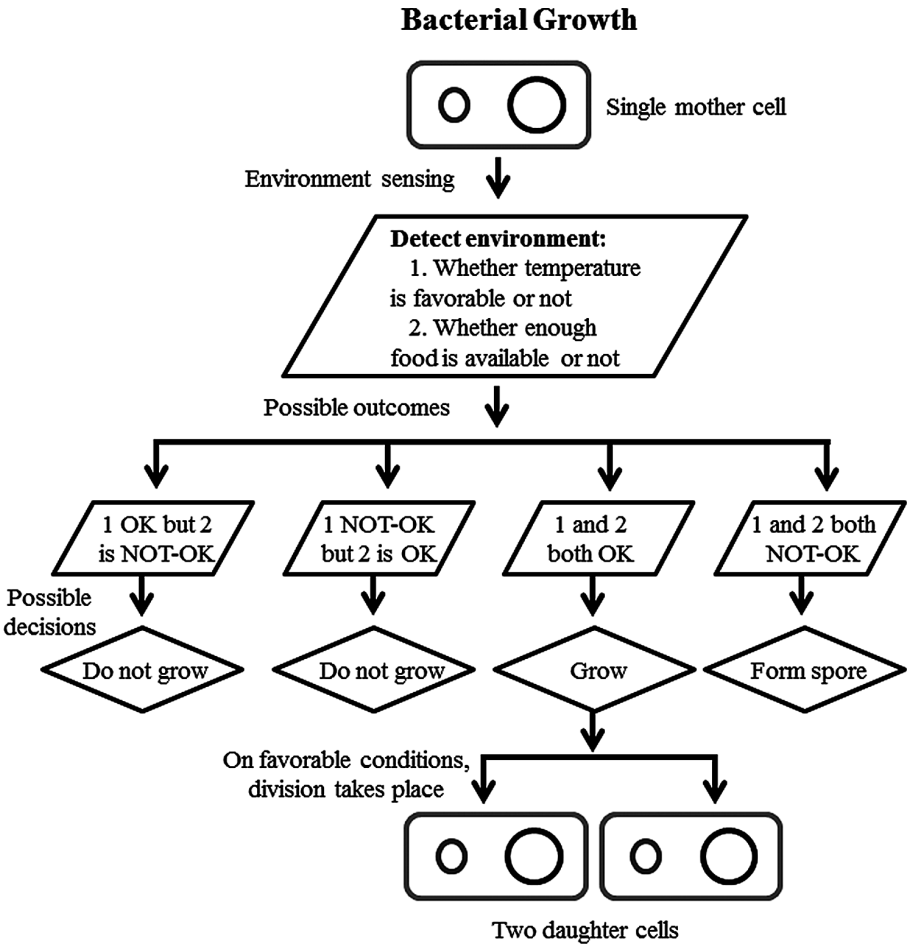
2. The traveling salesman problem:

Before we go in to the details of the problem, let's have a brief understanding of the ways data are processed by a computer. A computer processor primarily works in sequential mode. Although availability of multiple threads combined with massive speed, a computer processor can perform millions of calculations per second but at the heart of this speedy calculator lays a system which can only perform in sequential mode and thereby can only manage sequential inputs. Even in case of present day scenario which show cases the availability of multi-core processor and general purpose graphics processing units (GP-GPU) which are promoted to facilitate miniature to large scale parallelization (depending on the number of processor cores), it must be remembered that they are all essentially arrays of sequentially performing processor which is managed in a smart way (that too by another sets of sequentially performing processor) for a certain extent of performance gain. However separate lines of codes are required

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Flow diagram of the series of logical behaviors which a bacterial cell undertakes to make a decision on the suitability of its division

Like any computer program which assess the input values based on predefined conditions and logics to generate the output, bacterial cells also undergoes similar logical steps to make a decision on their division. First the bacterial sensing machinery senses the environmental conditions (mainly temperature and food) and based on their sensing outcome a decision is made on whether division favorable conditions exist or not. While in reality, several parameters are assessed, a two factor (temperature and food) conditions determination system shows that four different possible outcome of the sensing machinery, only one of which is favorable to continue with bacterial division.



to make a program able to harness this performance benefit and thereby results in its own additional energetic cost. The bottom line of this discussion is that true parallelization of computational architecture is yet to be achieved.

Coming to our point of discussion, the traditional travelling salesman problem is a classic example of efficient management of time and energy and any other humanly associated cost. Now if we look into a bee or ant colony (where lies a social higher archery of queen, king and worker individuals), there will be some individuals, generally termed as foragers (a part of the larger worker community which also harbors individuals like soldiers etc.) who has a primary role of finding food sources for the entire community. Now each community has several such individuals, each of whom, files on its own path of exploration and then returns back and intimidates fellow workers about the place (exact specific direction and loca-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion) of available food sources. This can be treated as a classic case of parallelization as discovery of multiple of food sources are quite (and often) possible and each discovery (or exploration) is independent of each other and is not controlled by any central individual along with the fact that multiple discovery results in the increased combined benefit for the entire bee or ant colony. Since the forager has limited travelling ability it automatically has to optimize its exploration path which increases with experience, a process known as learning (similar to machine learning features of a computer). More importantly the worker individuals who will continue to collect food (post discovery by forager who has to travel once) are required to perform multiple trips to make the best of a particular food source. To keep the energy cost minimal it is essential for the workers to travel as minimum distance as possible to reach the food source and return back to nest or hive. Since the forager one was the one who discovered the sources and intimidated its location to the works, the forager is also responsible for optimization of the path to be travelled by the workers. Along with the energy cost the minimal path is also essential to increase the survivability chances as traveling more distance will require more time meaning extended duration of exposure to probable predators (like birds or other such ant or bee hunting animals). Thus from this example it can be concluded that forager bees and their activities are a classic example of parallelization, optimization (in terms of energy and other cost) and learning.

From the above two examples it can be understood that biological entities function in as similar logic driven way (the bacterial growth example) to that of a computer and parallelization, optimization and learning are essential for survival for biological entities (the bee and ant example). Since a computer, which is a logically operating machine aimed at achieving combined greater outcome by performing in parallel with optimal use of energy and time (costs), bears striking similarity to biological systems or entities, the principle of CC focuses in harnessing these in-built capabilities of cellular systems to address day to day challenges either through engineered cells or via optimizations of computer algorithms with inspirations from biology.

In this context it is worth mentioning that there have been huge amount of available information on CC from a computer scientists point to view (Binitha & Sathya, 2012; Fisher & Henzinger, 2007; Navlakha & Bar-Joseph, 2011). Considering the huge amount of bio-inspired algorithms and their diverse field of application, availability of such information it is not surprising. However it should be noted that CC, irrespective of its way of implementation, is based on biological or cellular principles or behavioral properties. Thus it is essential to understand the logical parameters of biological properties or behaviors in order to successfully apply them. Without such knowledge it would be similar to applying technology in the absence of underlying science. In this chapter the authors have provided greater focus to bridge this gap as well as aimed at highlighting CC as an interdisciplinary approach to solve several challenges rather than highlighting CC as a collection of algorithms with inspirations from cellular systems.

BACKGROUND

Robert Hooke, the British naturalist, discovery the basic structure of a cell from dead cork cells using a very basic form of microscope (Hooke, 1665). Since then cells have been explored from almost all possible aspects and with the advent of molecular biology techniques, a clear picture of the underlying cellular machineries were gradually enlightened. However owing to the tremendous complexity of the cell, till today there lays a significant amount of lack of understanding of different cellular behavior even at the level of a single bacterium.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

With the advancement of computer science and hardware, biologists gracefully welcomed the contribution of computers in biological sciences. The contribution of computer in biology is as well diversified as biology itself. Whether it is in the field of microscopy and image processing or in the area of modeling biological systems, with the increase of speed and robustness of digital computers, biologists explored the full potential of these silicon chips for better understanding of the cells, organisms, systems and its interactions with surrounding environment. Efficient use of computers to unravel the secrets of biology gave rise to subjects like Bioinformatics, computational biology, systems biology and so on (Baldi & Brunak, 2001; Kitano, 2001).

On the other hand the in spite of the tremendous complexity of biological systems, cells or multicellular organisms exhibit a very fast response to the changes of its surroundings. While some responses like changes in surrounding temperature or pH, DNA damage are required to be addressed very quickly, other factors like evolution is an ultra-long time scale event which also affects the growth and modifications of biological systems. These characteristics of biological systems like damage control, adaptation, evolution etc. have inspired computer sciences to develop and optimize algorithms for increased stability, robustness and efficient processing of information. Collectively such algorithms became known as bio-inspired algorithms and this gave rise to a field of computer sciences known as biologically inspired or biologically motivated computer sciences (Binitha & Sathya, 2012). The main aim of this steam is not to create an artificial cells or organism but to create efficient data processing programs that shares the time tested characteristics of biological systems.

However the field of CC is not only limited to development of efficient algorithms with inspirations from biology, rather CC also deals with using cells or organisms for the purpose of data processing. The famous McCulloch-Pitts neuron, research on which generated a huge amount of information on neuronal data processing, became a path leader of studies in this area and till today it continues with greater enthusiasm and effort (Arbib, 1995; McCulloch & Pitts, 1943). Later studies by Alan Turing showed that given the availability of sufficient neurons, they can be subjected to logical behaviors as neurons simply behave as NAND gates (Christof Teuscher, 2002; Turing, 1969). Studies by Pattee (1961), Stahl and Goheen (1963) helped in further establishment of the concept proposed earlier by Turing. Sugita argued the fact that since biological systems are merely a well-ordered chemical system, there must be a way of representing them through electronic analogues (Sugita & Fukuda, 1963; Sugita, 1961, 1963). Subsequently the ideas of cellular automata and cells as an information processing system were established. While Schmitt discussed the idea of 'biological macromolecular memory' (Schmitt, 1962), the famous talk 'There's plenty of room at the bottom' by Richard P Feynman pioneered the idea of miniature scale electronics known as molecular electronics or nano-electronics (Feynman, 1960). However at the beginning of CC, his ideas served the purpose of a strong stimulant.

The famous Moore's Law, proposed by the famous Gordon Moore in 1965 (Moore, 1965) has dominated the traditional computational hardware field over the last few decades. Although this law still holds true and is expected to continue its domination to a foreseeable future, the fundamental limitations of the transistor architecture that Moore reported is gradually becoming clear (Kish, 2002) and there now lays an ever increasing need of discovery as well as establishment of an alternative way of information processing. The both wings of CC are expected to fill this void in near future. While bio-inspired algorithms can enable better use of presently available or upcoming digital computer, the information storage, processing and interpretations abilities of cells can reach beyond the physical and fundamental limitations of traditional silicon chips.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

DIFFERENCE WITH MOLECULAR COMPUTING

Molecular computing (MC), similar to CC, is also another field of interdisciplinary studies which deals with the process of using biological macromolecules like proteins or DNA for the purpose of computing i.e. storage, analysis and processing of information (Benenson, 2012; Fu, 2007; Lai, Sun, & Chuang, 2014). However there lies some fundamental difference between MC and CC. CC has a two way approach which has two primary goals – i) use of certain characteristics of biological cells or systems for the purpose of optimization of computer algorithms and ii) engineering of biological building blocks i.e. cells for the purpose of computation. On the other hand MC is a one way approach with the primary aim of engineering biological macromolecules for computing purposes.

Since a cell is composed of hundreds of thousands of macromolecules and both CC and MC aims at engineering them for computational purposes, MC apparently seems to be a part of CC. However that would be an incorrect assumption considering their underlying basic principle. In case of CC, the entire cell is treated as a unit while its underlying mechanisms are largely ignored whereas in case of MC, individual protein or DNA molecules are taken in to consideration. In CC, the behavioral or physiological changes of the entire cell, in response to certain input signal (mostly from the surrounding environment) is considered whereas MC takes into account changes in molecular level, sometimes extending up to individual bases of DNA.

Beyond this difference of order of magnitude (molecular level) between CC and MC, CC has another wing where several computation algorithms take inspiration from the behavior of biological cells for development or optimization purposes (a separate section discussing this aspect of CC is discussed later in to this chapter). However extension of macromolecular behavior, especially changes beyond their physic-chemical properties, for optimization of computational algorithms have not been well documented yet.

INHERENT CHARACTERISTICS OF CELLULAR SYSTEMS

As reported by Michael Conrad, a pioneering figure in the field of bio-inspired and cellular computing, cellular organisms have a different way of information processing compared to the digital computers. Traditional silicon chips based digital computers accomplish this task based on several layer of abstractions whereas living entities make the best used of physic-chemical properties of their constituent materials (Conrad, 1989). Cellular computing tries to bridge this issue of the way of information processing through optimization of natural and artificial systems by drawing inspirations from real life biological entities like a cell or an organism.

Thus for proper understanding of the impact of cellular systems on cellular computing, it is essential to understand several cellular properties that have been or can be further exploited for the progress of cellular computing.

Uniformity

Now a day, it is well known that every human, irrespective of their origin, are 99.9% identical. Not only humans, every species that exists on earth share such high degree of similarity of its genetic content among the members of that particular species. This kind of uniformity is essential for maintaining species identity as such compatible genetic content ensures the feasibility of reproduction only across the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

members of a species and thereby eliminates inter-species reproduction. The point to be noted from this kind of specific uniformity of biological systems is the level of security employed with passage of flow of information. Since production of offspring from inter-species courtship is rare and even in those rare cases is mostly infertile, flow of genetic information reaches an automatic terminus ensuring zero catastrophic effect. If such level of uniformity, paired with inbuilt security, can be employed in to computer systems, there can be massive impact on information exchange protocols.

Along with the security benefit of having species specific uniformity, there are several other benefits of having such uniform internal contents. The uniform nature of evolutionarily conserved biochemical pathways makes it easier to predict the nature of changes that can result from alterations of surroundings. Like a shift to non-permissible temperature, all bacteria, existing in that particular growth medium) will seize their growth immediately and this will result in an immediate halt on utilization of food sources which would have otherwise gradually decreased to make the bacterial growth sustainable. Thus the uniform behavior of bacteria facilitates easy modulations of their growth just by alterations of only one parameter (temperature in this case). Uniformity of any system makes it easier to control. In order to maximize proper utilization of computational and its associated resources (like power consumption), uniform behavior of computer programs are essential. However such features, till date, are far from implementation and there rarely exists any resource utilization uniformity across softwares or hardwares.

Scalability

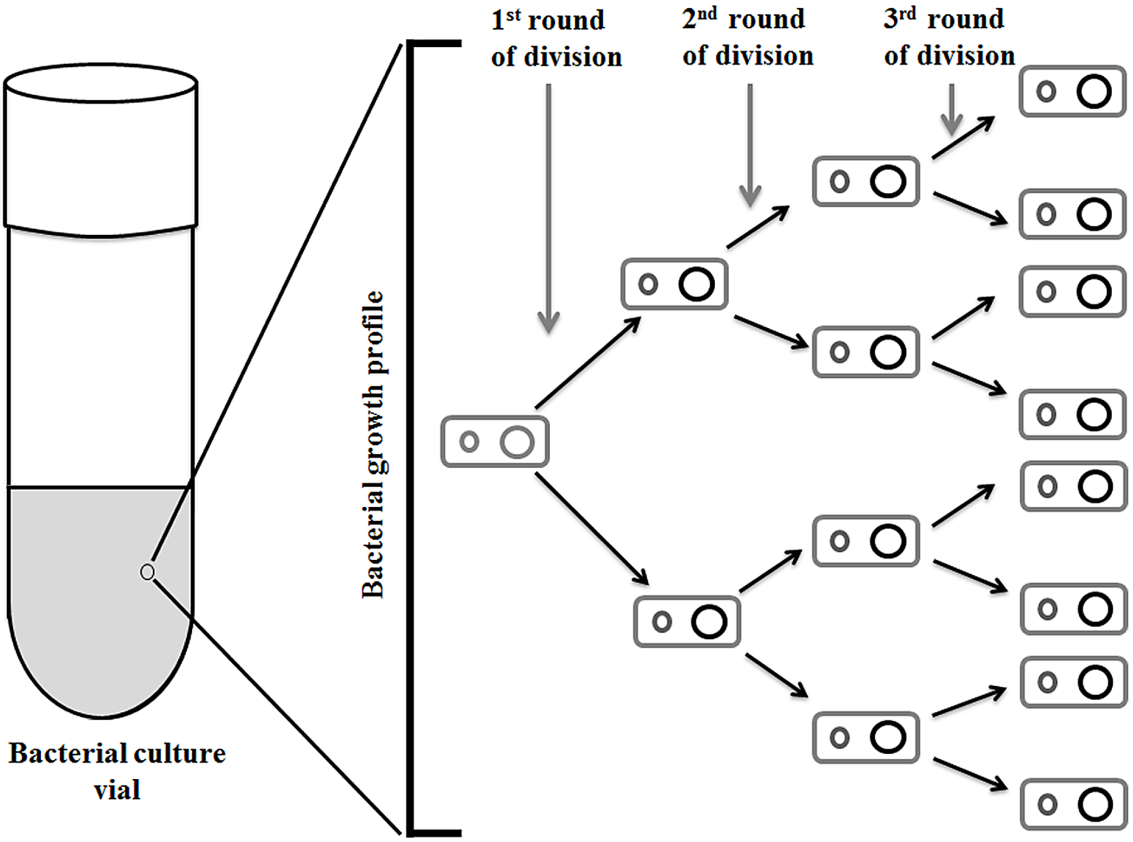
Scalability is an integral part of every cell and it exists in two forms i.e. ability to maximize the available resources as well as its ability to accommodate any increased task in response to changes in the internal and external conditions. When environmental conditions are favorable (as mentioned in Figure 1), a bacterium (for example *Escherichia coli*) can generally divide in 20-30 minutes. With this rate of growth (average of 2 divisions per hour), an overnight grown culture (standard 12 hours growth period which is sufficient enough for the growth curve to just reach a stable state) can contain slightly more than 16 million bacteria (precisely 16777216) even when originating from a single bacterium (Figure 2). Keeping aside the synthesized protein, just to accommodate the genetic material of these 16 million bacteria, around 70 million based of nucleotides have been synthesized and used up for replication (without any error). Thus it can be clearly envisioned, without much effort that such rate of scalability to maximize the available resources is extremely hard to replicate with any existing computational systems but with its implementation, even a fraction of this level, massive increase in resource utilization by computers can be achieved.

Parallelization

Biological systems are massively parallel and parallelism exists at all cellular levels i.e. within a cell, among cells and across multi-cellular systems. Several molecular pathways keep on undertaking their own chains of reactions independent to each other. For example glycolysis and TCA cycle (which are the main energy producing pathways) can simultaneously take place along with DNA replication or transcription. Similarly two cells of an organism can perform different tasks like nephrons facilitate filtering of excretory fluid while rod or cone cells empower the ability of vision despite the fact that both types of cells exist in the same body and share same genetic material as well as similar bio-chemical pathways. As mentioned in the beginning, the forager bees function in parallel and communicate with

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The growth of a bacterial cell
Bacterial cells (like E. coli) undergo binary fission where at each division the mother cell gives rise to two daughter cells. When favorable conditions are available, such binary divisions can generate 16 million cells from a single mother cell over a period of 12 hours. The chain of such bacterial division is shown up to first 3 divisions which can generate 8 daughter cells.



separate sets of worker bees even though they live in the same have. Thus it can be clearly envisioned that parallelism which is an integral part of any cellular or biological systems, exists at all levels and evolutionary selection have perfected it from all possible aspects. Despite relying on similar bio-chemical pathways, the parallelism exerted by cellular systems is very hard to replicate by traditional computers which mainly rely on von Neumann architecture. However parallelization is such a characteristic of biological systems which computer scientists and engineers should look in to with greater enthusiasm as efficient use of this property both at software and hardware level can increase computation speed and capabilities several thousand folds.

Robustness

Cells have tremendous capability to handle perturbations of its surroundings i.e. cells exhibit significant level of robustness both internally and externally. In terms of internal robustness cells employ several mechanisms to ensure the sequential integrity of its DNA (Papamichos-Chronakis & Peterson, 2013; Sirbu & Cortez, 2013) as any change, some of which even at a single nucleotide level, can have significant effect on the overall system, for example mutations in the p53 gene (Girardini, Walerych, & Del Sal, 2014;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Muller & Vousden, 2014; Powell, Piwnica-Worms, & Piwnica-Worms, 2014; Yeudall, 2014) or sickle cell anemia (Pace, Ofori-Acquah, & Peterson, 2012). Not only is the maintenance of integrity, compensation and fault tolerance are another important part of cellular robustness. Neurons have developed specific mechanisms to ensure only qualified (above certain threshold) external stimulus are eligible for neuronal transfer along with ensuring no loss of signal intensity as well as proper representation of each and every signal variations with accurate reproduction of type and intensity. Present day computers feature extreme information processing capabilities. However the speed and accuracy with which biological systems filter out noises and extract the required information still remains unmatched and computer science will definitely be benefited if such level of robustness (along with speed) can be employed.

Networking

Networking is an important aspect of both local and global information exchange system, especially in present days. Proper understanding of the network structure and dynamics helps in efficient management of the overall network. Like the computer network, biological cells also form a network where they can communicate with each other. Not only local cell to cell communications, where the communicating cells are connected to each other, long distance cellular communication is facilitated by biological messenger systems like the hormones. Microscopic organisms like slime molds also exhibit efficient network management systems like the slime mold food tunneling network (Latty & Beekman, 2011; Yip, Beekman, & Latty, 2014) where each available food source is connected to each other either via direct connection or through intermediated junctions. Evolutionary forces have made selection to favor only those network connections that ensure minimal cost and high robustness. Understanding the nature of such selections would have in development of efficient computer networks that in turn would ensure maximum utilization of networking components and fast and secure data exchange over such networks (Marwan, 2010).

Discreteness

Despite behaving very synchronously, cells at its core are discrete in nature where each individual cell relies on its own machinery. Such discreteness enables each cell to survive, function and reproduce independent to each other. Even in a multicellular system, where each and every cell must communicate with each other and function in an orchestrated manner, each cell maintains its discreteness. Such discreteness are essential for the survival of the cell in an environment where competition for resources (like food) are always at its limit and this feature in turn enables selection to select the best performing unit. Although each and every computer node of a network or a single computer is a discrete system, it, on its own, cannot undertake ways to survive in a resource limited environment. Intelligent algorithms can enable computers to maintain their discrete identities even when competing for resources with each other.

Speed and Specificity

Cells exhibit remarkable speed and precision with almost all of its functions. While the speed of neurons which is around 500 km/h, can be said to be significantly slower than the speed of a computer which in theory operates at a speed of electricity / light, when the complexity of biological information is taken it amount, the speed of biological phenomena is found to have no match at all. Even with present day super computer architecture, simulations of a single biological cellular activity is still out of question, whereas

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

cells keep on doing their work without any fail. The entry of a virus in to a cell which in general takes a few seconds can keep present day supercomputer busy for a handful of days trying to simulate this event even under much simplistic environment conditions. On the other hand each and every DNA sequence is composed of only four different nucleotides (adenine, guanine, cytosine and thymine), transcription factors are able to bind to their specific target sequences and that too can be found across millions of base-pairs of DNA of a cell, and even a variation of single base can be identified by the transcription factors and the time scale of such events are in to micro-seconds order. Another point to be noted in this context that cells only employ a fraction of its resources to perform such jobs and several such jobs continue to run in parallel within a cell at all times. When such factors (number of base pairs to search, identification of exact match, time taken to perform such job, amount of resource available for the job), it can be clearly understood that the combined speed and specificity of a cell still remains unmatched and there is a long way to go before achieving such level of combinations of precision and speed with traditional digital computers.

In-built encryption

Data encryption and flow of information in encrypted format across the World Wide Web is a constant field of improvement in present day. With the ever increasing threat of mishandling of personal and public data and storage of such data over cloud based storage system, encryption has received its highest level of attention over the last few years. But if we look into the cellular system, it is fascinating to find that encryption has always been an integral part of biological information storage as well as the passage of information across biological networks. Taking into the consideration of the central dogma of molecular biology (i.e. DNA > RNA > Protein), it should be noted that proteins are the primary structural and functional unit of any cell. However the protein coding information is stored into the DNA which has a completely different building block compared to the proteins (nucleotide bases for DNA while amino acids are the primary constituents of protein). Also the passage of information from DNA to Protein takes place via an intermediate stage of RNA. Also there are two other features of this biological information encryption system – i) requirement of only a handful of macromolecules and ii) one directional flow of information. For the first point it should be noted that DNA / RNA are made of only four different types of nucleotides (adenine, guanine, cytosine and thymine for DNA and uracil replacing thymine for RNA) while proteins are made of only twenty different types of amino acids. Thus all the genetic information of each and every species that presently exists on earth or ever existed can be made up of only four different nucleotide bases. Till date no such computer storage system exists that can hold such enormous data with only four different types of constituents and that too in an encrypted format. Same argument also exists for the proteins which are primarily formed by different combinations of 20 building blocks. To further understand the level of encryption that exists in biological systems, it should be noted that protein sequence can be interpreted from the DNA sequences whereas the reverse is almost (and practically) impossible to deduce due the redundancy of genetic code. Thus the decryption can only take place in one direction which is also favored by evolution as no biological machinery exists to undertake the reversed flow of information from proteins to RNA / DNA. If such level of encryption can be achieved by computer systems that can store information with such handful of elements, there would be a massive jump in terms of space required to store information as well as in terms of level of security of information storage.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Optimized Redundancy

Availability of redundant data sources ensures un-interrupted flow of information in case of failure of any node. However to determine the level of redundancy in data storage is a very critical parameter. Cellular systems, over the course of evolution, have developed a highly optimized redundant level of information storage. It is often seen that cells keep multiple copy of genes affecting exact or similar functions. This ensures that in case of deletion of any section of a chromosome or gene, it is functionally complemented by up regulating the expression of these duplicated genes (Gu et al., 2003). However not all genes are maintained in multiple copies. Only those genes which are highly essential for the basic survival of the cell are kept functionally redundant. Thus the challenges for network system specialists or data scientists is to determine which local node or which section of data is to be maintained redundantly to ensure combined benefit of the entire network. Detailed understanding of biological systems, especially gene disruption and duplication machineries and their underlying evolutionary forces would definitely help computer science in this aspect.

Uniqueness Identifying Ability

Uses of bio-metric security features like finger print, facial passwords have become a common feature now a day. While such software tools have become easily available only over the last decade, they existed across biological systems since its origin. Also biological systems execute this unique identifying ability with far less training than that is required by any computer program which often require hundreds or thousands of examples as training sets (Thorpe, Fize, & Marlot, 1996; Zhu, Rogers, Qian, & Kalish, 2007). Thus there lies an opportunity to employ the discriminating properties shown by biological systems to develop an algorithm which is capable of learning in one go (Fe-Fei, Fergus, & Perona, 2003; Fei-Fei, Fergus, & Perona, 2006).

ALGORITHMS INFLUENCED BY BIOLOGICAL ENTITIES

As previously mentioned, several computational algorithms are inspired by biological entities. For the ease of understanding, this section can be divided in to two sections – i) Algorithms inspired by cellular properties / organism behavior and ii) Cellular behavior or biological phenomenon with impact on algorithm optimization. While these two sections apparently seems to be similar, the difference lies in the ways of implementations of the interplay between biology and computer science – i) one algorithm may take inspiration from more than one biological principle while ii) one single biological phenomena may have several characteristics which have been utilized by more than one algorithms.

Bio-inspired algorithms can be broadly classified in to three groups – i) evolution influenced, ii) inspired by ecological systems and iii) swarm based (Binitha & Sathya, 2012).

Among these three groups evolutionary algorithms (EA) is the most well established and is based on evolution of biological organisms. EAs are non-deterministic in nature. The EA family consists of genetic algorithms, genetic programming, evolutionary strategy, differential evolution and paddy field algorithms (Back, 1996; Binitha & Sathya, 2012).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The natural ecosystem comprises of several biotic and abiotic factors which interact with each other in numerous ways. There also exist several levels of competition i.e. inter-species and intra-species completion for food and other non-renewable resources. Along with competition, there lies other modes of interaction like cooperation, predation etc. The natural eco-system thereby represents an ideal example of different level of interactions across a wide range of entities. These complex interaction networks and the flow of energy across the ecosystem have inspired several algorithms like the bio-geography based optimization algorithm which information sharing across candidate solutions (Simon, 2008). The idea of co-evolution of symbiotic organisms has been utilized in the optimization of PS2O algorithms (Chen & Zhu, 2008). Numerical stochastic search algorithms like the invasive weed optimization (IWO) is inspired by the ecological distribute of weeds and their colonizing properties (Mehrabian & Lucas, 2006).

While EAs constitute the most established group of bio-inspired algorithms and eco-system influenced ones takes in to account several properties of complex interactions of biological systems, the remaining type of the bio-inspired algorithms i.e. swarm based algorithms or optimization techniques exhibit maximum diversity. Swarm based algorithms or swam intelligence (SI) is relatively new (Bonabeau, Dorigo, & Theraulaz, 1999). While EAs underlying principle is the genetic adaption of organisms, collective social behavior of a group of organisms form the base of SI. The five fundamental principle of SI are – proximity, stability, adaptability, diverse response and quality (Kennedy & Eberhart, 1995). Intelligent water drops (IWD) algorithm is based on the observation of behaviors of water drops in a natural river (Shah-Hosseini, 2007, 2008). The behavior of human immune system in response to foreign antigens exhibit powerful learning and memorizing abilities, paired with high level of robustness and feature extraction capabilities. These properties have been exploited in to the artificial immune system (AIS) algorithm which is based on the clonal selection principle of the immune system (Dasgupta, 1999). Other than IWD and AIS, the foraging (mainly for food) activity of birds has inspired the development of particle swarm optimization (PSO) algorithm. The social nature of ant and bee colonies has given rise to algorithms like ant colony optimization (ACO) and artificial bee colony (ABC) algorithms (Blum, 2005; M Dorigo, Maniezzo, & Colorni, 1996; Marco Dorigo & Stützle, 2004, 2010). The schooling behavior of fishes has a tendency to sacrifice local minimum to active global success. This natural schooling behavior have inspired the development of fish swarm algorithm (FSA) and primarily exhibit three properties – search for desired resource (like food in nature), exhibit swarming to counteract any possible threat and follow to achieve a successful outcome (Azizi, 2014; X. Li & Shao, 2002).

Since several other chapters of this book incorporate a detailed discussion across almost all the above mentioned bio-inspired algorithms, they have been precisely limited to this point. Table 1 provides a brief description on the most well established major bio-inspired algorithms while Table 2 provides further insight in to some other biological phenomena that have been utilized by computer scientists for algorithm development and optimization purposes but have not been well categorized yet.

CC AND SYSTEMS BIOLOGY

At the very base of CC, its foundation is laid on understanding of the cellular system, especially its underlying logical behaviors. Unlike molecular computing, CC takes in to account the entire cellular system and in this aspect system biology plays an important role. With reductionist approach, understanding individual biochemical pathway or the functions of its individual components are of prime focus. However it should be noted that cells undertake each and every pathway in a very logical manner

Table 1. List of major algorithms inspired by different behaviors and characteristics of cellular or biological entities

Name of Algorithm	Underlying Biological Principle	Applications	Basic Characteristics	References
Artificial Neural Network	Structure of biological neuronal network and learning and processing ability of neurons.	Prediction or forecasting applications, Pattern recognition,	Massively parallel, distributed architecture, learning and generalization ability, fault tolerance	(Jain, Mao, & Mohiuddin, 1996) (Bishop, 1995)
Genetic Algorithm	Natural selection, evolution (select only the best, everything else is discarded)	Automated design, Biological sequence manipulation, evolutionary game theory, robot trajectory, strategy planning	Global and blind search methods, probabilistic transition, parallel implementation	(Goldberg, 1989)
Ant Colony / Travelling Salesman Problems	Figuring out the least path of travel	Task scheduling and assignment, vehicle root optimization, edge detection and linking, network routing	Global, parallel, learning ability	(Marco Dorigo & Stützle, 2004)

Table 2. List of cellular or organismic properties/behaviors that have inspired optimization of several computational algorithms

Cellular Property / Organism Behavior	Inspired Algorithm	Advantage(s)	Disadvantages(s)	References
Fly Sensory Organ Precursor Cells	Finding out maximal independent sets	Distributed, networked, stochastic, modular, robust	Non-adaptive	(Afek et al., 2011; Alon, Babai, & Itai, 1986; Luby, 1985; Rendel, Sheldon, & Finlay, 1965)
Regulation of Gene Expression	Optimized redundancy, fault tolerance	Distributed, networked, adaptive, modular, robust	Non-random	(Balaji, Iyer, Aravind, & Babu, 2006; Gitter et al., 2009; Gu et al., 2003; Guerraoui & Schiper, 1996)
Echolocation of Bat	Trajectory optimization, locating / positioning of movable objects	Robust, adaptive	Non-random, localized	(Yovel, Falk, Moss, & Ulanovsky, 2010)
Foraging of Slime mold	Network path, connection and efficiency optimization	Distributed, networked, stochastic, adaptive, robust	Less-flexibility	(Marwan, 2010; Tero et al., 2010; Watanabe, Tero, Takamatsu, & Nakagaki, 2011)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

with an aim of achieving greater combined benefit for the entire cell. Thus the reductionist approach has serious limitations because deeper knowledge about a specific pathway does not necessarily, which is often the case, reflect the overall outcome which is actually an outcome of several inter-connected (some serial and some parallel) pathways. Hence understanding the entire cellular system is of prime importance in order to take inspirations to apply CC for the betterment of daily life challenges. In this context the systemic approach takes in to account the limitations of the reductionist approach by looking in to interaction networks and the biological system properties which are an outcome of such interactions.

Gene regulatory network are the very basic but essential form of interaction networks of any biological system (Davidson & Levin, 2005; Lee et al., 2002). Qualitative models like random and probabilistic Boolean network, network motifs and asynchronous automata are associated with the modeling of gene regulatory network (Cardelli, 2007; Hecker, Lambeck, Toepfer, van Someren, & Guthke, 2009; Istrail, De-Leon, & Davidson, 2007). In another way the entire gene regulatory network can be represented as a 'genomic computer' which can potentially enlighten computation that takes place within nature as well within a human designed computer. While both the 'genomic computer' and a digital computer can perform logical calculations, there are some fundamental differences. As already mentioned, cells are better in exploiting the physico-chemical properties, silicon chips rely on multiple layer of abstractness. Information passes within a digital computer in the form of flow of electricity, cells achieve this through the change in electric potential across membranes which in turn modulates the state of activation of ion-channels (Cardelli, 2005).

Another major advantage of the 'genomic computer' is the absence of hardware-software barrier. In case of traditional computers, hardwares are typical electronic units which can only function when loaded with certain softwares or logically calculating features. While in a cellular system, the DNA itself serves as information storage material, a component of expression regulatory complex and many other purposes, most important of which is providing the necessary protein coding sequence. It can be compared with an imaginary digital computer where the processor itself stores all the required information and executes certain sets of programs depending upon the requirement. Also this imaginary processor is capable of re-writing its logics based on its experience as well as capable of creating another processor to which it can pass its essential and favored characteristics and logics.

Mechanical and metabolic obligations of a cell are taken care of by the biochemical networks which are mainly the interplay of proteins. At any given time point there exist several thousand molecules of proteins and there interaction network is tremendously complex which makes it really hard to represent protein interaction network in a logical manner. Especially the context dependent modifications of proteins and altered nature in presence of other proteins or factors make it extremely hard to model protein interaction networks. Kohn maps (Kohn, 1999) and textual bio-calculus (Nagasaki, Onami, Miyano, & Kitano, 1999) have made significant contributions in this aspect; however they are far from the desired level.

As already mentioned, engineering of biological cells for the purpose of computation, is another important aspect of cellular computing. Pioneering works by L. Adleman showed that biological macromolecules like DNA can be employed to solve mathematical works by utilizing their information storage and processing capabilities (Adleman, 1994). Since then considerable progress has been made reporting the uses of DNA, enzymes and other cellular macromolecules for solving computational and mathematical challenges. However engineering of the entire biological cells for such purposes is still at its infancy. Synthetic biology deals with this problem with an aim of building an artificial cell or artificial biological system for better understanding of natural phenomena.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Synthetic biology also incorporates modular architecture like building of bio-modules like pulse generator circuits which display responses (although transient in nature) to various input stimulus (Andrianantoandro, Basu, Karig, & Weiss, 2006). Due to inherent modularity, synthetic biology can also be compared with computer engineering (Endy, 2005).

Several approaches have been taken to artificially constitute a cell that only contains the essential number of genes that can produce proteins to undertake all the necessary biochemical pathways to support life, at least at bacterial level. Szostak and group (Sazani, Larralde, & Szostak, 2004) reported the creation of an artificial nucleotide set that is self-replicating in nature (Murtas, Kuruma, Bianchini, Diaspro, & Luisi, 2007; Paul, Springsteen, & Joyce, 2006).

Beyond synthetic and systemic approach to understand biological systems, '*in vivo* computation' or 'computation within a living cell' is the most direct approach to use cells for computing purposes. Approaches have already been undertaken to develop an '*in vivo* programming' and 'autonomous finite-state automation' within the *E.coli* bacteria (Nakagawa, Sakamoto, & Sakakibara, 2006). Construction of *in-vivo* logic gates as well as genetic circuits with ability to harness the (logical) power of cellular biochemical network have been reported (Ehrenfeucht, Harju, & Petre, 2004; Landweber & Kari, 1999). With insights gained from bacterial recombination and ciliate genome transfer, scientists working in the area of '*in vivo* computing' came up with the idea of 'bioware' which is based on template guided genetic recombination (Angeleska, Jonoska, Saito, & Landweber, 2007; Nowacki, Shetty, & Landweber, 2011).

CC AND BIOINFORMATICS – IMPLEMENTATION AND OPPORTUNITES: A CASE REPORT

Bioinformatics, especially the underlying algorithms of its associated tools, has immensely benefited from CC, especially from bio-inspired algorithms (Aboul-Ella Hassanien, Mariofanna G. Milanova & Abraham, 2008; Baldi & Brunak, 2001; Hassanien, Al-Shammari, & Ghali, 2013; S. Li, Kang, & Zhao, 2014; Mulder, Akinola, Mazandu, & Rapanoel, 2014; Valentini, Tagliaferri, & Masulli). This topic has been discussed several times. In this section, the authors describe a case report on characterization of a specific protein and its interaction that have taken place with the help of bioinformatics.

Cellular actin cytoskeleton is dynamically regulated by a number of proteins including formins which are further fine-tuned by formin-binding proteins. Among several formin binding proteins, one such protein namely formin binding protein 4 (FNBP4) was discovered way back in 1996 (Bedford, Sarbassova, Xu, Leder, & Yaffe, 2000; Chan, Bedford, & Leder, 1996) as a formin poly-proline rich region (PRR) interacting protein. However in the absence of further experimental characterization, further insights in to this FNBP4 - formin PRR interaction was never reported. Even some authors later doubted the practical feasibility of this interaction (Kondo et al., 2013). In this context several bioinformatic tools like BLAST (Altschul, Gish, Miller, Myers, & Lipman, 1990), Pfam domain search (Punta et al., 2012), molecular modeling and docking techniques, many of which rely on bio-inspired algorithms for search optimization, better output generation played significant role to computationally characterize this protein and its interactions with formin (Das, Bhattacharya, Bagchi, & Dasgupta, 2013, 2014, 2015a, 2015b), not only in human but also across several other organisms across different taxonomic groups. While several characteristics of FNBP4 were discovered through bioinformatics, there are numerous other properties of this protein is yet to be discovered. This protein is mostly reported to be a part of eukaryotic multi-protein interaction network. So discovery of its interaction network will prove to be very significant and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CC, especially the use of bio-inspired algorithms can play important role in this aspect. On the other hand FNBP4 being a large protein (average length of 800-1100 amino acids) (Das et al., 2014) would prove to be significantly challenging to determine its structure. Molecular modeling using rough sets data, especially using only amino acids, with the help of optimization algorithms also seems to be highly promising to address this problem. Thus it can be envisioned that implementation and opportunities of CC are far beyond than currently applied.

FUTURE CHALLENGES OF CELLULAR COMPUTING

Characteristics of CC lie in the interplay between the properties of the model and its implementation potentials. On should consider both of these aspects when trying to implement CC to solve some problem. Otherwise, which is often the case; the limitations of the underlying model would have serious effects on its implementations.

While simulations, mainly software based simulations have played the major role among experiments with CC, the ultimate challenge is to develop and successfully build a system which is based on several properties of CC. As highlighted by D. Hillis (Hillis, 1985), the major advantage of CC is the extreme lower level of connectivity which significantly lowers the number and cumulative bus(s) length and bus associated delay.

On the other hand one important fact that should always be kept in mind that biological systems or cells are a continuous system. Till date artificially inducing life in to biological components has not been achieved i.e. if all the components of a cell are assembled together, they do not necessary start to function as a living cell. A living cell can only originate from a living cell and continue to perform in similar manner till its underlying biochemical pathways continue to function in a coordinated manner. Once this coordination is lost, there is no way to get it back. Although the several advantages of a cell that we have discussing throughout this chapter, this limitation is still one of the biggest hurdle to overcome by scientists. Synthetic biology, with inputs provided by systems biology and CC models should, should apply greater focus in crossing this hurdle, at least for a unicellular or simple bacterial cells.

As highlighted in Figure 3, both arms of CC should work hand to hand and in synchronization with data provided by experimental biology as well as systems biology. While development and optimization of bio-inspired algorithms are dependent on training data set provided by classical biological observations, simulated executions can provide significant information for experimental biologists which in turn results in faster achievements of results and increased saving of time and physical resources. The field of bioinformatics is playing a greater role now a day. Several tools and techniques that are routinely employed in the field of bioinformatics rely on EA or similar algorithms for optimization purposes. Modeling of disease networks are increasingly helping in computer aided drug discovery (CADD) and over the last few decades several drugs have been designed based on inputs gained from CADD related studies. Not only drug design, molecular dynamics simulations are gaining more and more acceptance among biologists to gain detailed time to timer information about protein-protein interactions, protein-DNA and protein-small molecule interactions. Several biological interactions are explored with deeper insights (Das et al., 2013, 2015a, 2015b) with the help of bioinformatics.

It is very important to realize that CC is not an isolated approach with two aims – i) development of bio-inspired algorithms and ii) engineering of cells. Rather CC should be view as an integrated development platform which incorporates the power of computer science, experimental biology, systems biology,

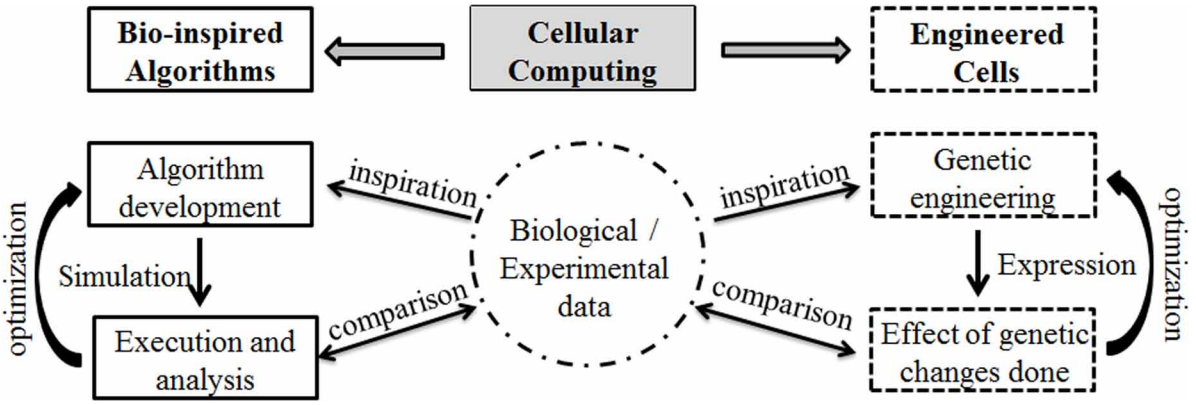
Figure 3. Schematic diagram showing the ways biological (experimental) data is used for the purpose of cellular computing, both for algorithm development and engineered cells
First of all inspirations are drawn from biological data (both traditionally known facts and experimentally obtained) for either algorithm development (in case of bio-inspired algorithms) or genetic engineering (engineered cells). Thereafter they are either simulated or expressed, depending upon the type, and the output is compared with the already known biological data. Based on the comparison of expected output, known data and achieved output, further optimizations are undertaken.



bioinformatics and computational biology in order to achieve greater benefit to the entire society. While such combined approach will provide the power the digital computer to solve biological challenges with the use of efficient algorithms, it will also help to reach computer beyond the limitations of von Neumann architecture and Moore's law (Kish, 2002; Moore, 1965; Sipper, 1999).

CONCLUSION

Simplicity, Parallelization and locality are the three main principle of CC (Figure 4). Combined with the in-built robustness (presence of only YES/NO type of outcome) and scalability (due to the absence of any central processor with which every node is required to be connected in a traditional computer system and presence of individual homogeneous nodes), implementation is fairly simple. Here comes the biggest question about areas of implementation i.e. the challenges where CC possesses inherent advantages compared to the traditional silicon chips. It can be tempting to envision biological entities performing standard mathematical or statistical calculations or bio-macromolecules storing data, but it should be noted that these are the primary targets or aims of molecular and quantum computing where an inspirational level of success have already been achieved. However specifically with CC, achievement of certain other sets of goals seems more logical and could potentially cater the urgent need of present day human civilization. Thus the aims or CC or the areas of implementation of CC can be broadly classified to three groups – A) Exploitation of inherent or embedded computing capabilities of a cell for diagnostic or therapeutic purposes, B) Using biological entities for advanced sensing purposes and thereby facilitating early or on time estimation or detection of probable or up-coming or ongoing changes, especially the ones associated with environment, C) breaking barriers of complexity and technological limits associated with silicon chips to develop advanced and efficient (energy and other costs) systems.

KEY TERMS AND DEFINITIONS

Bio-Inspired Algorithms: Computational algorithms which has been designed and optimized with inputs from the behavior of biological systems like an ant or bee colony or biological entities like a cell or neuron. Example: artificial neural network, genetic algorithm, membrane computing etc.

Cell: A cell is an independently sustainable and self-replicating unit of any organism. For multi-cellular organisms, a cell also serves as the structural and functional unit. Cells bear the capability of responding to surrounding environment through logical outputs of the received external or internal signals.

Central Dogma: The flow of genetic information, coded in DNA, to proteins via RNA is termed as the central dogma of molecular biology. It is mainly composed of two processes i.e. transcription which synthesizes RNA from DNA and translation which converts the RNA encoded message into a string of amino acids that subsequently folds in to a protein.

Genetic Engineering: A field of molecular biology that deals with purposeful manipulation of an organisms (or cells) native genetic content for the gain or deletion of certain traits through addition of foreign DNA material or deletion of certain portion of native DNA.

Modeling of Biological Systems: A part of systems biology that deals with the computational modeling of biological systems or pathways like signaling cascade, metabolic network, disease network etc. The main purpose of such modeling is simulated replications of biological phenomena for ease of understanding in the event of deviations of certain parameters from natural values and prediction of their possible impact.

Molecular Computation: The use of biological macro-molecules like DNA or proteins (like enzymes) for the purpose of computation like calculations, storing, analyses or processing of data is known as molecular computation or bio-molecular computation.

Natural Computing: Natural computing is an interdisciplinary arena that primarily encompasses computer science and biology along with indirect association with all other possible scientific fields.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Natural computing primarily encompasses three major areas – A) Development and optimizations of computational algorithms with inspirations from nature, mainly biological systems, B) Computation modeling of biological systems or pathways and C) Use of biological entities like cells for the purpose of computation.

Parallel Computing: A type of computation which facilitates simultaneous execution of different tasks which are primarily sub-tasks of a larger task. The main aim of parallel computing is improvement of total execution time by distributing parts of a task to separate computing nodes or cores from a single such computing unit.

Systems Biology: A biology centered interdisciplinary field of study that focuses on systemic study (holistic approach) of complex interactions of biological systems. With insights gained from experimental biology, systems biology incorporates computational and mathematical (with some statistical inputs) modeling and simulation techniques and tools for a comprehensive and quantitative analysis of biological interactions.

ABSTRACT

Cytopathology is a popular discipline since George Papanicolaou proposed the famous test pap about 60 years ago. Today modern cytopathology laboratories still use the microscope as the primary diagnostic device and additionally they host modalities performing medical tests and exchange data via networks and have imaging systems producing pictures and virtual slides; the volume of produced data nowadays is enormous. Simultaneously mobile phones and tablets have evolved; their capabilities compete desktop computers and have the advantage of being always connected and at the side of users. Despite there are rather limited applications relevant to cytopathology for the mobile device, there is potential for uses in numerous activities of the cytopathology laboratory, including and not limited to: training, reporting, diagnosis and consultation, laboratory management, whole slide imaging, interactions between patient-doctor, doctor-doctor and within the laboratory personnel, quality control and assurance. Mobile devices can offer important benefits to the modern cytopathology laboratory.

INTRODUCTION

Mobile Health (mHealth) is the practice of medicine and public health supported by mobile devices. The use of mobile computing and communication devices, such as mobile phones, tablet computers and personal digital assistants (PDAs), by health professionals, is nowadays rapidly growing. The mHealth applications are mainly used for collecting community and clinical health data, delivery of healthcare information, real-time monitoring of patient vital signs, and direct healthcare provisioning. In more detail, handheld computing has applications such as ambulatory medicine (K. Banitsas et al., 2005; K. A. Banitsas et al., 2006; Kiselev et al., 2012; Pavlopoulos et al., 1998; Rosales Saurer et al., 2009; Zerth et al., 2012), diabetes management (Quinn et al., 2011; Ribu et al., 2013; Skrovseth et al., 2012; Spat et al., 2013), asthma management (Finkelstein et al., 1998; Gupta et al., 2011), control of obesity (Patrick et al., 2009), smoking control (Ghorai et al., 2014; Ybarra et al., 2014), seizure management (Pandher et al., 2014), stress management (Clarke et al., 2014) and treatment of depression (Burns et al., 2011) among others. In the field of mHealth the majority of applications are for fitness (43%) followed by health resource (15.0%) and diet/caloric intake (14.3%,), while the user angagement has the form of self-monitoring and training (74.8%) (Sama et al., 2014); in contrast, despite there are applications targeting patinets, currently, there are rather limited applications targeting physicians and doctor-patient interactions (T. Martin, 2012). Pioneering field seems to be radiology consultation for X-rays and mostly Computer Tomography (Choudhri et al., 2012; Choudhri et al., 2013; Johnson et al., 2012; Toomey et al., 2010) and ECG transmission (Vaisanen et al., 2003). The applications are very limited in the fields of pathology and even less in cytopathology despite both specialties deal with images. In relation to pathology, the most reported uses of handhelds, are limited to experimental endeavors in education and telemedicine (Park et al., 2012). For cytopathology, even after a thorough search, there were not found published articles or reports. However, pathology and cytopathology share many common characteristics. Actually, in most countries, cytopathology is considered as a subspecialty of pathology. Thus concepts and ideas can be useful to both specialties; therefore applications can be transferred from one domain to the other.

Cytopathology is a medical sector/discipline that gained popularity when George Papanicolaou proposed the famous test Papanicolaou (known as Pap Test), about 60 years ago. Nowadays Pap Test is the most valuable tool for cervical cancer screening and prevention. Therefore, it is the reason that cytopathology is so popular. Additionally, cytopathology has the advantage of obtaining biological material using minimally invasive or not invasive at all methods. Cytopathology is a discipline that the diagnosis is mainly based on the examination of cells via the microscope, histopathology (or pathology) does the same; however using complete tissues (obtained via biopsy). The routine cytological examinations are performed, since the invention of the microscope, via the utilization of a glass slide and subsequent visual analysis. Today, the modern cytopathology laboratory is continuously changing. Nowadays, cytopathology laboratories perform additional examinations based on molecular techniques and immunocytochemistry methods. The modern cytopathology laboratory is equipped with a lot of modalities, these are capable of performing medical tests, as well as to exchange data via networks, there are available as well imaging systems, capable to create digital pictures of the slides or even virtual slides, which are complete slides in electronic format. The volume of data, in a cytopathology laboratory, nowadays is enormous; there are many applications that are available, and others that can be envisioned for the benefit of cytopathologists and the patients. The recent advances in handheld hardware and software; in parallel, with concurrent advances in whole slide imaging (WSI) and cloud computing, offer new opportunities

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and challenges for cytopathology. Cloud computing (one of the foundations required for mHealth) has already been proposed as a useful platform for modern cytopathology (Pouliakis et al., 2014a) as well as in other medical laboratories (Pouliakis et al., 2014d).

In this chapter we address the current state of the art in handheld hardware and software, provide the history of handheld devices, with special focus on pathology and cytopathology, and present use cases that have the potential to be future applications. Various aspects of the modern cytopathology laboratory are analyzed as well, we present a thorough research of mobile applications, related to cytopathology and try to foresee applications, that, if enhanced with mobility and are available on mobile devices, they may provide an important benefit to the modern cytopathology laboratory, as well as to the patients. Wherever possible, we propose new mobile applications, having the potential to enhance the routine of the laboratory. Finally we highlight issues, controversies and problems and try to propose solutions and recommendations.

BACKGROUND

In a two year old research (Park et al., 2012), an exhaustive search in PubMed revealed more than 6,500 articles on the topic of handheld computing, publication dates were from 1983. Of those, 55% were related to the usage of handhelds in medicine, rather than health risks caused by handheld devices (for example risk of cancer from radiation, likelihood of automobile accidents or electromagnetic interference in hospital devices). The vast majority of articles were published in the last decade; for instance, two articles were published in the year of 1983, compared to 61 articles in October 2011 alone (Park et al., 2012). A PubMed search for the terms cytology and handheld revealed 31 articles of which most are on miniaturized devices (for example mobile Flow Cytometer). However, only nine articles in the entire medical literature that deal directly with handheld computing in pathology there were found, ranging in publication date from 2004 to 2015. Based on the available literature, some conclusions may be extracted. Almost half of the scientific articles deal with static telepathology using mobile phone cameras, but there is only one paper that discusses whole slide imaging and about 25% of the articles deal with medical education. Despite not reported in the scientific medical literature, there are other innovative uses of handhelds in pathology. Nowadays, several reference laboratories, offer handheld applications that their clients can use to order tests and receive the results. There are available applications, that exploit the built-in phone camera, such as taking photographs through the eyepiece or interface a phone with a microscope directly (Breslauer et al., 2009). Concluding, the scientific literature, related to mobile pathology and cytopathology can be considered rather poor.

Perhaps there are multiple possible reasons for this. Pathology, despite not being the sole medical specialty in need to manipulate data and/or images, it is unique in the scale of data that must handle. It is considered that over 70% of the data in a typical electronic medical record are generated within the clinical pathology laboratory (Pantanowitz et al., 2007). In anatomic pathology, a Whole Slide Image (WSI) can easily be in the range of gigabytes in size, even when heavy compression with losses is applied (Pouliakis et al., 2014a); comparing this to radiology, being a medical specialty with heavy use of images as well, in which it is rather rare for a digital image to be more than a few hundred megabytes in size. In addition, radiologists work primarily on grayscale images (8-bit and now 12 or 16 bits when measurements are required) with resolutions in the thousands of pixels, pathologists work with color (24-32 bit, which, simply triples the amount of data). In pathology the resolution of images in the range

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of tens to hundreds of thousands of pixels. This dictates the need for a large amount of computational power, high-quality and high-resolution screens with large bit depth (aka color range), and fast network access (sometimes with metropolitan or global aspects and not just for within building communications). All these characteristics, which were not available in handheld (and sometimes not even on desktop) computers until very recently, were a barrier to the adoption of electronic data interchange in pathology and even worst in mobile pathology and cytopathology. Nowadays as the characteristics of mobile devices have changed, it seems that it is the time for mobile pathology (and cytopathology).

Mobile telephony is now more than 20 years in use; the recent advances, in the last decade, have contributed to the conversion of the mobile telephones into smart telephones; due to the sophisticated operating systems. Especially, during the last five years, there became available hardware components enriching mobile phones: more processing power (4 or 8 processors), high definition cameras (more than 10Mpixel nowadays) and large displays resolutions (nowadays more than 1500x2500). Moreover, the 4G and WiFi connectivity have created an always open, rather inexpensive, communication channel with the Internet. Today, there is no more the trend to shrink the telephone, in contrast, mobile phones are becoming larger and compete tablets in terms of size and weight, they are easy to use and have capabilities similar to computers available five years ago. It seems that the mobile devices have now the maturity of computers being used in health sector five years ago and are ready to be adopted. Some of the characteristics of mobile devices (most of them not relevant to the desktop computers) are summarized below:

- Battery with capacity lasting for days
- CPU with processing power competing desktop and laptops if we consider that users rarely use the full processing power
- Excellent graphics capabilities
- Processor memory in the range of gigabytes
- Flash memory for storage in the range of hundreds of Gigabytes
- Embedded GPS chips to allow global positioning
- 3G and 4G connectivity
- WiFi connectivity (150Mbit) competing standard (1,000 Mbit) LAN connectivity if we consider that LAN connectivity is shared as well
- Bluetooth connectivity for the creation of personal area networks
- USB connectivity for coupling the device to other devices
- Accelerometer
- Gyroscope
- Compass
- Thermometer
- One or more high-resolution cameras
- Large displays of high resolution
- Capacitive touch screen allowing a rich user interaction
- Connectors to interface with displays on high-end models

MOBILE CYTOPATHOLOGY

Over the last years, new types of cameras and microscopes, connected to computers made possible cytological image capture and transmission, named as telecytology (Archondakis et al., 2009; Pantanowitz et al., 2009; Pinco et al., 2009). The wide implementation of telemedical systems in this field became a necessity dictated by the need of real-time results for therapeutic decisions (Briscoe et al., 2000; Jialdasani et al., 2006; Mun et al., 1995; Raab et al., 1996; Weinstein et al., 1997; Yamashiro et al., 2004) as well as physician training (Stergiou et al., 2009). However, telediagnosis and training are not the sole applications relevant to cytopathology. other applications, include but are not limited to the everyday routine tasks of the modern laboratory, specifically there are interesting applications for results reporting, day to day laboratory management, Whole Slide Imaging (WSI), various interactions between patient and doctor, doctor to doctor and between members of the same laboratory, finally there are applications relevant to quality control and assurance. In the sequel we analyse the available applications and try wherever possible pinpoint potential applications.

Mobile Applications Related to Teaching

In 2006, a group of reasearchers, reported on the use of mobile phone cameras as a method of remote teaching in undergraduate pathology education (Sharma et al., 2006). Specifically, they noticed that students possessed photographs of nearly all the typical specimens they may encounter during examinations; these photos were considered by the departmental authorities harmless and similar to note-taking. Thus, they triggered a decission of the instutute to allow the mobile device during examinations, to be used as an aid to memory.

Five years later, another researcher (Collins, 2011), reported on the usage of iPads for the online distribution of digital textbooks for cytopathology. The application was based on the epub 3.0 standard, which facilitates the creation of electronic books (e-books). The author of the application used the Adobe InDesign CS5 software, designed and created an electronic book with text and images; these were possible to be accessed from a variety of different mobile platforms. The major benefits of this cytopathology e-book was the searchable content, the interactive text and references with high resolution cytopathology photomicrographs, the capability to bookmark a page for future reference after exiting, video embedding to have a multimedia rich content, instant access to medical references with a single touch of a finger. Additionally, images as well as the relevant text; could be viewed on stand-alone in full screen because the iPad could be connected to a larger, external HDTV screen. In this setting the zoom function of the iPad permitted detailed examination of image details. Moreover, content could be copied, pasted, printed, and emailed. The 64 GB capacity up the mobile device was considered as ample storage space for such applications. Nowadays, the cloud based storage and the always connected capability provides virtually unlimited storage.

Modern browsers, installed in the mobile phones today, are not proprietary anymore, in contrast they are identical to the browser installed on desktop PCs. This means that there is no need anymore, to develop web applications, specifically for the mobile device. Moreover, any advances in the usage of Web 2.0 technologies, in cytopathology related material, will be directly available to the mobile phones as well. Furthermore, handhelds today integrate numerous connectivity subsystems and surprisinglly relational databases, thus, there is the embedded capability to the handheld allowing its use both as server and client. Especially, in developing countries, and during disasters, the mobile devices have proved their

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

usefulness, mainlly because the tablets have a form factor and size similar to printed books. In 2004, another group of researchers (Ng et al., 2004), published a paper on using Internet search engines to find high-quality reference material for oral and maxillofacial pathology, and then caching this material on a PDA, nowadays caching is not a necessity as the mobile device is always connected.

Teaching applications on the mobile device, are not only for reasearch purposes. Since 2011, there are several commercial applications being placed online, the including handbooks (Elsevier, 2015), atlases, see for example the Johns Hopkins Atlas of Pancreatic Cytopathology (Meszaros, 2014) as well as the majority of cytopathology related scientific journals. Despite all these applications were designed taking to account the special characteristics of the mobile device, the modern mobile phone browsers, have turned all those pioneering efforts almost obsolete, this is because any web page can today be viewed by the mobile phone browser and the high resolution of the screen facilitates this to some degree.

Mobile Applications for Reporting the Results of the Cytopathology Laboratory

Cytopathologists and pathologists have to learn not only to formulate their diagnosis based on cellular/tissue features, but also how to communicate the results in a report being clinically useful. Indeed, even the choice of the appropriate reporting format may have consequences on patient treatment (Crowe et al., 2011; Hirsch et al., 2015). It is frequent, that medical reports produced in laboratories, do not contain all information required for clinicians, thus they are not guided towards a good choice. Moreover, these reports may be formulated inappropriately. A group of researchers (Skeate et al., 2007) in 2007, created a software environment, and subsequently reported the usage of knowledge bases on PDAs. Their main outcome was that PDAs can enhance resident learning and pathology report completion as well. Despite their application falls within the pathology discipline, similar outcomes are expected for cytopathology, because reporting for both disciplines has similar complexity. Their experimental setting included ReportSupport, a software system operational on PDAs. ReportSupport was a navigable document, developed in the Hyper Text Mark-Up Language (HTML) using Macromedia's Dreamweaver 4, and viewed using the device browser. Users log into the knowledge base, an introduction follows and subsequentlly instructions, then they can search for the diagnosis of interest (alphabetically or via first choosing the relevant organ systems), after this users receive a list of diagnoses in that system. The user chooses the appropriate diagnosis, and the device presents the elements required for a report to be considered complete. If the user clicks on an individual component, a description of how to determine, the value of that element is presented.

As it is based on HTML, ReportSupport could be provided in desktops as well. Indeed, since 2007 ReportSupport is available on the network as well. However, the investigators preferred storage of the application within the PDA because desktop computers were not always available in slide examination places and PDAs mobile connectivity was not always feasible that time. Nowadays this is not anymore an issue. The evaluation of the system, was based on an experiment involving two groups or residents; one group used the ReportSupport system, while the second did not. The performance of the first group on results reporting was evaluated three times: T0: before the availability of ReportSupport, T1: when the users had access to ReportSupport, T2: after T1 but the users did not had access to ReportSupport. The results indicated that use of the knowledgebase does not ensure report completeness, however, it was associated with complete reports and more accurate judgments of report completeness. Additionally, this performance persisted in the absence of the knowledgebase. Concluding the use of the mobile devices prooved to be a usefull tool for user training and guided towards better reporting.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As the massive volume of cytopathology reports is related to cervical cancer prevention (via Pap Test), it is worth looking at the use of the mobile device from a gynecologist. A very recent study (S. J. Martin et al., 2015), had the purpose to assess the baseline knowledge held by training and practicing gynecologists and obstetricians on mobile applications in their field of practice. The researchers developed an electronic questionnaire to be filled by residents at selected academic institutions. According to the responses analysis, more than 80% of practitioners were using mobile phone applications in their practice. The primary use was "physician and student reference." The predominant applications used were those for cervical cytology guidelines and obstetric wheels. According to the responses, more than 80% of health care providers would like to have more applications available for use. This study proved that the use of mobile applications for gynaecologists is an expanding technology. Health care providers may choose to implement these applications into clinical practice, however it is more important to promote these applications in such a way that physicians have increased awareness. Finally the authors reported that these new technologies may be a benefit and advancement in gynecology and obstetrics both for health services provisioning as well as for medical education.

Diagnosis / Telepathology / Telecytology on the Mobile Device Using Static Images

Digital imaging in cytopathology has undergone a period of exponential growth and expansion; this was catalyzed by changes in imaging hardware and gains in computational processing. Telecytology (Della Mea et al., 2000; Markidou et al., 1999; Williams et al., 2001) is the most obvious application having the potential to be transferred directly into the mobile device. In the past, telecytology has been used for reproducibility assessment (Archondakis, 2013, 2014; Archondakis et al., 2009; Tsilalis et al., 2012), in the field of remote diagnosis there is a plethora of applications as well (Breslauer et al., 2009; Briscoe et al., 2000; Jialdasani et al., 2006; Pantanowitz et al., 2009; Pinco et al., 2009; Raab et al., 1996; Ribu et al., 2013; Spat et al., 2013; Yamashiro et al., 2004), however in all cases are used fixed computers. Nowadays there are new advances in mobile devices: first on transmission speed and second on display resolution, only these two advancements seem to allow mobile cytopathology. Applications can be extremely simple and sometimes not even requiring development of special applications, for example images may be transmitted via e-mail or uploaded on a secure web place, additionally the image viewers are already embedded into the mobile devices. Definitely there are benefits for the health sector as mobile telecytology can be a valuable tool for medical doctors, in order to manage and promote interlaboratory collaboration mainly because it allows better cytological via instant data assessment and sharing.

In the similar field of histopathology, in 2009, two independent groups (Bellina et al., 2009; McLean et al., 2009) reported on the usage of mobile phone cameras, these were used to take static digital microscopy images through the objective lens of a microscope, subsequently those images were used for telepathology. In a more specialized field, namely teledermatopathology there are numerous applications (Borve et al., 2013; Chao et al., 2013; Janda et al., 2014; Manahan et al., 2015; Massone et al., 2009; Massone et al., 2010; Wu et al., 2015), these are based on the usage of mobile phones as tools to take static dermatoscopic images and to send them for teledermatopathologic consultation. In the field of cytopathology, the image capture using the mobile phone camera, directly from the microscope is obviously a very important application.

A telemedical application is a valuable tool for cytopathologists to manage and promote interlaboratory collaboration. The result is better cytological data management and sharing, this process, in gen-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

eral, can be both user-friendly and secure. Users should be able to separate easily shared and private images, and revoke access at any time. An mHealth based application for cytopathology will be able to invite collaborators and share digital slides via email or Instant Messaging (IM). With just a few clicks, they can even embed an image in a web page for viewing. Just as easily, live users can put limitations on shared files and collaborators. Several users can review and annotate images simultaneously with digital markers, making notes immediately visible to all collaborators, and all these can be available on the mobile device.

Whole Slide Imaging using the Mobile Device

Today, digitization of entire glass slides at near the optical resolution limits of light can occur in a few minutes; additionally whole slides can be scanned in fluorescence or by multispectral imaging systems. Whole Slide Imaging (WSI) or Virtual Slides have been successfully used in surgical pathology, but its usefulness and clinical application have been limited in cytology for several reasons, mainly the lack of availability of z-axis depth focusing in cytological samples in contrast to histological have a 3D structure. However, nowadays there are available systems capable for whole slide imaging with z-axis control. This has boosted the application of digital slides for cytology (Al-Janabi et al., 2012; Fung et al., 2012; Ghaznavi et al., 2013; Gutman et al., 2013; Hipp et al., 2011; Krishnamurthy et al., 2013; Rudnisky et al., 2007; Taylor, 2011; Wright et al., 2013).

A PubMed search for whole slide imaging or digital slides reveals that there are about 200 references. However, there is no single publication that is relevant directly to cytopathology along with the use of mobile devices. The technology seems ready to support such applications and perhaps it is only a matter of timeand recruitment of appropriate resources to implement such applications.

Nowadays, there are map/navigation applications for the mobile device. For example, Google Maps, and Microsoft Bing Maps. Those applications, functionally behave extremely similar to WSI. For instance, there are used pyramidal images broken up into tiles that are served to the viewer in real-time. There are efforts using the publically available map Application Programming Interface (API) from Google and Microsoft to create WSI viewers for the desktop (Triola et al., 2011). It is obvious that this can be transferred to the mobile device as it has already happened for map/navigation. The second aspect of WSI images is depth or z-axis. This feature is required because in cytopathology doctors focus the microscope to different depths, and as mentioned earlier modern WSI systems produce multilayer scans. The capability of APIs, to present different information layers, seems compatible with this requirement. Finally, the multi-touch user interface of the mobile device screen is an additional advantage capable to provide the reach user experience.

However, WSI can be considered as just a concept. The real applications are related to the purpose that clinical doctors use WSI. Reasons for WSI include: just for archiving, for diagnosis and consultation, for providing the examination media to the patient, or just for training. Actually, there is available an application for the iPad device, this is related to the online distribution of WSIs, as teaching sets especially for countries with low resources (Fontelo et al., 2012). The study was performed via a setting that involved iPad tablet devices and fifty 3rd and 4th year medical students. There were used two web servers, providing digital pathology virtual slides via a web interface. One server was remote while the second mirrored the content on the local network. The results indicated that the speed of serving the WSIs via the local server was much faster, thus, it was preferred by the students. This study revealed the critical role of infrastructures in the acceptance of mHealth applications.

Laboratory Management Using Mobile Devices

Laboratory management operations require accurate and within time-frame transmission of critical laboratory results to the caregiver; in order to timely provide intervention and to prevent an adverse outcome. These operations are strongly linked to the provisioning of quality health services (Pouliakis et al., 2014b; Pouliakis et al., 2014c; Shen et al., 2001). Part of this process is risk management (Sciacovelli et al., 2007), either during the pre analytical phase (Vacata et al., 2007; Westbrook et al., 2008) or during sample analysis or during the post analytical phase. For this purpose, laboratories install computerized systems (Laboratory Information Systems-LIS) (Pearlman et al., 2001; Pouliakis et al., 2014b; Pouliakis et al., 2014c) to facilitate work flow and automate required actions. Mobile devices, are ideal for such applications as they are always connected and near the user. In a published study (Saw et al., 2011), the research team, reported on their experience with a setting that used SMS in reporting critical lab values. They used SMSs to notify critical laboratory results in a large teaching hospital; this application was not only to provide appropriate services; additionally it was employed to meet the documentation and audit requirements of critical result reporting, as such requirements are posed by regulatory agencies and/or ISO 15189 requirements. There was used the text messaging system (Critical Reportable Result Health care Messaging System [CRR-HMS]) that allowed a receiver to acknowledge or reject a key result by replying to a short message. When there was no response of a confirmatory receipt within 10 minutes, there were activated procedures of escalation to an alternative physician, according to a constructed roster. The benefit of this approach was that the required time for physician response was decreased from 7.3 minutes to 2 minutes. The CRR-HMS proved to be a useful tool to communicate rapidly critical results from the laboratory to targeted physicians. Eventually this enabled rapid and timely information transmission and therapeutic or patient management interventions.

Patient Doctor Interaction via the Mobile Phone or Tablet

Another aspect of mobile cytopathology is related with patient communication. Today, it is impossible to imagine people without at least one mobile device; actually in most cases this is always connected (especially in the western world as well as in developed and developing countries with high speed networks either 3G/4G or local installations of Wi-Fi). This device serves as the terminal point that patients can be informed for the availability of the cytological result (especially for the popular Papanicolaou test) or receive a reminder for a forthcoming appointment related to cytological sampling and subsequent examination. Currently, IT systems can be relatively easily interfaced and transmit automatically SMSs, e-mails or any other type notification towards the patients. For example, immediately after the cytological examination result is released from the laboratory.

Other types of interactions, between doctor and patient, are related to consulting; quite often patients have questions about their test results, especially when they are abnormal. Despite, cytopathology is a specialty that usually provides services to other medical specialties; on the other hand, in clinical cytopathology, there are patients treated directly by cytopathologists. As the examination outcomes eventually arrive at the patients' hands, they have contact information of the laboratory, if they wish to communicate with cytopathologists to be informed of the meaning of their examination outcomes from the source, rather than consulting their clinical doctor (for example the gynecologist). The mobile device is always near the patient and the physician as well. Thus it provides the media and the communication channel to interact (speak, view or message) either in real time or asynchronously.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Doctor to Doctor Interaction via the Mobile Device

In a similar manner to patient-doctor interaction; the clinical doctors collaborating with a cytopathology laboratory may receive informative messages on their mobile devices. These messages are related to the availability of a cytological examination result, requests of the laboratory for additional data that may be related to a patient under examination. Thus, mobile technology is now an open channel between cytopathology laboratories and clinical doctors.

The typical cycle of the cytopathology laboratory, starts with the sample entrance to the laboratory, along with a referral form; and ends with the production and release of the cytological report (Pouliakis et al., 2014b). Relatively old fashioned cytopathology laboratories, produce reports printed on paper, and more advanced laboratories produce electronic reports that are distributed either via sending them using secure e-mail applications or by inviting the requesting physician to login into their account and retrieve them from a safe place (usually web based). The smartphone, embeds all the capabilities to receive SMSs or emails, so that the clinical doctor is immediately informed, in order to retrieve report information.

Similarly to the patient – doctor interactions mentioned in the previous section, clinicians have numerous options to consult cytopathologists for explanatory details on the results. The most popular applications used by gynecologists are related to the interpretation of Papapnicolaou test results; thus those interactions between gynecologists and cytopathologists seem to be of the most interest. Of course, it is not only gynecologists that request services from the modern cytopathology laboratory, the vast majority of available medical specialties requests examinations from the cytopathology laboratory as well, therefore the groups of users are very large.

Use of the Mobile Device for Interaction of Personnel within the Laboratory Environment

The third aspect related to mobile communications; is the exchange of information among the cytopathology laboratory personnel. Such communication involves the doctors' requests for ancillary examinations, urgent examinations or requests to repeat an examination. Nowadays those requests are either verbal/written or in the case that the laboratory is equipped by a LIS, they are available via fixed workstations. Mobile cytopathology seems to be an attractive technology having the potential to streamline everyday routine. Laboratory personnel can be independent from computers located in fixed physical locations. In contrast, a single mobile device adapted to their preferences, a personal mobile phone, or a mobile phone provided by the laboratory, can serve this purpose. The main reason is that users do not favor to carry on and take care of more than one devices. Additionally modern devices capable to have more than one communication channels (i.e. SIM cards) can serve both private and job related tasks. The mobile device is now configurable, thus can be optimized for user personal needs/tasks, and preferences and is available on every different work location. mHealth technology, when integrated into the daily workflow, can provide exceptional consultation opportunities to distant laboratories. mHealth technology innovations can improve the professional skills of the participating medical staff and make them feel more confident in their daily work.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Mobile Device for Quality Control and Assurance

ISO 15189:2012 for medical laboratories requires successful participation in proficiency testing programs. According to the requirements of this standard, one of the greatest challenges facing cytopathology laboratories today is the design and implementation of a board certified external quality assessment (EQA) program (proficiency testing). The purpose of the adopted program aims to ensure that microscopic (cytological) findings are correctly identified and interpreted by laboratory personnel, additionally they are stored and communicated properly (Archondakis, 2013, 2014; Friedman et al., 2006; Lee et al., 2003; Nagy et al., 2006; Vooijs et al., 1998). Nowadays EQA schemes are available as telecytological applications, for example virtual slides are stored on web sites, cytopathologists of the laboratory under certification, use their computers to remotely diagnose these virtual slides. To our opinion those applications can be easily transferred on mobile devices, thus facilitating immediate quality control and collaboration. More details on the use of mobile devices for quality control in cytopathology laboratories can be found in chapter entitled: "The Use of Mobile Health Applications for Quality Control and Accreditation Purposes in a Cytopathology Laboratory." within this book.

ISSUES, CONTROVERSIES AND PROBLEMS

As in all cases of emerging technologies, the early adopters encounter not foreseen problems. In the field of mobile cytopathology there may be numerous issues and problems.

When considering the use of WSI on a smartphone (Park et al., 2012); a major issue is that smartphone screens are small, which means physically small, because nowadays resolution of the mobile phone competes and sometimes is higher than desktop screens. The small physical size, is a requirement of the role of the device as a telephone, and thus it is not likely that future smartphones will have large enough displays (if they do then they will be no more telephones but rather tablets). A physically large display, however, is valuable and probably a requirement for viewing and interpreting a whole slide image. Screen size is not the sole issue, a second problem related to WSI and smartphones is the vendor specificity file/data formats, and these impede universal viewing in handheld devices and desktops as well. The slide scanner manufacturers use different and proprietary file formats for their whole slide images, mainly because the software that can interpret this proprietary format is the line of business for each manufacturer and a common standard is not agreed. Like in other business types cooperation among vendors is required for the benefit of the customer. Additionally, the fragmentation induced by all these proprietary formats, complicates any effort to create universal software for remote viewing of whole-slide images, especially from smartphones. Today, there are various efforts to create pathology-centric image viewers for handhelds, however, these are vendor specific (Leica Microsystems, 2011). The third issue related to WSI is related to the virtual slide size, this is enormous, ranging from more than tenths and thousands of mega bytes and up to Giga bytes, depending on the magnification, the scanned slide area and z-axis information. The large file size of WSIs seems to pose requirements for fast communication channels and device memory.

When dealing with applications on the mobile device there are numerous issues that may arise: protected patient data is stored remotely and is sent and received through the air. This makes the data vulnerable to security issues such as computer virus threats and hacker attacks. Additionally mHealth is expected to enhance usage of services related to cytopathology laboratories, thus more and more data

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

are expected to be produced. This large volume of data, especially when considering WSI, requires large storage, secured, expandable and safeguarded from failures. Similarly servers and networks require procedures to handle not only increased the load but failures as well.

SOLUTIONS AND RECOMMENDATIONS

Considering WSI on the mobile device, three issues have been identified: screen size (not resolution), proprietary formats and large file sizes. One solution to screen size could be the creation of smartphones that the screen can be expanded if needed, i.e. flexible screens. Actually there is already available a prototype by Sony announced in 2010 (SONY, 2010). This screen is so thin and flexible that can be rolled around a pencil. If smartphones with such types of screens may become widely available or the screen can be interfaced as a gadget, then, they would solve the problem of small screen size for WSI. A second solution could be the use of projectors with very small size, and thus the digital slide may be presented on the wall. Alternatively, a solution may be provided by the embedded connectors available on modern smart phones, specifically miniature HDMI connectors, that can be used to leverage a nearby large screen. As large screens are nowadays a consumer item, and available in large volumes in relatively low prices, they are available in many places, it seems that is a matter of development of the workflow and software that allows use of nearby displays from smartphones, even wirelessly.

The second issue related to WSI and smartphones; is the multitude of incompatible WSI image formats. Nowdays there is available a vendor neutral open source software library for WSI called OpenSlide (Goode A, 2008); this software library is available for desktop computers, but, porting to the mobile platform does not seem to be very difficult. Because OpenSlide is designed and implemented as a device driver, which can be found in all operating systems; it exploits vendor specific code and device resources of any type (at least this is the way expected to operate). OpenSlide supports remote viewing over the Internet as well and because the implementation is based on bindings with the OpenSeaDragon viewer (OpenSlide, 2015b) it is expected to be operational on the mobile platform as well, note that nowadays, whole slide images can be viewed over a 3G network on the smartphone browser at the OpenSlide demo site (OpenSlide, 2015a).

The third issue of WSI and the mobile device was related to the enormous image sizes. In terms of storage space, the cloud is the solution, as can provide an affordable storage space, easily expandable and moreover offers data storage assurance. Additionally no local maintenance by laboratory technicians is required. Transfer of such data volumes from/to the server towards the mobile device is an issue. However, the revolution in telecommunication networks may provide the required bandwidth. Alternatively, it is possible to transfer to the mobile device only the virtual slide parts related to the viewing fields, and the required resolution, the concept of tiles and pyramidal image formats along with multiple layers, as is the solution to reduce the volume of data required to be transmitted, ultimately viewing WSI on the mobile device may be similar to navigation application using satellite photographs, as it is already available nowadays.

In relation to the data and security issues raised by exposing data in the wireless networks as well as by exposing databases and servers in the edge of the networks, solutions may be proposed. Cloud computing, definitely is the choice (Pouliakis et al., 2014a; Pouliakis et al., 2014d) . Solutions are summarized as follows:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Threats of data security and privacy: may be anticipated by data encryption during storage and transfer and connecting with the server via encryption protocols, or via more enhanced methods proposed for the cloud environment, such as multi-cloud approach with a key sharing mechanism (Mouli et al., 2013) or patient identification cross reference numbers (Kondoh et al., 2013).
- Unauthorized access: may be anticipated by passwords and password control mechanisms and via mandatory biometric checks; note than nowadays mobile devices have the capacity for biometric security such as fingerprint recognition.
- Database safety and long-term archival: can be secured by passing this responsibility to Cloud computing service providers, in more detail:
    - Server failures may be avoided by maintaining mirror servers and/or load/ balncing
    - Efficiency of service, related to broadband speed may be ensured by multiple communication lines connected with multiple Internet service providers, thus preventing disruption of service can be assured.
    - Increased load can be easily minimized by adding more processing power to existing virtual servers and/or by splitting the application to run on multiple servers, either via load balancing or by the exploitation of multi-tier architectures and splitting to one or more separate application servers and database servers.

CONCLUSION

We have reached a point where both the software and the hardware of the mobile device platforms have matured and are powerful to be leveraged in cytopathology. The main advantage of implementing mHealth technology is that it gives all patients equal access to medical services, despite the fact that certain regions are more remote than others. This is especially important when it comes to specialists and other services usually inaccessible outside of large urban centers. mHealth technology also allows immediate collaboration among medical professionals.

Perhaps the most elegant and technically challenging application is mobile WSI. However, this does not seem to be the most used application, more demand appears to be on simple services, such as notifications, result transmission, education and perhaps laboratory management and the interactions.

One of the major benefits of the mobile platform is that provides capabilities irrelevant of time and place. The first (*freedom from time*) is delivered via the use of asynchronous communication channels: e-mail, SMSs, voice and even video mail. Simultaneously it is always possible to have a synchronous communication. The second (*freedom from place*) is related to the fact that the mobile device is personal, always on, always connected and available in every place. Therefore, there is no need for people involved in the cytopathology ecosystem to be at specific places to perform any related task.

Despite there are some security and privacy risks, that modern technology seems to have already resolved via the help of cloud computing, mHealth technology has some major benefits that the public sector and government IT organizations are would like to take advantage of.

In a very brief summary, they are as follows:

- Reduced cost (mainly for the devices)
- Flexibility: mHealth technology offers much more flexibility than past computing methods

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Mobility, employees can access information wherever they are, rather than having to remain at their desks

Work on handheld and mobile computing in cytopathology is scarce today. However, there is a great potential for new applications. Mobile hardware has nowadays become increasingly ubiquitous, reliable and fast via new devices with extremely high resolution, multicore processors, gigabytes of CPU memory and storage and multiple high-speed connectivity alternatives. Software support on such devices is comparable to that of desktop computing. However, handheld technology creates opportunities as well as challenges. Nowadays there are clear niches as well as several experimental successes with handhelds in cytopathology (especially for education purposes, telecytology, and care delivery via various communication interactions); however more study and development of standards for practicing and guidelines for validation are required. In addition, there are still questions related to security. Even so, it is likely that mobile computing will play a large role in cytopathology in the forthcoming digital decade. mHealth seems to have the potential to change the picture of future cytopathology and pathology.

KEY TERMS AND DEFINITIONS

Cytopathology: A specialty of medicine related to the study and diagnosis of diseases by the examination of cells.

E-Health: Is the healthcare supported by electronics, informatics and tele-communications.

E-Learning: Is a broad concept referring to the application of information and communication technologies (ICT) for learning purposes.

Laboratory Information System (LIS): Or Laboratory Information Management System (LIMS) is a software-based system for the support of operations in a modern laboratory, such as workflow, sample tracking, data exchange interfaces. LIS systems are often capable to be connected with medical analyzers for automated extraction and storage of measurements.

Mobile Health (mHealth): The practice of medicine and public health supported by mobile devices.

Quality Control: The set of processes by which entities review the quality of all factors involved in product, service or activity. During QC processes, the products, services and activities are tested or validated in order to reveal defects and problems, before their release.

Telecytology: The application of cytopathology from distance.

Telediagnosis: Is the determination of a disease at a site remote from the patient based on transmitted data.

Virtual Slide: or Whole Slide Imaging, a virtual slide is created when a glass slide is entirely scanned digitally.

Chapter 97
Examining the Influence of Information Technology on Modern Health Care

Edward T. Chen
University of Massachusetts, Lowell, USA

ABSTRACT

Health care costs continue to rise at a level that far exceeds the rate of inflation. IT will be necessary in the computation and organization of complex algorithms presented in bundled payments and other initiatives. Currently in health care, a patient's medical history is not easily accessible by physicians and other medical personnel. IT can play the pivotal role in rectifying this problem in tracking the record in a universally designed environment. Advanced databases are needed to integrate facilities within health care systems. This chapter is to explore the current framework of Information Technology in the U.S. health care industry and to examine the topic covering the following areas: (a) IT's influence on the Affordable Care Act, (b) the emergence of the Electronic Health Record (EHR), also known as the Electronic Medical Record (EMR), and (c) the integration of databases across health care organizations through advanced systems like Epic.

INTRODUCTION

The road to change in the health care industry is being paved currently by Health Care Reform. More specifically, the framework of the Patient Protection and Affordable Care Act (PPACA) has held stakeholders in the health care industry accountable for implementing IT modification within their organizations, government bodies, and society as a whole. Health care has an abundance of concentrations, all of which require some form of information technology resource in order for these bodies to achieve the highest service quality of patient care (Rosenbaum, & Margulies, 2011). The purpose of this chapter paper is to explore numerous avenues in the field of health care and to examine the impact that IT has on the U.S. health care industry.

The advancement of information technology in health care is pivotal to the guidelines set in the Patient Protection and Affordable Care Act. As health care organizations have become clinically data driven, the need for information systems and IT is imperative (Vo & Bhaskar, 2012). Analysts in IT departments at hospitals play the role in maintaining and implementing systems. Clinical staff members, such as nurses and physicians, play the role of end users and require the skills needed to effectively operate these systems and forms of technology in order to carry out their clinical duties (Najaftorkaman, Ghapanchi, Talaei-Khoei, & Ray, 2015). Key developments in IT include the transformation of the medical record from paper to digital, the use of mobile devices, and the emergence of integrated health care systems that have the capacity for handling the many complexities that the industry has to offer.

Equally impacted are all U.S. employers who offer health insurance to their employees and the dependents of their employees. While employers attempt to contain the trend of health insurance expense, information systems are needed to pinpoint conditions that prove to be the most costly and implement benefit redesign plans to reduce costs and promote wellness. Employers also keep their staff productive by keeping them healthy. In the same light, information systems help employees examine disease management programs that are geared towards steering employees to engage in healthy behavior and seek preventive care regularly. If health care was once described as being technically challenged when compared with other industries, that notion is being put to rest by the progression of IT in the industry (Vo & Bhaskar, 2012).

For health care to withstand the winds of change, innovation must be at the forefront of the movement. The industry has endured recent developments in IT, but new ideas and expansion in IT staff are imperative for Information Technology to continue to positively impact the health care industry. Ultimately, the goal of a health care organization should be to provide the best possible care to the patient and ensure the well-being of its surrounding community (Ku, Jones, Finnegan, Shin, & Rosenbaum, 2009).

RECENT GOVERNMENT DEVELOPMENTS ON HEALTH CARE IT

The Patient Protection and Affordable Care Act (PPACA) was signed by President Barack Obama on March 3, 2010 and upheld by Congress on June 28, 2012. The act mandates that all Americans are required to be insured with health coverage or pay a penalty to the government beginning in 2014. Another provision includes the expansion of Medicaid to adults whose incomes are at a defined rate at or below the federal poverty limit. Furthermore, the act seeks to decrease the cost of health care (Nussbaum, Tirrell, Wechsler, & Randall, 2010; Rosenbaum, & Margulies, 2011).

Exchanges have been established in the majority of the states either on their own or with the assistance of the Federal Government. The exchanges represent online marketplaces where participants can shop for health insurance plans. The exchanges also provide online resources that allow users to determine their eligibility for a federal subsidy (Carey & Appleby, 2013; Najaftorkaman, et al., 2015).

Healthcare.gov

Many organizations that offer medical insurance as an employee benefit to their staff have adopted online self-service enrollment options. Employees simply log in to an HR system, such as PeopleSoft, and enroll in coverage during their open enrollment period, as new hires, or in lieu of experiencing a qualifying event. Enrolling in coverage through an exchange works in a similar manner. A participant

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

visits Healthcare.gov or a state run exchange and then completes an online application. The system determines the eligibility for Medicaid or a subsidy from the government to offset the full price of commercial insurance coverage. The participant can then enroll in government sponsored or commercial insurance products (Ford, 2013).

Healthcare.gov was scheduled to go live on October 1, 2013 and enrollment in a plan would be effective as of January 1, 2014. However, the website failed. Visitors experienced pages that would not load and were advised through screen prompts to be patient. President Obama's administration announced that the site's issues would be resolved quickly. However, a resolution was not immediately reached and issues began to progressively grow. At this time, the site had been operating at about 43 percent. As a result of strenuous technical maintenance, the site began to operate at 90 percent but not until the beginning of December 2013 (Somashekhar & Sun, 2013).

So what happened? Experts in the field might argue that complex IT systems like the one rolled out with Healthcare.gov are prone to begin with a low level of success upon early stages of operation by end users. In a November 2013 article of *ComputerWorld* magazine, Lev Lesokhin, Senior VP at Cast Software, suggested that the complexity of Healthcare.gov could have been measured in the magnitude of the system's lines of code. Lesokhin estimated this number to be around 500,000. In the same article, author Patrick Thibodeau reports on the findings of Standish Group, a research services organization that specializes in uncovering successes and failures in IT projects. Of the 3,555 government and commercial IT projects from 2003 to 2012 in its database, Standish Group found that 52% were challenged, 41.4% were failures and only 6.4% were considered successful. Ultimately, the researchers came to the conclusion that Healthcare.gov had only a 6.4% chance of being successful. The site was destined to fail at some level (Thibodeau & Gross, 2013).

With enrollments needed to be made at the end of 2013 for a January 1, 2014 effective date, Healhcare.gov had limited time for development and testing phases. Regardless of Standish Group's findings, it is possible that developers did not have adequate time frames to complete testing phases that may have been critical in avoiding the initial failure.

IT in the Accountable Care Organization

Section 3022 of the PPACA introduces a Medicare Shared Savings Program for the Accountable Care Organization (ACO). An Accountable Care Organization is a health care provider that aims at delivering high service quality care and reducing the cost of care. In doing so, the ACO can expect to achieve an incentive in the form of shared Medicare savings (Berwick, 2011).

The ACO model depends greatly on Health Information Technology (HIT). HIT has evolved in the health care industry more and more as data becomes the centerpiece of delivering high service quality care, cost analysis and payment reform. The ACO concept links care and payment risk across multiple organizations and physicians. In order for the model to survive, data sharing will be crucial. The delivery and storage of this data is where technical resources come into play. The ACO portrays a team concept where multiple entities collaborate to achieve financial incentive while providing the best possible care. In order to do so, a patient's Electronic Health Record (EHR) must be electronically maintained and available across all clinical professionals involved. The EHR concept is at the early stages of development in health care and currently represents limited data sharing capabilities. It is evident that Accountable Care Organizations will be required to invest in IT interfaces that track the patients across the entire episode

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of care (Bitton & Filer, 2012). Clinical data is at the forefront of the ACO model. As organizations adopt the concept, they will require sophisticated IT resources to share data internally and externally with other acute and post-acute care facilities.

IT in the Patient-Centered Medical Home

The PPACA supports the establishment of the Patient Centered Medical Home (PCMH). The concept of the PCMH is that a single organization delivers comprehensive and primary care to children, youth and adults. This model intends to establish high service quality care for the patient while coordinating specialty care with supporting health care organizations in the community. The structure is such that each patient has a personal physician who leads a team of clinical staff within the PCMH. The clinical staff is responsible for providing ongoing care to the patient (U.S. Department of Health & Human Services, 2014). Ultimately, a medical home should eliminate gaps and foster care coordination that traditional primary care practices may be unable to accomplish. The PPACA supports the concept by making grants available to eligible providers that fit certain PCMH criteria (Epstein, Fiscella, Lesser, & Stange, 2010).

For medical homes to be successful, modern technology should be embraced in the patient to provider relationship. Practices benefit from data analysis and technological communication in the form of decision support systems, electronic registries, systems that facilitate the transition of care, and telehealth (Bates & Bitton, 2010; Fleurant, Kell, Love, Jenter, Volk, Zhang, Bates, & Simon, 2011).

Medical homes rely heavily on the data derived from clinical decision support systems. These are information systems that provide the data needed for clinical staff to analyze patient diagnosis, disease management, illness prevention, and treatment. Decision support systems have been found to be effective in health care organizations that utilize them as a computerized tool. Gurwitz and Wolfstadt (2008) discovered that orders guided by decision support systems were associated with a 90 percent reduction in adverse drug events. The medical home benefits greatly from the system's ability to produce this outcome. In addition, the decision support system can play the role of sending computerized alerts to both the provider and the patient, such as providing notification that a mammogram is due (Gurwitz & Wolfstadt, 2008).

Electronic registries offer clinical staff at medical homes the ability to manage populations with chronic conditions. One technological tool is the Registry Population Manager. This system enables nurses and other clinical staff to identify populations of patients with condition specific criteria. Once the population is identified, the PCMH staff can perform intervention techniques, such as mailings or callings (Fleurant, et al., 2011; Zai, Estey, Lester & Yee, 2008).

Transition of care is important to the PCMH as patients are discharged from acute or post-acute care facilities. Patients should receive post discharge follow up care and medication management from the health professional that typically would be in the form of the patient's personal physician in a medical home setting. Information systems that reconcile a patient's post-discharge and pre-admit electronic medication listing have been evaluated for effectiveness. The tool should allow for smooth transition for a patient's care from the admit facility to the medical home (Bates & Bitton, 2010).

Telehealth is the use of modern telecommunication and electronic information to enable long distance care from the clinician to the patient. Such technologies include video conferencing, email communication, and electronic image transfer. Texas curbs spending by $1 billion by deploying EHRs and telehealth in prisons for the past decade. A telemedicine systems allowed Texas prisons to access healthcare providers at The University of Texas Medical Branch at Galveston in Galveston and Texas

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Tech University in Lubbock (iHealthBeat, 2011). Telehealth was valued by The Center for Information Technology Leadership at a projected savings across the U.S. of $4.3 billion annually (Bates & Bitton, 2010). Thus, medical homes are at a financially incentivized advantage to adopt telehealth as an option for care. The PPACA's support for the Patient Centered Medical Home is an example of innovation in modern health care. The PCMH's quality of care delivery system should be guided by technological advancements (Krupinski, 2008).

THE ELECTRONIC HEALTH RECORD CONCEPT

In 2009, under the Health Information Technology for Economic and Clinical Health (HITECH) act, the U.S. Department of Health & Human Services released proposed regulations that would support the use to the Electronic Health Record (EHR) in the health care industry. Health care providers would benefit from additional Medicare and Medicaid reimbursement with approved use of the EHR in their practices and facilities. Additional funding for users of EHRs would be provided as well (Blumenthal, 2010).

Ultimately the HITECH act's purpose was to improve care for citizens of the United States and technology was seen as a key component. Laying the groundwork for the EHR adoption would become a guide for health care systems, stand-alone facilities and other providers to use technology in order to optimize care effectively. Providers who could be recognized as "meaningful users" would be incentivized to implement systems that would qualify. The meaningful users of qualifying EHR systems would be required to show use of systems with the following characteristics: electronically capture coded health information, track key clinical conditions, share the information with other providers and patients, and report service quality measures of clinical data and public health information. Proof of these characteristics would help ensure the government's sound investment in the concept (Najaftorkaman, et al., 2015).

The EHR feeds life into a new approach to health care where technology is embraced. Records are kept electronically in virtually all industries and health care, though late in the game, has followed accordingly with the EHR.

The Paper-Based Medical Record

Hospitals and other health care providers in United States have historically kept paper-based medical records of patient files. The information is predominantly hand written which can cause issues of misinterpretation. Generally, paper files can only be stored at the physical location where the patient received the care. In fact, paper files of a patient's medical history are scattered across several locations – from the office of the primary care physician to the specialist's office to the central medical filing stations at the patient's acute care facility. If a physician requires medical history to treat a patient, other providers must be contacted to share this information. The transfer of this information is both time consuming and costly as files are passed on via fax, scan, or mail. In an industry where historical information is essential to provide the best possible care, modern technology possesses the cure for this dated system of paper filing (Schoen, OsbornSquires, Doty, Rasmussen, Pierson, & Applebaum, 2012).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Electronic Medical Record (EMR)

An alternative to the paper file of a Care Delivery Organization (CDO) for any one particular patient is the Electronic Medical Record (EMR). The EMR is an electronic account of the patient encounter at the CDO. It contains clinical data, decision support, pharmacy data, and more across inpatient and outpatient environments of the CDO. It is important to note that the EMR does not store data from a patient's encounters at other CDO's, yet it serves as the basis for integrating a centralized record which will be discussed (Holroyd-Leduc, Lorenzetti, Straus, Sykes, & Quan, 2011).

The EMR's environment is the Clinical Data Repository (CDR). The CDR is referred to as a live database of patient information available to all practitioners within a CDO. Controlled Medical Vocabulary (CMV) is stored in the database and is pertinent to the patient encounter. This information must be accurately represented in the database in order for the Clinical Decision Support (CDS) and workflow of the EMR to perform as expected (Hillestad, Bigelow, Bower, Girosi, Meili, Scoville, & Taylor, 2005). The EMR components include clinical documentation, Computerized Provider Order Entry (CPOE), and pharmacy management (Garets & Davis, 2006).

The Electronic Health Record (EHR)

The Electronic Health Record (EHR) is reliant on the EMR being in place first. The EHR represents the environment where multiple stakeholders have access to a patient's medical information. The stakeholders include patients, providers, employers, payers (insurers), and the government. The stakeholders find value in obtaining this information to gain an advantage in accomplishing their purpose. While the EMR is owned by one singular CDO, the EHR is electronically shared and contains data of multiple CDO's within a community, region, state or even an entire country. National Health Information Network (NHIN) standards establish exchanges of data between the EMR to the EHR environment. The EHR environment consists of the stakeholder's and CDO's that rely on the data (Fontenot, 2014; Garets & Davis 2006).

EHR Advantages

Hospitals should predict beneficial outcomes that can be accomplished with the adoption of an EHR system. Advantages of EHR systems are exemplified by the hospital's ability to use the system in order to maintain preventive care measures, reduce operational expenses, pave the way for other forms of technology, and enhance access to data for hospital based research. EHRs can improve adherence rates for routine care and preventive screenings. Electronic alerts notify providers that a patient is due for a preventive screening. The alert system streamlines a process that would have normally been tedious and difficult to organize. The process is necessary and beneficial to the patients' health and well-being as preventive care is essential (Fontenot, 2014).

Treatments have become more effective with the use of EHRs. More patient information is available and easier to access by the nursing staff. One study found a 5% decrease in pressure ulcers after six months of an EHR system implementation (Menachemi & Collum, 2011). Menachemi and Collum (2011) found that the alert system, which is a part of Clinical Decision Support, accounted for an 11.3% appropriate hypertension treatment in primary care.

An initiative in the health care industry in recent years is to reduce "waste." Waste comes in the form of medical errors causing inappropriate costs, using less expensive alternatives of care, or fraud. Un-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

necessary laboratory and radiology tests are reduced with the presence of an EHR. This allows for the reduction in ancillary expense and the opportunity to fill the time saved performing inappropriate care with appropriate care (Menachemi & Collum, 2012).

An EHR capability that reduces errors in hospital operations is the Computerized Physician Order Entry (CPOE). A CPOE is an information system that is used in the medical field to communicate orders for a patient by a medical practitioner. The practitioner can electronically enter medication instructions, laboratory tests, radiology examinations and physical therapy orders. Prior to the development of this system, orders were written on paper and delivered to nursing, pharmacy and other medical staff. The existence of the CPOE system increases efficiency and reduces errors (Kaushal, Shojania, & Bates, 2003).

Operating expenses are reduced with the placement of an EHR system. The cost of chart pulls is virtually eliminated due to direct accessibility by the end user. Paper costs, previously used for creating paper based files, become almost obsolete. Salaries and wages can be reduced due the reduction in staff needed to perform duties that can be performed by the EHR. Legal expenses reduce as a result of increased communication across providers, adherence to medical guidelines, and reduction in malpractice claims (Mekhjian, Kumar, Kuehn, Bentley, Teater, Thomas, Payne, & Ahmad, 2002).

Hospitals that house research departments benefit from the EHR in that electronically stored data makes it more feasible for researches to collect information needed for studies. Measuring outcomes across a population in particular studies can be performed with ease because EHRs store data across multiple providers amongst numerous regions. The EHR advantages justify the effectiveness of the system. If the systems are implemented and maintained adequately, positive outcomes should be obtained.

EHR Limitations

There are several limitations of the EHR that have been recognized in the health care industry. These limitations include financial issues, changes in workflow, loss in productivity, threats to Protected Health Information (PHI) and others. The costs of implementing an EHR system include software and hardware purchases, overhead and additional salaries associated with converting existing paper based files to electronic, and training expenses for hospital staff. These costs affect both inpatient and outpatient settings in a health care organization. Ongoing maintenance costs include expenses related to regular updates and hardware replacement, salaries and benefits paid to hired technical staff to support the system, and fees paid to consultants and external contractors. Positive financial outcomes of an effective EHR system are shared by the third party insurance payer. The shared savings impact the payer as errors are eliminated and efficiency is improved from a billing standpoint. With the exception of Medicare, the payer does not invest financial resources in the adoption of the EHR. The entire cost is incurred by the health care provider. Thus, the benefit is reaped by the payer.

Loss in productivity can come in the form of medical staff spending non-productive time learning the system as opposed to providing medical care. EHR systems require extensive training for medical staff. Nurses, laboratory and radiology technicians, and other hospital staff are removed from their duties to learn the system. This process can take three months where a portion of the each staff member's worked hours are required for training each month. The productivity can be back filled with replacement staff. However, the replacement factor also leads to additional compensation, sometimes at a much higher hourly rate, which can burden the hospital budget. Because, hospital administrators emphasize the importance of keeping the Full Time Equivalent (FTE) budget on target, replacement can account for an unfavorable option.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

EHR's do not offer full protection in terms of patient privacy. As sensitive data is shared electronically over a network, Protected Health Information (PHI) data is at risk of IT security breaches just as credit card data is at risk in the retail industry. Regulations are required for hospital staff with access to PHI. Employees must adhere to the strong guidelines of the Health Insurance Portability and Accountability Act (HIPAA). This represents another challenge for health care organizations that must educate their staff on HIPAA regulations and how they are connected with EHR systems (U.S. Department of Health & Human Services, 2015).

Other limitations and setbacks of the technology can include an overdependence on the technology, increases medical errors if the system is poorly designed or if the employees are not adequately trained, and loss of autonomy for physicians due to system limitations. The limitations can be addressed with strategic planning by hospital administrators. Also, as systems become more mature, limitations are liable to be alleviated.

An EHR Study: Costs and Benefits Analysis

Gundersen Lutheran Medical Center in La Crosse, Wisconsin, was examined in a study of the outcomes demonstrated by one hospital that adopted the EHR. The hospital is a 325 licensed bed trauma center that implemented an inpatient EHR system in November of 2008. For comparison purposes, data were collected one year pre-EHR implementation and one year post-EHR implementation. For purposes of this study, the impact of the CPOE system implementation was considered in the results because of the proximity of the CPOE implementation to that of the EHR and for the reason that CPOE and EHR systems are directly linked in terms of their capabilities (Zlabeck, Wickus, & Mathiason, 2011).

Laboratory tests and radiology examinations were analyzed in the study. The analysis showed that the number of laboratory test per week per hospitalization reduced from 13.9 in the pre-EHR period data to 11.9 in the post-EHR data. Zlabeck, Wickus, and Mathiason (2011) point out that this decrease of 18% in the rate of lab tests begin to show signs of significant trend at month three of the post-EHR period. This leads to the suggestion that the reduction in tests was a result of the CPOE system's implementation. However, the EHR needed to be in place in order for the CPOE system's implementation to occur. Therefore, both systems should be recognized in this performance driven statistic. Similarly, the rate of radiology tests per hospitalization did not show signs of a decrease until month three of the post-EHR period. The number decreased from 2.06 in the pre-EHR period to 1.93 in month 9 of the post-EHR period.

Significant savings were demonstrated in transcription costs. The cost per month decreased from $74,596 to $18,938. This represented an impressive outcome where costs reduced by 74.6% from the pre-EHR period to the post-EHR period. Over the twelve month post-EHR period, total savings calculated to $667,896. This outcome was attributable to the EHR system directly (Zlabeck, Wickus, and Mathiason, 2011).

An obvious positive financial outcome came in the form of cost savings in supplies specifically related to a reduction in paper consumption. The EHR eliminates the need for paper based medical files, therefore this cost savings would generally be expected. The hospital experienced a 26.6% decrease in reams of paper orders, and one hundred and eighteen paper forms were eliminated. The total cost savings decreased in the post-EHR period by a total of $30,351. Medication errors were reduced after the EHR implementation as well. Errors per 1,000 hospital days dropped from 17.9 prior to the EHR system to 15.4 by month nine in the post-EHR period. As was the case with lab tests and radiology exams, the CPOE played a vital role in this outcome (Mekhjian, et al., 2002; Zlabeck, Wickus, & Mathiason, 2011) .

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The statistics prove that positive operational and cost benefits were associated with the implementation of the EHR and CPOE systems at Gundersen Lutheran Medical Center. The study also demonstrates that the adoption of the EHR can open doors to other modern formers of Health Information Technology. In this case it led to an effective implementation of the CPOE system (Mekhjian, et al., 2002).

Epic: Judith Faulkner's Systems

Judith Faulkner has built Epic Systems gradually and quietly over several years of development, capitalizing off of an evolving health care environment that has recently adapted to the benefits the EHR. Epic was founded in 1979 in Verona, Wisconsin and is presently becoming the preferred technological system solution for the majority of the stakeholders in the U.S. health care industry. Its clients include dominant health care systems such as Johns Hopkins and Cleveland Clinic (Moukheiber, 2012). Massachusetts-based Partners HealthCare, founded by the prestigious Massachusetts General Hospital and Brigham and Women's Hospital, is currently implementing the system across all of its hospitals – the first of which began in February of 2014 at Newton Wellesley Hospital. In an article in Forbes Magazine, it was determined that 40% of the U.S. population is being stored in an Epic digital record. This share continues to grow as the U.S. health care industry proceeds to become more innovative in the field of technology (Moukheiber, 2012).

Epic develops software for medical groups, hospitals and integrated health care systems. At a lower level, it serves community based hospitals, academic facilities, children's hospitals and health safety net providers (Ku, et al., 2009). The EHR methodology employed by Epic is based on a health care programming language referred to as MUMPS (Massachusetts General Hospital Utility Multi-Programming System). Its products include EpicCare EMR that normalizes care delivery for physicians, EpicCare Inpatient Clinical System that allows for health information sharing across organizations, mobile applications, and portals. Also available is a resource for patients to retrieve the same electronic medical records that are accessed by their physicians. A patient's Personal Health Record (PHR) is portable for both patients and providers alike through an Epic application known as Lucy. Epic also offers PlanLink which is a tool for payers (i.e., insurers) and employers that makes information available via the web (Bloomberg Business Week, 2014; Holroyd-Leduc, et al., 2011; O'Brien, 2006;).

In the era of digitalized health care, security is a strong selling point when it comes to investing in health care IT. Faulkner backs up her product's security status by proclaiming "to the best of our knowledge, in the 32 years we've been in business, there has never been a breach of Epic's data by a hacker" (Freudenheim, 2012). The company's leader stresses the importance of firewalls and security systems that Epic has in place to protect sensitive and protected data. In fact, Faulkner holds the position of an industry representative on a government panel that examines security issues in health care. Her goal is to assure the protection of the data while still allowing for the flow of information sharing. Such a balance is difficult to reach with success, yet Epic manages to do so strategically. The information sharing can only be shared across providers if they are clients or if they meet certain conditions. Organizations must prove patient consent and have a digital certificate to be presented to other organizations in order to engage in digital information sharing. The benefit of sharing health care data is something the Faulkner sees as a privilege that should be treated accordingly. The Health Insurance Portability and Accountability Act of 1996 mandates the privacy and security of sensitive patient data. Epic's reputation for safeguarding the data increases the effectiveness and marketability of its software products (Freudenheim, 2012; O'Brien, 2006).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

USE OF HEALTH CARE IT TO IMPROVE SERVICE QUALITY

Healthcare IT applications in the medical community bring in many strengths of service quality. The strengths, broadly speaking, include user satisfaction, employee productivity, and business performance. Weaknesses include stakeholder issues, regulatory environment, technical issues, and financial issues. Threats include government mandates, third party e-Health and e-Medicine, competition for scarce IT resources and talent, market and competitive pressure, and the threat of government run healthcare. There are opportunities as well. Institutions that are developing effective systems now have the benefit of being early adopters. They can affect change of standards toward those that are beneficial to them since these standards are just now being developed. They can appeal to younger patients searching for locations and healthcare professionals with better service quality. They can gain prestige among peers and increase their own service quality outcomes (Andrews, 2015; Lettieri, Bartoli, & Masella, 2013).

The strength of user satisfaction takes a couple of different forms. First there are now more Internet interactions than ever before. People are used to doing their banking, shopping for products, arranging food deliveries, paying bills, communicating, taking classes, and many other aspects of daily living online. They are often surprised that medical processes are still inaccessible in many facets. This has led to higher patient expectation that can be met with Health IT solutions. People are more tech savvy now as well that makes a more educated and able consumer. People are also beginning to shop for healthcare services and products including both physicians and facilities (Matysiewicz & Smyczek, 2013; Razzaque, Eldabi, & Jalal-Karim, 2013).

The strength of employee productivity is due to labor efficiency and service effectiveness. There is a shortage of health care professionals especially in the general practitioner area. Manual record keeping and searches are a laborious and time consuming process. Health IT can deliver instant information on demand to improve labor efficiency. The accuracy of health IT generated reports will improve the diagnosis and service effectiveness. Employee productivity can be increases by using health IT applications to free up data searching time and to help serve the growing patient need. The strength of business performance centers on using health IT to reduce costs. Health IT applications of efficiencies increase employee productivity and reduce operating costs. Health medical records are stored electronically and can be queried or reported in various customized ways. Business performance can be further increased by reducing malpractice through automatic guards, checks, and alerts (Menachemi, & Collum, 2011; Menon & Kohli, 2013).

Information Systems Guide Management in Health Benefits and Costs

In 2013, employer sponsored health insurance covered about 149 million employees and their dependents. Over the past decade, employer sponsored health insurance costs have trended at a rate much higher than inflation. Data from the 2003 and 2013 versions of the Kaiser Survey of Employer Sponsored Health Benefits depict an 80% increase in the average total insurance premiums and an 89% increase in the average employee contribution to the full premium. In 2003, employers subsidized the full health insurance premium by a very generous 75%. However, as the employee contributions have experienced an upward trend at a higher rate than the total, the employer sponsored subsidy has decreased over the ten year period to 74% (Kaiser Family Foundation, 2013).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The data infer that in an effort to withstand the astronomical spike in health benefit costs, employers have decided to cut benefits and push a higher share of the premium payments onto their employees. As companies seek to both cut costs and remain competitive from a compensation standpoint, they have invested in data warehouses such as Truven Health Analytics and other systems. The investment in these systems is a practice aimed towards organizations empowering themselves with the reporting capabilities needed to analyze data and develop strategies for mitigating the trend of health insurance costs (Vo & Bhaskar, 2012).

Truven Health Analytics offers a product to employers called Advantage Suite, which is a dynamic database that stores in-depth health and Rx claim data of employees and their dependents. Member information is submitted to Truven by the group health and Rx insurance carriers that the employer uses to offer health benefits to its employees. The employer submits job and demographic data that are combined to the claims data by Truven to build a database the employers can use to report on clinical and financial member data. Advantage Suite allows employers to dive into the data of their health benefit costs and utilization. Employers can determine the drivers for substantial increases in trend and develop plans of action to reduce costs. They can identify preventive measures, such as colonoscopy and mammography rates, in their population and compare these measures to norms using a built in benchmarking tool. The tool pulls information using a resource known as MarketScan data, a comparative application that can be industry and demographically adjusted. After interpreting the results, employers can take action to steer their population into healthy behavior and ultimately reduce costs or care related to chronic conditions. Employers can also use the system to develop forecast and budget assumptions on employee health expenses and perform benefit modeling analytics used to measure the cost impact of plan changes.

In a study performed by the Employee Benefit Research Institute (EBRI), Truven data were used to examine the costs of spouses in employer sponsored health plans. The EBRI sought to address the notion that spouses incur higher health costs in employer sponsored health plans. Using Truven Health Analytics MarketScan Commercial Database, researchers were able to analyze claims data of 317,180 couples and 634,360 individual members across multiple employers. The system allowed the researchers to dice the data by geographic location, health status, gender, and age. For the population analyzed, the results showed that the employees (i.e., policy holders) cost $5,430 on average while the spouses averaged $6,609. The findings revealed a 21.7% increase of the spouse cost per member over that of the subscribing employee. A powerful information system allows the end user to uncover the layers by drilling down into the detail to determine the root causes.

By running subsequent reports, Fronstin and Roebuck (2014) found that the majority of the $1,179 difference was due to gender, health status, and other factors. Researchers adjusted their reports to normalize the data and still found that average spouse costs were 7% higher than the average policy holder costs. The end result of the analysis was that, even when adjusting for outliers, spouses still carry a higher cost on average than the policy holding employee.

If an employer performs a similar analysis using a Truven product or a similar system, decisions can be made to reduce employee health costs. The EBRI indicates that the United Postal Service (UPS) applied the same approach to reduce health costs. UPS decided to change its benefit package by only offering coverage to the spouses of its employees who did not have coverage offered to them by their own employer. UPS actually cited the PPACA as the cause of its decision, indicating that the change enabled the company to provide affordable coverage. The PPACA requires employers to offer coverage to dependent children through the age of 26, but does not require coverage to be offered to spouses (Fronstin & Roebuck, 2014).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Were it not for a sophisticated technologically advanced system like Truven's, the analysis would have limitations and perhaps UPS would not be able to place a value on the cost impact of its decision. The investment in information technology by employers can prove to carry a positive return, because the accessible data empowers employers with knowledge that would otherwise be unavailable.

Information Systems Guide Employee Wellness and Productivity

A healthy workforce translates into a productive workforce. In order to remain competitive, an organization must take action in order to keep its workforce healthy and productive. Information systems, like Truven's, allow employers to track clinical measures on employee health to identify areas that can be improved upon. Truven's Advantage Suite data warehouse offers a reporting environment that allows employers to track the effectiveness of disease management programs.

Insurers often enroll members in these disease management programs, which are programs equipped with clinical staff who offer health coaching to members with certain clinical conditions. Using the condition of diabetes as an example, a member with the disease would generally be contacted with reminders to get their periodic exams such as HbA1c and eye tests needed to maintain the well-being of the member. An employer with Truven Advantage Suite could access the reporting environment, set their clinical condition criteria to diabetes, and query on the frequency of periodic exams and the overall health of their members. Because the database offers time constraints, the employer can track the improvement over multiple time periods to analyze trends. If the employer wishes to set parameters on the population within the clinical condition population, subsets can be created limiting the person IDs. The use of subsets is most effective when the analysis calls for an examination on cohorts. If issues are identified, such as an unfavorable rate in HbA1c testing, employers can deliver the results to the insurer and order further intervention (Truven Health Analytics, 2014).

An employer can also use the database to perform home grown analytics on the overall health and wellness of the employee population. For instance, through statistical analysis a company may reveal a portion of their population to have a higher prevalence for mental health conditions, such as depression. That company might decide to establish an employee assistance program for these employees in order for them to have access to counseling on site. HIPAA complicates the communication process, however, if done strategically the wellness initiative can foster a healthy workforce.

IT PROFESSIONS IN HEALTH CARE

Role of the Chief Medical Information Officer (CMIO)

The Chief Medical Information Officer (CMIO) role has recently been gaining popularity in the health care industry. The CMIO is responsible for directing the implementation and maintenance of clinical information systems. Generally, this position is held by a physician. The emergence of the EHR and EMR has added depth to the CMIO role as health care organizations convert to digital record keeping. Responsibilities also include facilitating data warehouse initiatives, physician website and email maintenance, and network security. CMIOs can be partially dedicated to performing direct patient care as attending physicians or fully dedicated to their roles in health care IT (Holroyd-Leduc, et al., 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CMIOs set goals and expectations for IT projects. They also lead the vendor selection process when new systems or technology are requested. For instance, the CMIO would be responsible for the selection process involved for a health care organization to choose Epic Systems to replace an existing system, such a Meditech. Once implemented, the CMIO would then direct plans for training registered nurses and other clinical staff on new information. CMIOs can also chair senior health system committees and information technology committees. Also, CMIOs participate and direct the establishment of information security and that HIPAA regulations are carried out from a systems standpoint. CMIOs lead staff reporting directly to them or collaborate with the organizations internal IT staff to achieve the effective completion of these initiatives (Leviss, Kremsdorf, & Mohaideen, 2006).

Nursing Informatics

The American Medical Informatics Association (AMIA) defines nursing informatics as the "science and practice (that) integrate nursing, its information and knowledge, with management of information and communication technologies to promote the health of people, families, and communities worldwide" (American Medical Informatics Association (AMIA), 2014). Positions in this field are staffed by health care organizations and include Nurse Informaticists and Chief Nursing Informatics Officers. Nursing informatics is expanding and the need for these positions is increasing. The 2014 Healthcare Information and Management Systems Society (HIMSS) Nursing Informatics Survey revealed that there are three areas where nursing informatics add value to an integrated health care system. These areas are the development and implementation of IT systems, optimization of HIT systems, defining context for patient care. The survey indicates that 30 percent of health care organizations support the CNIO position. The role is evolving as that number is expected to grow in subsequent years (Gabriel, Jones, Samy, & King, 2014; Pizzi, 2014).

Clinical Decision Support (CDS)

Clinical Decision Support (CDS) systems provide intelligence that fuels decision making in the health care environment. These decisions benefit clinical staff and patients, enhance the delivery of care, control costs, and increase revenue. CDS system analysts filter information to the health care environment using technical tools such as computerized alerts, reporting platforms, diagnostic support, and clinical guidelines. Ultimately, health care organizations improve from service quality decision support by increasing the quality of care, reducing errors and complications, improving efficiency, and satisfying patients (Kaushal, Shojania, & Bates, 2003; Romano & Stafford, 2011).

Health care organizations staff departments specifically dedicated to CDS. These departments tend to consist of analysts who operate and maintain databases used to provide support for the decisions made within their organizations. One of these systems is Allscripts EPSi. EPSi is a web-based information system that is specific to the health care industry and stores data and analytical tools that guide financial management. CDS analysts operate the system to provide integrated analytics, budget support, and general decision support. EPSi offers multiple modules to organizations that include Budget Manager, Capital Budget Manager, Strategic Product Budgeting, Productivity Manager, Cost Manager, Product Line Analyst, and EPSi Management Dashboard. Budget Manager allows the health care organization to combine payroll and capital budgeting with patient level budgeting so that realistic spending goals and assumptions can be made. Analyst can perform financial modeling using this module's ad hoc report writing resource and flex budget mode (Allscripts, 2014).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Analysts in health care organizations use IT resources, such as EPSi, in order to equip themselves and their organizations with the information needed to determine appropriate investment and allocation of resources. The information system makes this possible. Without the assistance of EPSi and other CDS systems, analysts would not be capable of impacting the health care system. CDS systems have paved the way for business intelligence professions in health care organizations.

CONCLUSION

Health care systems continue to swell into massive heaps of facilities, insurance companies, service organizations, consultants and more. Partners HealthCare consists of entities from acute care facilities to mental health facilities to rehabilitation hospitals and centers. Partners and other Massachusetts based systems, like Steward Health Care and Hallmark Health, base their business models on the concept of integrating care across their systems. IT has played in integral role in effectively coordinating care within any one particular system. What remains to be seen is how effectively IT will integrate all U.S. health care organizations. The Electronic Health Record will be the element that allows organizations to facilitate with one another from a technical sense. Patient information must be properly shared for the betterment of patient care and effectiveness of care delivery by health care professionals. As the adoption of the EHR spreads across the United States in future years, systems will improve their care delivery models and processes.

The government has established itself as a major player in the industry with the passing of the PPACA. President Obama's Health Care Reform has been designed to steer the industry improvement and adoption. As more focus is placed on IT resources within health care organizations, systems should continue to improve and IT departments should expand.

Epic will continue to sweep the nation with its state of the art systems catered to the current need for today's health care environment. Systems that previously controlled the market, such as Soarian and Meditech, will need to improve their products as soon as possible in order to withstand Epic's domination. The emergence of a new entrant into the world of IT systems will be a more likely scenario.

The access to systems will expand for organizations who offer employer sponsored health plans to their employees and the families of their employees. Systems, like Truven, will be adopted by both employers and benefit consultants across the U.S. The return on investment has been demonstrated by the early adopters of these IT systems and more employers will fall in line to cut costs and keep their workforce healthy and productive.

Health care organizations can be for profit or non-profit, acute or non-acute, outpatient or inpatient. Regardless of an organization's disposition, it cannot continue to exist without information sharing and gathering through technological advancements. IT analytical tools provide the business intelligence needed for health care organizations to survive and flourish. It is with these tools that health care professionals strive to fulfill their duties and work for the betterment of the patient in their care.

ABSTRACT

Early detection and prediction of dementia through unobtrusive techniques or obtrusive tests is still in exploratory status and despite the increase of interest in recent years, many challenges remain open in designing methodologies that can accurately predict its onset. This chapter addresses the problem of the early detection of dementia from two points of view: Detection based on unobtrusive paradigms both in lab and home environments (behavioral monitoring, serious games, home based assisted living applications in telemedicine) and detection based on neuroimaging approaches. The chapter also provides information on setting up ecologically valid home labs for dementia related experiments. Consequently, the aim of this chapter is to provide an overview of a complete methodology of how researchers can possibly detect or predict the onset of dementia through the current state-of-the-art, underline open challenges and illustrate future work in the field.

INTRODUCTION

Chronic illnesses impose a great burden on the lives of citizens worldwide. In modern health-care, decentralisation, de-hospitalization and self-management of diseases at home are crucial factors for improving the every-day life of the patients and the people close to them. People in general tend to dislike obtrusive monitoring on their daily activities, so the challenge for home care solutions is to implement systems that provide clinicians with adequate and concise information on their patients' health status while at the same time be unobtrusive and easy to use (Golle & Partridge, 2009; Röcker, Hinske, & Magerkurth, 2007). Based on sets of multimodal monitoring parameters and measuring scales feeding reconfigurable event detection mechanisms used for risk assessment and analysis, AAL systems aim to early detect symptoms that predict decline, avoid emergencies and secondary effects and, ultimately, prolong the period that patients can remain safely cared at home. In this chapter the authors aim at providing a description of current trends in context-aware ambient monitoring for the early detection of dementia and prediction of deterioration, as well as provide a background for minimally obtrusive neuroimaging approaches on prediction of dementia.

BACKGROUND

The current applied paradigm for dementia, revolves around patients in the later stages of the disease, where the patient is beyond the stage of the application of delaying/preventive measures. This follows as a result of the delay in seeking care from the majority of patients and caregivers, until the disease has progressed (Boise, Morgan, Kaye, & Camicioli, 1999). There is a gap in the clinical paradigm which does not include the need for the application of methodologies for early detection of dementia, at the onset of the very first symptoms. This is further exacerbated by the fact that most physicians delay providing a diagnosis as they perceive dementia as a "terminal" disease without adequate remedial ways of treatment. These factors put together, severely compromise healthcare quality for such patients and also deprive them of the chance to face their disease at its early stages where much can be done, directly impacting overall patient care.

Our current understanding of dementia and the underlying mechanisms is that the disorder may well begin one or two decades before symptoms appear (Reiman et al., 2012). Dementia itself is identified as a late stage in the pathological development of neurodegenerative disorders. In the recent years, there has been a clear shift towards addressing the disease at its earlier pathological stages, but still the main focus of clinical practice falls on the later stages, with most diagnoses after the moderate or even severe stage. On the other hand, there is a rising trend to turn our focus on earlier detection of dementia, seeking prodromal, MCI or even completely healthy subjects to volunteer at experimental protocols for the early detection of dementia. Here we discern a huge impediment: Although we are in need of patient populations at the very early stages of dementia, to begin constructively developing better and more efficient detection paradigms and thus enabling clinical research in the race for better treatments, most patients are diagnosed very late. These facts may contribute to delayed or undetected cognitive decline or even false diagnosis among primary care providers (Borson et al., 2013; McCormick et al., 1994).

In the race for early detection of dementia, much can be said and more can be assumed or predicted. Following the rising trend of multidisciplinary practices in many scientific fields, thus early detection of dementia is now moving away from pure clinical practice and clinical instruments and moving to-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

wards a holistic approach (Flicker, 1999; Hughes, Robinson, & Volicer, 2005). Making use of machine learning techniques, supporting multimodal data, ranging from biomarkers to behavioral metrics and from social activity to serious games, detection of so far invisible patterns of signs of dementia is now probable, in the near future.

Of course, despite the many advances, there is still a multitude of open problems that need to be addressed. These problems range from the mundane, yet fundamental lack of preclinical or even MCI subjects that are willing to participate in long-term trials, to the organization of experimental trials on home-based or home-like environments for monitoring as well as the more technical need for robust pattern recognition algorithms and decision support mechanisms to fully make use of the not-that-available data.

In 2015, there are over 34 million later stage patients worldwide and the current paradigm must undergo a severe shift towards another direction. By the time of the diagnosis, subjects have mostly declined to the point where they lack the mental capacity to play a role in their care and most certainly are beyond the point of providing useful data to the research community. Moreover, over 50% of patients with dementia go undiagnosed by their primary care provider (Boise et al., 1999; Bradford, Kunik, Schulz, Williams, & Singh, 2009; Kotagal et al., 2015).

Dementia care should and must shift to a different paradigm where focus is more on preventive and early detection methodologies than just remedial action after the onset of the later stages.

On the other hand, recent developments in connectivity analysis for brain functionality through neuroimaging, shows increased potential for early detection of dementia both in clinical environment and in "home-lab" environments –as addition to an AAL platform- through the use of low-obtrusiveness sensors (such as Emotiv)

PATIENT MONITORING ENVIRONMENTS

Before examining the actual details and challenges the problem of early detection of dementia induces, we must initially lift our point of view one level and examine the setup of patient monitoring environments. We have already described how the current established paradigm focuses on monitoring patients after the onset of the disease. Unobtrusive monitoring methodologies are effective when subjects are already in an advanced stage of the disease, but monitoring of healthy -or even MCI subjects- is hindered by the psychological factor: Even though monitoring is unobtrusive, the subject knows that it is being monitored. So, in conjunction with the possible unfamiliar environment (i.e if tests are being performed in the premises of the clinic), we face the problem of changed behavior. The subject is moved away from the familiar comfort zone of the home and being subjected to various tests by clinical staff and strange-looking equipment (McKanna, Jimison, & Pavel, 2009). That of course raises stress levels and leads to perhaps exaggerated reactions to the monitoring protocol. The subject's perception of the monitoring environment directly affects the monitoring parameters (especially behavioral ones and even some physical) so to facilitate valid results we must induce the concept of *ecological validity* in our monitoring environment.

By "ecological validity" we mean that the methods, materials and setting of the experiment must approximate the real-world situation that is being examined (Brewer, 2014). This is particularly important in studies relating to fields such as cognitive psychology, neuropsychology and apply to aspects relating to decision making and judgment, factors of grave importance to the -early or not- detection of dementia and its results on the subjects' behavior.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Apart from ecological validity as a crucial factor in conducting research on the early detection of dementia, we should shortly digress on another important issue, that of the lack of existing data pool. Until the current paradigm shifts towards early detection of dementia, which means that more researchers and more institutions focus their efforts on this, current research lacks from available data on which algorithms, methodologies and detection pipelines can be applied. This combined with the wide timeframe needed (in the order of magnitude of years) to generate meaningful results, leads us to conclude that as much data can be available to as many researchers as possible. The scientific community has to simultaneously produce and share data as widely as possible to facilitate swift progress on the early detection of dementia. Thus, we come to the combined need for ecologically valid monitoring environments built on an open data scheme of dissemination for more accurate data combined with real-time dissemination capabilities.

THE OPEN DATA ECOLOGICALLY VALID LIVING LAB PARADIGM

There are quite a few ongoing research initiatives focused on the creation of integrated unobtrusive smart lab/home environments supporting the independent living of elderly people. The main goal of these smart environments is the ambient monitoring of the elderly through a set of monitoring devices (which comprises a common monitoring model in research efforts across the world). The subjects are continuously evaluated in ecologically valid living lab/home environments and monitoring parameters -behavior, gait, sentiment, activity, memory test results etc- are being recorded and stored -anonymized- for processing and pattern recognition methodologies to be applied on them . Subjects are being analyzed as unobtrusively as possible, just by performing routine tasks they would anyway perform at their homes, or on another level being prompted to perform some light physical exercises, in an overall wellness scheme, through the use of serious games promoting physical exercise or activity. Thus, we collect and can analyze a multitude of data, as little as possible unaffected by perception and stress related distortion.

Such an example of an ecologically valid living lab setup as in Figure 1 would consist of a living-room space, a bathroom-like space and a hall-kitchen space, all in the same room. In this scenario, a number of elderly volunteers visit this environment daily and perform a set of routine activities just as they would at home. An ICT infrastructure (for example, NoSQL databases, Kinect streaming services, etc.) supports the recording of the raw information of all the sources, comprising Kinect(RGB, skeleton and microphone array information), Smart Watch (acceleration), Wii Balance Board (center of gravity during ExerGames interaction, related to the balance ability of the elderly) and health measurements. The data generated by such a monitoring scheme would reach a mean throughput of 10GB per hour swiftly generating a big database of ready to be reproduced, shared and analyzed by the wide scientific community (playback) (Evdokimos I. Konstantinidis, Antoniou, Bamparopoulos, & Bamidis, 2014). On top of this, the paradigm exploits an RDF database contains semantic annotation of the datasets which can be provided by an external observer. In such a monitoring scheme, the infrastructure and ICT tools (streaming on demand, cloud storage and processing, etc.), are based on already developed services and frameworks (such as the cac-framework.com) (Evdokimos I. Konstantinidis et al., 2014) to make these data available on demand. As stated by Konstantinidis et al. (2014), the scientific community will be able to experiment and to test their algorithms on data stemmed from an ecologically valid environment in lab settings. This approach will enable developers and researchers of early detection algorithms that rely on information similar to the existing datasets, by enabling the design and developed algorithms

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. An ecologically valid living lab in laboratory settings resembling a real common living room and kitchen

and software tailored to the elder's daily living patterns. Most importantly a preliminary evaluation of the service adoption has already been conducted on the programmers/developers front with encouraging results.(E. Konstantinidis, Antoniou, et al., 2014; E. Konstantinidis, Billis, et al., 2014).Therefore, such an approach would facilitate the ulterior aim of speeding up innovation, collaboration as well as development and testing of more accurate services, which is achieved by an early involvement of users (playback already existing datasets of elderly in an ecologically valid living lab) as co-creators.

We have stressed the need to produce ecologically valid environment datasets in a real time format, which will support and accelerate the collaboration among the scientific community, as well as in a datasets format for further exploitation of other entities, in a wide-open data scheme that will return back to the research community a wealth of information along with convenient tools for getting access to them.

ECOLOGICALLY VALID DATA COLLECTION

In the current monitoring paradigm, the assessment of a subject's cognitive and functional status is based on brief clinical visits, where various data is collected via short tests and compared with results from previous sessions. This is conventionally done by using a variety of validated clinical assessment tools and is heavily affected by the distorting lens of the subjects' and caregivers' recollection of events in the days preceding the tests as well as their capacity for self-assessment, which is -as already stated- affected by the "sterile" clinical environment. Moreover, infrequency and the actual short duration provide more confounding variables for the accuracy and efficacy of these tests.(Boise et al., 1999; Bradford et al., 2009)

So, the biggest challenge concerning not only the early detection of dementia, but also the more conventional monitoring of the progress of the disease itself, is the general lack of pervasive and unobtrusive environments that will exploit significant parameters, enhance adherence, provide constant monitoring by tracking activities and behaviors and thus a continuum of useful data, with underlying patterns that can be used to predict outcomes of mood, behavior, cognitive status and functionality, used as biomarkers for detecting trends towards dementia (Lyons et al., 2015). Moreover, although there is a

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

plethora of ambient intelligence examples of home monitoring applications, these are mainly focused on life threatening acute events and less on slow varying trends that can indicate future conditions such as dementia (Mihailidis, 2008). Therefore, aiming to fill the above gap, we must focus on utilizing low-cost, off-the-self, unobtrusive sensors and devices to detect both short-term monitoring - such as the detection of emergency events as well as the detection and assessment of ADLs and other contextual situations (Storf, Becker, & Riedl, 2009)– and, long-term monitoring to detect abnormal patterns of health or behavior and continuous health assessment (Chiriac, Röll, Parada, & Rosales, 2012; Monekosso & Remagnino, 2010; Xefteris et al., 2011). Since cognitive impairment is coupled with functional decline and depressive symptoms, (Mehta, Yaffe, & Covinsky, 2002) the need for a multimodal fusion scheme that monitors multiple aspects of the subjects' life is apparent. In this context, we must also keep our mind on the tradeoff between unobtrusiveness and accuracy, coupled with the subjects' adherence. Unobtrusiveness seems to be a critical factor that enhances acceptance and compliance, while on the other hand obtrusive or even invasive methodologies provide more accurate data.

The transition from monitoring the disease to actually detecting it at the very early stages or even years before, calls for data acquisition and processing platforms, collecting and fusing data in a multimodal environment (sensors, exergames, questionnaires, etc.). The trending paradigm's objective is to integrate and extend state-of-the art technologies for:

- Fusing and interpreting the parameters uni-modally extracted from raw sensor data into a semantic representation of human behaviour and physiological status.
- Extracting correlations from sets of fused data (cognitive, emotional and physiological measurements). Utilisation of various soft computing, probabilistic and data mining techniques is crucial in order to operate on sensor data to provide least error prone analysis and decision support indicators.

The main parameters, based on Activities of Daily Living (ADLs) that can provide us with useful data, collected unobtrusively, for the possible early detection of dementia and help us make predictions are analysed in the following paragraphs.

Mobility

Since 1998 (Camicioli, Howieson, Oken, Sexton, & Kaye, 1998) has demonstrated that reduced mobility precedes cognitive impairment in the elderly. Researchers now, develop new algorithms for continuous in-home assessment of both variability in movement speeds and movement patterns, to discern underlying signs of risk. On one hand, researchers can employ a scheme of "passive" monitoring via sensors installed in various places inside a home and collecting data on speed, frequency of passage, total activity etc, or by "active" monitoring via the application of ExerGames that both aim to promote and sustain a healthy and active lifestyle and collect possible "anomalous" data in the performance of the various exercises.

Passive monitoring via dispersed sensors has many advantages but also some caveats. On one hand, passive, unobtrusive sensors solve the problem of compliance and adherence, because monitored people tend to either avoid or even forget to wear the common actigraphy devices used for mobility monitoring. Moreover, simple accelerometers do not provide location information - which is significant itself- coupled with the fact that since in-home movement is generally slow and non-linear, data interpretation is very difficult. Thus, in the case of older adults, the notion of ecologically valid unobtrusive monitoring comes

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

back again as a very important factor. To that end, arrays of in-home sensors can be deployed supporting information collection of walking speed, location and frequency of passage. (Hagler, Austin, Hayes, Kaye, & Pavel, 2010; Hayes et al., 2008). The challenge remains though, to establish the individual activity patterns and manage to measure meaningful change that may have applications for predicting health parameters and functional status (Hagler et al., 2010) .

Exergames

The emergence of modern interaction interfaces (tablet, laptop with touch screen, smart tv) has been followed by the trend of transferring paper and pencil screening tests to computerized forms which are more acceptable from elders (Collerton et al., 2007). On top of this, and aligned with Plato's statement that "...you can discover more about a person in an hour of play than in a year of conversation..."(Robert et al., 2014), these computerized tests started turning into games with assessment aspects. Introduced with the term "Serious Games", these games are considered to provide more reliable assessment information compared to conventional methods (Bellotti, Kapralos, Lee, Moreno-Ger, & Berta, 2013; Robert et al., 2014). This can be attributed to the fact that users do not perceive serious games as a stressful testing procedure (Cassady & Johnson, 2002).

The assessment aspect of the cognitive serious games contribute to the early detection of neurological disease (Hagler, Jimison, & Pavel, 2014), while exergames, serious games promoting physical activity and exercise (S. Yang, 2010), are deemed as measuring physical health unobtrusively tools (E. Konstantinidis, Billis, et al., 2014; Staiano & Calvert, 2011). This has recently started to change and exergames have just introduced in the field of cognitive assessment(E. I. Konstantinidis, Bamidis, Billis, Kartsidis, & Papageorgiou, 2015). Only recent studies concerned correlations of physical activity features of SGs with cognitive assessment utilizing virtual environments and treadmills and correlating muscle strength and walking time with global cognitive measurements (Tarnanas et al., 2013). Touch screen serious games and a diversity of serious game have been lately employed towards cognitive Parkinson's Disease prediction(S. Liu, Shen, Mei, & Ji, 2013) and cognitive performance inference (Byun & Park, 2011) respectively. Konstantinidis et al. (2014) introduced the FitForAll exergaming platform towards physical exercise promotion. However, its potential role as contributor to the detection of early cognitive decline signs classifies it to a distinct position. The in-game metrics analysis exhibits classification accuracy greater than 72% when discriminating cognitively normal from mild cognitive impaired elderly. This study show also that FitForAll was more accurate than MMSE and comparable to the MOCA.

Sleep

Sleep patterns comprise a crucial indicator of various health problems, both standalone and as associated symptoms (i.e of pulmonary and cardio-vascular problems). In addition, sleep disruption have been identified as correlated with MCI and Alzheimer's disease. (Lyketsos et al., 2002; Tractenberg, Singer, & Kaye, 2005). Lately, sleep disruption has been linked with decreased performance on memory tests even on cognitively intact elderly (Seelye et al., 2015). In this context, it is obvious that in the framework of an unobtrusive monitoring platform that focuses on the early detection of increased risk factors for dementia, sleep patterns provide rich background information. Making use of off-the-shelf sensors like pressure mats and wrist-worn actigraphy monitors, we can employ a scenario of long term monitoring and assessment spanning months rather than a single day, providing a robust baseline that

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

excludes outliers that skew our data and provide comparison backgrounds for between healthy and MCI subjects. In such a study (Hayes, Riley, Mattek, Pavel, & Kaye, 2014)it was found that amnestic MCI (aMCI) patients typically exhibit less sleep disruptions than non-amnestic MCI (naMCI) patients, who in their turn exhibited less than healthy (cognitively intact) individuals. Seelye et al.(2015) also showed that sustained periods of sleep disruptions have a clear impact on cognitive function in healthy adults. Duration of sleep was not related to the cognitive test performance. These findings suggest that continuous assessment of sleep patterns does provide significant information on factors that can contribute to variable or decreased cognitive function.

Social Engagement

Social engagement is an indirect sign of cognitive status. Moreover, higher levels of social activity have been shown to be a preventive measure for the avoidance of cognitive decline. (Akbaraly et al., 2009; Fratiglioni, Wang, Ericsson, Maytan, & Winblad, 2000; Scarmeas, Levy, Tang, Manly, & Stern, 2001)

As researchers now have a better grasp of the relationship between social engagement and cognitive decline, we can use this information in a twofold way:

1. Deployment of methodologies for the early identification of cognitive decline risks and
2. Development of intervention frameworks based on social engagement as a tool to improve cognitive function.

The greatest advantage of using social engagement metrics as cognitive decline risk for individuals is that most of its aspects can be easily measured in a passive way. These can include time spent out of home, frequency and duration of telephone use, frequency and duration of visitors as well as internet use (e-mail, chat etc).

Decision Support

In the previous paragraphs we examined the milieu of a patient monitoring paradigm that is established in an ecologically valid environment, with open access to monitoring data and input parameters spanning activities of daily living (ADL), behavioral aspects and physiological measurements with the express goal to detect adverse signs in order to enable the early detection of dementia. In this paragraph we go behind the monitoring front-end and try to provide a brief working example of a context-aware system that processes this data via pattern recognition and decision support methodologies to provide detection and prediction results on the subject's status. (Xefteris, Andronikou, Tserpes, & Varvarigou, 2010)

We will use the example of the USEFIL project (Artikis et al., 2012; Billis et al., 2015) which provides both short term monitoring for the detection of emergencies through context-aware detection and assessment of ADLs (Storf et al., 2009), and long-term monitoring for the detection of baseline divergent (abnormal) patterns of health, behavior and general health assessment (Chiriac, Röll, Parada, & Rosales, n.d.,2012).

USEFIL is an innovative data acquisition and processing platform that collects and fuses multimodal data (from sensors, exergames, questionnaires etc). Raw data collection is performed in-home and initial data are processed locally to provide user reminders and alerts, with group-level processing performed on a central database.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The DSS component of the USEFIL platform endeavors to recognize early deterioration signs for a multitude of medical problems as well as deviations from a behavioral baseline that indicate decline, alerting both formal and informal carers as soon as possible. The component performs these operations with the use of data mining and pattern recognition techniques in three steps:

1. Collect of the relevant data that is already filtered and pre-processed.
2. Project data segments into a time-series to enable pattern recognition.
3. Classify the occurring temporal fluctuations to diagnosis types.

The USEFIL DSS system is thus designed as a spatio-temporal model comprising A.I methods that process data related to user activity and physiological classification. The DSS utilizes soft computing, probabilistic and data mining techniques on the sensor acquired data to perform least error prone analysis and decision support.

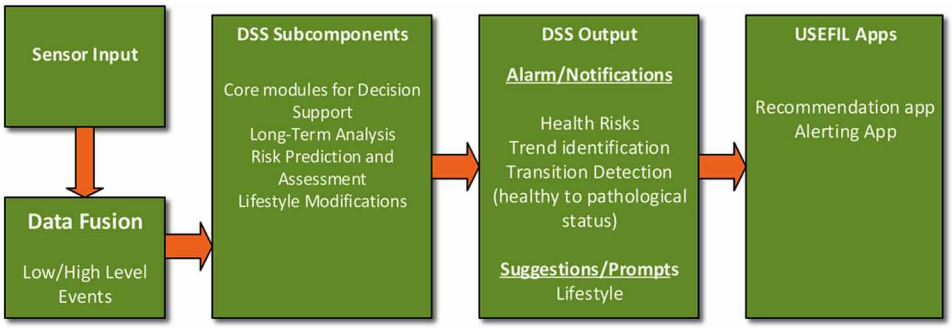
Aiming to accomplish the aforementioned objectives, the USEFIL DSS system is designed to be a spatio–temporal model consisted of artificial intelligence methods manipulating data related with user activity and physiological classification. The progress beyond the current state-of-the art of the specific component is:

- Both short- and long-term monitoring.
- Hybrid decision support system, based on rule-based expert systems combined with fuzzy cognitive maps (FCM) -a type of fuzzy inference scheme.
- Involvement of medical experts in the design process of the DSS, in order to improve the targeting and acceptance of the system with professional carers (Papageorgiou, Billis, Frantzidis, Konstantinidis, & Bamidis, 2013).

The conceptual approach of the DSS component is shown in Figure 2.

The concept followed is that within the Data Fusion Tool the raw data are fused and activity states or transitions among them concerning behavioral and physiological states are stored as events. (Katzouris, Artikis, & Paliouras, 2014)

Figure 2. USEFIL DSS conceptual architecture (I/Os and modules)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Sensor Data Fusion tool outputs these events to the other DSS subcomponents that take care of detecting the various possible pathological states, extrapolate the possibility for future deterioration and identify possible pathological trends as well as suggest remedial approaches. These outputs are categorized in alarms/warnings/notifications or into prompts and suggestions, providing triggering flags to other USEFIL applications (such as an Alerting App) that interact with the subject or the carer. Long term analysis results may be also used as input to the other components (Billis, Papageorgiou, Frantzidis, Konstantinidis, & Bamidis, 2013).

The flowchart in Figure 3 provides a depiction of how the different DSS components are interconnected. (Panagiotis D. Bamidis, Tarnanas, Tsolaki, & Hadjileontiadis, 2015). The various outputs can be considered as standalone DSS results or be used by other DSS components for the production of further conclusions. As an example, the presence of severe symptoms can be used as a standalone result of the long-term analysis component or be combined with the DSS to classify a senior as suffering from a specific pathological condition.

These detected trends may be also used by the Risk Assessment Component, in order to provide estimation of potential future adverse situations. The DSS forms a "pool of evidence" comprising estimation of health trends, current health status and possible future outcomes, in order to procure the appropriate strategies for the alleviation of health problems and for helping the subject stay independent. The produced strategies are proposed via the "Lifestyle Modifications Suggestion". This transforms the DSS from a simple passive monitoring application to an active suggestion system, not only detecting and predicting, but also being actively engaged in possible remedial actions.

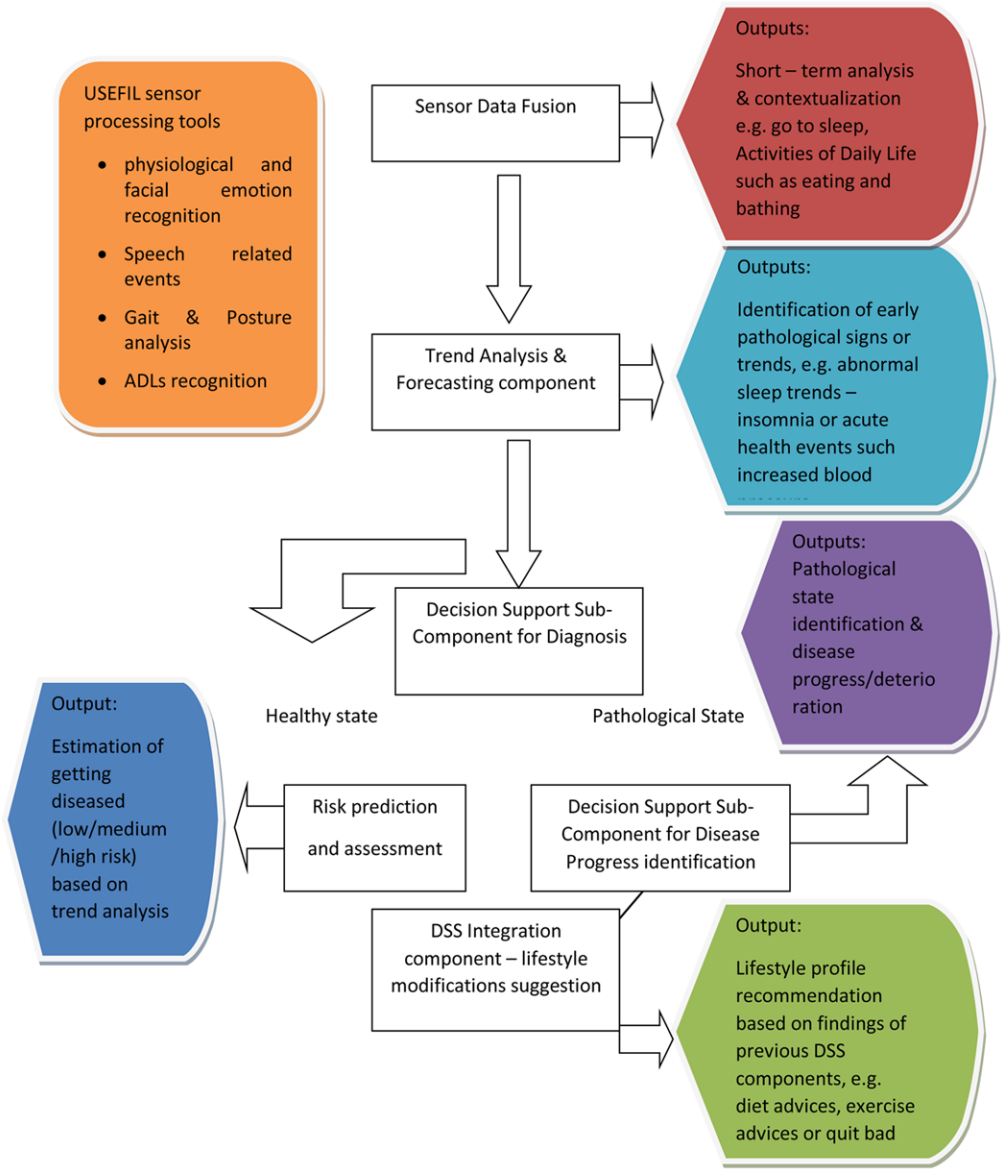
The USEFIL DSS approach is encapsulating the essence of the early detection paradigm by actively engaging in long term monitoring for the identification of adverse trends, providing significant forecasting capabilities for the prognosis of potential future deterioration while at the same time providing possible solutions for delaying this deterioration by the application of certain life-style modifications.

In Vitro Detection with Neuroimaging

We have so far discussed the efficacy of unobtrusive methodologies as reliable markers for the detection of dementia. Nevertheless, reliable biomarkers for the early detection of dementia can be obtained from obtrusive methodologies as well, namely the most common techniques (see next section) usually employed in the field of neuroimaging. Indeed, recent research has shown promising results in the detection process by adding distinctive and reliable neuroimaging biomarkers to the diagnostic criteria of Alzheimer's disease (AD). For instance, (Dubois et al., 2007) demonstrated a significant potential for methodologies that aim to keep cognitive functions active or enhance their performance across the adult lifespan. Engaging seniors into computer based interventions of training schemes tailored to their specific capacities shows great promise in allowing for the longitudinal evaluation and monitor of their cognitive status (Bamidis et al., 2014; Busse, Gil, Santarém, & Filho, 2009; Colcombe & Kramer, 2003; Tardif & Simard, 2011). In parallel, our current understanding of neuroplasticity and the employment of neuroimaging biomarkers have the potential to offer additional solutions in the existing clinical routine for early detection and also for monitoring the disease's progression. The aim of this paragraph is to present recent neuroimaging findings on the dementia detection that can be employed to unravel the functional and structural reorganization of the aging brain.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. The interconnections between the USEFIL DSS components



Neuroimaging Modalities

The process of aging induces changes in the brain and directly in the activity of neurons and subsequently, the cognitive function. With recent advances and techniques, we are now able to study both brain structures and functions. Though obtrusive in nature, techniques such as EEG, MRI, fMRI, MEG, and DTI are non-invasive, painless and easy to apply, thus quite significant in the study of the aging brain in healthy as well as pathologic subjects. These methods enable us to reconstruct images of the structural (grey and white matter) and/or functional (electrophysiological, blood flow, metabolic) characteristics

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the brain, in spatial scales ranging from a millimetre to several centimetre and temporal scales from a millisecond to hours. Each methodology has strengths and caveats in terms of resolution and thus, the decision on which to apply is dependent on the application.

Brain Plasticity

The process of aging is considered to be a progressive state of continuous decline. New research findings though provide us with quite a different milieu: It is apparent now that the brain retains its adaptability and flexibility across a person's lifespan and many cognitive abilities are preserved further than previously thought.

Plasticity refers to the ability of the brain to reorganize both structural and functional components. Plasticity is an ability that in healthy subjects remains active across the lifespan (Boyke, Driemeyer, Gaser, Buchel, & May, 2008).In contrast to an earlier notion that age-related neuroplastic changes were the result of cell death or dendritic deterioration, it is now well accepted that they are the result of lower synaptic densities in older adults (Hedden & Gabrieli, 2004). The aging process alters the biophysical properties of neurons and this affects the brain network dynamics resulting in poor signal to noise ration (SNR) (Burke & Barnes, 2006)and lower neuromodulatory system function in older brains (Mahncke et al., 2006). These changes mainly affect the prefrontal cortex and the medial temporal structures.

Therefore, intensive training of cognitive or motor processes, can stimulate brain plasticity, inducing changes in the underlying cortical structures (Mahncke et al., 2006). For instance, recent MEG findings indicate that two weeks of intensive multisensory training may induce neuroplastic changes in the functionality of frontotemporal cortical regions in adults (Paraskevopoulos, Kuchenbuch, Herholz, & Pantev, 2014). Inducing behavioral interventions enables the ability of the brain to reorganize itself, even in the case of the aging (Mahncke et al., 2006)

Since the cognitive deterioration of the brain may onset well before the aging process begins, and changes in plasticity at brain synapses combined with the loss of neurons are the key indicator for oncoming functional decline, it is apparent that detecting these changes at an early stage, can be instrumental in the early detection of dementia. These changes are precursors to dementia related impairments and precursors of AD, such as amyloid beta deposits, brain inflammation, tau tangles and ApoE4 proteins. They directly affect areas of the brain responsible for learning, memory and cognition by impairing synapses and contributing to cell death. Early neuron loss and changes in synapse function have been observed in the hippocampus and the neocortex, the regions involved in language, memory and higher cognitive functions, so using neuroimaging to detect such changes can alert clinicians to the future onset of dementia and provide a route to preventive actions, rather than the established remedial paradigm.

Structural Neuroimaging in Aging and Dementia

Age related structural changes in the brain have varying extents. The threshold between healthy and pathological aging is very thin as many of these brain changes extend in dementia and AD. The aging of the brain can range from a healthy (successful) state, where structure and volume is completely retained until almost the end of our lives, to a more typical or near pathological aging. Some typical dementia related structural changes can be also a part of a healthy aging curve in middle aged subjects as well as elderly subjects who are essentially cognitively intact. Some extent of brain atrophy can be present in healthy aging but when followed by cognitive decline it may induce an increased risk of neurodegenerative

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

diseases. In this context, structural neuroimaging can be instrumental in detecting preclinical stages of age-related cognitive decline and be of great help in the early detection of the progression of dementia. In order to efficiently characterize age-related disorders such as dementia, we need to disentangle the mechanisms of the structural changes (i.e. atrophy) that take place in healthy aging.

MRI Detection of Dementia

In current clinical practice, structural MR imaging is widely available and reasonably inexpensive. The main challenge of MRI, concerning early detection of dementia or other neurodegenerative diseases is to discern MCI patients that will in the future fulfil the clinical criteria for dementia or AD. MRI can also be used to distinguish between non-AD and AD dementias -for instance, hippocampal atrophy is absent in dementia with Lewy bodies (McKeith et al., 2005)and vascular dementia (Barber et al., 1999). MRI is an efficient tool for the very early diagnosis of an individual suspected of dementia and its subtyping, through detection of hippocampal reductions. (Shi, Liu, Zhou, Yu, & Jiang, 2009). Moreover, MRI is employed for predicting the risk of AD progression in populations that are both cognitively healthy and MCI.

Though more research is needed to establish the clinical value of MRI in MCI, measuring these significant reductions due to AD can have a powerful impact on the early diagnosis of MCI and AD. In addition, MRI is employed for the prediction of the risk of dementia progression. (Risacher et al., 2009) established that the MRI biomarker measuring the degree of neurodegeneration of MTL structures was the best for imminent conversion and the biomarker of decreased hippocampal volume the most robust.

So, having established the as early as possible detection of the disease, MRI metrics such as brain volume fluctuations through time, can be used to evaluate and keep track of the disease (Fox & Freeborough, 1997).

DTI Detection of Dementia

Changes in grey and white matter are promising biomarkers of dementia. These markers are detected by microstructural abnormalities on DTI-based diffusivity indexes. These alterations enable the prediction of dementia progression independently of possible volume loss in prodromal situations (Canu et al., 2010; Fellgiebel et al., 2006; Oishi, Mielke, Albert, Lyketsos, & Mori, 2012) and are evident in both healthy brain aging as well as in MCI and dementia, but also in other neurodegenerative disorders (Kantarci et al., 2011; Oishi et al., 2012; Rogalski et al., 2012) .

In MCI patients, higher baseline diffusivity in the hippocampal head indexes a bigger risk of progression to AD. Thus, diffusion findings can be employed as complementary biomarkers to hippocampal atrophy in identifying progression. When taken in earlier stages of life, these findings can be indicators of the future appearance of symptoms.

Functional Neuroimaging and Resting State Analysis

To understand the effects of aging on neural plasticity, we have to initially examine the effect of age on the brain's functionality. Functional neuroimaging detects age-related increases and decreases of neural activity, in conjunction with cognitive decline. These approaches provide a link between the various implications of aging on our brains by measuring either resting state activity or neural activity while subjects perform cognitive tasks.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In this context, neuroimaging studies make use of resting state measurements for the definition of a baseline which is later compared with the results from the performed tasks. At rest, the cortex's functional characteristics show a high degree of reproducibility and stability and some brain regions show a consistent activity than during cognitive tasks (Greicius, Srivastava, Reiss, & Menon, 2004). The implicated brain regions include the posterior cingulate cortex (PCC), MTL structures, dorsal and ventromedical PFC and lateral (mainly inferior) parietal cortices (Mevel, Chételat, Eustache, & Desgranges, 2011). Due to its functional characteristics this is dubbed the Default Mode Network (DMN) (Raichle et al., 2001) . The DMN is characterised by a highly stable functionality which makes it a valuable tool for the evaluation of cognitive and neurological disorders such as amnsestic MCI (aMCI) (Garcés et al., 2014) and AD (Greicius et al., 2004).

Using fMRI for Resting State Analysis

fMRI is a highly promising biomarker for dementia, repeatable many times over the course of longitudinal studies. fMRI studies examining the effects of dementia in activation patterns and organization of DMN of dementia patients (Y. Liu et al., 2008) and age-matched healthy subjects revealed that dementia groups exhibit decreased resting state activity in almost all of the cortical regions involved in the DMN and most prominently in the hippocampus and the PCC, thus suggesting disrupted connectivity between these two regions in dementia(Greicius et al., 2004). In an earlier study (Shi et al., 2009)it was established that dementia patients exhibit diminished connectivity of the hippocampus to other regions, compared to healthy elderly individuals. In this study, a group of MCI patients had intermediate values, also significantly different from the dementia group. Lack of presence of this connectivity breakdown in the visual cortex suggests that the sensory systems may be affected only in later stages of the disease. Studies also revealed that the functional connectivity of the hippocampus with the medial PFC, ventral anterior cingulate cortec (ACC), right inferior temporal cortex, right cuneus (Cu) and precuneus (PCu), left Cu, right superior and middle temporal gurys and PCC was disrupted in dementia patients compared to healthy adults (L. Wang et al., 2006)

In Sheline et al.(2010) it is revealed that the functional connectivity breakdown of the DMN that dementia patients exhibit might predate the pathological effects of amyloid plaque toxicity.

Thus, detecting early connectivity breakdowns in the DMN via fMRI in resting state, could be of big help in a future early dementia detection paradigm.

Using MEG-EEG for Resting State Analysis

EEG has a high temporal resolution which makes it an ideal tool for studying the cortical connectivity of DMN. Several studies employed this approach searching for disrupted connectivity between cortical regions of the DMN, indicative of neurodegenerative diseases.

In a 2014 study, (Frantzidis et al., 2014) used EEG to reveal a significant reduction in the small-world brain architecture in both aMCI and mild demented patients relative to the group of healthy controls. These findings correlated significantly with the cognitive function as evaluated by MMSE. All of the above are in line with the notion that the AD may be grounded on a connectivity breakdown and may actually constitute a disconnection syndrome, as suggested by Delbeuck (Delbeuck, Collette, & Van der Linden, 2007).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Apart from structural and connectivity analyses, several studies have used another approach and ventured to identify the electrophysiological effects of dementia and MCI to the functionality of the DMN. These studies are focused on comparing the EEG activity measured across different frequency bands between dementia, MCI and healthy subjects. The results of such studies indicate that dementia patients in contrast to healthy subjects exhibit increases in the power of low frequency bands such as delta (-4Hz) and theta (4-7 Hz) in central and frontal electrode sites as well as a decrease in the power of posterior alpha (8-15Hz) and beta (16-30Hz) (Babiloni et al., 2004, 2013; Bennys, Rondouin, Vergnes, & Touchon, 2001). These findings are corroborated by MEG studies which exhibit increased power in the activity of parietal delta sources(Fernández et al., 2006) and more significantly, these abnormalities seem heavily correlated with global impairment of cognitive function via an MMSE evaluation (Jeong, 2004).

Comparing MCI patients with healthy controls, reveals the same pattern of findings (increase in power of low frequency bands in posterior sites and decrease of alpha and beta bands for MCI patients). Thus, we are led to pose the hypothesis that there can be a linear transition point between healthy and MCI and MCI and dementia, and that these EEG findings may provide stable screening biomarkers for the risk of onset of dementia and prediction regarding the progression from MCI to AD(Babiloni et al., 2013). Recently, an EEG study explored the effects of combined cognitive and physical training on resting state brain activity of MCI patients in comparison to the effects of solely cognitive or physical training as well as in comparison to active and passive control groups. The effect of the combined intervention was interpreted as beneficiary neuroplasticity changes (i.e. decrease delta and theta rhythms in the precuneus/posterior cingulate cortex) across MCI patients and these changes correlated with cognitive status improvement.(Styliadis, Kartsidis, Paraskevopoulos, Ioannides, & Bamidis, 2015).

FUTURE CHALLENGES

In 2013, over 35 million people around the world were estimated to have dementia.(Camicioli et al., 1998) The number of people worldwide with dementia is expected to increase to 65.7 million in 2030 and 115.4 million in 2050, which is approximately a doubling of sufferers every 20 years. ("WHO | Dementia: a public health priority," 2012). Dementia is a syndrome of progressive cognitive and functional deterioration which is incurable. There are diverse symptoms and various levels of impairment depended on affected brain regions and types of dementia. Contemporary medical technologies related to dementia have proven track record for detection and intervention but have also been distilled in more mild modalities to be implemented in the case of less severe needs. Recent technological advances that allow the in-vivo study of brain structures and functions in human subjects have greatly contributed to a better understanding of the brain changes that occur due to aging and are likely to impact the cognitive function and neuronal activity. The non-invasive nature of most of these techniques (i.e. Electroencephalography – EEG; Magnetoencephalography – MEG; Magnetic Resonance Imaging – MRI; functional MRI – fMRI; Diffusion Tensor Imaging – DTI) makes them an invaluable tool in the study of the living brain in healthy as well as pathologic subjects (Styliadis, Kartsidis, & Paraskevopoulos, n.d.).

With diagnostic modalities providing significantly early detection of various dementia types the question becomes one of choice of interventions. Additionally, with studies outlining depressive symptoms, as a consistent factor which is negatively related to self-rated QoL of people with dementia living in long-term care facilities (Beerens, Zwakhalen, Verbeek, Ruwaard, & Hamers, 2013) as well as the self-evident costs related with long term care the Ambient Assisted Living (AAL) approach to the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

maintenance of quality of life and health care interventions provide greater flexibility and respectful interventions at the behavioral level with unobtrusive and transparent monitoring and interventions at familiar home environments.

Beyond the, now established, monitoring with unobtrusive sensors and devices that are natively ICT enabled an emergent field in elderly healthcare is the Internet of things (Ashton, 2009). Transparent and ubiquitous communication capacities by ad-hoc networking of various devices and actuators has begun finding application in elderly healthcare. This technology has been demonstrating, rather recently -e.g. (G. Yang et al., 2014), a significant number of enabling capacities in the field of elderly healthcare, especially for people with cognitive decline. Inkjet printed, flexible bio-patches that allow for portable and very unobtrusive ECG measurements; RFID enabled medication packaging that can sense how many medication slots have been opened, facilitating dramatic increase in medication adherence of elderly people; unique RFID tagged medical ids linked to detailed medical records for protection against false medical history. Such unobtrusive and transparent technologies provide critical quality of life improvement and subsequent lifestyle and healthcare maintenance.

With all these advances in ubiquitous networking and unobtrusive monitoring an area that appears to not have been heavily tapped into is the technologically enabled communication and collaboration between elderly that are suffering from one or another form of non-trivial age based cognitive decline. The effect of an existing, active and supporting social network in real life has been explored providing evidence that it is associated with the well-being of the elderly (X. Wang, 2014). What hasn't been explored so far in sufficient detail is the extent in which an electronic social network of dementia patients and their carers would impact in their quality of life. Although folksonomies (folk-generated taxonomies from custom subject tagging in social networks and forums (Adamic & Adar, 2005)) have led to emergent social networking the use of such provisions are still not sufficiently explored. In the context, however, of AAL environments and protected but ubiquitous networking there is significant potential for unobtrusive behavioral monitoring and intervention in the, now widely accepted, form of an electronic social network.

From the previous discussion, distilling content from this whole work three overall monitoring and intervention feedback loops emerge. In the purely biomedical level the aforementioned brain activity and anatomy monitoring and imaging capacities (e.g. EEG, PET, fMRI) provide immediate feedback to the medical doctor for medicinal or non-medicinal treatment of dementia's underlying pathogeny at the purely neurophysiological level. On a different level, ambient, unobtrusive sensor based monitoring and assessment in the home environment provides the necessary data that are usable for prescribing and suggesting personal behavioral modification that will improve or at least maintain quality of life (e.g. physical exercise programs, exergaming interventions). Furthermore, even though largely unexplored in the context of ICTs, real world support group interventions of elderly with varying degrees of dementia provide to the expert crucial data for intervening at the social level and creating a fertile social environment for the patients to maintain or even improve their way of life (Leung, Orrell, & Orgeta, 2015).

Medical diagnostic modalities, intervention protocols, unobtrusive ambient home monitoring and intervention as well as social support infrastructure have the capacity of creating an immense amount of data. From patient records and imaging to real time sensor data these are sources of information that can provide a wealth of additional meta-information using context, time evolution and aggregation techniques. In order to achieve "human activity recognition" (Rashidi & Mihailidis, 2013) a number of techniques must be applied in order to transform raw sensor data to human activity patterns. In that endeavor methods of either supervised learning through annotation, using annotated data and supervised machine learning algorithms can be utilized, or, even more abstractly, unsupervised data mining

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

techniques can be incorporated (Rashidi & Mihailidis, 2013). These algorithms, in order to cope with the needs of interpreting activity in various contexts as well as discriminating outliers with significant anomalies in activities have widely adopted the use of modelling metadata and ontologies in order to codify both context and underlying semantic relationships.

Evolving from information theory, efforts are made to explain and exploit the cross-scale information processing that is apparent in natural dynamical systems. By viewing physical, biological, or social systems as networks of information exchange, statistical tools from information theory can be used to causally explain and quantify the effect that each participant of this network contributes to the overall behavior of the network (Quax, Apolloni, & Sloot, 2013). Through such toolbox, outcomes from contemporary physics, such as resonance phenomena and non-trivial propagation phenomena can be quantified and predicted (Czaplicka, Holyst, & Sloot, 2013). In that way specific structural changes in a network's characteristics can dramatically alter the dynamic evolution of various metrics of the system that is described by it. Such scientific paradigms can and have been used to explore the not only the fundamental processes on different and separate scales of dynamic systems, but also the cross-scale coupling of them and any possible resulting emergent properties that can be exploited for pattern recognition or efficient interventions (e.g.("dynanets.org," 2015)).

This kind of analysis tools have found use in a variety of disciplines and fields where implementing a specific hypothesis about a network, based on the characteristics of the participating nodes can lead to tangible conclusions about macroscopic and measurable characteristics of the whole system. For example information dissipation length (IDL) has been introduced as an index of global instability of the time series of USD and EUR interest rate swaps (IRS) presenting a specific pattern of gradual increase and subsequent decrease before and after the Lheman Brothers collapse, respectively (Quax, Kandhai, & Sloot, 2013). On another example by introducing the concept of transmission networks and proposing a filter reduction method in combined data from social networks and phylogenetic analysis, tangible results regarding correlation of cross-group sexual behavior and HIV transmission has been found (Zarrabi et al., 2013).

Bringing all these themes together, smart sensors and semantic technologies provide aggregated high level data about daily activities. Contemporary decision support and machine learning technologies can consume such high level data streams, in real time, providing intervention suggestions at both the physical and mental pathogeny level. Neuroscience advances provide assessment tools able to rapidly validate, and intervene with gamified and collaborative activities for mental health and overall wellbeing. What is at the moment missing is a formalization, both at a high level of abstraction, as well as at the prototype implementation level, of the role of these technologies and interventions, in the paradigm of maintaining wellness through structured interaction. Utilizing the aforementioned information theory background. Such a synergetic use of these technologies would provide both a conceptual paradigm and an implemented assessment and intervention prototype for more effective and impactful dementia monitoring and intervention. From this discussion of the previous sections on modalities and means, combining the previous discourse it becomes apparent that, apart from following through in researching specific aspects of dealing with the dementia patient, a significant future challenge will be the integration of the technologies and methods into something beyond an incoherent mashup of randomly interacting parts. Detailed data aggregation methods can provide detailed but also seamless exploration of various modalities' and interventions' impact. This methodology can explore, utilizing the previous theme of cross scale feedback propagation, the necessary exact prescriptions for all the components of this palette for achieving rigorous integration to protocols. In that effort the support from ecologically

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

valid dementia oriented living labs in conjunction with the treatment space (hospital, personal physician) become an organic research testbed for this integration. Only through such a coordinated infrastructure of integrated research can, large scale trials explore the cross-scale and cross-modal impact of an emerging ecosystem of dementia prevention, treatment and care in order to provide an appropriate, immediate and personalized monitoring and intervention "prescription" that will ensure each individual patients length and quality of life.

Chapter 99
Opportunities and Challenges of Big Data in Healthcare

Wafaa Faisal Mukhtar
Sudan University of Science and Technology, Sudan

Eltayeb Salih Abuelyaman
University of Dammam, Saudi Arabia

ABSTRACT

Healthcare big data streams from multiple information sources at an alarming volume, velocity, and variety. The challenge that faces the healthcare industry is extracting meaningful value from such sources. This chapter investigates the diversity and forms of data in the healthcare sector, reviews the methods used to search and analyze these data throughout the past years, and the use of machine learning and data mining techniques to mine useful knowledge from such data. The chapter will also highlight innovations of particular systems and tools which spot the fine approaches for different healthcare data, raise the standard of care and recap the tools and data collection methods. The authors emphasize some of ethical issues regarding processing these records and some data privacy issues.

INTRODUCTION

We live in the age of Big Data, where every single data entry to any computer at home or office is being recorded in data centers and processed later in order to get valuable information or knowledge. IDC (International Data Corporation) defines Big Data technologies as a new generation of technologies and architectures, designed to extract economical *value* from very large *volumes* of a wide *variety* of data produced every day, by enabling high *velocity* capture, discovery, and/or analysis (Gantz & Reinsel, 2011). Other institutes and companies such as SAS, IBM and Oracle have other dimensions for Big Data, but they all address same concepts.

Several organizations create very large databases, such as consumer data and transaction histories of sales records, patient records, images at hospitals, fingerprints and DNA samples at crime scenes, and data acquired via satellites or surveillance cameras. It is apparent that there is a huge gap between the amount of available information and its corresponding knowledge, which gives an opportunity for extracting hidden knowledge.

Healthcare can be considered a major sector for producing big data. Healthcare data have many dimensions such as personal information regarding dates of birth, nationality, sex, location and other information about income and education plus other specific data about history of the patient with medical centers and/or disease. It is generated by everything around us at all times in intensive care units and in surgical operation room, inward_from every digital process in systems or sensors.

The aim of this chapter is to discuss the notion of big data when applied to the healthcare sector. The next section reveals how and why big data are represented in health care. Big Data's Vs will be emphasized for healthcare data in the third section. The fourth section highlights different techniques that are well suited for intelligent data analysis. Section five illustrates the challenges facing Big Data and the opportunities available for valuing analysis, and some ethical, legal and social concerns about manipulating healthcare data specifically. Some implications are contending in the future directions showing how they can play an important role in the overall improvement of the healthcare industry.

BACKGROUND

Medical data are at once the most rewarding and challenging of all biological data. For decades everyone was infatuated by the liability of keeping every record and collecting any possible information about everything in their life. The healthcare industry has also experienced these practices about generating and keeping large amounts of data driven by record keeping at physicians' clinics, which is referred to as patient records. This includes forms filled by the patient regarding his/her personal information and oral examination recorded by physicians during visits. Other forms of checkups, different laboratory examinations, and CT scan as well as X-ray images are also kept in hospital's emergency room when examining patients. Moreover, data about compliance & regulatory requirements, and patient care is also evolving from national and international organizations that monitor and administer the healthcare industry.

Electronic health records have experienced several studies. Drug safety study (Trifirò et al., 2009) investigated adverse drug reactions with other diseases, in (Jensen, Jensen, & Brunak, 2012), they combined the HER with the genetic data to reveal gene-disease association, (Almodaifer, Hafez, & Mathkour, 2011) discovered the interesting and concise medical rules for prediction purpose to assist the medical decision makers.

Medical diagnosis researches have proven a great success, because the data about the disease and the patient under examination is always available. In fact the medical diagnostic knowledge can be automatically derived from the description of cases solved in the past. (Kumar, Sathyadevi, & Sivanesh, 2011) proposed using an intelligent clinical decision support system to assist physicians in diagnosing. An automatic diagnosis system was presented in (Karabatak & Ince, 2009b). Soni & Ansari, 2011; Kharya, 2012; Huang, Chen, & Lee, 2007; (Ha, 2011) (Kononenko, 2001) summarized several machine learning techniques used for classifying diseases such as naïve Bayesian and neural networks, his work also highlighted the specific requirements for good performing machine learning algorithms in solving medical diagnostic tasks.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Image parameterization observed in medical records is very useful in quality control, identification, image grouping, surveillance, image storage and retrieval, and image querying. Texture classification is closely related to diagnostic process to diagnose coronary artery disease (Kukar, Kononenko, & Grošelj, 2011).

Big Data V's

The V's that characterizes Big Data (volume, variety, velocity, and value) will be identified with exceptional respect to healthcare sector.

Volume

The volume of generated and stored data is extremely expanding every year, and there is an evolution amongst the country level, in digitizing all transactions. Electronic health records (EHR) are stored in databases since the eighties of the past century. These records are generated when a patient gets medication service at a physician clinic, hospital or even from the pharmacy. In the past there was no collaboration between these different entities which resulted in duplication and inconsistence of patient records. According to data.worldbank.org the world population is about 7 billion, where about 15% lived in developed countries. EHRs types, which vary from any, basic to fully functional, were adopted in these developing countries, and there are plans to establish health systems in other urban areas, which describe the volume of records in anticipation of processing. Moreover, data also is generated during laboratory examinations of blood and other fluids, images of different types and are all kept recently in electronic formats. These records are kept not only for living people, but also for the people who died several years ago. Data about drug specifications, formulations, interaction, side effects and safety are all kept as pharmaceutical documentary records. Billing, financial transactions and insurance claims are also archived over years.

Variety

The variability and complexity of healthcare data come from different resources that provide the data in different formats. Patient records by themselves can have different forms, since some clinics or hospitals can adopt a similar format, although some private clinics may not. Some records may contain images with different size and dimensions like X-Ray, CT Scan or MRI which increase the complexity of handling these data. Laboratory tests may also differ between clinics and hospitals. The prescription advised by the physician can be kept as text or scanned image. In the operation or intensive care units, nurses and doctors may keep observatory text notes and examination checks.

Survey information on population health, such as causes of deaths, community health, and health care systems are collected in Population health metrics. National health organizations control enrollment into health insurance plans in order to administer health care delivery. Huge statistics on public health databases and registries concerning births, deaths, disease incidence, health event case reports, demographics and more are available at United Nations organizations.(HealthData.gov, 2014)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Velocity

Medical databases are constantly updated in critical health conditions. Dealing with data from intensive care units (ICUs) and operating rooms (ORs) are a challenge in hospitals. Continuous and high priority monitoring add new records and tests in every second. There is a necessity to update the databases since doctors and nurses write progress notes. Drug prescription and delivery is changed and charted several times a day. Monitors generate large amounts of data on a continuous basis, as well as therapeutic devices such as mechanical ventilators, syringe- and infusion pumps for drug and fluid administration, or renal replacement therapy machines. Blood samples for ICU occupants are drawn for laboratory analysis several times a day, and microbiology sampling occurs several times a week (Meyfroidt, Güiza, Ramon, & Bruynooghe, 2009). At Home monitoring systems for critical disease patients through sensing devices such as heart monitors, ventilators, cell phones accelerometer or wearable devices provide real-time data.

Value

It is, however, the value, veracity, or 'data assurance' that should generate an improvement in the healthcare industry. In order to benefit from the mass of collected data; researchers, practitioners and policy makers should analyze these data and get implication which will strengthen decision making and improve healthcare management. Organizations should be able to analyze health problems through investigating health claims, get a more complete view of health processes and their interactions by analyzing patients' records, evaluating a greater number of scenarios quicker and more cheaply to best achieve operational efficiency at ICU units and operation rooms, employees satisfaction, and risk reduction for healthcare organizations across the nation. Drug safety researchers need to get new experiences into medication drug collaborations that have not been completely comprehended or anticipated during clinical trials, this can be achieved by association analysis at the pharmacology level and public health researchers. (Silvia & Claps, 2013)

The healthcare industry is moving from reporting truths to disclosure of experiences, getting to be information driven. Converting data and information into actionable insights by several procedures of data analytics to prevent inefficiencies and adapt workflows for improved healthcare outcomes across the end-to-end patient journey will be paramount. It will empower better joint effort among clinical experts, engaging general health authorities to supervise the individualized gathering anticipation movement, and providers to implement new industry models, pushing performance by reward could set scales for financing healthcare services, making it available extensively for people. (Silvia & Claps, 2013)

Eventually, it is the value that will make Big Data a genuine power of progress in healthcare, ensuring value while preserving quality.

HEALTHCARE DATA ANALYSIS

In addition to the high volume and velocity, the complexity and variety of big data, Gartner IT dictionary has added that big data also demand cost-effective, innovative forms of information processing for enhanced insight and decision making (Gandomi & Haider, 2015). Data can be described as big if the growth of data far exceeds the efforts done to understand it.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

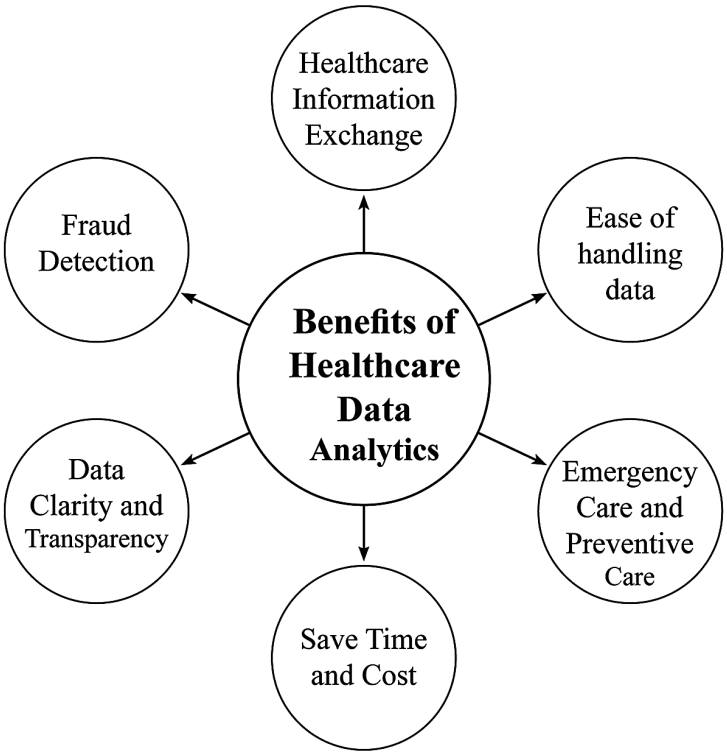
Healthcare data analysis can be advantageous in building predictive modeling that can lower attrition and results in fine procedures in clinical operations and drugs safety. For public health improvement, analysis of largely produced medical data can help in finding disease patterns and tracking epidemic diseases, turn data into actionable evidence to improve services and prevent fraud and crises (Raghupathi & Raghupathi, 2014). Figure 1 illustrates that different employees in the healthcare sector will aggravate better choices concerning strategy making, inventing new instruments to capture data, new strategies for diagnosing and prognosis, developing patient engagement, optimizing operations, putting off fraud as well as threats, and profiting by introducing a new supply of income.

Due to the variety of data, which holds images, forms, databases and surveys, analysis techniques that deals especially with large amount of data is adopted. Machine learning algorithms and data mining techniques proved to be the best practices which aids and supports the process of decision making.

Machine Learning

Statistics for decades was the best analytical tool for medical students and researchers. It was used for survey analysis, generating reports and representing charts, comparative studies about different health care distribution and disease/drug relationship. Due to the fast evolution in computation and computers, machine learning became the new solution. A major subfield of artificial intelligence based on statistical foundation, machine learning is a multidisciplinary field involving information theory, philosophy, neurobiology and other fields.

Figure 1. Benefits of healthcare data analytics
Dergurahian, 2011.



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The fast growth of databases and the lack of knowledge mining, challenged researchers to benefit from the low-priced computation power. Big Data investigation requires enormous programming effort, which can be simplified using intelligent systems that support learning making it simple and comprehensible, a program can be automatically driven. Machine learning algorithms are probably the most valuable candidates for health care data analytics because they can deal with different and large amounts of data integrated from different sources and they also rely explicitly on previous domain knowledge or experience in the analysis, providing several programs for intelligent data analysis.

Supervised learning algorithms discover automatically a knowledge model as a result of the learning process that provides a description of the data explored. Support Vector Machine (SVM), Decision Tree (DT), Artificial Neural Networks (ANNs), Regression, K-nearest neighborhood (KNN), Bayesian Networks (BN) and many more algorithms were considered for machine learning to classify and organize big data easily. The aim of the knowledge model is to predict the value of the target attribute for new unseen patterns.

Another type of learning is unsupervised learning, which analyzes the information or data with unknown target variable, building the model which solely describes the data analyzed. The goal of the process is to build a model that describes interesting regularities in the data.

These learning techniques are mostly used in medical diagnosis, and classifying patients accordingly to different attributes available in their medical records (Hariz, Adnan, Husain, Aini, & Rashid, 2012; Kononenko, 2001; Meyfroidt et al., 2009; Yang & Wu, 2006), Lots of researches regarding machine learning in medical data and bioinformatics are available in (Larrañaga et al., 2006; Prompramote, Chen, & Chen, 2005; Lavrac, 1999; Lavrač, 1999).

Data Mining

As the gap between produced data its understanding is widening, it is high time to look for potentially useful information which lies hidden in all these hypes of data or information. Data mining or Knowledge Discovery from Databases (KDD) helps extracting such patterns (Witten, Frank, & Hall, 2011). Data mining has been used earlier in market analysis, financial data analysis, business management, space exploration and proved to be the best solution for various domains especially medical data analysis (Tomar & Agarwal, 2013).

Healthcare industry can benefit from using data mining techniques to take considerable actions regarding: (Tomar & Agarwal, 2013)

1. Effective management of Hospital resource,
2. Hospital Ranking,
3. Better Customer Relation,
4. Hospital Infection Contro,
5. Smarter Treatment Techniques,
6. Improved Patient care,
7. Decrease Insurance Fraud,
8. Recognize High-Risk Patients,
9. Health Policy Planning.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The nature, complexity and growth of the data in healthcare sector, brings medical data mining to the edge of new technologies, proposing a powerful tool for analyzing and extracting important knowledge.

The knowledge can help building models that might support prediction of diseases or recommend drug, understanding the nature or describe associations of the data been collected. Applying data mining concepts, such as prediction, description, summarization and visualization to the healthcare big data improved the industry, saving time, money and life (Jacob, 2012).

Medical data may take tabular form or standard format *m.n* array where *m* represents the size of the data in rows and *n* represents the features or attributes in which data is described. Classification techniques, built across supervised learning techniques, dominates other data mining techniques because it is can assist in the future prediction by building a model of a classifier. Practitioners may seek for quantitative or qualitative description of the data, grouping patients with similar features or having similar disease type, using association analysis and clustering techniques.

Natural language processing and text mining can be applied for medical records or drug prescription, applying different techniques for classification, clustering or even discover new associations. Images can undergo digital image processing and then apply image mining to extract useful and hidden patterns.

Medical diagnosis systems can be developed using mining techniques, investigate symptoms and patient medical history to detect certain disease, classify image as malignant or benign for tumer detection, find explanation for causes of diseases through descriptive analysis such as association analysis, clustering and sequential pattern mining. Data mining patterns could be analyzed to prevent developing of diabetes or high blood pressure for example.

Challenges and Solutions

The significance and value of Big data lies in the storage facilities, functioning processes and procedures used for sharing and capturing data and tools used to analyze and search very large data sets.

The first challenge that faces medical data mining is the lack of a standardized clinical vocabulary (Jacob, 2012). The mass of healthcare data is buried in heterogeneous databases scattered throughout many institution, tied in with a lot of missing, distorted, conflicting, and non-homogenous data in different formats in diverse data sources, thus most probably might be ignored during analysis. The stored information becomes less useful if it is not available in an easily comprehensible format. Nevertheless, large portion of this gathered data will be unprocessed, for instance, video streaming data are deleted after a week, instead some sort of archiving should be adopted every period and some arrangement of knowledge extraction, such as using it for performance auditing (Raghupathi & Raghupathi, 2014).

Bio/medical big data has major challenges, computation power and data analysis. Computation cost while analyzing the biological data especially after using the next generation sequencing technology that produces large size of data. Bio/medical cloud services have developed integrated tools and biological databases to formulate complex systems (Chae et al., 2013).

Data Mining Tools

Powerful automated tools to analye, visualize and interpret useful information from different data sources will be benificial. Many manufacturers support such tools to discover patterns involving methods using the artificial intelligence, machine learning and statistical analysis. KD nuggets offered many Analytics and Data Mining Suites, supporting classification, clustering, data preparation, visualization, and other tasks,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

it also provides a list of specific healthcare analytics solutions (Kdnuggets, 2015). Microsoft developed the SQL Server Analysis Services platform to build high performance multidimensional and tabular analytical models for interactive data analysis, reporting, and visualization (Russo, Ferrari, & Webb, 2012). DB2® Intelligent Miner(TM), was developed at IBM to provide Intelligent Miner analytics such as modeling, scoring and visualization (Ibm, 2014). DB2® was integrated with Clementine data mining workbench since 2004 (Ibm, 2007). SAS and Intel provide an analytical solution as well, SAS® Enterprise Miner™, that can handle accurately large amounts of data and produce predictive and descriptive models (Sas, 2014). Oracle Data Miner deploy data mining models inside the relational database environment (Tamayo, 2005). There are also open source tools for data mining, and the six powerful and mostly used are RapidMiner, Weka, R, Orange, Knime and Natural Language Toolkit(NLTK) (Goopta, 2013).

Novel Frameworks

Practitioners need systems and tools in order to capture and store this information, researchers need optimal processing power, analytics capabilities and skills to search and share the information. Big Data organizations start investing in the development of new infrastructures for running operational, real-time applications that can cope with the enormous and various amounts of information produced.

Yahoo after working with Nutch and Google released Hadoop as an open-source project for reliable, scalable and distributed computing in 2008, but it is now supported by Apache Software Foundation (ASF), it can perform two tasks: data storage and processing (Sas.com, 2014). The Hadoop platform comprise of three main components;

- **Hadoop Distributed File System (HDFS):** A Java based distributed file system that provides high-throughput access to application data that can store all kinds of data without prior organization.
- **Hadoop YARN:** A resource management framework for job scheduling, handling resource requests from distributed applications and cluster resource management.
- **Hadoop MapReduce:** A software programming model for parallel processing of large data sets. It is also accompanied by some other products for handling scalable data bases, warehousing, machine learning, data mining and many more(Apache.org, 2015).

Traditional relational databases can no longer handle and get value from healthcare big data, JustOneDB is a new high performance NoSql relational databases suitable for Big Data storage, load, and fast retrieval of queries and predictive analytics for healthcare industry (JustOneDB, 2015).

Recently bio/medical cloud services have begun evolving from simple and primitive applications to offering integrated and complex systems. The bioinformatics cloud service provides systems such as Galaxy, DNAnexus, Crossbow, SoapSNP and many others, not only without worrying about the manual system installation and data integration processes, but also with reduced data uploading/transferring time. (Chae et al., 2013)

High speed transfer of large volumes of data is achieved byAspera and Intel. Aspera's patented fasp* transport technology is designed and implemented to have no theoretical throughput limit on Intel® Xeon® processor E5-2600 product family in Virtualized Environments (Intel, 2013).

Ethical, Legal, and Social Issues

Medical data contains sensitive, private and confidential information about patients, accordingly the public may fear of data misuse, abuse and disclosure. Data ownership is an open question, since data is collected at different healthcare position, processed mainly by third party. Patient might hesitant against the release of information, although data analysts need to combine various records sometimes from another society. Records are shared and linked more widely nowadays than before while working on the open internet platforms. Security of patient's data during electronical transfer through the internet should be handled within ownership. Furthermore, medical data mining can drive the fear of lawsuits directed against healthcare providers. Patients may raise claims about unnecessary tests performed, confident questions asked and particular conclusion derived unconsciously.

RECOMMENDATIONS AND FUTURE RESEARCH DIRECTIONS

Healthcare Big Data by its different dimensions provide big opportunities for researchers and healthcare practitioners. Everyday activities are moving online, shared and linked to medical transactions or others. Data gathered during any medical transaction should be secured, encrypted or anonymized. Easily accessed and explored data storage facilities will have made it easy to govern and direct plans and strategies to provide the best quality healthcare services. Medical data mining can practice new algorithms for real time data analysis.

Healthcare records have to be standardized to avoid the future data cleansing and inconvenient data. Control over medical data ownership will minimize legal suits against health institutes. Improving care quality consequently will produce value to identify modern approaches for healthcare administration.

CONCLUSION

The chapter went through the advent of Big Data in Healthcare industry and emphasized its four dimensions. The critical manner of processing such data which are of various forms in big volumes and rushing in high velocity in time is clarified. Extracting knowledge or value is a need using new methods and technologies available. Some of the new storage and transfer platforms as well as high performance computing, on the cloud were mentioned. Privacy and confidentiality issues were discussed when trying to merge or analyze such data.

Big data in the health industry is still promising, offering new opportunities for new data storage, transfer and analysis frameworks, and try to get from the exploding information gathered.

KEY TERMS AND DEFINITIONS

Big Data: Large amount of data, in many different formats, that flows rapidly in real time. This data should undergo some sort of analysis in order to extract useful information or knowledge.

Cloud Computing: High performance computing service which does not require location setting, but instead use a grid of computers over the internet.

Data Mining: The process of extracting new, useful, understandable and previously unknown knowledge from information that might help in decision making.

Electronic Health (Medical) Record: The narrative record written by the nurse or the physician during patient examination.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hadoop: Hadoop is an open-source software framework from IBM, capable for storing and processing big data in a distributed fashion on large clusters.

Machine Learning: The subfield of artificial intelligence that uses learning algorithms in handling problems.

Medical Diagnosis: Investigating the symptoms and causes of certain disease, either by oral examination or laboratory tests.

Chapter 100
Wireless Body Area Network for Healthcare Applications

Danda B. Rawat
Georgia Southern University, USA

Sylvia Bhattacharya
Georgia Southern University, USA

ABSTRACT

Wireless Body Area Network (WBAN) is an emerging field of research which has been progressing rapidly in recent years. WBAN is a network utilized for continuous monitoring of physiological state of the subject, where the patient can perform his regular activities while his body parameters get measured continuously and are accessed by the physician remotely. This chapter provides a thorough survey of current WBAN technologies in the healthcare sector. Besides the recording of physiological parameters, discussions have been provided on remote data transmission to a server called Virtual Doctor Server (VDS). During this transmission, WBAN network uses various technologies namely Ultra Wide Band WBAN, Technology Enabled Medical Precision Observation 3.1 (TEMPO 3.1), J2ME and Bluetooth. Details of several existing WBAN related projects have been discussed along with their applications. The next section of the chapter deals with the use and design of medical sensors in WBAN. Performance comparison between WBAN and WSN (Wireless Sensor Network) has also been provided.

1. INTRODUCTION

WBAN is the joint application of biomedical science and wireless communication systems. The development of this technology will have the impact of drastically reducing the time a patient has to spend in his house or in a medical care center for treatment. This technology utilizes the principles of wireless communication to relay data (such as heart rate, ECG) continuously to remote areas (Mundt et. Al., 2005). The data are measured by sensors in a person's body. Besides drastic development in medical instrumentation, it is now also important to have compact machines like portable blood pressure measurement kits that can be attached to a body and be able to measure the parameters round the clock.

WBAN has a wide range of applications in medical science. Gait analysis, asthma detection, cancer detection, physiotherapy, brain activity analysis, etc. are some of the applications. In these applications, sensors are installed either inside or outside the body to determine the pattern of movement, to compare the result with standard data and to keep records of the physiological parameters of the patient. In this paper, it has been explained thoroughly how each of these physiological parameters are measured with the help of WBAN round the clock.

The recorded data are sent to a server where they are analyzed. These servers are the point from where the physician get access to the report of the patient round the clock. This server is called the Virtual Doctor Server (VDS). VDS performs a number of important responsibilities which includes maintaining records of patient data to build up the history of the patient, keeping track of patients' medicine timing and giving alarm to the patient to take the pills on time, giving advice to the patients assistant according to the physiological performance of the patient's body recorded by the sensors, alerting doctor or calling ambulance in time of emergency, maintaining confidentiality and privacy of patients' data records (Sghaier, et al., 2011).Patient can input his clinical feelings to the VDS system and then the VDS can give instant suggestion or advice based on the patients' history and vital signs. During this transmission, WBAN network uses various technologies namely Ultra Wide Band WBAN, Technology Enabled Medical Precision Observation 3.1 (TEMPO 3.1), ZigBee, J2ME and Bluetooth. Details of several existing WBAN related projects have been discussed in this paper along with their applications. The projects that have been discussed are Life Guard, Code Blue, Medisn, Wriscare, Mob health, WiMoCA, and Care Net (He et. al., 2013).

Biomedical sensors form a huge part of the patient monitoring system. A biomedical sensor is such an electronic device that senses, processes, sends or receives biomedical data. It has three main parts, the sensing unit, the processing unit and the receiving unit. There are micro controller units at the sensor node and a memory (RAM, ROM) to store the data (Lee et. al., 2006).The function of the sensor is controlled by software consisting of operating system. There are large varieties of biomedical sensors having separate functionalities such as electrocardiogram, electroencephalograph, etc. These sensors can be classified into in-body sensors and on-body sensors. Characteristics of each type of sensors are discussed in detail in this paper. Sensor networks have also been discussed extensively. They comprise of a large number of sensors and sink nodes and all of them are connected to each other wirelessly with the help of multi-hop or single hop communication systems. The data flows from the sensor node to the sink node which finally communicates the data to a gateway. The capabilities of the nodes vary with size, cost, battery lifetime, etc.

The security of WBAN is extremely important since it contains recorded data of patients and mishandling of such data may even cause death of the patient. The main factors affecting data security are confidentiality, dynamic integrity assurance, dependability. Security requirement is applicable to each device or communication link as data integrity, data confidentiality, authentication, availability, privacy, access control and non-repudiation. Each of these factors have been discussed in detail in this paper.

The remaining sections are organized as follows. Section II gives a brief idea about the background of WBAN along with a complete description of the process of WBAN. Section III describes the virtual doctor server which is the master server that works on the results obtained from patients body. Section IV describes the various technologies that are used in WBAN and the various ongoing projects in WBAN. Section V describes the sensors used in WBAN followed by a table showing the differences between the general sensor network and the wireless body network. Section VI is very important as it deals with

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the privacy and security of the whole system and at the end of this section the requirements for security in this type of network is stated. Section VII concludes the paper and presents the future goals in the commercialization of WBAN.

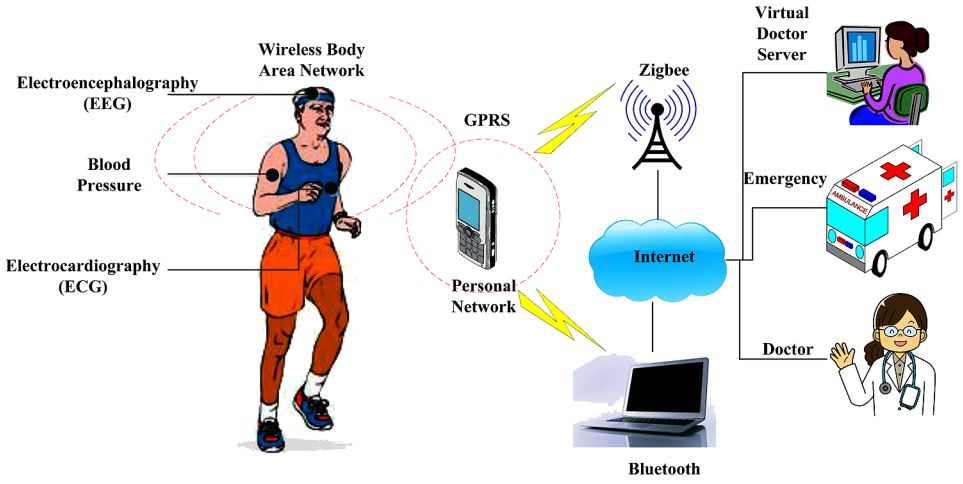
Figure 1 shows the whole mechanism of body area network. It shows how the personal area network records the physiological signals from the various sensors attached to the body and transmits the information to the virtual remote server or physician or emergency center.

The WBAN uses different wireless networks and access technology that leads to complex network as shown in Figure 1. One can easily see the difference in terms of data rate and average power consumption for WBAN applications. We note that Wireless USB and Wi-Fi based technologies offer high data rate but consume high power as shown in Figure 2.

2. BACKGROUND

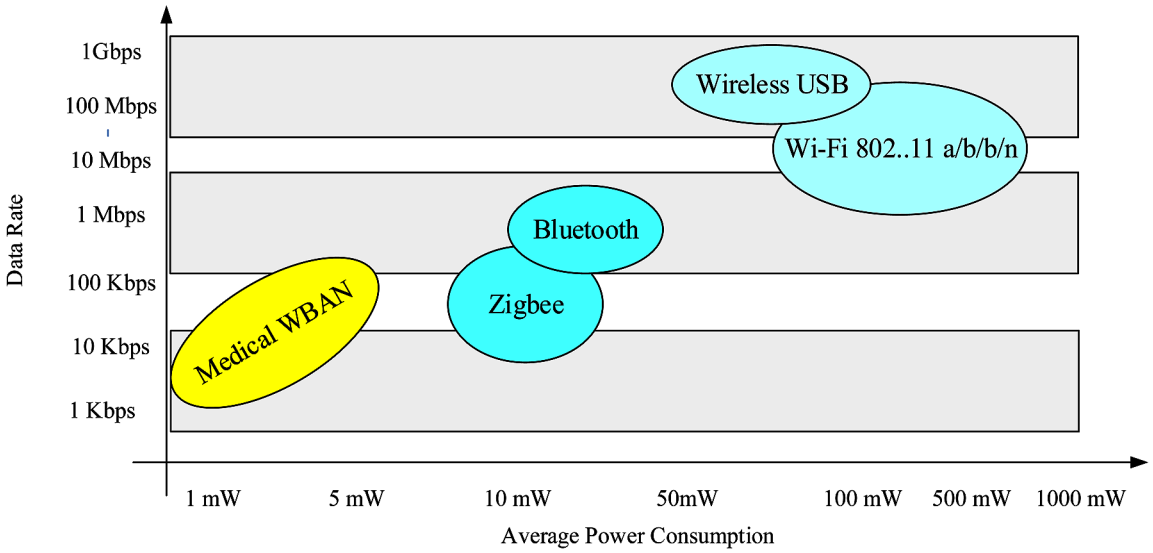
The technology of WBAN started developing in 1995 from the concept of Wireless Personal Area Network (WPAN) around the human body (Gafurov et. al., 2010). WBAN uses the technology of Wireless Personal area network (WPAN) as the gateway to communicate to longer ranges. With the help of this gateway, connection can be established with the human body sensors through internet and doctors or physicians can access the medical data of patient through this internet to keep the track round the clock. The drastic development in wireless technology and the increasing amount of sophistication in sensor technology has helped in the realization of the concept of WBAN. The medical sensors are used to monitor the medical parameters of the patients during treatment of chronic diseases such as asthma, blood pressure, diabetes etc. (Ivanov et. al., 2012) and to control patient rehabilitation (Bajcsy, 2007). The sensors have to be so designed such that they are comfortable and do not cause any harmful impacts on the body. An external processor transfers the information further after the sensing mechanism of the sensor is completed (Motoi et. al. 2006). Doctors who have the authority to access the data can visualize

Figure 1. Schematic diagram of a wireless body area network



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Data rate vs. power profile of different wireless technologies



the result from any part of the world. The doctor can send messages to the patient instantly through this system if he figures out any abnormalities or in emergency situations. Therefore, WBAN can be used to alert the hospital that a patient may experience a heart attack soon by measuring changes in their vital signs. WBAN can also be programmed to perform certain tasks in case of emergency conditions. For example, insulin can be injected in the body when blood sugar levels drops out. Other applications of WBAN can be extended to include sports, military and security services.

3. VIRTUAL DOCTOR SERVER (VDS)

VDS is an intelligent system that is designed in such a way that it can assist a physician in diagnosis of the medical parameters that are functioning abnormally. VDS also collects medical information about the patient from the medical history available from the doctor in order to understand and better diagnose the problem of the patient. They have a virtual doctor construction like a robot which mimics the physician. This robotic doctor interacts with the patient through their voice and examines the various physiological parameters of the patient in order to detect the problem in the health of the patient (Smith et. al., 2013). Diagnosis comprises of both physical and mental state of the patient namely physical ontology and mental ontology respectively. These two ontologisms are compared with each other in order to find similarity with medical history to diagnose the problem. These two ontologisms are compared with the help of Bayesian network which is based on the knowledge of expert doctors. This methodology has been verified by many researchers in their experiments and is successfully done. An integrated computerized model is constructed which mimics a human physician and with the help of it; an interface between that model and the real human user (patient) is utilized for initial diagnosis. Numerous research is already going on the field of WBAN. Apart from the general model of the WBAN, a VDS system is also added to it for better patient care after the physiological states are recorded by the sensors placed on the patient

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

body (Anis et. al., 2010). VDS is a smart intelligent system which records the physiological factors of the patient round the clock and sends the reports to the physician and in case of emergency can call the physician, relatives or even can give basic instructions to the patient.

The system consists of sensors both in body and on body placed in order to record physiological parameters like ECG, EEG etc. The data recorded by the sensors is then sent to a central processor unit in order to analyze and further process the recorded raw data. The mobile phone of the patient can also be used to send the data to the VDS system for further assessment and expert advice. This whole network system is named WBAN where each and every body is assigned an IP address to get distinguished from each other.

The interaction between patient and computer interface is stated in many paper which gives us further detail of the process. Two types of states are described in the research. The first one is the mental state which is the mental behavior of the patient due to a disorder and second is the physical behavior of the patient due to the disorder which is generally the consequence of such a disorder. The two types of bodily states are mapped and described using two software named OWL-S and SWRL which diagnoses the reason to such bodily state. An integrated computerized model is constructed which reflects a diagnostic system for human being as computer model and with the help of it, the patient and the system can interact with each other in order to diagnose the disorder caused to the patient. The VDS system use the knowledge that is obtained from UMLS for testing, and the integrated mapping of the two states of body which is represented through OWL-S framework.

The VDS system performs a variety of responsibilities which are as follows:

- Keeping record of patient data to build up the history of the patient.
- Keeping record of patients medicine timing and giving alarm to the patient to take the pills on time.
- Giving advice to the patients assistant according to the physiological performance of the patient's body recorded by the sensors.
- Calling doctor or ambulance in time of emergency.
- Maintain confidentiality and privacy of patients data records.
- Patient can input his clinical feelings to the VDS system and then the VDS can give instant suggestion or advise based on the patients history and vital signs.

Hence, the VDS is a very important part of the WBAN in terms of data analysis and for providing suggestions based on the medical data. On the other hand when patient is moving from one place to another, it is very important to have this kind of automatic intelligent system to take care of the patient's health giving him important suggestions and reminders.

4. WBAN TECHNOLOGIES

The different existing WBAN Technologies are Ultra Wideband WBAN, TEMPO 3.1, J2ME and Bluetooth. Each of these technologies are discussed in detail in this section.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.1 Ultra Wideband WBAN (UWWBAN)

Ultra WBAN is used for medical sensing and for in-body tracking and imaging (Khaleghi et. al., 2010). There is an antennae designed for on-body tracking that can communicate with same efficiency as in free space when the distance between the antennae and human body is 16mm (Anis et. al., 2010).

Primary function of UWWBAN is to interface between medical sensors and personal server (PS) in telemedicine systems (Francisco e.t al., 2009). UWWBAN can reduce the probability of detection for protecting patient's data with high security. This can reduce the need to hide the algorithms in sensors which reduces complexity and makes the device smaller in size. Hence the algorithms in the machine are required to be hidden and hence it gives a much smaller handy shape and size. UWWBAN does not interfere with any nearby signals and hence protects security and privacy of patients' data. UWWBAN has no tendency to react with any surrounding network and hence data remains completely protected within the system (Monton et al., 2008). This technology is mostly useful in future for transmitting information over short distance range with a very high speed. The bandwidth of this type is in the range of microwave and it is limited by the Federal Government rules (Takacs, 2006). The UW WBAN transmits data at very low rate pulse and hence it is very suitable for WBAN.

Ultra wide band (USB) radar is designed on the basis of impulse radio and hence it can detect the physiological parameters like blood pressure, insulin level etc. With the development of semiconductors the sensors of UWWBAN are made of low power consumption materials and hence are very efficient for wireless transmission task in WBAN. All the antennas in the system is simulated with the help of a software named Antennae a Simulator (Degli-Esposti, 2014). From all the research literature survey on UWWBAN, the most interesting application of UWWBAN is in Capsule Endoscopy. In this technology a camera is used which is small equivalent to a capsule size and is used to visualize gastrointestinal tract. They are designed in order to record images of digestive tract in order to detect gastrointestinal diseases .Even real time imaging of the gastrointestinal tract is possible (Fabre et. al., 1992).

Depending on their location of operation, there are three sensors associated with UWWBAN namely in- body sensor, on-body sensor and an external sensor (Alvarez-Folgueiras et. al., 2011).The in-body sensors are implanted inside the human body and on body sensors are placed on human skin whereas the external sensor is not in contact at all with the patient skin. Endoscope capsules are the in body sensors and the radars used are the external one. Once their inter connection is established they constitute the WBAN. In-body sensors are very critical and have the hardest structure. Hence an implanted device should be handled carefully as complexity of its circuit and its transmitting power is also very critical. The on body sensors are called gate nodes as their main function is to transmit information from the in body sensors to the WBAN. The circuitry of on body sensor is less complicated and most of its application is seen in Electromyography (EMG). Real time analysis of EMG is not necessary as in case of ECG. The principal component which detects and records all the medical information gathered by the sensors in WBAN is called network coordinator (NC). ECM-368 is the network coordinator which is used for the connection between the NC and P (Rasmussen et. al., 1996). It gives supports to data rate which is very high and also cognitive radio in some of the parts of Europe.

4.2 TEMPO 3.1

TEMPO 3.1 is an acronym for Technology Enabled medical Precision Observation 3.1. It is a third generation sensor which accurately captures and processes six degree of inertial data in a noninvasive

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

factor. The complete system of TEMPO comprises of Hardware and Software part design of TEMPO 3.1, a custom case design and an operating system that manages signal acquisition, processing and management of all data received. The system is then compared to BASN hardware platform (Wu, 2010).

BASN has its application in a number of fields namely healthcare, entertainment, fitness, etc. (Sanchez et. al. 2011). Recent advancement is BASN technology includes noninvasive technology to sense physiological signals and to transmit them across the body by low radio power. BASN should be designed in smaller size with smaller batteries. Many BASN sensors are now being developed for commercial and research use (Vos et. al., 2014). Hardware of BASN is now capable of real time imaging, have lithium batteries, have reduced size of the setup and developed sensor interfacing.

TEMPO 3.1 provides full rotational and translational sensing at the same site. The angular rate is measured by two separate MEMS gyroscope. Functions of TEMPO are data collection, streaming and signal processing. Microcontroller is also used for long term and which is energy efficient. The two networking protocols are Bluetooth and ZigBee which operate in 2.4GHz.

TEMPOS are real time operating system and it carries out signal acquisition, processing and control. They operate under many constraints like such as real time execution, memory utilization and minimum user input. It operates with the help of MSP430 microcontroller and for more efficiency allows access to low level hardware. For processing complex signals new signal processing algorithms are treated as application like Haar wavelet decomposition (Degli-Esposti, 2014). TEMPO3.1 is wearable and non-invasive with plastic and custom casing to allow minimal spatial overhead. There is no hardware user interface in the TEMPO setup except a charger point at the top of the machine. No interface is kept for the following reasons:

- If there are exposed buttons then its body cannot be designed water resistant.
- When it is working on a body, user can impatiently change the buttons in order to change the mode of operation which is not desirable.
- Users do not have to change their habit of wearing TEMPOS regularly as it has no buttons and can function autonomously.

On body sensors have already shown their use to a great extent. TEMPO 3.1 has certain impacts in several areas. There are lots of diseases that are cause due to human movements like Parkinson's disease, Gait disorder, cerebral palsy. Monitoring these diseases carefully can prevent, diagnose and treat these kinds of diseases. When a patient reports on his own by self-assessment, it does not give an accurate result and hence we should rely on sophisticated tools. Hence such self-reports are considered as under sampled, unnatural and unreliable. BASNs such as TEMPO 3.1 can correct such data by continuous monitoring all over the patient's body for a long period of time. Tremor suppressing deep brain stimulation and prosthetic control can be detected by motion capture feedback derived on body from TEMPO 3.1. TEMPO is now IRB approved for four clinical researches involving gait, tremor and akathisia. It has also its function in fitness. It is exclusively useful for athletes and amateurs alike. On body inertial sensing fills current niche which exists between pedometers and machine vision system.

4.3 J2ME and Bluetooth

With the continuation of research in wireless body area network, another technology came into prominence named Bluetooth area network which is operated by Bluetooth and Java technology. Smart phone

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and Java are the central nodes of Bluetooth area network of a patient (Bratchikov, 2007). The general architecture of Bluetooth area network is as follows:

- A low power short range wireless interface medical sensor.
- Central coordinator communicates with sensors and it also performs the function of internet gateway to other networks in order to transmit bio signals from sensors and receive information.
- A central node which stores the sensor signals and detects alarm and sends patients physiological report to doctor via email, SMS, etc.

This technology is hence a monitoring network of Bluetooth biosensors which is connected to a 3G cell phone via WLAN. This setup is designed to perform the following functions:

- Visualizing and analysis of the physiological status of the patient.
- Recording the outdoor location of the patient using the system.
- Gives medical assistance in case of emergency.

There are three basic components of this Bluetooth system:

1. Internet Bluetooth Area Network (I BAN) to monitor the patient remotely,
2. A central control server (CCS), and
3. A mobile control monitoring unit which is carried by the doctor (MCMU. I BAN consists of a commercial pulse oximeter, a GPS and an Intelligent Node (IN).

Wi-Fi or GPRS is used to send information from IN to CCS and to MCMU (Fabre et. al., 1992).To keep the Bluetooth connection alive the device should be in coverage area of IN so that as soon as any emergency occurs the IN can inform the server. The data rate depends on the mode of operation of the BAN. There are two modes, namely Default mode (mode 1) and verbose mode (mode 2). When a MCMU receives an SMS alert, the physician should start the J2ME monitoring application which displays the patient and sensor data. The Java application is incorporated in the system for the IN. It uses the following application program interface (API):

- Bluetooth API JSR-82 which manages the Bluetooth.
- Location API JSR-179 to get more reliable data from GPS.
- Wireless messaging API JSR-205 for sending SMS and MMS.
- File connection API JSR-75 which records patient's data in mobile phone and memory chip.

The MMS sent by the IN is in the form of ordinary MMS which gets directly into the inbox of the cell phone. The doctor can access the network from any place through internet using Remote Method Invocation which is supported by Java application (Alvarez-Folgueiras et. al., 2011).

Some of the popular WBAN projects being undertaken around the world are listed below:

- Lifeguard (Mundt et. Al., 2005) is a set up that was designed for the astronauts and can be used for monitoring vital signals from patient. It is capable of monitoring various kinds of data such as heart rate, blood pressure, respiratory and pulse oximeter. The physiological data are collected by

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

a wearable device called Crew Physiological Observation device (COPD). It is comprised of skin temperature sensors and 3 axis accelerometer. There is a Bluetooth tablet that displays the data and stores it from COPD for further future analysis.

- Code Blue (Sghaier, et al., 2011) is another hardware and software platform that is designed by Harvard University. The hardware includes a design for 2 lead ECG system, pulse oximetry and a board for motion analysis. The software architecture is based on a routing framework and each end user communicates with this Code Blue system by a specialized program named Pub Subbase.
- Medisn (Lee et. al., 2006) is another example of a set up that monitors the unattended patients in emergency rooms of John Hopkins Hospital. The set up has four parts namely mi Tag, mi Net, mi Store and mi Viewan. mi Tag consists of all the medical information tags and mi Net is the wireless network connection for communicating the in formations from mi Tag. mi Store stores all the in formations regarding the collected patient data and mi View an is used to display the data to some end users who are designated to analysis the patient data.
- WrisCare (Kim et. al., 2009) is a setup for monitoring heart rhythms for a long period of time. It can detect the changes taking place with heart rhythms. It is of two types namely, home system and institutional system. The home system consists of a wrist band and a base station and is used by the people who live independently in their own houses while the institutional system is used by people who are admitted in Hospitals or Nursing home.

5. SENSORS AND WBANs

Any wireless network comprising of sensors connected to each other is called Wireless Sensor Network (WSN). Basically, in WBAN the sensors are of three types, in-body sensor, on-body sensor and network conductor. This wireless communication system relieves from the pain that is caused due to the cables induced in wired medical communication system. Body area Sensor network nodes should have ergonomic design, have small factors and smaller batteries. A third generation body area sensor is also designed called TEMPO (Technology Enabled Medical Precision Observation) that accurately captures data of human movement and transmits it wirelessly. They can process the data continuously as it is a real time operating system that manages signal processing, control acquisition and everything (Shih-Yeh Chen et. al., 2011). In some wireless area networks mobile phone is used for collecting data. A lot of research is done by the scientists where they used android phone as the medium to communicate the whole process (He et. al., 2013). A light weight activity recognition is detected due to data constraint.

WSN is composed of thousands of nodes and each node is connected to each other as a network so that information gets transmitted from one node to the other (Wu, 2010). These nodes again have several parts. They are microcontroller, a circuit that connects with both the sensor and an energy source, a radio transceiver which is either connected to an external antennae or an internal one, and a battery or any other energy source device. The size of sensor node varies from one another. Similarly the cost of sensor nodes also varies depending on the complexity of the node. Depending on the size and cost constraints of sensor nodes resource constraints such as energy, memory, computational speed and communications bandwidth depends. Routing is the propagation technique between the hops of the networks. WSN topology varies from star network to mesh network which advanced and multi hop wireless.

Biomedical sensors are used mainly in three types of places (Rasmussen et. al., 1996). They are hospital, nursing home and patient's residence. Progressive work is done in this field and a lot of demonstrators

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

are found. The demonstrator for emergency is Field care demonstrator, WiSMoS demonstrator is for post-operative monitoring whereas blood glucose demonstrator is mainly used for monitoring patients at home (Polastre et. al., 2005). The working principle of all these demonstrators are same. They use biomedical sensor to collect patient data and the data is sent to a data collector for further processing and then that data is further sent to the hospital monitoring system for final analysis. The person who is responsible for processing and analyzing these data can access them directly. The principle properties of a WSN are as follows:

- Power consumption constraints for nodes using batteries or energy harvesting.
- Ability to cope with node failures (resilience).
- Mobility of nodes.
- Heterogeneity of nodes.
- Scalability to large scale of deployment.
- Ability to withstand harsh environmental conditions.
- Ease of use.
- Cross-layer design.

Cross-layer is becoming an important studying area for wireless communications.

WBAN and WSN are part of each other and have many things similar to each other. But the basic differences of the two network systems are stated in Table 1.

6. SECURITY AND PRIVACY

Not much work has yet been done regarding the privacy and security of the system. Data security means securing a database from unwanted actions of unauthorized users. It is the relation between collection and dissemination of data, technology, privacy and legal and political issues around. While starting with security of WBAN, we should keep in mind the efficiency of the system too. Even if the device is compromised the patient related data should always remain confidential. Medical data is very vital and it will result into disastrous result if it is modified. The three main factors that makes it important for keeping the data secured are:

Table 1. Comparison of WSN and WBAN

Factor	WSN	WBAN
Subject	Environment	Human Body
Required Security Level	Low	Higher
Bio Compatibility	Not required	A must
Mobility	Stationery	Moves from one place to another
Data rate	Event based	Continuous data
Power	High	Low
Node Size	Large or Small	Essentially small

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Confidentiality:** The data that is recorded constantly from the patient's body is stored for the consultancy of the physician but it needs to be kept at a secured location in order to prevent unwanted people from accessing them. The data is usually stored at a node or a local server. Here the data does not get leaked during their storage time. The data confidentiality must be resilient to device compromise to attack.
- **Dynamic Integrity Assurance:** A patient who has WBAN for detecting his physiological parameters are critical patients and hence their data are very vital. A little bit of modification of the original data might lead to dangerous consequences. Hence data integrity shall be protecting dynamically all the time (He et. al., 2006). This will help to detect the changes made by the end user and also check that during storage periods in order to detect malicious modifications and an alert is sent to the user.
- **Dependability:** WBAN data are very important data and should be retrieved any time. If there is any problem with getting data on time it can be life threatening. Fault tolerance is very useful in order to manage the threats caused by network dynamics. Hence patient data should be managed such a way that it can retrieved anytime even during node failure or some malicious modifications (Huang et al 2013).

Authentication is a very important step for securing data. It prevents false data injection, DoS attacks and also it verifies the identity of the user before letting the person to access the data. Moreover it is very essential to secure data during transfer with in WBAN system. When a person's data is recorded and processed and transferred from one station to another for further analysis, it is handled by more than one user and hence this path is very risky. Any user can hack the data and modify it. So, it is very important to have user authentication at each step of data transfer where user needs to put a password and get into the system to access the actual data (Xuange et. al., 2010).

High efficiency is very important for the security of a WBAN. The sensors used in recording the parameters should be light and efficient in design and if the authentication protocol is not fast enough then DoS can attack easily (Sung-Yuan, 2001). Privacy of the patient data is destroyed if it is accessed publicly and hence security is one of the most important thing of WBAN. It is very difficult to maintain privacy and security of the data together. Hence it is very difficult to design such a system which is practical. Very few studies are done on this and even the one those are done are far from mature. In Code Blue project a sensor network is developed for pre hospital and emergency responses (Sanchez et. al. 2011). In this system an epileptic curve cryptographic based public key is used for authentication. But there is no other security for stored data and even the access cannot be controlled.

Chess a et al. proposed Redundant Residue Number System which is a secured data storage and sharing scheme for wireless mobile networks (Vos et. al., 2014). In Wang's scheme privacy, dynamic integrity and dependability is achieved all together which is important they usually contradict which each other. Pietro et al found out the solution for data survival problem in wireless (Atallah et. al., 2009). Fine-grained distributed control is an important security service in healthcare. It is designed as role based access model. It prevents handling the patient data publicly and restricts its users with authentication according to their roles. There are 3 types of schemes that are proposed namely SKC based, and ABE based (Ivanov et. al., 2012). SKC was proposed by Morchon et al. (2015). In this method patient can establish connection easily with one entity after authentication. But there are certain disadvantages in the SKC scheme. They are as follows:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Due to high key management complexity, fine gain access control is hard to be achieved.
- User collision can take place.
- Compromising a node may leak the data or information.

ABE is a very effective scheme. Here the cipher text is allowed to be read by only a group of user who satisfy a certain authentication process. It is collision free. Whenever any data is generated by a WBAN an authentication verification goes with the cipher text (Bhoir et. al., 2014), it supports tree like access policy structure and is easily expressive and it is easy to integrate the context related parameters as attributes like time. One point multiplication and pairing operation takes seconds and hence it might not be a good choice on the sensor nodes (Kathuria et. al., 2014). But it is capable than any other technique as far as obtained after research .but none of the schemes satisfactorily support the security and hence further research in this field is required.

Bluetooth is another extremely popular technology which is short range and low power which is used for portable computing and communication devices. Bluetooth establishes connection automatically which is a great advantage but it has some risks too. There is a huge chance of data getting vulnerable with other low power radio waves (Kathuria et. al., 2014). Unwanted people may receive private information and even people can send files or virus without any permission. The weakest part of the blue tooth technology is that, while establishing connection for the first time between two devices, an authentication is done by each other but without encryption and hence if the hacker actually gets to know the password then he can easily guess the initiation keys and can get all the data that is transferred between the two devices. A very common way of attacking through blue tooth is during pairing process. At this time the connection between the devices is forcefully broken by flooding the channels with packets indicating the slave has lost the key. And when the pairing process is repeated, the hacker observes the encryption keys and gets the link. The BD ADDR is globally unique just like the MAC address (Shen et. al., 2013). In 2005, the researchers at CSAIL found that there is a big vulnerability in it (Ramachandran et. al., 2007). An attacker can assemble list of commonly used BD ADDR in a device and can change his Blue tooth module setting and starts getting packets .then he can attack by sniffing packets or injecting packets. Integrity threat and denial of service are very common in blue tooth communication. Some of the reported attacks in Bluetooth are:

- MAC spoofing attack.
- Attack to crack pin.
- Blue jacking attack.
- Blue printing attack.
- Blue snarfing attack.
- Blue bugging attack.
- Blue over attack.
- Cabir attack.
- DOS attack.
- Skull worms attack.
- Lasco worm attack.
- Brute force attack.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

GSM is a standard network used worldwide but it is also attacked. GSM uses several cryptographic algorithms are used by GSM for security. Air voice privacy is protected by using A5/1 and A5/2 stream ciphers. Denial of Service attacks are one of the most powerful attacks. They are so dangerous that they hack the patients' medical data and substitute those valuable data with insensible bogus messages. Now a days a new scheme of location signature is introduced. Symmetric or asymmetrical key cryptography is used which encrypts / decrepit to hide the medical data of patient. Biometric encryption is widely used in most of the places but it is very weak. No, method is strong enough to protect the medical data of patient, so, the security should be strengthened for WBAN to be successfully commercialized. The security requirements of each device and communication link are listed below:

- **Data Integrity:** It assures the correctness of data protection against modification, deletion or replication from an unauthorized user. Usually MAC provides data integrity using secret keys.
- **Data Confidentiality:** Encryption and access control links are the main methods that ensure data confidentiality. It protects the data from handling by unauthorized users. Medical data is very vital and hence it is very important to keep it confidential.
- **Authentication:** This is process when a verification is done with a password in order to choose the right user. There are two kinds of authentication namely message authentication and entity authentication. Biometrics is the most trustworthy authentication possible. There is an ID certificate for the user and a device certificate for the WBAN which achieve authentication.
- **Availability:** This protects from the event taking place and impacting the network. There can be many existing attacks and they results in loss of availability. There are some physical actions that are taken for availability in order to make up for the loss of availability.
- **Privacy:** The medical data may consists of some ones routine health checkup or a particular physiological parameter .These data need some privacy and should not be shared with everyone. Privacy is very important for a patient and these data can only be accessed by people who are allowed to do so.
- **Access Control:** As firewall provides access control, there is personal server that works as a part of firewall. This protects from unauthorized user to access the medical data. It remains open to only few people who are part of WBAN to access data of patient.
- **Non Repudiation:** The process which always keeps evidence. When a user sends or receives it always keeps an evidence of the same. This evidence can be presented to a third party in order to prove that such event has taken place in case of any problem.

7. CONCLUSION AND FUTURE GOALS

Wireless body area network (WBAN) is an emerging field of research which has been progressing rapidly in recent years. The development of this technology will have the impact of drastically reducing the time a patient has to spend in his house or in a medical care center for treatment. This technology has numerous advantages and is very safe helpful if proper security system is incorporated. This technology can get even more popular in use once its privacy and security section is built high. With this development, it can be one of the most successful innovations in medical science. The security issue of this system is very important and from the survey that is performed it can be seen that there is awareness of the importance of these patients' data but not sufficient work has been done yet on this topic. Many scientists have

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

built some models to protect a part of the system. But, the patient monitoring system consists of several process and each and every step should be highly secured so that the information doesn't get leaked at any point of the network. The main focus of this paper has been to draw attention of the researchers to this technology to develop it to make it more commercialized. The future goal includes making it more cheap, safe and popular.

Chapter 101
Information and Communication Technologies in the Healthcare:
Future Trends for Project Success

Jorge Gomes
Universidade de Lisboa, Portugal

Mário Romão
Universidade de Lisboa, Portugal

ABSTRACT

Web portals, sensors, electronic records, video communication, on-line gaming and mobile apps. These are all examples of information and communication technologies (ICT) applications or devices that might cause benefits to healthcare. The ICT has the potential to dramatically change the way individuals or society see the sector, and provide tremendous opportunities for supporting professionals, improving effectiveness and efficiency. Healthcare organizations have become more and more challenged on how to assure a fair return from ICT investments. Thus, the application of project management in health is important because it allow more productivity and, as a direct result, more accessibility, higher quality care and a safer environment to patients. The study of the success of these initiatives has become vitally important for the hospitals performance. The article collects relevant data and provide recommendations about the perceived benefits of ICT project implementations, proposing a review of the published work to provide some insights into the benefits of these implementations.

INTRODUCTION

The world has witnessed significant health gains in recent decades due not only to advances in science, technology and medicine, but also in expanding infrastructure, rising incomes, better nutrition, sanitation, literacy and opportunities for women (Dzenowagis, 2005). While promoting population health has been the classic goal of public health practices and policy, in recent decades new objectives in terms of autonomy and equality have been introduced (Munthe, 2008).

Healthcare systems around Europe are facing major challenges related to chronic diseases, demographic changes, nursing shortages, medical accidents and increasing costs (EC, 2009; WHO, 2011, 2015). The proportion of people over 65 is expected to almost double by 2050 (Eurostat, 2005) and average public spending for health and long-term care in OECD countries may rise to 10-13% of the GDP (WHO, 2011). Today, the problem of improving healthcare delivery in the developed countries is more about the equitable distribution of available resources to the population than about technological issues (Bukachi & Pakenham-Walsh, 2007).

Since the 1990´s, the health sector has sought to improve its effectiveness and efficiency by adopting ICT solutions to increase the levels of services quality, namely, patient safety, organisational efficiency and patient satisfaction (Bates and Gawande, 2000). The aim of ICT for healthcare is to improve the quality, access and efficacy of healthcare for all citizens (Ammenwerth et al., 2004; EC, 2009). ICT for healthcare have been referred as a key instrument that facilitate communication, processing and transmission of information by electronic means, with the aim of improving health (Bukachi & Pakenham-Walsh, 2007; Drury, 2005; EC, 2009; Häyrinen et al., 2008). The ICT usage in health is a means to reach a series of desired outcomes across the entire health ecosystem and are part of the continuous quality improvement of healthcare: According to Brandrud et al. (2011), three main key success factors must be guaranteed: (1) Reliable information; (2) Engagement of all stakeholders in all phases of the work improvement; (3) A proper infrastructure involving multidisciplinary teams.

ICT in healthcare represents the integrated effort to collect, process, report and use health information and knowledge to influence policy-making, program action and research and further states that they are essential to the effective functioning of health systems worldwide (WHO, 2006). Furthermore, ICT underpin the expansion of the world's health knowledge: linking systems, enabling research, improving capabilities and communication for healthcare (EC, 2009).

METHODOLOGY

This study is aimed to research the pattern of ICT implementations in healthcare units, using articles published in academic health management journals. The documents were retrieved based on a literature review undertaken using the keywords 'ICT in Healthcare' and 'ICT in Hospitals', available in the following sources: ProQuest, Sciencedirect/Elsevier, Ebscohost, Emerald, Jstore, Medline/Pubmed, Taylor & Francis Online, Sagepub, and Wiley databases. The final set of selected articles resulted from the comparison between the documents collected and the objectives of our study.

BACKGROUND

ICT Implementations

The introduction of ICT can radically affect the healthcare organizations and the healthcare delivery (Ammenwerth et al., 2004). Although the increasing role and importance of ICT in healthcare, the understanding of why, how, and when technology enables the productivity improvement is in its early stages, resulting most often in a lag in productivity growth (Jorgenson & Stiroh, 2000). The main goal of ICT is to manage information from all healthcare-related activities, including planning, monitoring, coordination, and decision making. The real-time access, exchange and receipt of clinical data provided by the system have improved clinical documentation, reduced the duplication of care services, and supported better decision making related to patient care (Mäenpää et al., 2009). It is commonly accepted that the use of ICT offers tremendous opportunities to support healthcare professionals and to increase the efficiency, effectiveness and appropriateness of care (Kohn et al., 2000).

Nowadays ICT implementations are mostly meant to extensively support disparate conventional data processing tasks. Ranging from simple application systems, such as transaction processing systems, to more complex ones, such as clinical decision support systems, here are some examples: (1) Patient centered system - manage comprehensive patient care information such as medical records and appointment scheduling (Cliff, 2012; Krist & Woolf, 2011; Snyder et al., 2011); (2) Administrative support - record the main business processes and routine transactions of organizations such as patient admission, discharge and transfer, or bill processing (Jiang et al., 2000; Peabody et al., 2004); (3) Clinical system - collection of specific data for patient care, research, management, planning and maintenance of national data repositories (Ammenwerth & de Keizer, 2005; Gardner & Shabot, 2001); (4) Specific systems (Radiology, Laboratory…) - support the acquisition and analysis of specific function of the different departments (Paré & Sicotte, 2001); (5) Telemedicine - provides and supports healthcare services across distances via electronic communications and IT (Gawande & Bates, 2000); (6) Clinical decision support systems - designed specifically to aid clinical decision making (Kaushal, et al., 2003); (7) Hospital information system - integrated hospital information processing systems. Support healthcare activities at the operational, tactical and strategic levels (Ammenwerth & de Keizer, 2005; Van der Meijden et al., 2003) (8) Cloud computing services such as software as a service application - explored by the scientific and medical communities for their potential in advancing and accelerating research and reducing costs (Sultan & Sultan, 2012).

The focus of investments in ICT projects lies mainly in improvements on the organizational performance and business efficiency, in other words, improving processes and changing the ways the work is performed (Ammenwerth, 2004; Ward & Daniel, 2012; WHO, 2011, 2015).

Seven different stages were proposed in the development of health information system (HIS) (Haux, 2006): (1) Shift from paper-based systems to computer-based processing and storage; (2) Shift from local to global information system architectures; (3) Health information system used by professionals and patients/consumers; (4) Data used for patient care, healthcare planning and clinical research; (5) Shift of focus from technical health IS problems to change management and strategic information management; (6) Shift from alpha-numerical data to clinical images and data on a molecular level; (7) Steady increase in new technologies for continuous monitoring of health status.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In various aspects, these implementations are different from project implementations in other industries. The diversity of systems and devices, together with the growing challenge of integration and interoperability are the main issues of the health environment (Abouzhara, 2011). The academy agrees with the existence of success-related factors for projects, namely the Project Success Criteria (PSC), referring to the group of principles or standards used to determine project success; and, the Critical Success Factors (CSFs), referring to specific conditions and circumstances that contribute to project success. While the potential and benefits from the use of ICT projects in health are large, the risks are also substantial. Therefore, it seems wise to advocate that organizations should give more attention to adopting formal project evaluations and benefits management methodologies to ensure the realization of the expected benefits from investments in those project implementations (Schultz, 2006; Ward & Daniel, 2012). Studies have shown significant correlation between organizational maturity and ICT project success, and project management practices and ICT project success (Gomes, 2018; Thomas & Mullaly, 2008), which reinforces the value of applying these tools.

ICT Project Maturity

Concerning the ICT environment, maturity is regarded as a measure to evaluate the capabilities of an organization (de Bruin, & Rosemann, 2005). Maturity models in ICT projects are understood as tools that facilitate internal and/or external benchmarking while also showcasing future improvement and providing guidelines through the evolutionary process of organizational development and growth (Mettler et al., 2010). Not surprisingly, the concept of maturity was also diffused to the project management field. Different views exist on maturity related to project management. These approaches assume that increases in project management maturity will lead to more consistent and more successful project outcomes. A significant number of competing perspectives attempt to describe mature project management practices (Cooke-Davies & Arzymanow, 2003; Ibbs & Kwak, 2000; Jachimowicz, 2003; Skulmoski, 2001).

Some studies have discussed the correlation between the level of project management maturity and project performance (Ibbs & Kwak, 2000; Jiang et al., 2004). The theory highlighted that investment in organizational maturity and in project management practices increases the results in enhanced project performance and project success that should translate into cost saving and other benefits (Gomes, 2018; Jiang et al., 2004). Due to their nature, maturity models are an important managerial tool that have been used extensively in ICT development (Wetering & Batenburg, 2009; Crawford, 2006). Studies supported the assumption that a positive correlation exists between maturity and project success. Higher levels of organizational maturity are expected to be more successful in terms of project effectiveness and efficiency and foster a competitive advantage in the marketplace (Cooke-Davies & Arzymanow, 2003; Gomes, 2018; Ibbs & Kwak, 2000; Sergeant et al., 2010; Skulmoski, 2001; Young et al., 2014).

ICT Project Failures

Despite remarkable technical progress, failures have still been reported when integrating technically sound systems into processes of care (Lorenzi & Riley, 2003). The investments on ICT in healthcare are financially relevant and still growing worldwide. Many results have revealed a waste of financial resources in acquiring large sized systems, which are totally ineffective (Heeks, 2006).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Studies have identified high failure rates in ICT projects in various sectors, particularly in hospitals. Heeks (2008) states that 35% of IS/IT projects are total failures and 50% partial failures, with only 15% being considered successful. A study by Gheorghiu (2006) found that 70% to 80% of all information technology and information systems fail. Similarly, Kaplan and Harris-Salamone (2009) confirmed a value greater than 30% for the failure rates of major health information technology projects. Project failures in healthcare are in part due to the following reasons (Lewis et al., 2011): (a) Lack of senior management commitment being incomplete or missing altogether (Bukachi and Pakenham-Walsh, 2007; Liu et al., 2010); (b) Difficulties in the engagement of health professionals, and a lack of focus on end-users (Elder and Clarke, 2007); (c) Incorrect specification requirements (Lucas, 2008; Gauld, 2007); (d) An absent or inadequate process of change (Yeo, 2002); (e) Poor knowledge of the complexity of health systems (Al-Ahmad et al., 2009); (f) Missing investments in human resources (Elder and Clarke, 2007; Bukachi and Pakenham-Walsh, 2007); (g) Proper training (Allen et al., 2000).

The study of the success or failure of these initiatives has become vitally important for the performance of health organisations. They must then improve their business practices and internal procedures to answer to the increase demand of health professionals and citizens in general for better, timely delivered and accurate information (Delpierre et al., 2004; Rahimi and Vimarlund, 2007).

Successful ICT Projects

A comprehensive literature review on large-scale ICT projects executed in several countries/regions identified a set of CSFs (Nagi et al., 2008). Of these, some are recurrently cited in ICT healthcare studies, namely (Hung et al., 2014): (1) Information systems adjustment (Jessup & Valacich, 2008); (2) Business process adjustments (Chatterjee & Segars, 2006); (3) Organizational resistance (Kamhawi, 2007); (4) Top management support (Gil-García & Pardo, 2005; Liu et al., 2010); and (5) The capability of key team members (Siakas & Siakas, 2008; Turner & Lloyd-Walker, 2008; Yang, Kang & Mason, 2008).

Amongst the several PSC that are mentioned, 'iron triangle' seems to be the basis of the most of ICT project success approaches, because fulfilling the criteria for the completion of a project on time, within budget and according to performance specifications are easy to assess (Agarwal & Rathod, 2006; Fortune & White, 2006; Jugdev & Müller, 2005). These classic criteria remain as the most widely used measure of project success and its main value is in offering a simple, direct measure of performance of the project, but it neglects whether the deliverables fulfilled the objectives of the project (Ika, 2009).

According to Sabherwal et al., (2006), ICT projects success in healthcare sector also refers to user satisfaction, system use, perceived usefulness and system quality. PSC have evolved from simple quantifiable 'iron triangle' criteria, which primarily are related to project efficiency (Bryde & Brown, 2005), to measures that have a longer-term perspective directly relating to effectiveness, business success, organizational impact and stakeholder's satisfaction (Atkinson, 1999; Ika, 2009; Jugdev et al., 2001; Müller & Turner, 2007; Shenhar et al., 1997, 2001; Shenhar & Dvir, 2007; Turner & Zolin, 2012).

Success in the strategic use of Healthcare ICT projects relies on the integration of all systems, such as patient records, clinical decision support, transaction processing, digital imaging, and information reporting (Jensen, 2013).

FUTURE TRENDS

Today's technology plays a significant role, permitting the storage and rapid retrieval of clinical patient records and other important data/information. At the same time, patients expect that their sensitive personal information to be handled appropriately, to ensure accuracy and confidentiality.

Hospitals are complex organizations and this complexity magnifies the opportunity for inevitable human errors (Weick & Sutcliffe, 2001). A poorly integrated healthcare application system can increase the frequency of medical errors, decrease operational efficiency, and reduce the quality of healthcare services (Themistocleous et al., 2009).

The selected publications emphasized two main aspects regarding the development of ICT initiatives in the healthcare sector; The slowness of adoption of these initiatives and the resistance to change from the part of professionals, mainly physicians (Leonard, 2000, 2004). According to Robinson (2007), appropriate leadership, good communication, detailed roadmap of implementation, setting realistic and measurable goals and specific attention to the active involvement of human resources in terms of motivation and training were considered the most important factors affecting the success of the implementation of these systems.

Extant research largely focuses on the consequences for ICT projects from management support (Dong et al., 2009). Top management support has been argued to be the most critical factor for ICT project success (Liu et al., 2010). Lorenzi & Riley (2003) claimed that organizations need to have three types of skills to produce successful projects, such as: (1) Technical skills - which include a broad range of skills, such as the technical knowledge, experience, and abilities; (2) Project management skills - which include the knowledge, techniques, and skills necessary to manage successfully the ICT projects; and (3) People and organizational skills - which include the wide range of skills necessary to effectively interface with all the ICT stakeholders.

Miller and Oliver (2015) highlighted that the participation of different stakeholders' groups in the design and development process can be essential for a project's success. Reyes-Alcázar et al. (2012) identified several CSFs for the success of ICT projects: (1) Leadership - the importance on improving the quality of healthcare (West et al., 2004); (2) Team work - A multidisciplinary process focused on a healthcare team that shares common goals (Mickan, 2005); (3) Autonomy and responsibility - the need for more autonomy amongst health professionals (Harrison & Dowswell, 2002); (4) An integrated view of healthcare - The quality of patient care as perceived by end-users is a key element (Torres Olivera, 2003); (5) Professional skills - Promoting skills encourages professional development (Reyes-Alcázar et al., 2012); (6) Results focused - The measurement and evaluation of clinical performance, hospital management and end-user satisfaction (Kariami, 2015); (7) Internal and external audits - the concept of continuous improvement of quality (Hyrkäs & Lehti, 2003).

Healthcare processes rely heavily on both data/information and knowledge. In this context, management information plays a crucial role. Numerous studies have shown the positive effects of using ICT in healthcare (Lenz & Reichert, 2007). The support of these systems provides an important asset for specialized services, which increases the quality and safety of patient care by minimizing the likelihood of medical errors (Low & Chen, 2012). Supported on ICT, the complex process of medical decision making could be significantly improved in several ways (Lenz & Reichert, 2007), such as: (1) Contributing to improve data quality, such as timeliness or completeness (Van Walraven, et al., 2004); (2) Contributing to better monitor the current state of a patient (Bates et al., 2001); (3) Detecting mismatches between existing guidelines and the actual patient treatment process (Shiffman, 2004); (4) Generating reminders

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to ensure that planned actions are not forgotten; (5) Helping to calculate drug dosage from previously entered data (Ambrisko & Nemeth, 2004); (6) Calculating disease probabilities (Hejlesen, 2005).

The benefits that of a good ICT system can bring to healthcare organizations are: (1) Citizens' better access to health systems; (2) Reduce the risk of errors due to lack of data/information; (3) Reduce the time required for the provision of clinical reports; (4) Reduce costs by avoiding repetitive efforts and unnecessary resources.The challenges to be addressed in order to successfully implement these solutions are: (1) Interoperability; (2) Timeliness, integrity, availability and confidentiality of data/information; (3) Alignment of software with sound principles of applications architecture and content management structures; (4) Establishment of rules that allow the user informed consent to the access of their data by professionals; (5) Ensure how to overcome the tremendous difficulties of a change management process.

An important challenge for the future is to seek for a real clinical integration of systems. Clinical integration between providers and hospitals has historically been a goal, still continually sought, but rarely achieved. It will become crucial that the design of future applications be more easily integrated into existing systems, some of them legacy systems, through open communication interfaces that comply with known standards.

CONCLUSION

The investments in ICT implementations have the potential to dramatically change the way individuals, professionals or even society perceive the healthcare sector, and also provide huge opportunities for supporting healthcare professionals, and for improving effectiveness and efficiency in this relevant sector.

Healthcare ICT projects are different from other types of projects in several aspects, such as: the environment in which they are implemented, the diversity of systems and devices they need to work with, the integration and the interoperability between different systems and health organizations, the diversity of interests of the professional groups, the increasing pressure from end-users to an easier access to healthcare services, and the governments pressure to cut costs of subsidizing the public health sector.

Most of times the success or the failure of a ICT project does not only rely on technological factors, but on many other factors, such as, the governance model, the policy environment, multi sectorial involvement of stakeholders and effective human resource management. ICT healthcare projects are generally made up of a significant number of complex tasks and processes, and they depend largely on the quality of existing data/information. A major obstacle is that the diverse players in the health ecosystem traditionally run their own applications with no interconnection among applications. The result is a disintegrated view of how patient care and citizens health information is delivered across the health ecosystem. This situation does not allow obtaining the advantages of a holistic view of a patient's health.

ICT implementation in healthcare need to have well-defined terminologies and standards for interoperability, along with comply with legal requirements. Ideally, these systems should improve quality of care, reduce costs, while maintaining long-standing beneficial patterns of communication, collaboration, quality, safety, and healthcare delivery. ICT projects in healthcare are complex and very difficult to reach a full agreement about what is success. Achieving a successful change will be easier if all stakeholders are appropriately engaged and motivated around the same goal.

In summary, ICT projects in healthcare can lead the industry toward an interconnected healthcare platform by delivering an optimized technology infrastructure combining traditional, cloud-based, and hybrid computing models, pulling together the disparate parts of the healthcare ecosystem, thereby enabling better care, workforce mobility, and security-enhanced data-delivery models.

ABSTRACT

Healthcare robotic applications are a growing trend due to rapid demographic changes that affect healthcare systems, professionals and quality of life indicators, for the elderly, the injured and the disabled. Current technological advances in robotic systems offer an exciting field for medical research, as the interdisciplinary approach of robotics in healthcare and specifically in surgery is continuously gaining ground. This chapter features a review of current applications, from external large scale robotic devices to nanoscale swarm robots programmed to interact on a cellular level.

INTRODUCTION

Since the beginning of human history, surgical operations even in their primitive form have been on the frontier of medicine, due to the lack of non-invasive diagnostic techniques and the traumatic nature of the majority of health issues resulting from centuries of wars and battles. Surgeon, a term introduced in the 14th century means 'a person who heals by manual operation on the patient and has its roots in the Latin world chirurgiae from Greek *cheirourgiki (χειρουργική) and* more specifically their – hand and ergon – work. Surgery, the physical manipulation of the body aimed at the diagnosis, prevention and eventually treatment of diseases and traumas and from early on, the most critical factors that had to be dealt with, were bleeding, pain and infections.

Among the first surgical operations were laceration suturing, amputations, cauterization of wounds and trepanation with evidence such as prehistoric remains in cave paintings and ancient Greek writers' descriptions. In ancient Egypt engravings of surgical tools and papyri with recipes and pharmacopeia for the treatment of numerous diseases have been discovered and in China, physicians performed surgery with the aid of anesthesia, 1600 years before it was adopted in Europe. The evolution and incorporation of anatomy in medical education in the middle ages and Renaissance provided the basis for the systematic research that established the discipline of modern scientific surgery, as a common and safe practice.

Nowadays challenges such as pain management and infections are addressed with the latest technological advances in anesthesia, antisepsis, and novel diagnostic procedures. In our never ending quest for lower mortality rates, less pain and quality services, current economic and social trends guide surgical advances to less invasive techniques that eventually lead to lower hospitalization and recovery times, thus ensuring profit and quality of life to all relevant stakeholders and patients relatively.

BACKGROUND

In the delicate balance between minimally invasive surgery and high-cost state of the art technology, lies robot-assisted surgery, a field rapidly evolving in conjunction with other disciplines, such as micro and nano machines, wireless communications, bioengineering and information technology.

Minimally invasive procedures refer to techniques that target at limiting the incision site, so that wound healing times, pain and infection risk are controlled and minimized. It is widely used by interventional radiologists, employing imaging techniques and catheters, used as interventional instruments directed at the targeted vessel or organ, but also by general surgeons with laparoscopic procedures.

There are several techniques that surgeons use to perform minimally invasive surgery with the patient under general or local anesthesia, depending on the procedure. Usually, laparoscopic instruments either have a telescopic rod lens system that is connected to a camera, or the laparoscope is digital and the charged – couple device is placed at the end of it (Swanstrom, 2013).

The demand of robots in healthcare and specifically in surgery comes from the finite human capability to perform certain actions with adequate efficiency. As described above, latest trends in healthcare align towards automatization, robot – assisted surgery and minimization and therefore efficiency must be maximized along with patient safety, security and sensitivity. The manipulation of robotic instruments via a console, directly or indirectly that translate the surgeon movements to precision actions, was first introduced in 1983 with the Arthrobot (Paul, 1992), a bone mountable hip arthroplasty surgery robot and in 1985 the PUMA 560 (Piltan, 2012) was introduced, for a needle brain biopsy, under CT guidance. In 1988 it was used to perform a transurethral resection and a year earlier for the first laparoscopic cholecystectomy. In 1992 the Robodoc was introduced to mill out precise fittings in the femur for hip replacement (Schulz, 2007).

IDENTIFIED NEEDS

Robot-assisted surgery originally developed to overcome certain limitations of minimally invasive procedures. Based on the analysis of sensor information, healthcare robots use systems capable of doing mechatronic actions to provide healthcare services, such as diagnosis, interventions, treatment, support

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

rehabilitation and prevention (Bogue, 2011). Patients, healthcare professionals and relevant stakeholders such as public institutions, insurance companies, and researchers, are setting the clear lines around the needs and challenges regarding technological evolution and turning points in robot-assisted surgery.

Safety is the most important requirement from patient's point of view and at the same time, professionals like doctors and nurses must maintain safety because of their obligation due to the nature of their profession. Therefore, procedures performed by robotic systems or with their assistance must ensure safety to both patient and healthcare professionals. In general, robots offer newer, better and safer treatments compared to the traditional approaches in many procedures (Finkelstein, 2010).

Even though quality improvements in diagnosis and treatment are crucial and recognized as a need, this must never outweigh safety issues as well as accuracy and consistency in delivering stable, reproducible and predictable results. Surgical accuracy and efficiency, as well as quick recovery times, are important factors, as they are directly affecting indicators of overall efficiency of health systems, and consequently improving the quality of life for patients and working conditions for healthcare professionals.

A specific need that initially triggered the development of telemedicine is medical care in remote areas on earth or even in space missions and even disaster scenarios, where medical facilities as we know them may not be available (Zygomalas, 2015). It is important therefore to develop and evolve flexible and portable, autonomous or remotely controlled semi-autonomous robotic surgical systems that can function in the above cases. From macro-world to micro and macro again, robotic-assisted surgery offers the possibility to access otherwise inaccessible human body areas, without major incisions and perform delicate operations, even on a cellular level in the future.

In the era of big data and information technology, robot-assisted surgical interventions have the possibility to provide detailed information about each case, which can be analyzed and contribute to further research. Furthermore, extended documentation of the procedures provides traceability, improved surgical and recovery time, and consequently lower costs which make health care accessible to all social classes in a long-term perspective.

CLASSIFICATION OF SURGICAL ROBOTS

Several classification systems have been suggested for robotic systems in healthcare in general (Kim, 2016), most distinguishing between imaging, rehabilitation, simulation, prostheses and surgical assistance technologies. The hypothesis behind classification lies on pillars such as potential benefits, technological challenges, and configuration. Factors such as accuracy, space constrictions, compatibility and extension issues, user experience and interface, application specific functionalities, size, sterilization and imaging (CT, C-Arm, MRI) compatibility, sensing and haptic technological challenges, degree of autonomy (passive, active, teleoperative and interactive systems) are also taken into consideration, allowing for future clinical and technological advances to be explored.

Two major categories of surgical robots for general abdominal surgery can be identified, distinguishing in relation to the positioning of the main robotic system and the effective arms with the medical instruments in relation to the human body and the targeted surgical field (Zygomalas, 2015); A) External robotic systems, and B) Internal robotic systems.

The external surgical robots have their basic operating mechanism outside of the surgical field, yet instrumentation is inside the abdomen (or the target area), regardless of the incision approach, which can either be through multiple incisions, one incision (Laparo-Endoscopic Single-Site), or through

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the body's natural orifices (Natural Orifice Transluminar Endoscopic Surgery) (Rosen, 2011). The external workstations are usually large installations that have to be situated inside the operating room. External endoscopic workstations, specifically oriented towards NOTES surgical techniques have been developed, as well as flexible endoscopic systems (Bardaro, 2006) that allow navigation and surgery in tight workspaces. As it is mentioned above, current trends in surgery are incision minimization with quality improvement and external robotic systems, have been under interdisciplinary research, in terms of miniaturization, in research activities and implementation, offering a new area for development with miniaturized external robots (Sanchez, 2013).

Regarding internal robotic systems, miniaturized laparoscopic systems, that are located entirely inside the human body, have been described and developed (Lehman, 2007; Oleynikov, 2005) that are introduced into the abdominal cavity via various methods and once positioned, function completely inside the abdomen. For applications in NOTES techniques, internal endoscopic miniature systems, that can be swallowed and self- assembled have been proposed (Assembling Reconfigurable Endoluminal Surgical system, 2014).

In addition to mini-robotic devices, endoscopic swallowable capsules have been developed that allow for imaging, telemetry, and even histology if provided with appropriate biopsy tools (Saurin, 2016). Finally, the evolution of nanotechnology contributes positively to surgical technologies, with the introduction of swarm intelligence robotics, interacting on a cellular and intra-cellular level (Mavroidis, 2013).

External Laparoscopic Robotic Systems

Laparoscopic surgery in which operations are performed through small incisions (usually 0.5–1.5 cm) reduces patient trauma and diminishes recovery times but at the same time limits surgeon's dexterity and vision because of the degrees of freedom that are lost due to the entry incisions, the rigidity of the laparoscopic instruments and the two-dimensional visual feedback.

The best known robotic system today is the da Vinci® Surgical System (Intuitive Surgical (2002) which incorporates a magnified vision system with a 3D high-definition view of the area and robotic technology that allows surgeons' hands movements to be translated into smaller, precise movements of its tiny wristed instruments inside the patient's body. Currently, there are several surgical systems under development that are marketed as daVinci's rivals, such as the SportTM Surgical System (Titanic Medical, 2016), the Telelap AlF-X (TransEnterix, 2016), the Raven Surgical robot (Kehoe, 2014) and the Araknes project (Sanchez, 2013) among others.

The daVinci surgical system is a proprietary technology, consisting of the surgeon's console, a patient-side cart, a vision system and instruments. The surgeon operates from the console, viewing the 3D image of the surgical field. It seamlessly translates the surgeon's movements in real time into precise, movements of the surgical instruments. More specifically, the 3D image featured in the console, provides HD vision and natural colors, up to 10x magnification, and the patented instruments have 7 degrees of freedom and a range of motion, greater than the human hand. The surgeon's hand tremors are minimized, and the console features built-in microphone in order to facilitate operating room communication.

The laparoscopic robot arm is equipped with a 3D camera and a light at the end. The camera sends the images from the abdominal cavity to the video monitor in the operation room and the surgeon console. The surgeon is at all times 100% in control of the system. Since its operation it has brought minimally invasive surgery to more than 3 million patients, covering various medical specialties such as cardiac, colorectal, general, gynecologic, head & neck, thoracic, and urologic surgery.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The SPORT™ Surgical System, which is yet under development comprises a robotic platform, surgeon – control for a single incision that incorporates a 3D HD vision system and multi articulating instruments for minimally invasive surgery. There is also a surgeon workstation that provides surgeons with an interface for controlling the instruments as well as the 3D view during the minimally invasive procedures. It is a surgical system, designed to provide the multi-articulating instruments and the 3D vision system for insertion into the patient's body cavity through a single incision of approximately 25mm with the surgeon being able to control it from the workstation. The instruments are designed to be coupled with sterile single use tools so that quality is ensured. The robotic platform is also designed to include a mast, a boom and wheels for optimal configurability for a variety of surgical indications and the ability to be maneuvered around the operating room and surgical centers where applicable.

The Telelap ALF-X surgical system, acquired by Transenterix Inc., is granted a CE mark, intended to be used for laparoscopic surgery in the abdomen and pelvis (Stark, 2015). It features haptic feedback, which leads to improved safety and allows for certain maneuvers to be performed with greater confidence. The system also tracks the surgeon's eye movements, positioning the camera, so the field of view is centered where the eyes are looking. The system is highly adjustable for an optimal ergonomic experience.

The SurgiBot System, by TransEnterix as well is designed to be a minimally invasive surgical platform that allows multiple instruments to be introduced and deployed through a single incision. The flexible instruments may be controlled directly by the surgeon from inside the sterile field, with robotic assistance. Its arm stabilizes the camera and alleviates the need for a dedicated person to hold it, and the instruments were developed to minimize incisions.

The Raven Surgical Robotic System was developed by the universities of Berkeley, Davis, and Santa Cruz mainly. It is a state-of-the-art open architecture (software & hardware) surgical robotic system and a prototype system including four arms which is currently available at the Bionics Lab (UCSC), while several other identical systems are to be distributed among leading groups across the US (Harvard, Hopkins, U. Nebraska, UCLA, UCB, UCSC, UW). The system uses a new statistical approach, Apprenticeship learning in terms of robot learning, targeted at allowing at robotic surgical assistants a higher level of autonomy, by being able to execute specific subtasks with performance exceeding human potential in regards to speed and smoothness. The latest version of the Raven Surgical System is IV, which was developed at the University of California – Santa Cruz and it includes two cameras and four robotic arms, and it facilitates a collaborative effort of two surgeons interacting with the surgical site in teleportation. The surgical arms are based on a spherical mechanism with a remote center located at the point of entry of the tool into the human body. Two surgeons in different remote locations can be connected via UDP protocol, as it is designed in the system architecture, with the use of a proprietary client interface and thus remotely operate the robots in the master/slave standard configuration. In experiments, several fundamental laparoscopic surgeries were completed while using a sampling rate of 1kHz.

Miniature External Robotic Systems

The Araknes Project, under the Large-scale integrating project (IP), FP7-ICT-Challenge 3: Components, systems and engineering/Micro/nanosystems funding scheme (Sanchez, 2013), is targeted at engaging micro and nanotechnologies from on-bench applications to in vivo surgical scenarios in endoluminal surgical approaches, thus further reducing operative trauma and enhancing therapeutic outcome of minimally invasive procedures. The system is based on an array of micro robotic instrumentation with components that include a flexible oro-pharyngo-esophageal access port and an umbilical access port,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

assistive and operative micro-robots allowing a bi-manual operation, an imaging system consisting of an endoscopic camera for global vision and a stereoscopic camera for visualizing the operative area, biosensors for tissue analysis (normally not available during laparoscopy) and an operating console incorporating the image of the operative field.

The developed robot under the project - ARAKNES SPRINT, Single-Port Laparoscopy bimanual robot - is yet a single incision master-slave robotic platform in terms of configuration, which consists of two high dexterity anthropomorphic manipulators, a stereoscopic camera and a master console for the robot control by the surgeon.

Even though external surgical robots have been an established reality in the medical community, there are still facing many challenges, mostly of technological and financial nature that must be addressed in the years to come, with an interdisciplinary approach and methodology (Vitiello, 2013; Marcus, 2013). In order for such an expensive technology to be incorporated in the services of health care systems, extensive cost- benefit analyses and needs assessments must be performed in mentioned environments, so that potential benefits can be substantiated.

At all times, the pre-operative diagnostic data must be matched in the surgical field so that localization of pathology is accurate. Furthermore, the tissue deformation that occurs by the manipulation of the tissue with either tools or physiological processes must be modeled and characterized in real time so that pathology may be identified in real time and deformations predicted. Haptic environments and tools may offer significant benefit together with visual technologies that will improve the restricted vision provided from current cameras.

Above all, as surgical robots are designed for all case scenarios, there is the size factor, that dictates new systems to be light-weight (versus current bulky systems) and with flexible access platforms (Noonan, 2011) that incorporate actuators and sensors.

Internal Laparoscopic Robotic Systems

Internal surgical laparoscopic robots aim at overcoming the obstacles of the classic and even the robotic laparoscopic surgery by including systems that augment vision and improve dexterity, using externally controlling robots that are completely located inside a body cavity. In vivo miniature robots, with either fixed-base or mobile platform, that fit entirely inside the peritoneal cavity, are now a novel technology offering a different approach (Rentschen, 2004; Zygomalas, 2015).

When it comes to fixed based laparoscopic robots, the main purpose is to provide an enhanced view of the surgical field, by augmenting vision and depth perception. Robots are placed with classical laparoscopic tools and are possible to be moved throughout the procedure, without the need to change the sterile field and make a new incision. Miniature PT (pan tilt) cameras have been developed as initial work allowing for panning of 360o and tilting of 45o, rotating two independent axes and with the use of LED lights (Oleynikov, 2004). Such robots were inserted within the standard laparoscopic port into the peritoneal cavity and had provided additional views of the cavity.

Laparoscopic robots, which feature a movable platform, remotely controlled, consist of systems that provide forward, reverse and turning motion (Rentschen, 2006). There is usually a mechanism that allows for counter rotation prevention and wheels are incorporated so that it is possible to maneuver on organs, like liver, spleen and bowels without causing damage. Similar robotic mobile laparoscopic systems have been developed (Rentschen, 2006) that feature adjustable focus cameras to improve depth perception within the peritoneal cavity, thus eliminating the need for camera port incisions eventually.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Biopsy instrumentation in addition to vision assistance has been added in several systems for one-port laparoscopic biopsy. Forceps providing adequate biopsy samples in porcine subjects have demonstrated promising results, with the onboard camera used to locate the biopsy site as the robot traverses the peritoneal cavity (Rentschen, 2007).

Apart from fixed base camera and wheeled robots, magnetic drive robots for biopsy, vision, and task assistance has been developed (Lehman, 2007), and tested in vivo. These robots assisted surgeons in laparoscopic surgery by providing manipulators with a dexterity not limited by the entry incision, alongside with an enhanced view.

Internal Endoscopic Robotic Systems

In advancing minimally invasive surgery an evolving field that initiated interest in the medical community since 2005 is Natural Orifice Transluminal Endoscopic Surgery. NOTES features operations where scarless abdominal operations are performed with the use of endoscopic systems or miniaturized robots that are passed through the natural orifices of the human body and then through internal incisions, therefore avoiding external incisions and scars. NOTES is the integration of laparoscopic surgical techniques with endoscopic instrumentations and the current technological focus of the development of flexible or autonomous wireless platforms that incorporate robotic technology, thus using micro or nanoscale robotic devices providing capabilities such as imaging, retraction, tissue and organ manipulation, and precise maneuverability in the abdominal cavity. NOTES can be classified according to primary routes of access as transvaginal, transrectal and trans gastric (Kaloo, 2004; Marescaux, 2007).

The transvaginal entrance has already been established as a beneficial technique, as it is performed under direct visualization and through 2010 in 64% of the cases, rigid endoscopes were used in hybrid procedures (Auyang, 2011). Transrectal procedures are less common (Bulian, 2014) and trona gastric access has been less frequently used, as it had the technical challenge of gaining peritoneal access and a challenging gastrostomy closure.

Swallowable microsystems, which can be reassembled in the stomach cavity are proposed and developed, with potential to change their configuration according to location and task assigned, while monitored by navigation systems and controlled via wireless communication consoles operated by surgeons or healthcare professionals (Nagy, 2009). Within the ARES project (Assembling Reconfigurable Endoluminal Surgical system, 2014) such a system was developed, that can be disassembled after the operation, into individual models or reconfigured for a consequent intervention, eventually reassembled into a snake type structure. The modular nature of the proposed system can incorporate various extra modules, even during operations or dispose of unnecessary modules that can be discarded or replaced, with the use of magnets as the driving mechanism of self-assembly. Magnets can provide a reversible connection – disconnection platform due to the nature of the phenomenon per se and can enhance reconfiguration options. Modular mini robots for possible use in NOTES or laparoendoscopic single site (LESS) surgery, have also been investigated in-silico using professional robotics simulation software with promising results (Zygomalas, 2011, 2012, 2014).

Magnetic anchoring and guidance systems (MAGS), that usually consist of an external magnet and an intracorporeal device with a camera or surgical instrumentation, have been proposed to be used for NOTES. The idea features insertion of the internal part through either an incision or a natural orifice and coupling via magnetic fields, across the skin tissue layer. The use of cameras with LED-wrapped trocars (Park, 2007) and the insertion of cautery and retractors modules have been tested in experimental models (Zeltser, 2007).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Endoluminar miniaturized robots are a much promising technological field for minimally invasive surgery, even though for the time being, implementation in real practice is limited mainly due to size constraints (Zygomalas, 2015).

ROBOTIC CAPSULES

In addition to miniaturized robotic devices that are endoscopically inserted into the abdominal cavity, capsule endoscopy, is a trend that has been an uprising in current medical research and it has started from imaging and telemetry capsules, used for diagnostic issues. A robotic system for capsule endoscopy has modules for power, vision, telemetry, localization and diagnosis and/or manipulation. Robotic capsules are now incorporating locomotion capabilities and are evolving into devices able to perform interventional tasks. One of the most critical issues is the development of an adequate propulsion system that will be delicate enough not to damage tissues, yet powerful enough to advance in complex tissue structures and perform surgical tasks with accuracy, safety and efficiency. The propulsion system is part of the overall design of the capsule that has a critical role in the successful deployment of the device. It can either be internal, external or hybrid where more than one propulsion mechanisms are used. Various methods have been proposed according to the geometry of the target area, like leg or paddle like mechanisms, activated by micro motors, magnetic actuators, or wall-to-wall motion with the aid of micro-propellers.

When it comes to internal propulsion mechanisms, the robotic system is more autonomous, having better control of its mobility. Legged propulsion systems have already been developed (Gorini, 2006), extending from 3 to 12 legged as nature is providing inspiration with bio-mimetic (bio – inspired) systems, that can vary from earthworm/inchworm-like that are based on piezo actuators or shape memory alloy springs (Kim, 2004, 2005, 2009). In such nature-inspired propulsion systems, the modules are to be swallowed and then reassembled inside the gastrointestinal track, using magnetic or wireless communication systems (Kim, 2013; Fang, 2015).

Cilia and flagella, cell organelles, similar in structure but with different functions, provide different motions, with the motion of flagella undulating and wave-like, whereas cilia motion is more complicated, 3D and with a power and recovery stroke. Both have been suggested and used as the basis for propulsion mechanisms of robotic endovascular systems (Li, 2006; Feng, 2007; Kosa, 2007) while other systems have been created with paddling based propulsion robots, that mimic canoeist paddling (Park, 2006, 2007). These feature linear actuators with dual cylinders that perform a cyclic motion, which helps the robot to advance in cycles.

Apart from external mechanisms, it is possible to use the electrical stimuli produced by the natural contractions of the intestinal smooth muscles that can be applied via electrodes to the robot (Woo, 2009, 2011). The peristalsis that occurs (the natural movement of the bowels) creates a force that allows potentially for a robot to move opposite to the contraction end of the lumen and it can be bidirectional depending on which electrode is activated.

Vibratory propulsion is a concept where the robot has an eccentric rotating motor that generates a (Carta, 2011; Zabulis, 2008) centripetal force thus allowing for the horizontal component of the force to propel the robot.

In the principle of internal reaction propulsion, the robot moves by the reaction force caused by the movement of an internal mass, without legs or wheels as in other systems (Liu, 2008), exploiting the piezoelectric phenomenon, incorporating a linearly-moving mass generate the reaction force. The most

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

common mechanism for external propulsion, which bypasses the issue of internal actuators, releasing space for other instrumentation, is external propulsion by means of an external magnetic field interacting with internal magnetic components. It can be either guided by an MRI device, with its magnetic field interacting with potential coils incorporated in the robot or by an external permanent magnet that can be operated by a healthcare professional or even a robotic navigation system (Lien, 2012).

In order to combine advantages of internal and external propulsion systems and reduce risks and disadvantages mentioned above, hybrid systems have been developed that combine magnetic and motor mechanisms (Menciassi, 2009) with motion achieved by external magnetic fields and orientation by internal mechanisms. Other hybrid systems, bring together legged actuators with external magnetic dragging (Simi, 2010).

With the microelectromechanical systems advances, it is possible to integrate into miniature robotic capsules several tools like sensors for pH measurements, pressure and temperature sensors and blood detection platforms. Integration of interventional tools, is still under development. However interventions such as biopsy, suturing, clipping and drug delivery, have already been tested in vitro or in vivo in porcine models (Iddan, 2000).

NANOTECHNOLOGY AND SURGICAL ROBOTS

Since the miniaturization of electromechanical systems (MEMS) and their incorporation in general surgery (Rebelo, 2004), the next goal set by science was to advance further on the nanoscale, thus manipulation of the matter on an atomic, molecular, and supramolecular scale, with at least one dimension sized from 1 to 100 nanometers. Nanotechnology in medical applications and more specifically in surgery has been part of research, from drug delivery systems to diagnostics and interventions. Nanorobots, controllable electromechanical systems, are capable of actuation, sensing, communication, propulsion, signal and information processing and interaction with tissue. They can also manifest swam behavior and have a unique potential in delivering clinical results of high quality and accuracy (Mavroidis, 2013).

Apart from diagnosis and treatment of diseases with nanoscale delivery systems (Lenaghan, 2013; Dadkhah, 2013), monitoring and treatment of chronic diseases (Cavalcanti, 2008) or even incisionless surgery is the next potential application. In order for the nanorobots to be functional, several conditions must be met. Initially, the swarm intelligence (Bonabeau, 1999), which is the collective behavior of nanorobots that can self-organize them, should be accompanied by appropriate propulsion so that movement and navigation inside the human body can be realized. For sensors and actuators, communications, control, and decision-making functions, it is important to incorporate a power supply system, capable of supporting the described functions for the estimated time of the surgical intervention.

Nanorobots will be scaled to fit inside a drop of saline and then can be programmed to move to specific locations, to areas of interest and interact with cells directly, instead of manipulating tissue in a macro scale. This interaction on a cellular level means that cells can be guided to either die or regenerate with simple commands, inspired by computer programming. The input taken from cells will serve as logical input that can train and enhance logical function and cognitive behavior of the nanorobots, sustaining and advancing their autonomous intelligence.

Apart from collecting information and interacting with living cells, nanorobots can be integrated or even compiled of compatible biomaterials and serve as scaffolds in surgical interventions that require bone or soft tissue reconstruction.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

As the world marches towards a new era of intelligent technologies, interacting autonomously within an environment of shared information and big data, it is but certain that self-aware cognitive robotic systems will be incorporated into everyday medical practice. Minimally invasive surgeries, performed with micro and nano-robots, will be ensuring minimal tissue damage, high accuracy, and quality, as technological advances will be incorporated into the discipline, along with accumulated experience. New capabilities and procedures will be developed, and it is likely that human horizon and possibilities will expand including thought controlled devices and what once was science fiction, will become mundane reality.

KEY TERMS AND DEFINITIONS

Laparoscopy: A type of surgical procedure, in which the incisions are small and through which instruments and a viewing tube are inserted.

Micro – Electro – Mechanical Systems: Mechanical and electromechanical structures and devices that are made with microfabrication techniques and with dimensions that vary from below one micron to several millimeters.

Modular Microrobots: Robotic Systems that consist of diverse several subunits that could be assembled in order to construct a functional miniature robot.

Natural Orifice Transluminal Endoscopic Surgery: A novel surgical technique that uses the natural orifices of the human body in order to approach the peritoneal cavity.

Robotic Surgery: Surgical procedures that incorporate as aid, the latest technological developments in robotic systems.

Chapter 103
A Next Generation of IT:
A Health Record Example with Terminology Binding

Anthony J. Mallia
Edmond Scientific Company, USA

ABSTRACT

A potential new generation computing environment is emerging which combines wiki technology with semantic web concepts. This has brought about the fusion of the wiki execution ecosystem, a semantic web for model-driven applications, and a high-level language as an extension to wiki text for accelerated development. Semantic MediaWiki provides this platform and a fragment of a health record, including allergy intolerance as structured in HL7 FHIR with terminology bindings to SNOMED CT and to HL7 terminologies was developed by the author in a short timeframe (approximately 10 hours). The system navigates around the health record and controls the entry of terms in the record from controlled ValueSets. All terminologies and ValueSets are integrated into the prototype.

INTRODUCTION

There is a pending information system development revolution. The arrival of the sixth generation of computing is imminent and it is found in the mechanism for developing applications based on two concepts:

1. Open data platforms providing execution of a high-level language (annotation markup) and supporting distributed ecosystems based on wiki technology
2. Emergence of Semantic Web as a knowledge structure for use in ordinary applications (not just artificial intelligence)

The fourth generation of computing has fourth generation language (4GL) support and is aimed at improving development productivity. Enterprise resource planning (ERP) systems typically use 4GL to define system behavior.

The fifth generation is aimed at the field of artificial intelligence based on Semantic Web which introduced the triple store, as well as the management of graph knowledge structures beyond the relational database.

So, in the migration to this next generation we need to be aware of the changes to software construction needed to take advantage of new capabilities and not just apply old programming practices. Specifically, this necessitates the implementation of concepts such as structured data capture in the language of a Semantic Web platform and not in Java (which is not a 4GL).

Part of the motivation for using a Semantic Web platform is the speed with which implementation can be achieved over traditional programming mechanisms. Some precursor development tools exhibited productivity gains in the order of 20 times over traditional development methods Gartner Inc. (2003).

The change of thinking, which must occur between existing programming techniques and those supported by Semantic Web platforms, is demonstrated by how an Electronic Health Record (EHR) could be migrated to this environment.

The paper explores implementation of an EHR in a sixth generation as represented by Semantic MediaWiki. It examines a specific case of the binding of a health care record entry to a term expressing the entry's type as part of a standard terminology where both the record and the terminology are loaded in a Semantic Web environment.

THE CHANGE IN THE BINDING MECHANISM

Existing approaches have binding from a health record entry to a terminology as a multi-string match (a coded element structure including the code system and the term code) to a terminology concept often through a Common Terminology Service (CTS).

The CTS is a service to access the terminology callable by the health record system with legacy programming techniques. One function is that it allows access to the display value of a concept.

The binding example which is described here illustrates the lower capability of existing traditional programming environments compared to the Semantic Web. Data is stored in primitive types – strings, numbers, dates and all relationships are built in the constructed software. Examples of this are found through multiple generations of Health Level 7 [HL7] including the latest standard Fast Healthcare Interoperability Resource [FHIR]. (HL7 FHIR, 2018)

A healthcare record is a complex graph usually anchored with a patient resource. Healthcare actions planned and taken for this patient are recorded in clinical and administrative records (subgraphs) linked to the patient. Identification, coding from terminology systems, and display representation precisely state the records' contents. Examples of terminology systems include Logical Observation Identifiers Names and Codes (LOINC), International Statistical Classification of Diseases and Related Health Problems (ICD), and Systematized Nomenclature of Medicine Clinical Terms (SNOMED International).

The HL7 coded element, as part of the health record entry, supplies a structure containing the unique identity of the coding system (namespace), version of the coding system, unique code, and display text of the semantic. These components will be called system, code, and display. To achieve a precise semantic identification, the system and code components are required. The display is derived from their combination.

Here is a fragment of an HL7 FHIR Allergy Intolerance (HL7 FHIR, 2017) in XML where the entry display is "No Known Drug Allergy."

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Code Fragment 1. (FHIR Allergy Intolerance Code in XML)

```
<AllergyIntolerance xmlns="http://hl7.org/fhir">

  <code>
    <coding>
      <system value="http://snomed.info/sct"/>
      <code value="409137002"/>
      <display value="No Known Drug Allergy"/>
    </coding>
    <text value="NKDA"/>
  </code>
```

The binding is achieved by matching <system> and <code> against the terminology service to extract the display value= “No Known Drug Allergy” which is inserted in the record. This binding must be explicitly implemented in traditional programming.

As expression of terminology moves to Semantic Web and ontologies, the existing binding is not optimal for a semantic web platform - the approach does not make use of link closure between a reference and its target.

While the terminology developers and in particular SNOMED have advocated a health concept be represented by an OWL Class and there has been discussion that an entry in the health record could be an instance of that concept, there has been no discovered literature discussing the specific implementation which would then behave well within a semantic web platform.

If the semantic web platform is potentially the next generation of computing, then it would be important to establish how the health record and the terminologies behave in this environment. This also provides a bridge into clinical decision support where clinical knowledge is also linked to the terminologies and patient record although this topic is not covered in this paper.

In the search of Semantic Web literature references, there are few mentions of its use for Health Records or the binding to terminology except in the HL7 RDF Working group. The expression of terminology in Semantic Web is well referenced but the Health Record side is not. (Rector, Qamar, & Marley, 2009)

No exploration of binding through a proof of concept has been done to the author’s knowledge. The feasibility of this approach is explored in this paper by implementation of a fragment with an available semantic web platform.

WHAT SOLUTIONS EXIST IN LITERATURE

SNOMED CT shows a representation in OWL where the Concept is an OWL Class with a single identifier concatenating the namespace with the term id {sctid}. The OWL representation of SNOMED CT makes use of URIs for identifying Concepts with a structure:

http://snomed.info/id/sctid
(International Health Terminology Standards Developmemt Organization (IHTSDO), 2014)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, the binding from the health record entry to the concept should have a reference to this single identifier. The prevailing thinking is that the health record entry is an instance of the term as a class which defines its type.

Additional work has been referenced for LexWiki and ICD10 Collaborative Revision Platform (Solbrig, 2008). This is a platform for editing terminologies. In this approach each term has a single name which identifies it. No binding to the Health Record is described although it is assumed that it would be an instance to class relationship. Discussion with the author has confirmed this.

Thus, an instance of Allergy Intolerance associated with a patient can have a link to a type http://snomed.info/id/409137002 (no known drug allergies). The prefix identifies that it is a SNOMED term and the number is the term identifier.

The HealthCare RDF Research

In 2014, the Health Level 7 (HL7) standards development organization formed the "RDF for Semantic Interoperability workgroup" jointly with the World Wide Web Consortium (W3C) to establish semantic interoperability of structured healthcare information. It used the W3C Resource Description Framework (RDF) and related standards to express machine-processable meaning. It supported the HL7 mission to increase the effectiveness and efficiency of healthcare delivery.

The first work in the workgroup was to create an RDF representation of Fast Healthcare Interoperability Resources (HL7 FHIR, 2018). During this activity some prototype FHIR resources in RDF were constructed and imported into Protégé by the author to demonstrate what an RDF representation of a health record might look like on a Semantic Web platform. The current representation of FHIR, as a set of connected resources with their classes, is useful for managing healthcare information (not just exchanging it), and led to the exploration of a representation of the FHIR EHR as a Semantic Web ontology.

Semantic Web mechanisms can be used for low order problems which are not about discovering new knowledge but are about capturing and sharing existing knowledge. The concepts Class, Individual, and Property become the model element types of the description. Triple stores become the database. Thus, a complex graph can be represented by a Semantic Web platform to manage the model, instances, and user navigation in an integrated ecosystem.

In Semantic Web, an instance (individual) can have multiple rdf:type relationships and a Semantic Web platform understands the Class behavior including its sub-classing (rdfs:subClassOf) mechanism used heavily in the SNOMED CT representation.

WHICH KIND OF EVALUATION WAS PERFORMED ON THE SOLUTION

The evaluation of the approach was done by practical demonstration of health record and terminology fragments not only to illustrate the binding mechanism between the health record entry and the terminology which was technically easy, but also to evaluate whether the health record functions could be implemented in the platform without the use of legacy languages.

A mock health record fragment, aligned with HL7 FHIR was created and a subset of SNOMED CT was entered so that the binding would happen automatically by closure in the platform. Display values of the Concepts were available from the terminology to be shown in the health record and allowable concept ValueSets defined by FHIR were presented for selection during structured data capture.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Three use cases were tested:

1. Ability to pick from a ValueSet of permitted terms during structured data capture
2. Display of the human readable term display value from the terminology when viewing the record
3. Ability to display the definition of a term or ValueSet from the terminology when viewing the health record

Decision for the Prototype Implementation

Two implementation options for the prototype were considered

- Traditional programming environment - OWL API (OWL API) and Java
- Semantic MediaWiki (SMW) and Wikitext

Traditional Programming Environment: OWL API and Java

A prototype application involving the definition of a graph ontology and the creation, editing, and reporting of information structured with this ontology was first developed by the author in Protégé using the OWL API.

The user interface would have to be built with Java tools. This is not only a much larger project but did not show the Semantic Web Platform only feasibility.

Semantic MediaWiki (SMW)

A number of applications have been prototyped by the author with SMW using Wikitext, the Wiki markup language to develop a working system.

Although this is not a pure Semantic Web platform with regard to RDF/OWL, it does have export mechanisms to RDF. The platform is very fast when implementing an ontology. It also has reasonable user interface development capabilities for viewing, navigating and structured data capture.

Decision

The example health record was implemented with Wikitext extensions for Semantic MediaWiki (https://www.semantic-mediawiki.org/wiki/Semantic_MediaWiki). This early stage proof of concept uses SMW to deploy the ontology both the type definitions and the instances.

This decision is partly influenced by the difference between Protégé and OWL being Open World Assumption based and Semantic MediaWiki being more oriented to a Closed World Assumption where the intention is to constrain allowable values and which is more in line with the governance of an EHR.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

DESCRIPTION OF THE HEALTH RECORD AND TERMINOLOGY FRAGMENTS

Semantic Web Description of FHIR

The HL7 RDF work group (HL7 FHIR/RDF, 2017) chose RDF to be the same structural representation as the other HL7 FHIR formats – XML and JSON so that round trip conversion could be performed.

This RDF example of Code Fragment 1 (FHIR Allergy Intolerance Code) represented in RDF turtle looks like:

Individuals are anonymous (blank nodes) and are nested within some structure (not shown). Thus the matching process was the same as the legacy mechanism with a string match of Coding.system (http://snomed.info/sct) and Coding.code (409137002) against the terminology. At this stage it has not progressed to using the closure mechanism we are expecting.

Semantic Web Description of SNOMED CT

SNOMED International is the trading name of the International Health Terminology Standards Development Organization (IHTSDO). IHTSDO's core product is SNOMED CT, however there are many other supporting products and services that are required in order to ensure the successful adoption of the SNOMED CT which are provided by IHTSDO as secondary services.

SNOMED International released a version of SNOMED CT in Web Ontology Language (OWL). Here is a code fragment showing the SNOMED concept used above:

The sample concept name http://snomed.info/id/409137002, is a concatenation of the system prefix http://snomed.info/id/ and the code 409137002 as defined by SNOMED. The element is an OWL class rather than an instance or individual. The display is an rdfs:label, which is used for human viewing. The concept also uses the assertion in a subclass of http://snomed.info/id/138875005, which is the top-level concept in SNOMED CT as shown:

Code Fragment 2. (RDF Allergy Intolerance Code)

```
[a fhir:AllergyIntolerance;

  fhir: AllergyIntolerance.code [
    fhir:CodeableConcept.coding [
       fhir:Coding.system [ fhir:value "http://snomed.info/sct" ];
       fhir:Coding.code [ fhir:value "409137002" ];
       fhir:Coding.display [ fhir:value " No Known Drug Allergy (situation)" ]
    ]
  ]
];
```

Code Fragment 3. (SNOMED Concept in RDF)

```
<http://snomed.info/id/409137002> rdf:type owl:Class ;
   rdfs:label "No Known Drug Allergies" ;
   rdfs:subClassOf <http://snomed.info/id/138875005> .
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Code Fragment 4. (SNOMED Top Concept)

```
<http://snomed.info/id/138875005> rdf:type owl:Class
    rdfs:label "SNOMED CT Concept"@en .
```

(Author note: in a later version of SNOMED CT there are intermediate classes between the 409137002 term and the top-level concept).

Thus, the SNOMED Ontology is a Class graph with every member being a subclass (not necessarily directly) of the SNOMED CT Concept.

A number of approaches have converged on the single identifier for a concept but there appears to be no existing work to examine what has to happen to the health record to bind to this single identifier.

The binding is thus a single string match which would have to be coded in a traditional programming environment. However, in a semantic web platform this binding is computed by the platform itself so that a graph is known where the Allergy Intolerance instance has closure to a Terminology Class and can be traversed with Semantic Web instructions.

The method for doing this binding was identified in the HL7/W3C RDF working group to be the application of the rdf:type as a semantic class of the CodeableConcept.coding individual (an anonymous individual or blank node) in the record. This then supported both the string match and the closure to the type.

Here is the structure of a record fragment in turtle with the added type “a http://snomed.info/id/409137002”. This is the same as “rdf:type http://snomed.info/id/409137002”). Turtle introduces a special abbreviation for the rdf:type property using the”a”keyword.

Closure will only occur if the full qualified identities match.

There are two options to get the rdf:type if the Coding.system and Coding.code are known:

- Using a reasoner
- Explicit transformation

Code Fragment 5. (Allergy Intolerance code RDF binding to SNOMED CT)

```
[a fhir:AllergyIntolerance;

  fhir: AllergyIntolerance.code [
    fhir:CodeableConcept.coding [a http://snomed.info/id/409137002;
       fhir:Coding.system [ fhir:value "http://snomed.info/sct" ];
       fhir:Coding.code [ fhir:value "409137002" ];
       fhir:Coding.display [ fhir:value "No Known Drug Allergy (situation)" ]
    ]
  ]
]
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Using a Reasoner

Given some additional information, a reasoner can infer the type and cause the closure to happen. This additional information could be provided in a bridging ontology if we do not want to change the record or terminology.

The bridging ontology can declare a general Class axiom which shows the mapping to the Concept Type (or OWL Class as we have been working in OWL) to the values in the coding:

This general class axiom infers that all individuals which have of the restricted property code and system values (defines a class) will be a subclass of the SNOMED class http://snomed.info/id/409137002.

This approach was tested using Protégé and was found to work. It effectively generates the triples needed to navigate the graph and allow every instance of No Known Drug Allergy to be linked to that SNOMED Terminology Class.

However, the volume of statements needed to define the binding is excessive since there needs to be this restriction statement for every member of the terminology – reaching in the hundreds of thousands.

Explicit Transformation

Another way to do the binding is to programmatically insert the rdf:type in the record as needed. This mechanism is preferred given the following discussion of the long-term approach to semantic representation. The other overriding reason is that SMW does not have a reasoner for scalability concerns.

In the proof of concept, the records were entered with the direct binding as shown below. Since we are only dealing with a Semantic Web environment the string matching Codeable Concept can be omitted since we can enter the rdf:type directly.

As will be shown later the Codeable Concept values can be added to the term class.

Code Fragment 6. (Bridging Ontology)

```
[ rdf:type owl:Restriction ;
  rdfs:subClassOf <http://snomed.info/id/409137002> ;
  owl:onProperty fhir:CodeableConcept.coding ;
  owl:someValuesFrom [ rdf:type owl:Class ;
                       owl:intersectionOf ( [ rdf:type owl:Restriction ;
                                              owl:onProperty fhir:Coding.code ;
                                              owl:allValuesFrom [ rdf:type owl:Restriction ;
                                                                  owl:onProperty fhir:value ;
                                                                  owl:hasValue "409137002"
                                                                ]
                                            ]
                                            [ rdf:type owl:Restriction ;
                                              owl:onProperty fhir:Coding.system ;
                                              owl:hasValue <http://snomed.info/sct>
                                            ]
                                          )
                     ]
] .
```

Code Fragment 7. (Snomed Binding to the individual)

```
[a fhir:AllergyIntolerance; a http://snomed.info/id/409137002;

   other properties
];
```

The reason the rdf:type can be applied to the whole AllergyIntolerance and not to the object of AllergyIntolerance.code is that the HL7 FHIR meaning of "code" is a classification of the Allergy Intolerance and maps to an rdf:type. This is not the case with all properties of an instance where the semantics of the term need to be declared such as Clinical Status and there will be a specific property for AllergyIntolerance.clinical status having a blank node value that is purely its term as an rdf:type.

ValueSet Representation

ValueSets are constraints on the allowable codings to be used in the context and in HL7 FHIR are aligned to string matching. A value set specifies a set of codes drawn from one or more code systems (HL7 Vocabulary, 2018).

In Semantic Web, the allowable set of codes is a Class based on its set theory origin. The subclasses of the particular ValueSet Class represent the allowable Class identities which can be used in the context of each element of the patient record.

String Matching Declaration

In the Allergy Intolerance example, FHIR defines the ValueSet as:

http://hl7.org/fhir/ValueSet/allergyintolerance-code

This ValueSet (HL7, 2018) includes codes from the following code systems:

Import all the codes that are contained in http://hl7.org/fhir/ValueSet/substance-code
Include codes from http://snomed.info/sct where concept is-a 418038007 (Propensity to adverse reactions to substance)
Include codes from http://snomed.info/sct where concept is-a 267425008 (Lactose intolerance)
Include codes from http://snomed.info/sct where concept is-a 29736007 (Syndrome of carbohydrate intolerance)
Include codes from http://snomed.info/sct where concept is-a 340519003 (Lysine intolerance)
Include codes from http://snomed.info/sct where concept is-a 190753003 (Sucrose intolerance)
Include codes from http://snomed.info/sct where concept is-a 413427002 (Acquired fructose intolerance)
Include codes from http://snomed.info/sct where concept is-a 716186003 (No known allergy)

However, the actual list of codes to be matched is large and must be deployed to achieve the match.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Semantic Web Declaration of ValueSet

All the actual values do not need to be articulated since the term classes may be subclasses of the ones defined in the ValueSet.

The equivalent definition in Semantic Web is:

http://hl7.org/fhir/ValueSet/substance-code
or http://snomed.info/id/418038007 (Propensity to adverse reactions to substance)
or http://snomed.info/id/29736007 (Syndrome of carbohydrate intolerance)
or http://snomed.info/id/340519003 (Lysine intolerance)
or http://snomed.info/id/190753003 (Sucrose intolerance)
or http://snomed.info/id/413427002 (Acquired fructose intolerance)
or http://snomed.info/id/716186003 (No known allergy)

The Allergy Intolerance instance must be a member of the union of the sets defined by the classes. By the previous definition, this union is the class representing the ValueSet.

Combination of Health Record, Terminology and ValueSet

The combination of these ontologies through closure allows semantic navigation from the record through the hierarchies (classes, subclasses) of the terminology ontology. Thus, an adverse reaction to a concept which is a higher concept than a medication type can be detected in the intersection of the class sets of concepts.

Integration of the health record with the terminology allows the practical implementation of ValueSets for restriction of concepts to be applied to the health record during data capture.

However, when we are dealing with a Semantic Web platform we may not have access to the traditional programming mechanisms for identifying and selecting the class URI under the restriction of the ValueSet identified for that element.

The binding from the Record entry is therefore restricted to a subclass of the ValueSet Class.

The approach was tested initially with Protégé which could show the closure only. Then in a fuller user implementation in Semantic MediaWiki, the ValueSets for data capture could be demonstrated with a selection window without resorting to traditional programming techniques.

SEMANTIC MEDIAWIKI OVERVIEW

The introduction of Semantic Web concepts to wiki was achieved by the Semantic MediaWiki (SMW) extension to MediaWiki. In general, historical applications added semantic tagging to wiki pages. However, the tool extension “Page Forms” allows for the collection and manipulation of classical fielded information. Coming from the system development area, the capabilities are equivalent to 4GL. (Kamel Boulos, 2009)

SMW uses the wiki features strong in the areas of user presentation and its high-level annotation markup - Wikitext, was extended by SMW’s open source project based out of Karlsruhe Institute of Technology to support Semantic Web concepts.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In SMW, the rdf.type is called Category when it refers to the set that the individual belongs to. When rdf:type refers to the metaclass SMW uses Namespace to identify it.

The SMW Wikitext has a powerful in line query function aligned to SPARQL.

Code Fragment 8 is an example of an in-line query to retrieve instances of Category Parks. It displays them using their geographic coordinates in Google Maps:

Code Fragment 9 is an example in a data capture Form showing the selection of a Category from a tree structure of Categories underneath the Top_Category.

The tree structure is displayed from the Category subclass relationships under the Top_Category. This will be shown later in the ValuesSet prototype structured data capture example.

The Semantic MediaWiki Term Binding

In SMW the sample SNOMED CT concept was implemented as:

Category SCT:409137002 (No Known Drug Allergies)

The name has concatenated the System as a prefix "SCT:", the code "409137002", and the display in parentheses. The prefix SCT: represents the URI prefix http://snomed.info/id/.

This was purely pragmatic to get the best use of the platform.

The Category page may contain information as shown in Code Fragment 10 (SNOMED CT Concept in SMW). The [[Category:]] statement defines this category to be a subcategory of SCT: 138875005. The page was designed with fields in a template called Terminology. This provides the breakout of properties System, Code, Display, and Definition which are used in the run time implementation and provide the translation with the traditional Code structure – System and Code.

Code Fragment 8. (SMW #ask Query)

```
{{#ask:[[Category:Parks]] | ?Has coordinates | format=googlemaps}}
```

Code Fragment 9. (Semantic tree entry)

```
{{{field|Category | input type=tree | top category=Top_Category | height=200}}}
```

Code Fragment 10. (SNOMED CT Concept in SMW)

```
{{Terminology
|System=http://snomed.info/sct
|Code=409137002
|Display=No Known Drug Allergies
|Definition=No known history of drug allergy
}}
[[Category:SCT:138875005 (SNOMED CT Concept)]]
```

The Prototype Electronic Health Records (EHR) fragment

The prototype EHR fragment, defined using Unified Modeling Language (UML) Class diagrams, shows links between the instances and the types identified by categories. See Figure 1. UML representation of the ontology.

The graph structure is defined in the class diagram through class attributes and associations and also through subclassing relationships. The example FHIR:AllergyIntolerance declares the structural type along with semantic restrictions. In Semantic Web, class restrictions determine the allowed properties (from their domain). In SMW, the restrictions are applied in a template and form definitions.

A FHIR fragment was translated into a semantic web ontology described in UML before entry to SMW. The FHIR structure ontology is transcribed using category, property, templates and form page SMW editors alongside the health records entered with Forms. Thus, structural types such as Allergy-Intolerance, the SNOMED terminology, and the patient record are all computationally accessible in the SMW environment.

The SMW template declares fields in the page along with the property linking the page to the field. Thus, a "Start Date" field may have a property "Has Start Date" linking the page (instance) of the activity to its start date. The triple store and the value in the page field link a named individual to a simple data type or to a reference to another page. Another page name becomes an HTML link in the user interface.

The editing of the value in the page field causes the triplestore to be edited and the user is not aware of this process although the results can be viewed in the property browser.

The instance identity structure is designer chosen. In this example it has the server location prefix, which must be unique within that server (wiki) see linked data later in the paper. The server prefix is followed by any context qualifier which makes the remainder of the identity unique.

The ontology is expressed in SMW as categories (classes), subcategories, properties (attributes and associations), and instances (sometimes referred to as "articles" in SMW). The structure is documented using UML with explanation. A dependency relationship (dotted line with arrow) is drawn by linking the object (individual) to its classes.

The ontology diagram omits most attributes (data properties) for clarity.

Properties in semantic web are unidirectional in their declaration. However, they may be traversed in both directions with an inverse property. The directional arrow shows the declaration direction. For example, instances of allergy intolerance point to instances of patient using the property FHIR:AllergyIntolerance patient (not the other way). The in-line queries support navigation from the patient to the allergies.

In SMW an inverse property is declared with a negative sign prefix to the property. -FHIR:AllergyIntolerance patient navigates from the Patient to the AllergyIntolerance instance.

FHIR ONTOLOGY PROOF OF CONCEPT IMPLEMENTATION

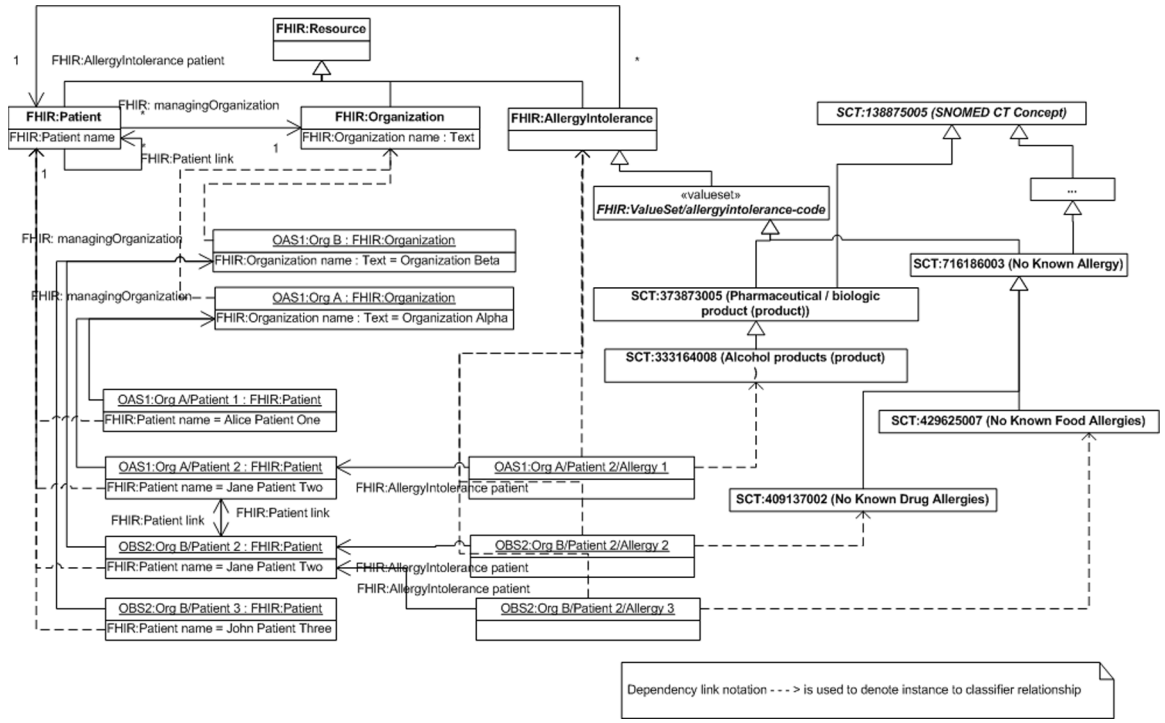
All figures in this section are captured screenshot fragments from SMW (except for the UML diagrams).

The General Ontology

Figure 2 shows the introductory user interface where the contents are generated with in-line queries and includes several patients at different managing organizations. The two managing organizations are

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. UML representation of the ontology



organizations alpha and beta. The records are located on server 1 and server 2. The servers are managed by each organization. They are identified with the prefixes OAS1 and OBS2, which are used as prefixes to define the location of a resource (e.g., OAS1:xxx).

Patients are identified by one or more organizations (assigning authority) where the assigning authority prepends the patient id. OAS1:Org A/Patient 1 has an assigning authority of organization alpha. The record is located at server OAS1.

The properties, reformatted from the HL7 FHIR properties are established to link this together:

1. FHIR:AllergyIntolerance patient
2. FHIR:Organization name
3. FHIR:Patient link
4. FHIR:Patient managingOrganization
5. FHIR:Patient name

The template for FHIR:Patient defines the field "name". It also defines that the property FHIR:Patient_name has the value from the field "name". Field names are local to a template. Although this is an oversimplification of name, it shows the relationship between the template view and the underlying ontology view of named individuals (pages) and properties in the triplestore.

The line "! Patient name" defines the label to be used in display (see 10) where the patient name is displayed. Templates control the viewing behavior of a page. Forms define the data capture behavior.

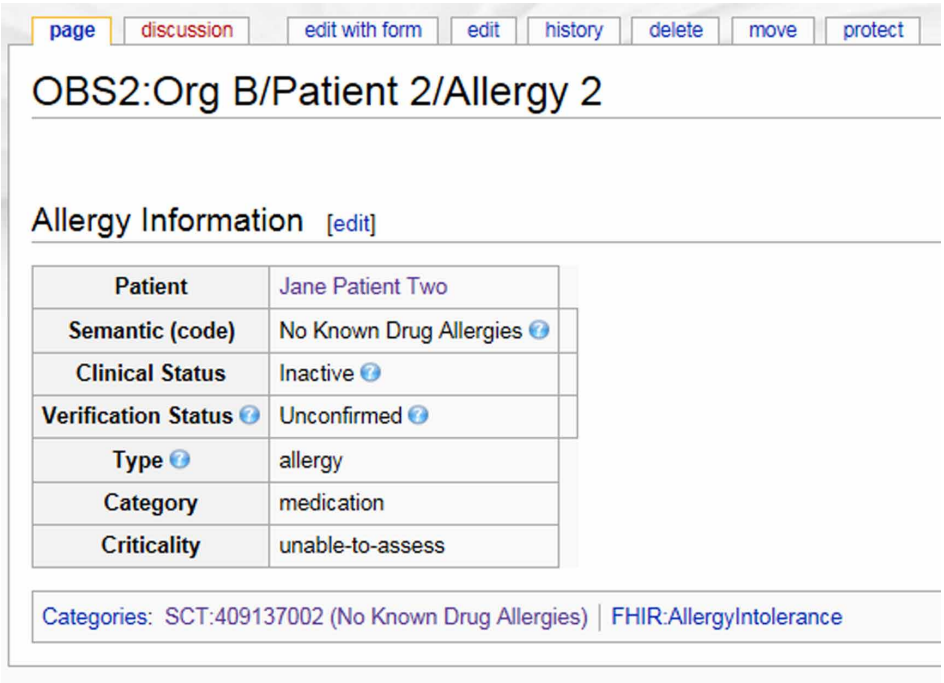
|-
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. User interface view of an allergy



Allergies

Allergies, linked to the term, are displayed in the user interface in Figure 3.

To do this, the two ontologies—the patient record with the code "SCT:409137002 (No Known Drug Allergies)" and terminology categories with semantic concepts were entered into SMW. Therefore, there is closure on the concept class in SNOMED and the instances of the class in the FHIR patient record. There is no programming required to make the match.

The allergy has two categories:

1. **Semantic Type:** SCT:409137002 (no known drug allergies)
2. **Structural Type:** FHIR:AllergyIntolerance

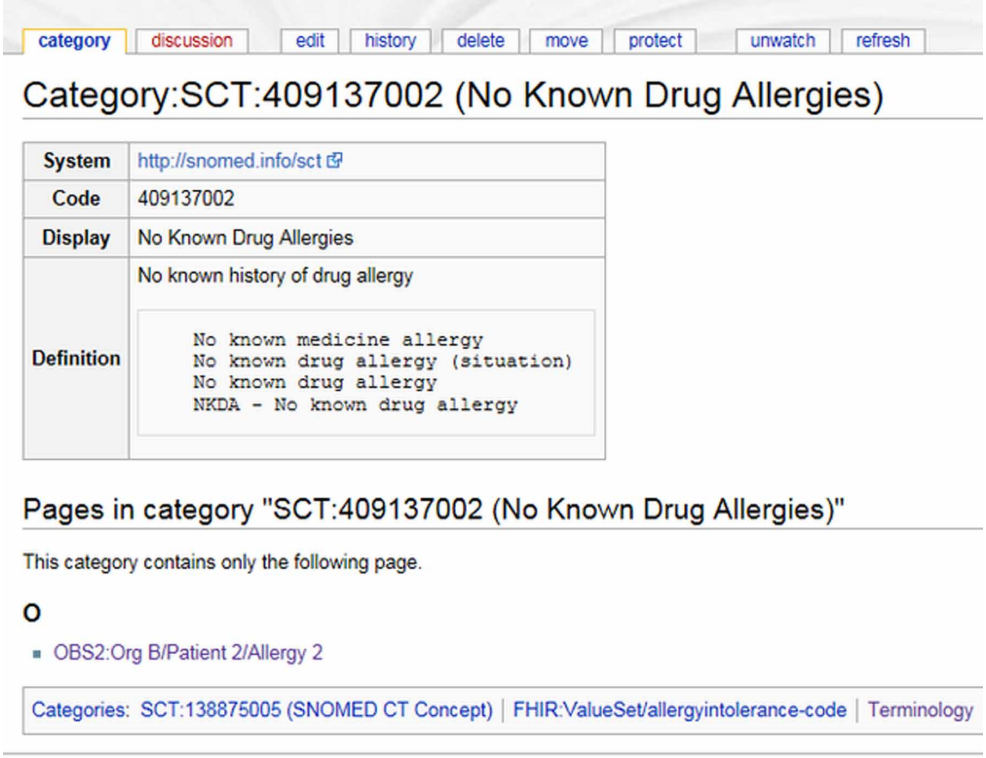
The display property is derived from the rdfs:label of SCT:409137002 (see Code Fragment 3) and can be accessed from the "Display title of" property of the concept category which is already linked. Note that SMW allows properties in Category pages. This additional information to the term allows transformation from the HL7 Codeable Concept which is expected with an implementation of the EHR with APIs supporting HL7 FHIR exchanges with other systems.

The category display provided by the platform shows its identity, label, and the super-category SCT:138875005 (SNOMED CT Concept). This is the root of the SNOMED CT ontology (see Figure 4).

For ease of implementation, the name of the concept includes its semantic in parentheses. This makes it very useful in the structured data capture forms shown later.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. User interface view of a SNOMED CT concept



The terminology becomes an integral part of the health information navigation. It allows the simple reference to the "Display title of" value which is equivalent to the rdfs:label.

Definition is used as information mouse over for an element in Figure 5.

Here is the SMW Wikitext defining the mouse over information:

The definition is retrieved from the terminology definition in the specific category – in this case "FHIR:allergy-clinical-status/inactive" which has the definition property entered (Figure 6).

Allergy Intolerance SMW Instance

The instance of the allergy intolerance in SMW conforms to the template Template:FHIR:AllergyIntolerance where the fields reference the appropriate other instance in the case of patient and category for all the terminology links.

The semantic field is treated differently in that it applies to the whole Allergy Intolerance so that the instance is typed No Known Drug Allergy as seen at the bottom of Figure 3.

ValueSet Implementation

A ValueSet specifies a set of codes drawn from one or more code systems to specify which codes can be used in a context.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

```

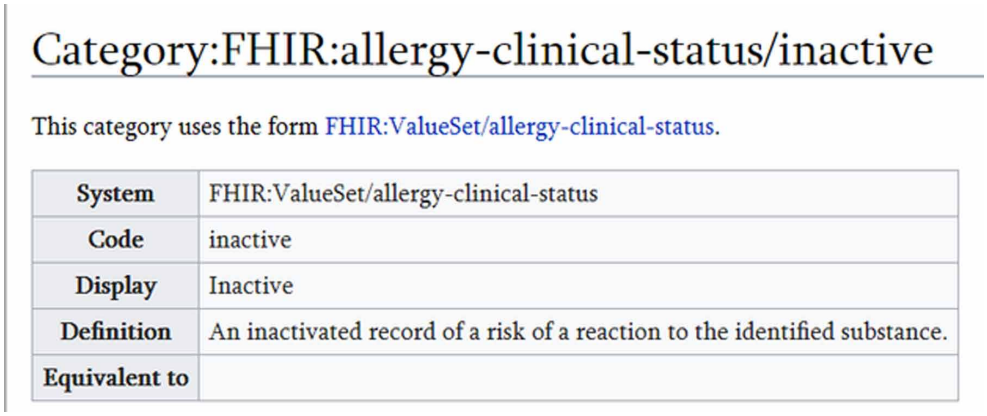
Figure 6. Clinical Status Category-inactive



Category:FHIR:allergy-clinical-status/inactive

This category uses the form FHIR:ValueSet/allergy-clinical-status.

System	FHIR:ValueSet/allergy-clinical-status
Code	inactive
Display	Inactive
Definition	An inactivated record of a risk of a reaction to the identified substance.
Equivalent to	

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Code Fragment 13. (FHIR Fields in SMW template)

```
{{FHIR:AllergyIntolerance
|patient=OBS2:Org B/Patient 2
|semantic=SCT:409137002 (No Known Drug Allergies)
|clinicalStatus=FHIR:allergy-clinical-status/inactive
|verificationStatus=FHIR:allergy-verification-status/unconfirmed
|type=FHIR:v3/NullFlavor/NA (not applicable)
|category=FHIR:v3/NullFlavor/NA (not applicable)
|criticality=FHIR:v3/NullFlavor/NA (not applicable)
}}
```

In this simplest approach, the member classes of the terminology are subClassOf a class representing the ValueSet. This example shows it as FHIR:ValueSet/allergyintolerance-code to align it with the HL7 FHIR ValueSet (see Figure 7).

The example's SNOMED concept and any SNOMED subcategories would be allowable for the AllergyIntolerance code. In theory, the assignment of FHIR:ValueSet/allergyintolerance-code would mean that the type has not been declared. Therefore, it is abstract.

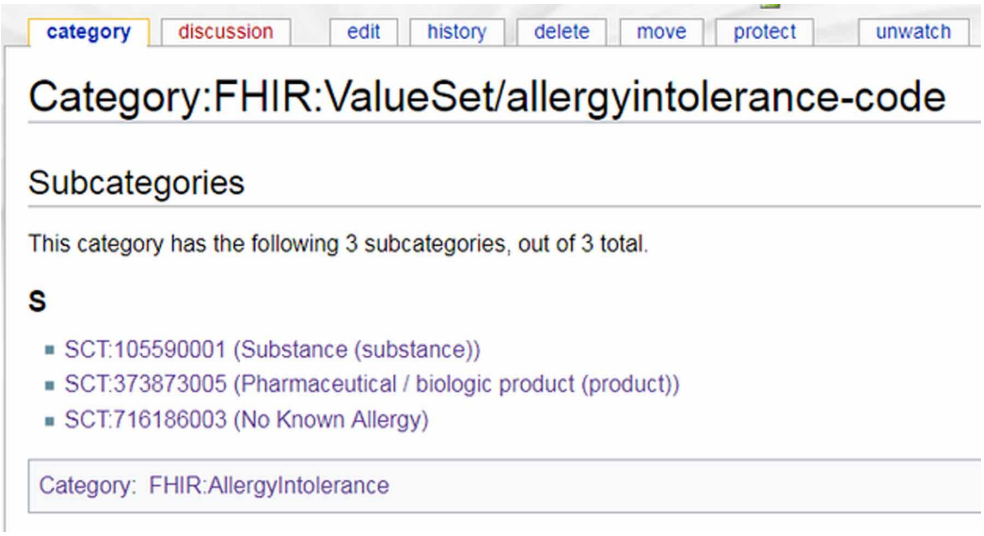
FHIR:ValueSet/allergyintolerance-code is bound to the FHIR:AllergyIntolerance category as a subcategory in SMW. Thus, the declaration of an individual as rdf:Type FHIR:AllergyIntolerance means that the semantic types are constrained to the ValueSet subcategory hierarchy. This includes the SNOMED concepts.

In UML, this ValueSet is represented with a stereotype «valueset» as shown in Figure 8.

FHIR:ValueSet/allergyintolerance-code is shown as abstract (UML italics), which means that it cannot be applied to an individual. This is interpreted later in the SMW form as hideroot in the selection.

The platform user interface for assigning the concept from the ValueSet is supported by a form construct. This provides a "tree" input type to display a category tree box (excluding abstract types). Figure 9 is an example of the form user interface during editing of Allergy 2.

Figure 7. User interface of a ValueSet



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. UML representation of the ValueSet

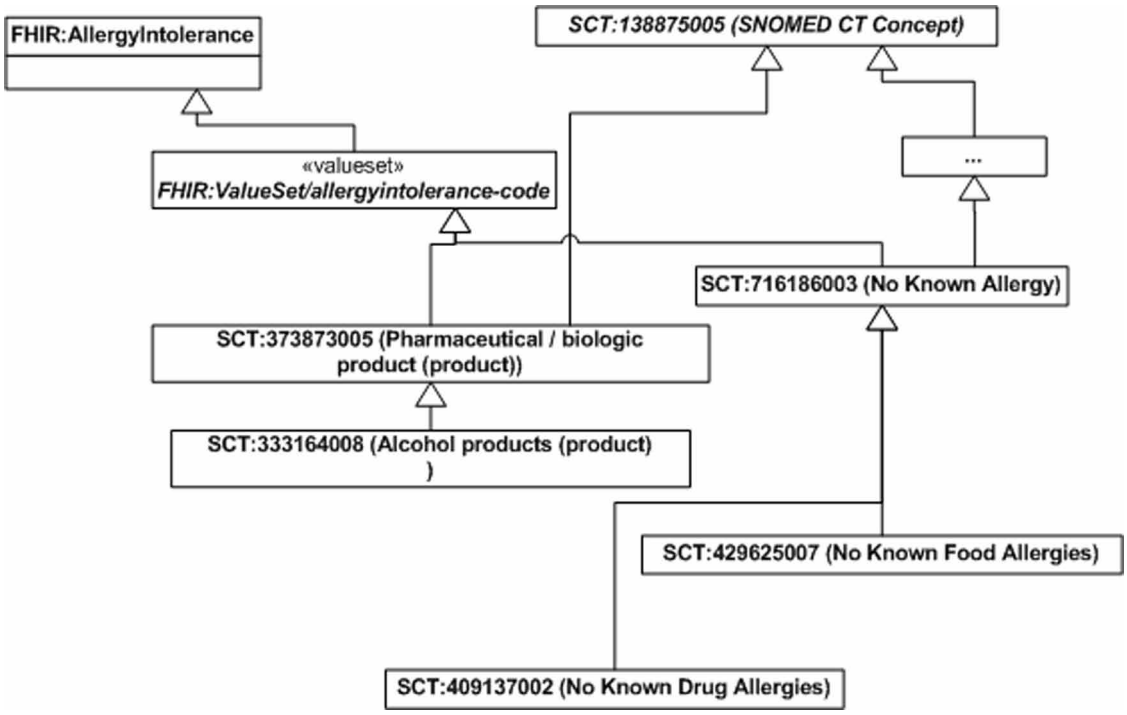


Figure 9. SMW ValueSet tree for selection in Data Capture

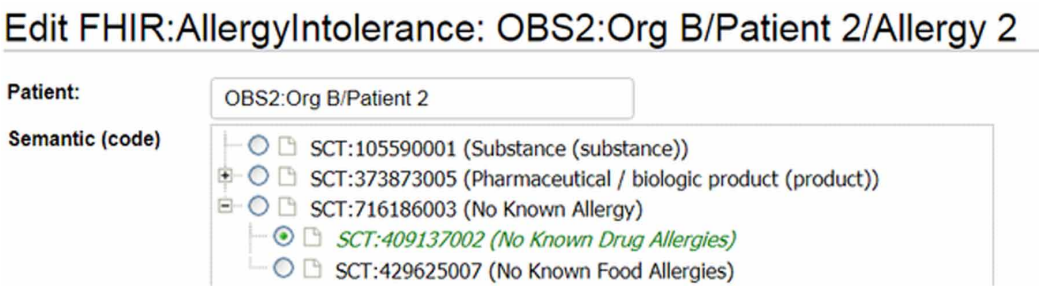


The Wikitext to support the semantics field entry in SMW looks like:

The top category is declared as the ValueSet. The abstract value set is hidden with hideroot. In a similar way, other fields have dropdown lists to reflect the allowable values and links.

Linked Data

If property targets in the graphs support URL dereferencing outside the wiki, then we can support a network of SMW stores where the location of the data is flexible. Although designed but not tested in the proof of concept, SMW supports an interwiki access mechanism to distribute pages.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Code Fragment 14. (SMW Form Fragment defining a Field with its ValueSet restriction)

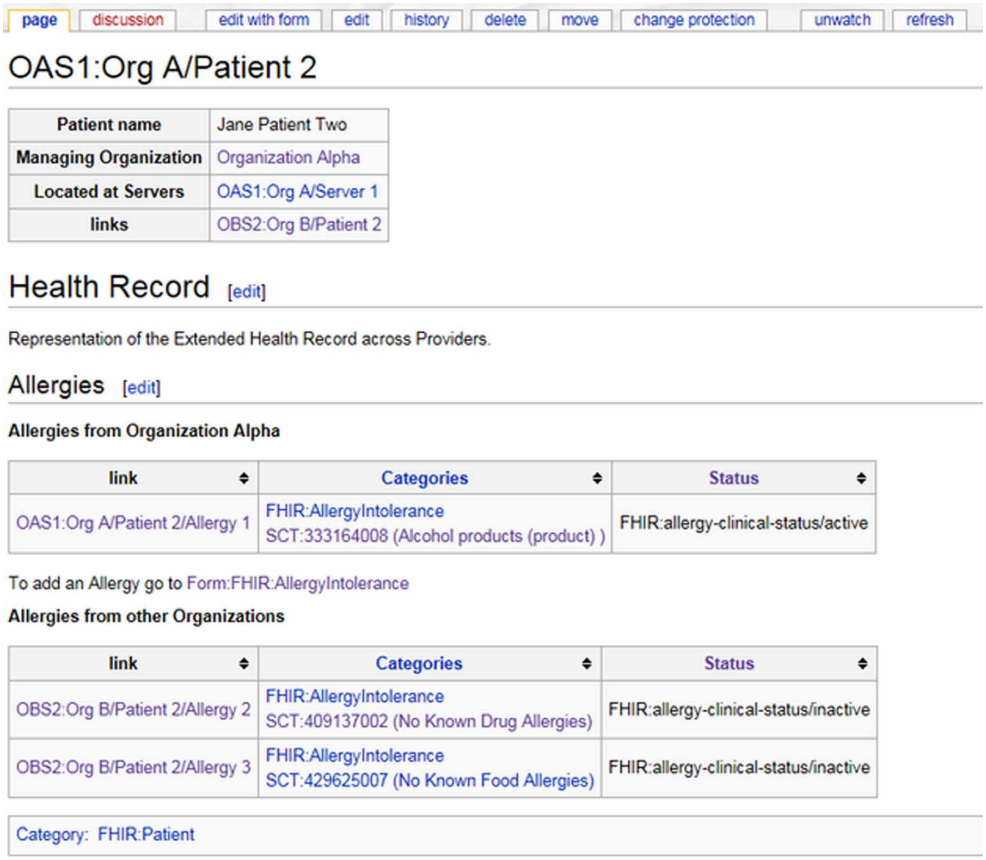
```
{{{field|semantic|input type=tree|top category=FHIR:ValueSet/allergyintolerance-code|rows=20|hideroot|}}}
```

The proof of concept explored the distributed nature of the health exchange (although it is deployed on only one wiki). Prefixes representing servers (e.g. OAS1, OAS2) can be expanded by the platform to the full dereferencable URL needed for access to that page on that external wiki (see Figure 10).

The example had "Jane Patient Two" linked across alpha and beta organizations. This view is of the patient resource at Org A on Server 1. The patient is linked to OBS2:Org B/Patient2 on Server 2. The extended health record can be displayed through in-line SPARQL-like queries supported by SMW. They walk the semantic graph from OAS1:Org A/Patient 2 to find resources assigned to the primary patient or linked patients at any known server.

The split of the display between the local context—organization alpha and other organizations—is a design decision in the prototype. The structure and formatting decisions of display are supported SMW with extensions to Wikitext specifically the #ask inline query parser function. The #ask parser function can navigate property chains including inverse properties by accessing the triplestore.

Figure 10. SMW user interface for patient with health record summary



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Code Fragment 15. (In line query using #ask parser function)

```
'''Allergies from other Organizations'''

{{#ask:[[Category:FHIR:AllergyIntolerance]]
[[FHIR:AllergyIntolerance_patient.-FHIR:Patient_link::{{PAGENAME}}]]
|mainlabel=link
|format=table
|?Category=Categories
|?FHIR:AllergyIntolerance clinicalStatus.Display title of=Status
|headers=plain
}}
```

The query for "Allergies from Other Organizations" uses chained properties to acquire the Allergy Intolerances for the linked patient (inverse property) as well as the Display title of for clinical status.

The query result is rendered automatically by queries executing when the user navigates to a patient page. The example above is an embedded query in the Patient template page which is passed to all pages (i.e. Patients) using this template.

The compactness and power of the SMW extensions to Wikitext are reasons for the high development productivity in SMW.

Power of semantic navigation was enabled by having health record structure (e.g., HL7 FHIR) and terminology (e.g., SNOMED CT) expressed in SMW Semantic Web mechanisms of Categories, Individual Pages, and Properties and controlled by Templates and Forms.

CONCLUSION

The paradigm shift is threefold in this prototype:

1. Implementation of health record ontologies in Semantic MediaWiki with terminology references using a single identifier
2. Use of category for terminology terms defined as ontologies replacing the need for coded elements for semantics
3. Programming changes to declarative semantic annotation of Wikitext instead of traditional programming language.

Two conclusions are reached in this proof of concept:

1. The binding from a health record element to a term in a terminology is facilitated using closure mechanism in a semantic web platform.
2. Semantic MediaWiki is a feasible platform for implementing an EHR with binding to terminology which is loaded onto the platform. Semantic annotation is powerful enough to implement an EHR without recourse to traditional programming languages.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Binding Conclusion

Direct mapping to type in a Semantic Web platform allows the bindings to occur with an instance to semantic category (class) link in addition to instance to structural class. Expression of the terminology as an ontology of classes and subclasses is supported by behavior and integration of terminology into the complete picture of the executing health record.

The proof of concept was to implement this binding in an open data platform, specifically Semantic MediaWiki. The proof of concept has been demonstrated to work and screen shots are included in this paper from the working prototype.

Platform Conclusion

In implementing a proof of concept in Semantic MediaWiki (SMW), the ease and velocity of implementation were impressive. The entire initial prototype took less than 10 hours to implement. Additional user interface refinement and additional elements to the fragments extended this time.

While SMW is not thought of for implementing mission critical applications, it will eventually be adopted for this purpose. It is an example of potential sixth generation computing, which combines high-level language and Semantic Web into a platform for application development and execution.

In this paradigm, a model-driven design, system distribution, and interoperability are built into the platform rather than the application. The SMW platform used in the example is not specific to healthcare.

This approach is not in conflict with HL7 FHIR because it requires a unified platform whereas FHIR can bridge between platforms. It would be expected that a SMW implementation would provide FHIR APIs to connect with external systems which do not use SMW.

KEY TERMS AND DEFINITIONS

4GL: A fourth generation (programming) language (4GL) is a grouping of programming languages that attempt to get closer than 3GLs to human language, form of thinking and conceptualization. 4GLs are designed to reduce the overall time, effort and cost of software development. The main domains and families of 4GLs are: database queries, report generators, data manipulation, analysis and reporting, screen painters and generators, GUI creators, mathematical optimization, web development and general-purpose languages.

Clinical Terminology: Clinical terminology is a structured vocabulary used in clinical practice to accurately describe the care and treatment of patients. It covers complex concepts such as diseases, operations, treatments and medicines.

FHIR: Fast Healthcare Interoperability Resources (FHIR, pronounced fire) is a standard describing data formats and elements (known as resources) and an Application Programming Interface (API) for exchanging Electronic Health Records.

Semantic MediaWiki: Semantic MediaWiki (SMW) is a free, open-source extension to MediaWiki – the wiki software that powers Wikipedia – that lets you store and query data within the wiki's pages. Semantic MediaWiki is also a full-fledged framework, in conjunction with many spinoff extensions, that can turn a wiki into a powerful and flexible knowledge management system. All data created within SMW can easily be published via the Semantic Web, allowing other systems to use this data seamlessly.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Semantic Web: According to the W3C (World Wide Web Consortium), "The Semantic Web provides a common framework that allows data to be shared and reused across application, enterprise, and community boundaries". The term was coined by Tim Berners-Lee for a web of data that can be processed by machines.

ValueSet: A ValueSet is a list of codes and corresponding terms, from NLM-hosted standard clinical vocabularies (such as SNOMED CT, RxNorm, LOINC and others), that define clinical concepts to support effective and interoperable health information exchange.

Wiki: A wiki is a website on which users collaboratively modify content and structure directly from the web browser. In a typical wiki, text is written using a simplified markup language and often edited with the help of a rich-text editor.

Wikitext: Wikitext, also known as Wiki markup or Wikicode, consists of the syntax and keywords used by the MediaWiki software to format a page.

This research was previously published in the International Journal of Privacy and Health Information Management (IJPHIM), 6(2); edited by Francesco Longo and Letizia Nicoletti; pages 50-71; copyright year 2018 by IGI Publishing (an imprint of IGI Global).
