As a result of intrinsic resource limitation, DB and KB in mid- and down-streams are rather restricted to handle the numerous CVD and over-complicated medical diagnosis. Therefore, UUS system is specialized as backyard on-line assistance to support the functionality of versatile distributed CVD diagnosis and enable remote communication between thousands of home users, healthcare center, and hospital server.

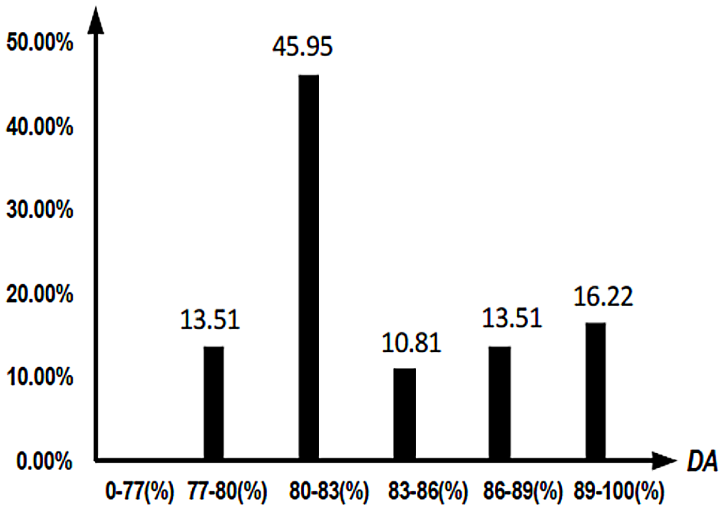
Figure 19. Distribution of DA for the testing samples



As depicted in Figure 20, the architecture of UUS contains five parts, namely help request delivery, help request pretreatment, customized help request management, disease driven rule base update and synchronization. There among, help request delivery and rule base updated are performed in local devices in mid- and down-streams while other processes are conducted in server of upstream.

Whenever the users need uplink help, they can send a customized help request to server. During local self-diagnosis, the diagnostic results, detailed explanations and suggestions are displayed on GUI. Meanwhile, a help enquiry button is displayed to see whether the user wants to confirm the results. Once the user chooses to ask for help, the type of help will be obtained from the local results which could be normal or critical. After that, the acquired biomedical signal, local diagnostic results, personal information, as well as the encoded help type could be combined to form the help information. After compressing the help information, a customized message file is obtained and transmitted to the selected server.

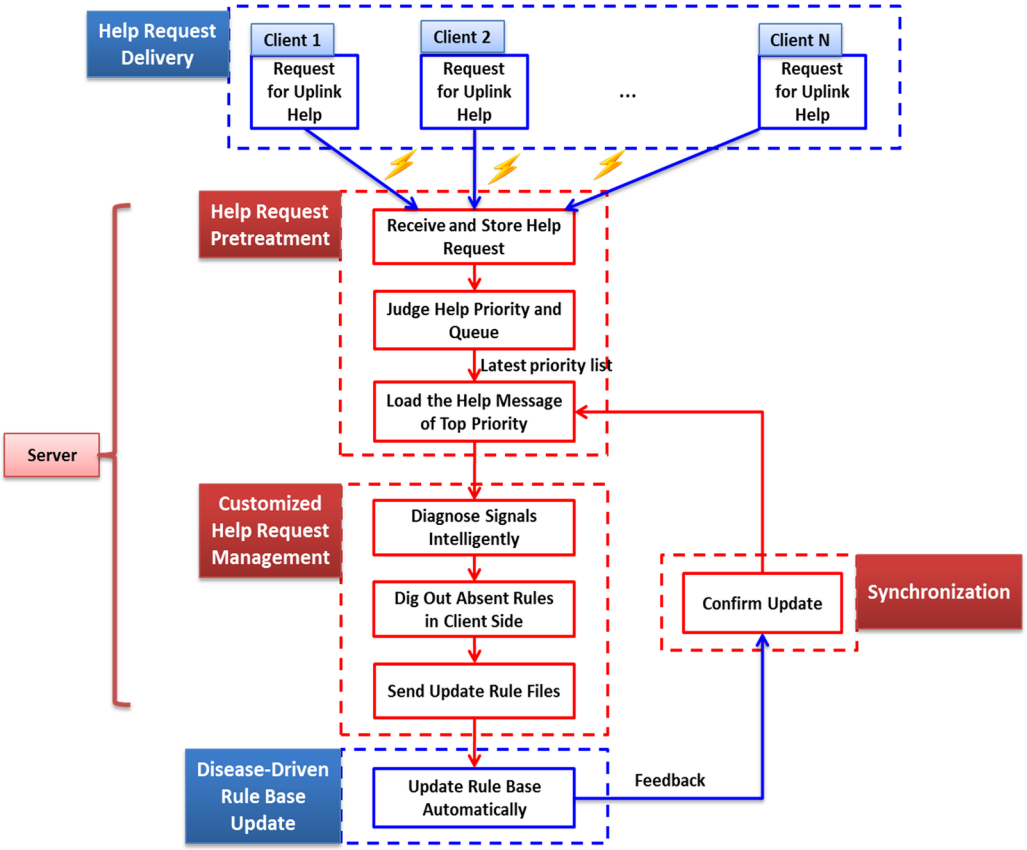
On receiving the help message, the server would first store and decompress it to get the original information from which the help type and user ID are obtained. According to the level of help type, the priority list is updated where critical help is ranked higher than normal ones. If the priority of new incoming help request is higher than all the existing help requests, an interruption scheme can be activated otherwise the new request would be inserted to the waiting list. The help message with top priority is always loaded for further processing.

After pretreatment, a customized management scheme is performed. First, based on the acquired signals, top-level intelligent diagnosis in server is conducted to obtain high precise diagnostic results and the useful rules during diagnosis are recorded with four digit number. Afterwards, these diagnostic results are compared with local results. If the same results are obtained, which indicates that the local devices can handle such diseases, a confirmation feedback message is sent to local device. Otherwise, update procedures are triggered automatically. According to the client's rule numbers, server can dig out the absent rules in client's rule base. These absent rules as well as the top-level diagnostic results are then packaged and compressed to be transmitted to local devices.

In order to reduce the size of update package and conduct update process with least resource and band-width, a delta update scheme is proposed (Choi et al., 2014). Instead of sending back all the re-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 20. Functional architecture of uplink, update and synchronization scheme



lated useful rules, only the absent or outdated rules for certain disease are dug out and transmitted to local devices. Such a delta update scheme could minimize the necessary dataflow between up and lower streams in band-restricted network, and it also contributes to easy execution of local update without the need of re-installation.

Once the up-down communication link is established, the whole update process is carried on automatically and intelligently without manual intervention. Upon receiving the feedback rule update package, it is firstly decompressed to obtain the original update files, including top-level diagnostic results and absent rules. Then the local results are updated and displayed. At the same time, the update process of rule base in client devices is conducted automatically in the background by inserting absent rules into the original local rule base. Note that rule base update is the key part of UUS to customize the local KB for tailor-made diagnosis. During the update process, several unexpected situations may occur, such as sudden power off, system failure, system exit etc. Such update failure may damage the original KB file and even the overall system. Therefore, in virtue of reliable and efficient update, a master-slave KB update scheme is proposed in the design of UUS. The original local KB file is regarded as master KB, which takes the responsibility of diagnosis until the successful completion of update process. Instead of directly overwriting the master KB, a blank file is created as slave KB. By analyzing the received update package and original master KB file, up-to-date rules can be recorded in the slave KB. During the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

update process, if any interruption happens, the incomplete slave KB file is deleted without influencing the following diagnosis. After successful update, the slave KB is adopted as master KB. In addition, the original master KB is archived for backup, in case the user wants to roll back to the original version. Such dedicated update scheme guarantees the robustness and reliability of the entire system.

As the last procedure of communication, as soon as the confirmation feedback message from client is received, the corresponding synchronization procedure is triggered. Synchronization step is executed to confirm the success of update and guarantees the data consistency between server and local client devices.

FUTURE RESEARCH DIRECTIONS

In order to efficiently prevent from chronic diseases, alleviate the burden of medical personnel and decrease the cost of accessible healthcare service in the context of current medical service industry, a novel paradigm '*e*-health' plays a critical role. Ubiquitously, *e*-health is enjoying a booming development push from various scientific and technological fields, including ICT, mobile technology, WBSN, intelligent technology etc. With the aid of WBSN and embedded link devices, *e*-health provides platform for monitoring individual's health related parameters as well as processing and providing relevant information to the healthcare consumers and/or medical professionals on regular basis. On the other hand, by delivering healthcare for anyone, anytime and anywhere, *e*-health removes the location, time and other restrains and increases both the coverage and quality of healthcare services.

Undoubtedly *e*-health is accelerating towards the remarkable shift from conventional hospital-centered provision paradigm to customized individual-centered proactive approach. Now to facilitate such a change, as the future research directions, one could expect to have advanced developments in the field of *e*-health. To name a few, this could include the advances in *e*-health tools, such as personalized electronic health records, lifetime health records, medical information management system etc.; introduction of *e*-health awareness/education, such as public health education, personalized healthcare professional continuing education etc.; advances in web technology in *e*-health for remote health monitoring, including telehealth and tele-care, virtual healthcare teams and wards etc. In short, the goal of attaining the customized individual-centered proactive healthcare approach is already defined. Yet, to reach such a goal, one could expect to have research and development of various key technologies in the field of *e*-health.

CONCLUSION

This chapter introduces systematic framework architecture of a versatile wired and wireless distributed *e*-home healthcare system to enable comprehensive and timely healthcare services for patients suffering from CVD. The proposed design merges intelligent multi-vital sign acquisition, customized information management and hierarchical diagnosis in wired and wireless platform to form as a complete healthcare system that enables cardiac health self-monitoring and reserves the need of hospital services for only critical and emergency situations. Thus, the model principally addresses the key challenges of network dependence and medical personnel necessity in the existing *e*-health application and promotes patient-centric healthcare. As a concluding remark, such a system in place would not only cater the aging population in monitoring their health status but could also encourage people to adopt a preventive healthcare lifestyle and reduce the mortality rate due to cardiac failure. Moreover, though the proposed wired and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

wireless distributed *e*-home healthcare system is mainly designed for CVD monitoring and diagnosis, the methodology can be generalized and adapted for many other *e*-health services for aging population, including monitoring and diagnosis of diabetes, Parkinson's disease, dementia etc.

ACKNOWLEDGMENT

KEY TERMS AND DEFINITIONS

Cardiovascular Disease: Refers to any pathological condition caused by the dysfunction of the cardiovascular system.

***e*-Health:** The healthcare practice supported by multiple key technologies including information and communication technology, mobile technology, body sensor networks, intelligent technology, etc.

Electrocardiogram: The biological signal which is used to measure/monitor the cardiac electrical activity through measuring the electric action potentials that are conducted through the heart muscle.

Embedded Link System: It is a computer system with hardware and software part specifically designed for a dedicated function, often used for real-time computing.

Heart Sound: The sound generated from the cardiac system due to mechanical activity of the heart, including blood flow, vibrations of chamber walls and opening and closing of valves.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Inference Engine: It is a software system that interprets and evaluates the rules/facts in the knowledge base defined based on expert's knowledge or large data analysis to draw the final conclusion.

Sphygmogram: It is the arterial pulse wave contour used to measure/monitor the pressure gradients caused when the heart contracts and the blood travels along the arterial walls.

Wireless Body Sensor Networks: Advances of wireless communication and network technologies linked with the computing and biological sensing techniques used towards the development of wireless network of wearable or implantable computing devices.

Chapter 38
Hybrid Ensemble Learning Methods for Classification of Microarray Data:
RotBagg Ensemble Based Classification

Sujata Dash
North Orissa University, India

ABSTRACT

Efficient classification and feature extraction techniques pave an effective way for diagnosing cancers from microarray datasets. It has been observed that the conventional classification techniques have major limitations in discriminating the genes accurately. However, such kind of problems can be addressed by an ensemble technique to a great extent. In this paper, a hybrid RotBagg ensemble framework has been proposed to address the problem specified above. This technique is an integration of Rotation Forest and Bagging ensemble which in turn preserves the basic characteristics of ensemble architecture i.e., diversity and accuracy. Three different feature selection techniques are employed to select subsets of genes to improve the effectiveness and generalization of the RotBagg ensemble. The efficiency is validated through five microarray datasets and also compared with the results of base learners. The experimental results show that the correlation based FRFR with PCA-based RotBagg ensemble form a highly efficient classification model.

INTRODUCTION

Cancer is caused due to the changes or mutation in the expression profiles of certain genes which elevates the importance of feature selection techniques to find relevant genes for classification of the disease. The most significant genes selected from the process are useful in clinical diagnosis for identifying disease profiles (Yang et al., 2006). The discriminative genes are selected through feature selection techniques that aim to select an optimal subset of genes. But, high dimension and small sample size characteristics of microarray dataset creates lot of computational challenges for selecting optimal subsets of genes

such as the problem of "curse of dimensionality" and over-fitting of training dataset. Feature selection is often used as a preprocessing step in machine learning. Only non-redundant and relevant features are sufficient enough to provide effective and efficient learning. However, selecting an optimal subset is very difficult (Kohavi & John, 1997) as the possible number of subsets grows exponentially when the dimension of the dataset increases.

The feature selection techniques can be broadly classified into filter (Hall, 2000; Liu, Motoda & Yu, 2002; Yu & Liu, 2003) and wrapper model (Hsu et al., 2011; Dash, Patra & Tripathy, 2012). The filter model uses specific evaluation criterion which is independent of learning algorithm to select feature subset from the dataset. It depends on various evaluation measures which are employed on the general characteristics of the training data such as information, distance, consistency and dependency. The wrapper method measures the goodness of the selected subsets using the predictive accuracy of the learning algorithm. But these methods require intensive computation for high dimensional dataset. Apart from this another key factor in feature selection is search strategy. The trade-off between optimal solution and computational efficiency is attained by adopting an appropriate search strategy such as random, exhaustive and heuristic search (Dash & Liu, 2003).

There are feature selection methods available for supervised (Yu & Liu, 2003; Dash & Liu, 1997) and unsupervised (Dash, Choi, Scheuermann & Liu., 2002) learning methods and it has been applied in several applications like genomic microarray data analysis, image retrieval, text categorization, intrusion detection etc. But, the theoretical and empirical analysis has demonstrated that the presence of irrelevant and redundant features (Kohavi & John, 1997; Hall, 2000) in the dataset reduces the speed and accuracy of the learning algorithms, thus need to be removed from the dataset. Most of the feature selection techniques employed so far has considered individual feature evaluation and feature subset evaluation (Guyon & Elisseeff, 2003; Abraham, 2004). Individual feature evaluation method ranks the features with respect to their capability of differentiating instances of different classes and eliminates the irrelevant and redundant features likely to have the same rankings. The feature subset evaluation method finds a subset of minimum features satisfying measure of goodness removes irrelevant and redundant features. It is observed that the advance search strategies like heuristic search and greedy search used for subset evaluation even after reducing the search space from $O(2^N)$ to $O(N^2)$ prove to be inefficient for high-dimensional dataset. This shortcoming encourages exploring different techniques for feature selection which will address both feature relevance and redundancy for high-dimensional microarray dataset.

There are various uncertainties associated with fabrication of microarray data such as the gathering of data, hybridization and image processing. They introduce lot of noises which need to be addressed by a robust and reliable classification model (Piao, Piao, Park & Ryu, 2012). On the other hand, conventional machine learning algorithms encounter many challenges to develop an effective and reliable classification model. The generalization capability of such kind of classifier algorithm based on a few significant genes and small number of training samples cannot be dependable. Therefore, it is essential to devise generalized robust classification methods which could overcome the constraints of small sample size and uncertainties associated with the datasets. This study motivates to develop ensemble classifier which is not very sensitive to the above specified constraints.

Ensemble learning technique is an advanced mechanism to combine multiple number of learning techniques to achieve better prediction accuracy (Liu et al., 2010; Dietterich, 2000; Yang, Yang, Zhou & Zomaya, 2010). It has the advantage of ignoring the constraint of sample size and the potential threat of overfitting by averaging and incorporating over multiple learning models (Hansen & Salamon, 1990). That is how the dataset is being used in an effective way, which was highly difficult for many bioin-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

formatics applications to handle. The research findings of ensemble learning have shown a promising improvement in the classification accuracy while dealing with data under uncertainties (Dietterich, 2000; Hansen & Salamon, 1990). However, the ensemble classifier only can outperform its own individual base learners if and only if its base learners are accurate and diverse (Dietterich, 2000). The base learners are considered as accurate, if the classification error rate of new samples is better than the randomly guessing classes. Similarly, two base learners can be regarded as diverse if their decisions on the same sample are different and always they do not converge to a single decision.

The ensemble methods employ a base learning algorithm to the training sets permutated differently. The popular examples of these techniques include Bagging (Dietterich, 2000; DeBock, Coussement & Vanden Poel, 2010), AdaBoost (Zhang & Zhang, 2010), Rotation Forest (Liu & Huang, 2008), Random Subspace (Breiman, 1996) and Random Forest (Zhang & Zhang, 2008). In bagging, bootstrap method is used to construct each base classifier from the original training set T i.e., a random sample is derived with replacement from the original dataset. Then majority voting is used to find the classification accuracy of the ensemble classifier where the new test data is being assigned with a class having highest number of votes obtained from the base learners (DeBock, Coussement & Vanden Poel, 2010).

Another ensemble method which is very popular in terms of simplicity and adaptability is AdaBoost (Zhang & Zhang, 2010). It builds an ensemble of classifiers by using a specified learning algorithm as base learner for the datasets that are obtained from the original training set either using resampling or reweighting (Zhang & Zhang, 2010). However, AdaBoost attempts to produce new "strong" classifiers that are able to better predict the hard instances of the training set.

Rotation Forest (Liu & Huang, 2008) is a variant of bagging ensemble method. But this ensemble classifier is built with a set of decision trees as the base learners. The bootstrap method is used to extract samples from the original training set to construct a new training set for each base learner. Subsequently, the features of the new training dataset are split randomly into some subsets, which are then transformed individually using some transformation techniques. As we know, a small perturbation may build a complete different tree but transformation techniques only can guarantee the diversity of the ensemble system (Liu & Huang, 2008; Dash, 2015). Moreover, at the same time Rotation Forest (Liu & Huang, 2008) enhances the generalization capability of the base learners as well as the diversity in the ensemble classifiers when compared with other ensemble classifiers, such as Bagging (Breiman, 1996), AdaBoost (Freund & Schapire, 1997), and Random Forest (Breiman, 2001).

C. Zhang and J. Zhang (2008) have developed a novel ensemble classifier "RotBoost" by combining two different ensemble techniques i.e., Rotation Forest and AdaBoost. They have replaced the base classifier of Rotation Forest with AdaBoost and established that the RotBoost performs better than the individual ensembles integrated together in this model. The performance of the model is also validated with gene related datasets from UCI repository.

In this paper, a hybrid ensemble learning methodology is proposed by combining a correlation based feature relevancy and redundancy (CO-FRFR) (Dash & Dash, 2014) feature selection method and PCA-based RotBagg ensemble classification technique. The efficiency of the model has been verified through publicly available microarray datasets and also compared with the experimental results of ICA-based-RotBoost (Osareh & Shadgar, 2013) technique. In addition to this, the efficiency of CO-FRFR-PCA- RotBagg has also been compared with the ensemble techniques used as base learners in the proposed model. To fix the values of the parameters of the base learners and of the ensemble model, a comparison among two variants of the RotBagg model such as PCA-based RotBagg and RP (Random Projection)-based RotBagg has been made. The integrated PCA-based RotBagg ensemble with CO-FRFR

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

exhibited superior average performance in terms of achieving generalization accuracy in comparison to other ensemble classifiers. Therefore, this model needs to be recommended as the most effective and efficient classification technique for predicting microarray datasets. The rest of the paper encompasses section 2 explaining feature relevance and redundancy concept and section 3 proposing the framework of RotBagg ensemble technique and feature selection method. In section 4 an empirical study of the proposed method in terms of efficiency and effectiveness comparing with other approaches are discussed. Section 5 provides a conclusion with future directions.

RELEVANCE AND REDUNDANCY OF FEATURES

It is observed that, a considerable number of features are not informative because of their irrelevance or redundancy (Abeel et al., 2010) to the class concept in high-dimensional dataset. Redundant and irrelevant features reduce classification accuracy and run-time of the system (Hall, 2000; Dash, Choi, Scheuermann & Liu., 2002). Conventional approaches of feature selection have given more emphasis on relevant data but very little attention to feature redundancy (Kohavi & John, 1997; Liu et al., 2010). The features of the dataset can be broadly classified into three categories considering feature relevance characteristic namely strongly relevant, weakly relevant and irrelevant (Kohavi & John, 1997). These three concepts of feature relevance cannot handle redundancy all alone. The formal definition can be stated as: Let F be a full set of features and for a feature F_i, $S_i = F - \{F_i\}$

Definition 1 (Strong relevance) *A feature Fi is strongly relevant iff* $P(C\backslash Fi,Si) \neq P(C\backslash Si)$.

Definition 2 (Weak relevance) *A feature Fi is weakly relevant iff* $P(C|Fi,Si) = P(C|Si)$ and $\exists S_i' \subset S_i$, *such that* $P(C \mid F_i, S_i') \neq P(C \mid S_i')$

Definition 3 (Irrelevance) *A feature Fi is irrelevant iff for all* $S_i' \subseteq S_i$, $P(C \mid F_i, S_i') = P(C \mid S_i')$

An optimal subset contains strong relevant features and the removal of which always affects the conditional class distribution. In case of weak relevance, the feature may not always require for an optimal subset but at certain conditions it may be required. Irrelevance suggests that the feature is not required. An optimal subset should contain all strongly relevant features, none of the irrelevant features, and a subset of weakly relevant features. Unfortunately, the definitions do not explain which of the weakly relevant features need to be selected for the optimal subset and which are not. Therefore, at this stage feature redundancy need to be investigated among relevant features. It is observed that, two features are redundant to each other if they are correlated completely. But, when a feature is partially correlated with a set of features, it may not be so easy to determine the feature redundancy existing in the dataset.

Correlation Measures

In feature selection process, we deal with mainly two types of correlation measures namely, linear and non-linear which exist between genes or between target class and genes. In the proposed method, non-linear correlation measures which are based on the information –theoretical concept of *entropy,* a measure of the uncertainty of a random variable is applied. The entropy of a variable X is defined as:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$H(X) = -\sum iP(x_i)\log_2(P(X_i))$$

and the entropy of *X* after observing values of another variable *Y* is defined as

$$H(X / Y) = -\sum jP(y_j)\sum iP(x_i / y_j)\log_2(P(x_i / y_j))$$

where the prior probability is $P(x_i)$ for all X_i and the posterior probability for all X given the values of Y is $P(x_i/y_i)$. The additional information given by Y to X is called *information gain,*

$$IG(X / Y) = H(X) - H(X / Y)$$

In this article, symmetrical uncertainty has been used to make up for information gain's bias towards high valued features and confines the values in the range of [0, 1]. Value 1 informs that if we know the value of either of the features we can completely predict the value of the other and value 0 indicates both are independent of each other. It can be expressed as:

$$SU\left(X,Y\right) = 2\left[\frac{IG(X / Y)}{H(X) + H(Y)}\right]$$

ENSEMBLE FRAMEWORK AND FEATURE SLECTION METHOD

RotBagg Ensemble Framework

The proposed ensemble method, RotBagg, is a hybrid intelligent classifier developed by combining the concept of Rotation Forest and Bagging ensemble classifier techniques with the objective of achieving higher accuracy than either of the individual techniques. Rotation Forest is a robust multiple classifier system which employs base classifiers which are accurate and the diversity among them is low. The framework of this method requires a linear transformation technique to project the dataset of each classifier or base learner into a new feature space and then is described as follows. In the framework of Rotation Forest, a linear transformation method is required to project data into new feature space for each classifier, and then the base classifiers are trained in different spaces so as to increase the accuracies of base classifiers and reduce the diversity in the ensemble system. Principal component analysis (PCA), non-parametric discriminant analysis (NDA) and random projections (RP) are used as feature transformation techniques in Rotation Forest.

Rotation Forest is a multiple classifier system which extracts different set of features to train independently all the *L* decision trees (base learners) (Breiman, (2001)). Let X be the training set, ω be the labels of each training sample and F *i*s the feature set. Assuming that there are N *t*raining samples with n *f*eatures in a microarray dataset, then X *i*s an N×*n m*atrix. Let ω be the set of class labels $\{\omega 1, \omega_2$. . . ω m} ass$_i$gned to each training sample. The training of base classifiers Ci req*u*$_i$res a mapping to be established between the input sample spaces and the class labels. If the feature set F is s*p*lit randomly

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

into k subsets of approximate size, then there may be L base classifiers required for the Rotation Forest which can be denoted by D1, . . ., D*L. There*fore, L and *k* are *t*wo important parameters which need to be determined carefully.

Now the following steps need to be followed to process the training dataset of an individual classifier Di.

Step 1: Randomly split F into k disjoint subsets and assume that the size of each subset be M = *n/k.*

Step 2: Consider F*ij* be the j th subset of features for training classifier D*i,* and X*ij* be the dataset X for the features in F*ij.*

Step 3: Select randomly a nonempty subset of classes from *Xij* for each subset. Then apply bootstrap technique to extract 75% of data from the original dataset to form a new training dataset, which is denoted by *Xij*'.

Step 4: Apply a linear transformation technique on *Xij*' and generate coefficients in matrix *Qij*. Denote the coefficients by *aij*1, ⋯, *aij*mj. This indicates the size of Xij' i*s M* x 1.

Step 5: At the end, construct a sparse rotation matrix Ri u*si*ng the coefficients generated in matrix Qij *(C.*-X. Zhang and J.-S. Zhang, 2010).

$$R_i = \begin{pmatrix} a_{i1}^{(1)},\ldots,a_{i1}^{(M_1)} & \{0\} & \{0\} \\ \{0\} & a_{i2}^{(1)},\ldots..,a_{i2}^{(M_2)} & \{0\} \\ \{0\} & \{0\} & a_{ik}^{(1)},\ldots...,a_{ik}^{(M_k)} \end{pmatrix}$$

Now the columns of sparse rotation matrix are rearranged as per the original feature sequence and it is denoted by Rai. Then the transformed training dataset for the corresponding classifier Di would be represented by XRai. The above process shows all the classifiers will be trained in a parallel manner.

During the validation phase of the classification process, for a test sample x, the classifier Di will have the probability dij (XRai) for the hypothesis that x belongs to the class φj . The confidence of a class can be computed by using average combination method which is shown below:

$$\varphi_j(x) = \frac{1}{L}\sum_{i}^{L} = d_{ij}(xR_i^a), \text{j} = 1,\ldots,\text{m}$$

In the proposed RotBagg ensemble classifier, the base classifiers D1, . . ., DL of Rotation Forest are replaced by Bagging classifiers. Bagging (Bootstrap aggregating) was introduced by Breimen (Breiman L., 1996) and it randomly replaces the original training dataset by N items. The replaced training sets are known as bootstrap replicates wherein some instances may not appear but others may appear more than once. The ensemble classifier is constructed by aggregating the base classifiers where all of them have equal vote.

The integration of bagging with rotation forest enhances the computational ability in terms of accuracy and diversity of the integrated RotBagg ensemble classifier. RotBagg is more advantageous than bagging because it has the ability of parallel execution.

The pseudocode 1 explains how each sub-ensemble created by bagging learns without depending on other ensembles. The learning principle is explained through pseudocode 1. Some of the important

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

parameters of RotBagg ensemble classifier need to be decided beforehand i.e., the values of S and T which specify the number of iterations performed by rotation forest and bagging respectively. Similarly, the values of another two parameters such as k and M which specify the number of subsets and the size of each subset respectively need to be fixed. After fixing the above parameters, the RotBagg ensemble algorithm can be implemented. However, the fast decision tree learners (REP Tree) are being employed as the base learners of the proposed RotBagg ensemble algorithm.

Transformation Techniques

As it is known that decision trees are used as the base learners to construct rotation forest and RotBagg, they need to satisfy the two characteristics of ensemble system i.e., accuracy and diversity. A bootstrap mechanism is used to form a new training set from the original for each base classifier of the ensemble. Then the new training set is randomly split into disjoint subsets which are then transformed individually by a linear transformation technique. The transformed features of each tree, subsequently reconstruct the full feature set of the ensemble. Since a small rotation in the axis creates a different tree, the transformation technique can guarantee the quality of diversity of the ensemble system. As a matter of fact, all the outputs are fused by the average rule. Mostly, there have been three types of transformation techniques adopted by different researchers (Kuncheva & Rodriguez, 2007) such as non-parametric discriminant analysis (NDA), principal component analysis (PCA) and random projections (RP). It has been found that PCA -based rotation forest performs better than the other two. Indeed, the principal components use to preserve all the discriminatory information of the dataset after transformation and the rotation of axes primarily generate diversity among the base classifiers instead of weakening the individual classifiers. In addition to this, an efficient sparse random projection (RP) method has been mentioned (Kuncheva & Rodriguez, 2007) with effective performance. Therefore, in this paper PCA and RP method has also been considered for comparison in the microarray dataset classification experiment.

Pseudocode-1 of RotBagg Ensemble Classifier

Input

1. **L**: a training set, L= $\{(x_i, y_i)\}_{i=1}^{N}$ = [XY]

where X is an N × n matrix containing the input values and y is an N –dimensional column vector containing the class labels.

2. **K**: number of attributes subsets (or M: number of input attributes contained in each subset).
3. **C**: a base learner.
4. **S**: number of iteration for Rotation Forest.
5. **T**: No of iteration for Bagging.
6. **x**: a data point to be classified.

Training Phase
For s = 1, 2, ..., S

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Use the steps similar to those in Rotation Forest to compute the Rotation matrix, say, R_s^a and let $L^a = [XR_t^aY]$ be the training set for classifier C_5.
2. Initialize the weight distribution over L^a as $D_1(i) = 1/N(i=1,2,\ldots,N)$
3. For t = 1, ..., T
   a. According to distribution D_t perform N extractions randomly from L^a with replacement to compose a new set L_t^a
   b. Apply ω to L_t^a to train a classifier C_t^a and then compute the error of C_t^a as

$$\varepsilon_t = Pr_{i\sim D_t}(C_t^a(x_i) \neq y_i) = \sum_{i=1}^{N}(C_t^a(x_i) \neq y_i))D_t(i)$$

   c. If $\varepsilon_t > 0.5$ then set D_t (i) = 1/N (i = 1, 2, ..., N) and go to step(a); if $\varepsilon_t = 0$, then set $\varepsilon_t = 10^{-10}$ to continue the following iterations
   d. Choose $\alpha_t = 1/2\text{In}((1- \varepsilon_t)/ \varepsilon_t)$
   e. Update the distribution D_t over L^a as:

$$D_{t+1}(i) = \frac{D_t(i)}{Z_t} \times \begin{cases} e^{-\alpha_t}, if C_t^a(x_i)=y_i \\ e^{\alpha_t}, if \ C_t^a(x_i)=y_i \end{cases}$$

where Z_t is a normalization factor being chosen so that D_{t+1} is a probability distribution over L^a .

End for

4. Let C_s (x) = argma $x_{y\in 0}\sum_{t=1}^{T}\alpha_t I(C_t^{\alpha}(x) = y)$

End for
Output

5. The class label for x predicted by the final ensemble C^* as

$$C^*(x) = \text{argma } x_{y\in 0}\sum_{s=1}^{s} I(C_s(x) = y)$$

where I (.) is an indicator function.

Feature Selection

The sample size of microarray datasets available in public database is very small compared to the number of attributes involved and this ratio problem is referred to as curse of dimensionality. This problem becomes a challenge for many classification techniques. As a matter of fact, only a small subset of attributes of microarray dataset is responsible for causing cancer. This necessitates the development of a data reduction technique to remove irrelevant, redundant and noisy data to find an effective solution

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to increase the classification accuracy. On the other hand, if RotBagg ensemble is applied directly to the dataset without reduction then a rotation matrix with thousands of dimensions is required for each tree which increases the computational complexity to a large extent. There are two major categories of feature selection algorithms (Dash & Dash, 2014) such as filter and wrapper algorithm used to find the predictive genes. The filter model finds the significant attributes using only the general characteristics of the dataset without the learning algorithm involvement whereas the wrapper model uses incremental approach involving an evaluation function to validate the subsets of features generated. Although, this method finds subset of features which provides a superior learning performance, still they are computationally expensive than filter model (Dash, Patra & Tripathy, 2012). In this paper, a correlation based feature relevance and feature redundant (CO-FRFR) technique which is already applied in (Dash & Dash, 2014) and suggest that CO-FRFR identifies the redundancy among relevant features. The advantage of this model is it uses interdependence of features along with the dependence to the class and identifies predominant features by reducing the dimension to a greater extent. Thus, it improves the classification accuracy in return. It has been explained in pseudocode-2.

Pseudocode-2 of Correlation Based Feature Relevancy and Redundancy Algorithm (CO-FEFR)

Relevance Analysis

1. Rank the features according to the decreasing values of $SU_{i,c} > Rel\text{-}parameter$
2. Redundancy analysis
3. Initialize F_i with the value of first feature in the list
4. Compare and eliminate features for which F_i forms an approximate redundant cover
5. Set F_i as the predominant feature in the list
6. Repeat step 3 until the end of the list
7. Evaluate the predictive significance of the predominant feature list using RotBagg ensemble

EXPERIMENTAL STUDY

Microarray Dataset

The efficiency of the proposed method is measured through three publicly available multi-category and two binary microarray datasets. The datasets include MLL Leukemia, Lung cancer, ovarian cancer, CNS and SRBCT. Table 1 summarizes the characteristics of the microarray datasets. The out-liars of the datasets are removed through preprocessing which is an important step for handling gene expression data. This includes two steps: filling missing values and standardization. The missing values of the datasets are filled using the average value of the corresponding gene. Standardization is performed so that every gene expression has mean 0 and standard deviation 1.

Experimental Design and Analysis

In this work, we have used open source tool WEKA to implement the proposed RotBagg ensemble classifier and the feature selection / reduction techniques. The efficiency of the proposed feature reduction technique (CO-FRFR) has been compared with two representative feature reduction methods such as correlation-based feature selection (CFS) and ReliefF in this experiment. The dataset is cleaned removing all missing values and converting it to mean 0 and standard deviation 1.

ReliefF (Dash & Dash, 2014; Ambroise & McLachlan, 2002) has the ability to deal with multiclass problems and more robust towards noisy and incomplete data. It evaluates the worth of an attribute by repeatedly sampling an instance and considering the value of the given attribute for the nearest instance of the same and different class. The CFS method (Hall, 2000) depends on a set of heuristics to assess the adequacy of the subsets. The heuristics used in this method take in to consideration both the correlation among the features and the dependency of features to the class.

To select the most informative features and reduce the computational complexity of the problem, all the feature selection method such as CFS, ReliefF and CO-FRFR are used to derive the features for each method. The selected features are shown in Table 2 for each datasets and it is evident from the table that the selection of features is different for each dataset and largely depends on the feature selection algorithms. It is quite apparent from Table 2 that CO-FRFR selects least number of predictive features while achieving highest reduction in dimension of the datasets. Therefore, it conforms to the theoretical concept of CO-FRFR to recognize and ignore redundant features.

The classification accuracy of the selected features is evaluated using RotBagg ensemble using a fast decision tree (REP tree) as the base learner and compared with the performance of integrated ensembles RotBagg and also with the base learner performance which is shown in the Tables 3 to 14. This learner is applied to the reduced datasets obtained from the feature selection algorithms and the overall classification accuracy is recorded using stratified 10-fold cross validation method to achieve statistically reliable predictive measurements (Dash & Liu, 2003; Dash & Liu, 1997). It is observed from the table that, CO-FRFR outperforms the other two feature selection algorithms in terms of achieving least number of features. The classification accuracy, precision, F-score, MCC, ROC area of all the datasets are significantly better for the CO-FRFR based hybrid ensemble RotBagg when compared with other combination of feature selection methods. Two types of transformation techniques such as PCA and RP are used along with the hybrid ensemble classification. It is observed from the experiment that PCA based transformation outperforms RP transformation in hybrid RotBagg as well as in single Rotation Forest ensemble. To compare the classification performance of the classifiers, 10-fold cross validation has been used for all the experiments. In this method, each dataset is divided into 10 disjoint sets, each

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

having roughly same distribution. But, the single classifier such as a decision tree does not provide results like an accurate classifier when it is applied to microarray gene classification problem which suffers lot of limitations like uncertainties, noises and curse of dimensionality. The results obtained from Table 6 to Table 14 conforms the findings of (Osareh & Shadgar, 2013).

The challenges encountered by a single decision tree algorithm have been overcome by a robust and accurate ensemble algorithm "RotBagg". This ensemble classifier operates on the discriminative features obtained from the feature selection method CO-FRFR, ReliefF and CFS. Along with the RotBagg, another two ensemble classifiers namely rotation forest and bagging are also developed and trained using the reduced data in this experiment. All the ensembles have used a decision tree as a base learner (Yang, Yang, Zhou & Zomaya, 2010) because it is more sensitive to the changes made in the dataset. A first decision tree learner (REP tree) was used by all the methods as the base learners without pruning. Now each of the ensemble methods will train a large number of base classifiers nearly 100 in numbers to construct the ensemble classifiers. The total number of iterations for both rotation forest and bagging can be balanced by setting $S = T = 10$ which is similar to (Osareh & Shadgar, 2013). As per the concept, a moderate value needs to be set for the parameter M according to the size of the feature set F. Therefore, the performance of RotBagg will vary for different size of the features contained in each subset M. But, when compared the performance of the classification results varying M from 1 to 20, it is observed that the variation is insignificant. This shows there is no consistent relationship exists between M and the learning accuracy (Ambroise & McLachlan, 2002). In this experiment an optimum value is set for M i.e., $M = 3$ to established a consistent relationship between the diversity and classification accuracy of the base learners.

To find the most effective transformation technique to maintain the diversity and accuracy of the base classifiers, two well-known transformation techniques i.e., PCA and RP have been used in this experiment. After the transformation of the datasets, the principal components preserve the discriminatory information. Then the axes are rotated optimally which primarily develops the diversity among the classifiers rather than weakening the individual classifiers. As a result, a trade-off between diversity and accuracy can be maintained.

The small number of instances in the microarray dataset led to unreliable solutions. To counter this problem, 10-fold cross validation method (Peng, 2006) was suggested to split the datasets into 10 equal fold to validate the solution. However, in this work, a 10-fold cross validation is deployed to evaluate the performance of the feature selection algorithm.

Table 3 shows CO-FRFR based RotBagg classification accuracy, precision, F-score, MCC, ROC area and FP rate for all the five datasets when both the transformation matrix are applied. The classifier is trained 10 times such that in each iteration a different set is kept for testing. The AUROC (Area under the Receiver Operating Characteristic) value and MCC are computed as the average of each of these iterations. Many statistical techniques have been applied to compare the performance of classifier across multiple datasets. Again the performance of the classifiers can be ranked (Kuncheva & Whitaker, 2003) using average AUROC values with 1 being the best. Similarly, Friedman and Bonferroni-Dunn tests (Kuncheva & Whitaker, 2003) are performed to determine whether or not the newly introduced methods are statistically better than the existing methods. It is quite apparent from Table 3 that PCA-based RotBagg performs significantly better than RP-based RotBagg for all the datasets and achieves full rank for ovarian cancer and SRBCT. It can also be noted from Table 3 that PCA–based RotBagg ensembles outperform RP-based counterparts in terms of accuracy of classification. Also it is important to record that all these experiments have been performed on the features selected by CO-FRFR algorithm.

After choosing the transformation method, a comparative study on the performance of PCA/RP-based RotBagg using ReliefF and CFS feature selection methods to reduce the feature space is made. Table 4 and 5 demonstrates the classification accuracy of each classification method on the selected datasets. CO-FRFR based PCA-RotBagg ensemble performs significantly better than bagging and rotation forest invariably for all the datasets.

The most important issue of ensemble learning technique is the balance between diversity and accuracy of the classifiers involved in the ensemble as base learners. The base learners in an ensemble should have high accuracy and should avoid making misclassification errors. Thus, the accuracy of fused outputs will be more than that of the individual classifier (Ambroise & McLachlan, 2002). However, the diversity conflict with accuracy of base learners, i.e., the more accurate the base learners are, the lower the diversity is. So, it is difficult to define a single measure of diversity that measures the performance of ensemble. In this experiment, pair wise diversity measure has been utilized to measure the ability of the proposed PCA-based RotBagg which can build accurate and diverse base learners effectively.

Comparing the performance of Table 3, 4 and 5 with 6, 7 and 8, it is understood that the performance of hybrid ensemble is more significant when paired with CO-FRFR. But it is also apparent from the table that irrespective of the feature selection method chosen the performance of the hybrid RotBagg is most effective than the performance of the individual ensembles and the decision tree learner.

The classification performance of the RotBagg ensemble obtained for the reduced dataset derived from ReliefF and CFS is compared with the performance of individual ensemble and observed that RotBagg performs better than others can be observed from Table 9, 10, 11, 12, 13 and 14.

In order to measure the level of agreement between a pair of base learners, a k-metric or kappa statistic (Pomeroy et al, 2002) is used while correcting the chance. For c- class labels, k is defined on $c \; x \; c$ coincidence matrix M of the two classifiers. The entry $m \; \mathrm{k}_{,s}$ of M is the proportion of the data set, which Di labels as wk and Dj labels as ws. Now, the agreement between Di and Dj is given by

$$\mathrm{Ki,j} = \frac{\sum Km_{k,k} - \mathrm{AB}C}{1 - \mathrm{AB}C}$$

If_{th}e value of $k = 1$ then the classifiers decisions are the same otherwise $k = 0$, which represent the case when the classifiers are entirely independent, and the agreement of the two classifiers equals that expected by chance (Cohen, 1960). Table 3 shows the value of kappa statistic k for both P*C*A-based-RotBagg and RP-based- RotBagg ensemble classifiers. It is observed from the table that for ovarian cancer and SRBCT the value of k is 1 i.e., the classifiers decisions are same whereas the value of k for CNS is 0.65 in PCA-based RotBagg. In Table 3, 4 and 5, the value of kappa statistic is very close to 1 for RotBagg ensemble for all the three feature selection methods whereas it is significantly less for all the individual ensembles shown in remaining tables.

CONCLUSION

In this study, we proposed a novel concept of correlation based feature relevancy and redundancy (CO-FRFR) selection algorithm and a hybrid robust ensemble classifier, "RotBagg". This ensemble technique preserves the most essential characteristic of an ensemble framework, i.e., accuracy and diversity. In

order to overcome the limitation of curse of dimensionality, uncertainties and noises, a small subset of most informative features were selected using 3 representative feature selection techniques namely, CFS, CO-FRFR and ReliefF. Then the ensemble classifier RotBagg was employed on the selected datasets. The experiment was conducted using two types of transformation matrices, i.e., PCA and RP method to implement RotBagg ensemble.

The efficiency of the proposed ensemble was assessed with different ensemble algorithms including rotation forest and bagging. The experimental results showed that the combination of CO-FRFR feature selection and PCA-based RotBagg ensemble with decision tree as base learners construct a robust classifier for the microarray datasets. The proposed method has achieved the highest generalization ability in comparison to its counterparts. It has also established a trade-off between the diversity and accuracy of the base learners involved.

KEY TERMS AND DEFINITIONS

Base Learners: The component / individual learner of the ensemble which are combined together strategically is referred to as base learners. Base (weak) learner must focus on correctly classifying the most highly weighted examples while strongly avoiding over-fitting.

Correlation-Based: Fluctuation of one variable reliably predicts a similar fluctuation in another variable i.e., change in one causes the change in other.

Diversity: The relation that holds between two entities / objects when and only when they are not identical; the property of being numerically distinct.

Ensemble Learning: It is the process by which multiple models, such as classifiers or experts are strategically generated and combined using a particular rule to solve complex computational intelligence problem.

Feature Redundancy (FR): Duplicated features or information, that adds as a precaution against failure or error.

Hybrid Ensemble: Combining two different ensemble models to enhance the prediction/ generalization capability of the ensemble model.

Principal Component Analysis: It's a method of analysis which involves finding the linear combination of a set of variables that has maximum variance and removing its effect and repeating this successively.

Random Projection: In mathematics and statistics, random projection is a technique used to reduce the dimensionality of a set of points which lie in Euclidean space.

Chapter 39
Fall Detection Depth-Based Using Tilt Angle and Shape Deformation

Fairouz Merrouche
University of Science and Technology USTHB, Algeria

Nadia Baha
University of Science and Technology USTHB, Algeria

ABSTRACT

The population of elderly people is in growth. Falls risk their life, to disabilities, and to fears. Automatic fall detection systems provide them secure living; helping them to be independent at home. Computer vision offers efficient systems over many developed systems. In this article, the authors propose a new vision-based fall detection using depth camera. It combines human shape analysis, centroid detection and motion where it exploits the 3D information provided by a Kinect to compute the tilt angle to discriminate falls. Experimental tests were done with SDUFall dataset that contains 20 subjects performing five daily activities and falls, demonstrate the efficiency of the proposed system, and show that our method is promising achieving satisfactory results up to 84.66%.

INTRODUCTION

In recent years, the increase of life expectancy has led to the growth of aging population. Independent living and not needing help can lead to severe consequences. Falling are risky event that can occur in an elder person life and repeated falling are the major danger ("Health Organization Department," 2008), hospitalization and traumatic injury-related deaths (Stevens and Rudd, 2010) for person aged 65 or elder. Furthermore, fall can have physiological consequences such depress, avoidance of activities, a fear of falling that increase from suffering (Friedman et al., 2002).

There have been various researches, in order to overcome elderly fall risks and prevent these incidents. Some of these technologies are based on wearable sensors such as accelerometers, gyroscope (Cheng et al., 2013). Nevertheless, these sensors are ineffective when the user forgets to wear them or forgets to recharge or to replace the battery.

Vision-based technologies that use commodity cameras have proven to offer better solutions. Cameras have a low price, and not required to be worn by the user (Rougier et al., 2011).

Recently, Kinecth has received much attention of lot of researches due to its low-cost price and many other advantages against regular RGB camera like the privacy of person's life. In this paper, we will present a new vision-based method for fall detection in an indoor environment. The main contribution of this work lies on detecting falls differently in simple way by using the tilt angle based on head tracking and centroid movement.

In this paper, we outline a new vision-based approach using depth camera Kinect to detect falls and exploiting person shape based on tilt angle and motion.

The remainder of this paper is organized as follow section 2 presents the related work in the field of fall detection systems. Section 3 presents the stages followed to fall detection. In section 4, experimental results are presented and discussed. Finally, section 5 concludes the paper with some remarks.

RELATED WORK

In the last few years, various approaches have been put forward by many researches to improve fall detection solutions. Fall detection methods are subdivided into two classes: computer vision-based methods and non-computer vision method.

In this section, we will review some works proposed for fall detection starting by non-vision category. Many sensors have been exploited. In the work of (Cheng et al., 2013) the authors have attached two accelerometers to chest and thigh of 10 persons. Decision tree was applied to recognize posture transitions with threshold to detect falls. The main disadvantage of this method is to wear the sensor.

Another work was proposed in (Sannino et al. 2015) where a wearable accelerometer and a mobile device were used to monitor the patients in real time, the data recorded by the accelerometer is sent to the mobile device to analyze them. This approach has three phases. First, gather data and make a set of simulated falls with the corresponding class "fall" or "non-fall". Second, knowledge extraction as a set of IF-THEN rules and the last phase consists in patients monitoring in the decisional layer in real time but this approach still preliminary, the tests were done for just three people.

In the work of (Alwan et al., 2006), a special piezoelectric sensor coupled to the floor is used, a binary fall signal can be generated in case of fall, and however, the main drawbacks can be false alarms.

In (Yazar et al., 2014) fall was detected based on three sensors consisting of a vibration sensor and two PIR sensors. The vibrations were converted into electrical signals and then Feature vectors from the vibration waveforms are extracted using the complex wavelet transform (CWT) and they are classified using support vector machine (SVM). PIR sensors were used as additional sensors to detect the infrared radiation emitted by moving objects in the room and that to eliminate falls alarms generated when the vibration sensor signal energy is concentrated in low-frequency bands such as vibration from door slams and other similar events.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In recent work in (Jokanovic et al., 2016) a new method was proposed based on radar technologies to detect falls, the authors proposed to use time-frequency (TF) which is able to reveal higher order velocity for different part of human body and based on deep learning which learns and captures the properties of the TF signatures without human intervention then it is fed to a classifier achieving 87% success rate.

These solutions are promising but cannot be effective due to noise they generate and cannot satisfy the elder user due to the inconvenience they provide why the computer vision-based solution has been adopted by many researches. There are some methods that used shape analysis to detect fall. Generally, the first step is to detect the person in each video frame using separation of people from the background. In 2D sensors, the bounding box aspect ratio was used to distinguish if the person is in an upright position or not (Liu et al., 2010).

In (Foroughi et al., 2008), an ellipse approximated the shape of the person. Despite their performance, these approaches are not feasible for fall into the direction of the camera, therefore a multi camera system was proposed to overcome this problem which benefits from the 3D features to detect fall.

(Worrakulpanit and samanpiboon, 2014) also proposed a fall detection method based the orientation standard deviation of the Ellipse, so the silhouette s approximated by an ellipse and then the motion is quantified by calculating pixel value of Motion History Image. Fall is discriminated from other activities by using standard deviation of C-Motion. According to the author this method is robust.

In (Anderson et al., 2008) multi-camera system is used where fall detection has been presented in two levels. The first level infers the states of the object in each frame. The second level consists in linguistic summarization of 3D person's states called voxels.

(Rougier et al., 2011) proposed another approach where they used four cameras were mounted in one room for classification using GMM to detect fall by analyzing the deformation in human shape. (A. Mousse et al. 2016) propose a multi-camera system based on two relatively orthogonal views to measure the percentage of the orthogonal views of the person which is in contact with ground according to the information provided by each camera and this to differentiate between lying down activity and other activities the results were promising 95.8% sensitivity and 100% specificity.

Recently, the 3D camera has attracted a lot of attention and the use of Kinect is widely emerged because of its low cost. In (Stone and Skubic, 2015) the centroid height of the person relative to the ground and centroid velocity were used to detect occluded fall. The person was tracked over time to obtain persons vertical state to segment on ground events and then an ensemble of decision trees to compute a confidence that a fall occurs before an on-ground state.

In (Bian et al., 2015) the key joint of human body is extracted using an RDT algorithm trained with Shannon entropy and then track these joints. SVM classier is employed to detect fall based on head joint distance trajectory. A new shape-based method to detect fall is used in (Ma et al, 2014) where CSS features of the silhouette in each frame and the actions are represented by a bag of CSS words and then fall is detected with classification using VPSO-ELM that uses particle swarm optimization.

In (Kwolek and Kepski, 2015) a new fall detection method is presented combining an accelerometer with Kinect. The accelerometer was used to filter out a non-fall events and Kinect sensor to authenticate the fall, which leads to good performance and another work of (Pramerdorfer et al. 2016) where they emphasize person detection and tracking using features that invariant with respect to sensor position, and detect falls in three steps state prediction, event detection and fall verification. They tested their method on experimental condition and they had good results and robust to partial occlusions.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Wang et al., 2016) proposed an automatic fall detection method where they combine Histograms of Oriented Gradients (HOG), Local Binary Pattern (LBP) features extracted by deep learning Framework Caffee to form a new feature HLC. They achieve an average result of 93.7% sensitivity and 92.0% specificity on three datasets.

In the work of (Baha et al., 2016) another work was proposed using two Kinect sensors. The first one is frontal and the other is on ceiling. The first one is based on the person's depth information and his velocity by computing the surface of the bounding box and then measure surface difference and velocity to detect fall and validate it. The second one is based on the variation of bounding box parameters and its velocity (frontal Kinect) and fall is detected based on the value of width to height of the bounding box and also to velocity. A combination of the two methods was performed to improve accuracy achieving up 95%.

In (Fan et al., 2017) a normalized directional histogram is developed around the center of the ellipse to represent a human posture by multidirectional statistical analysis and then 12 static and 8 dynamic features where extracted these features were fed into a directed acyclic graph support vector machine to distinguish four human postures A fall-like accident is detected by counting the occurrences of lying postures in a short temporal window and a fall event is detected by immobility verification.

In (Li et al., 2018) a combination of Kinect and mobile phone is exploited. Two methods are proposed which are based on threshold for mobile phone and support vector machine for Kinect. Fall is detected using the fusion of the data provided from the two subsystems based on two methods the logical rules-based and D-S evidence fusion this approach achieves 100% of accuracy.

In (Cameron et al. 2018) the authors propose fall detection based on machine learning method. They used gradient-based local visual feature extraction including histogram of oriented gradients (HOG), histogram of motion gradients (HMG), histogram of optical flow (HOF), and motion boundary histograms (MBH). They provide a comparative study with different scenario and they demonstrated the effectiveness of this approach.

In this work, we propose a novel human shape-based fall detection that makes use of Kinect and benefits from its advantage against RGB camera and we use shape information based on the angle of the line linking the head and the center of mass of the person.

PROPOSED FALL DETECTION METHOD

The proposed system uses Kinect sensor which is a special camera developed by Microsoft for Xbox360 console, first introduced in 2010. This sensor is composed of an RGB camera and an infrared (IR) depth sensor, which are characterized by a resolution of 640x480 at 30 fps.

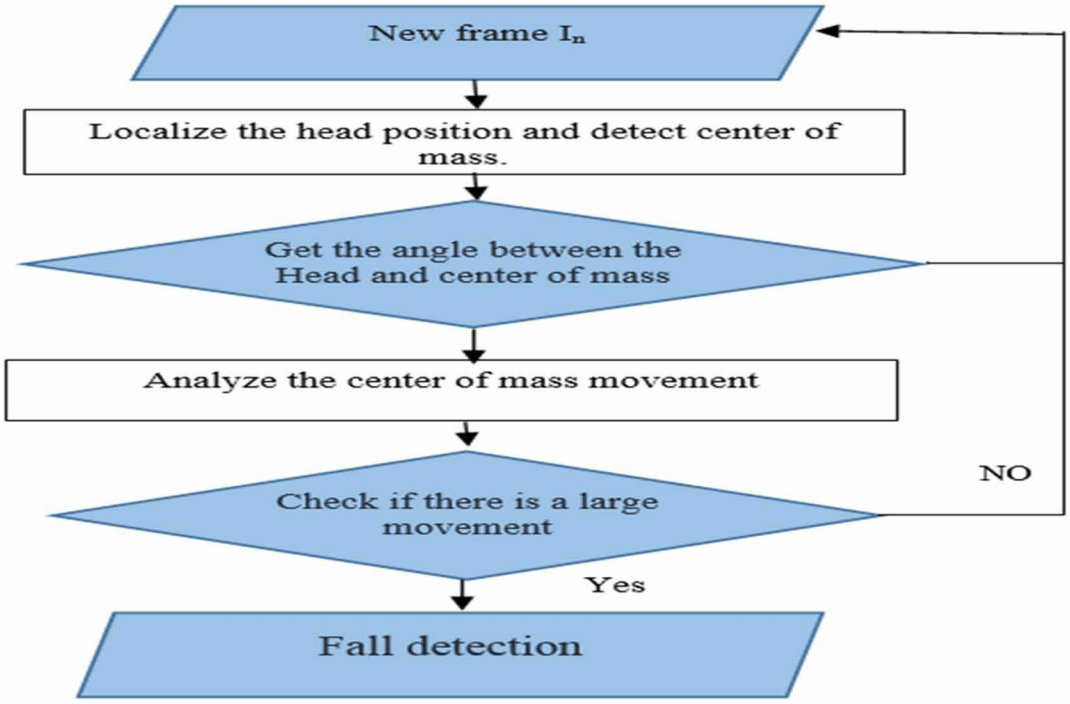
The Kinect is able to provide a depth map where each pixels gray scale represents the distance in millimeters between the Kinect and the objects. The infrared sensor is able to work even in a dark room, which represents an advantage for any surveillance system. In this work, we will exploit the advantage of this sensor and use only the depth map to respect the privacy of the elder people. Figure 1 shows an image of Microsoft Kinect.

In the following sections, we will describe in more details how we use human shape analysis and movement for fall detection. In the first time, we start with preprocessing stage. Second, we localize the position of the head at each frame using a tracking method, then, we measure the position of the centroid, after that we compute the tilt angle. Finally, fall is detected and validated. Figure 2 shows an overview of fall detection method.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Microsoft Kinect

Figure 2. Overview of fall detection method



Usually, most computer vision systems need preprocessing steps to have accurate fall detection. In the following subsections, we will detail these steps.

Background Subtraction

Getting the human body silhouette is an important step in our system. A Gaussian mixture model GMM background subtraction method is used to extract the foreground where each pixel is characterized by a mixture of k Gaussian. Every pixel is evaluated for its probability whether it is belonging to Background or to Foreground, then morphological operators: erosion and dilatation are applied to discover any left pixels belonging to the foreground or to the background. Figure 3 shows an example of an image before and after background subtraction step.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Background subtraction example

Head Tracking

Once the silhouette obtained, a tracking method is used in order to localize the head at each frame. In this work, the head is approximated by an ellipse and tracked using particle filter. Particle Filter is widely used for tracking because of its performance and its complexity. It employs a Sequential Importance Sampling algorithm or Monte Carlo method to compute the posterior density of a variable given an observation (Gordon et al. 1993), the posterior density function PDF over the state can be approximated by a set of particles. Each particle x_i^t represents a state with associated weights w_i^t which is the observation likelihood:

$$w = p(z^t \mid w^t) \tag{1}$$

where z^t is an observation measurement.

In our case, the observation combines the score between the ellipses and head point. The tracking algorithm has three steps, first, the initialization step; second the update and then the resampling step. Algorithm 1 in Figure 4 illustrates the use of particle filter for head tracking and an example of use of tracker is illustrated in Figure 5.

Tilt Angle

Some works in the literature used the tilt angle to detect falls (Foroughi et al. 2008). But they use generally the 2D information where the angle is computed in the x-y plan. Contrary, in the proposed method, we will present another view of the angle where the 3D information provided by the kinect sensor will be exploited to compute the angle. We agree that the y direction gives us the information about the vertical deformation of the human shape and the z direction (axis) gives us the other very important information deformation along depth. Therefore the tilt angle is computed as the angle between the projection of the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

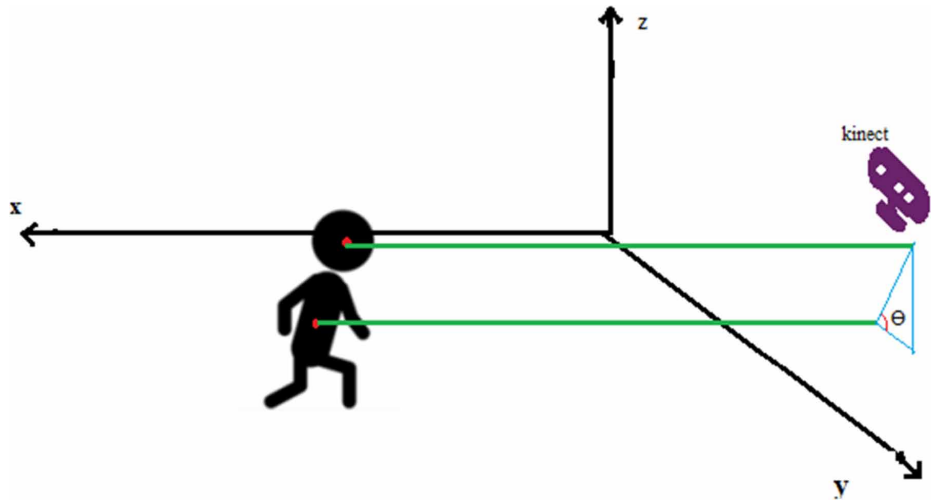
Figure 6. The angle θ between the head and centroid



head point and centroid point P_h (x_h, y_h, z_h) and P_c (x_c, y_c, z_c) respectively on the y-z plan as illustrates in Figure 6.

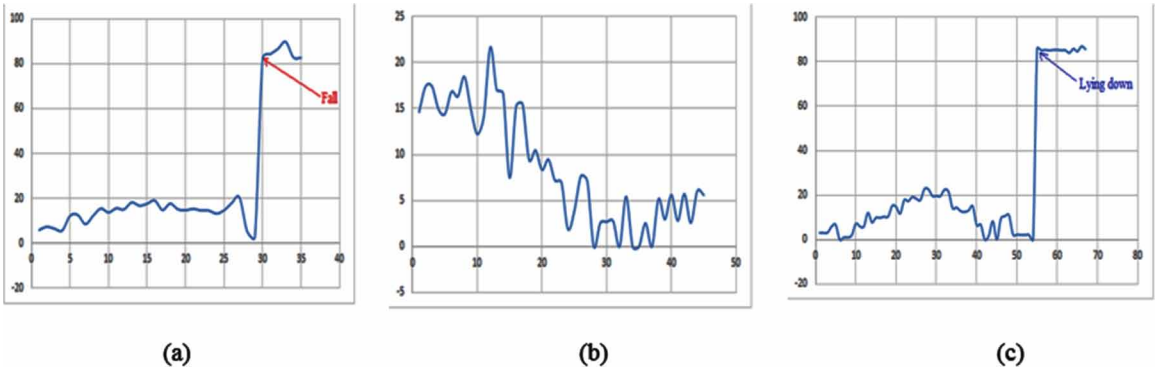
The tilt angle θ is computed using the following formula:

$$\theta = arctan \frac{z_h - z_c}{y_h - y_c} \tag{2}$$

When the angle θ exceeds a certain threshold Thf, lying down pose and squatting pose event which are very similar to lying down pose are detected.

In Figure 7, we represent the angle variation, which characterizes a fall, lying down and squatting events.

Figure 7. Angle variation in the case of (a) Fall event, (b) Squatting, (c) Lying down event



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

To distinguish between the three events (falling, lying down or squatting), motion information will be exploited. As the motion of the centroid changes smoothly during human movements as well as when there is a sudden and rapid movement like fall. The displacement of the centroid movement will be measured. Therefore, we will adopt the method of (Merrouche and Baha, 2017) and we measure the position of the centroid at each frame.

We generate a curve t_c tracing the centroid movement at the beginning of a suspicious event (falling, squatting, lying) by going backward t seconds. The t value represents the time average that falling event can take to occur, less than one second (Rougier et al., 2007), in our implementation, we fixed it to ~ 0.83 seconds.

We will compare the resultant curve to the free fall curve. We generate this curve using the next formula:

$$z_t = z_0 - 0.5a\left(t - t_0\right)^2 \tag{3}$$

where z_t represents the centroid ordinate at each time t and z_0 represents the centroid ordinate at t_0. t_0 defines the beginning of the suspicious event. a is the acceleration.

Generally, when an older person squats, he squats slowly but in the data set (Ma et al. 2014), that we use, some actors simulates squatting action with large movement, to overcome these false alarms it is necessary to adopt another feature. For that, we choose the distance to the floor due to its discriminant propriety. Figure 8a represents angle variation for squatting event that is returned as fall alarm and Figure 8b represents its velocity.

Figure 9 illustrates an example of fall detection obtained for person 9 of SDUFall dataset (Ma et al., 2014) falling down.

The steps detailed previously are summarized in algorithm 2 in Figure 10.

EXPERIMENTAL RESULTS AND DISCUSSION

In this section, different experiments conducted are detailed.

Data Base

To test the performance of our method, we use SDUFall dataset available at http://www.sucro.org/homepage/wanghaibo/SDUFall.html. The SDUFall Dataset contains several actions of 20 person men and women. These data were recorded with Kinect installed at 1.5 heights where sitting down, lying down, bending, squatting and falling actions were performed 10 times with different condition like carrying or not an object, turning the light on and off and changing the direction towards the camera. These conditions were chosen randomly.

In total, there are 1200 depth video with frame size of 320x240 recorded at 30 fps in avi format.

Results and Discussion

All experiments were conducted on a PC with Intel (R) Core i5 1.80 GHz. Algorithms were implemented using C++ language and openCV library. We used the following parameters to evaluate the proposed method of fall detection (Bian et al., 2015):

TP: True positives are the number of fall events detected as fall.
TN: True negatives are the number of non-fall events detected as non-fall events.
FP: False positives are the number of non-fall events detected as fall events.
FN: False negatives are the number of fall events detected as non-falls events.
Sensitivity: Indicates the capacity of the algorithm to detect fall events computed as:

$$sensitivity = \frac{TP}{TP + FN} \tag{4}$$

Specificity: indicates the capacity of the algorithm to detect non-fall events computed with following formula:

$$specificity = \frac{TP}{TN + FP} \tag{5}$$

Accuracy: Indicates how many true results were correctly detected amongst all measurements computed as:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{6}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The results show the performance of the proposed method to detect fall alarms and its ability to discriminate between falls, lying down events and squatting. Four people from SDU-Fall dataset were chosen here for demonstration. In Table 1, 2, 3 and 4, we present the three actions falling, lying down and squatting performed 10 times. We can observe from Table 1, 2, 3 and 4, that the result for true positive is 100%. The specificity and sensitivity varies between 70% and 100%.

Although the proposed method presents good results, however, in some cases, the system presents some errors. There were some false negatives, the most likely explanation of these results is the errors that occur in head tracking step and some other false positives occurred when a person brutally lies down. Other error detections were due to errors in background subtraction step for that, in the future we must use more robust background subtraction method. Figure 11(a) shows an example of false alarm due to error with background subtraction and Figure 11 (b) shows an example how the tracker missed the head.

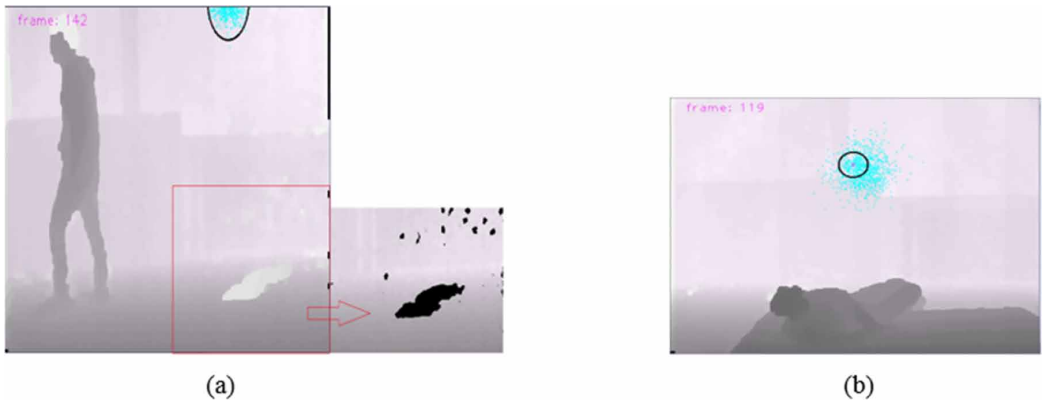

Figure 12 represents the results obtained with all the events in SDUFall DataSet and Table 5 shows the performance obtained by the proposed approach.

In this paper, the focus attention was to demonstrate the robustness of the use of the tilt angle to discriminate falls. Compared to the state of the art, we computed the angle in a simplified way. Also we exploited the data recorded by Kinect to detect backward an afterward falls as the angle was measured on the y-z plan unlike the work of (Rougier et al., 2007) where the angle represents the angle of a fitting ellipse in x-y plan and in contrast to the work of (Yang et al., 2014) where the angle was represented as the angle between the central line and y axis. Moreover, the results show that the proposed system is able not only to detect falls, but also to differentiate between falls, lying down and squats efficiently, and without forgetting the advantage of Kinect to protect the elder person privacy.

CONCLUSION

In this paper, we have presented a novel fall detection method using Kinect sensor. The method combines shape features and centroid movement. The head has been tracked using particle filter.

Centroid was detected at each frame. The angle between the head and the centroid was measured. The movement of the centroid was analyzed which allowed us to distinguish between lying down, squatting and fall events.

In this paper, we demonstrated the robustness of our method. The conducted experiments showed that our method is efficient and can detect falls accurately compared to the state of the art. The accuracy has been achieved up to 84.66%. Further work needs to be performed to compute the tilt angle on both x-y plane and y-z plane and combine them to improve accuracy.

As our results are encouraging should be validated by a larger sample size. We will address to have complicated behaviors with more scenarios such as backwards fall and fall from chair.

Chapter 40
Energy Efficient Particle Optimized Compressed ECG Data over Zigbee Environment

Dilip Kumar
SLIET, India

Rajeev Kumar
DAVIET, India

Tony Singla
DAVIET, India

ABSTRACT

Standard Electrocardiogram Tracking instruments are huge to carry away over the remote areas for the surveillance. Holter is the compact instrument meant for collecting ECG of a patient without a pause while the patient is on the go of their daily activities. Holter works on battery for 48 hours without any angle of transmission but when allowed to transmit battery power dies soon, for these purposes some energy saving techniques is required. In this chapter the authors have proposed a Wavelet based Compression Technique, followed by Optimization under Genetic Algorithm and Particle Swarm Optimization. Compressed and Optimized ECG data has been transferred over Zigbee IEEE 802.15.4 with the intention of saving energy implicating it on a hardware chip. Transferred data will be available to the Doctor for on time treatment and further examination and storage. Embedded prior techniques in Holter can enhance its life, with fact of sending crucial data.

INTRODUCTION

Present time reveals the truth that there is a raise in the aging population, busy world and life taking diseases (Maneesha V. Ramesh et al., 2012). Ongoing era demands the early detection and prevention of death threatening diseases [2], out of a huge number here the main focus is on cardiovascular diseases

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(S. Muthulakshmi and K. Latha, 2012). Cardiovascular diseases take a handsome share in the chart of death threatening diseases. People are too busy in their lives; this thing added a lot in pre death (UK. Jin Yoon et al., 2010). Scenario demands a system that will have a high check over the heart's abnormality, any oddness in daily life demands a Electrocardiogram (ECG) check up (Agus Dwi Swarjaya, 2012). This demands the idea of a technology that is fast, reliable and easy to communicate. In order to satisfy this desire we have to think for a new and efficient wireless technology called Wireless Sensor Network (Ali N. Akansu et al., 2010).Moreover, this has a revolutionary impact over the various research areas, out of a large number of areas our intention is on biomedical area which cover ups a large number of diseases that comes in human lifecycle (R. Gupta and M.mitra, 2012). Electrocardiogram is one of biomedical application which is closely related to WSN (Youssouf Zatout, 2012). Rhythm of heart is a electrical activity which is governed by the traditional ECG machine by placing various electrodes (which work as sensors) that senses the electric change and the same is passed onto the machine through wires which is reportedly drawn on a graph paper in the form of waves with each represented by P,QRS, T and U (S. Karpagachelvi et al., 2010). But our scenario has changed the traditional fact by miniaturizing the size of machine and making the sensing wire free and placing it on proximity of humans by keeping in mind sometime an instant check may not report the abnormalities, so some device need to monitor the patient continuously for a period of time (Benny P.L. Lo et al.). Holter is a monitoring device which actually works in the same way as the normal ECG machines work but on a go. Usually works for 24 or 48 hours after which the stored data will be used by the doctor to report the abnormalities (Shao. Yen Tseng et al., 2009). Where if Holter instead of storing large amount of data keep on sending its acquired data continuously, but this procedure will eat up all the battery cells and Holter machines dies soon before even lasting for 24 hours because during wireless communication most of the energy is wasted. Various authors have tried to overcome this drawback to certain extent they succeeded, out of a number of reach, some have tried to work with the compression method whose job is to cut down the irrelevant data as in the previous work Discrete Cosine transformation is used which creates discrete samples, compresses them and send them wirelessly (Tellez Camiilo et al., 2009). Lack to overcome the battery life of Holter machine as Bluetooth transmission is being used and only the frequency component of ECG is taken into consideration. Our work has overpowered the drawbacks by implementing discrete wavelet transformation (DWT) as a compression method, which discretely compresses the various frequency and time samples over discrete times before compression pre-filtration is done with the help of various filters depending upon the noise ECG data contains (Li Xuemei et al., 2008). Compression only removes the unwanted or less important data from the main data but this is not enough to save energy, this puts up with the idea of optimization (Emran Mohammad Abu Anas et al.,2010).Optimization means how well the compressed data can be further enhanced without changing the meaning of the overall data (Sateh M.S. Jalaleddine et al., 1990). Optimization works on the mirror image samples, whose removal will not lead the data in unwanted state or non-meaningful (Jos Hulzink et al.,2011). Great optimization techniques have been proposed out of large category some of them are listed below-Genetic algorithm, Particle swarm optimization, Ant colony optimization etc (Rozeha A. Roshid et al., 2008).

Genetic algorithm basically gives a simple solution termed as chromosome, where its collection called as population (Hossein Mamaghanian et al., 2011). Each chromosome undergoes a process of fitness evaluation in order to check the suitability of the candidate solution for the problem. Some chromosomes undergo the process of crossover as chromosomes exchange their values or genes, where some undergo mutation where an old value is replaced by new value. Chromosomes that undergo crossover process

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and mutation process is based upon their crossover rate and mutation rates respectively (Manpreet Kaur et al., 2011). Generation puts a boundary over the evaluation of chromosome that passes through a different above mentioned processes.

Particle swarm optimization gives us a solution as particle; each particle is set to move in a space where it compares its fitness with neighbours (Mehdia Ajana EI Khaddar et al., 2012). Each particle carries two things one is the fitness value and other is its velocity. Fitness factor has two values one the value of particle it has reached so far (pbest) and second is the global value (gbest) that is decided by Particle swarm optimizer and broadcast the value to each particle in the space or population, sometime local value is broadcasted based upon topological location. Every iteration bring up with a updated value that the particle will carry, updated values include the pbest, gbest and velocities of respective particles. Iterations and velocity (Vmax) are predefined parameters.

Compression and optimization have reduced the sample rate in order to match the sample rate media for transmission is selected that is Zigbee Standard is designed and named by IEEE as 802.15.4 which actually works at low cost and low power wireless communication (Guojun Li et al., 2012). Zigbee works on the radio frequency bandwidth of 2.4 GHz / 868MHz/915 MHz. India is specified to use the 2.4 GHz range with 16 channels available with data rate of 250kb/s (P. Manimegalai et al.,2012) .Zigbee is the proprietary standard used in Wireless Communication or more precisely in Wireless Sensor communication. Zigbee operates with low power best paired with Holter machine; this in totality results in saving the battery power and allows battery to stay for few more hours.

PREVIOUS METHODS

Compression and transmission plays a pivotal and subsequent role in the field of health monitoring. Death chart grabs our attention as there is vigorous rise, due to the deadly chronic diseases that are prevailing around the humans. Among the huge number of diseases cardiac diseases are the one that need immediate attention. Cardiac diseases are visualized by the fact of Electrocardiogram (ECG) data which represents the usual heart activity of the humans in a wave cycle representing peaks as P, QRS, T and U. Various devices have been proposed but how efficient these are still a question. Efficiency depends upon the concept of data acquisition and its transmission over terrains of range while dealing with the energy optimization. Energy optimization is considered at both the hardware level and software level, there is great revolution in the field of hardware for saving energy as it gives only 30% of its share in energy saving cycle, while the rest 70% is maintained by the software part which is still in research. So far numerous software techniques have been implemented and their results have shown some satisfaction. Software part is broadly categorized as 1) Compression Techniques, 2) Optimization Techniques and 3) Transmission techniques. Over the years of research a heap of compression techniques have been proposed and modified timely. Compressing the ECG data of the patient's heart, gives us a picture to rectify the symptoms of the particular cardiac disease a patient is going through so that on time help can be availed. In our system a remarkable attention has been paid to work out with the prominent features of ECG. Discrete cosine transformation and LZW hybrid scheme has been proposed by Bo Yu et al. (2010) in their research paper. Drawbacks are as considered hybrid approach only works in the time domain of ECG and consumes more energy with lesser data rate during its transmission as media used is Bluetooth. A low power wearable cardiac device has been proposed by Maneesha V. Ramesh et al. (2012) in their research paper. Drawback different set of modes have been proposed, switching among

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

different modes is time consuming and non-efficient as energy is wasted unnecessarily while transition happens. Our proposed system is far away from the fact of mode changer and attention has been paid to the compression method's reliability and transmission media for communication. An adaptive cosine Fourier Transform approach is proposed by Patompon Chaiyakum and Paramote WardKein (2012) in their paper. Drawback is neglecting the period can put the ECG data in an unrecognizable form as time is one of the prominent factor in ECG. An optimal thresholding algorithm for denoising ECG has been proposed by Sami M. Isa et al. (2011) in their paper. Drawback although thresholding is good concept but when limited to a small section of data samples if samples are in large number it fails deliberately resulting ECG in a fix. In our proposed system has nothing to do with the thresholding concept as Samples are pre de-noised using certain set of filters which makes the compression task quite easy.

A new algorithm has been proposed by Anubhuti Khare et al. (2011) to compress the lossy ECG data in their research paper. Drawback is considering the lossy nature of ECG certain hidden corruptive signals have been neglected, and will be modified or compressed with the technique that has been used. Our proposed system deals with the hidden corruptive signals produced due to the body artifacts, and are removed quietly before compression. Wearable wireless sensor equipment has been designed to compute oxygen saturation and Heart rate and sending it on a wireless media as presented by Cristian Rotaria and Vasile Mante (2012) in their paper. Drawback of proposed system wireless media used is access point to send data over Wi-Fi, it eats up the battery soon with lesser amount of data travelled in totality. Our proposed system has tried to rectify this flaw by using another set of wireless media, which is capable of sending data efficiently with lesser energy consumption and good data rate. New compression technique has been proposed by Mohammad Abo. Zahhad et al. (2012) in which data is considered in 2D format for compression, with attention paid over the single part of ECG. Drawback of the proposed scheme is it only works for images not for digital signals in 1D, secondly it has considered only the QRS factor among the number of factors that represents ECG in more appropriate way and thirdly conversion of 1D data to 2D consumes more energy and space. Mostly the data acquisition equipments are liable to collect data in digital form; this is taken into consideration in our proposed system, working with digital signals is bit easy as compared to analog signals, whose handling is a difficult task. Optimization techniques followed by compression techniques are quite energy saving schemes.

Optimal algorithm has been designed by Grisha Garg et al. (2010) which are based upon the various thresholding concepts added with the DWT compression method shown in their research paper. Drawback in the in this chapter main focus is on the various thresholding techniques instead the kind of DWT scheme is used, thresholding adds a bit difficulty in determining the exact value for each set of thresholding schemes. Our in this chapter has nothing to do with thresholding as sample space is large but instead of thresholding concept optimization techniques have been used to remove redundancy in the samples. Ubiquitous health care monitoring equipment has been designed by Wan. Young et al. (2008) for evaluation of ECG, Accelerometer and SpO_2 presented in their research paper. Major flaw in the proposed system is that acquired data is transmitted directly without any set of compression or optimization technique, this can increment the energy and space usage during transmission. In our proposed system all these flaws have been rectified by proper usage of compression, optimization and transmission techniques. This wholesome reduces a remarkable amount of energy usage that is consumed during transmission of the data after specific steps of denoising, compression and optimization. Health decision support system is designed by Sing. Hui Toh et al. (2009) for monitoring biomedical signals as shown in their research paper. Major flaw in the proposed scheme is type of transmission media used; CDMA consumes more energy when uncompressed data travels from patient's cell phone to server where this is

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

analyzed with the preset of values. Two set of communication medias have been used that will consume more power than single media and this kind of system is feasible in local domain as its global application can lead this into complications. Wearable equipment is designed by Antonio J.Jara et al. (2012) for continuous data transmission via a Bluetooth medium as shown in their respective work. Drawback can be seen in the flow of continuous data over a media that provides lesser data rate, range and consumes more energy, for one time this can be ignored but the continuous flow of data from a wearable device can end up very early as continuous monitoring leads to the more usage of battery and the device can die soon. In our proposed system samples have been evaluated over discrete levels and treated separately over discrete times as this in whole will save the energy consumption and device can work for few more hours. Whereas the transmission media is concerned optimized wireless technology is preferred over Bluetooth for sending and receiving the discrete compressed packets.

Dealing with the redundancy found in the ECG coefficients a new algorithm has been proposed by S. Akhter and M.A. Haque (2010) entitled in their research paper. Disadvantage algorithm works only in time domain but our proposed system has taken this into consideration. ECG is represented in two broader domains as time domain and amplitude domain. ECG data holds the various corruptive signals which hide its functionality, steps to be considered in order to remove those corruptive signals produced by the various movements of the body before the compression. Optimal way of recognizing the various abnormalities in ECG data using Neuro-Fuzzy approach shown by P.D. Khandait et al. (2012) in their research paper. In this paper major drawback is more energy, time and space consuming with less concentration on the artifacts that causes abnormalities every set of abnormality whose negligence cannot be afforded is not recognized by Neuro-Fuzzy technique. In our in this chapter we have statically mentioned the major abnormalities and removed them under a course of steps this saves time, energy and space, precisely design comes up with the data that is important and make it ready for transmission after removing set of abnormality as the received data is an impression for the doctor to find out the oddness so as to reach the patient instantly and timely.

CHAPTER'S HIGHLIGHTS

Electrocardiogram (ECG) data can be compressed by number of techniques but technique mentioned in the base paper is DCT (Discrete Cosine Transform) followed by LZW (Emran Mohammad Abu Anas et al.,2010) and compressed data is sent over the Bluetooth environment, as DCT is restricted to the certain compressed ratio and it blocks some of the important features of the signal and another drawback of the DCT (Anubhuti Khare et al., 2011)is that it represents the signal in the frequency domain but ECG composed of two domains as frequency and time domains. Both domains are equally important to extract the right meaning of the ECG data, for this Discrete wavelet transform (DWT) is used to represents the signal in the frequency and time domain. After compression the second important thing is the transmission of data, whereas in the base paper transmission is done over the Bluetooth media. Medium that has been chosen seems unreliable and more power consumer which results in early dying of the Holter's battery, these drawbacks have been corrected in our chapter with full attention has been paid to the energy utilization. Wavelet transformation compression technique and Zigbee environment overcomes the drawbacks of DCT (Patompon Chaiyakum & Paramote WardKein, 2012) and Bluetooth respectively. Some set of add-on is done in the proposed scheme that is optimization technique, which further reduces the number of samples to be sent over the wireless media.

NEED AND SIGNIFICANCE OF THIS CHAPTER

Need of the in this chapter is illustrated by the Related work as said that ECG data that is evaluated continuously while patient is involved in his daily activities, and secondly its transmission consumes more energy than energy consumed during its compression. Continuous ECG (Uk.Jin Yoon et al., 2010) will be compressed in discrete form under wavelet transformation and transmitted over the Zigbee IEEE802.15.4 protocol and reaches the Doctor or care taker for immediate assistance. Continuous monitoring of data and its transmission without compression can lead the device out of power after few hours but if we correct the transmission by just sending the compressed data over time-domain as a constraint and better protocol for transmission, by this power can be saved and the device can operate for few more hours under set of various environmental conditions. Whereas the significance is concerned it is illustrated by the fact that energy is being saved on account of Compression method and transmission is made better by use of Zigbee IEEE802.15.4 (Wan.Young Chung et al., 2008) protocol as it consumes less power for transmission, easy to operate than Bluetooth (Antonio J. Jara et al., 2012) along with these techniques some optimization techniques have been proposed which further reduces the number of samples to be sent. Results signify the better working of the proposed system under set of parameters as energy. IEEE802.15.4 has a peculiar significance that although its data rate is less than the Bluetooth but consumes less power while transmitting the data as compared to the Bluetooth wireless technology.

EXPERIMENTAL DESIGN

In this paper we have proposed a approach to compress the ECG data after removal of noise from the raw ECG data collected which is obtained from the real time simulator through Virtual Labs (Vlabs) and then passing it through optimizers and then the optimized data is tested over the Zigbee (802.15.4) Environment. Although some performance metrics have been used for evaluation. Once the different ECG data (normal, muscle, respiration and baseline wandering) are obtained from the simulator these undergo a noise removal process respectively at very first step of the proposed signal processing algorithm. Three basic types of noises such as muscle artifact, respiration artifact and baseline wandering will be eliminated which can be probably caused by muscle movement, breathing problem and in contact with high voltage respectively. The first step is to eliminate the baseline drift/wandering (Manpreet Kaur et al., 2011) which is a type of noise got generated during the signal recording process. Baseline drift will be eliminated using a smooth filter.

The next step is to remove the muscle artifact using median Filter. After removing the muscle artifact, the next objective is to remove the spikes or respiration artifact from the ECG data that arises because of any voltage fluctuation using average Filter. Various metrics have been evaluated before and after filtration process using equations 1, 2 and 3.

Then the single-level one-dimensional wavelet decomposition is performed on the ECG signal, which decomposes the signal using discrete wavelet, DWT compression usually compresses the whole received pre-processed signal and transforms it in two components one is approximation coefficient and other is detail coefficient. Coefficients designed above envelopes vital information that is passed on for further processing respectively. Along with Compression some metrics have been evaluated like PSNR (GirishaGarg et al., 2010), MSE (Sani M. Isa et al., 2011) and PRD (Mohammed Abo.Zahhad et al., 2012) by following equations 1,2 and 3.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$PSNR = 10 * \log_{10}\left(\frac{255 * 255}{MSE}\right) \tag{1}$$

$$MSE = \frac{1}{n} * \left(\sum_{i=0}^{n} (x[i] - x'[i])^2\right) \tag{2}$$

$$PRD = \sqrt{\frac{\sum_{n-0}^{n-1} (x[i] - x'[i])^2}{\sum_{n-0}^{n-1} (x[i])^2}} * 100 \tag{3}$$

x[i]- Original ECG data, x'[i]- Transformed ECG data, n- Number of samples.

Above metrics are evaluated at two stages that is at the former stage of compression and secondly at the latter stage of compression. The decomposed signal is passed to the particle swarm optimization and genetic algorithm for the signal optimization process. The ECG signal is optimized using the above two algorithm to get the best ECG signal out of the obtained ECG signal.

The detail of our execution of GA has been described as follow;

Genetic Algorithm Procedure

Input: Compressed ECG data
Output: Optimized ECG data
Step 0: attribute the various variables (population size, crossover rate, mutation rate and utmost number of generations)
Step 1: initialize population randomly as (G(0))
Step 2: calculate present population (find the fitness of chromosomes/genes)
Step 3: while (condition not met) do [step 4-8]
Step 4: select G(u) from G(u+1) [execute selection process]
Step 5 again combine G(t)[do mutation and crossover]
Step 6: caluculate present population (find the fitness of chromosomes/genes).
Step 7: u=u+1
Step 8: go to step 3 repeat the process again

The detail of our execution of PSO has been described as follow;

Particle Swarm Optimization Procedure

Input: Compressed ECG data
Output: Optimized ECG data
Step 1: For each bird/value
Step 2: attribute the values/birds
Step 3: End

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 4: Do
Step 5: For each bird/value
Step 6: apply fitness check
Step 7: If resulted fitness is enhanced than pBest in history
Step 8: set pBest equal to current value
Step 9: End
Step 10: Choose the pbest among all the birds/values assign it as the gBest for all the birds repeatedly.
Step 11: evaluate bird velocity with equation (a)
Step 12: Update bird position with equation (b)
Step 13: End

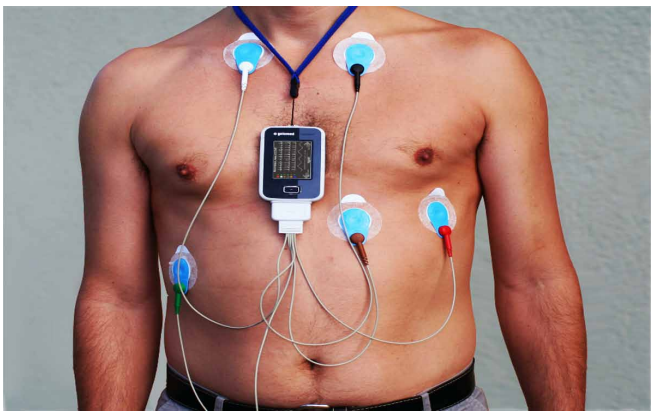
$$\mathrm{a[i]} = \mathrm{a[i]} + \mathrm{d\,1} * \mathrm{rand}() * (\mathrm{pb[i]} - \mathrm{pre[i]}) + \mathrm{d\,2} * \mathrm{rand}() * (\mathrm{gb[i]} - \mathrm{pb[i]}) \tag{4}$$

$$\mathrm{pre[i]} = p\,\mathrm{re[i]} + a\mathrm{[i]} \tag{5}$$

a[i] - particle velocity; pre[i] -current solution that particle holds randomly; pb[i] and gb[i]-local and global best fitness values respectively for each particle; rand ()- random number (0,1), d1, d2 -are learning factors [0 2].

Energy is calculated for both of the optimization processes that is for Genetic algorithm and Particle Swarm Optimization. The one with the lesser energy will be allowed to forward its Optimized compressed ECG data (noise free) for transmission to the medical database server for further analysis by doctor via Zigbee environment experimented on a hardware module. Zigbee consumes lesser power and work without any fatal error. This allows ZigBee networks to form ad-hoc, with no control from the centralized department or high-power transmitter/receiver able to reach all of the devices. Received ECG data is the optimized data along with position where the best sample is residing is used for decompression process. The examined result and all the vital information is later saved to the medical database along with the received ECG signal under the patient ID from where it was received earlier, by this immediate medical assistance is stipulated to the targeted patient and further patient is under regular surveillance (Figure 1).

Figure 1. Flowchart of experimental design



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 1: Different types of ECG data are collected from the online virtual lab (Vlab) site simulated in real Time

Step 2: Collected ECG data are termed as normal, muscle artifact, baseline wandering and respiration artifact.

Step 3: Extracted data is passed on to different filters for removal of noise based upon the type of collected data filter is used.

Step 4: Muscle artifact data is passed to the median filter for removal of spikes, baseline wandering data is passed to smoothing filter and respiration artifact data is passed to average filter respectively.

Step 5: Performance metrics have been evaluated before and after filtration.

Step 6: Pre-processed data is ready to undergo a wavelet Transformation DWT

Step 7: Performance metrics have been evaluated before and after compression according to equation number 1,2 and 3 respectively.

Step 8: while (iteration terminated)

Do (Step 8)

Step 9: Compressed ECG data passed through optimizers named as Genetic algorithm and Particle swarm optimization.

Step 10: Best optimized ECG data obtained based upon energy consumed by both optimizers, one with less is preferred

Step 11: Optimized compressed ECG data ready for transmission over Zigbee environment.

Step 12: Received ECG data analyzed and stored in medical database for further analysis

Step 13: End.

SIMULATION RESULTS

In this research, a novel heart beat signal propagation and computation model is developed for the patients using body wearable sensors for heart rate monitoring (also known as Holter) connected through Zigbee Environment with the medical database. These kinds of scenarios are usually designed for the special medical environment where patients are monitored on the regular basis to avoid the critical health hazard situations. In this research project, the aim is to improve the ECG signal propagation process by making the whole process energy efficient. The energy consumption can be minimized by optimizing the signal, which will yield out a small-sized equally detailed optimized ECG signals. This optimized ECG signal can be propagated on the ZigBee environment by consuming less energy than the non-optimized signal, for sake of easiness hardware Zigbee module is designed for communication. Also, one more aim of this research is to compute the energy consumption by Genetic Algorithm and Particle Swarm Optimization on the Holter (Body Wearable Heart Rate Recording Wireless Sensor). The signal with the lower energy consumption will be propagated on the ZigBee environment and other complex signal consuming more energy will be discarded.

Various patients have been put on test and evaluation under same set of conditions and various set of performance metrics have been evaluated as- peak signal to noise ratio, mean square error and percentage root mean square difference, all these when taken into consideration have come up with new results that shows remarkable difference among the values before and after filtration and compression respectively based upon different filter size. Tabular representation shown in Table 1 shows that peak signal to noise ratio is more after compression than before compression, whereas mean square error is

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

less after compression than before and same is with the percentage root mean square value which shows a decrement in its value after compression than before compression. Simulated results show that error or corruptive signals have been removed during compression before the signal is ready for transmission.

Table 1 shows the various values of performance metrics before filtration of noisy ECG data with different window sizes (5, 6, 7, 8, 9) respectively. Comparison represents that in case of normal data the value of PSNR is infinite for respective window size, value for MSE is zero and value for PRD is 100 for respective window size, this shows that the normal data is accurate and further comparisons can be drawn from this normal ECG data. Various values of Peak signal to noise ratio, mean square error and percentage root mean square difference for the muscle artifact, respiration artifact and baseline wandering ECG data are listed below with respect to the normal ECG data.

Record shows that values differ from their parent values; apart from their parent values they have values that are different, which gives us a sign that may be some noise is present which needs certain methods for their removal.

The results in the below Table 2 has proved that after filtration of noise from muscle artifact, respiration artifact and baseline wandering ECG data various performance metrics have changed where PSNR has decreased constantly and the same fall is seen in PRD Values and but there is a increase in MSE values with different window sizes respectively which illustrates that there is an noise/error in the signal has with respect to the parent data. Calculated values in Table 2 also represent the values before compression of ECG data (Muscle artifact, respiration artifact and baseline wandering free).

Table 3 shows the values of various performance metrics after the compression process which shows that there is an increase in the PSNR, same increase in seen in PRD values but there is a fall in MSE values with different window sizes respectively which shows that error has been removed now the data is error free as shown in tabular form.

In Table 4 particle swarm optimization outperformed Genetic Algorithm. PSO has taken almost less than half energy than GA for the ECG signal optimization. Each patient's ECG data is examined in this project is of the length 40 seconds and has recorded on the 100 samples per second as a sampling rate.

This research project has been developed along with a GUI using the graphical user interface developer called GUIDE in the MATLAB software. The GUI contains various push buttons, text fields and signal plot axis. The buttons are used to process all of the tasks listed in the project one after one in a particular sequence. The processes listed to run on the buttons are main simulation, import signal (normal, muscle artifact, respiration artifact and baseline wandering ECG data), filtration (median, average and smooth filter), DWT filter, optimization (GA & PSO) and Comparison (GA and PSO). The general GUI is shown in the Figure 2.

Table 1. Recorded performance parameters (statistical errors) before filtration

Window Size	Normal ECG Data			Muscle Artifact			Respiration Artifact			Baseline Wandering

Window Size	Muscle Artifact			Respiration Artifact			Baseline Wandering		
	PSNR	MSE	PRD	PSNR	MSE	PRD	PSNR	MSE	PRD
5	63.4	0.02	91.92	63.83	0.021	93.87	61.66	0.044	85.38
6	64.69	0.022	93.98	64.31	0.024	94.99	61.66	0.044	85.38
7	65.73	0.01	95.52	64.72	0.02	95.54	62.72	0.03	89.08
8	66.36	0.01	96.44	65.10	0.020	95.95	62.72	0.03	89.08
9	66.74	0.013	96.60	65.48	0.018	96.30	63.77	0.02	92.26

Table 4. Energy consumption by PSO, Genetic Algorithm and ZigBee -Environment

Sample Types	Energy Computed by GA	Energy Computed by PSO
Normal ECG data	49.03	27.42
Muscle artifact ECG data	50.49	26.98
Respiration artifact ECG data	48.10	37.75
Baseline wandering ECG data	49.04	25.22

Figure 2 and 3 shows the imported ECG data from the Virtual Labs. The various noises in the signal are removed is the step after plotting the original signal as shown in Figure 3 and 4.

After the respiration artifact and muscle artifact are being removed a significant change occurs in the signal structure shown in the Figure 5.

Noise produced by the baseline wandering is being removed such that the structure of the signal is changed as shown in Figure 6.

After the process of filtration process each ECG data is passed through compression module which in turn decreases the number of samples to be sent as shown in Figure 7 and 8 respectively.

After the compression process, compressed ECG data still contains certain mirror samples which further are removed with the optimization process under genetic algorithm and particle swarm optimization, individual algorithm is checked for the energy consumed by them during optimization process and one with lesser energy is preferred as shown in Figure 9 and 10 respectively then this data is allowed to be sent over wireless environment.

Optimized data received from the algorithm that consumes lesser energy, in our scenario which shows that PSO is dominating GA. Former data is ready for transmission over the Zigbee environment, in order to ease the transmission a hardware Zigbee module is designed which a circuit board embedded with transformer, followed by microcontroller, diodes, resisters, capacitors, Zigbee transmission mote, MAX-232 cable to connect it with the Personal computer, and the whole system takes the battery and system of personal computer for its proper working. Figures 11 and 12 shows the transmission process over Zigbee hardware module transmitted to and from MATLAB with the set of various instructions.

FUTURE RESEARCH DIRECTIONS

There is a future scope that further takes this to another level as the combination of various compression algorithms can be implemented on the various types of ECG data. Pre-filtering of the noisy ECG data can be done by the applications of various hybrid filters further work can be considered based upon the transmission process of wireless communication. Moreover, bandwidth dedication, channel allocation and delay related factors are some of the issues on which the work can be performed, as this will not only enhance the data transmission but will allow the device to send the more accurate data on-demand. In addition to this, certain other artifacts that can be identified with the help of the ECG transmitted will be an icing on the cake. What's more, work can be further carried forward by considering the various uproars near the patient who is under surveillance. Further, this chapter gives someone a platform to deal with the high prioritised discipline that is health, which nowadays demands a lot more attention than any other field of the education, as this field highly represents the way to deal with all the detrimental problems and how to curb with those diseases by initiating certain steps before it is too late for the patient, who actually needs this kind of help for themselves.

CONCLUSION

In this research project, we have proposed an effective ECG signal optimization and propagation framework using particle swarm optimization (PSO), Genetic Algorithm (GA), ZigBee wireless environment, discrete wavelet transform, noise removal filters and signal drift removal filter techniques and technologies. All of the technologies have been combined on one platform to increase the performance of the ECG signal recording using body wearable wireless sensors for ECG monitoring and low energy propagation of the ECG signal by compressing the signal using optimization techniques irrespective of the loss of ECG signal details. When compared with the base paper which includes only DWT compression over different mode consumes more energy when devices switch from one mode to other. In the base paper [1] compressed data was allowed to traverse through Bluetooth technology which is not efficient and consumes lot of energy and data packets are of low rate which is not feasible. Above two problems have been rectified in the proposed chapter with due concentration over the Energy consumption as there is no mode change it operates continuously but sends data discretely based upon the DWT compression technique. Maximum energy is consumed during transmission so Zigbee environment is preferred over Bluetooth to send the data with data rate higher than Bluetooth. Proposed paper do include another set of energy saving technique that is optimization techniques which are missing in the base paper, this overall saves more energy while data that is meant for sending is lesser in amount as unwanted or repeated data will be flushed away by PSO and GA . Out of two one that has consumed significantly lower energy than the other for the process of ECG signal optimization will be traversed over communication channel. Whereas it is also recorded that ZigBee environment has also consumed significantly lower amount of energy than the non optimized ECG signal propagation environment. Transferred data is being stored in a database for further analysis.

Chapter 41
Electromyogram and Inertial Sensor Signal Processing in Locomotion and Transition Classification

Deepak Joshi
Indian Institute of Technology (IIT) Delhi, India

Michael E. Hahn
University of Oregon, USA

ABSTRACT

Signal processing in biomedical engineering is essentially required for classification while serving mainly two aims. The first is noise removal and the second is signal representation. Signal representation deals with transforming the signal in such a way that the signal is most informative in that particular domain for the application at hand. This chapter will describe signal processing methods like spectrogram with specific applications to locomotion and transition classification using Electromyography (EMG) data. A wavelet analysis application on foot acceleration signals for automatic identification of toe off in locomotion and the ramp transition is also shown. Finally, the performance of EMG and accelerometer performance across different time windows of a gait cycle in locomotion and transition classification is presented with an emphasis on fusing the data from both sensors for better classification.

INTRODUCTION

A signal is a single-valued representation, real or complex, of information as a function of an independent variable recorded from some sensing device. Physically, it is a form of energy being produced by a process. Various types of signals exist and the method of signal processing needed to process a signal heavily depends on the type of the signal. Broadly, there are four types of signals:

1. Deterministic,
2. Stochastic,
3. Chaotic, and
4. Fractal.

Deterministic signals can be represented mathematically using certain parameters and hence prediction of deterministic signal in future, based on past values, is possible. Stochastic signals are random in nature with no closed loop mathematical expression and hence are not predictable in future. Fractal signals have interesting property of scale-invariance i.e. at any level of magnification the signal looks similar in structure. Chaotic signals lie somewhere between deterministic and stochastic signals. They deemed to be deterministic in a very sensitive sense and hence are not predictable in future with reasonable accuracy. Biomedical signals are generally stochastic in nature and need signal processing methods for various applications. Biomedical signal processing in various applications serves mainly two aims. The first is noise removal and the second is signal representation. The main source of noise in biomedical signals is noise in electronic instrumentation. Other sources consist of electromagnetic interference and skin motion or physiological artifacts. For example, while recording electromyogram (EMG) nearby the chest one can observe the artifacts of electrocardiogram (ECG) in the EMG profile. There have been many provisions in hardware and experimental protocols to remove such noise and artifacts, however complete removal is not possible without using signal processing tools. Signal representation deals with transforming the signal in such a way that the signal is most informative in that particular domain for the application at hand. One such application is classification of locomotion and transitions in assistive devices where noise removal and signal representation are critical for successful, rapid and safe classification.

Locomotion classification is crucial in lower limb prosthesis control. Powered lower limb prosthesis provides sufficient torque and stability to the amputee so that they can negotiate in different terrains with reduced energy consumption. The key component for powered prosthesis to be facilitated with such features is accurate locomotion classification. Based on the classified locomotion, the artificial limb changes the damping profile to provide with net required torque output. For seamless transition in a powered prosthesis it is critical to classify the upcoming locomotion ahead of time (ideally before toe off of the transitional gait cycle) to ensure safe transition. Hence the selection of required data is critical and depends on the application at hand. For example, if someone is interested in analyzing the offline data of a cerebral palsy patient then the full gait cycle (heel strike to heel strike) may be available. However, for the application of real time actuation in prosthesis and orthosis control, the data available is limited. Hence, within this framework of classification the selection of sensors is critical. EMG represents the muscular activity and has been used widely for various applications like prosthetic control, gait analysis, disease diagnosis, and neuro-muscular coordination (Gea Drost et.al. 2006; Anjana Goen and D. C. Tiwari 2013). With the advancement in technology, miniaturized inertial sensors like accelerometers have shown promise in locomotion classification and other clinical gait analysis applications. Ambulatory monitoring of daily activities is the other area where accelerometer is of great importance as a sensing device.

EMG is the summation of electrical activity, action potential, of all the motor units recorded by the electrode. EMG signals are recorded by placing electrodes in, on, or near a muscle and amplifying the electric potential between two electrodes, that results from the generation and propagation of action potentials along muscle fibers. These muscle fibers are innervated by motor neurons from the spinal cord. The electrodes used are generally made of silver/silver chloride (Ag/AgCl) with some application of conductive gel at the skin-electrode interface. The electrodes serve as a transducer which converts

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the ionic activity of cells inside the body into the electric current outside the body. To reduce the effect of common mode electromagnetic noise the electrodes are used in differential mode. Such a differential mode also offers to measure localized activity within the muscle. After removing the noise from the EMG signal it is required to represent the EMG signal for the application in hand. Signal representation of EMG signal for various applications essentially consists of representing the signal in 1) time domain, 2) frequency domain, and 3) time-frequency domain. Time domain processing may include autocorrelation, whitening, normalization, etc. Autocorrelation gives a measure of matching the signal to itself while shifting the signal, known as lag, in past and future. Therefore, the autocorrelation is a function of lag. Whitening temporally decorrelates the value of signal at various instant of time thereby increasing the statistical degree of freedom. Normalization involves scaling the time and amplitude axis of the signal with respect to a reference value. Frequency domain processing may include filtering, coherence, etc. Filtering involves removing the unwanted frequency from the signals while coherence evaluates the frequencies in synchronization between two signals. The time-frequency domain processing consists of simultaneous time-frequency representation, including Spectrogram, wavelet decomposition, etc. Spectrogram is a fixed resolution time-frequency representation while wavelet offers a choice of multi-resolution. The present chapter will describe these signal processing tools like spectrogram with specific applications to EMG.

The popularity of using tri-axial accelerometers in locomotion classification has increased in recent years for clinicians and researchers. Accelerometers directly measure acceleration and hence avoid any error of calculating acceleration by integrating velocity and displacement. Accelerometers for human movement quantification generally utilize sensors like strain gauge, piezoresistive, capacitive and piezoelectric. A tri-axial accelerometer simultaneously records the acceleration in all the directions. The signal processing tools for EMG are equally applicable to accelerometers as both of them represents the movement information; however, care must be taken for low frequency and gravity biased signal from an accelerometer while selecting a signal representation method. For example, approximate entropy and fractal analysis have been considered as important time domain signal processing tools for quantification of human movement via accelerometry. Apart from locomotion classification, accelerometry has been especially advantageous in the identification of gait events like heel strike and toe off. A particular wavelet application on acceleration signals of the foot for automatic identification of toe off in locomotion and the ramp transition is presented.

In recent years, multisensory fusion and integration has shown several benefits over single sensor data for biomedical systems. In a particular case of locomotion and transition classification, the sensor fusion approach provides better classification accuracy and robust performance. In this chapter, the EMG and accelerometer performance across different time window of a gait cycle in locomotion and transition classification is presented.

This chapter presents a brief review of approaches for the EMG and accelerometer signal processing in locomotion and transition classification. It is organized in the following sections: Locomotion and transition classification, where some popular methods in use will be briefly described; Spectrogram approach for EMG signal representation, where basic principles of spectrogram approach presented; wavelet analysis of foot acceleration for gait event detection; and finally, a comparison of acceleration and EMG across gait cycle in locomotion classification is presented with an insight on sensor fusion.

LOCOMOTION AND TRANSITION CLASSIFICATION

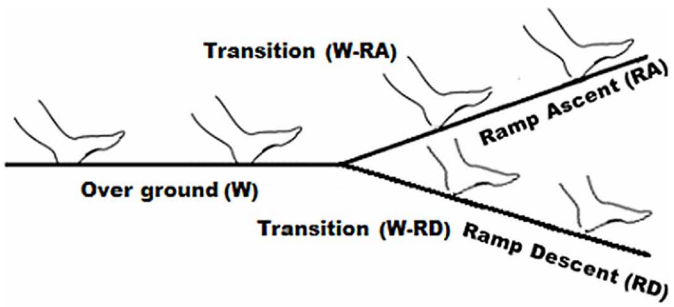
The estimated number of lower limb amputations every year in the United States is 120,000 leading to limited involvement of the individual in various physical activities (T. R. Dillingham et.al. 2002). Lower limb prostheses are designed to partially restore function in the lower limb. Passive prostheses allow for level over ground walking but do not provide net torque for walking over varied terrain. Advancements in embedded system technology have facilitated the introduction of powered prostheses which allow desired impedance for terrain walking (Au. S. et. al. 2008; F. Sup et. al. 2008). Hence, it becomes critical to accurately classify the locomotion in current powered prosthesis. Moreover, an ideal powered prosthesis must also provide the seamless transition while switching between the locomotion modes which requires to accurately identify the movement intention of amputee. While the classification problem needs to know what the amputee is currently doing; the seamless transition is an anticipation problem and therefore needs to know that what the amputee is about to do. A ramp transition is schematically shown in Figure 1.

Current powered prostheses lack in such anticipation and requires some "cueing" in the form of either manual intervention or compensatory movements which add cognitive load to the amputee resulting in non-effective use of the prosthesis. As mentioned, the seamless transition is an anticipation problem and hence becomes challenging as the future data is not available in the real time scenario. This leads to a broadened scope to investigate choice of sensors, methods in signal processing and signal representation, and various classification algorithms to solve this anticipation problem.

SENSORS

Various choices of sensors have been explored in past few decades for locomotion and transition classification. The primary criterion to select a sensor modality is the richness of information – the other criteria being the relative ease of placement (i.e. donning and doffing), the cosmesis and social acceptance (R Kobetic et. al. 2009). A detailed review of sensors for locomotion and transition classification can be found elsewhere (Michael R Tucker et. al. 2015). As EMG represents the true physiological representation of muscle contraction, it is perhaps the most promising source of information for decoding the motion intention, and potentially other application of classification. However, due to the non-stationary nature of locomotion and EMG signal being highly susceptible to noise – due to artifacts and sweating,

Figure 1. Ramp ascent and descent transition from overground walking



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

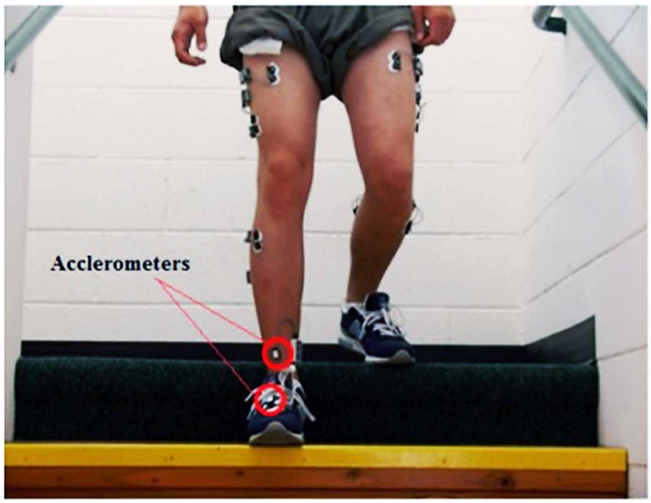
it requires extensive signal processing, followed by signal presentation, before being fed into the classifier. Particular to application in motion classification, EMG signal has shown respectable accuracy in respective applications (R. H. Chowdhary et.al. 2013; D. Graupe et. al. 1982; D. Graupe et. al. 1985; Y Huang et.al. 2005; X Zhang et. al. 2012). Due to the miniaturized sensing technology, the body mounted sensors have been used extensively in the last decade for various applications.

Specific to locomotion classification the accelerometer has been the preferred choice. A range of classifiers – including Simple threshold, Hierarchical scheme, Decision Trees, k-nearest neighborhood, Artificial Neural Network (ANN), Support Vector Machine (SVM), Naïve Bayes and Gaussian Mixture Model (GMM), Fuzzy Logic, and Markov Models (Culhane et.al. 2004; Ermes et. al. 2008; Maurer et. al. 2006; Parkka et. al. 2006; Doukas and Maglogiannis 2008; Wu et. al. 2007; Allen at. al. 2006; Salarian et. al. 2007; Pober et. al. 2006), have been used for activity classification using features from accelerometer data. A detailed review can be found elsewhere (Stephen J. Preece et.al. 2009). Subjects worn with EMG and accelerometer are shown in Figure 2.

SPECTROGRAM APPROACH FOR EMG

Due to their easy computation and reduced computation time, the time domain representation of EMG signal has been used extensively for locomotion classification (Miller et.al. 2013; Huang H et.al. 2009). However, limited signal representation in the time domain demands high number of features (Huang H. et.al. 2011), leading to high dimensionality for good classification accuracy close to 95%. Moreover, the significantly enhanced classification accuracy of activity identification by introducing frequency domain features (S J Preece et.al. 2009) is appealing for exploration of the simultaneous time-frequency representation of EMG signals in locomotion and transition classification. Such a time-frequency representation can be served by two means:

Figure 2. A subject stepping down in stair terrain wearing EMG and accelerometer sensor on foot and ankle



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Spectrogram, and
2. Wavelet transform.

Though the wavelet transform offers multi resolution analysis in time and frequency domains compared to fixed resolution in spectrogram, wavelet transform provides redundant information in terms of a large number of wavelet coefficients, thus overburdening the classifier, and wavelet transform is suited to specific applications (Fernandes FCA et.al. 2001; Valens CA 1999). Spectrogram representation of EMG was first presented to analyze fast movement and constant contraction of human hand muscles (Hannaford B and Lehman S, 1986), however little is known about its utility in classifying locomotion modes or transitions using lower extremity EMG. A spectrogram, fixed resolution time-frequency representation, of the data segment uses periodogram approach to calculate the spectral density as following:

where N is the total number of data points in the data segment, ω is the frequency and m is the length of the window. The spectrogram is then calculated, using Matlab 2015, as the magnitude square of each periodogram as follows:

$$Spectrogram\left\{x\left(n\right)\right\}\left(m,\omega\right)=\left|P_{x}\left(m,\omega\right)\right|^{2} \tag{2}$$

The periodogram gives a good estimate of spectral density of non-stationary signals like EMG, calculating the Fourier Transform of auto-correlation to give a better estimate of spectral density. Spectrogram of a 256ms EMG with 64 ms window and 50 percent overlap is shown in Figure 3. A detailed description of periodogram can be found in (Cooper GR and McGillem CD 1999).

Such a periodogram is transformed to threshold based binary conversion (TBBC) by utilizing a threshold (0.5) in energy via the following equation:

$$F_{i,j}=1,\ \ if(|\ F_{i,j}\ |)^{2}\geq 0.5*\max((|\ F_{i,j}\ |)^{2})\ \ \forall i,j=0,\ \ otherwise \tag{3}$$

where F is the value of spectrogram in the bin indices, by i and j. A high threshold value of 1 may lose critical information while a lower threshold value may introduce noisy, redundant information. For this method development, the threshold value of 0.5 was selected. The spectrograms, after TBBC, from all training trials were pooled to develop the 2D histogram. Prior knowledge was extracted from the previous gait cycle. This prior knowledge was integrated into the system as follows: If the previous class is walk then there is no possibility that next class can be stair ascent. The only possibility for next class is either walk or the transition from walk to stair ascent. Hence, for a given EMG data set with prior knowledge of locomotion as walk, the classification should not return stair ascent. Thus, the prior knowledge is able to restrict the possible intended locomotion state, effectively reducing computation time and increasing classification accuracy. By training a few if-else rules using developed 2D histogram of seven lower extremities EMG, bandwidth between 3-500 Hz, namely – Tibialis Anterior (TA), Medial Gastrocnemius (MG), Rectus Femoris (RF), Vastus Lateralis (VL), Biceps Femoris (BF), Gluteus Maximus (GMax) and Gluteus Medius (GMed), of thirteen healthy subjects an overall classification error of less than 20% for over ground walking (W), stair ascent (SA) and the transition from over ground walking to stair transition (W-SA) was achieved, using leave-one-subject-out-cross validation. This error was further reduced to less than 11% by utilizing knowledge of previous gait cycle i.e. prior knowledge. More details of clas-

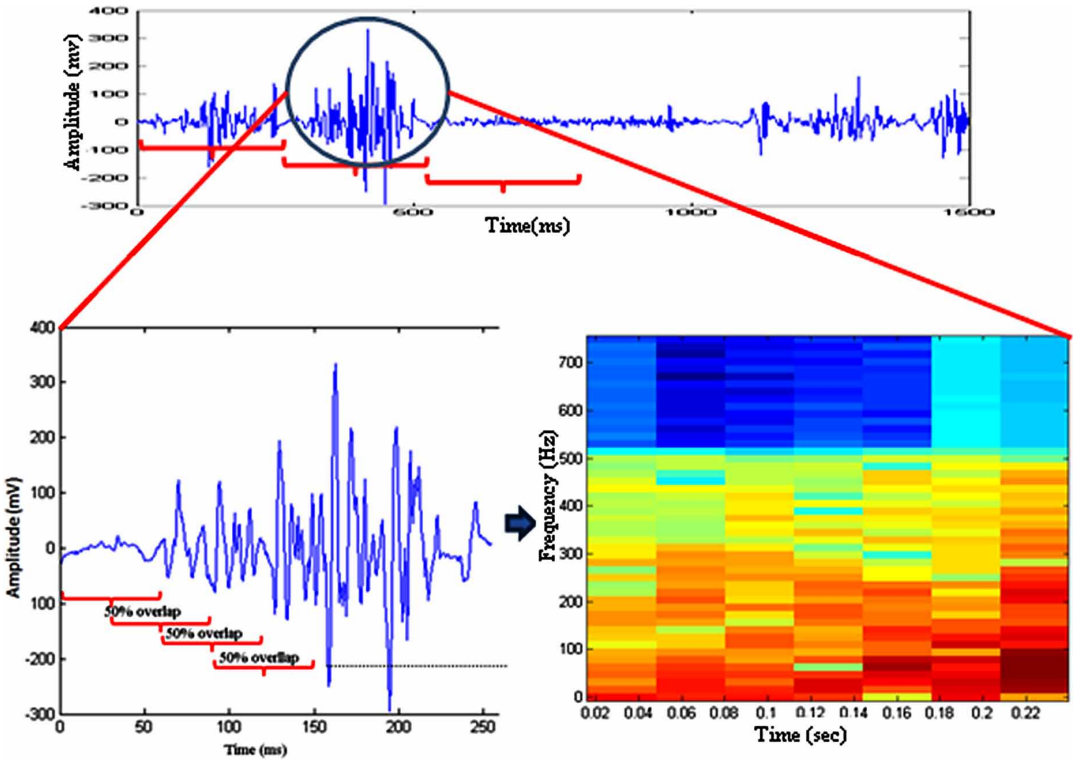
Figure 3. Spectrogram of a 256ms EMG signal with 64 ms window and 50 percent overlap



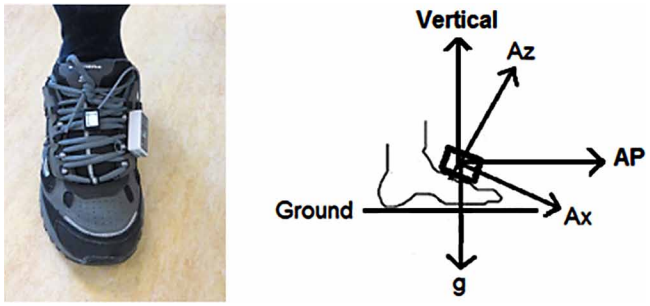
sification method and neural input can be found in (Deepak Joshi et. al. 2015). Spectrogram involves frequency transformation and hence requires obvious computational time resources. It was observed that with the computational resources of Intel Core i7 CPU @ 3.40 GHz and 8 GB RAM it took 53.5 ms and 2.5 ms for calculation of spectrogram information and classification decision, respectively. The fast classification is due to if-else rules which are computationally easy to calculate.

WAVELET APPLICATION OF ACCELEROMETRY DATA

Once the classification for locomotion is performed it is desirable to provide appropriate damping for swing and stance phase separately for the respective locomotion. Hence it becomes critical to correctly identify gait events like toe off to separate the swing and stance phase in real time. This becomes critical when the amputee is transitioning from one terrain to another. Ground reaction forces (GRF) and kinematic data from motion capture have been the golden standard for toe identification of toe off in over ground walking and treadmill walking (Y H Chang et. al. 2000; A Hreljac and R N Marshall 2000; J K De Witt 2010). Both of these sources are limited to laboratory settings and hence are not suitable for some applications like Functional Electrical Stimulation (FES) and monitoring of activity of daily living (ADL) where ambulatory monitoring systems are required. Moreover, these sources have not been tested in different terrains or in transitions. With the advent of miniaturization sensor technology and high end signal processing like wavelet it is appealing to explore inertial sensors like accelerometers

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Placement of accelerometer and associated global and local coordinate reference

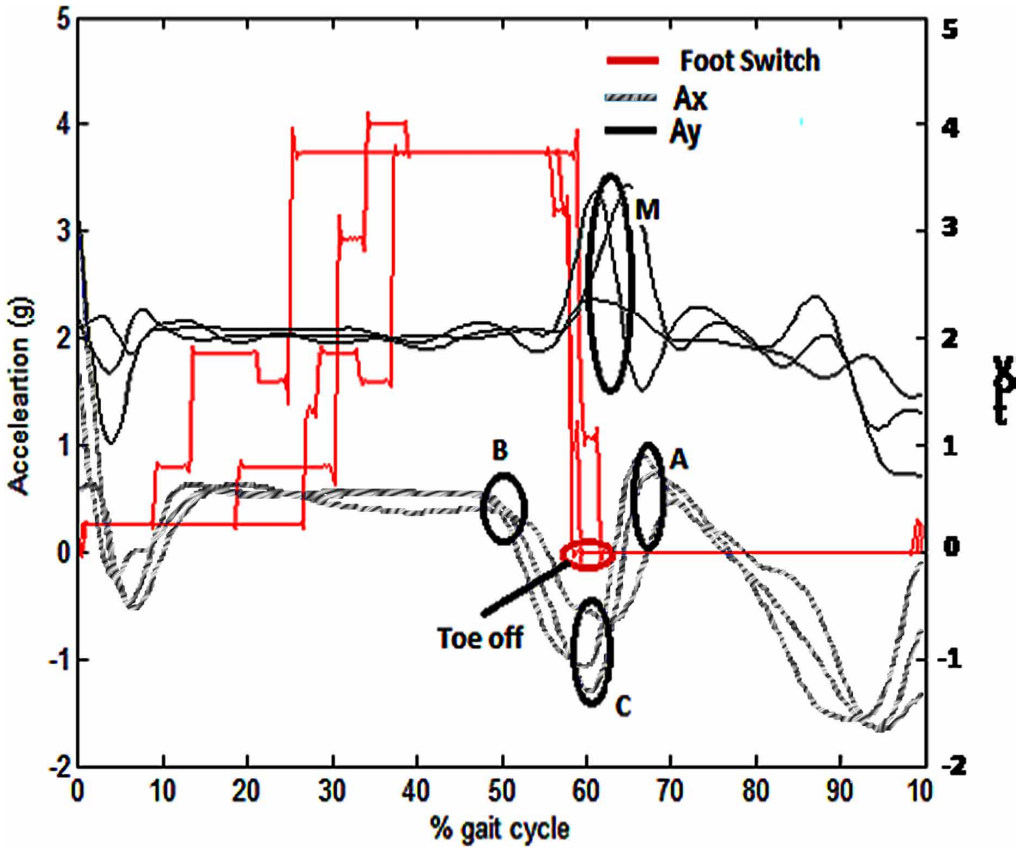


with high end signal processing for identification of toe off in different terrains and the transitions. A tri-axial accelerometer and its placement on dorsum of the foot along with its axis towards the movement are shown in Figure 4. With respect to a global coordinate reference of anterior-posterior (X) and vertical direction (Z), placement of the accelerometer on the foot led to primary measurement directions as Ax and Az (Figure 4), with Ay representing the medial-lateral direction, orthogonal to Ax and Az.

As noted in Figure 4, Az and Ax were not purely aligned with the global vertical and Z, being dependent upon the orientation of the dorsum of the foot. Foot movement during walking is generally in a low frequency range. To reduce data redundancy, we down-sampled the original data by a factor of 5, resulting in an effective sampling frequency of 300Hz. Down sampling reduced the redundancy while maintaining the critical information. The accelerometer data were filtered with a low pass second order Butterworth filter with 10Hz cut off frequency. This cutoff frequency, compared to other options like 20 and 40 Hz, avoided the local minima and maxima in the acceleration data while maintaining meaningful information of source signal to develop the heuristic algorithms. To remove the gravity component, the residual acceleration value in all directions during a period of quiet stance, is removed from the filtered data. Most of the movement of leg during locomotion is in the direction of progression i.e. Anterior Posterior (AP) and vertical. Hence, these two directional data were explored for identification of toe off event. Various signal processing algorithms and classification schemes have been employed for the identification of toe off in a gait cycle. Heuristic approaches have been especially attractive and appealing due to easy computation and ease in real time implementation algorithms (J. M. Jasiewicz et. al. 2006; A. M. Sabatini et.al. 2005). However, due to the advancement in signal processing algorithms and machine learning, researchers have been able to achieve better accuracy in toe off identification (Aung et.al. 2013). Algorithms need to be robust in identifying the toe off event in locomotion as well as in the transition gait cycle. As toe off marks the transition from stance to swing phase, a discontinuity at this transition in the vertical component of acceleration is expected. Such short period transitions are better highlighted in wavelet analysis due to the high time resolution capability for high frequency in wavelet. Further to reduce the computation time, the transition can be localized in the gait cycle using a heuristic approach before applying the wavelet transform. Figure 5 shows the toe off event localized by points A, B, C, and M. These points can be heuristically identified using the acceleration data in Ax and Az directions. Point A and B were identified utilizing mutual information in the Ax and Ay acceleration data. Specifically, point M is the maximum Ay acceleration peak in a gait cycle, and is the closest unique point in proximity to point A, which is the peak Ax acceleration. Further, point C is the maximum negative Ax peak prior to point A. We segmented Az acceleration of a gait cycle between point A and point B to locally search for the toe off.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The Ax and Ay with foot switch data during ramp walking (ascending, RA). Three separate cycles are shown from one example subject; representing those with minimum, maximum and median stride duration. The Y-axis unit for acceleration and foot switch are ±g and Volt, respectively and are shown with respect to time-normalized gait cycle. The marker C corresponds to the region of Toe-off for all the three stride cycles showing that it lies between point A and B exclusively.
Note: Acceleration in Ay direction is shown with an offset of +2g for visualization purposes.



Further, wavelet analysis can highlight the toe off event in the localized segment identified by the heuristic approach. Such an approach has been utilized recently and was demonstrated to be superior to other approaches in the past while detecting the toe off in walk (W), ramp ascent (RA), ramp descent (RD) and both the transitions (W-RA and W-RD) (Deepak Joshi et.al. 2014). Estimation error was first defined as the time difference between the toe off detection by foot switch and toe off detection by the proposed algorithm. Absolute value of this error value was calculated and averaged across the subjects to report mean absolute estimation error. Note: As the effective sampling frequency was 300 Hz, the error of a single sample of time corresponds to 3.3 ms. A comparison of accuracy in correct toe off identification is given in Table 1.

Among the other findings, the average stride durations for steady state locomotion were 1.08 ± 0.078, 1.07 ± 0.10 and 1.06 ± 0.067 seconds for W, RA and RD, respectively and 1.07 ± 0.081 and 1.06 ± 0.076 seconds for the transition W-RA and W-RD respectively. No significant differences were found between any possible pairs of within or between transition and steady state locomotion (paired t-test, α

*The results are shown for db1 wavelet which showed better accuracy than db2 wavelet.

= 0.05). Point A, B, C and M were detected with 100 percent accuracy utilizing the Ax and Ay acceleration data; no trial was missed in examining toe off due to misidentification of any instance of point A, B or C. Hence, the Az acceleration was segmented correctly in all the trials across all subjects. The mean absolute estimation error using db2 was 25.6 ± 18.3, 32.5 ± 15.3, 33.2 ± 21.7, 32.5 ± 19.5 and 26.8 ± 16.2ms compared to 17.4 ± 12.5, 13.8 ± 8.5, 22.0 ± 16.4, 20.1 ± 15.5 and 17.1 ± 13.7ms using db1 wavelet, for W, RA, RD, W-RA, and W-RD, respectively. The db1 wavelet performed significantly better than db2 in identifying toe off with high accuracy ($p < 0.01$).

EMG AND ACCELEROMETER COMPARISION

It was concluded in a previous section that the accelerometer and EMG performed with reasonable classification accuracy in different applications for lower limb prosthetics. It will be interesting to see the performance of both sensors in a common application of classification in order to derive a fair comparison of both the sensors. Such an application is to classify the locomotion transition in grouped transition of terrain and direction. For terrain type classification, the data from W-RA and W-RD were compiled and further class labeled as ramp. Similarly, the data from W-SA and W-SD were compiled and further class labeled as stairs. For direction type classification, data from W-RA and W-SA were compiled and further class labeled as ascent. Lastly, the features from W-RD and W-SD were compiled and further class labeled as descent. In summary, the terrain group represent whether the transition is to stair or to the ramp irrespective of the direction (i.e. up and down). In a similar way the direction group represents whether the transition is to up direction or the down direction. Such a classification scheme is often described as hierarchical classification. Other than classification accuracy, it is important to see the comparison across different events of gait cycle specifically with reference to toe off as the toe off marks the transition from swing to stance phase. The toe off was marked by using foot switch data. Based on the toe off event three windows from a transitional gait cycle were extracted as follows:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Pre Toe Off:** A data segment starting from toe off and extending backward to foot strike of the transitional gait cycle. Window sizes varied from size of 50–350 ms with an increment of 50 ms.
2. **Post Toe Off:** A data segment starting from toe off and extending forward to foot strike on new terrain. Window sizes were similar to pre toe off.
3. **Transitional Window:** A combination of pre and post toe off segments.

EMG and accelerometer sensors were placed exactly as mentioned in previous sections. Data were sampled at 1500 Hz using the Noraxon Telemyo DTS system (Noraxon, Scottsdale, AZ). All post-processing was conducted using custom-written programs in Matlab (Mathworks, Natick, MA). EMG signals were band pass filtered between 20 and 500 Hz using a 4th order digital Butterworth filter. Accelerometer signals were low pass filtered with 10 Hz cut off using a 4th order digital Butterworth filter, in addition to removal of mean before further processing. Figure 6 shows the data from accelerometer and EMG sensor across the gait cycle for mentioned events.

To derive a fair comparison between both sensors it is important to represent the information from both sensors in an equal number of dimensions. Principal component analysis (PCA) is a multivariate technique that transforms the original feature space into a set of new orthogonal variables called principal components such that the variance in new dimensions is maximized. PCA finds these dimensions by directly observing the Eigen vectors of covariance matrix. For the features given in table II for both the sensors, PCA revealed that among top five Eigen vector directions EMG data could capture the 97.45%

Waveform Length (WL)	Mean Trend
Number of Slope Sign Change (SSC)	Windowed Mean Difference (WMD)
Root Means Square (RMS) value	Variance Trend
Third-order Auto regressive (AR) coefficient	Windowed Variance Difference (WVD)
----------	Maximum Difference Acceleration (MDA)
Feature Space = 7 Channels X 8(5+3AR coefficient) features = 56 Dimension	Feature Space = 6 Channels X 7 features = 42 Dimension

of variance compared to just 90.36% of variance in accelerometer data (Deepak Joshi et. al. 2015). EMG data were collected from seven channels as mentioned in previous sections; however accelerometer for this study was collected from two tri-axial accelerometers on foot and shank thus constituting six channels as shown in Table 2.

Support vector Machine (SVM) and linear discrimant classifier (LDA) classifiers were used for pattern recognition. LDA is a supervised dimension-reduction technique and well-assessed classification method. The LDA involves finding a linear combination of the independent variables that minimizes the probability of misclassifying the individuals into their respective groups. It projects the dimension into one direction, useful for data classification. The ultimate goal is to find the projection to a line such that the samples from different class are well separated. SVM is a classification method that uses kernel functions to map the original features into high-dimensional feature space for constructing an optimal hyperplane to separate binary classes. A linear kernel was used for the SVM classifier; $k(x_i,x_j) = x_i^T x_j$, where x_i and x_j are the feature vectors of i^{th} and j^{th} classes, respectively, and T denotes transpose. The leave-one-out-cross validation (LOOCV) method was used to test and train the classifiers. Out of total ''n'' trials from all subjects, one trial was used for testing and n-1 trials were used for training the classifier. This procedure was iterated until all the trials had been included in training and testing. Classification accuracy (CA) was then calculated as a percentage; (number of correctly classified trials/total number of trials)*100. Comparison of classification accuracy between terrain and direction type was evaluated statistically, using a paired two-tailed *t* test. For the grouped classification (Terrain vs. Direction), overall the accelerometer performed better than the EMG in the transition gait cycle. However, the performance of both sensors was complementary to each other. In the time windows where accelerometer failed to perform well the EMG could classify the transitions with respectable accuracy. Overall, both the sensors tended toward higher accuracy for terrain type than direction type. Among the three windows the transitional window showed superior performance than the pre-toe off and post-toe off windows. A detailed analysis of the performance of both sensors in different windows of gait cycle can be found in (Deepak Joshi et. al. 2015). In this study, the toe off event during the transitional gait cycle was considered as the gold standard for separation of locomotion modes. It appears to be a good approximation for small distances, where toe off occurs close to the physical transition interface. However, if toe off occurs at a greater distance, this approximation would likely need to be modified. For a short distance, it can be

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

fairly assumed that immediately after toe off the coming locomotion mode is engaged. However, in circumstances where the distance is greater, even after toe off a major part of the gait cycle can still be considered to be within the previous locomotion mode and may violate the assumption. The potential effect of greater distances in transition should be addressed in future studies.

DISCUSSION AND CONCLUSION

The signal processing methods like spectrogram and wavelet have been presented with application to locomotion and transition classification. Frequency domain representation, spectrogram, proved to be successful in classifying the locomotion and the transition. However, it has to be yet tested for an extended number of locomotion and classification. In that case it is advised to explore a greater number of relevant features from the frequency domain representation other than the spectrogram energy only. Accelerometer and EMG data both show reasonable accuracy and complimentary information in a gait cycle. This confirms the result of a recent study (A J Young et. al. 2014) which reported that combining accelerometers and EMG data gives better classification accuracy than using either of them alone while classifying the locomotion, walk, stairs, and ramp from the data of transfemoral amputees. However, the analytical combination was not tested on locomotion transitions.

The wavelet decomposition of just one set of accelerometer data on the foot was able to achieve superior accuracy in toe off identification compared to other algorithms utilizing a machine learning approach. This study allowed us to observe that the combination of signal processing and a heuristic approach is better than a heuristic approach alone at identifying toe off using accelerometry data. This may be due to the fact that heuristic approaches are generally subjective, while signal processing approaches are data driven and hence more adaptive to signal source. The 'gold standard' for toe off detection in this study relied on foot switch data, which itself has some inherent error, due to variations in the size and shape of subjects' feet. This can lead to large variation in estimation error across subjects. It may be necessary to determine any biasing or offset between the estimations derived from foot switch and GRF plates. This offset could be further added or subtracted from the estimation of the proposed algorithm to test it against the GRF true estimation.

It was observed that throughout the transitional gait cycle the high classification performances of EMG and accelerometry were complementary to each other. This difference in window-dependent performance can be explained by the fact that EMG appears prior to the corresponding motion while acceleration is actuated during the motion, demonstrating the well-known electromechanical delay observed in skeletal muscle activation. Seemingly, an optimal combination of both sensor types across the transitional gait cycle can strengthen the revelation of transition patterns. It appears that transitions are better classified as terrain than direction type. A terrain focused approach may thus be ideal for an efficient classification structure. Our findings demonstrate that EMG and accelerometry data sources complement each other across transitional gait cycles. This presents the opportunity for an optimal sensor fusion for robust classification in application. Overall, the findings of this study suggest that a terrain and direction focused classification approach will be useful for inclusion in classification approaches utilized in lower limb amputee samples and possibly in future efforts to enable smooth locomotion transitions using powered prostheses and assistive devices.

LIMITATIONS AND FUTURE DIRECTIONS

Able bodied participants were selected for the studies described in this chapter. With amputation the movement pattern and hence EMG and accelerometer will change as well. In future, it will be crucial to see how these sensors and the classification schemes perform with amputee data. With the complementary nature of both sensors across the gait cycle, it will be worthwhile to explore the fusion of both sensors in order to develop an optimal classification strategy. To recognize the intent of type of transition (direction/terrain) it may be important to include the visual cue as a precursor for the classification. Such a preparatory cue for obstacles and locomotion has been reported previously (R. M. Wilkie et al. 2010; R. M. Wilkie et. al. 2008), however there is a need to effectively integrate such cues into a seamless real-time classification strategy.

ACKNOWLEDGMENT

The studies described in this chapter were carried out under financial support from the U.S. Department of Defense; grant W81XWH-09-2-0144. The authors are grateful to Bryson Nakamura, Eileen Deming, and Daniel Jones for their help in data collection and post processing.

Chapter 42
A Hybrid Kernel Extreme Learning Machine and Improved Cat Swarm Optimization for Microarray Medical Data Classification

P. K. Dash
Siksha 'O' Anusandhan University, India

ABSTRACT

This paper presents the pattern classification of the binary microarray gene expression based medical data using extreme learning machine (ELM) and its variants like on-line sequential ELM (OSELM) and kernel based extreme learning machine (KELM). In the KELM category two variants namely the wavelet based kernel (WKELM) extreme learning machine and radial basis kernel extreme learning machine (RKELM) along with support vector machine (SVMRBF) and support vector machine polynomial (SVMPoly) are used to classify microarray medical datasets. Further to reduce the high dimensionality of Microarray medical datasets giving rise to high number of gene expression and small sample sizes, a modified evolutionary cat swarm optimization (MCSO) technique is adopted. The efficiency of the proposed algorithm is verified using a set of performance metrics for four binary medical datasets belonging to breast cancer, prostate cancer, colon tumor, and leukemia, respectively.

1. INTRODUCTION

Microarray analysis and classification play very important role for early diagnosis and treatment of disease like cancer. It shows the highest rate of morbidity and mortality in both economically developed and developing countries (Kanovas, 2006) where two hundred types of cancers in human beings have been recorded using microarray technology (Ferley et al., 2012). Molecular analysis of four common types of cancers belonging to lungs, female breast, bowel and prostate (Siegel et al., 2015) reveals that their gene expression profiles and high-density DNA microarray measures (Li et al., 2011; Lee & Lee, 2003) are different and therefore they can be used to diagnose them with significant accuracy. Early detection of these cancers can prolong human life and therefore it is pertinent to classify and recognize these types of cancers mentioned above as early as possible (Li et al., 2011).

Microarray technology that produces big datasets with gene expression values for thousands of genes (6000~60000) in a cell mixture (Guyon & Andre, 2006) are economically unviable where the number of samples (n) is much larger than the number of features (p) (Bolon-canedo et al., 2014). Thus for reducing the dimensionality problem efficient feature extraction and optimal feature selection of the medical datasets are required. To overcome this problem, microarray medical datasets need dimension reduction (Bolon-Canedo et al., 2014; Saeys et al., 2007; Tan, 2006; Liu & Hiroshi, 2007). Several feature extraction techniques like the principal component analysis (PCA) (Subasi & Ismain, 2010; Lopez et al., 2009; Karg et al., 2009), kernel principal component analysis (KPCA), linear discriminate analysis (LDA) (Subasi & Ismain, 2010; Lopez et al., 2009) and canonical correlation analysis (CCA) (Vert et al., 2002) have been used widely by several researchers. However, from the extracted features an optimal feature selection approach is essential to improve the classification accuracy and its better interpretation. Feature selection methods proposed in the literature include Fast Correlation Based Filter (FCBF) (Senliol et al., 2008), Relief algorithm (Zhang et al., 2008), Support Vector Machine recursive feature elimination technique (Duan et al., 2005), sequential forward (SFS) selection and sequential backward elimination (SBE) (Peng et al., 2005). Amongst several approaches for optimal feature selection SFS and SBE outperform all others and exhibit ease of implementation and low computational complexity. However, both SFS and SBE suffer from nesting and feature deletion problems (Dunne et al., 2002), respectively, and, therefore, evolutionary techniques are used. Various evolutionary optimization techniques for feature selection include genetic algorithm (Huang et al., 2006), simulated annealing (Lin et al., 2008), ant colony optimization (Kanan et al., 2008), particle swarm optimization (Unler & Alper, 2010; Fong et al., 2013; Lie et al, 2011), differential evolution (Khusaba et al., 2011; Al-Ani et al, 2013), bacterial foraging optimization (Jakhar et al, 2011), harmony search (Dias et al., 2012), cuckoo search (Rodrigius et al., 2013), firefly (Banati et al., 2011), bat algorithm (Nakamura et al., 2012) and cat swarm optimization (Lin et al., 2009), etc.

Dimensionality reduction helps in the classification of microarray medical datasets by improving its accuracy. The important role of medical data classifier is to provide the explanation and justification for the accurate prediction of the disease (Li et al., 2011). Many traditional classifiers like KNN (Guo et al., 2003), naïve-bayes (NB) (McCallum et al., 1998), decision tree (Vlahou, et al., 2003), random forest (Diaz-Uriarte et al., 2006), ID3 (Elias, 2003), C4.5 (Quinlan, 2014) and various neural network based classifiers like multi layer perceptron (MLP) (Chaudhuri & Bhattarya, 2000), RBFNN (Subasini et al., 2009), FLANN (Misra & Dehuri, 2007), SVM (Chu & Lipo, 2005; Cortes et al., 1995; Furey et al, 2000; Hsu et al, 2003) are found in the literature. Amongst all the classifiers, ANN and its variants are extensively used by researchers to classify medical datasets (Delen et al., 2005). The success

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the ANN based classifier is mostly dependent on the number of hidden layers, number of nodes in each hidden layer, values of the weights between input to hidden layers, hidden to output layer and the learning algorithms. In the literature, it is generally seen that when ANN is associated with gradient descent learning algorithm the performance of the model becomes time consuming and computationally prohibitive (Fernadez-nakerro et al., 2012). Besides random choice of input weights for the gradient descent learning algorithm leads to slow convergence and local minima. Thus to avoid these limitations, Huang et al. proposed a novel learning algorithm i.e. extreme learning machine (ELM) (Huang G.B. et al, 2012) using a single hidden layer architecture. In recent years ELM and its variants have gained acceptance as a powerful tool for regression and binary and multiclass classification (Zhang, 2007; Huang G.B. et al., 2012) and outperform neural networks in gene expression and medical data classification. However, amongst all the ELM variants the kernel extreme learning machine (KELM) (Sundaram et al., 2010) is immune to the choice of random weights and biases between the input and hidden layers and provides better classification accuracy without satisfying Mercer's theorem (Huang W. et al., 2010; Bencherif et al., 2015).

A modified cat swarm optimization (MCSO) technique is proposed in this paper to select the most optimal features from microarray medical datasets and Kernel Extreme Learning Machine (WKELM and RKELM) to classify the features obtained from MCSO algorithm. From recent studies it is found that CSO based feature selection outperforms DE and PSO (Chu et al., 2007; Panda et al., 2011) based approaches. Further the MPSO algorithm is expected to improve search efficiency by getting the most optimal features from the high dimensional microarray medical dataset. The proposed feature selection methods employ k-nearest neighbor algorithm as the classifier and use five-fold cross validation technique to determine the classification accuracy.

The paper is organized as follows; section 2 describes the process model and benchmark microarray medical datasets, while section 3 deals with modified cat swarm optimization based feature selection method (MCSO). All the classifiers used in this study i.e. ELM,WKELM, RKELM and SVM are discussed in section 4. While section 5 presents performance evaluation measures, computer simulation results and discussion appear in sections 6 and 7 with concluding remarks in section 8, respectively.

2. PROCESS MODEL FOR CLASSIFICATION OF MICROARRAY DATASETS

In this section, the whole process like data normalization, feature selection and classification of binary microarray medical data is described. The steps are given in Figure 1. All the datasets are normalized using max-min normalization method as shown in equation (1).

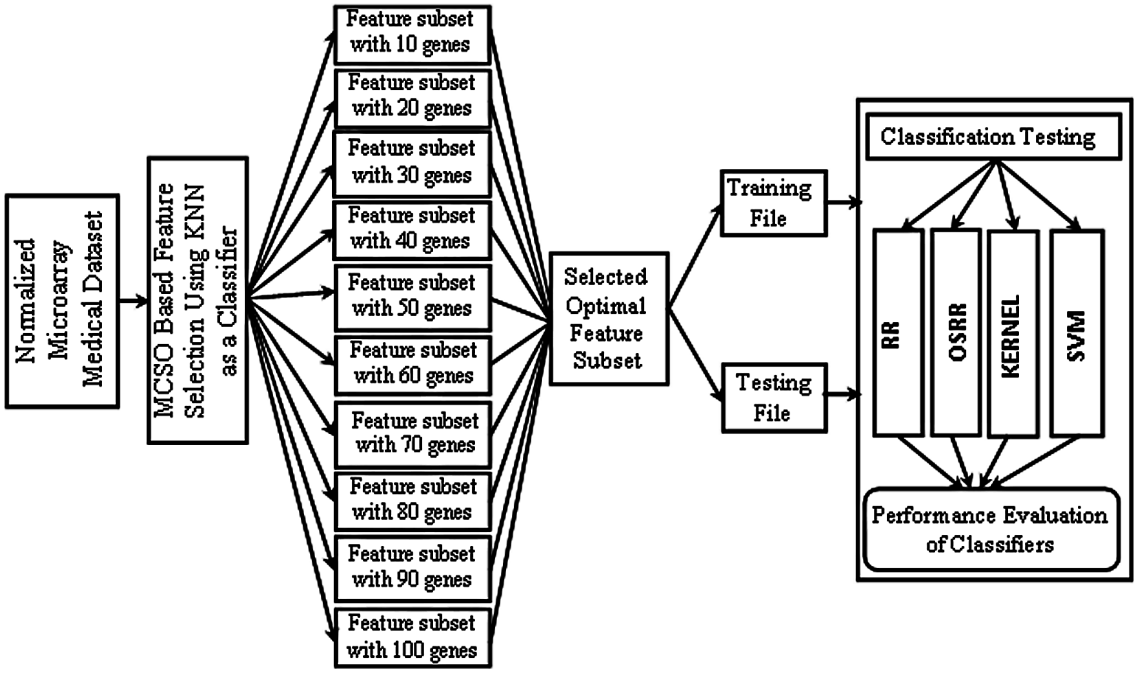
$$x_n = 2^* \frac{\left(x - x_{min}\right)}{x_{max} - x_{min}} - 1 \tag{1}$$

where x_n is the normalized form of original value x, $x_{\min}$ and $x_{\max}$ are the minimum and maximum of the dataset, respectively.

The modified cat swarm optimization algorithm (MCSO) (Saha et al.; 2013) is used to select the optimal feature subsets from these normalized datasets. For each dataset, MCSO is used to derive 10 subsets consisting of 10 to 100 genes in the interval of 10. To get the most optimal candidate features,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Process model used for classification of microarray medical datasets



k-nearest neighbor (KNN) classifier is considered to find out the classification accuracy. The subset with lower number of genes and highest classification accuracy (Statnikov et al., 2005) is chosen as the optimal candidate subset. The obtained subset is finally divided into training and testing files and used as input to all the models like ELM, WKELM, RKELM and SVM.

Four benchmark microarray binary datasets -Breast Cancer, Prostate Cancer, Colon tumor and Leukemia- are obtained from references (Li & Huiqing, 2002; Chen et al., 2012). Each dataset is divided into two data files i.e. training and testing. For binary datasets the output is either 0 or 1. Table 1 provides the features with the classes, number of samples taken for training and testing, respectively.

The Breast cancer contains 24481 features and 97 samples (Chen et al., 2012). Out of which 46 are from patients who had developed distance metastases within 5 years (labeled as "relapse"), the rest 51 samples are from patients who remained healthy after their initial diagnosis for interval of at least 5 years (labeled as "non-relapse").

Table 1. Benchmark medical datasets

Datasets	Dimension	Class	Samples	Features	Selected Features	% of Feature Reduction	Train. sample	Test. sample
Breast Cancer	97x24482	2	97	24481	50	0.2%	70	27
Prostate Cancer	136x12601	2	136	12600	50	0.4%	101	35
Colon Tumor	62x2001	2	62	2000	20	1.0%	40	22
Leukemia	76x7130	2	76	7129	100	1.4%	50	26

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Prostate cancer data set contains 12,600 features with 136 samples in which 77 samples are prostate tumor and 59 samples are normal (Liu Bing et al., 2004). The classification task is to identify the expression patterns that correlate with the distinction of prostate tumor from the normal.

The colon cancer dataset contains 2000 genes and 62 samples collected from colon cancer patients (Liu Bing et al., 2004). Amongst them, 40 tumor biopsies are from tumors and 22 normal biopsies are from healthy parts of the colons of the same patients. Originally this dataset contains 6500 genes. Based on the confidence in the measured expression levels two thousand genes are selectedand put into the feature selection process.

The Leukemia dataset consists of 7129 genes from 47 samples of Acute Lymphoblastic Leukemia (ALL) and 25 samples of Acute Myloid Leukemia (AML) (Liu Bing et al., 2004). Figure 1 shows the process model used for classification of microarray binary medical datasets.

3. CAT SWARM OPTIMIZATION BASED FEATURE SELECTION

Feature selection is an important aspect in micro array medical data classification. The main advantage of feature selection is getting the most optimal candidate features that help in improving classification accuracy and reducing computational overhead, resource demand and storage space requirement. In the process, the most influential features get selected so that the user can be able to interpret the relation between the features and classes (Bolon-Canedo et al., 2014; Fong et al., 2013). In this study, evolutionary algorithm CSO and MCSO (Lin K.C. et al., 2014) has been applied to select the most optimal features from the binary microarray medical data sets.

The CSO (Lin K.C. et al., 2014) is a relatively new population-based, meta-heuristic evolutionary algorithm that models the behavior of cats into two modes namely the seeking mode and the tracing mode. One important characteristic of cats is that they spend most of their time in inertia and preserve their energy for future chase. In normal time their movement also very slow. When they sense a prey they chase it very quickly spending large amount of energy. The CSO refers to these two behaviors; resting with slow movement and chasing with high speed and energy as seeking and tracing modes. Similar to particle swarm optimization Cats are used in CSO as particles in D dimensions with velocities in search space. Further every cat in the CSO is associated with a fitness function and a flag to indicate whether the cat is in seeking mode or in the tracing mode. The soaring speed in seeking mode is mathematically mapped as a large change in its position.

3.1. Seeking Mode

The seeking mode has five operators namely: Seeking Memory Pool (SMP), Seeking Range of selected Dimension (SRD), Counts of Dimension to Change (CDC), Self Position Consideration (SPC) and Mixture Ratio (MR).

SMP describes the pool size of seeking memory or number of copies of a cat produced i.e. if the value of SMP is fixed as 10, than each cat is competent to store 10 solution sets as candidates.

SRD is used to state the mutative portion for the selected dimensions i.e. if a dimension is selected for mutation, the difference between the old and new values may not be out of range.

CDC corresponds to the number of dimensions to be transformed in the seeking process.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

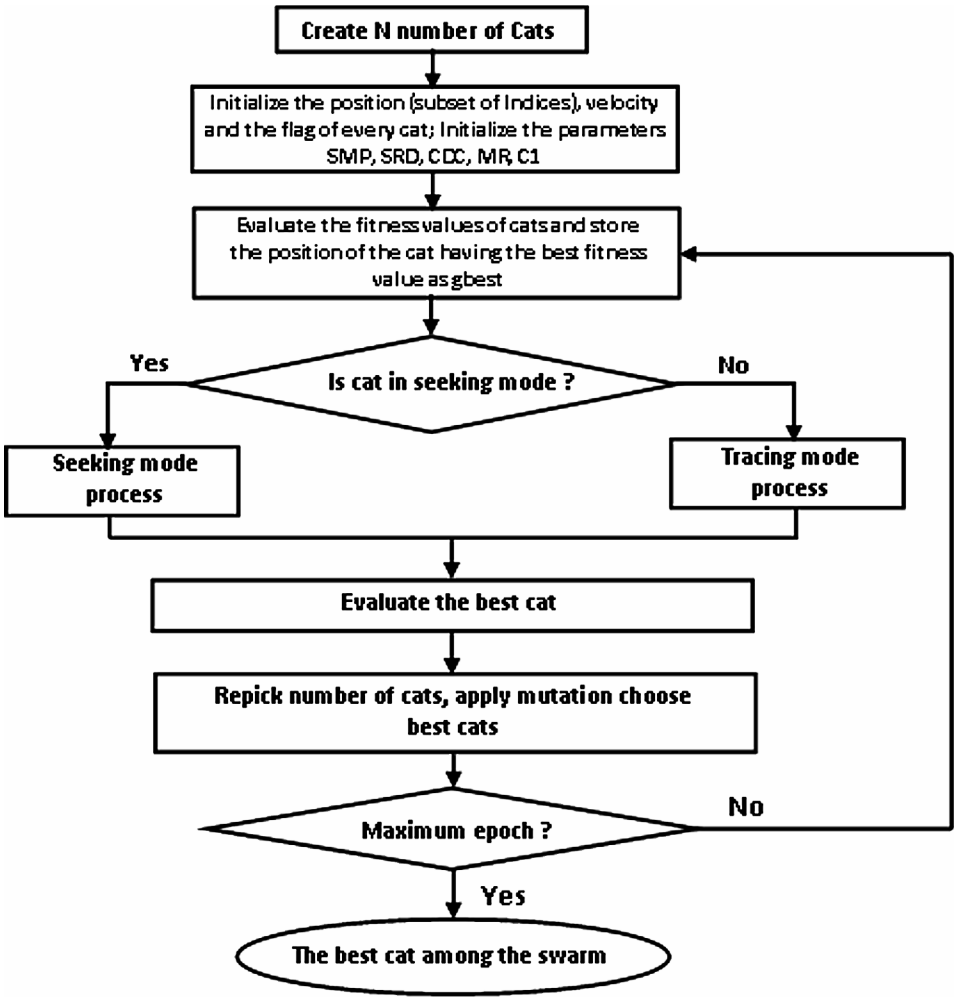
SPC is a Boolean value and if it is true, one position within the memory will save the current solution set and not be changed.

MR is a very small value i.e. fraction of population is used to guarantee that the cats spend most of their time in seeking mode.

The flow chart of CSO is given in Figure 2 and the steps executed in seeking mode are given as:

Step 1: Number of cats i.e. N are created by initializing the position, velocities and the flag of each cat.
Step 2: Pick a number of cats and according to MR put them into tracing and seeking mode.
Step 3: Evaluate the fitness value based on its positions.
Step 4: If the termination condition is met, final solution will be the best position of each cat in the solution space. Otherwise, go to Step 2.

Figure 2. Flow chart for Cat Swarm Optimization



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.2. Tracing Mode

Tracing mode is very much similar to the local search method of swarm in particle swarm optimization algorithm. In this mode, cats trace the targets with high energy by changing the positions with their own velocities. Position and velocity of the i^{th} cat in the D dimensional solution space are represented as

$$X_i=[X_{i1},X_{i2},X_{i3},.....X_{iD}] \tag{2}$$

$$V_i=[V_{i1},V_{i2},V_{i3},.....V_{iD}] \tag{3}$$

Global best position of the cat swarm is represented as

$$gbest=[gbest_1,gbest_2,.....gbest_D] \tag{4}$$

Update the velocity and position of the current cat using equations (5) and (6)

$$V_{iD} = w * V_{iD} + c_1 * r_1 * (gbest_D - X_{iD}) \tag{5}$$

$$X_{iD} = X_{iD} + V_{iD} \tag{6}$$

where w is the inertia weight, c_1 is the acceleration constant and r_1 is a random number uniformly distributed in the range (0,1). A large inertia weight facilitates a global search while a small inertia weight facilitates a local search. In this study, w is set as 0.9 initially. Normally the inertia weight has a large value in the beginning of the search and it decreases as the global best solution is achieved. Let $F_{g,k}$ is the best fitness value corresponding to $gbest_D$ and fitness differential between kth and k-1th iteration is obtained as

$$\Delta F_k = \left|F_{g,k} - F_{g,k-1}\right|, \text{ and } s=\Delta F_k/f_1,\ s\leq 1 \text{ and } s>0 \tag{7}$$

Here s signifies the convergence speed and f is obtained as

$$f = \max[\Delta F_1, \Delta F_2,\ldots,\Delta F_k] \tag{8}$$

In swarm optimization the diversity of population of cats is computed using the standard deviation of fitness values of population and is obtained as

$$\sigma = \sqrt{(1/pop)\sum_{j=1}^{pop}(\frac{F_{j,k} - F_{avg,k}}{ff})}, \quad F_{avg,k} = (1/pop)\sum_{j=1}^{pop} F_{j,k} \tag{9}$$

$$ff = \max[(F_k(1) - F_{avg,k}),(F_k(2) - F_{avg,k}),.....,(F_k(pop) - F_{avg,k})] \tag{10}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

where $F_{avg,k}$ is the average population fitness in the kth iteration. $F_k(i)$ is the ith particle fitness at the kth iteration. Finally the inertia weight is iteratively tuned as

$$w_k = w_{k-1} + \alpha s + \beta\sigma^2 \tag{11}$$

where α, β are factors which are to be chosen. Here $\sigma^2>0$,$s>0$, $0.4\leq w\leq 0.9$.

In equation (5) c1 is an acceleration coefficient to influence the velocity of the cat in the solution space and is normally chosen as 2.0. However to provide adaptive nature to CSO, this is updated as

$$c_1 = c_0 - \frac{(k_{\max} - k)}{2k_{\max}}, c_0 = 2 \tag{12}$$

A cat swarm represents a set of indices. Using these indices, corresponding reduced feature subset is derived from the original dataset. It may happen that at the time of selection one or more number of indices may not fall within the range of columns present on that particular dataset. The following formula is adopted to select every new index value within the range of columns.

if index_value≤max_*column* && *index_value*≥0.25*max_*column*

new_index =index_value-SRD% of in*dex_value* *(13)*

else

*new_index =index_va*lue+SRD% of *index_value* *(14)*

*To get most optimal cand*idate features with better classification accuracy, Modified Cat Swarm Optimization (explained in next section) is applied to all the datasets.

3.3. Modified Cat Swarm Optimization (MCSO)

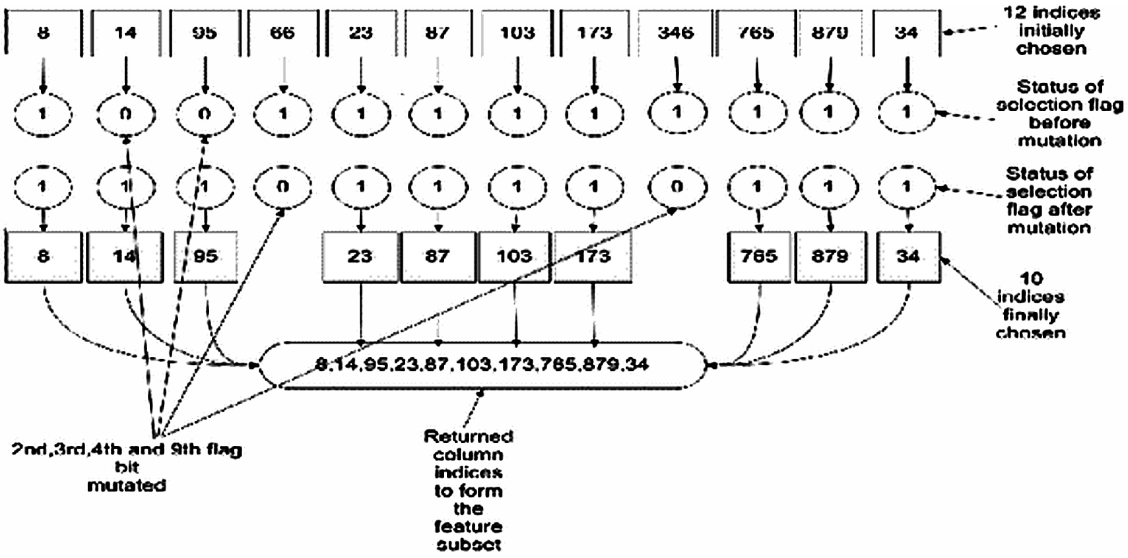
This study proposes a modified cat swarm optimization (MCSO) to improve searching ability in the locality of the best cats. In cat swarm optimization, tracing mode helps the cats in updating their velocities using equation 5. Once the best cats are chosen based on their fitness, the CSO method re-picks the number of cats and on the basis of mixture ratio (MR) distributes them into seeking mode and tracing mode. But in MCSO method, the re-picked cats are again subjected to mutation (Lin K.C. et al., 2014) and in the process randomly chosen indices are mutated. The mutation operation in MCSO is briefly described in the following sub section.

3.3.1. Mutation Operation in MCSO

Mutation operation helps in generating new solution sets in the vicinity of other solution sets. As mutation is applied randomly over the feature subset, every feature has a chance to be altered i.e. from selected to unselected and vice versa. At first, all the indices have been marked by setting their individual status

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Introduction of mutation in MCSO algorithm



flag as 1 (selected) and 0 (unselected).Initially for generating an optimal feature subset consisting of 10 features, 12 indices are chosen by MCSO in which 10 indices are marked as selected i.e. 1 and two indices are marked as unselected i.e. 0.The procedure is explained in Figure 3. When mutation is applied to 2nd,3rd indices, their stat[us] h[av]e been changed to 'selected' and status of 4th and 9thindices become u[ns]electe[d.] Finally, the mutated subsets with minimum features with maximum accuracy are selected for the real classification using ELM, WKELM, RKELM and SVM.

While determining the fitness of the cats, K-Nearest Neighbor (KNN) (Nakamura et al., 2012), the most popular and traditional classifier, has been chosen to determine classification accuracy of the feature subset. In KNN, 5-fold cross validation technique is used to determine the classification accuracy.

3.3.2. Modified Cat Swarm Optimization Algorithm

```
Begin
       Generate an Initial Swarm of 'n' no. of cats or different solutions xi
(i=1, 2,..,n)
       Initialize  position(subset of indices), velocity,  flag of every cat
       Initialize  parameters- SMP,SRD,CDC,MR,C1
       while (it<NI)
              do
                     distribute the cats into seeking/tracing mode
                            while (t< Max_Cats)
                                   do
                                          Get a Catt and Evaluate its fitness
Fi using KNN
                                          if  (Catt is in seeking mode) then
                                          Search  by seeking mode process

```
else
Search  by tracing mode process
                              end if
                              Update the best cats/solutions
                            Repick the number of cats and apply mutation
                     find the current best cat among the swarm
end while
       end while
    Generate the optimal feature subset using the selected indices
end
```

In Table 2, number of gene selected and the classification accuracies obtained from both CSO and MCSO using KNN classifier for all four data sets are depicted. Finally, the highest classification accuracy with the minimum number of genes are selected and considered for the real classification using ELM, WKELM, RKELM and SVM models. Figure 4 shows the number of selected gene and the corresponding classification accuracy obtained from KNN algorithm and MCSO based feature selection technique.

4. ELM, KERNEL ELM AND SVM CLASSIFIERS

This section discusses all four classifiers -ELM, Kernel ELM and SVM- used to classify binary microarray medical datasets.

Table 2. Number of gene selected and classification accuracy using KNN from all the datasets after CSO, MCSO based Feature Selection

Genes Selected	Breast Cancer		Prostate Cancer		Colon Tumor		Leukemia	
	CSO	MCSO	CSO	MCSO	CSO	MCSO	CSO	MCSO

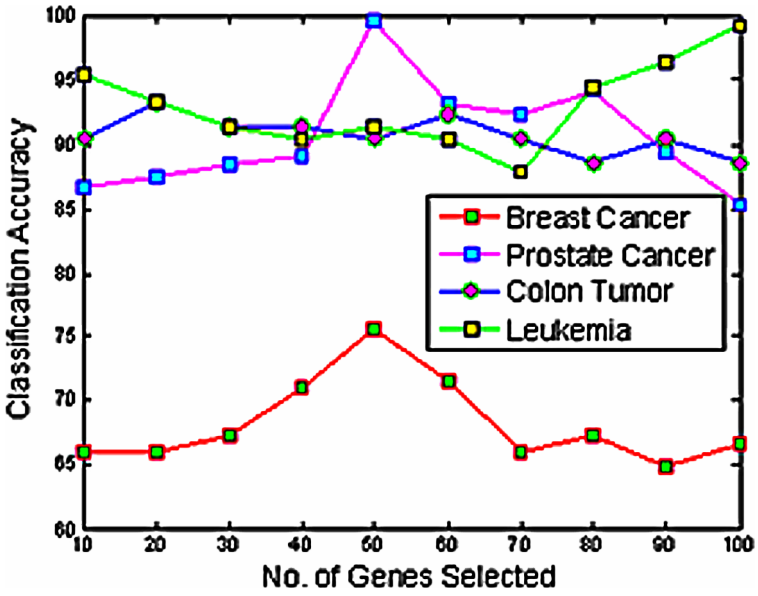
Figure 4. No. of gene selected and classification accuracy (MCSO)



4.1. Extreme Learning Machine

Extreme learning machine (ELM) originally proposed by G.B. Huang (Huang G.B et al., 2012) for single layered feed forward neural networks (SLFN) provides efficient learning paradigms when applied in clustering, regression and classification of real world problems. The hidden layer parameters of the ELM are computationally free from iterations that make ELM extremely fast by significantly reducing the computational time required to train the SLFNs. The SLFN model often requires high number of hidden neurons while generating optimal solutions. Further the hidden layer parameters can be chosen in a random manner independent of the training samples. Figure 5 shows the architecture of the ELM chosen for classification of binary microarray medical datasets. The output function of the ELM with L hidden nodes can be represented by the following equations.

$$f_L(x) = \sum_{i=1}^{L} \beta_i g_i x = \sum_{i=1}^{L} \beta_i G(a_i, b_i, x), x \in R^d, \beta_i \in R^m \tag{15}$$

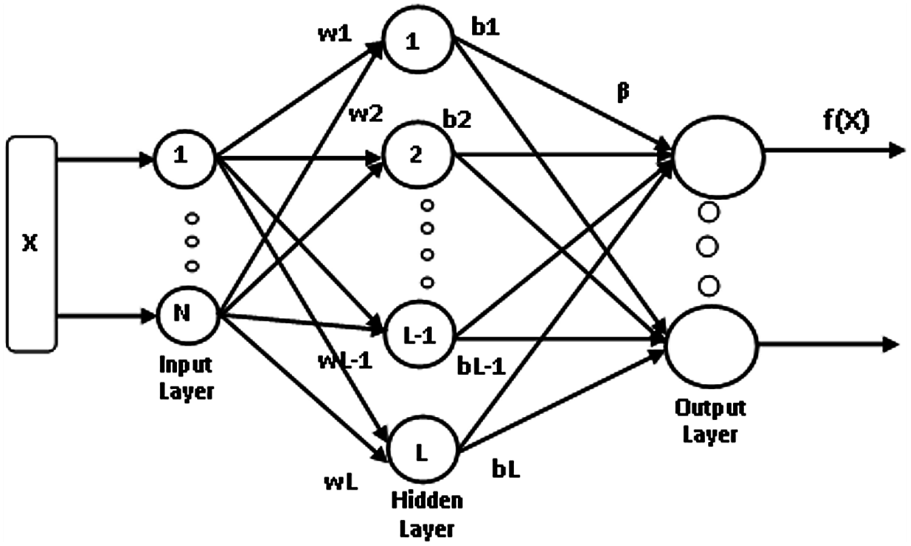
For additive nodes with activation function g, g is defined as

$$g_i = G(a_i, b_i, x) = \mathrm{g}(a_i x + b_i), a_i \in R^d, b_i \in R \tag{16}$$

$$\sum_{i=1}^{L} \beta_i G(a_i, b_i, x) = t_j, j = 1, \ldots\ldots\ldots N \tag{17}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Architecture of ELM



The above equation is rewritten as

$$H\beta = T \tag{18}$$

where

$$H(w_1 \ldots w_L, b_1 \ldots b_L, x_1 \ldots x_N) = \begin{pmatrix} g(w_1.x_1 + b_1) & \cdots & g(w_L.x_1 + b_L) \\ \vdots & \ddots & \vdots \\ g(w_1.x_N + b_1) & \cdots & g(w_L.x_N + b_L) \end{pmatrix} \tag{19}$$

$$\beta = \begin{bmatrix} \beta_1^T \\ \vdots \\ \beta_N^T \end{bmatrix} \tag{20}$$

$$T = \begin{bmatrix} t_1^T \\ \vdots \\ t_N^T \end{bmatrix} \tag{21}$$

H represents the hidden layer output matrix of the neural network, *T* is the target vector, and β represents the weight vector between the hidden layer neurons and the output layer neuron. It has been shown in reference (Huang G.B et al., 2012) that given an arbitrary small value $\in > 0$, if the hidden layer activation function is infinitely differentiable, the number of hidden neurons $L \leq N$, the input weights

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and hidden layer biases can be evaluated, then ELM can be trained to solve a linear system optimization problem using the following equation.

$$|| H \hat{\beta} - T ||= \min_{\beta} || \mathrm{H}\beta - T || \tag{22}$$

where $\hat{\beta}$ is obtained as,

$$\hat{\beta} = H^{\dagger}T = (H^{T}H)^{-1}H^{T}T \tag{23}$$

and is the smallest norm least square solution of w_i=T; $H^{\dagger}$ represents the Moore Penrose generalized inverse of H.

The procedure of ELM can be summarized in the following three steps:

Step 1: Choose the input weights w_i and hidden layer biases b_i randomly.
Step 2: Compute the hidden layer output matrix H.
Step 3: Obtain the output weight $\hat{\beta}$ using the equation $\hat{\beta} = H^{\dagger}T$

Here the function $g(w_1x_1+b_1)$ in equation is chosen as

$$g(w_1x_1+b_1) = \tan h(w_1x_1+b_1) \tag{24}$$

and w_1 and x_1 are the first weight and pattern vectors, respectively.

4.2. Kernel Extreme Learning Machine

In standard ELM, the role of the hidden layer is to map the input layer neurons to the hidden layer neurons i.e. hidden layer neurons of the ELM are mapping data from the data space to some higher dimensional space, where each dimension corresponds to a hidden neuron. Hence, the performance of ELM mostly depends upon the hidden layer neurons and it is application specific. To avoid the above said hidden neuron selection problem a newly developed kernel ELM (Lin Bin et al., 2014) (KELM) has been used to classify all microarray medical datasets considered in this study. In KELM, a positive regularization coefficient 'C' is introduced to make it more generalized and stable. Now the output weight β is

$$\beta = H^{T}\left(\frac{1}{C} + HH^{T}\right)^{-1} T \tag{25}$$

here H is the hidden layer output matrix, C is the regulation coefficient and T is the output matrix. The output function of ELM becomes

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$f(x) = h(x)H^T \left(\frac{1}{C} + HH^T\right)^{-1} T \tag{26}$$

Here, instead of knowing the hidden layer feature mapping, $h(x)$, its corresponding $k(u,v)$ can be computed. The absence of L i.e. hidden layer neurons in KELM further simplifies Kernel ELM computation process. The kernel matrix of ELM based on Mercer's condition can be defined as

$$\theta_{ELM} = HH^T : \theta_{ELMi,j} = h(x_i).h(x_j) = k(x_i, x_j) \tag{27}$$

Hence the output of the kernel based ELM is written as

$$f(x) = h(x)H^T \left(\frac{1}{C} + HH^T\right)^{-1} T = \begin{bmatrix} k(x, x_1) \\ \bullet \\ \bullet \\ k(x, x_N) \end{bmatrix}^T \left(\frac{1}{C} + \theta_{ELM}\right)^{-1} T \tag{28}$$

where $\theta_{ELM}=HH^T$ and $k(x_i, x_j)$ is the kernel function of hidden neurons of single hidden layer feed forward neural network. Amongst the different kernel functions satisfying Mercer's conditions available in the literature the wavelet kernel (WKELM) and radial basis function kernel (RKELM) are considered in this study. Radial basis kernel function is a typical local kernel function in which λ and Υ are used as the parameters. On the other hand, the complex wavelet kernel function uses vector i.e. [d, e, f] as parameters. Depending on the datasets, right choice of kernel function and proper tuning of the parameters are highly required to get better results.

- Radial basis kernel

$$k(x, y) = e^{\left(-a\|x-y\|\right)} \tag{29}$$

- Wavelet kernel

$$k(x, y) = \cos\left(d\frac{\|x-y\|}{e}\right) e^{\left(-\frac{\|x-y\|^2}{f}\right)} \tag{30}$$

Kernel ELM is advantageous in comparison to ELM because there is no requirement of knowing the hidden layer feature mapping and setting the number of hidden layer neurons L. It achieves better generalization, more stability compared to ELM and is faster than SVM.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. PERFORMANCE EVALUATION METRICS

Performance of all the classifiers are evaluated by different measures like training accuracy, testing accuracy, confusion matrix, Receiver Operating Characteristic curve (ROC), sensitivity, specificity, Gmean, and F-score, etc.

5.1. Confusion Matrix

Confusion matrix represents the values of TP, TN, FP, FN (Abdulahamit, 2004; Ferri et al., 2009; Bowes et al., 2012). TP (True Positive) - correctly classified positive samples, TN (True Negative) - correctly classified negative samples, FP (False positive) - misclassified negative samples and FN (False negative) - misclassified positive samples.

5.2. Classification Accuracy

The classification Accuracy (Abdulahamit, 2004; Malathi et al., 2010) is a commonly used evaluation criterion for a standard classification system.

$$\text{Accuracy}= \frac{TP+TN}{TP+TN+FP+FN} \tag{31}$$

5.3. Sensitivity

Sensitivity (Abdulahamit, 2004) is also known as TPR (true positive rate) or recall. Sensitivity evaluates how well a model can recognize abnormal records. Higher the sensitivity is better the classifier becomes. It always identifies proportion of accurately classified samples to total samples.

$$\text{Sensitivity}= \frac{TP}{TP+FN} \tag{32}$$

5.4. Specificity

Specificity is regarded as the TNR (true negative rate). Specificity measures the ability of the proposed method to identify normal cases. It identifies accurately classified negative samples to total samples. If specificity becomes high like sensitivity and their difference is very less (<1%), then the classifier is a better one. Consider

$$\text{Specificity}= \frac{TN}{TN+FP} \tag{33}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5.5. Gmean

Gmean (Bowes et al., 2012) is used when the combined performance of the two classes need to be judged by a single metric. It measures both the sensitivity and specificity in a balanced manner.

$$Gmean = \sqrt{Sensitivity * Specificity} \tag{34}$$

5.6. F-Score

Like Gmean, F-score (Ferri et al., 2009; Bowes et al., 2012) is also an important metric to check the combined performance.

F-score =(2*Sensitivity*Specificity)/(Sensitivity+Specificity) (35)

5.7. ROC

ROC curve (Slaby, 2007) is a graphical representation of sensitivity against (1-specificity).

6. SIMULATION RESULTS

In this section, obtained results from all six models -ELM, OSELM, WKELM, RKELM, SVMRBF and SVMPoly–and the datasets considered in this study have been given. All the classifiers are implemented in the following environment, Operating System: Windows XP professional, CPU: Intel Core i3-370M (2.4 GHz), and Memory: 4GB RAM.

The number of hidden nodes 'L' in ELM is varying from 2 to 22 with an increment of 2 neurons each time. A vector consisting of three parameters [p1, p2, p3] is given as an input to WKELM. The parameters p1 and p3 are kept constant as 1 and 10, respectively whereas p2 is varied from 4 to 44 at an increment of 4. In RKELM, λ is varied as 2^1, 2^1.5,……,2^6 and ϒ is varied as 2^-1, 2^-1.5,……2^-6, respectively. Simulation results for binary class datasets in respect of ELM, OSELM, kernel extreme learning machines like WKELM and RKELM are demonstrated through graphs and Tables. Figures 6-9 show testing accuracy of ELM, OSELM, WKELM, and RKELM, respectively. Since from Figure 7 it is observed that OSELM does not perform as well as the ELM, subsequent performance measures like Sensitivity and specificity of only ELM, WKELM and RKELM for all binary class datasets are shown in Figures 10-15, respectively. Figure 16 represents sensitivity vs specificity vs Gmean of WKELM of Breast cancer dataset. Figures 17 and 18 represent ROC for WKELM and RKELM of all the datasets, respectively. Results obtained from all the datasets like time required for training (Trg time), training accuracy (Trg Acc), testing accuracy (Tst Acc) and standard deviation of testing accuracy (stdv Tst Acc), TP, FN, FP, TN, sensitivity, specificity, Gmean, F-Score and Wt-norm, training and testing accuracy for ELM is demonstrated in Tables 3 to 6 along with the training and testing accuracy of OSELM, respectively. Tables 7-10 and 11-14 display results obtained from WKELM, and RKELM, respectively.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

All microarray medical datasets are classified using SVM scikit learn (Pedregosa et al., 2011). Two types of kernels i.e. RBF and Polynomial are chosen. The simulation results like precision, recall, F_1-score, classification accuracy, AUC values and confusion matrices for binary appear in Table 15.

7. DISCUSSION

In this paper, extreme learning machine variants like ELM, OSELM, WKELM, RKELM, along with support vector machines models like SVMRBF and SVMPoly are used to classify binary microarray medical datasets very effectively. The evolutionary meta-heuristic algorithm like CSO and MCSO are used to select the most optimal candidate subsets. Number of gene selected and classification accuracy obtained from KNN in feature selection step are analyzed and compared. From Table 2, it is clearly demonstrated that MCSO yields better classification results in comparison with CSO.

Maximum classification accuracy and AUC for all the models and datasets are given in Table 16. It is observed from the Tables that the Kernel ELM exhibits testing accuracy of 97, 97, 95, 95 percent for breast cancer, prostate cancer, colon tumor, leukemia respectively. This clearly demonstrates the superiority of KELM in comparison with ELM, OSELM, SVMRBF and SVMPoly models. Further amongst the two variants of KELM i.e. WKELM and RKELM, the former produces better accuracy than that of the latter in all datasets except one i.e. prostate cancer. Maximum classification accuracy obtained from all the models and datasets are represented through a bar graph shown in Figure 19. Also it is seen from Figures 10-15 WKELM produces higher sensitivity and specificity as compared to other models. Also WKELM shows better ROC, in comparison to that of RKELM as demonstrated in Figures 17 and 18. KELM gives more AUC value in all the four datasets of breast cancer, prostate cancer, colon tumor, leukemia considered in this study as compared to those belonging to ELM, OSELM,SVMRBF and SVMPoly, respectively. Further, it is seen from the literature that the classification accuracies ob-

tained from all the datasets are at par with the contemporary researchers. For example in (Nguyen et al., 2015) the classification accuracy of breast cancer data using PNN, SVM, FARTMAP, ANFIS, SAM and GASAM models are 94, 96, 95, 96, 96 and 97 respectively.

8. CONCLUSION

Microarray data analysis and classification are very pertinent for the effective diagnosis of different varieties of cancer. However, microarray medical datasets exhibit high dimensionality thereby causing difficulties in accurately identifying the type of cancer. Thus the most relevant features are extracted from the data by using a meta-heuristic cat swarm optimization (CSO) technique. Further to improve the feature selection process a modified CSO known as MCSO is proposed in this paper and its performance

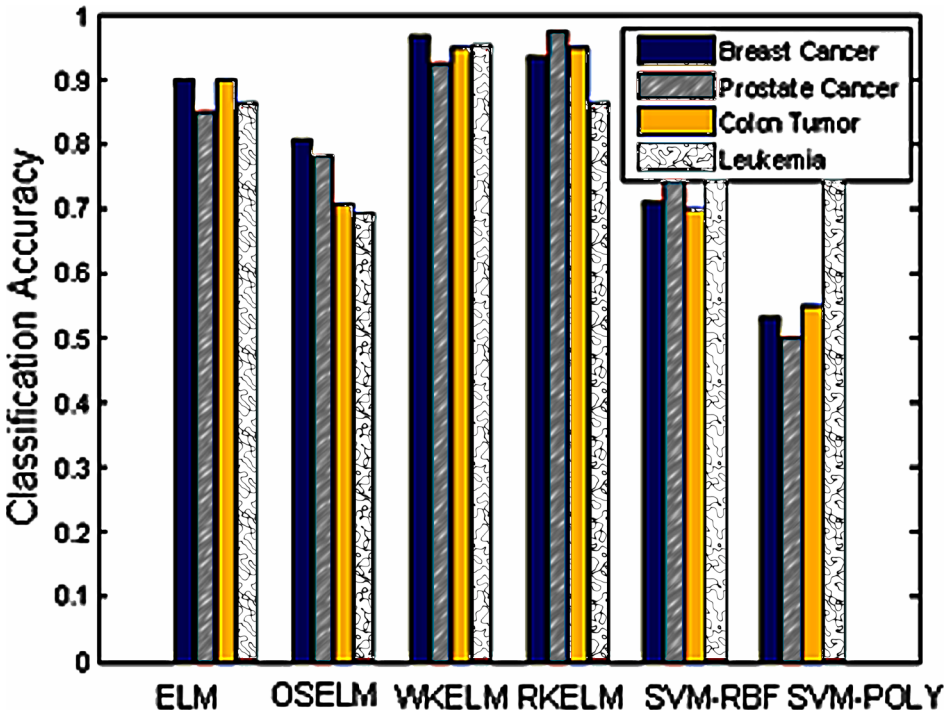
Figure 19. Testing accuracy for all models with all datasets



is compared with CSO validating its superiority over the latter. The selected features are used as inputs to ELM and its variants OSELM, WKELM and RKELM for microarray medical data classification. To provide comparison two powerful SVM classifiers known as SVMRBF and SVMPoly are used for classification of the microarray data. Various performance metrics like training and testing accuracy, sensitivity, specificity, confusion matrix, Gmean, F-score and the area under the receiver operating characteristic (ROC) curve, etc. are used to evaluate the efficacy of all models. From simulation experiments it can be concluded that the kernel ELM (KELM) outperforms ELM, OSELM and SVM computing models irrespective of the datasets used. However, when the comparison is made between two variants of KELM i.e. WKELM and RKELM, WKELM yields better accuracy in three out of four datasets used.

ABSTRACT

Crackles are adventitious respiratory sounds (RS) that provide valuable information on different respiratory conditions. Nevertheless, crackles automatic detection in RS is challenging, mainly when collected in clinical settings. This study aimed to develop an algorithm for automatic crackle detection/characterisation and to evaluate its performance and accuracy against a multi-annotator gold standard. The algorithm is based on 4 main procedures: i) recognition of a potential crackle; ii) verification of its validity; iii) characterisation of crackles parameters; and iv) optimisation of the algorithm parameters. Twenty-four RS files acquired in clinical settings were selected from 10 patients with pneumonia and cystic fibrosis. The algorithm performance was assessed by comparing its results with a multi-annotator gold standard agreement. High level of overall performance (F-score=92%) was achieved. The results highlight the potential of the algorithm for automatic crackle detection and characterisation of RS acquired in clinical settings.

INTRODUCTION

Acute and chronic respiratory diseases are a major health, societal and economic burden worldwide (World Health Organization, 2008). Therefore, during the last decade, several research efforts have been dedicated to improve the diagnosis, management and monitoring of patients with respiratory diseases (Dinis, Campos, Rodrigues, & Marques, 2012).

Although several measures are available to diagnose and monitor respiratory diseases, conventional auscultation remains the most widely used. The stethoscope has been used for 200 years to perform clinical examinations as it is simple, non-invasive, economic, practical and useful in all populations and settings (Bohadana, Izbicki, & Kraman, 2014). However, it is known that conventional auscultation is subjective, i.e., the interpretation of respiratory sounds depends on the stethoscope properties (Welsby & Earis, 2001), hearing ability and clinical experience of users (Sovijärvi, Vanderschoot, & Earis, 2000) and their capacity to memorise sound patterns (e.g., number and characteristics of adventitious respiratory sounds) (Marques, Bruton, & Barney, 2006).

To overcome the subjectivity associated with conventional auscultation, research efforts have been devoted to improve computerised respiratory sound analysis (CORSA). CORSA consists of recording respiratory sounds with an electronic device and objectively analysing/classifying them based on advanced digital signal processing techniques (Sovijärvi, Vanderschoot, & Earis, 2000). The digitalization of respiratory sounds recordings has the advantages of: i) being compatible with digital signal processing techniques for sound analysis and classification; ii) allowing the precise definition of recording characteristics (e.g., recording level and bandwidth), which can be adjusted to the type of signals that are going to be studied (Cheetham, Charbonneau, Giordano, Helistö, & Vanderschoot, 2000); and iii) overcoming the barriers associated with clinicians having to memorise sound patterns. Through CORSA, respiratory sounds were found to be a more sensitive indicator, detecting and characterising the severity of respiratory diseases before any other measure (Gavriely, Nissan, Cugell, & Rubin, 1994). Furthermore, CORSA can also boost the development of mathematical models of the underlying physical mechanisms of respiratory sound production, to characterise the interaction of mechanical forces, airflow and sound transmission within the respiratory tract (Earis & Cheetham, 2000). This may provide important information to understand and relate different processes of diseases (Earis & Cheetham, 2000).

Computerised respiratory sounds are thus a simple, objective and non-invasive measure to assess the function of the respiratory system (Bohadana et al., 2014). Therefore, special attention has been given to their automatic detection and characterisation, as changes in their properties can early inform the presence of several respiratory conditions (Sovijärvi, A., Malmberg, L., et al., 2000), e.g., pneumonia (Piirila, 1992), bronchiectasis and cystic fibrosis (Marques, Bruton, & Barney, 2009).

Briefly, respiratory sounds can be classified into normal and adventitious respiratory sounds. Adventitious respiratory sounds are continuous (i.e., wheezes and rhonchus) or discontinuous (i.e., fine crackles and coarse crackles) sounds superimposed on normal respiratory sounds (Bohadana et al., 2014). The specific characteristics of wheezes, such as its duration (longer than 100 ms) and exhibition of distinct peaks in the frequency domain (> 100 Hz) have facilitated the development of methods for its automatic detection and characterisation (Taplidou & Hadjileontiadis, 2007). Crackles, however, are discontinuous, transient and explosive sounds of no more than 20 ms (Sovijärvi, A., Malmberg, L., et al., 2000). These characteristics introduced additional complexity in their automatic detection, and thus further research is needed to overcome this problem.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Crackles occur frequently in cardiorespiratory diseases (Charbonneau et al., 2000; Sovijärvi, A., Malmberg, L., et al., 2000) and their presence has been associated with the severity of diseases. Therefore, the study and detailed analysis of these discontinuous adventitious sounds is important to early detect respiratory diseases and enhance their assessment and monitoring. Previous research has predicted that crackles originating from smaller airways are shorter in duration (i.e., fine crackles) than those originating from larger airways (i.e., coarse crackles) (Sovijärvi, A., Malmberg, L., et al., 2000). Fine crackles are high-pitched inspiratory events that tend to occur in the mid-to-late inspiration and coarse crackles are low-pitched and often occur in the early inspiration and occasionally in expiration as well (Sovijärvi, A., Malmberg, L., et al., 2000). The most studied crackles parameters are:

- The initial deflection width (IDW), which is the duration of the first deflection in a crackle waveform;
- The largest deflection width (LDW), which is the duration of the deflection of the largest amplitude in a crackle waveform;
- The two cycle duration (2CD), which is the time from the beginning of the initial deflection of a crackle to the point where the waveform of the crackle has completed two cycles (Charbonneau et al., 2000; Sovijärvi, A., Malmberg, L., et al., 2000).

These and other parameters are represented schematically in Figure 1.

Despite the great value of crackles to contribute for the diagnosis and monitoring of respiratory diseases, their recognition and characterization in respiratory sound files recorded in clinical settings is particularly challenging. Concerning human detection, the level of agreement among health professionals' annotation of crackles has been reported has poor, independently of the health professional

background and years of experience (Allingame, Williams, Jenkins, & Tucker, 1995; Brooks & Thomas, 1995; Machado, Oliveira, Aparício, & Marques, 2015). Computerised methods for automatic detection of crackles eliminate this subjectivity (Hadjileontiadis & Rekanos, 2003; Lu & Bahoura, 2008; Vannuccini, Rossi, & Pasquali, 1998). However, the performance of computerised methods is also uncertain, as respiratory sound files acquired in clinical settings have often artefacts (e.g., environmental noise and movement artefacts), which affect the recognition accuracy of algorithms (Chang & Lai, 2010).

Several signal processing techniques have been proposed, including digital filters (Ono, Arakawa, Mori, Sugimoto, & Harashima, 1989), spectrogram analysis (Kaisla et al., 1991), time-domain analysis (Kaisla et al., 1991), auto-regressive models (Hadjileontiadis & Panas, 1996) and wavelet-packet transform methods (Lu & Bahoura, 2008), fuzzy filters (Mastorocostas, Tolias, Theocharis, Hadjileontiadis, & Panas, 2000) and fractal dimension filtering (Hadjileontiadis & Rekanos, 2003). Despite the high values of sensitivity and specificity associated with these techniques, limited testing (Hadjileontiadis & Rekanos, 2003; Lu & Bahoura, 2008; Vannuccini, Rossi, & Pasquali, 1998) have been performed with respiratory sound files recorded in clinical settings and few have been validated against a multi-annotator gold standard (Quintas, Campos, & Marques, 2013). The gold standard annotation of respiratory sound files can only be achieved by human expert annotation (Marques et al., 2006). Nevertheless, human annotation has an underlying subjectivity (Marques et al., 2006) and therefore, manual annotation performed independently by multiple annotators is essential to produce a more accurate gold standard. Thus, the gold standard must result from the application of statistical agreement criteria to multiple independent annotations obtained for each file (Quintas et al., 2013). Therefore, the acquisition of respiratory sounds in clinical settings and the validation of automatic detection algorithms against a multi-annotator gold standard, are key features to address in the development of more robust algorithms.

Taking these factors into consideration, it may be hypothesised that, when tested in such conditions (i.e., sounds recorded in clinical settings and validation of results against a multi-annotator gold standard), the signal processing techniques proposed in the literature will have lower performances than originally reported. Therefore, a robust algorithm to detect and characterise crackles in respiratory sound files acquired in clinical settings is needed.

This study aimed to develop a new integrated approach for automatic crackle detection and characterisation (based on fractal dimension and box filtering techniques), and to evaluate its performance and accuracy against a multi-annotator gold standard (obtained by the agreement among three experts). Accordingly, this paper is organised in the following four sections: i) *Methods*, which describes the methodologies underlying the development and validation of the proposed algorithm; ii) *Results*, which presents the results of the algorithm's validation in terms of sensitivity (SE); positive predictive value (PPV) and F-score; iii) *Discussion*, which discusses the results and highlights possible improvements; and iv) *Conclusion and future work*, which concludes the paper and presents future work.

METHODS

The development and evaluation of the algorithm for automatic crackle detection and characterisation was performed using a sample of twenty-four respiratory sound files. Fifteen respiratory sound files were acquired in a community clinical setting from 6 adult patients with pneumonia (3 females; mean age 46 $\pm$ 14.6 years old) and 9 respiratory sound files were acquired in a hospital environment from 4 patients with cystic fibrosis (6 females; mean age 32.3 $\pm$ 18.1 years old). The selection of these respiratory sound

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

files was based in previous research showing that pneumonia and cystic fibrosis are respiratory diseases characterised by the presence of crackles (Marques et al., 2009; Piirila, 1992). These respiratory sound files were obtained from 2 academic repositories managed by one of the authors of this paper (Alda Marques). Respiratory sounds of patients with cystic fibrosis were collected during a PhD project at the School of Health Sciences of the University of Southampton (SFRH/BD/21375/2005). Respiratory sound files of patients with pneumonia belong to a repository built at the School of Health Sciences of the University of Aveiro in the scope of a research project (PTDC/SAU–BEB/101943/2008). Approvals for these studies were obtained from institutional ethic committees and respective national data protection.

All respiratory sounds were acquired following CORSA short-term sound acquisition guidelines (Rossi, Sovijärvi, Piirila, Vannuccini, & Dalmasso, 2000). After 5 min of quiet sitting, patients were instructed to breathe normally through the mouth while respiratory sounds were recorded.

Recordings were acquired three times in seven chest locations (trachea; left and right: anterior, lateral and posterior), for 25 seconds (Rossi et al., 2000). Two digital stethoscopes have been used: Thinklabs® digital stethoscope (Thinklabs® Rhythm: ds32a, Colorado, US) in patients with pneumonia, and with a WelchAllyn digital stethoscope (WelchAllyn Meditron, 5079-402) in patients with cystic fibrosis. Recordings were performed at a sampling rate (fs) of 44.1 kHz and saved in .wav format. Written informed consents were obtained before any data collection.

CRACKLES MANUAL MULTI-ANNOTATION

Firstly, each file duration was reduced to 10 seconds, because manual annotation is a time-consuming process, since there can be many crackles in a file of few seconds long (Dinis et al., 2012; Oliveira, A., Pinho, Dinis, Oliveira, & Marques, 2013). Then, all respiratory sound files were manually annotated by three respiratory researchers, with experience in visual-auditory crackle recognition, who independently identified the presence of crackles in each respiratory sound file. When the researcher considered that a crackle was present, he/she was requested to annotate the beginning and the end of the crackle. Respiratory Sound Annotation Software V1.1 was used to perform the manual annotation (Dinis et al., 2012).

For each respiratory sound file, a gold standard annotation was obtained by combining the annotations from the three researchers. An event was flagged as a crackle if at least two researchers had identified it, i.e., agreement by majority (Gross, Hadjileontiadis, Penzel, Koehler, & Vogelmeier, 2003). The agreement among the three researchers was set considering the maximum absolute peak within each crackle annotation (Quintas et al., 2013) and was assessed by dividing the number of crackles in which researchers agreed by the total number of crackles annotated. An agreement of 86% was achieved among the three researchers.

AUTOMATIC CRACKLE DETECTION

The proposed algorithm can be summarised in the following main steps:

1. Extraction of a window of interest of a potential crackle based on fractal dimension estimation (Hadjileontiadis & Rekanos, 2003; Katz, 1988; Lu & Bahoura, 2008) and box filtering techniques (Shen, Shen, Castan, & Zhang, 2002; Taplidou & Hadjileontiadis, 2007);

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. Verification of the validity of the potential crackle, considering CORSA established criteria (Charbonneau et al., 2000; Murphy, Del Bono, & Davidson, 1989);
3. Characterisation and extraction of crackle parameters;
4. Optimisation of algorithm's parameters.

To reduce computation requirements, the signal was down sampled to 11025 Hz (fs), after appropriate anti-aliasing filtering (i.e., a low-pass digital filter applied to significantly attenuate frequencies above 5512.5 Hz, which would otherwise interfere with the lower frequencies after down sampling). The signal filtering consisted in the application of a passband filter of [100 – 2000] Hz (finite impulse response, designed with a 83ms Blackman window), to eliminate high frequency noise, ensuring that the main features of the crackles were still preserved (Sovijärvi, A., Malmberg, L., et al., 2000; Vannuccini et al., 2000). A detailed description of each one of these steps is given below.

Extraction of a Window of Interest

The extraction of a window of interest identifying a possible crackle involved four different signal processing steps:

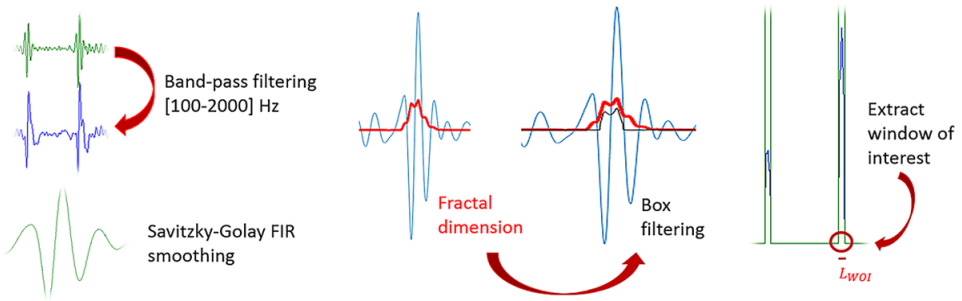
1. Savitzky-Golay (polynomial) finite impulse response (FIR) smoothing (Vannuccini et al., 1998);
2. Fractal dimension estimation (Hadjileontiadis & Rekanos, 2003; Katz, 1988; Lu & Bahoura, 2008);
3. Box filtering (Shen et al., 2002; Taplidou & Hadjileontiadis, 2007);
4. Application of a threshold to extract the beginning and the end of a window of interest.

A diagram summarising these steps is presented in Figure 2.

Firstly, a smoothing in the signal was performed to extract the remaining high frequency peaks of noise.

Secondly, the fractal dimension of the signal was estimated using a sliding window of length L_{FD}. Fractal dimension is a statistical measure that indicates an object's complexity in fractal geometry and it is used to evaluate the complexity of a waveform. The method proposed by Sevcik (2010) was used, as it is more sensitive to waveform changes and faster than other commonly used methods, such as the signals envelop method. Fractal dimension is defined by:

Figure 2. Main steps performed by the algorithm to extract a window of interest of length (L_{WOI}), i.e., identifying a potential crackle



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$FD = 1 + \frac{\ln(L)}{\ln(2N')} \tag{1}$$

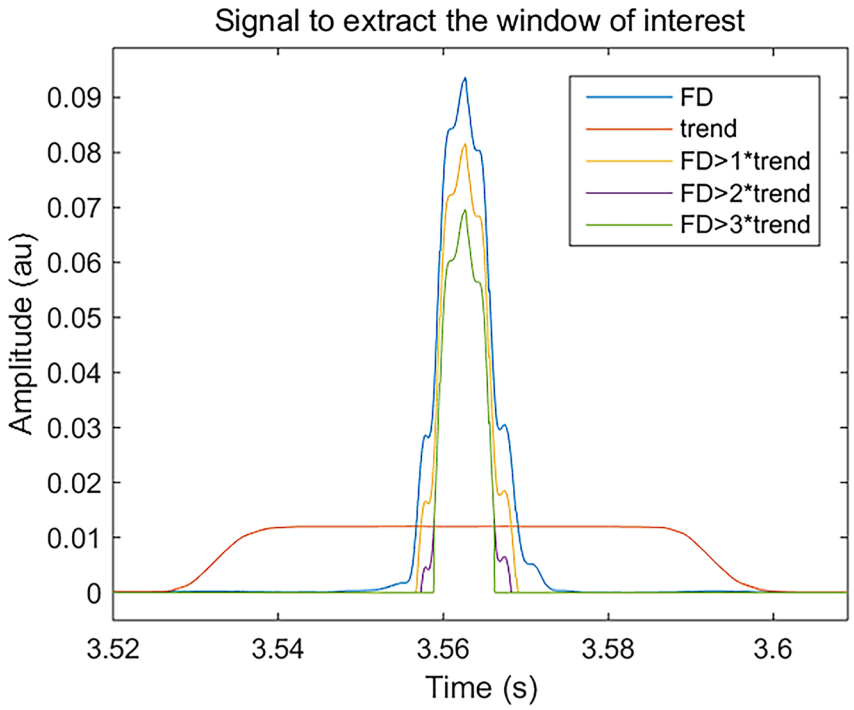
where N' is the number of steps in the waveform $\left(N' = L_{FD} \times fs - 1\right)$ and L represents the total length of the waveform, i.e., the sum of the Euclidean distance between successive data points:

$$L = \sum_{i=1}^{N'} dist(i, i+1) \tag{2}$$

Thirdly, an additional smoothing to estimate the trend of the fractal dimension signal in each time instance was applied. The estimation of the trend was based on box filtering, also known as average or mean filtering, with a sliding window of length L_{BF}. This is a commonly used technique to reduce noise, accomplished by replacing each amplitude sample with the average value of the surrounding samples, including itself. Therefore, the large amplitude variations between samples were removed and a much smoother signal was produced (i.e., the trend). This enhances the identification of crackles in noisy signals, such as sounds acquired in a clinical settings or sounds containing other adventitious respiratory sounds, e.g., wheezes.

In the fourth step, the fractal dimension signal was compared to an adaptive threshold to identify the window of interest of a potential crackle by *FD>X×trend*, where *X* is a free parameter for optimisation (Figure 3).

Figure 3. Adaptive threshold applied to the fractal dimension (FD) signal to identify the window of interest of a potential crackle by FD>X×trend, where X=1,2,3



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The final length of the window of interest was defined as the variable L_{WOI}.

Verification of Crackle

A function was developed to evaluate the validity of the potential crackle. This function intended to verify if the window of interest extracted met the CORSA established criteria for crackles detection (Kaisla et al., 1991). Also, additional considerations empirically established by the analysis of noisy signals were implemented to correct errors in the detection. Therefore, the following set of conditions were established:

1. The amplitude of the different peaks of the crackles had to be progressively lower than the LDW;
2. Peaks had to be progressively wider after the IDW (variable defined as W_{peaks});
3. Crackle zero-crossings were verified: minimum of 5 zero-crossings, to guarantee the calculation of 2CD, and maximum of 16 zero-crossings;
4. The mean absolute amplitude of the crackle had to be higher than F times the mean absolute amplitude of the background noise estimated from a segment of length L_{bckg} preceding the crackle (considering the CORSA criteria, that suggests that crackle amplitude have to be higher than 2*background noise);
5. Crackle IDW had to be higher than 1/8 of the LDW.

Characterisation and Extraction of Crackle Parameters

The following parameters were extracted to characterise the identified crackle: IDW, LDW and the 2CD (Charbonneau et al., 2000; Sovijärvi, A., Malmberg, L., et al., 2000). A detailed description of these crackle time-domain parameters is presented in the Figure 1 (please see the section *Introduction*). Furthermore, the classification of the crackle as fine or coarse was established, based on the criteria proposed by CORSA, i.e., a fine crackle was defined as having a 2CD $\leq$ 10 ms, and a coarse crackle has having a 2CD > 10 ms (Sovijärvi, A., Dalmasso, F., et al., 2000).

Optimisation of Algorithm's Parameters

Seven parameters were chosen to allow tuning the automatic crackle detection algorithm to improve performance. Three different values were tested for each parameter, resulting in a total of 2187 (3^7) combinations. The best combination was defined as the one achieving the highest F-score similarity with the gold standard annotation agreement.

The chosen tuning parameters and corresponding tested values were:

1. The width of the fractal window of approximately half the length of the crackle (Lu & Bahoura, 2008) (L_{FD} = *4, 6, 8 ms*);
2. The width of the box filtering window (L_{BF} = *40, 60, 80 ms*);
3. The *X* parameter applied in the adaptive thresholding step to identify the window of interest (*X = 1, 2, 3*);
4. The minimal length of the window of interest of each crackle (L_{WOI} = *0.5, 1, 2 ms*);
5. The widening tolerance range (= *1/5, 1/4, 1/3*) associated with the width of the peaks following IDW (W_{peaks} ± *widening tolerance* × W_{peaks});

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

6. The length of the background sound before the crackle (L_{bckg} = *20, 40, all* ms*) *considering all background length before the crackle;
7. The factor multiplied by the amplitude of the background sound (*F = 1.6, 1.8, 2*).

Parameters 6 and 7 were established to evaluate the amplitude of the crackle when compared with the background noise (condition 'iv' defined in the section *Verification of crackle*). Only the background length before the crackle window was evaluated. This strategy was adopted to allow the extraction of crackles previously detected in that signal, ensuring that only the fluctuations of the background sound were considered and not the superposition of adventitious sounds (i.e., crackles).

Figure 4 provides the flow diagram of the proposed integrated approach to automatically detect crackles.

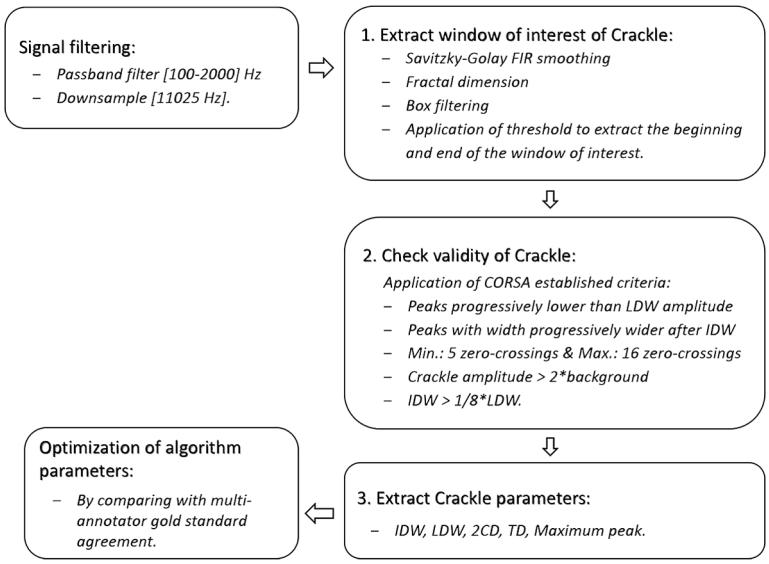
The algorithm regarding the proposed integrated approach was written in Matlab®R2009a (Mathworks, Natick, MA, USA).

CLASSIFICATION MEASURES TO VALIDATE THE ALGORITHM

The validation of the performance and accuracy of the automatic crackle detection algorithm was obtained by comparing the maximum absolute peak within each identified crackle with the results of the multi-annotator gold standard agreement, which for respiratory sounds is the judgment of respiratory experts (please see section *Crackles manual annotation*).

Formally, the proposed classification system is based in two classes (Cheetham et al., 2000), i.e., each event is mapped with a positive (P) (i.e., a crackle) or negative (N) (i.e., non-crackle) class label. The classification model then maps events to predicted classes (Fawcett, 2004, 2006). The event measure is given by the multi-annotator gold standard results, and the classifier refers to the algorithm outcomes. Thus, given a classifier and an event, it is possible to count four well-known parameters:

Figure 4. Flow diagram of the proposed algorithm to detect crackles



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. **True positive (TP):** If the event is flagged as crackle (i.e., positive) by the gold standard and classified as positive by the algorithm;
2. **False negative (FN):** If the event is flagged as positive by the gold standard and classified as negative (i.e., non-crackle) by the algorithm;
3. **True negative (TN):** If the event is flagged as negative by the gold standard and classified as negative by the algorithm;
4. **False positive (FP):** If the event is flagged as negative by the gold standard and classified as positive by the algorithm.

A two-by-two confusion matrix is used to describe this classification system and provide information regarding the actual and predicted classifications (Akay, 2009; Fawcett, 2006), Table 1.

This matrix forms the basis for many common metrics. Sensitivity (SE) and specificity (SP) are two measures that estimate a classifier's performance on different classes (Fawcett, 2006; Sokolova, Japkowicz, & Szpakowicz, 2006).

SE is defined as the ratio between crackles correctly detected (TP) and the sum of TP with the number of crackles not detected by the algorithm (FN), Equation (3):

$$SE = \frac{TP}{TP + FN} \tag{3}$$

SP is defined as the ratio between the events correctly classified as not a crackle (TN) and the sum of TN with the number of crackles incorrectly detected by the algorithm (FP), Equation (4):

$$SP = \frac{TN}{TN + FP} \tag{4}$$

As the analysed files are composed by 110250 points (i.e., $10s \times 11025s^{-1}$), even for a maximum number of crackles (e.g., 200), the order of magnitude of TN will be around 500 times above the FP count, and thus the SP value will always be approximately 100%. Thus, SP metrics were not considered in the results.

Other classification metrics is the positive predictive value (PPV) (Akay, 2009; Fawcett, 2006). PPV is the ratio between TP and the total number of crackles detected by the algorithm, i.e., correctly detected (TP) and incorrectly detected (FP), Equation (5):

Table 1. Confusion matrix representation

	Predicted	
Actual	**Positive**	**Negative**
Positive	True positive (**TP**)	False negative (**FN**)
Negative	False positive (**FP**)	True negative (**TN**)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$PPV = \frac{TP}{TP + FP} \tag{5}$$

The total performance F-score (F) is a multi-class classification metrics that combines PPV and SE, presenting, therefore, a more robust measure of the algorithm's performance, see Equation (6):

$$F = \frac{\left(1+\beta^2\right) \times SE \times PPV}{\left(\beta^2 \times PPV\right) + SE} \tag{6}$$

The parameter β allows to weight more heavily SE or PPV, i.e., $\beta > 1$ favours PPV and $\beta < 1$ SE (Hripcsak & Rothschild, 2005; Sokolova et al., 2006). In the F-score defined in the proposed classification system was assumed $\beta = 1$, i.e., an evenly balance between SE and PPV (Hripcsak & Rothschild, 2005; Sokolova et al., 2006), Equation (7):

$$F = 2 \times \frac{SE \times PPV}{SE + PPV} \tag{7}$$

RESULTS

From a total of 2187 combinations of the threshold parameters, the performance of the automatic crackle detection algorithm was optimised with the following set of parameters: $L_{FD} = 6\ ms$; $L_{BF} = 60\ ms$; $X = 3$; $L_{WOI} = 2\ ms$; *widening tolerance = 1/4*; $L_{bckg} = 20\ ms$ and $F = 2$. A summary of the results obtained with this set of parameters is presented in Table 2.

The number of crackles identified with the optimised algorithm (from 1 to 108) was similar to the one obtained by the multi-annotator gold standard (from 2 to 129). These results, per respiratory sound file, are shown in Figure 5.

Figure 5. Crackles detected by manual annotation (multi-annotator gold standard agreement) and by the proposed algorithm for each respiratory sound file

24	20	20	18	2	2	0.90	0.90	0.90

Note: N. File: number of sound files analysed; Algorithm: number of crackles detected by the proposed automatic crackle detection algorithm; GS – gold standard: counts of crackles identified by the multi-annotator gold standard agreement; TP – true positive: counts of crackles correctly detected; FP – false positive: counts of crackles incorrectly detected; FN – false negative: counts of non-crackles incorrectly identified; SE – sensitivity, PPV – positive predictive value, and F – F-score, present the results obtained for the three different classification metrics assessed to validate the algorithm performance.

Figure 6 presents the SE, PPV and F-score of the algorithm for each respiratory sound file. It can be observed that files 18 and 22, acquired in patients with pneumonia, were those in which the algorithm presented the lowest performance, F-score of 57% and 67% respectively.

However, when considering the 24 respiratory sound files, the average of SE, PPV and F-score of the proposed algorithm were considerably high (SE=89 ± 10%, PPV=95 ± 11% and F-score=92 ± 10%).

DISCUSSION

Crackles are adventitious respiratory sounds that frequently occur in cardiorespiratory diseases (Charbonneau et al., 2000; Sovijärvi, A., Malmberg, L., et al., 2000). Thus, their automatic detection and detailed analysis is of major importance for the diagnosis and monitoring of respiratory diseases. Nevertheless, the techniques provided in the literature for this calculus, e.g., Hadjileontiadis & Rekanos, 2003; Lu & Bahoura, 2008; Vannuccini et al., 1998, are poorly tested in clinical settings and not validated against a multi-annotator gold standard agreement.

Therefore, an integrated approach for automatic crackle detection has been proposed in this study to overcome the identified problems, based on:

1. The use of the combination of fractal dimension estimation and box filtering techniques to enhance the recognition of crackles in noisy signals;
2. The establishment of a set of rules to verify the validity of the detected crackle, grounded by CORSA established criteria (Charbonneau et al., 2000; Murphy et al., 1989);
3. The use for a multi-annotator gold standard manual annotation to validate the performance of the proposed automatic detection algorithm;
4. The optimisation of seven parameters established to improve the performance of the automatic crackle detection algorithm.

The results obtained from the optimisation of the seven parameters tested in a sample of 24 respiratory sound files acquired in clinical settings, demonstrated that this was an efficient and robust method for crackle detection/classification and highlights its potential to be used in respiratory sound files acquired in clinical practice.

The conditions initially implemented in the algorithm strictly followed the ones proposed by the CORSA criteria. However, during the iterative assessment of the algorithm, a sharp divergence between the results obtained with the algorithm and those from the gold standard was verified. To address this

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

problem, and as CORSA criteria are not updated since 2000, some refinements of the standard rules were implemented. For example, in the criteria stating that the width of the peaks should be progressively wider after IDW, a deviation of 25% was allowed. It should be noted, that despite the high subjectivity associated with human detection of crackles, this is still considered the only valid method for its detection (Marques et al., 2006), as health professionals are the ones who use it routinely to establish diagnosis and monitoring patients. Therefore, from the authors' point of view, algorithms should be developed to always match human gold standard annotation and not the opposite. Though, as human annotation has an underlying subjectivity the gold standard annotation should be provided by the statistical agreement criteria of multiple independent annotations (i.e., three or more) obtained for each sound file. Thus, in this study a multi-annotator gold standard agreement from three independently manual annotation experts was established.

The SE (89%), PPV (95%) and F-score (92%) of the proposed algorithm are comparable or even higher than those of other previously published methods (SE 80–91%; PPV 83−88%; F-score 86.7%) (Quintas et al., 2013; Vannuccini et al., 1998). However, it should be noted that, contrarily to other algorithms, the presented one was tested with respiratory sound files recorded in clinical settings, which further increase its potential to be used by health professionals in their daily practice. Only in two respiratory sound files from patients with pneumonia, the performance of the algorithm did not reach these high standard values (F-score of 57% and 67%). Such findings are related with the low number of crackles presented (TP) in these two respiratory sound files (1−9 crackles in the sound files), causing the few FP and FN to have a negative impact in the F-score. Nevertheless, this finding may not be clinically relevant as it has been reported that even healthy people present approximately 4 crackles per breathing cycle (Oliveira, Ana & Marques, 2014). Hence, errors of this magnitude might not be clinically significant for diagnosis and monitoring of respiratory diseases.

LIMITATIONS

This study has some limitations that need to be acknowledged. The proposed algorithm was developed by comparing the results against a multi-annotator gold standard obtained from the annotations of three respiratory researchers. Despite the high agreement achieved (86%), it is well-known that human annotation is associated with high levels of subjectivity, thus future studies should consider creating a repository of respiratory sounds annotated by an additional number of experts (e.g., five or more) to minimise bias. Also, a small sample of respiratory sounds files was included from adult patients with pneumonia and cystic fibrosis. Therefore, it would be a great asset to validate the proposed algorithm in large sets of data from patients with other respiratory diseases and different age ranges (young children and infants). Finally, although the proposed algorithm is currently processing in real-time, making it suitable to be used in the clinical practice, it would benefit from being included in Clinical Decision Support Systems. This would allow comparisons between patterns of samples and provide info/pre-diagnosis to the caregiver (Musen, Middleton, & Greenes, 2014), which is not addressed in the current version of the algorithm.

CONCLUSION AND FUTURE WORK

The proposed integrated approach for automatic crackle detection achieved a high performance (F-score 92%). This promising result highlights the potential of this new approach for automatic crackle detection and classification in respiratory sounds acquired in clinical settings. Future research could also test the developed algorithm in home-based environments and to be used in patients' tele-monitoring devices.

It would also be of great interest to develop a portable technology including a sound acquisition device plus an open source software integrating the developed algorithm. This would allow health professionals to have instant feedback on their respiratory sound recordings. Additionally, international collaborations are being established to acquire a large database of normal and adventitious respiratory sounds (including crackles, wheezes, rhonchi, stridor, etc.) that could be used to find unsuspected relationships between normal/adventitious respiratory sounds and respiratory diseases, summarise respiratory data into patterns and thus be used in Clinical Decision Support Systems.

ABSTRACT

Loss or impairment in the ability of muscle movement or sensation is called Paralysis which is caused by disruption of communication of nerve impulses along the pathway from the brain to the muscles. One of the principal reasons causing paralysis is Spinal Cord Injury (SCI) and Neurological rehabilitation by using neuro-prostheses, based on Functional Electrical Stimulation (FES) is extensively used for its treatment. Impaired muscles are activated by applying small amplitude electrical current. Electromyography (EMG), the recording of biosignals generated by muscle activity during the application of FES can be used as the control signal for FES based rehabilitative devices. This method is predominantly used for restoring upper extremity functioning (wrist, hand, elbow, etc.), standing, walking (speed, pattern) in stroke patients. FES, collaborated with conventional methods, has the potential to be utilized as a useful tool for rehabilitation and restoration of muscle strength, metabolic responses etc. in paralyzed patients.

INTRODUCTION

The EMG signal is produced by active contraction of the muscles. So, since electromyogram shows some function of muscle states it has been long harnessed for being used as a feedback signal for functional electrical stimulation or FES. Although there had been innumerable works on EMG for normal muscle conditions, less is known about electrically stimulated muscle EMG. (N Chesler et al, 1997)

Functional electrical stimulation can be controlled by signals obtained from surface EMG of activated voluntary muscles. EMG does not only signals muscular FES but also neuromuscular FES (Baldi, J. C. et al., 1998). It is so done that the recording electrodes are placed properly in position with respect to the stimulation electrodes. After that required processing is done on those recorded signals so as to minimize the artifacts and non-voluntary M-wave contribution. (B Daruish et al, 1998) It poses added difficulties on detecting EMG signals in the presence of FES as the FES electrode signals are of much higher magnitude as compared to the muscle generated signals and hence can result in saturating the biopotential amplifiers for a significant amount of time (Durfee, 1995). Hence many researchers earlier had considered removal of stimulation artifacts. But with newer researches this theory is abandoned and instead control scheme for FES is developed. Thus many studies have been carried out on optimal compromisation between voluntary muscle activity detection and artifact removal. (C Robinson et al, 1997)

The desired characteristics of the EMG electrodes are low noise, high impedance, high common mode rejection ratio preamplifier having typically a gain around 100 and a frequency range of 10 to 10,000 Hz. The preamplifier signal is then usually fed to a high pass filter, full wave rectifier and a blanking device that is used to reject the aforesaid stimulation artifacts. The signal now obtained is thus used a trigger signal for initiating or stopping stimulation (A Demosthenous et al, 2008)

Artificial neural network can be also an good option for eliminating adaptive interference effectively. Since the last two decades there had been studies over EMG controlled FES using ANN (artificial neural network) for pattern recognition and discrimination of EMG signals which in turn is used to control the FES. (Z Li et al, 2012) Prior to nineties there had been various studies on ANN implementation on EMG but all those were related to artificial limbs but not functional electrical stimulation. Controlling FES with the same idea was a difficult challenge as FES involved the controlling of peripheral nerves. Back propagation theory of Artificial neural network was used initially to answer this problem which was then modified with time. (H Yamaguchi et al, 2000)

In FES applications EMG are particularly used in those situations where an indication for muscle fatigue is needed. (Durfee 1995) Hence it can massively help in detecting muscle collapse in cases where FES is applied to treat hemi or paraplegic patients(Graupe et al, 1982) or those having ambulation aids or patient suffering from stroke(I Jerman et l, 2009) or spinal cord injury, (Hamzaid et al, 2009) there are quite a few methods to track fatigues but the most common fatigue tracking performance indicators are derived from the root mean square of electromyogram signal amplitude and from the MF i.e. the median frequency of EMG power spectral content. It has been found that such results indicated that for practical FES application it is pretty difficult to obtain proper fatigue tracking indicators.(J winslow et al, 2003)Thus it is very evident that EMG controlled FES has a very promising field of application and has multiple usages for varied kind of human diseases.

Apart from EMG signals, plenty of other signals get generated due the different activities going on continuously in the human body, known as Biosignals (Kaniusas, E. et al., 2012). These signals are basically used as the control signals needed to drive the FES devices. In case of feedback systems, these feedback signals are also extracted from these biosignals. The biosignals available with the human body

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

system are mainly Electrocardiography (signals generated from heart) (Fye, W. B., 1994), Electroencephalography (signals generated from brain) (Niedermeyer, E.et al., 2005), Electromyography (signals generated from muscles) (Oh, S. J. 2003), Electrooculography (signals generated from eye movement) (Miyake, Y. 2006), Electroneurography (signals generated from nerves) (Smorto, M. P. et al., 1974) and likewise. Few of these signals have been employed to drive the FES devices besides EMG signals like ENG, EEG. But EMG based FES is the most common among all the available methods. Other methods of controlling FES are discussed in details later in this chapter.

FUNCTIONAL ELECTRICAL STIMULATION (FES)

Electricity plays a major role in driving the nervous system of the human body. Whenever a cell or tissue gets stimulated, it becomes electrically activated and generates a very short electrical impulse known as action potential (Kandel, E et al., 2000). This action potential then stimulates the cell adjacent to it and then the subsequent cells and as a result the input stimulus gets propagated through the nervous system (Johnston, D., 1995). Apart from that, the brain also sends electrical pulses to muscles through nervous system for making the relevant muscles contract (Ebashi, S et al., 1969). These contractions are basically responsible for movement of different body parts. The idea of using electrical pulses for clinical application was first proposed by J.A. McWilliam in 1899 (first artificial pacemaker). After that a number of research works were executed for applying this idea for different types of clinical uses. W.T. Liberson et al. (1961) devised a stimulator for the prevention of drop foot in hemiplegic patients. This work evoked the idea of a new method of rehabilitation within scientists, known as Functional Electrical Stimulation (Rushton, D. N. 1997). This is a technique of stimulating inactive muscles by applying electrical pulses to it. FES is mainly applied to those muscles which are uninjured themselves and excitable but does not have an uninterrupted neural pathway. This means, the body cannot deliver the stimuli to these muscles in the natural way as because the neural pathway is damaged due to spinal cord injury, vascular accident, other neural disorders and likewise and that is why another method (FES) is required for delivering these stimuli without using the nervous system (Peckham, P. H. et al., 2005). This method is widely used for providing neural rehabilitation to patients (Granat, M. H.et al., 1993 and Chantraine, A. et al., 1999). The need of FES is discussed in detail in the next section.

NEED OF FES

FES has numerous applications in the medical field. Providing neural rehabilitation to patients is undoubtedly the most important application of FES (Peckham, P. H. et al., 1992). Loss or impairment in the ability of muscle movement or sensation is called Paralysis which is caused by disruption of communication of nerve impulses along the pathway from the brain to the muscles. The primary causes of paralysis are spinal cord injury, vascular accidents, strokes or other existing disorders of nervous system (Birbaumer, N. et al., 2008). FES is manly used for improving the overall muscle contraction, assisting the patients in walking, reinstating the upper extremity and lower extremity to former state, increasing dexterity and strength in the limbs, restoring function in bladder, bowel, respiratory system and such (Stephenie Anna Haapala et al., 2008 and Chan, C. K., 2008). Apart from rehabilitation, FES has found application in several other domains like reduction of pain, improvement in blood circulation, inhibition

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of urinary bladder, influencing auditory and visual systems, reduction of seizures caused by epilepsy, excitation of spinal cord neural networks, increase in bone growth, prevention of scoliosis and many more (Alojz R. Kralj et al.,2000). FES basically helps to provide a better quality of life to the users.

Electromyography (EMG)

A myoelectric signal or a motor action potential is an electrical impulse which is responsible for producing contraction of muscle fibers in human body. These signals travels between muscles and nervous system thus regulating the movement of different parts of the body (Kumar, S.et al., 1996). The technique concerning the development, recording and analysis of these myoelectric signal is called Electromyography (EMG). Whenever the connection between brain and the muscles i.e. the neural pathway between them gets affected, the myoelectric signals generated within the muscles also change. As a result, study of these electrical signals generated is a very useful tool for diagnosing any abnormality in the muscles and also in the entire motor system. It was primarily used as a diagnostic tool earlier but with the advent of technology, the applications of EMG increased substantially (Reaz, M. B. I. et al., 2006 and 42 Merletti, R. et al., 2004). One of the most important applications of EMG is obtaining control of limbs artificially which is done mainly by using it to control FES and providing rehabilitation to the patients.

PURPOSE AND USEFULNESS OF EMG BASED FES

EMG based FES serves a very versatile platter of purpose and usefulness. To begin with, we must on the very onset mention about its role in treating muscular diseases and modeling various muscular models for the same purpose. EMG based FES has been used to construct muscle model based on the relationship between the frequency of stimulus and force. Another kind of physiological muscle model was also built based on the relationship of EMG and force. Many similar kinds of EMG-force relationship based (Perry, J. et al., 1981) experiments were carried out by many researchers across the globe to establish proper estimation required to build such models. To study muscle tone EMG based FES has been used with the help of muscle sound application. Muscle torque relationship using artificial neural network was also establish using EMG based FES (Hincapie, J. G. et al., 2009). Not only in the field of voluntary muscles but EMG based FES has been also applied to treat denervated muscle and smooth muscles present in bladder walls. Another very common area of application is fatigue compensation of different kinds of muscles present in human body.

The second most common area of application is for treating paralytic patients. Various degrees and extent of paralysis has been successfully treated using EMG based FES. Studies revealed that EMG based FES method was successful in making a paraplegic patient, stand up on his own feet. It is also many a times used to train extremity coordination in hemiplegic patients. Researchers and scientists had also developed artificial neural network based patient responsive ambulation aids for paraplegic conditions using EMG based FES. (C Komiyama et al, 1994)(D Popovic et al, 2007)

Several control strategies for limb extremity movements as well as joint models are designed using EMG based FES.(C A Kirkwood et al, 1989) There are instances where special EMG based FES models have been developed hand function restoration with patient driven loop. This technique is non-invasive and hence has a very promising field of application. Control strategies for orthotic exoskeleton of hand

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

are also designed with EMG based FES. For both upper and lower limb joints various kinds of musculoskeletal models have been developed. Such models are most prevalent for elbow joints or 2 joint systems of lower limbs. (M hayashibe et al, 2009)

In the continuation with the above field of application it is important to mention another common area of EMG based FES system application which is gait analysis. Many dynamic musculoskeletal models have been developed since long time for gait application. EMG based FES has been used to treat drop foot correction by studying the effect of walking speed changes on tibialis as obtained from its gait analysis. in people having partial paralysis gait initiation has been applied with the help of electromyography triggered FES. (A Dutta et al, 2009)

Electromyography based functional electrical stimulation can also be used for the purpose of neuromuscular rehabilitation. Literature suggests the Neuromuscular Modeling with Full Physiological Dynamics has been built using this methodology. Even FES evoked leg exercise has been designed for patient suffering from spinal cord injuries with the help of electromyography. (K Subramanya et al) (R.E.S. Shalaby, 2011)

Post stroke rehabilitation also needs special mention amongst the different areas of application of EMG based FES. Different studies are there that presents event related desynchronization modulated FES for post stroke rehab purpose using EMG. Neuromuscular stimulation are given after stroke to patients using this method. Also researchers used EMG based FES to aid walking in stroke patients.(M takahashi et al, 2012)

EMG BASED FES SYSTEMS

Since Nineties the usefulness of EMG based FES has been recognized and harnessed by researchers and scientists for the purpose of rehabilitation. It is found to serve as treatment for a wide range of diseases and disabilities. In this section a brief overview on the application areas of EMG based FES that has been in research or practice since 1990 is given. It will mainly cover the review about the rehabilitation of paralytic patients, stroke patients, upper and lower limb rehab, functioning of denervated musculatures, gait analysis and neurorehabillitation.

Paralysis

Chifuyu Komiyama *et al* long back in 1994 applied the idea of using EMG based FES for making paraplegic patients stand up. They developed an open loop control mechanism as such in which EMG was recorded from the quadriceps femoris and gluteus maximus muscles using surface electrodes, at a stand up posture of non paralyzed persons based on which they designed the stimulus that is to be applied to the paraplegic patient. The functional electrical stimulus was a constant current signal having amplitude modulated monophasic pulses. They did set a standard FES pattern for all paralyzed patients and then customized those stimulus patterns according to the requirement of different patients.

Daniel Graupe *et al* applied neural network theory to implement FES based on EMG on patients suffering from paraplegia. They used an ART-1 neural network scheme for the purpose of controlling the functional electrical stimulus that would facilitate patient responsive ambulation by paraplegic patients. They proposed such an ART-1 NN that would discriminate above lesion upper trunk EMG time series for activating stand up and walking functions and also control the electrical stimulus levels using

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

response EMG signals. Thus they successfully designed a single system effective for two purposed i.e. pattern recognition and control. Their system was so designed that it also gave the patients, space for manual over ride in case any error occurs.

In 2011 CH Chou *et al* implemented the idea of EMG based FES system in order to train hemiplegic patients for extremity coordination. It so happens in hemiplegic condition that not only does drop foot occurs but the upper extremity limits too while the patient tries to walk. In general only FES is applied to the drop foot to cure but this lacks the upper limb coordination and hence the researchers implemented the integration of a two channel EMG to improve the bad walking posture of CVA patients and also prevent their frequent falling down with enabling proper coordination between the drop foot and the upper limb swings. This not only helped in treating such cases of CVA patients but also corrected their bad standing or walking postures.

Gait

Anirban Dutta *et al* in 2009 proposed a gait model for partially paralytic people based on EMG triggered functional electrical stimulus. In people who suffered from incomplete spinal cord injury (iSCI) the muscle activities can be partially regained with FES triggered by electromyogram based gait event detector i.e. an EMG trigger. It emerges as a more natural command source rather than manual switches and hence provide improved coordination during gait.

C A Bryne *et al* in 2006 conducted an research study that aimed at producing an optimized stimulation envelope for drop foot correction. They employed EMG pattern of tibialis anterior obtained during healthy gait to design the required stimuli emvelope. Their objective was not to alter the walking speed of the person but was to provide data to enable the adaptation of the envelope with the walking speed. Their work result suggested that the FES envelope that produces larger EMG amplitude for toe off burst than the heel strike burst, would be more appropriate for hemiplegic patient's walking speed.

Muscle

Takashi Watanabe *et al* in 1999 developed a simplified model for electrically stimulated muscle based on EMG signals with a force frequency relationship for the application of FES. The EMG signals were obtained from neurologically intact persons. The relationship between force and frequency of electrically stimulated fast and slow type muscles was predicted in their muscle model. This model also described the summation of muscle contraction. All this finding were suggested to decrease the parameter identification time for patients on clinical purpose.

In 1994, T Yamamoto *et al* applied the idea of EMG along with muscle sound to assess muscle tonus, muscular strength, its tolerance and fatigue level of electrically stimulated muscles for the purpose of FES. This study established a strong relationship between muscle sound and inner pressure of fascia and also proved that muscle sound is a very good parameter to determine muscle tonus.

Mitshuhori Hayashibe et al in 2009 proposed an EMG to force estimation for voluntary muscle contraction that has a manifold application in human machine interface, rehabilitation and robotics. EMG based FES model of activation patterns of separate individuals can be very fruitful for estimating of muscle force. Previous to their study only macroscopic physiology of "hill type model" was prevalent

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

but with this study they successfully established a microscopic physiology for the same as well. This model brought about the understanding of internal biophysical dynamics and also revealed new insights about neuromuscular activations.

Zhan Li *et a*l in 2012 found that it is important to have torque estimation and prediction as feedback information for actual muscle state in order to make a good adaptive FES control. For this purpose they chose evoked EMG signals as according to them it was very correlated with FES induced torque under variety of muscle conditions. Hence in order to establish a repation between this evoked EMG and FES muscle torque they applied a nonlinear ARX model or NARX model of recurrent neural network. This RNN model identified and predicted FES induced muscle dynamics with Eemg. This is a very robust model and gives promising results.

In 2002 Winfired Mayr *et al* in one of their paper presented the fact that EMG based FES system can be very useful to regenerate, restore and maintain denerveted muscles. To effectively activate such denerveted musculature using surface EMG electrodes long duration biphasic impulses are required habing a pulse width varying from 1- to 300 ms with amplitude ranging from +- 100 to -+250 mA. But such situation may arise safety issues for application purpose. Though no such clinical set up has yet been developed yet many experimental purpose protypes are made which aims at addressing this safety issues at the same time serve the purpose.

Jeremey Laforet and David Guiraud developed a model for smooth muscle for FES application based on EMG in 2008. Their model enabled the stimulation of FES induced contraction, their smooth muscle model for bladder wall included muscle cell calcium dynamics. Their work was unique in a sense that they used this EMG based FES system in order to establish relation between calcium concentration and electric potential of cell membrane. They also refined the mechanical model and validated their results using simulation models. Hence not only to determine muscle fatigue or activate muscles, but EMG based FES system is also found to be used for biochemical studies.

Limb Control

In year 1995 William K Durfee *et al* carried an experimental verification of a lower limb 2 joint model with EMG based FES for gait application. Their model had 10 links, 14 degrees of freedom and aimed at facilitating the controller design for maximized artificial gait system performance. Primarily they conducted experiments to know whether a subset of the full model can be used for force and motion prediction of actual limbs in order to ensure high level of accuracy. The angle of knee and hip joints were measured for passive initial condition releases and also for activating single muscles by FES.

Musculoskeletal Joint models stared developing way back in nineties on the principle of EMG based FES. Takashi Watanabe *et al* in 1998 conducted experimental tests on such a model for FES applications. They tested this model on a normal subject with surface stimulus . the stimulation data were based on EMG signals as obtained from his upper limb muscles. Parameters used in this model was based on force measured under isometric condition. They found that the output for the tuned model matched well with that of the experiment of a single muscular stimulation at high amplitude.

Han chang in 2000 developed a versatile multichannel direct synthesized electrical stimulator for the application of FES. This stimulator developed by them was an arbitrary waveform stimulator. The authors proposed the idea of an element envelope and applied digital signal processor for synthesizing the stimulation patterns having high resolution. Their system aimed at reducing memory requirements along with keeping the space for flexibility of waveform type. The system was also well equipped to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

adjust its stimulation parameters dynamically. The output stage of their system provided a biphasic voltage controlled constant current patterns that had wide enough bandwidth and high compliance. Thus this EMG based FES system had the capability of feedback processing and also the flexibility for pattern generation.

In 2004, Ying Han Chiou *et al* proposed a non invasive scheme of FES based on patient driven control loop for restoring hand movement functions. It was so designed that any patient could use their well-to-do limb extremities to control the functional electrical stimulus that would in turn excite or activate their paralyzed muscle cells. The system would receive EMG signal as trigger to serve the purpose of system initialization and adjustment of electrical stimulation parameter. Thus a complete patient driven control loop was developed by the researchers with an EMG based FES system.

Mathew Dicicco *et al* in 2004 constructed a very low profile light weight orthotic exoskeleton to restore the dexterity of upper limb extremity that would be controlled by patient residual EMG signal. They compared several such systems of EMG based FES for this restoration purpose and found that electromyogram signals retrieved from ipsilateral biceps is supposedly the best option for developing a very reliable natural reaching and pinching algorithm.

Neuro-Muscular Rehabilitation

In 2007 R Lyne *et al* in one of their review paper presented different comprehensive uses of EMG based FES for neuro-rehabilitation. The main functional application in this field is to active paralyzed neuro-musculature to get tasks done properly with high precision. It is mentioned in this study that apart from post stroke rehab other common neuronal support that can be provided using FES based on EMG is renervation of respiratory tract, urinary bladder, prevention of neuromuscular collapse and prophylaxis of deep venous thrombosis and similar kinds.

Stroke

R Li *et al* developed a novel type of EMG based FES robotic system that aimed at post stroke rehabilitation for wrist movement impairment in the year 2008. The control algorithm of this robot was so designed that it interacted with the voluntary motor inputs from the stroke patient. They represented their result by root mean square error and root mean squared jerk of the trajectories of wrist tracking as obtained from their tasks that were supported by FES. It showed that the integrated robot system was effective in improving tracking performance for cases of both acute and chronic stroke patients.

Juan Nicholas Cuenca *et al* published in a paper in 2004 that how EMG based FES system helps in physiotherapy after a person had a stroke. It is said to be a very effective tool for the purpose of maintaining the trophism of muscle. It also helps in reducing the appearance of edema and fibrosis in paretic muscles that suffered post effects of stroke. If combined with cognitive activation this system would also allow the voluntary access of patient to the concerned muscles.

In 2003 Yukihiro Hara presented various area of application of rehabilitation with EMG based FES for stroke patients. In many cases after a stroke it so happens upper limbs becomes hemiparetic. EMG triggered FES can in particular improve the motor function of such limbs. It has been found that triggered FES is much more effective than non triggered one as it induces greater muscle contraction that is proportional to integrated voluntary EMG signals. Wrist movement, shoulder flexion, finger extension

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

can be improved in stroke patient if a daily basis therapy of EMG based FES is applied. Also sensory motor impairment can be treated with the same as the cerebral blood flow increases in sensory motor cortex of brain when EMG triggered FES is applied.

In a review article published in 2014 by "Different strokes" organization of United Kingdom the beneficial aspects of EMG based FES system for walking aid purpose for stroke patients has been presented elaborately. People often suffer from drop foot syndrome after stroke. This can be cured applying EMG based FES. It brings about natural walking pattern in the patient along with the increase in the walking speed too. They are even able to walk in uneven surfaces. People become enabled for walking relatively longer distances. The frequent tendency to fall down also reduces manifold as it reduces spasticity. Regular use of this FES triggered by EMG system actually treats the stroke survivor pretty well since he becomes able to walk with appreciable speed after a certain period of therapy time all by himself when the FES is switched off. A brief summary of the above discussion is given in Table 1.

Table 1. Chronological overview of EMG based FES applications

Year of Publication	Author	Category	Objective	Area of Improvement
1994	Chifuyu Komiyama *et al*	Paralysis	To Make a Hybrid FES orthosis to make patient stand up in paraplegic condition	Experiments were conducted on healthy subjects
1994	D Graupe, H Kordylewski	Paralysis	To use Neural network to control FES in paraplegics for patient-responsive ambulation	
1994	T Yamamoto, H Takano	Muscle Activation	To study the Application of muscle sound to assess muscle tonus of the electrically stimulated muscle for FES	Not applicable for fully paralytic musculature
1995	D Graupe, H Kordylewski	Paralysis	To use Artificial neural network for controlling FES for patient responsive ambulation in paraplegic condition	
1998	Takashi Watanabe *et al*	Joint Dysfunction	To conduct Experimental tests of a musculoskeletal model of the elbow joint for FES applications	The reproducibility of the model was not satisfactory
1999	Takashi watanabe *et al*	Muscle Modelling	To present An approach of muscle model with a stimulus frequency-force relationship for FES applications	The muscle model needs some improvisation for obtaining more accurate predictions
2000	Han-Chang Wu, Shuenn-Tsong Younz, Te-Son Kuo	Limb Dysfunction	To make a versatile multichannel Direct-Synthesized Electrical Stimulator for Applications of FES	
2004	M DiCicco, L Lucas, Y Matsuoka	Limb Dysfunction	To compare the control strategies for an EMG controlled orthotic exoskeleton for the hand	
2004	Ying-Han Chiou, Shih-Ching Chen, Jin-Shin Lai, Te-Son Kuo	Limb Dysfunction	To make a Noninvasive Functional Electrical Stimulation System with Patient-Driven Loop for the purpose of Hand Function Restoration	The system is more time-consuming in comparison to other systems
2007	L R Sheffler, J Chae	Neuromuscular Rehabilitation	To study the application of Neuromuscular electrical stimulation in neurorehabilitation

Table 1. Continued

Year of Publication	Author	Category	Objective	Area of Improvement
2007	C A Byrne, D T O'keeffe, A E Donnelly, G M Lyons	Gait	To study the Effect of walking speed change on tibialis anterior EMG during healthy gait for FES envelope design in drop foot correction	Only male subjects were considered for the study
2008	R Li, X L Hu, K Y Tong	Stroke	To develop a Combined EMG-driven system FES for post-stroke rehabilitation	Smooth tracking of the FES system was hindered because it depended on the subject
2008	E Lazar, J Nicolás Cuenca	Stroke	To study the effectiveness of Functional electrical simulation in treating stroke patients.	
2009	A Dutta, R Kobetic, R J Triolo	Gait	To study gait with EMG triggered electrical stimulation in people having partial paralysis	
2009	M Hayashibe, D Guiraud, P Poignet	Muscle Modelling	To make EMG-to-force estimation with full-scale physiology based muscle model	More accurate estimation of muscle force from EMG signal is desired
2011	C Chou, S Chen, Y Hwang, C Ho, C Chen	Paralysis	To study the application of FES for hemiplegia in order to train extremity coordination	
2013	Yukihiro Hara	Stroke	To use Functional Electrical Stimulation in Stroke Patients for rehabilitation purpose	
2014	"Different strokes" organization	Stroke	To do drop foot correction in patients who suffered from stroke.	

OTHER METHODS OF FES

It is quite evident from the above discussion that the most popular method of controlling FES systems is by using EMG signals. Apart from EMG signals, other signals like ENG and EEG have also been used for driving these kind of systems(Thomas Sinkjaer et al.,2003). EEG or Brain Computer Interface based FES systems were first introduced in late 1990s(Lauer RT, 1999 and Stein RB,1980). A number of research work has been undertaken for developing stimulators for controlling hands, limbs and other parts of the body(An H Do et al., 2012, Ang, K. K.et al., 2013). Besides EEG, researchers have tried to utilize another biosignal namely Electroneurography(ENG) signal. Both EEG and ENG signal has been used as controlling signal in laboratory but ENG signals have found application mostly as feedback signal for controlling any device.

After EMG signals, EEG signals are the most preferred signals to be used as command signals for stimulators. Over the past few years, scientists have explored this particular area quite intensively, specially how this technology can be utilized for the improvement of the quality of life of people suffering from different neural disorders. In 2005, a study was performed by Gert Pfurtscheller et al. to use an asynchronous EEG based Brain Computer Interface system for controlling an FES stimulator. The stimulator was designed to assist a tetraplegic patient for improvement of his hand grasp without any help from outside sources. The subject was required to imagine foot movement and the brain wave

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

generated by the patient while doing so was recorded by the EEG machine and converted to command signals by the BCI system to control the Functional Electrical stimulator. The result obtained by them was quite satisfactory because the patient was successful in grasping the desired object with his paralyzed hand completely on his own.

Another study was conducted in 2008 to provide rehabilitation to stroke patients. A BCI based FES system was proposed in the study in which the motor intention of subjects were recorded in form of EEG signals. Basically they tried to extract the Event-Related Desynchronization from which the motor intention of the subjects could be detected and these signals were then used for improving the limb activity. The main objective of using FES in this system was to stimulate the relevant muscles, which generates a sensory feedback to the brain, creating kind of a pseudo loop between the brain and the muscles.

FES DEVICES

The FES based systems are basically of two types external devices and implants. Both of these systems have some advantages and disadvantages associated with them. The FES system based implants or devices have evolved to a large extent in the past few decades. The development of the implants has been quite rapid and so far three generations of implants can be properly distinguished. The first generation of implants mainly consisted of simple electronic circuits and no measures were taken to eliminate the noises incorporated with the signal by displacement of the receiver with respect to the transmitter (Syms 3rd, CA et al., 1997 and Brindley GS.et al., 1994). In the next generation of FES implants, the power was derived from an inductive link before but the only difference was that the system was modified to provide stabilized output. The difference between the second and the third generations of stimulators is that, the third generation devices were powered by a battery instead of an inductive link. Vienna FES implant is one of the earliest designs used to assist tetraplegic patients. It was implanted for the first time in 1982(Winfried Mayr et al., 2001). It is basically an 8 channel implant and powered by inductive link. This design has been modified and few different designs of implants were derived from it which are still at the research level.

In 2004 (Fumihiro Sato et al.), A new contactless transmission based design was proposed. This system consisted of two parts. One coil, placed outside the limb and another part implanted within the body. This implanted part consists of two segments of coil- one to receive the signal and another to transmit the same. The RF frequency required for both reception and transmission of signals are different. In this design both the power and the signal required for stimulating the muscles get transmitted together from outside but they get separated inside the muscles. They also introduced a capacitor in the secondary coil to increase the power output of the entire system.

The development process of the FES system had several hindrances among which the problem of proper muscle recruitment is of utmost importance. Djordje Popovic et al. in 2005 evaluated the recruitment properties of the BION implant. This implant is basically a compact and self sufficient implant which can be inserted within the muscle. This implant is quite suitable for eliminating the problem of muscle recruitment (Djordje Popovic, 2007).

In another case (Anirban Dutta, 2009), the FES system was used to assist patients suffering from incomplete spinal cord injury while walking. In this system, both the EMG data acquisition and stimulation was done by means of surgically implanted electrodes. The anatomical positions suitable for placing these electrodes were detected prior to this implantation with the help of surface EMG electrodes. The stimulation was given to the muscle through this implanted stimulator.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Coming to the external devices, different forms of these devices have also been utilized for the remedy of neuromuscular diseases or neurological disorders. A number of research work has been performed in order to provide remedy to such problems. One of the examples of this kind of devices is exerciser. The first exerciser was an FES based cycling system designed by Petrofsky and Phillips (J.Petrofsky et al, 1984). This system was mainly suitable for people suffering from Spinal Cord Injury(SCI). In 2009, a Leg Stepping Trainer was developed to provide rehabilitation to these particular category of patients. They are mostly incapable of doing exercise because of their paralyzed leg. This isokinetic device maintained a static speed throughout the period of exercise and mainly strengthened the weaker muscles and restricted any extra movement or extra stepping effort of the leg (Nur Azah Hamzaid et al., 2009). It was actually used efficiently for two reasons viz. leg resistance training and cardiorespiratory training at comparatively higher speed.

Yoon-Kyu Song et al.(2007) proposed a new fiber optic based design of an FES device. In this device, light energy was converted to electrical energy which in turn was used to stimulate a sciatic nerve of a frog. At first, infrared pulses were made to enter a multimodal optical fiber, which then guided these pulses to a photovoltaic device. At this photovoltaic cell the light got converted to current and this current was responsible for stimulating the target nerve. This approach might be quite useful in fabricating new fiber optics based neuromotor prostheses.

The timing for application of the electrical pulses in any FES system is very crucial to get the desired effect and should be taken into consideration at each and every instant. An wearable device was developed in 2009 by Goro Obinata et al. for detecting the state when the switching of the walking motion is taking place. They also used Artificial Neural Network(ANN) for estimating this phase switching time. The results obtained by them showed that this wearable device rendered quite a good estimation of this timing.

Over the years, huge number of studies have been performed for modification of the FES systems. One of the aspects on which the scholars have concentrated is to increase the flexibility of the electrical pulse delivery system. Haibin Wang et al.(2012)devised an FES system which was capable for regulating the amplitude, frequency and waveform of the electrical pulses which are to be applied to the muscles. This system has application both the domains of medicine and research.

FES systems have been used even for rehabilitation of knee joint. The FEXO knee (Yong Ren et al., 2014) is an example of such a device. In this device, the stimulator was combined with an exoskeleton to make the entire system more effective. A number of similar devices have been designed, tested and applied clinically. Researchers are putting an enormous amount of effort for modifying these devices or systems so as to devise better and more sophisticated systems which will help people suffering from the previously mentioned maladies regain their former state of life.

FUTURE RESEARCH DIRECTIONS

Neuromuscular diseases (nmds) are listed to be one of those maladies that pose severe threat on the human race. However, the only feasible option to reinstate the patients, suffering from these genre of disability, to their former state is to provide them with next generation rehabilitation. These rehabilitative aids not only help them to overcome their disabilities but also gift them a better quality of life.

Previously, people victimized with such diseases could not have dreamt of having their life restored back to their healthy state. But with the advent of technology, such as EMG based FES, researchers and scientists have been successful to quite a good extent to realise their dreams which were once next

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to impossible. However, there are many loop holes that are yet to be filled in order to make the next generation of rehabilitative devices flawlessly effective.

One of such major drawbacks in present day's EMG based Functional Electrical Stimulators is that, most of these devices are implantable ones which demands the patient's body to be operated, that causes pain and hassle for the patient. Besides, there can also be biocompatibility issues that can result in infection of the patient concerned or in worst case rejection of the device. Also, those devices which are placed percutaneously, can cause discomfort and swelling.

As because the entire method relies on the application of electrical pulses to the human body, hence there always remains a probability for the patient to get affected by electric shock. This can often result in worsening of the affected muscles or even dysfunctioning of healthy musculature. Again if the duration or the amplitude of the applied pulses exceed the permissible limit, it can impose burns or other adverse effects.

The above mentioned shortcomings of EMG based FES systems can actually form the basis for the future direction of research works. For example, power isolation can be provided between the device and the patient so as to avoid mishap caused by electric shock. Apart from that, optimization of power consumption of these devices can also increase their acceptability.

CONCLUSION

The main aim of this chapter is to put up the technique of EMG based FES as a promising rehabilitation method for patients with neuromuscular impairment. From time immortal neuromuscular maladies have been a great reason of concern for human race to which the most suitable remedy is functional electrical stimulation. FES is mainly used to provide short duration electrical pulses to those muscles which suffer from nervous disorder in order to treat them. The EMG signals from the affected muscular region is used as biofeedback to the functional electrical stimulator Though from quiet a long time it has been in use for many clinical application but still there are many aspects of this method that is yet to be explored. Various categories of disorders can be treated using this system of which the most popular area of treatment are paralytic patients having hemiplegic, paraplegic or tetraplegic conditions, stroke patients and post stroke neuromuscular rehabilitation, patients suffering from muscular fatigue and limb movement control for physically disabled patients. Apart from these function electrical stimulation using EMG is also widely used for the purpose of Gait analysis of healthy as well as physically handicapped persons. But despite of having a lot of advantages like all other systems it too poses some certain disadvantages like risk of electrical shock, bio-incompatibility issues (in case of implantable ones), and relatively high power consumption. From quiet a long time this method has found a prominent usage in treating many patients but yet till now there is a lot of scope for improving this entire EMG based FES system in order to make it full proof and robust.

Chapter 45
A Novel Delay-Based GFSK Demodulator in 65 nm CMOS for Low Power Biomedical Applications

Iven Mareels
University of Melbourne, Australia

ABSTRACT

This article describes how, in recent years, with the development of microelectronics, implantable electronic devices have been playing a significant role in modem medicine. Examples of such electronic implant devices are, for instance, retinal prosthesis and brain implants. It brings great challenges in low power radio frequency (RF) and analog designs. This article presents a low power Gaussian frequency shift keying (GFSK) demodulator designed for Medical Implant Communications Service (MICS) band Receiver. This demodulator utilizes a novel structure that a wide IF range can be handled and presents the smallest Δf/f ratio in any published GFSK demodulators. In theory the demodulation method can be applied to any RF frequency. The demodulator draws 550uA from a 1 V power supply. A maximum data rate of 400 Kbits/s can be achieved within the 300 KHz channel bandwidth defined by MICS. A simulated signal-to-noise ratio (SNR) of 15.2dB at AWGN channel is obtained to achieve 10^{-3} bit error rate (BER). This demodulator is fabricated on 65-nm CMOS and occupies 0.12mm2 silicon area.

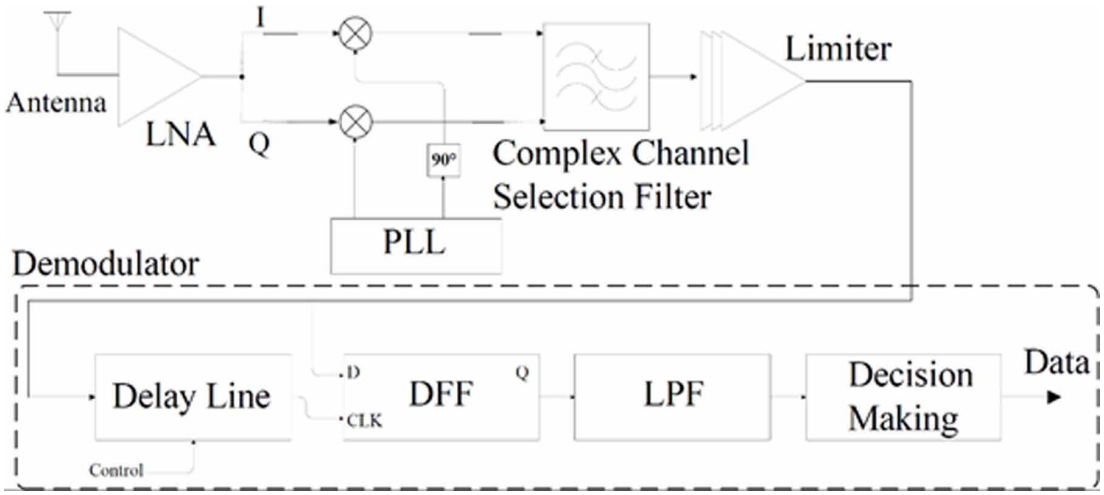
INTRODUCTION

The MICS band is an ultra-low power, unlicensed mobile radio service for implanted medical device. Ten 300 KHz channels are allocated at 402-405 MHz frequency band ("FCC Rules and Regulations," 2002). Implanted wireless device has a requirement of high reliability and ultra-low power consumption. Recent CMOS technology has enabled the design of reliable, low power and cost effective wireless transceiver. This demodulator is designed on 65nm technology under 1 V supply. It intends to be used for the epi-retinal prosthesis (Bionic Eye) to demodulate data for a 32x32 electrode array. In order to support these 1024 electrodes, a data rate more than 300 Kbps is required to make fully functional. Achieving high date rate and low power consumption from this limited 300 KHz bandwidth are challenges in the design of such system. So far, amplitude shift keying (ASK) and binary shift keying (BFSK) have been widely used in biomedical implants (Ghovanloo, Beach, Wise, & Najafi, 2002; Ghovanloo & Najafi, 2003). However, these two methods are not bandwidth efficient. This paper presents a demodulator that can work for both continuous phase BFSK and GFSK modulation schemes. Using GFSK, a data rate up to 400 Kbit/s is achieved within the given 300 KHz bandwidth. This demodulator is also immune to a frequency offset up to 4 MHz. A BER of 10^{-3} is obtained at SNR of 15.2 dB at the input.

DEMODULATOR ARCHITECTURE

The Architecture of the RF receiver is shown in Figure 1. The RF frequency is down converted from MICS band, 402-405MHz to around 5 MHz. A channel-select filter is used to reject the image and select the desired channel. Then the limiter amplifies the IF signal to rail-to-rail swing. Block diagram of proposed GFSK demodulator is shown in the dashed box of the figure. It consists of four blocks: delay line, delay flip-flop (DFF), gm-c low pass filter, and decision-making circuit. The delay element delays the IF input by approximate half the bit period. Then the DFF uses the delayed signal as the clock to sample the original signal. So the frequency information of GFSK signal is mapped into the density and width

Figure 1. Block diagram of receiver with the proposed GFSK demodulator



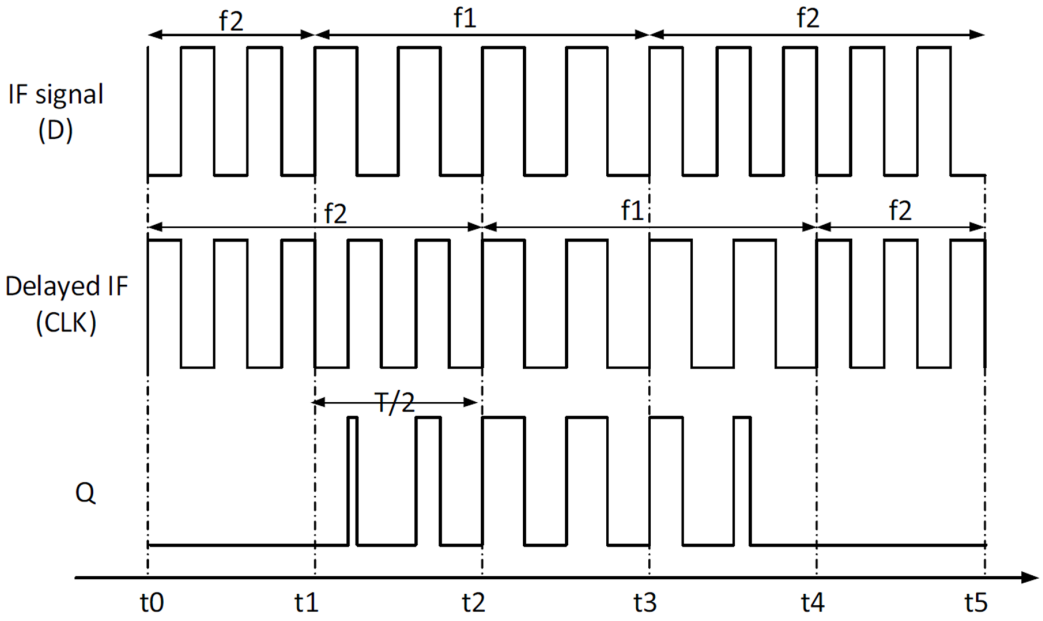
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the pulse train. After that, the low-pass filter converts the frequency information into voltage level difference. The voltage level after low-pass filter (LPF) may experience variation, as it can be affected by the frequency offset, pulse width variation, and process variation. The decision-making circuit is at the final stage to make a decision on the specific input.

Compared with conventional phase-quantization-based GFSK demodulator (Han & Zheng, 2009) and delay-line based BFSK demodulator, the proposed demodulator can tolerate much larger frequency offset. In other words, it is capable of working at a wider frequency range. Figure 2 shows the principle how this demodulator works at different frequencies. A BFSK signal with bit sequence starting with "010" is used as IF input. Two frequency tones f1 and f2 are used to present logic "1" and "0" respectively. Frequency deviation is Δf, where Δf = f2 - f1. From time t0 to t1, IF signal is sampled by its own delayed signal with same frequency f2, therefore the DFF produces a pulse train with equal pulse width at Q output. Then between time t1 and t2, frequency of original signal, f1, is smaller than that of the delayed signal, f2, so the pulse width at Q output of DFF is drifting. Since t2, both original signal and delayed signal are represented by frequency f1, the output of Q maintain the same width until t2 when the bit transition of original signal occurs. From t3 to t4, the two signals again are having different frequencies. But this time IF signal is sampled at a lower frequency f1. This is a reversed process of the pulse width drift happened between t0 and t1.It can be concluded that output pulse width is fixed at the center of each bit period, pulse width drift occurs around bit transition. Thus, frequency information of FSK signal is contained in the pulse train. When GFSK signal is applied, a similar output would be resulted except that the width of pulse changes continuously. Simulation result with GFSK input will be shown in the last section.

An important feature of this technique is that it is suitable not only for IF but also RF band, while other published works such as Han and Zheng (2009) and Xia et al. (2003) only work for low IF application as they require a relatively large ratio of bandwidth over carrier frequency to work properly. Same as in

Figure 2. Operation concept of self-sampling



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fu et al. (2010), this demodulator uses a low-pass filter to convert frequency information into voltage variation. However, in this work, the big bandwidth-to-carrier frequency ratio is not necessary. After LPF power averaging, DC voltage level variation between bit "1" and bit "0" could be expressed as:

$$V_{var} = \frac{n\left(\frac{1}{2f_1} - \frac{1}{2f_2}\right)}{\frac{1}{f_1}}, \quad \mathrm{n} = \frac{\frac{T}{2}}{\frac{1}{f_1}}.$$

where *n* is the number of pulses during the half bit period of the original signal. Also,

$$\frac{1}{f_1} - \frac{1}{f_2} = \frac{f_2 - f_1}{f_1 f_2} = \frac{\Delta f}{f_1 f_2} \approx \frac{\Delta f}{f_1 f_1}.$$

So, voltage variation can be re-written as:

$$V_{var} \approx \frac{n\left(\frac{\Delta f}{2f_1 f_1}\right)}{\frac{1}{f_1}} = \frac{\frac{\frac{T}{2}}{\frac{1}{f_1}}\left(\frac{\Delta f}{2f_1 f_1}\right)}{\frac{1}{f_1}} = \frac{\Delta f T}{4}$$

So, it can be concluded that the DC voltage variation is only dependent on Δf and bit period T. The only limit of using this demodulator for RF band is due to the difficulty providing large delay at a higher frequency.

DEALY ELEMENT

A delay element is a circuit that introduces a delay to the input signal and produces a lagged waveform with a similar shape at the output. The delay element used in this work is based on the concept of thyristor (Kim, Kim, Chang, & Kim, 1996). Schematic of this thyristor delay element is shown in Figure 3. Transistors *M1, M3, M4, M5* and *M9* are involved with delaying the rising edge of the input, while falling edge is delayed by *M2*, *M6, M7, M8* and *M10*. Operation concepts of rising edge delay and falling edge delay are exactly the same. Falling edge delay is indeed accomplished by delaying the rising edge of the inverted input signal. So only the rising edge delay operation needs to be discussed. When input changes from low to high, it switches on *M3* and *M4* and starts discharging 'OUT' through the pull-down network composed of *M11* and *M12*. Then, after 'OUT' drops below (V_{DD} - V_{Tp}), *M1* is switched on. *M5* has already be turned on since 'IN' went high. Once both *M1* and *M5* are on, they start charging up 'OUT'. Then 'OUT' reaches to *M9*'s threshold voltage V_{Tn}, turns on *M9* and pulls further down the voltage of 'OUT' until it drops to Vss. During this process, *M2, M6, M7, M8* and *M10* all stay in 'OFF' state. The

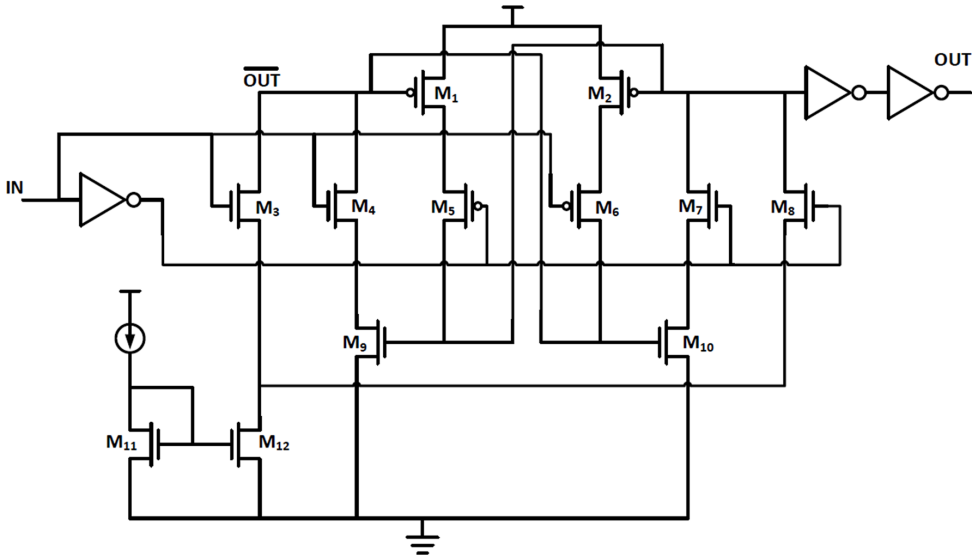
Figure 3. The CMOS thyristor as delay element



delay time is determined by the current source, thus can be easily controlled. Thyristor based delay element provides good signal integrity (Kim et al., 1996). Because of the positive feedback configuration, relatively sharp rising and falling edges can be obtained. Note that overall delay time of any delay cell cannot be larger than the pulse width. Multiple delay elements are required to provide enough delay.

TRANSCONDUCTANCE-C LOW PASS FILTER

The low-pass filter is a key block in this demodulator. It averages the power in the pulse and converts the pulse density that carries the frequency modulation information, into a voltage variation. Passive devices are traditionally adopted for the low-pass filter at high frequency. However, at a low cut-off frequency, conventional LC low-pass filter occupies too much area and it is not suitable to build on the chip. Nowadays, active transconductance-capacitor (also referred to as gm-c) filters have become more prevalent and are widely used for on-chip integration.

Various transconductance (OTAs) have been applied in gm-C filter design. Natua's OTA is chosen in this application, because of its good linearity and infinite bandwidth (1992). The structure of Nauta's OTA is shown in Figure 4. Assume that nfet and pfet of an inverter are perfectly matched by choosing appropriate size of the transistors. pfet is about three times larger than nfet to compensate the lower electron mobility. When both pfet and nfet are operating in saturation region, the drain current can be analyzed as follow:

$$I_{dn} = \tfrac{1}{2}\,\beta_n\,(V_{gsn}-V_{tn})^2, \text{ with } \beta_n = \mu_n\,C_{ox}\,W_n/L_n$$

$$I_{dp} = \tfrac{1}{2}\,\beta_p\,(V_{gsp}-V_{tp})^2, \text{ with } \beta_p = \mu_p\,C_{ox}\,W_p/L_n$$

Subtraction of I_{dn} and I_{dp} would give the output current:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$I_{out} = I_{dn} - I_{dp} = a\,(V_{in} - V_{tn})^2 = b\,V_i\,n + c$$

where

$$a = \tfrac{1}{2}\,(\beta_n - \beta_p)$$

$$b = \beta_p\,(V_{dd} - V_{tn} + V_{tp})$$

$$c = \tfrac{1}{2}\,\beta_p\,((V_{tn})^2 - (V_{dd}+V_{tp})^2)$$

For perfect matched pfet and nfet, $\beta_n = \beta_p$ and current of the n-channel device equals current of the p-channel device. When both devices are in saturation, the output current is 0. Threshold voltage of the inverter, also known as common mode voltage, is equal to 1/2 V_{dd}. The first level of inverters perform the basic V-to-I conversion. Without the second level inverters, the output current of inverter 1 and inverter 2 can be calculated and the value of differential output current I_{od}:

$$I_{o1} = a\,(V_c - V_{tn} + \tfrac{1}{2}\,V_{id})^2 + b\,(V_c + \tfrac{1}{2}\,V_{id}) + c$$

$$I_{o1} = a\,(V_c - V_{tp} + \tfrac{1}{2}\,V_{id})^2 + b\,(V_c + \tfrac{1}{2}\,V_{id}) + c$$

$$I_{od} = I_{o1} - I_{o2} = V_{id}\,(\beta_p\,(V_{dd} - V_c + V_{tp}) + \beta_n\,(V_c - V_{tn}))$$

So, the differential output current I_{od} is linear with differential input voltage, $V_{id}=V_{inp}-V_{inn}$. It can be approved that the linear relationship is valid even with imperfect matched pfet and nfet. Another import feature of Nauta's OTA is that it achieves infinite bandwidth voltage to current conversion. Note that the first level of inverters performs voltage to current conversion with no internal nodes. The second level inverters are used to control DC gain and do not present any other internal nodes as well (Nauta, 1992).

Figure 4. Nauta's transconductance

Figure 5. Fifth order Butterworth bandpass low-pass filter prototype

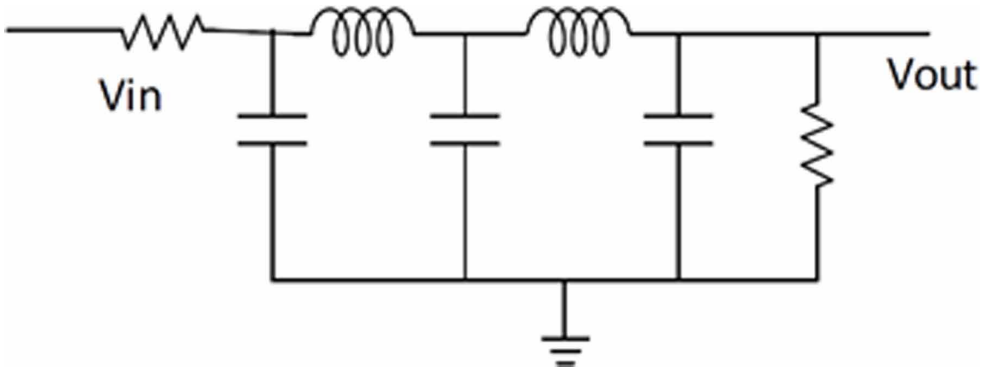

Figure 6. a) A grounded inductor and b) realization of the grounded inductor with gyrator

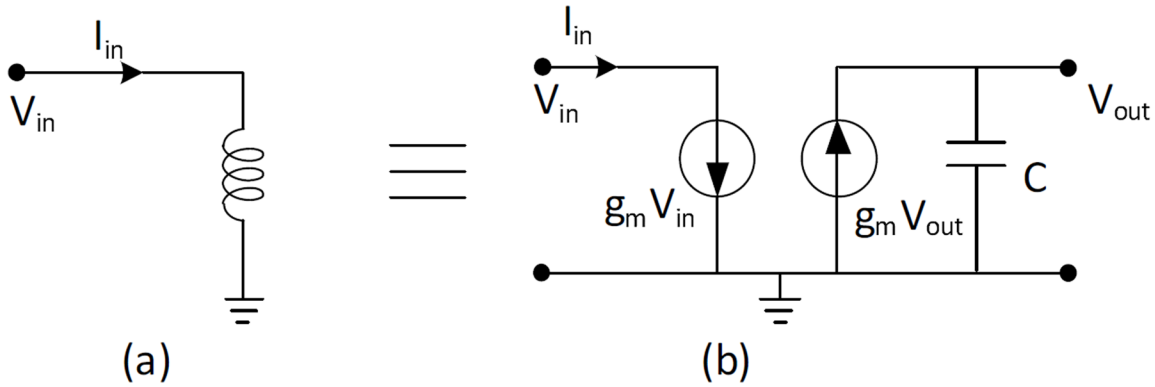


As shown in Figure 5, a fifth order bandpass low-pass Butterworth filter is selected as the filter prototype for its small ripple. The cut-off frequency is designed to be 200 KHz. By using replacement method of LC ladder, each inductor in the filter prototype can be replaced with a gyrator-capacitor circuit. The transfer function of an inductor is equivalent to capacitively loaded gyrator. Figure 6 shows the principle of LC ladder simulation of a grounded inductor. Similarly, a floating inductor can be simulated with two gyrators loaded by a capacitor in the middle. When the relationship between inductor and gyrator-capacitor can be written as

$$L = C/g_m^2$$

DECISION MAKING CIRCUIT

Then DC voltage level after low-pass filter could be affected by frequency offset, delay and process variation. In order to eliminate the effect of varied DC voltage level, a final decision should be made on the specific input. Figure 7 presents the architecture of proposed decision-making circuit (Koli & Halonen, 1997). A peak detector and a valley detector (Han & Zheng, 2009) detect and save the maximum

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

voltage, V_{peak}, and minimum voltage, V_{valley}, of the incoming signal separately, and then stores them in capacitors. A voltage divider is used to find the average voltage of V_{peak} and V_{valley}, where

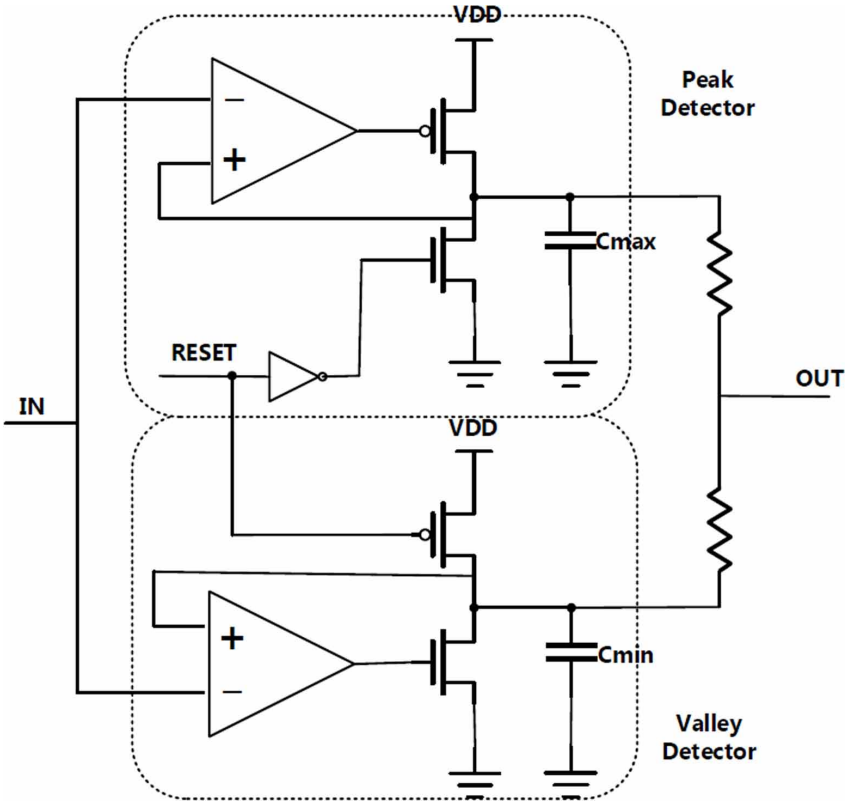
$$V_{avr} = (V_{peak} + V_{valley}) / 2$$

A final decision could be made by comparing the input with V_{avr}. A "0" is obtained when the input is below V_{avr} and a "1" is obtained when the input is larger than V_{avr}.

BIT SYNCHRONIZER

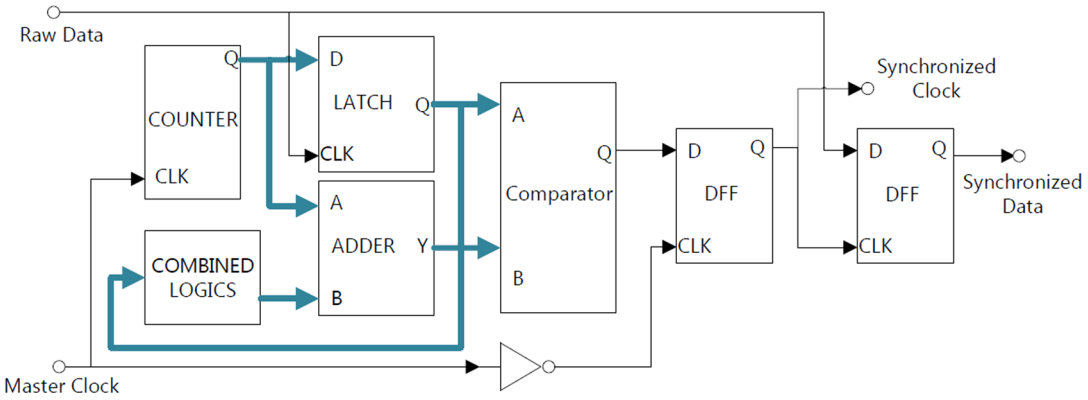
After decision making, demodulated data will not have 50 percent duty cycle. When simulating the demodulators with process variation (Monte Carlo simulation) and at different corners (such as FF and SS corners), the duty cycle can vary between 30 percent and 70 percent. Also, the bit stream is not synchronized with the system clock. This bit stream with un-perfect duty cycle is fed to the bit synchronizer, which will synchronize the bit stream to the system clock and reshape it into 50 percent duty cycle. The bit synchronizer is first reported in Piedade et al. (2005). As shown in Figure 8, it consists of a counter, a 4-bit latch, a 4-bit adder, two D flip-flops, a comparator and some logics.

Figure 7. Peak detector, valley detector and decision making



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Peak detector, valley detector and decision making



The master clock frequency is 4MHz, which is ten times of the bit rate of output from the demodulator. Rising edge of the first input bit will trigger the counter. Then it starts counting the master clock. The counter is able to count from0 to 9. When it counts to 4, the raw date is being sampled. There are ten master clock cycles within each bit period. So sampling point is in the middle of the first bit. After first bit is sampled, the counter will be reset and continue counting another 10 cycle regardless whether the raw data is 0 or 1. After bit synchronizer, demodulated data is re-shaped with 50% duty cycle and synchronized with the master clock.

SIMULATION RESULTS

This section presents the simulated performance of proposed GFSK demodulator. GFSK signal with *100KHz* frequency deviation and additive white Gaussian noise is applied to the demodulator. Figure 10 shows the signal with *14dB* SNR. Peak to peak voltage swing at input of the demodulator is *300mV*. 10^{-3} bit error rate is achieved at signal noise ratio of *15.2dB*. A *6μS* delay is introduced during the process of demodulation. The group delay remains constant over bit transition. Figure 9 shows the layout of proposed demodulator. Simulation results are present in Figure 11, 12, 13, 14. The demodulator consumes *550μA* from a *1V* power supply and occupies 0.1mm^2 silicon area.

CONCLUSION

A low power, wide input frequency range GFSK demodulator in 65nm CMOS was designed and simulated with post-layout extraction. The self-sampling technique greatly improves the tolerance of frequency offset and relaxes the sensitivity requirement of final decision making. With low power consumption, sufficiently wide input range, and MICS band operation, this demodulator is well suited for the retinal prosthesis and other biomedical implanted devices. The novel demodulation method also makes PLL-less receiver possible for low-power biomedical applications. This demodulator is part of a sub-1mW PLL-less MICS band receiver.

António Abelha
University of Minho, Portugal

José Machado
University of Minho, Portugal

ABSTRACT

Hospital inpatient care compromises one of the most demanding services in health institutions for providing a careful and continuous healthcare assistance. Such demands require a constant update of the patients' health record allied with support systems responsible for monitoring their clinical information. In this context, the problem in this study becomes a process of continuous improvement. To define the case study, it was necessary to use research tools such as questionnaires and interviews. With these techniques, it was possible to delineate the state and dimension of the problem. Subsequently, the approach and solution was established and a new web platform for the daily monitoring of patients was proposed focused on nurses. The tool incorporates a real-time data visualization, and a patient record during an inpatient care episode. Moreover, this article also highlights the required adaptability of this platform for each health unit according to needs. With this solution, it is expected to correct many of the problems detected through quantitative results.

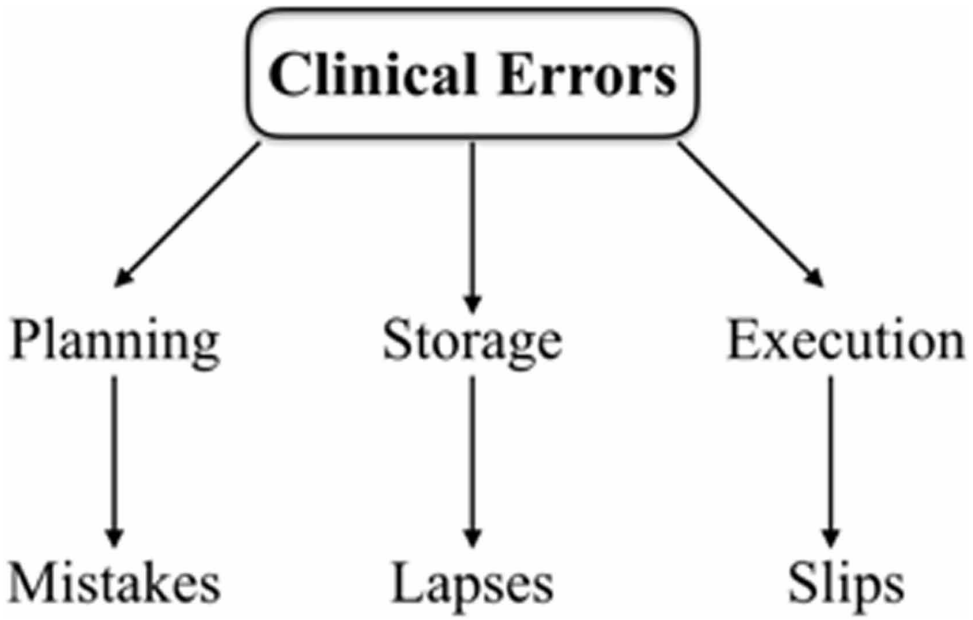
INTRODUCTION

In a hospital environment, the patient security is one of the major concerns in health, in the sense of improving the efficiency of healthcare delivery, and minimizing delays or failures that could lead to other consequences. These consequences can be translated to a considerable portion of clinical errors which can be of several types, depending on the approach taken. Regarding effects, Reason (2000) argues that errors can be active, with an immediate or latent impact. Thus, the results can appear in short-term or long-term, respectively. According to Reason, these errors can have different sources, disclosed in Figure 1. Moreover, James Reason's "Swiss cheese" model of error causation defines that in complex organizations such as hospitals, errors occur due to the holes or flaws in the multiple layers of defense, causing adverse outcomes to the patients (Reason 2010, Salazar et al., 2013, Duarte et al., 2011, Portela et al., 2014).

The Institute of Medicine's Quality of Health Care in America valued that about 98000 people every year die due to clinical errors at hospitals. Comparing to other main causes of death in America, this causes a greater impact in the scientific community, becoming one of the most emerging public problems today (Donaldson 2000).

The continuous and dynamic alteration of patients' clinical status in healthcare institutions is one of the major causes of the occurrence of adverse events. This level is very high becoming urgent to find connections with other areas, such as information technologies (IT) (Peixoto et al 2012). This is one of the most explored fields in medical informatics, raising great challenges in terms of development, implementation and maintenance. Thus, over the years, and due to the high data flow, efficient and user-friendly support systems for health professionals have been emerging, called hospital information systems (HIS) (Coiera 2003).

Figure 1. Classification of clinical errors according to (Reason, 2010)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The high number of professionals involved in clinical acts, combined with their diversity of academic backgrounds, has led to high level of automation of services, from the well-known clinical software, which has several advantages such as financial, administrative, and recruitment, until reaching the medicine itself. There, the role of these developed HIS is crucial (Khodambashi 2013, Machado 2007). Its main goal is to streamline and support the provision of direct healthcare to the patient, being some of them oriented to the use of a certain group of professionals, such as doctors and nurses (Kim & Park 2011).

In Europe, the Health2020 strategic program organized by World Health Organization (WHO) highlights nurses and their important role in improving healthcare delivery, since they are the most direct and continuous contact with the patient throughout the hospitalization episode. The essence of nursing is "caring", i.e., providing the highest possible quality care for an assertive practice. As such, these professionals are responsible for providing safe, high quality and efficient healthcare services. To provide this high quality, all the conditions must be attended. Thus, one of the main focuses of this program is the nursing team (World Health Organization 2015, Duarte 2011, Rocha & Rocha 2014).

To overcome failures in shifts change, such as administration of a given medication with the wrong dosage or omission of some relevant information about the patient, it emerged the motivation to develop a nursing care support system in the hospitalization. This platform aims to automate information for an easy visualization, excluding the need to resort to other means that would certainly take more time. All the patient's relevant information for nurses can be consulted on this platform, such: the location of his/her room; identification of number of the bed; the type of fasting that is attributed to him with a specific examination or analysis that he/she will carry out; the alerts and medication associated with the patient; among other attributes. This data is updated continuously.

The main contributions with this work are:

- Potential reduction of occurrence of clinical errors (medication errors, dosage errors, diagnostic errors, among others) committed through clinical information made available in real time;
- Support health professionals during the hospitalization episode, gathering relevant and updated information about the patient, introducing relevant attributes before the clinical act;
- Increase the efficiency of health care provided;
- Improve the quality of patient care;
- Application of the platform developed in the various hospital services, being initially tested in the Hospital Center of Porto (CHP) Cardiology service.

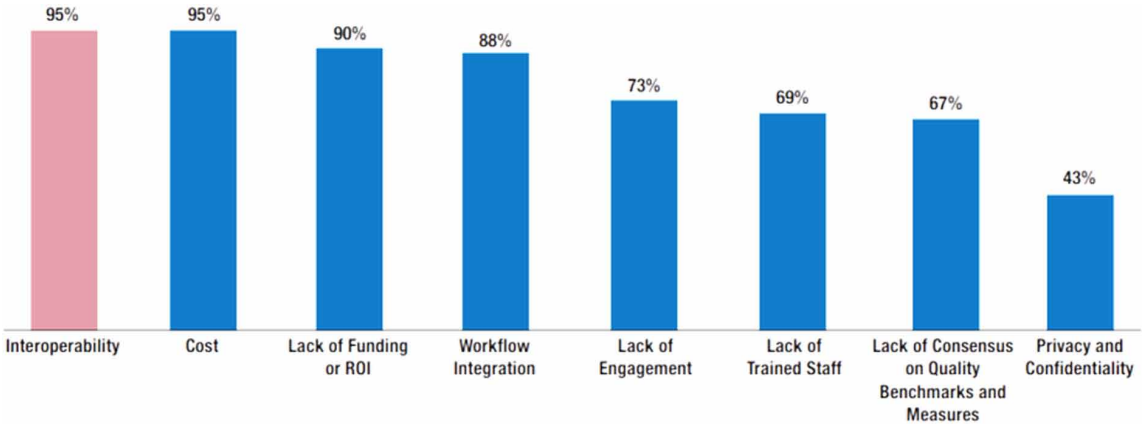
The presented paper is organized as follows: the next section describes the importance of the interoperability of systems and how this can be guaranteed through multi-agent technology. Thereafter, depicts the research methodologies used in the project as well as main features and advantages of the web platform developed and discusses its relevance respectively. Finally, a main conclusion is outlined according to this work.

INTEROPERABILITY AND MULTI-AGENT SYSTEMS

The presentation of clinical information is done in several ways, depending on the kind of data stored in the systems. For this reason, it often becomes difficult for health professionals to integrate quickly into the patient's condition.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Percent of ACOs reporting largest barriers to using health IT effectively, 2014 (American Hospital Association, 2015)



In this context, a USA study shows the current state of interoperability in the country. Of the 62 Accountable Care Organizations (ACOs), health organizations according to the American health model, 95% referred to interoperability as one of the main obstacles to harnessing the true potential of IT in health (American Hospital Association 2015) (see Figure 2).

For all HIS to operate at their maximum efficiency and to relate to each other without communication failures and with high coherence, the concept of interoperability takes great importance in this context (Cardoso 2014).

In the middle of 1960s, the Healthcare Information and Management Systems Society (HIMSS) emerged a non-profit association, whose mission is to unite efforts to improve health through information technology continuously (Duarte 2016). Following their definition "Interoperability describes the extent to which systems and devices can exchange data, and interpret that shared data. For two systems to be interoperable, they must be able to exchange data and subsequently present that data such that it can be understood by a user…" (HIMSS, 2017). Nowadays, a high percentage of relationships between HIS still lacks interoperability among them. This is caused by the high development and complexity of the current databases that support hospital systems. There are several advantages provided by interoperability in health, among them the reduction of the probability of occurrence of clinical errors and consequent improvement of the quality of the services provided (Dove, 2005). The exchange of useful information between different health institutions has proved to be a necessity. For example, after a period of inpatient care, the patient is followed by a general practitioner and the electronic clinical record must be properly updated (Lang, 2006). Clinical decision support systems also contribute to improved health care delivery by helping health professionals to make their daily decisions (Berner & Moss, 2005, Moreira et al., 2017). These realities, among others, reveal the need for constantly updated and easily accessible clinical information. These features can be ensured through investment at the various levels of interoperability. One of the most common and effective solution used to solve the miss of interoperability are multi-agent systems (MASs). These systems consist of an environment created by the interoperation of two or more agents that make adaptable but standardized information flow enabling interoperability in a loosely coupled manner (Miranda *et al*. 2012). Moreover, they are associated with data warehouses for efficient data storage and query. For that matter, this was adopted in this project.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Multi-Agent Systems

Currently, the volume of clinical data is very high and there has been a need to build consistent and organized data models, such as Data Warehouses (DWs). DWs are subject-oriented, integrated, time-variant, and non-volatile collections of data in support of management's decision-making process (Inmon, 1996). To coordinate and update their content, multi-agent technology was used.

Being multi-agent architectures a field of research of distributed artificial intelligence, this technology is intrinsically connected to the concepts that define a distributed architecture, while being distinct in the definition of an agent versus the properties of the general middle-wares of many others distributed architectures. Being distributed by nature its characteristics define MAS as an abundant and fiercely adaptable technology with great interest mainly due to the research interests in this area (Miranda et al., 2012). A MAS consists of a computer system with multiple autonomous agents that cooperate together to perform certain tasks or achieve certain objectives. An agent can be classified as homogeneous or heterogeneous and is defined as an element able to respond autonomously to problems, operating asynchronously, always respecting other existing agents. Its main characteristics are the autonomous capacity to make decisions, as well as the capacity to interact with other agents through social interaction protocols, reaching the desired levels of coordination, cooperation, competition and negotiation.

Study Considerations

The main goal of this study is to automate the hospital information, updating it constantly, without any effort or action that might interfere with the process of healthcare delivery. To accomplish this purpose, a web application was developed, dedicated to nurses, able to show the inpatient's information in health units. Since we are dealing with big data, the solution adopted addressed the use of multi-agent systems for monitor and manipulate the developed DW. This DW is suitable for a system that is capable of crossing several kinds of information from different sources (Machado et al., 2007, Machado et al., 2006). With the DW built, bridges between different HIS, previously non-existent, are established. Regarding the current study, some information was transformed and adapted to the project, given the needs of the users of the platform. The operation of the developed MAS will be described posteriorly, as well as the strategy established so that the DW information is constantly assured and updated. At this stage of the project, the interoperability between the systems used is guaranteed, reducing some possible communication failures at any level (Duarte et al., 2010).

METHODOLOGIES OF RESEARCH

In the initial phase of the project, several studies and tests were carried out in order to understand the needs of the project. Afterwards, the results obtained were analyzed for a later validation of the best model and architecture. Two methodologies and three research techniques were used, as will be presented.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Case Study

A case study (CS) is a methodology which contributes to the definition of research topics, for a given context. Among several methodologies used in information systems, the CS was chosen for the definition of the project, given its highlight among other strategies, especially in the organizational context.

Pozzebon & Freitas (1998) claimed that the researcher must define clearly the initial goals and the reason for the choice of the research target, and describe in detail the techniques and sources used for the analysis and collection of data, avoiding some common mistakes detected in the application methodology. Additionally, the researcher must be impartial, ignoring his/her personal opinions that can interfere with the results. Moreover, according to (Benbasat et al., 1987), CS has as main characteristic the versatility, which can be used in distinct approaches. Thus, they defined the following eleven points, that will be respected in this work:

- The object of study is evaluated in its natural context;
- The collection data is performed in several ways;
- A few entities are analyzed (groups, persons or organizations);
- The complexity of the unit is studied intensively;
- CS is more suitable for exploration, classification and definition of several stages of developing, being a process of knowledge;
- The research stage does not include control or experimental manipulation;
- The independent and dependent variables might not be defined a priori;
- The results are dependent on the type of integration;
- During the gathering of hypotheses, changing types can occur (local or methods of collecting data);
- CS is suitable to respond questions like “how” and “why”;
- The focus lies in real and actual happenings.

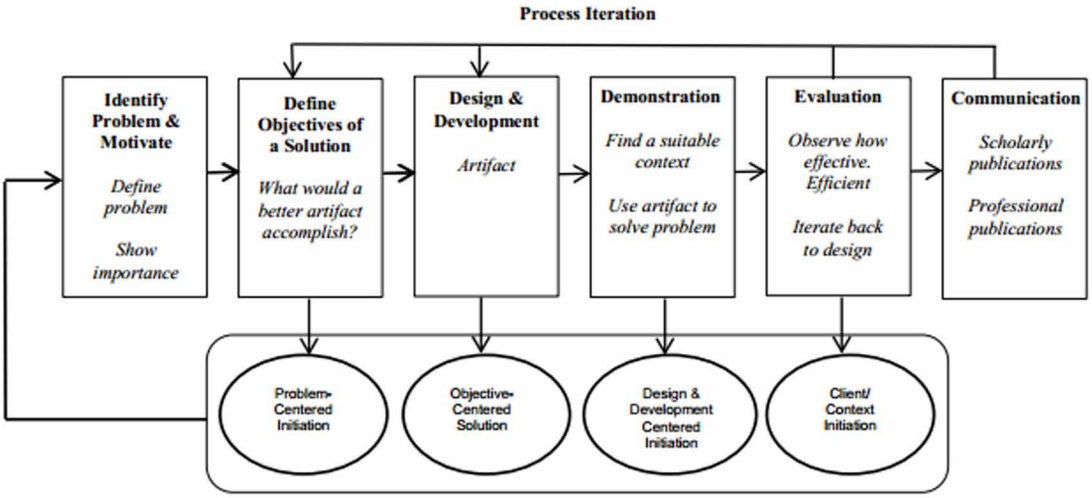
Design Science Research

The design science research (DSR) model used was the one proposed by (Peffers *et al*. 2007) with the structure shown in Figure 3.

The starting point was the identification of the problem. The problem that arises is how the whole relevant clinical information of each patient at the time of hospitalization can be provided at the same place. This information is dispersed by several systems and can be stored in several ways. The goal is to find a solution to the above problem, which helps health professionals to have access to the information they need at a given moment, in a fast and intuitive way. Thus, the chosen solution was to develop an artefact capable of showing all the necessary and constantly updated information about each patient. This artefact in production will be subsequently implemented, firstly in the Cardiology health unit of CHP. Afterwards, the next goal is the its propagation to the remaining units. After its implementation, its impact will be reassessed by the users with specific models.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. DSR methodology process model (Peffers et al., 2007)



Techniques of Research

The methodologies were implemented using research techniques, with the objective of searching and collecting data.

Literature Review

An exhaustive bibliographic analysis was carried out in search of similar existing projects. This stage is very important in all research projects, not only for a better definition of the case study, but also to understand with greater precision the developments of the subject in question, now. According to Cardoso (Cardoso et al., 2010), all investigators must in detail analyze the work of others who proceeded and only after that, proceed to their own adventure. The constant evolution of science must be considered. A good review leads to an easier delimitation of the problem under study and to the discovery of new lines of investigation, avoiding possible repetitions and proposing future goals.

No support platform for hospital inpatient care was found, with specifications that will be described later. However, there are several developments in this area, such as the hospital management system (Bento et al., 2017), which consists of the classification of patients with different degrees of care (minimum, intermediate, high dependency, semi-intensive and intensive) for the organization of appropriate care and sizing of the required nursing professionals.

Interviews

The interviews are a relevant technique in the research process. The involvement of future users provides an accurate feedback about their needs.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The researcher can feel the reality and clarify the objectives, the structure that intends to follow during the interview and its goal, earning the trust of the interviewing to assure its collaboration in the future (Lavrakas, 2008).

To accomplish these stage, several visits to the health unit of Cardiology of CHP were done, more precisely, to the nursing room. The chef-nurse was the main person interviewed, who showed great collaboration and interest in the proposed platform. During the interviews, it was reported the major difficulties that nurses from that unit feel daily and discussed the main strategies to the outcome such problems.

Questionnaires

The questionnaires technique is very similar to the interviews with the difference that the interviewer does not has direct contact with the interviewing, and they answer the questionnaire anonymously. Regarding the type of questions, the researcher must be careful since they should be clear, coherent and with maximum neutrality (Williams 2006).

In the first phase of the project, a questionnaire with eight questions was carried out. The group of interviewees where some nurses from the cardiology department, with a final result of 35 questionnaires answered.

Objectivity and simplicity were concerns considered when the questions were constructed, aiming to understand the main failures that respondents have in their workplace.

Among the eight questions addressed, four were highlighted:

Question 1: In your opinion, patients are well monitored throughout the shifts?
Question 2: Are the changes in the clinical status of the patient known to all nurses in the health unit?
Question 3: Have you ever faced with the possibility of complications of the patient's condition due to information system failures?
Question 4: Have you ever been confronted with medication / dosage errors?
Question 5: Have you ever witnessed the occurrence of communication failures, for example, about changes in patient accommodation (bed changes)?
Question 6: Have you ever faced with communication failures, particularly in the absence of records from the previous shift?
Question 7: Have you ever had difficulty accessing the updated patient's clinical process?
Question 8: In your opinion, it would be appropriate the support of the new technologies to the daily provision of health care in your unit?

A statistical analysis of data was performed, through the results obtained. These quantitative results were normalized to realize a qualitative analysis of data, thus identifying patterns and trends. This analysis was chosen contrary to the Data Mining process, because the results sample is relatively low. Consequently, problem identification is immediate and direct.

The questionnaires were handled one by one through Tableau Software, a tool that allows you to organize and interpret data, easily answering qualitative questions and identifying patterns and trends.

The most Business Intelligence (BI) users use Data Visualization Tools to handle their raw data and transform them into useful and informative data. Nowadays, Tableau Software is one of the most widely used data analysis and visualization tools in the world. Compared to other tools such as QlikView and MicroStrategy Analytics, Tableau provides three versions (online, desktop and server version). Combined

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

with its high speed, this software is easy and User-friendly, and contains a highly competitive feature, the access with multiple platforms. Currently, its list of clients is very varied, with names like: Deloitte, eBay, Google, The New York Times, PayPal, Skype and many more (Reddy, 2015).

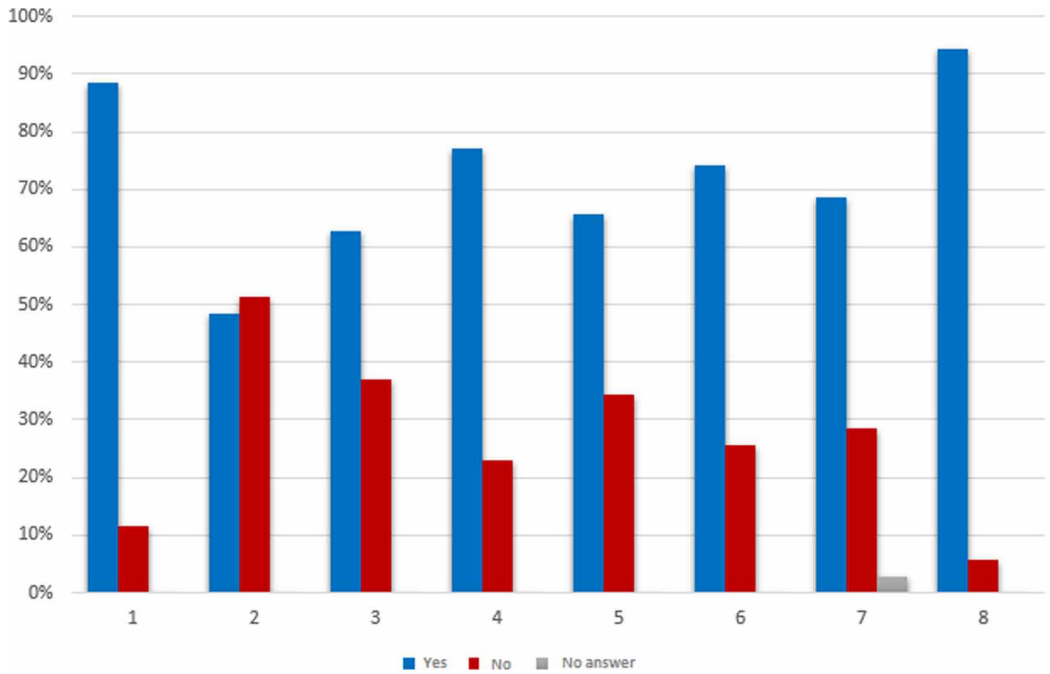
The data entered in the data source were of the nominal type. Thus, the value 0 was used to "No" answers and the value 1 to answers "Yes". To facilitate the analysis and understanding of the data, the results are presented as a percentage. The answers to the questionnaire can be found in Figure 4.

The interpretation of the results led to several of the initial motivations of the project being strengthened and reinforced. The idea that the support of the new technologies in the provision of healthcare in a hospital unit is fundamental. The need for integration and interoperability between systems, devices and health professionals is vital.

NURSING PRACTICE SUPPORT SYSTEM

The support system for nursing practice in an inpatient setting aims to help the health professional, in this case nurses, in real time. Nurses should obtain a more quick and effective access to all kinds of useful information about the patients and their tasks and actions at their health department. Besides, the application has a repository component that can be accessed at any time, called Patient History. Here each patient will have all their detailed information from the beginning of their hospitalization. The Patient's History was built according to the results obtained in the questionnaires mentioned above. It is very important for the process of nurse shifts. This feature ensures that no information is lost and is visible for all health professionals.

Figure 4. Result of the answers to the four questions in the questionnaire analyzed



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Characteristics

The main characteristics of the Nursing Practice Support System are described below:

1. Frequency of Data Update:
    - Minimum: Day to day;
    - Maximum: 5 to 5 minutes.
2. Usability:
    - Real-time updated patient information;
    - Simple and effective organization of information, making it easy to perceive and consult;
    - Alerts of future events, in particular, analyzes and examinations for executing or changing medications and types of diets, of each patient;
    - Easy location of inpatient in the health unit;
    - Availability of the daily tasks of nurses in their healthcare department;
3. Information Content:
    - Medication administration;
    - Upcoming Examinations, Analyzes, and Surgeries;
    - Diagnostics;
    - Type of Diets;
    - Location of patient in health unit;
    - Daily Nursing Tasks.

Data Sources

The information in the support system for nursing practice during hospitalization comes from different types of data sources:

- Electronic Nursing Record;
- Electronic Health Record;
- Agency for the Integration, Diffusion and Archiving of Clinical Information;
- Drugs System.

For this project to be possible, there was a need to gather information from several HIS. Consequently, it was developed a process capable of executing all the phases of extraction, transformation and loading (ETL) of the information in an autonomous way.

This new system of support to hospitalization has as main features the high interoperability existing between the different existing systems. Thus, the system avoids that during its tasks the health professional must manually access each one of these systems.

Multi-Agent System

As can be seen in Figure 5, eight agents were created with sequential and cyclic behaviors, and the first seven are responsible for completing each auxiliary table (Diet, Medication, Analyzes, Examinations, Tasks, surgeries). To avoid duplication of information, a truncate is done to each one of them before

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the information is entered. It was decided to create different agents for each auxiliary table to not compromise the performance of actions. Each table contains an attribute named "flag" with initial value 0. When the auxiliary tables are fulfilled with the new information (by the first seven agents), the flag of each one of them takes its initial value (0) and then the eighth agent updates the main table with that information, checking if the value of the flag is 0 (means is new information). In the end, he updates the flag of each auxiliary table to 1.

DISCUSSION

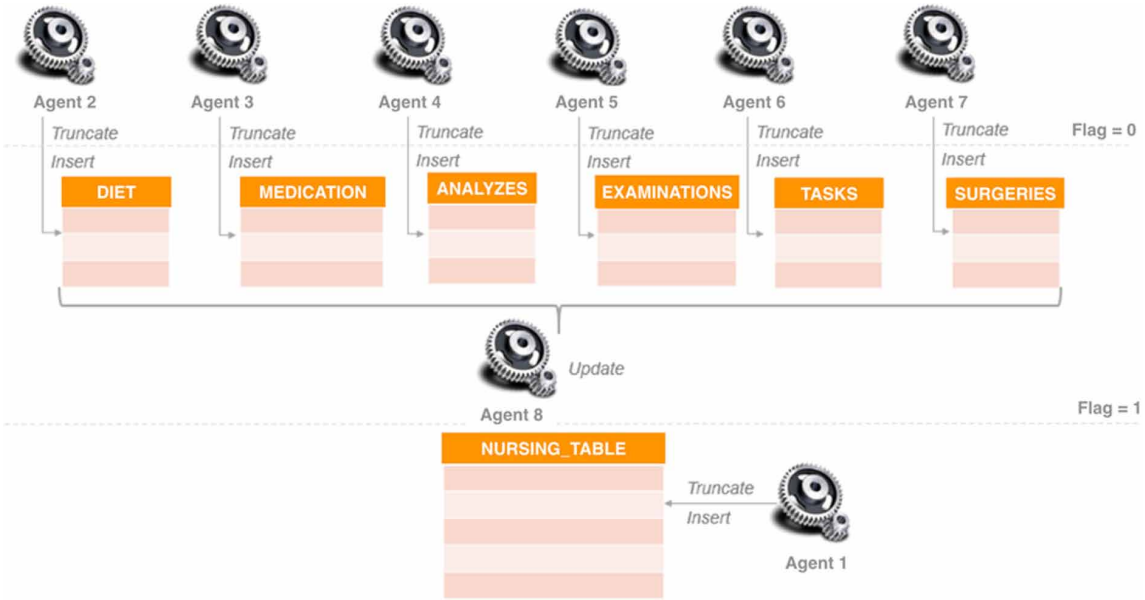
The support system for inpatient nursing practice is a project under development. It was previously discussed and approved by clinical leaders of the healthcare institution and later by health professionals who will be their future users. Through this new system, the information is getting available in real-time. For this, it is used autonomous agents to constantly execute ETL processes constantly. The update frequency depends on the refresh rate associated with each kind of data.

The fact that the system presents only the most relevant information, most succinctly and assertively as possible, confers to the application a high level of security and, consequently, a high confidence in the presented solution.

The major advantages of this project are:

- Improving quality of health record by the health professionals;
- Improving quality of the data, from its collection to its processing and validation;
- Increasing of the number of relevant information about the patient in the same place;
- Easing access to information (easy reading and interpretation).

Figure 5. Schematization of the multi-agent system developed



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The platform was developed respecting the principles of information automation, interoperability, usability, adaptability, integrality, distribution and competition. Therefore, the result was a web application easy to understand and use, with the ability to adapt to different operating systems and HISs.

The first implementation and testing phase of the prototype was carried out at the CHP hospital, which demonstrated the feasibility of the solution.

CONCLUSION

Increasingly, the use of new technologies for providing better healthcare is emerging. In this context, the proposed system aims to contribute to improving the patient's healthcare quality. Thus, the solution focuses on the patient and his well-being, reducing the possibility of the exposure to clinical error. The health professionals seem to be enthusiastic and confident with the solution. They have the awareness that the solution can be of great impact in their daily work.

The main motivations for this project regarding the results obtained in the questionnaires performed to health professionals were the decrease of the probability of clinical error or adverse events; and the creation of interoperability bridges between the several HIS holders of the different kinds of gathered information.

As future work, this application can be extended to other health departments of the hospital, suffering adaptability depending on the requisites of each service. Another improvement will be its portability to a mobile version, where health professionals will be able to consult it using a Smartphone or a Tablet with different operating systems. The system also will be a target of several studies of usability and technology acceptance. In the next few steps, the interface can undergo some improvements.

ACKNOWLEDGMENT

Chapter 47
An Analysis of Factors Affecting Postnatal Depression Intervention Adherence

Omobolanle Omisade
University of Portsmouth, UK

Alice Good
University of Portsmouth, UK

Tineke Fitch
University of Portsmouth, UK

Jim Briggs
University of Portsmouth, UK

ABSTRACT

Adjunct mobile support for postnatal depression could promote treatment adherence and long-term maintenance of behavioural change. The aim of this article is to establish the factors that determine adherence to postnatal depression intervention and support. Also, this article is intended to establish attitudes that women have towards postnatal depression intervention and support. Eighty-four women with a previous diagnosis of postnatal depression completed an online questionnaire on their previous use of postnatal depression intervention and factors inhibiting adherence, as well as attitudes towards the intervention. Results showed that adjunct support and combining multiple interventions would improve adherence. The provision of treatment guidance will also positively enhance treatment uptake and retention. Therefore, these factors should be considered for the development of theory-based adjunct mobile application for postnatal depression.

INTRODUCTION

Women are vulnerable to the affective mood disorder postnatal depression (PND), which can occur in the first three months after childbirth (Culjak & Spranca, 2006; O'Mahen et al., 2013). From the literature, PND represents the most frequent form of maternal morbidity following delivery (Cuijper, Brannmark, & Van Straten, 2008; Gibson, McKenzie-McHarg, Shakespeare, Price, Gray, 2009). A meta-analysis of 59 studies reports that 13% of women having babies suffer from PND with about 70,000 women experiencing PND in the United Kingdom every year (Caramlau, Barlow, Sembi, McKenzie-McHarg, & McCabe, 2011; Dennis, 2003; Evans, Donelle, Hume-Loveland, 2011; Glover, Onozawa, & Hodgkinson, 2002; Morrell, 2006). Like other episodes of depression, PND affects a postnatal woman's feelings about herself and her interpersonal relationships; and she may be functioning only minimally in her role as a mother (Beck, 2001). Additionally, PND can have serious consequences for the infant, which can include lower weight; impaired mental and emotional development; difficult temperament; poor self-regulation; low self-esteem; sudden infant death syndrome; or an overall higher frequency of hospital admissions and long-term behavioural problems (Forman, Videbech, Hedegaard, Salvig, & Secher, 2000; Glover et al., 2002; Grace, Evindar, & Stewart, 2003 Morrell, 2006; O'Mahen, 2013).

Antidepressant medication is usually the first treatment offered to treat the symptoms of PND. There is evidence to support its efficacy when used as prescribed, but it is often associated with side effects (Hou et al., 2013; Kaltenthaler et al., 2002). A study compared the effectiveness of antidepressants with placebo for the treatment of PND in an 8-week study (Yonkers, Lin, Howell, Heath, & Cohen, 2008). Women were randomised to either a placebo group or to take paroxetine antidepressant. Seventy women qualified for the study and only 31 completed between 7 and 8 weeks of treatment. While results indicated that there was a great improvement in the overall clinical severity for the paroxetine group compared with the controlled group, the study was restricted by high attrition rate and this complicated the interpretation of the findings. The high attrition rate in PND interventions remains a major problem that needs to be solved. One possible reason for high attrition for the use of antidepressants might be related to the fact that postnatal depressed mothers consistently indicate that they prefer therapy to antidepressants because of the concern over safety when breastfeeding (Hou et al., 2013; Ruaro, 2013). However, the authors cannot make a general conclusion.

Alternatively, psychotherapy is an effective treatment and support for PND. Milgrom et al. (2006) suggested that counselling informed by the principles of Cognitive Behavioural Therapy (CBT) (a form of psychotherapy) is effective when delivered by maternal and child health nurses. Interpersonal Therapy (IPT) has also been found to be effective for this population (Klier, Muzik, Rosenblum, & Lenz, 2001). However, the postnatal period still presents specific barriers to adequate improvement in depression, and a large number of women remain without treatment, do not adhere to the prescribed intervention or show only moderate improvement in depression (Boath, Bradley, Anthony, 2004; O'Mahen, 2013). More recently, computerised self-help approaches using the Internet have been developed to provide greater access and flexibility of receiving psychotherapy while requiring minimal input from a therapist (O'Mahen, 2013). The National Institute for Health and Care Excellence (NICE) has recommended the use of Computerized Cognitive Behavioural Therapy (CCBT) software for depression (NICE, 2006). CCBT has shown to be effective, with less time required in usual care and shorter therapist time needed while providing engagement and quality support (Churchill, et al., 2001; Gerhards, et al., 2010; Giridher, Wasilewska, Wong, & Rekhi, 2010; Graham, Franses, Kenwright, & Marks, 2000; Ingram, 2013; Kaltenthaler, Parry, Beverley, & Ferriter, 2008; Kaltenthaler et al., 2002; Marks, Shaw, & Parkin, 1998;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Merry et al., 2012). However, in clinical settings where women are only able to access CCBT from health centres, there is still the problem of long waiting lists for assessments and support (Andersson et al., 2005; Henshaw, 2004; Marks, Cavanagh, & Gega, 2007; O'Mahen et al., 2013; Proudfoot et al., 2004). The number of sessions of CCBT ranges from four to a maximum of 12 sessions and, in some cases, these sessions do not fit into a baby's variable and demanding schedule, resulting in poor adherence and inequality in access to appropriate treatment (Kaltenthaler et al., 2002; O'Mahen et al., 2013; Wan, Hu, Moore, & Ashford, 2008).

Research suggests that, despite effective treatment options, a large number of depressed women comply poorly with treatment or show only moderate improvement in depression (McCarthy & McMahon, 2008). In some cases, depressed women with other young children attributed poor adherence to struggles and cost associated with transportation or overwhelming responsibilities that can interfere with the ability to attend regularly scheduled appointments (De Graaf et al., 2009; Kaltenthaler et al., 2008; McCarthy & McMahon, 2008; Merry et al., 2012; Wan et al., 2008). Other barriers include stigma, long treatment sessions, sleep difficulties associated with infant sleep schedules and problems adjusting to and managing busy schedules of an infant balanced against other valued tasks (Kaltenthaler et al., 2008; O'Mahen et al., 2013).

The increase in the use of mobile phones and mobile applications may offer additional opportunities to provide support and may circumvent many of the difficulties that lead to poor adherence in PND. An adjunct mobile application could potentially be used to motivate postnatal depressed women to adhere to treatment and sustain treatment outcome in the long-term by providing guided support (Cuijpers, Donker, van Straten, Li, & Andersson, 2010; O'Mahen et al., 2013). It could offer the opportunity to provide just-in-time support and resources to those that have particular needs for flexibility (Kaltenthaler et al., 2008). A mobile application for PND would enable personalised interaction in a more practical and nonintrusive fashion as well as specialised treatment adaptation (O'Mahen et al., 2013). However, to develop an intervention that will increase adherence, there is a need to identify the factors that determine positive intentions to adhere to PND treatment. Furthermore, if you want to change the attitude towards a behaviour, you need to find out the beliefs people hold and the consequences of their attitude. A knowledge of these will also help to adapt the right kinds of beliefs, and, thus, a change in behaviour (Ajzen, 2002).

Studies have shown that, for optimum effectiveness, an intervention should have a sound theoretical basis. According to the Theory of Planned Behaviour (TPB), human action is influenced by three major constructs: behavioural beliefs/attitude (favourable or unfavourable), subjective norm (pressure to perform or not perform the behaviour) and control belief (perceived capacity to perform the behaviour) (Ajzen, 2002). They are all conceptualised as directly related to intentions towards behaviour. The targets of this paper are the behavioural beliefs and attitudes women have towards adhering to PND treatments as well as the control beliefs. Attitude towards a behaviour is assumed to be a function of beliefs about the behaviour's likely consequences, together with the valence attached to those consequences (Ajzen, 2011). It is assumed that a knowledge of women's beliefs and attitudes towards intervention outcome could predict their behaviour towards treatment adherence and their intention to use a support application. Fishbein advocates identifying salient beliefs from the intended population and developing suitable and appropriate materials based on the elicited beliefs (Fishbein, von Haeften, & Appleyard, 2001). Furthermore, a person may hold a positive attitude concerning a behaviour, but not always carry out their intentions towards it (Ajzen, 2011). In this context, a postnatal depressed woman might have positive intentions towards treatment, but there are many reasons as to why she does not adhere to it, and this can be classified as

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the degree of control that the woman has over behavioural performance. If a depressed woman has the capacity, skills, time, resources or whatever it takes to perform the adherence behaviour, then she will be able to carry out her intention, but not if some of these are lacking. However, women with PND are faced with overwhelming responsibilities and undergo some changes after childbirth that could affect their adherence behaviour (De Graaf et al., 2009; Kaltenthaler et al., 2002). There is, therefore, need to understand women's beliefs and attitudes toward interventions, control beliefs and how they form their intentions to engage, perform or not the adherence behaviour.

Identifying women's beliefs and attitudes towards PND interventions could potentially benefit practitioners who intend to change or motivate the adherence behaviour. In this context, this knowledge will inform the development of a theory-based adjunct mobile application to support the wellbeing of women with PND. It will also help to decide on the factors and beliefs that should be supported or discouraged by a mobile application for PND. The authors envisage that an adjunct mobile application would promote the self-monitoring and social support needed to motivate treatment adherence and long-term maintenance and control over adherence behaviour.

Study Aims and Objectives

This study aims to investigate the TPB constructs, behavioural and control beliefs to establish some of the factors that lead to treatment adherence and sustained outcome. The objectives are to identify the obstacles to the performance of adherence behaviour that should be discouraged within the mobile application. For women who are already motivated, the authors will also identify factors that could facilitate them to implement their intentions to adhere to treatment. This study will be more related to the type of treatment used and its effectiveness, as opposed to relaying past experiences of PND specifically.

METHOD

Design

The study used an online survey to collect data from participants. Ethical approval was obtained from the author's University Ethics Committee (ID number - BO1/OM1)

Recruitment

Participants were recruited by advertising on UK-based social media platforms, sending email invitations to women who are members of parenting support groups and fertility forums. This took place from February to May 2016. Moderators of the groups were consulted concerning the research, prior to actively targeting potential participants. Once approval had been granted, recruitment involved voluntary participation of women with previous diagnosis of PND.

Interested participants provided informed consent prior to participating and then accessed information describing the aims and objectives of the study and eligibility. It was recognised there may be a possibility that participants might have found that some of the study questions triggered distressing memories; therefore, the authors designed the questionnaire to ensure that questions related more to the type of

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

therapy used and its effectiveness, as opposed to relaying past experiences of PND specifically. In the event they became distressed, the study also provided a set of resources that could support women. The authors did not ask any questions relating to children being at risk or other likely distressing memories.

Participants were provided with sufficient details of the study at an appropriate level of understanding and were informed that they had the right to withdraw at any time during the course of completing the questionnaire. Given the possibility, albeit minimal, that participants may incur psychological stress in relation to carrying out the survey, information was provided at the end of the survey advising women where they could seek support. The survey was designed to exclude any women who had a current or recent diagnosis of PND.

Instrument

Ajzen's (2002) instructions for constructing a TPB questionnaire were adopted to develop items used to collect data on treatment adherence behaviour. This study is simply measuring the attitude towards PND treatment adherence and the perceived control beliefs; therefore, this was measured by eight items with possible responses ranging from strongly disagree to strongly agree. See Figure 1 for how the construct was operationalised in the current study. The questionnaire included questions about the types of intervention participants have used in the past, the effectiveness of intervention on wellbeing, the effect of intervention on symptoms, factors that might cause non-adherence and demographics. See appendices for questionnaire items.

For the purpose of this study, eight PND interventions are considered in order to identify participant's attitude towards treatment adherence:

- Cognitive Behavioural Therapy (CBT)
- Medication (Med)
- Monitoring and Assistance (MA)
- Self-Help from peer group (SHP)
- Psycho-education
- Wellbeing therapy
- Interpersonal therapy
- Problem solving therapy

The natures of these interventions are described in the following studies: Klier et al. (2001), Cooper (2003), Milgrom, Ericksen, McCarthy, & Gemmill (2006), Pampallona et al. (2002 and Yonker et al. (2008). This study classified symptoms as:

- Isolation
- Poor communication
- Prioritising demand
- Relationships
- Stress management
- Negative thoughts
- Self-confidence

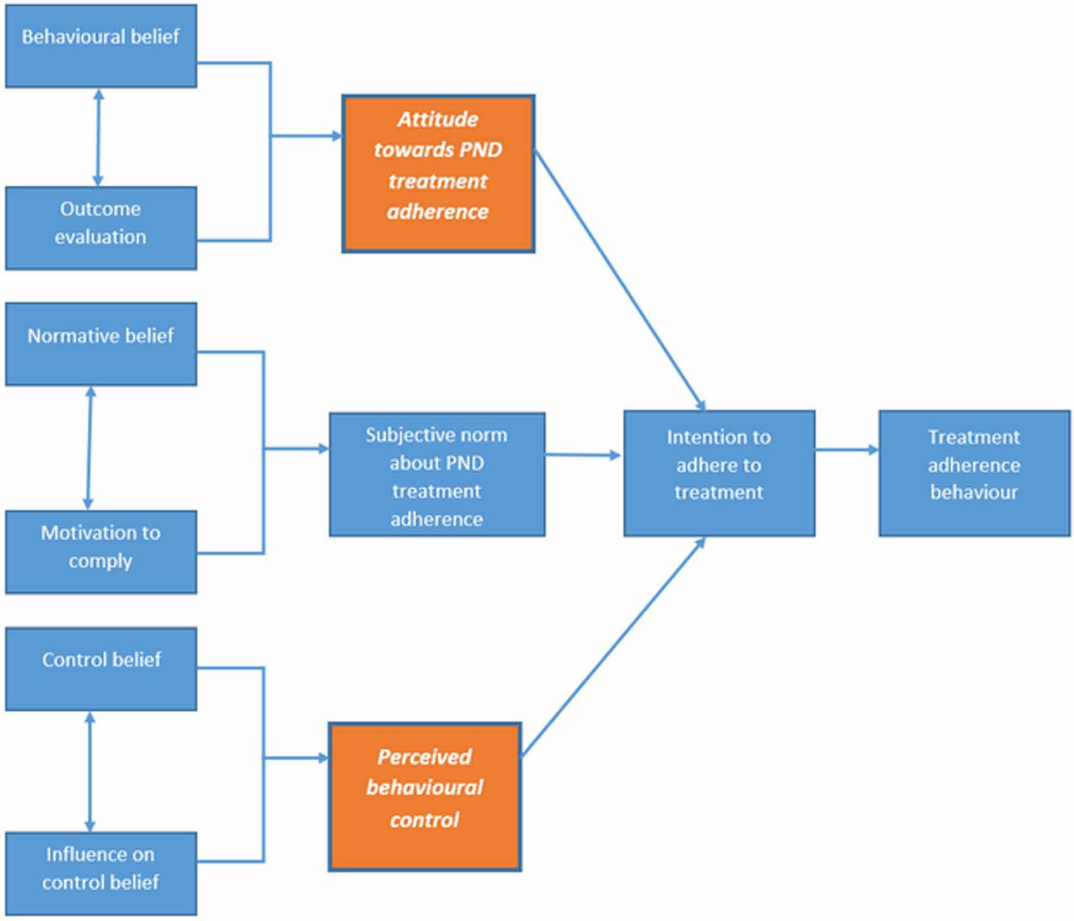
Figure 1. Adapted Theory of Planned Behaviour Construct for predicting treatment adherence behavior (Ajzen, 2002)



Participants

Potential participants were screened for eligibility using multiple questions in the questionnaire. In order to determine whether a participant is currently ill or well, the authors asked the question "Do you presently suffer from postnatal depression". Eligible participants were women with previous diagnosis of PND, yet who had not suffered any symptoms of PND in the last two years prior to recruitment. This study group was used because it places us in a position to explore women's view about the short and long-term effectiveness of the intervention on their recovery from PND. Men, women who currently suffer from PND, have experienced PND in the last two years, or have not received treatment in the past were excluded from the study.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sample

This study estimated a sample size of 382 postnatal mothers to achieve effect size. This is based on a population of about 70,000 women suffering from PND in the UK (Caramlau et al., 2011; Dennis, 2003; Evans et al., 2011; Glover et al., 2002), with 5% margin of error and confidence level of 95%. 460 women were invited and, in total, 181 participants started the survey. After screening for depression, 97 were not eligible for the study. Of those, 55 (30.4%) were excluded because they were current sufferers of PND, 11 because they had never suffered from PND and 23 (12.7%) because they had not received any treatment for PND. A further eight respondents that did not complete any further questions had to be excluded due to the lack of further responses to analyse. The final group of participants comprised 84 (46.4%) postnatal women (mean age = 32 years, range 27-41). It is important to note that not all participants responded to all questions asked. Table 1 presents further details on the number of included and excluded participants.

Data Analysis

Throughout this study, the widely used IBM SPSS statistics package was used to analyse quantitative data (Brace, Kemp, & Snelgar, 2012). For this study, an outcome is statistically significant if the significance level "p" is less than 0.05. This study explored the differences in scores of a non-parametric dependent variable between three or more groups of a single independent variable. Therefore, the Kruskal-Wallis test, which is a non-parametric equivalent of the between subject analysis of variance (ANOVA) test, was employed to evaluate significant differences. The Kruskal-Wallis test only tells us that there is a difference, but does not tell us where the differences are according to each pair of analyses (Brace, et al., 2012). Therefore, an additional Mann-Whitney U test was used to locate the differences, one for each pair of groups.

Furthermore, this study measured the degree of relationship and association between symptoms and adherence variables. However, it is important to note that correlation does not imply causation, but will provide a measure of strength and direction of relationship. The Pearson correlation was used for normal data. For non-parametric data, Kendall's Tau-b test of correlation was used to predict the relationship between variables. The study assessed relationships in terms of the positive or negative correlation coefficient (r). The correlation coefficient describes the strength of the association between

Table 1. Number of included and excluded women

	Excluded women	**Included women**	**Percentage (%)**
Women not suffering from PND	11		6.1
Women not treated for PND	23		12.7
Women excluded due to the lack of further responses to analyse	8		4.4
Current sufferers	55		30.4

two variables. It provides a direct representation of effect size. Using Cohen's (1988) conventions for categorising effects sizes, the study described the strength and size of the relationship for particular values of correlation coefficient.

RESULTS

Depressed Women Without Treatment

Our survey revealed that, despite effective treatment options, some women remain without treatment. Although those women who had PND and remained without treatment were excluded from the main part of this study (see Table 1), our sample showed that 12.7% (23/181) of respondents fell into this category. Our findings agree with the literature that suggests that, despite effective intervention options, postnatal depressed women remain without treatment (Kaltenthaler et al., 2002; O'Mahen, 2013; Wan et al., 2008).

The Use of Multiple Interventions

Our results showed that 81% of depressed women rely on combinations of treatment strategies, with medication being the most common intervention that was combined. Figure 2 presents the frequency of the number of women who used multiple interventions. Table 2 shows that women found one intervention more effective than the other.

Can Combine Multiple Intervention Aid Symptoms

Further tests were carried out to identify women's attitudes towards the benefits and purpose of using multiple interventions. The Kruskal-Wallis test was used to identify differences between using one intervention as opposed to combining multiple interventions for PND symptoms. The results show that there is no significant difference between using one, two, three, four, five or six interventions on PND symptoms. Non-significance was apparent across all the symptom factors except relationship: $\chi 2\ (5) = 12.942$, $p = .024$, see Table 3.

Is There Similarity in Intervention Effects on Symptoms

All women in the study reported having all the symptoms used in this study. This study assumes that several interventions will have the same effect on symptoms. A statistical test was used to identify the belief of how the effects of intervention on PND symptoms differ. The authors identified significant differences between intervention groups about isolation, communication and managing negative thoughts. The result for prioritising demands, relationship, self-confidence, and stress management that were not statistically significant. A subsequent Mann-Witney U-test showed that these differences were particularly apparent between CBT and SHP ($z = -2.318$, $p = 0.02$), MED and SHP ($z = -2.540$, $p = 0.01$). Concerning scores on isolation and for communication, differences were found between the MED and SHP categories ($z = -2.863$, $p < 0.05$) and between managing negative thought CBT and SHP ($z = -2.451$, $p = 0.02$). Although, the results were apparently between neutral and disagree, it shows that various interventions have different effects on symptoms.

Association Between Non- Adherence and PND Symptoms

This study assumes that there is a relationship between non-adherence factors and the effect of PND intervention on symptoms. To evaluate this assumption, the authors considered poor adherence control factors available from the literature to be the cost of receiving intervention; the duration of appointments; waiting times; and location convenience. All women in the study reported facing the control factors used in this study. The results in Table 4 show that there was a weak and non-significant correlation between most of these. Although the correlation between the location and stress management was significant, it is a small effect (r= 249, p= .01).

Furthermore, we identified how women followed treatment instructions as prescribed by their practitioners. Research suggests that half of those women for whom treatment regimens were prescribed do not follow them as directed - this is termed as non-adherence (World Health Organisation, 2003). The researchers asked women how often they followed their treatment instructions. Table 5 shows that 63% (mean = 3.77; sd = .89) of the final group of the women followed the instructions as directed by their practitioners. However, there was a weak and non-significant relationship between the frequency of following instructions and the effect on symptoms (see Table 6).

Table 4. Association between PND symptoms and factors that might affect adherence to PND treatment (control factors)

Manage negative thoughts	-.066	0.55	.291
Self confidence	.081	0.45	.656

The Soothing of One PND Symptom Might Alleviate the Effect of Other Symptoms

The Pearson correlation coefficient was used to examine the degree of association between symptom factors. This test was used because there was a normal distribution of data. Prioritising demands was found to be significantly and positively correlated with communication ($r\ (n=79) = 0.464$, $p < 0.001$); relationship ($r(n=79) = 0.434$, $p < 0.001$); stress management ($r(n=79) = 0.408$, $p < 0.001$); managing negative thoughts ($r(n=79) = 0.329$, $p < 0.001$) and self-confidence ($r(n=79) = 0.474$, $p < 0.001$). These indicate that depressed women with a higher level of prioritising their demands tended to have a good relationship with people, have reduced stress, are able to manage negative thoughts and have faith in themselves. However, isolation was found to have a very weak relationship with prioritising demands ($r(n=79) = 0.164$, $p = 0.148$), communication ($r(n=79) = 0.208$, $p = 0.065$), and relationship ($r(n=79) = 0.177$, $p = 0.119$) (see Table 7).

DISCUSSION

This study documents the beliefs and factors that might determine adherence to PND treatment, and ensure increased sustained outcome. Firstly, a favourable attitude towards combining multiple interventions influences the actual adherence behaviour. There are several possible reasons why depressed women combine interventions, one being seeking support for normalisation of their mothering (O'Mahen et al., 2013). Previous research has shown that many women begin to incorporate alternate plans after

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Association between symptoms considered in this study

Symptom	2	3	4	5	6	7

the initial core sessions of their initial intervention (Christensen, Griffiths, & Farrer, 2009; O'Mahen et al., 2013). A poor patient-doctor relationship might cause some women to be inconsistent in attending treatment sessions, thus finding themselves using alternative treatments. In previous research, women have expressed negative experiences of seeking help, and this is particularly likely to cause them to seek additional treatments. Long waiting lists for treatments might be a barrier; therefore, they then seek additional support during waiting times. In some cases, treatments are not equivalently distributed geographically (Goodman 2009; Payne & Myhr, 2010). Finally, perceived stigma can also lead to women seeking additional support that will provide the level of anonymity they require (Dennis & Chung-Lee, 2006; Goodman, 2009; O'Mahen, et al., 2013). Although our results show that combining multiple interventions does not have any significant effect on symptoms, the authors identified, however, that different interventions have different levels of effect on PND symptoms, therefore combining multiple interventions should be increased. This is further supported by research that suggested that to improve adherence, medication should be combined with other support strategies such automatic reminders, reminder packaging, medication boxes, device aids, counselling, telephone support, patient education etc., (Desteghe et al., 2017).

In this present study, women's belief is that the soothing of one symptom factor alleviates the effects of other symptoms. The authors identified a weak relationship between symptoms; this could mean that women are encouraged to adhere or not when the effect of treatment on one or more symptoms is obvious. This is similar to a study that revealed that it was only after women got into a supportive treatment relationship and improved their communication that they felt able to disclose their distress to others (McCarthy & McMahon, 2008). However, further study may be needed to highlight the factors that suggest the relationship between PND symptoms and the effect they have on each other.

Another strength of this study is that treatment cost, duration, location and waiting time, identified as control factors that inhibit adherence to PND treatment, are not related to increased adherence, but not in all cases. One possible explanation is that these factors should not totally hinder women from adhering to prescribed treatments. However, the location where intervention is received is seen to have a relationship with stress management; therefore, it should be recognised that there may be a possibility that depressed women become distressed by the location of receiving treatment. This could be due to transportation difficulties faced by some women. In regard to location, studies have documented the inability of women to attend regularly scheduled appointments (Goodman, 2009; O'Mahen et al., 2014). Additionally, this might mean that an adjunct support should be provided as a control measure in the event they should become distressed by the treatment location. It is also useful to provide guidance as

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

moderator of intention-behaviour and, thus, this might enhance treatment uptake and retention (Cuijpers et al., 2010; O'Mahen et al., 2013). This compares favourably with other research suggestions that only women who get a supportive treatment are able to show sustained outcome (Cuijpers et al., 2008; O'Mahen et al., 2013; McCarthy & McMahon, 2008). Furthermore, following instructions as prescribed by practitioners did not have an effect on PND symptoms. The underlying causes as to why following instructions did not have effect on symptom are still unclear. Therefore, the authors are careful in making their conclusions on this finding.

Implications

This study identified women's attitudes towards postnatal depression interventions and the factors that could motivate improved adherence. A knowledge of these factors will allow the development of a set of guidelines which can inform the development of an adjunct mobile application for postnatal depression and future improvement research. This will also facilitate the development of a mobile application that is tailored towards positive treatment adherence attitudes. Furthermore, it will potentially support future applications for a larger study to undertake a full trial of mobile applications for PND.

Limitations

Limitations of the current study are largely related to the fact that not all participants provided us with a complete data set. Although all participants satisfied the eligibility criteria, the women who completed the study are best considered a convenient sample that may not be generalised to all postnatal depressed mothers. Finally, it is possible that the use of only two TPB constructs (behavioural and control beliefs) might have influenced the ability to identify more factors that facilitate or inhibit adherence behaviour.

CONCLUSION

This study has identified the TPB variables that might predict the intention to adherence to PND treatments. Firstly, increasing access to adjunct support for PND has the potential to influence adherence positively, and long-term sustained treatment outcome. In particular, providing an intervention that combines support features of several interventions is recommended for increased adherence. This intervention could also provide the flexibility of treatment adaptation. Additionally, it may circumvent many of the barriers to treatment delivery and motivate women to self-manage their wellbeing as well as give them access to supplementary wellbeing support.

It is essential that the option to combine multiple interventions should also be balanced, this could mean that it should not be encouraged or discouraged. This is because combining multiple interventions does not have any significant effect on symptoms; however, different interventions have different levels of effect on PND symptoms. Therefore, the authors recommend a platform that will facilitate using additional support to prescribed treatments for PND. This is in line with a growing body of research demonstrating that the provision of additional support to prescribed treatment could enhance achieving the desired outcome and sustained effect (Broom, Ladley, Rhyne, & Halloran, 2015). Adjunct treatment needs to remain available to women receiving intervention, both during and after the intervention has ended (Turner, Chew-Graham, & Folkes, 2010). The effect of adjunct support was revealed in a

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

study that recorded high compliance (Rojas et al., 2007). The multicomponent intervention used in that study was supported by regular phone calls from trained mental health workers, and depressed women were constantly reminded in sessions about the need to take medications as prescribed (Rojas, et al., 2007). The authors also recommend that, rather than providing women with a single intervention for all PND symptoms, there should be a multiple-choice option that is open to adapting support to depressed women's specific needs. This should hopefully give them the opportunity to have control over their desired intervention outcome.

Furthermore, this study demonstrated that a greater guidance tool designed to make treatment effect on symptoms noticeable could be beneficial and help control adherence behaviour. A structured support plan is viewed as a behavioural control tool, critical for achieving increased treatment understanding, self-management and adherence.

Given these promising findings, there is a need to develop and evaluate methods of promoting adherence and sustained treatment outcome in the PND population. Mobile Health is growing as a method to improve adherence and health outcomes. An adjunct mobile application is one method that may hold the promise of doing such. Developing a suitable and appropriate mobile application is desirable, given its potential to increase adherence to the behaviour being promoted (Desteghe et al., 2017). This tool could support individuals with treatment/work already offered by practitioners, thus allowing sessions to be offered at a reduced frequency, duration and at a cheaper cost and convenient location. In order to develop a mobile health intervention that will increase adherence, using a theory based approach, this study sought to understand women's perspective on obstacles to the performance of adherence behaviour that should be discouraged within the mobile application as well as factors that could facilitate them to implement their intentions to adhere to treatment. Based on our findings, we recommend that the development of a PND adherence mobile application should include features designed to:

- Help manage and monitor the use of multiple interventions.
- Keep a record and manage the impact of symptoms so that changes are noticeable.
- Keep records of prescription instructions and provide positive prompts to users for better communication.
- Include prompts and reminders as a means of self-guidance.
- Help users stay in contact with healthcare providers, family and friends when further guidance or help is needed.

Additionally, research has shown that self-incentives are key motivators and successful in changing health behaviours, adherence to daily care and improve health outcome. As a result of this insight we recommend that the mobile app should also include a feature that is:

- Related to self-incentives and will make the environment enjoyable and stimulating for users.

The current findings highlight beliefs about PND interventions that are necessary for developing adherence behaviour change intervention for this population. These findings will inform the design of an adjunct mobile application for PND. However, there is a need to establish the suitability and appropriateness of a mobile application. The mobile application should be evaluated for suitability and appropriateness to enhance the likelihood that the tool can effectively change behaviour. Further research

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

is also needed to determine the acceptance of such a mobile application by both women with PND and practitioners. Such research should allow us to establish the requirements under which a mobile application for PND may be offered as effective and accessible support.

APPENDIX

Questionnaire

1. What therapy did you use for postnatal depression? (*Please tick all that apply*)
    - Cognitive Behavioural Therapy
    - Monitoring and assistance (by a GP, Nurse or Therapist)
    - Medication
    - Psycho-education and information
    - Self-help from peer group
    - Interpersonal Therapy
    - Well-being Therapy
    - Problem-solving Therapy
    - No treatment
    - Other
2. Which ONE of these therapies did you find MOST effective for postnatal depression? (Please choose one)
3. How effective was the therapy you chose in question 2 in addressing the following?
    - It helped to reduce my isolation
    - It helped me talk to other people
    - It helped me prioritise demands on things I have to do
    - It helped my relationship with my children
    - It helped reduce my stress
    - It helped me to manage negative thoughts
    - It helped me to have faith in myself
4. How long did it feel you had to wait between when you were diagnosed with postnatal depression and when you started receiving therapy? (Please choose one)
5. When you had appointments to receive therapy, how convenient was the location of the facility for you?
6. How affordable was the cost of therapy to you? Costs include bus fare, travel costs, child care or time of work.
7. Thinking about the time you spent on each appointment, how acceptable did you find the length of time spent receiving treatment
8. How long did you have to use your most successful therapy for postnatal depression until recovery?
9. How often did you follow instructions specific to using your therapy when you had postnatal depression?
10. How frequently did you use your most successful therapy for postnatal depression?
11. How long did you have to use your most successful therapy for postnatal depression until recovery?
12. How often did you follow instructions specific to using your therapy when you had postnatal depression?

ABSTRACT

Modelling and teaching complex biological systems is a difficult process. Multi-Agent Based Simulations (MABS) have proved to be an appropriate approach both in research and education when dealing with such systems including emergent, self-organizing phenomena. This chapter presents NetBioDyn, an original software aimed at biologists (students, teachers, researchers) to easily build and simulate complex biological mechanisms observed in multicellular and molecular systems. Thanks to its specific graphical user interface guided by the multi-agent paradigm, this software does not need any prerequisite in computer programming. It thus allows users to create in a simple way bottom-up models where unexpected behaviours can emerge from many interacting entities. This multi-platform software has been used in middle schools, high schools and universities since 2010. A qualitative survey is also presented, showing its ability to adapt to a wide and heterogeneous audience. The Java executable and the source code are available online at http://virtulab.univ-brest.fr.

INTRODUCTION

The theory of complex systems has become more and more relevant over the last thirty years to understand concepts such as emergence and self-organization and their role in biological, physical, chemical and social systems (Jacobson & Wilensky, 2006). Modelling and simulating these concepts behind the theory of complex systems is now very important, especially for biologists (students, teachers, researchers). For example, recent works have highlighted the complementarity of modelling both bottom-up and top-down (aggregated) approaches (Stroup & Wilensky, 2014). It has been shown though that teaching and learning complex systems are challenging tasks, and raise a lot of pedagogical issues. The two main issues are:

1. A widely taught top-down approach that have led students to think in that unique way; and
2. System dynamics that are difficult to understand and can be non-linear and counter-intuitive (Jacobson & Wilensky, 2006).

Among different strategies, the use of Multi-Agent Based Simulations (MABS) in research, teaching and learning has proved to be an efficient way of answering (some of) these issues (Epstein, 1999; Jacobson & Wilensky, 2006; Ginovart, 2014). Indeed, the individual-based approach, in opposition to a population-based approach (such as ordinary differential equations), focuses on the entities of the system, their behaviour and their local interactions to explain the global system's behaviour. As such, this concept is easier to understand, more intuitive and do not require advanced mathematical skills (Ginovart, 2014). The use of computer tools to implement these models in virtual environments and simulate them allows researchers and students to generate hypothesis, test them and, especially for students, build their knowledge more efficiently (in a process of *abduction* (Houser, 1992)), see Section 2.2). NetLogo (Wilensky, 1999) is a good example of such agent-based software, and has been used in a lot of works, both in education (Gammack, 2015) and research (Banitz, Gras, & Ginovart, 2015).

This chapter focuses on how to teach complex biological systems to, for example, university students in Biology, middle school and high school students; students who often do not have any experience in computer programming, and/or are reluctant to implement any code. The problem is that most of agent-based software require knowledge and skills in programming languages such as Java (*e.g.* the Repast software (North, Collier, & Vos, 2006)) or the NetLogo environment. This is an issue that occurs more and more as the use of agent-based software, both in research and teaching, grows in social and life sciences. In (Ginovart, 2014) and (Gkiolmas, Karamanos, Chalkidis, Skordoulis, & Papaconstantinou, 2013), a model of a predator-prey system is used with NetLogo to help respectively first-year and high-school students to understand individual-based approaches and eco-systemic mechanisms. Despite its interest, this model is a ready-made one, coded in NetLogo, where the students can change some parameters of the simulation, but are not implied in the process of creating their own simulation from scratch. Indeed, implementing this model is considered as "a hard task" by the students (Ginovart, 2014) and could be counterproductive: looking for errors in the code instead of thinking at the rightness of the model. The authors argue that using pre-existent models could have a part in preventing students for building their own system's *representation* (this point will be developed in Section 2.2). The gap between most of agent-based software prerequisites and the actual programming skills of students (and sometimes researchers) in these fields has to be dramatically reduced and the processes of implementing a model and simulate it should be more intuitive.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This chapter essentially looks at the modelling of biological systems at and around the cellular scale. However, it is interesting to note that a lot of works have been focusing on modelling and simulating systems at the molecular scale, resulting in several software developed for students. For example, it is possible to find molecular visualisation systems like PyMol (Schrödinger, 2015) or software that help the docking of molecules like AutoDock Vina (Trott & Olson, 2010). There is also an automatic plotting of protein-ligand interactions with Lig-Plot (Wallace, Laskowski, & Thornton, 1996). It is possible to visualise molecular interaction networks and biological pathways thanks to software like CytoScape (Shannon et al., 2003). When focusing on DNA, a complete suite in Python can be used for the sequence alignment (BioPython - Cock et al., 2009). All these software are sources of inspiration when dealing at the cellular level.

In this chapter, the authors propose a software called NetBioDyn working like a game construction kit, where entities are located in a 3D grid environment and follow simple local transformation rules. In the name NetBioDyn, Bio stands for Biology, Dyn for Dynamic and Net comes from Internet because initially NetBioDyn was a Java Applet. Though this software is dedicated to cellular systems where several cells are in interaction, it can also model and simulate molecular mechanisms in a simple and symbolic way. The process of building models and simulations is facilitated by a graphical user interface similar to a drawing software like Microsoft Paint. Researchers or students can build their own models, continuously visualize a clear representation of these models, and see them evolving in time and space. The results are displayed like a chess board with moving and changing coloured entities and can be analysed thanks to recorded population curves. From the point of view of the researcher (who usually is a teacher too), the software can help to explain non-intuitive and complex biological systems in a visual way, easily understandable by his peers or students. The authors present in this chapter the key principles of the software in rigorous but comprehensive language and develop three examples coming from real biological systems. The first example is a predator-prey system involving two bacteria. The second one simulates the mechanism of oxygen exchange in the zebra fish gills between water and blood. The third one simulates the blood coagulation mechanisms in a small section of a vein. A discussion is then engaged to show the interests of such software as well as the limits and drawbacks. A qualitative survey is also presented to show how students in biology and students in computer sciences have received the software. After the conclusion, different perspectives are presented in order to improve both the software and its use.

BACKGROUND

The use of computers in teaching biology can be divided into three common practices:

1. The development of models and simulations using a programming language like C++, Python or Java. This practice is powerful but takes time and requires advanced programming skills.
2. The use of customizable software, where students work on pre-existent models and can only change some parameters in simulations. This approach is very easy to use with students, but is not as efficient as building their own models.
3. The use of modelling software to help students develop their own models without any programming skills.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This third practice requires though the development of complex software that simplifies the process of modelling, by proposing for example, a graphical representation and construction of virtual agents, their behaviours and their environment.

Naturally, these three practices can also be found in the use of Multi-Agent Based Simulations and agent-based software in teaching biology. A quick overview of:

1. Agent-based modelling software that allow the development of models and simulations thanks to a programming language,
2. Agent-based modelling software that propose pre-made simulations, or
3. Computer aided-design modelling software is presented here.

A more complete review of agent-based environments has been made by Nikolai and Madey (2009), where more than 50 platforms are classified and discussed. Readers who wish to deepen the potential of the multi-agent approach for the simulation of complex systems can refer to the book edited by Weiss (2000), especially the chapter "Search Algorithms for Agents".

Agent-Based Software in Biology

Programming Languages

NetLogo (Wilensky, 1999) is one of the most well-known software allowing the development of agent-based programs, including simulations. It has a simplified programming language and simple mechanisms to create interfaces. This software is widely used in the community of biologists and many biological systems have been developed thanks to it. It has also been specifically used to help students understand the mechanisms behind complex systems (Stroup, 2014, Jacobson & Wilensky 2006). Nevertheless, pupils or students have to learn a programming language if they want to create their own models (Ginovart, 2014, Gkiolmas et al., 2013). One can also mention AgentSheets (Repenning, & Sumner, 1995) and AgentCubes (Repenning, Smith, Owen, & Repenning, 2012), which are simple programming environments allowing middle school pupils to learn programming in an appealing manner. These software are designed for multi-purpose applications and mostly games. They are based on a multi-agent system where behaviours are created by drag and drop condition-action algorithms. Although the programming is easy, some code is still required. Among generic multi-agent platforms, one can cite Breve (Klein, 2014; Klein & Spector, 2009) and Repast (North et al., 2006). Despite the fact that they have integrated development environments, the creation of models and simulations needs the knowledge of a programming language like Python, Groovy or Java. More recently, Biocellion (Kang, Kahan, McDermott, Flann, & Shmulevich, 2014) allows accelerating discrete agent-based simulation of biological systems with millions to trillions of cells. It uses cluster computers by partitioning the work to run on multiple compute nodes. It requires though mathematical modelling backgrounds and C++ programming skills.

Pre-Maid Simulations

Different simulations of multi-agent systems have been developed with NetLogo. The community models website of NetLogo proposes, for example, a customizable simulation of a predator - prey - poison system with 11 parameters: initial number rabbits and coyotes, rabbit reproducing probability, grass regrowth

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

time, poison quantity, etc. (Jenkins, 2015). Concerning the simulation of multicellular systems, one can cite VirtualLeaf (Merks, Guravage, Inzé, & Beemstaer, 2001) which allows the simulation of tree-like structures based on agent representing cells and regulation network. It includes 12 different models and about 60 parameters that can be adjusted (e.g. cell mechanic or mathematical integration parameters).

Computer Aided-Design Software

In addition to a simplified programming language, NetLogo provides a "System Dynamic Modeler" that can be used to represent the dynamic of the system, entities inter-relations, feedback loops, flows and stocks. However, this tool requires a global understanding of the system (that is often missing with an agent-based approach) and is quite difficult to use as an intuitive modelling tool. Ioda (Interaction-Oriented Design of Agent simulations) and Jedi (an implementation of the Ioda concepts), allow the creation of multi-agent simulations in a very simple manner (without any coding skill), where predefined interactions can be added between agents (Kubera, Mathieu, & Picault, 2008). As Jedi is a demonstration software, it cannot be used to create complex simulations (4 agents maximum can be manipulated at the same time and there is no graphical user interface to precisely build the initial state). AnyLogic (XJ Technologies Company Ltd., 2012) is a multipurpose simulation software with a visual development environment. It has pre-built object libraries allowing users to create models by a drag-and-drop of elements. Its generic architecture makes it a powerful software but it could be relatively complex to understand for some students, especially the secondary ones. Another very interesting human-computer interaction is developed in the SimSketch software (Bollen, 2013). In this approach, the user draws the agents using an integrated paint tool then adds a name, a type and different pre-defined behaviours. This software focuses on primary and early secondary school students whereas this work focuses on the end of the secondary school to the university. Note that, this tool is not yet totally usable to create multicellular systems because there is no if...then...else structure. The software called CompuCell3D (Izaguirre et al., 2004) allows the simulation of multicellular systems with a user-friendly interface. The Python programming language can be used to create models but an XML file can also be edited to create simulations without coding. SimBioDyn (Ballet, Zemirline, & Marcé, 2004) is a software based on a hybrid multi-agent and mass-spring system designed to graphically create multicellular systems. Although rich in features (cell deformation, migration, adhesion and differentiation, molecular production and consumption and configurable through scripts in Python), it remains hard to use by non-specialists without a course of several hours (Ballet et al., 2004).

Among computer aided-design software, there are also some interesting works that have focused on modelling biological systems following other bottom-up or top-down approaches. For example, one can cite Virtual Cell (Shin, Liu, Loew, & Schaff, 1998), a software allowing to model intra-cellular mechanisms thanks to differential equations. It has a rich web-based Java interface to specify compartmental topology and geometry, molecular data and interaction parameters. However, the purpose of this software is to simulate a single whole cell or sub-parts of a cell but not multicellular systems, and it is not fitted for non-specialist users as advanced skills in mathematics are needed.

In this chapter, the authors focus on teaching pupils or students with no programming knowledge complex biological systems, such as multicellular systems.

In this context, the interests of using computer aided-design software are multiple:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The student do not focus on how to program but on what to model (they remain in the field of biology).
- They cannot make syntactic or lexical errors: their models are always functional despite the fact that they can make semantic errors.
- They are no longer in charge of just some simulation parameters, but become the main actors of the model building, thus favouring the building of their knowledge.
- The teacher visualizes quickly where a student has insufficient knowledge.

So what is needed is a modelling software designed to be used by students with no programming knowledge and dedicated to agent-based multicellular systems modelling and simulation. However, this survey shows that many computer aided-design software exist, but to our knowledge none of them are intuitive enough to be used in this context. In order to answer these issues and give students the ability to easily create their own models, the authors have developed the software called NetBioDyn.

Reasoning About Complexity

Presenting essential concepts on system dynamics has become very important for students in biology. Teaching and reasoning about complex systems still raise a lot of pedagogical issues as shown in particular by Jacobson and Wilensky (2006).

Lynch and Ferguson (2014) argue that grasping the complexity requires a representational framework able both to describe executable computer models *and* to support reasoning as a simply readable "external representation", as opposed to internal representations that are the user's mental models (Zhang and Patel, 2006). According to them, a good external representation affords the classic scientific approach, called *abduction*, emphasizing the observation, the build of hypothesis and the tests to verify the relevance of assumptions (Houser, 1992): it promotes the exploration and understanding of a phenomena thanks to a practical approach. It should be too constructed by the students themselves for two principal reasons: the first one is that it improves their learning (better memorization, quasi-physical experimentation of the model and appropriation of fundamental mechanisms) and the second one concerns the amelioration of their self-commitment (Prain, & Waldrip, 2006). Lynch and Ferguson define an ideal representation as "some written, external representation to complement user's internal representations [...], producing an external cognitive artefact which facilitates exploration and discovery [...] while also offering the ability to be executed".

Lynch and Ferguson summarize the 9 properties of a suitable external representation that were previously defined by Zhang and Patel (2006):

- Short-term or long-term memory aids.
- Directly perceived information.
- Knowledge and skills that are unavailable internally.
- Support for easy recognition and inference.
- Unconscious support for cognitive behaviour.
- More efficient action sequences generated.
- Facilities to stop time and make information visible and sustainable.
- Need for abstraction reduced.
- Aids to decision making through high accuracy and low effort.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Following these properties, the authors claim that NetBioDyn, thanks to its graphic interface and its simulation tools proposes a suitable external representation. It gives to students and teacher a simple way to create and experiment and test models of biological systems, while providing at any time a simplified and complete view of the system's state.

More generally, readers who want to improve their knowledge on "learning by doing" in virtual environments (VE) can read the book of Aldrich (2009).

NETBIODYN, A PEDAGOGICAL AND INTUITIVE AGENT-BASED SOFTWARE

NetBioDyn is a fully open source Integrated Development Environment (IDE) dedicated to teaching activities in biological complex systems, mainly at the cellular level and secondarily at the molecular scale. It gives the possibility to teachers and students to create simulations of multicellular and multi-molecular systems in a simple and visual manner. NetBioDyn does not require any skill in computing and lays on the agent-based approach. Besides being simple to understand for students, this approach allowed the authors to design an intuitive graphical user interface to easily manipulate the agent-based concepts: entity, behaviour and interaction.

In this section the graphical user interface of the software is first presented. Then, the section goes inside the software architecture with the description of the entities populating the simulated environment and how they can evolve thanks to algorithmic behaviours (movement, differentiation, division, apoptosis, *etc.*). In the next section, three examples of easily reproducible simulations are detailed. The code and the executable (for UNIX, Mac and Windows Operating Systems) are available for download on the website http://virtulab.univ-brest.fr.

Graphical User Interface

For educational purpose, the design of a graphical user interface is a crucial point. For the student or the teacher who creates a simulation it must be:

- Intuitive, to prevent the user from being lost in multiple buttons or lists.
- Logic, to build a structured simulation.
- Clear, to show important data and hide less important ones.
- Accessible, to concentrate on "what to simulate" instead of "how to simulate".
- Complete, to have a powerful tool that can simulate advanced biological behaviours.
- Attractive, to stimulate student's imagination and motivation.

For the teacher who uses the software in a course, it must:

- Be robust, avoiding the teacher to help students in case of inappropriate action (for example, no source code is required, avoiding student to make syntax mistakes - only semantic errors can be made, which are the most relevant ones to test the student comprehension of the modelled biological system).
- Show relevant information, to quickly see where each student is and if he is mistaken.
- Allow a short learning curve, not to spend more than one hour to explain how the software works.

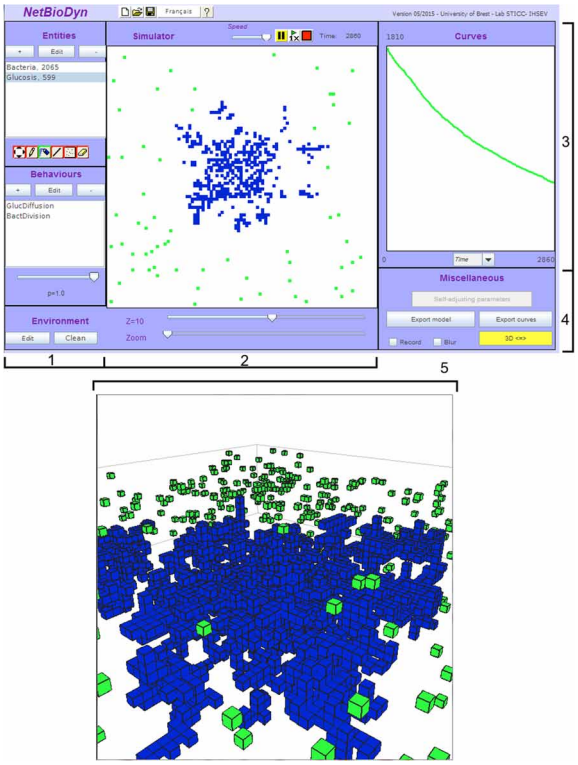
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

To try to achieve these points, the authors decided to use Multi-Agent Based Simulations (MABS) to guide the development of the graphical user interface. MABS are naturally close to how biological objects like cells are described, reducing the abstraction needed to make simulations. In this chapter, the authors use the term "entity" to represent biological objects (or group of objects) and the term "behaviour" to explain how the entities evolve in time. The word "environment" is used to represent the space where simulations occur. A good analogy can be done with board games like chess: an entity is a piece, a behaviour is a game rule, the environment is the board and the initial state of the simulation corresponds to the initial positions of the pieces.

Figure 1 shows the different parts of the interface. The first part of the graphical user interface is made of a list of entities, followed by a list of behaviours and then a button to change the environment's properties (such as size and textual description). The position order of the two lists is logic: entities must be defined before their behaviours. Nevertheless, note that a new entity or a new behaviour can be added, changed, renamed or removed at any time by the user to support the creation process which is rarely linear. The environment button is located below the two lists because the default properties do not change frequently.

The second part of the graphical user interface is the placement and the display of entities in their environment. A central panel serves as a paint area where entities can be individually or collectively located or removed thanks to classic drawing tools like pen, spray, line and eraser, plus a random initializer tool. Entities are located in several layers that can be displayed or hidden using the Z slider. The simulator is controlled by three buttons:

Figure 1. NetBioDyn graphical user interface



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Play (a green right arrow),
- Play one step (an orange right arrow), and
- Stop (a red square).

The simulator can also be paused at any time to observe a specific state or make a screen capture, and its speed can be reduced or increased.

The third part displays the population curves of entities evolving in real time. Several curves can be displayed at the same time to compare their values according to the simulation steps. The user can also display several population curves according to a specific entity (for an example, see next section Examples).

The fourth part enables the user to change miscellaneous properties and export simulation data in the well-used formats in Biology CSV (spreadsheet) and R programming language. A tool to automatically adjust the simulation's parameters according to *in-vitro* results is a work in progress and will be available soon.

The fifth and last part display in a specific frame the environment in 3D in real-time.

In the next subsection, the NetBioDyn entities are described in details.

Entities

An entity in NetBioDyn is a simple cube of size 1 x 1 x 1, located as a grid element of the environment (which is described in details below), having a unique name and a unique colour. Other forms (triangle, disc, star) or images can also replace the coloured cube.

An entity also has a half-life parameter indicating its speed of degradation or destruction.

For each entity, a short description can also be added. This is made for two main reasons. The first is to encourage students to comment their models because they will have to maintain and share their work. The second reason is to help students to understand pre-made models that the teacher created.

Finally a cleanable property can be unselected to prevent entities from being removed when the environment is cleaned by the user. This is useful when the teacher created a simulation where the initial state contains a minimum of entities located at specific positions: the student can clean his own entities but the teacher's ones always remain.

The entity configuration window can be seen on Figure 2.

In the following sub-section the behaviours allowing entities to change their states are explained.

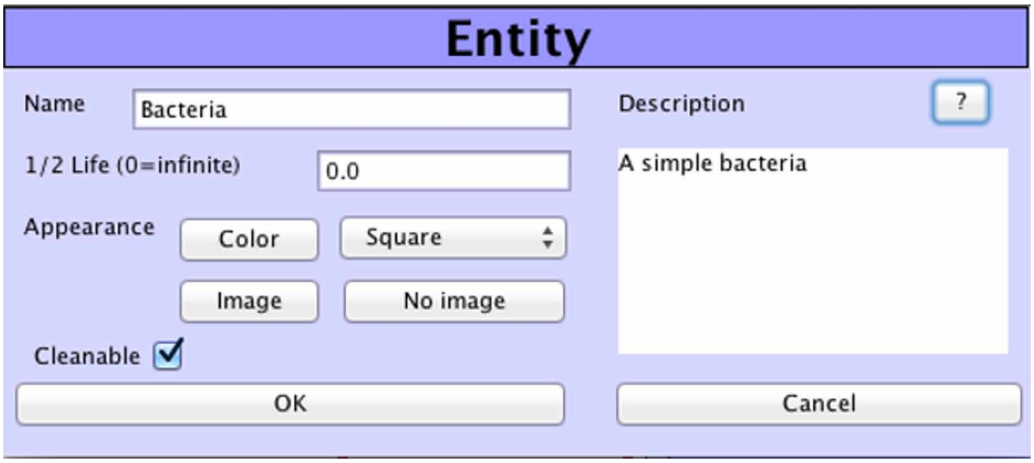
Behaviours

In NetBioDyn, a behaviour aims to change entity's states. For example an entity can be put in motion, differentiated or destroyed. Four parts are required to define a behaviour, three conditions and one action:

- Conditions
  - Which entities are involved?
  - Where are they located from each other?
  - Is the probability validated?
- Action
  - What will happen to them?

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The name, the half-life and the appearance of an entity is made in the entity configuration window. Note also the description field on the right and the cleanable check-box at the bottom-left



The first condition identifies all entities that are involved in the simulation. Only those that are in a good position from each other are kept (condition two). Thanks to the third condition, a behaviour is probabilistically performed: a random number between 0.0 and 1.0 is generated and must be inferior to the probability of the behaviour.

If the conditions are validated at different areas in the environment, a behaviour applies several times during one simulation step. Conflicting areas are detected where a same entity can be used two or more times by behaviours. In this case, only one area is randomly chosen among the conflicting areas (see Figure 3).

In order to ease the design of behaviours, the authors created a graphical representation consisting of two main parts (see Figure 4). The first part containing three lines indicates the behaviour's name, its description and its probability to occur. The second part is divided in three columns: the left one contains the entities involved in the behaviour (reactive), the middle one indicates where the entities are located one from each other and the right column indicates how entities are changed.

In the software NetBioDyn, the graphical user interface is very close in terms of displayed data. The entities are selected thanks to a combo-box containing all the created entities. The positions are selected by clicking on the light or dark squares. The cross at the left allows the user to remove a full line of reactive and products (see Figure 5).

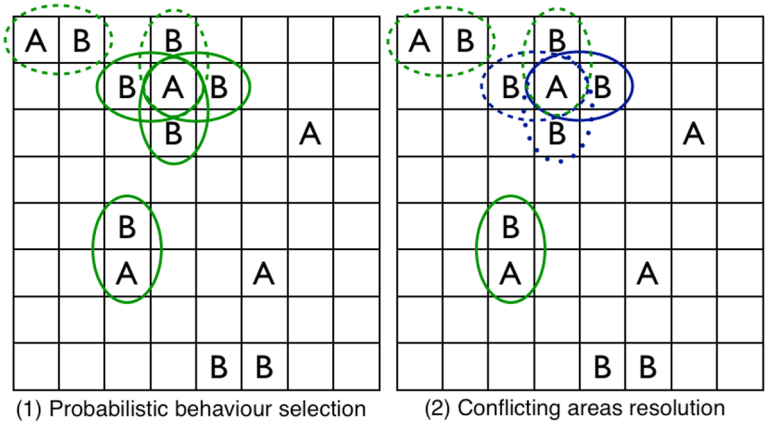
The next subsection describes the environment, where entities are placed and behaviours occur.

Environment

The environment represents a 2D or 3D space where entities evolve and behaviours take place. It is a simple grid where a grid cell contains none or a maximum of one entity. An entity occupies a whole grid cell. It follows Von Neumann neighbourhood: it has four neighbours in 2D and six in 3D. The size of the environment is by default 100 x 100 x 2 but can be changed by the user. The view is only 2D when the user put, move or remove entities but a 3D view can be activated for a better and more intuitive rendering.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. In (1), a behaviour can be applied several times during one simulation step. In this example the system detects that the entities A and B are in contact. The probability to perform the behaviour, if the entities are found in contact, is 0.8. So, of the six areas where the behaviour can be performed, four are kept (continuous circles) whereas two are not (dotted circle). Note that this area configuration can change accordingly to the random numbers generated. Moreover notice that three areas are in conflict and must be treated before the action can be applied (continuous circles including the same entity A). In (2), the system manage the conflicting areas. Among them, only one can be kept (the horizontal continuous circle) whereas the two others cannot. All conflicting areas have the same probability to be kept (or not kept). Note that the probabilities of behaviours have already been validated before the conflicting areas are treated. Finally, only two areas will apply the behaviour (continuous circles)



From the principles presented, the next section develops three examples that can be realised by pupils or students.

EXAMPLES

The examples detailed in this section can be performed using the software NetBioDyn freely available at http://virtulab.univ-brest.fr.

It can be made by pupils from age 14 to university students. The first example deals with a prey-predator system involving two species of bacteria: Bdellovibrio and Photobacterium leiognathi. The second example models the dioxygen exchanges between water and the blood of zebra fishes. Finally, the third one aims to reproduce and understand the blood coagulation mechanisms.

These examples show to the students how to create a model in four stages:

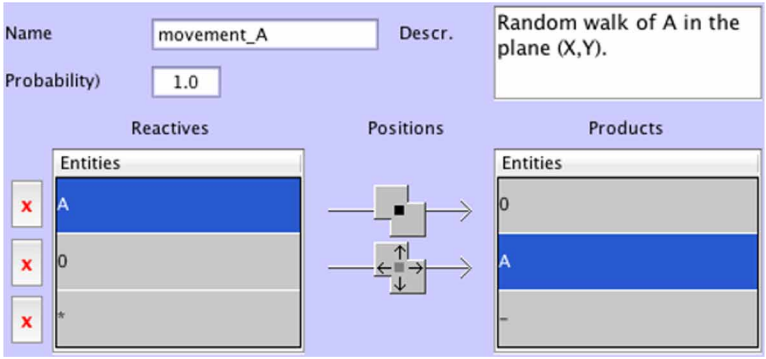
- **The Real System**
  - What is the current knowledge?
  - What part of the system would I model?
  - What are the limits of my study (dimensions, time, energy, *etc.*)?
  - Am I able to distinguish, among the current knowledge, what are hypothesis and what are facts?

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. For this example, the behaviour is read like this: "the entity A, which is the centre of the behaviour (+) must be in contact with one entity B and one entity C. B can be anywhere (up, down, left, right, front, behind) around A and C can be at the left, the front or behind A. Moreover, if the probability is validated and the possible conflicts resolved, A will become A', B will become B' and C will be changed in C' ". The first reactive is always at the centre of the reaction. A reactive or a product can be 0 which means no entity. The diagonals are not taken into account in the positions

Name	**behaviour**	
Description	Short text of explanation	
Probability	Decimal number in [0, 1]	
Reactives	Positions	Products
A	+	A'
B	⊙ ↑ ← A → ↓ ⊗	B'
C	↑ ← A ↓	C'

*Figure 5. The graphical user interface of behaviours in NetBioDyn has the same properties as seen previously. In this example, an entity A is removed from its current position (first line of the lower part), to be placed at a free location (second line). The third line contains the symbol * as reactive (which means anything) and the symbol - as product (which means do nothing). This behaviour applies a random walk to all A entities in the simulation*



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **The Simplifications**
  - What have I to keep absolutely from the real system?
  - What can be neglected?
- **The Model**
  - How to represent real entities using virtual ones?
  - How to model biological mechanisms thanks to algorithms or equations?
  - What are the dimensions and the topology of the environment and how to represent it on a computer?
- **The Simulation**
  - Can I trust the results?
  - What are the limits concerning explanation and prediction?
  - Are the results qualitative or quantitative?
  - Does the simulation inspire me in order to prepare real experiments?
  - Is the simulation robust to small changes (probabilities or initial state for example)?
  - Is the simulation clear enough to share and confront my knowledge with others?

The next sub-section expose in details the process of modelling three cellular and molecular systems, following these four stages from the real system to the simulation.

Bdellovibrio and Photobacterium Leiognathi

Real System

Bdellovibrio and Photobacterium leiognathi are marine bacteria. The interactions between these two bacteria represent a good example of a predator-prey system. Bdellovibrio is a predator of Photobacterium leiognathi. It penetrates inside its prey, proliferates, kills the host and finally releases its progeny. This cycle time is about 4 hours. Bdellovibrio is a bacterium of 1 μm in size and thanks to its flagellum, moves very fast (up to 160 μm/s). The size of Photobacterium leiognathi is about 2 μm. They usually are in symbiosis with fishes and, in this case, have not shown to be motile.

Biological systems involve too many parameters, objects and behaviours to be fully modelled and simulated. A simplification of the system described here is needed in order to focus on the predator-prey principles.

Simplification

In order to reproduce the Bdellovibrio and Photobacterium leiognathi relationship, a simplified model which takes into account five objects and five behaviours is proposed:

- Biological entities:
  - Bdellovibrio (Bdel).
  - Photobacterium leiognathi (Leio).
  - Photobacterium leiognathi infected (LeioInfected).
  - Fish tissue where Photobacterium leiognathi lives (FishT).
  - Nutriment for Photobacterium leiognathi coming from the fish (Nutri).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Biological behaviours:
  - Bdellovibrio movement (BdelMvt).
  - Infection of Photobacterium leiognathi by Bdellovibrio (LeioInfection).
  - Photobacterium leiognathi lyse and Bdellovibrio release (LeioLyse).
  - Photobacterium leiognathi division (LeioDiv).
  - Nutriment production for Photobacterium leiognathi (NutriProd).

This model has to be also adapted to our simulator. The next section explains how to put the model in the software NetBioDyn, which has its own possibilities (*i.e.* multiple entities and behaviours) and constraints (*i.e*. the environment is a 3D grid and a grid element has a maximum of six neighbours).

Model

The entities chosen for the simulation are Bdel, Leio and LeioInfected. The fish tissue and the nutriments are implicit in our simulation. This is a choice which can be changed if the fish tissue or the nutriments must be quantitatively taken into account or if their spatial distribution has to be studied. The graphical representation used for entities are simple coloured cubes of volume 1 μm^3. In this example Bdel is red, Leio is blue and LeioInfected is purple. Bdel and Leio have a half-life of 100 simulation steps (which means that after 100 simulation steps a Bdel or a Leio entity has 50% of chance to die, or said differently, after 100 simulation steps for a non-reproductive population of N individuals, only N/2 individuals will remain).

Four behaviours have been kept to simulate the bacterial system (see Figure 6):

1. The movement of Bdel entities which is a simple 3D random walk. The probability of this behaviour is 1.0, the maximum possible, because no other behaviour is as fast as this one. The bibliography gives the speed of 160 μm/s for Bdellovibrio. This is a maximum and an instantaneous speed. Due to its frequent directional changes, its average speed is closer to few μm/s. A grid cell can contain one bacterial entity at the same time, so a grid cell represents a cube of 1 x 1 x 1 μm^3.
2. The infection of Leio by Bdel. The probability of infection is 0.1, indicating that one contact over ten can produce an infection.
3. The lysis of Leio and the release of two Bdel. The probability is chosen to reproduce the 4 hours of incubation for Bdel. A time step is equivalent to one second, so 4 hours are simulated by 14400 steps. At this time, this is supposed that 99% of the LeioInfected have been killed.
4. The division of Leio following the nutriment intake.

The environment is a 100 x 100 x 2 grid. All the Leio entities are at z=0 in order to imitate the fact that they are on the fish tissue.

Simulation and Results

The initial state of the simulation is given by Figure 7. The initial state is made of 1000 Leio entities and 100 Bdel entities randomly located in the environment. Leio entities have been placed at z=0 while Bdel entities are located at z=1. The number of preys is ten times inferior to the number of predators in order to initiate the system without having the preys eaten by too numerous predators at the beginning. They all are located at random in the same 3D environment.

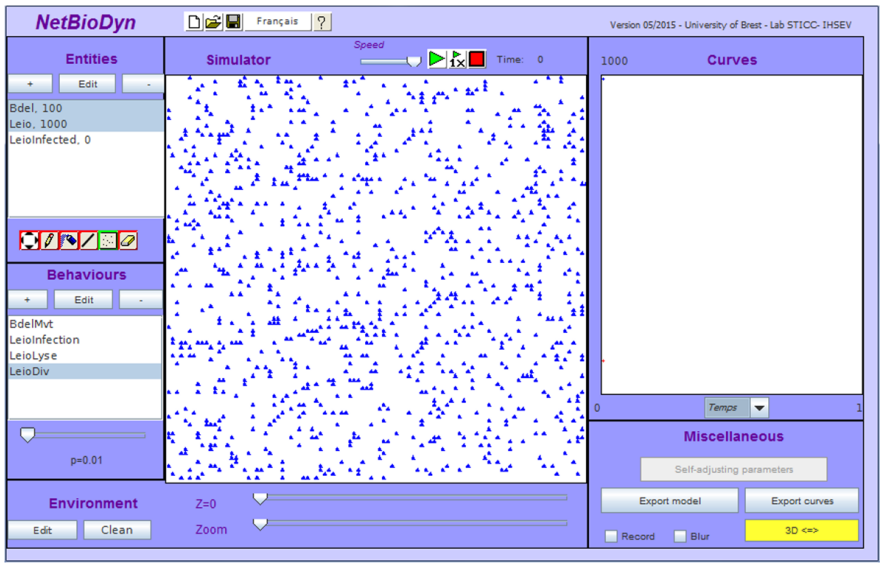
Figure 7. This screen capture of NetBioDyn shows the initial state of the simulation where 1000 Leio (triangles) and 100 Bdel (squares) have been placed at random in the environment using the random initializer tool. Only entities placed at z=0 are here visible



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8 shows two snapshots of the simulation at time steps 1490 and 12840. At time step 1490 (upper screen capture), the first predator-prey cycle is shown, where the Leio population (preys) grows initially, just followed by the growth of the Bdel population (predators). Then, the Leio population decreases because they are eaten by the Bdel, and then the Bdel population decreases too by lack of food, resulting in an increase of Leio due to the fact there are less Bdel entities. The two peaks of the curves are shifted in time: the peak of the preys (Leio) occurs before the peak of predators (Bdel) because the predators need the preys to grow. Small spots of Leio entities appear because of their bacterial division. Five other cycles are shown at the lower part of the figure (time step 12840). The stochastic aspect of the simulation is well shown in the irregularities of curves and entity positions. The predators are close to the preys not because they are attracted by them but simply because they divide inside them. Smaller cycles inside the main cycles can also be seen. Those emerging global behaviours can also be observed in real predator-prey systems (see the Canadian lynx and snowshoe hare pelt-trading records of the Hudson Bay Company over almost a century (Odum, 1953)).

The simulation expresses classical cycles of predator-prey systems, indicating that the results are qualitatively correct.

Figure 8. Screen captures of the simulation at time steps 1490 and 12840. From left to right: the environment states, the population curves of entities Bdel (dark grey) and Leio (light grey) according to time, and the population curve of Leio according to Bdel (after change of the abscissa)

Water-Blood Dioxygen Exchanges in Zebra Fish

Real System

Zebra fishes have an efficient respiratory organ able to extract dioxygen from the water to their blood. Their gills use a counter-current system to improve the dioxygen exchange. Figure 9 represents how the system works. The water contains dioxygen molecules which circulate from the left to the right. A permeable membrane, that only gazes can cross (dotted line), separates the blood from the water. The dioxygen can cross the membrane from the water to the blood or from the blood to the water with exactly the same probability. In the real system, the blood circulates in the opposite direction. However, by using the simulation, the benefits of such mechanism will be studied as compared with the co-current one. The simulation will aim to evaluate the impact of the current direction (counter-current co-current) on the blood oxygenation.

Simplification

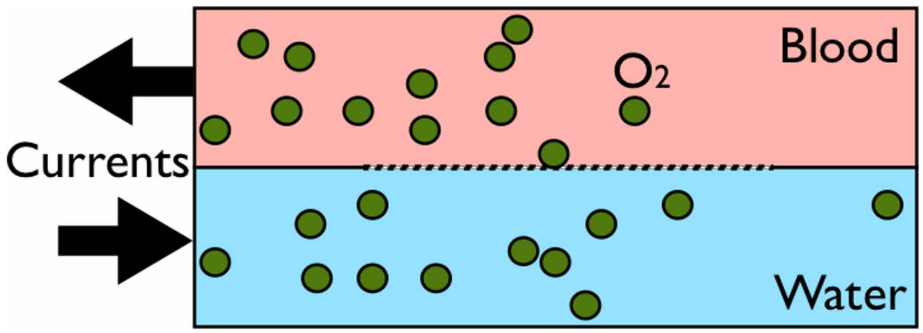
The simulation focuses on a small part of the system of the Zebra Fish, where the dioxygen exchanges occur. The red blood cells responsible for the transport of the dioxygen in the blood are not modelled, because this mechanism occurs essentially after the exchange. Other blood components, like immune cells for example, are not modelled because they do not interfere in the dioxygen exchange.

Model

The model is made to test the efficiency of the zebra fish counter-current respiratory system where the O_2 is central. The chosen model has three types of biological entities, the O_2 in various states, and two membranes:

- The O_2 is divided into three types of entity in order to give them different behaviours and count them according to their locations:
  - The O_2 in water (O2Water).
  - The O_2 in blood (O2Blood).

Figure 9. Mechanisms of dioxygen exchange inside the zebra fish gills



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

    - The O_2 in water which can no longer go to the blood (O2WaterLost) because it has been evacuated outside the respiratory system.
- The permeable membrane that can be crossed by the O_2 (Membrane).
- The impermeable membrane (Wall).

To complete the model, four dedicated types of entity have been used:

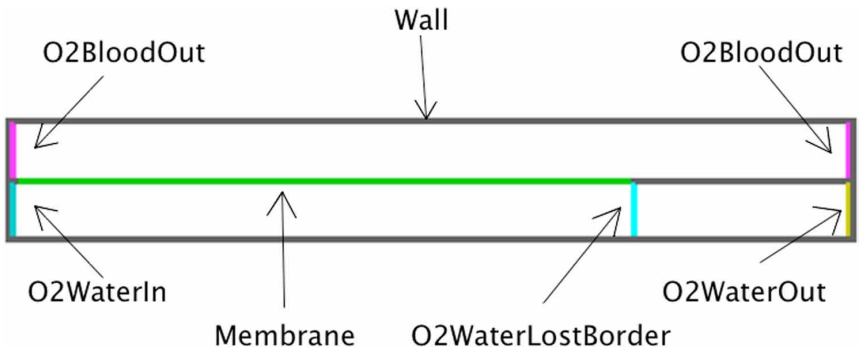
1. Entities O2WaterIn, which perform the addition of O2Water thanks to the behaviour called O2WaterGetIn.
2. Entities O2WaterOut, which remove O2Water thanks to the behaviour O2WaterGetOut.
3. Entities O2BloodOut, which remove O2Blood thanks to the behaviour O2BloodGetOut.
4. Entities O2WaterLostBorder, which detect O2Water entities that can no more go into the blood thanks to the behaviour O2WaterIsLost.

Figure 10 shows how entities are located in their grid environment at t=0.

Only two biological entities are placed: the impermeable membrane (Wall) and the permeable membrane (Membrane) which creates the upper row of blood circulation and the lower row of water circulation. There is also the four ad-hoc entities (non-biological entities). Note that the O_2 is not present at t=0 but will be added at the right to the ad-hoc entities O2WaterIn. When O_2 entities in the water diffuse to the right, they can cross the Membrane to go in the blood. The O_2 in the blood can also go back to the water by crossing again the Membrane. The O_2 entities in water reaching the O2WaterLostBorder can no longer cross the Membrane, and they become lost for the blood (O2WaterLost). The region between O2WaterLostBorder and O2WaterOut only contains O2WaterLost entities that will be counted to test the efficiency of the current and counter-current mechanisms. The O2BloodOut are located at both left and right sides of the upper row in order to evacuate the O_2 in the blood whatever the direction the current follows.

Nine behaviours have been made to add movement, membrane crossing, transformation, creation and removal of entities. O_2 entities move up, down or right at random in water at each simulation step (probability set to 1). The same mechanism is used to define the movements of O_2 in blood and O2WaterLost entities. Note that this behaviour can be modified by changing the left direction by the right, giving the

Figure 10. The gill model at its initial state (t=0)



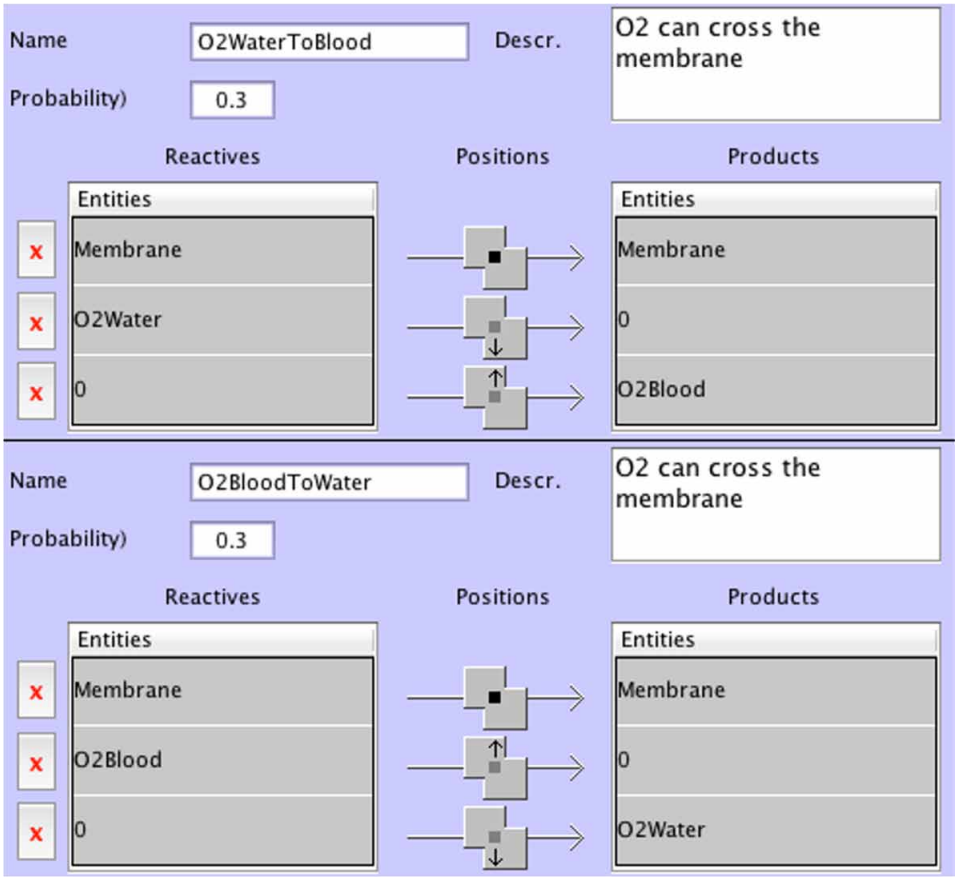
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

possibility to test the impact of the O_2 transfer efficiency from the water to the blood according to the relative direction of both flows.

Figure 11 shows how the O_2 crosses the membrane. The behaviour indicating how the O_2entities in water become lost for the blood is described in Figure 12.

Finally, Figure 13 shows the only one behaviour that adds entities in the environment. It creates O2Water entities just on the right of O2WaterIn entities with a probability of 0.1. It means that one time step over 10 (on average), one O2WaterIn adds one O2Water (if there is an empty space at its right). The same mechanisms are used to define two more behaviours: the behaviour removing the O_2 entities in the water that are too far from the membrane to be useful for the blood (O2WaterLost), and the behaviour removing the O_2 entities in blood (probabilities at 1). Defining these behaviours led to create dedicated entities O2WaterIn, O2WaterOut and O2BloodOut that do not exist in the real system. They only are here to simulate the continuous flow of O_2 in the water coming from the left and disappearing on the right, when they go out of the simulation area.

Figure 11. The two behaviours of this figure indicate how O_2 entities cross the membrane separating the blood and the water. The left one concerns the crossing of O_2 in water (O2Water) to the blood (O2Blood). The right one describes the crossing of O_2 located in blood (O2Blood) toward the water. Both of these behaviours have the same probability: 0.3



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 12. This behaviour changes O2Water entities touching the O2WaterLostBorder into O2Water-Lost entities. Thus, O_2 that cannot be used by the blood can be counted to evaluate the efficiency of the counter-current mechanism as compared with the current one. The less O2WaterLost entities are present, the more the gills are efficient

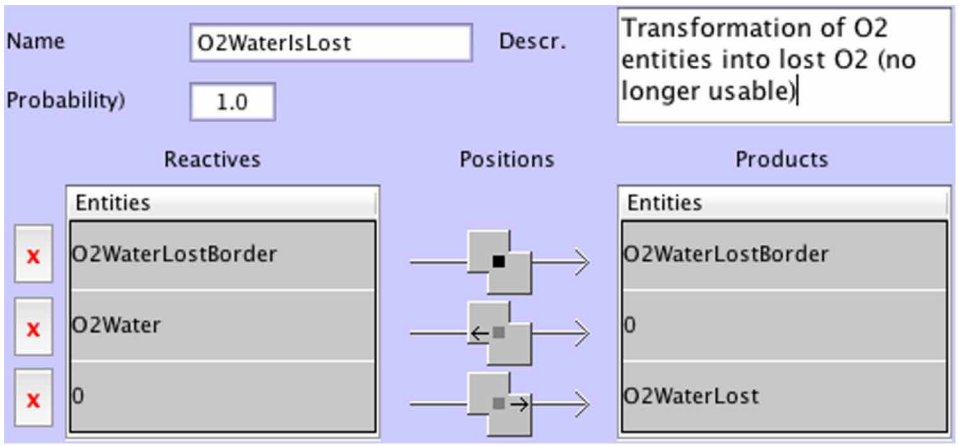


Figure 13. The behaviour adding O2Water entities in the environment

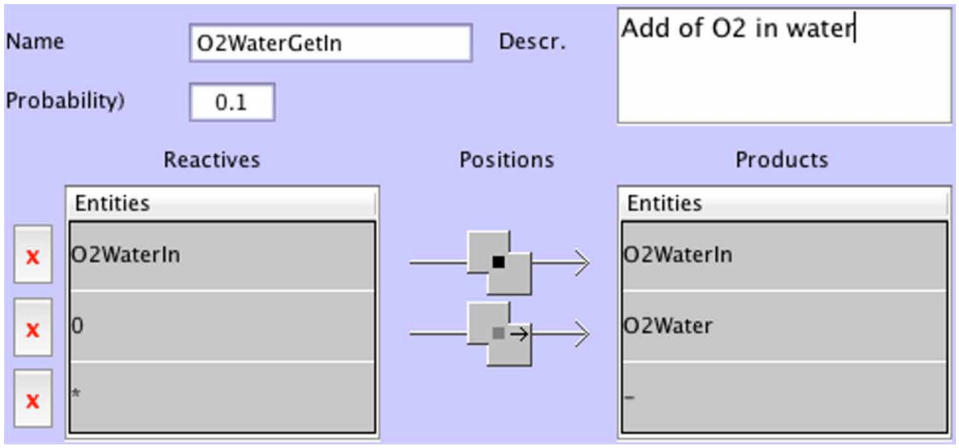


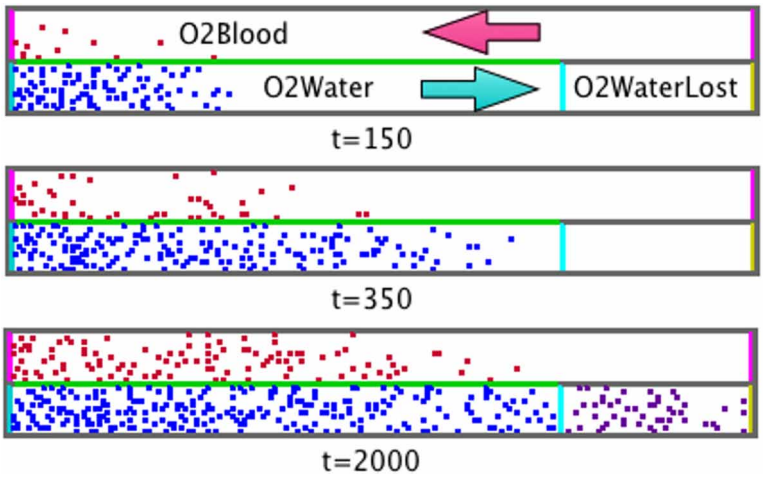
Simulation and Results

The simulation using the counter-current behaviour is shown as an example of the dynamics of the gills (see figure 14).

The counting of O2WaterLost gives the efficiency of the system and shows that, for the given initial state and the given behaviours' parameters, the co-current mechanism is about 42% worse in O2WaterLost as compared with the counter-current one. To evaluate the benefit of the counter-current direction as compared with the same current direction, the number of O2WaterLost has to be counted when the simulation is in a relative permanent state. To calculate when the permanent state arises, we need to know how long it takes for the O_2 newly created in water to cross the entire lower compartment. By looking at the behaviour of O2Water (normal or lost), it is clear that the right movement occurs, in

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 14. Three screen captures show how the system evolves when the currents are in opposition (water comes from the left and circulates to the right; blood circulates from the right to the left). At t=150, the O2Water created by the O2WaterGetIn behaviour starts to diffuse to the right of the water compartment (the lower one). The O2Blood entities that reach the O2BloodOut are removed from the simulation thanks to the O2BloodGetOut behaviour. Few O2Blood, coming from the O2Water having crossed the membrane, move in the opposite direction. At t=350, O2Water entities reach the O2WaterLostBorder. At t=2000, the system is in a relatively stable state and O2WaterLost entities can be seen



average, one time over three (the two other possible movements are up and down). The length of the compartment is about 100. So, at least, 300 time steps are needed for the O_2 in the water to run through the lower compartment. Moreover, the O_2 can cross the membrane and go back to the left, following the blood flow. About 3/4 of the compartment have the permeable membrane, slowing down the movement of the O_2 in the water. Because this is a stochastic simulation, only probabilities can be calculated. The chosen criterion is arbitrary set by looking at the curves of O2LostWater concentration and by choosing a time from which the state looks permanent enough. The average number of O2LostWater is calculated between 1000 and 4000, which seem consistent (see Figure 15).

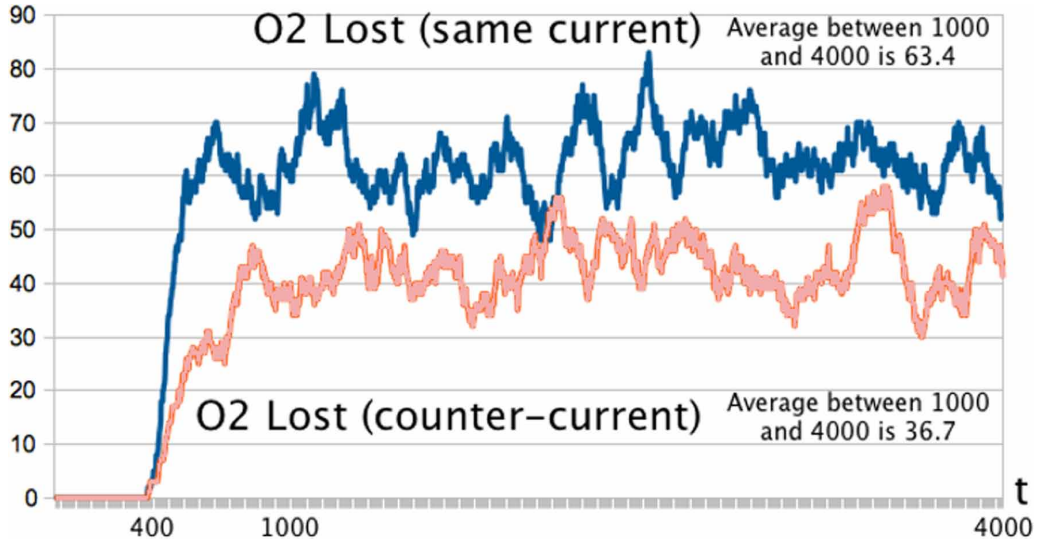
Blood Coagulation

Real System

The real system simulated in this example is a small section of a vein, in which a lesion is present. The aim of this model is to reproduce some of the molecular and cellular mechanisms during the blood coagulation leading to the formation of a blood clot. Three stages are usually described. The primary hemostasis starts with the vein lesion and finishes with the formation of a plug covering the lesion. The plug is made of platelets and soluble rod-like shaped proteins called fibrinogen. The secondary hemostasis is the transformation of the platelets plug into a blood clot thanks to the conversion of the fibrinogen into insoluble strands called fibrins. The third and final stage is the fibrinolysis, when the clot is broken down.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 15. The average number of O2WaterLost under the co-current condition is 63.4 and 36.7 under the counter-current condition. That makes a loss of O_2 which is 42% superior in the case of co-current. Note that this percentage depends on the size of the compartments and the size of the membrane: this can be easily seen on the screen captures where the density of O_2 in water decreases according to the distance from the O_2 creation, at the left



Model

The model presented here includes the primary hemostasis but not the secondary one nor the fibrinolysis. Moreover, not all the known mechanisms are simulated to improve the model clarity. The model is described using all the involved entities (cells, molecules and others), their initial state (stored into a 2D matrix) and their behaviours (interactions, transformations, creations and blood flow).

Two types of entities can be distinguished. The first ones are those which directly represent real biological entities like molecules or cells:

1. Fibro (for the fibroblast cells).
2. Endo (for the endothelial cells).
3. PlaC (for the circulating platelets).
4. PlaF (for the fixated platelets).
5. Fibri (for the fibrinogen molecule).

The second ones are those which do not exist as such, but are needed to simulate abstract biological mechanisms, like the blood flow in this case:

6. FlowS (for start of the blood flow).
7. FlowE (for end of the blood flow).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The initial state looks like a rectangle in which the upper edge consists of one layer of endothelial cells. The lower edge contains one layer of endothelial cells (with a discontinuity representing the lesion in the vein) plus one layer of fibroblast cells, below the endothelial layer. The left edge is made of entities regulating the blood flow entrance and the right side consists of entities regulating the blood flow exit (see Figure 16).

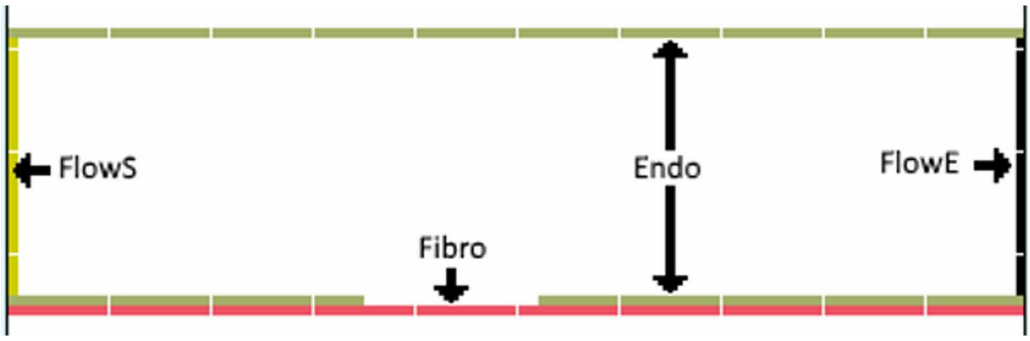
The behaviours developed in this simulation aim to model the blood flow and the core mechanisms of primary hemostasis. Firstly, five behaviours are needed to model the blood flow (see Figure 17):

- One behaviour to model the apparition of the platelets coming from the left of the vein section.
- Two behaviours to model the blood flow circulating from the left to the right which are applied to the platelets (PlaC entities) and the fibrinogens (Fibri entities).
- Two behaviours to model the disappearance of the circulating entities (PlaC and Fibri) when they reach the right of the vein section.

Secondly, three behaviours are needed to model the coagulation (see Figure 18):

- The first behaviour models the fixation of circulating platelets on the lesion (on the fibroblasts).
- The second one models the fixation of circulating platelets on the plug of platelets in presence of fibrinogens.
- The third behaviour models the indirect production of fibrinogens by fibroblasts. Note that this last behaviour is a simplification of a more complex molecular pathway.

Figure 16. The initial state, and more generally all the simulation, takes place into a 100x28 matrix where entities are distributed according to a simple rectangle corresponding to a vein section. The vein is made-up of three layers, two of endothelial cells (Endo entities) and one layer of fibroblast cells (Fibro entities). Note that the bottom layer of endothelial cells has a hole in order to simulate a lesion, resulting in a direct contact between the fibroblast cells and the circulating blood. The two vertical edges do not exist as real biological entities but are necessary to represent, at the left side of the vein, the incoming of circulating entities (FlowS entities) like the platelets and, at the right side of the vein, the disappearing entities (FlowE entities). The flow of circulating entities moves from the left (Start) to the right (End)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 17. The blood flow is simulated thanks to five behaviours. The two firsts (upper-left) are the movements of circulating platelets and fibrinogens entities from the left to the right. Note that they can also move vertically to reproduce the non-linearity of the blood flow. The third behaviour (upper-right) is the addition of platelets from FlowS (start of flow at the left of the vein section). The probability is 1% and can be changed to simulate different concentrations of platelets (according to the patient for example). The fourth and fifth ones (bottom of the figure) simply remove circulating entities that reach the end of the simulated vein section

The end of the growth of the platelet plug is not modeled thanks to a behaviour but emerges from the simulation. More precisely, when all the fibroblast cells are covered with the anchored platelets, they simply cannot produce fibrinogen, stopping the growth of the plug.

Simulation and Results

In the simulation, 1 step corresponds to 1 second. The size of the vein is about 3 millimeter long and 1 millimeter large. As outputs, the shape of the plug is observed and the quantity of circulating fibrinogen is measured at each time step (see Figure 19).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. The core mechanism governing the apparition of a plug of platelets is only made with three behaviours. The first behaviour (upper-left) is the creation of fibrinogen entities from fibroblast ones. In the real system, it does not occur like this, but it is a convenient simplification for this simple example. The second one is the fixation of circulating platelets that enter in contact with the fibroblast cells of the lesion. The third one, involving three reactive entities, simulates the fixation of circulating platelets onto the plug of anchored platelets, allowing it to grow

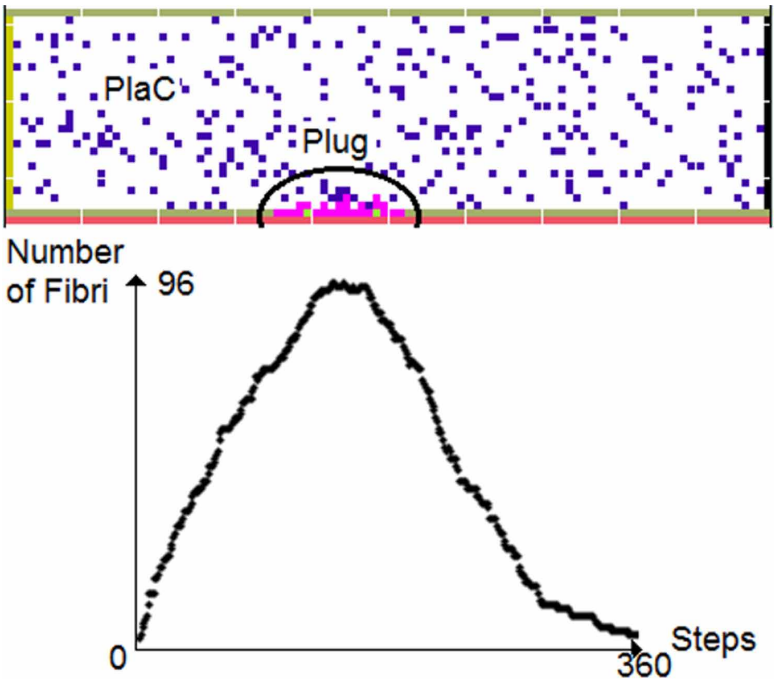
Fibri	↑ ← PlaC → ↓	0

The simulation shows that the plug of platelets starts after 139 steps (2 minutes and 19 seconds) and ends at step 254 (4 minutes and 14 seconds). After this step, no more fibrinogen entity is produced because the fibroblasts are no more in contact with the blood flow. The remaining fibrinogen disappears at the right of the vein section. The simulation is stopped at 360 steps, when all fibrinogen entities have disappeared.

With such a model, it could be possible to use the results of different simulations to build a synthetic and formalised mathematical model of the primary hemostasis. The virtual experiments can be performed quickly and at a very little price. Another interesting feature of such a model is that during a simulation it is possible to create new lesions, change the size or the shape of lesions, modify the platelet concentration, etc. The user can experiment many different scenario and hypothesis and see the validity but also the limits of the model.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 19. After 360 steps of simulation, corresponding to 6 minutes, the plug is formed and the circulating platelets continue to flow from the left to the right (upper diagram of the figure). The quantity of circulating fibrinogen is drawn on the lower part of the figure, showing its growth up to the value of 96 which could be multiplied by a given factor to match real experiments



DISCUSSION

Here, the authors discuss the interests and the drawbacks of NetBioDyn.

NetBioDyn Interests

The use of software in biology and education is interesting, both for teachers and students. It enables teachers to explain complex systems in an intuitive and pseudo-experimental way. It also helps students to create their own computational biological systems and see the important stages by creating a virtual system that rebuilds the real system. They can learn efficiently how the real system works.

From the teacher point of view, the modelling and simulation using such a software enable to:

- Create explicative and predictive simulations which can be easily handled by students
- Teach the students how to “program” complex systems with very little knowledge in computer sciences.
- Improve the learning curve of students.
- Stimulate students’ creativity.
- Quickly find out which students have assimilated the course and which have not.
- See where, in the system, a student is right or wrong.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

For the students, NetBioDyn gives the possibility to:

- Build or explore biological systems in an intuitive way with entities, behaviours and environments.
- Focus on the main mechanisms of a system and acquire a synthetic view.
- Pay attention to important mechanisms even if they look like details.
- Learn partially by themselves what is important and what is negligible.
- Organise their data and knowledge.
- Play at a motivating construction-like game.
- Explore the impact of parameters or behaviour variations in a simple way.
- Show the teacher what is their comprehension or misunderstanding of the real system.
- Share their knowledge with other students in a formal way.

A survey of 30 students (between 22 and 25 years old) has been made to assess the interest of the use of NetBioDyn in class. The results are presented in Figure 20. What is noteworthy is that biologist as well as computer scientist students are mostly interested by such an approach. The question of ease of use for NetBioDyn obtains the most "Very Good" answers for the two master students. Note that this survey is anonymous and that no teacher was present.

This software has also been successfully used by pupils (between 14 and 16 years old) of the middle school Max Jacob in Quimper (France) in May 2011.

Figure 20. Survey of 24 students in Master 1 Biology and 6 students in Master 2 Computer Science at the Université de Bretagne Occidentale. 10 questions have to be answered on the course they had on computational biology and on the use of the software NetBioDyn. Answers show that both the course and the software are considered important for their training. Moreover, the software is adapted to their skills (no code is required). Finally, the course on modelling and the software interest them and are useful for their studies

NetBioDyn Drawbacks

The limitations of NetBioDyn can be divided into two kinds. The first concerns the multi-agent approach itself and the second specifically concerns the software.

Multi-agent systems involve many interacting agents. This usually requires powerful computers, in term of computation and memory, to perform all the entities and their interactions. NetBioDyn reduces this problem by only implementing algorithms of complexity N+B (where N is the number of entities and B the number of behaviours). This is possible because the simulator only uses a small local neighbourhood on a grid. Another problem with multi-agent systems is the number of parameters that can be very important. The simulations made with NetBioDyn could become difficult to control and understand if too many types of entities and behaviours are added. Usually the authors recommend to their students not to add more than 20 types of entity or more than 20 different behaviours. Note that a type of entity is not an entity: a type of entity is a prototype that can be instantiated many times into entities without any problem of parameters.

Regarding the software limitations, the most important one is the entity shape that can only be a cube, implying that the simulations cannot be multi-scale. This last point can be partially circumvented as seen in all the presented examples where molecules, cells and tissues are mingled. For instance, an entity can represent far more than just one molecule, but a group of molecules. An entity can represent a single cell, but also a part of a tissue. What is important here is that an intrinsically multi-scale problem can generally be flattened.

CONCLUSION

The simulation of complex multi-cellular systems using computers represents a great challenge, both scientifically and technically. Scientifically, it serves the comprehension of fundamental mechanisms governing cells, from single-cell behaviours to whole systems involving numerous interacting cells.

Technically, the creation of computational models imitating multicellular systems requires advanced computational skills.

This is why the authors have developed and presented in this chapter a software making it accessible for non-computer specialists by simplifying the process of modelling and simulation.

This simulator is made to create and manipulate models whereas most of educational software are already-made models that researchers or students can test by only changing some parameters or initial state (see for example the simulator presented in (Meir, Perry, Stal, Maruca, & Klopfer, 2005)).

Three simulations have been presented to show the diversity of models that can be done and to explain how they can be made.

To support this statement, this software has been evaluated by pupils of middle school and higher education students, especially those in the field of biology.

The interest of this software has been discussed to bring out both positive contributions like focusing in what to model instead of how to model but also negative ones like the absence of multi-scale entities.

The perspectives are multiple and can be divided into two parts. Firstly the software itself can be improved. One of the most important features could be the possibility to factorise similar behaviours into one. This could be performed for the entities by adding generic behaviours like Random Walk. Another one is to increase the number of graphical tools to quickly draw shapes of entities like squares, circles

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

or filler. The authors are also working on a self-adjusting system to find the proper values for all the parameters involved in a simulation (behaviours' probabilities, entities half-lives etc.), in order to stay close to real results obtained for example *in vitro*.

Secondly, in terms of communication between NetBioDyn users, the main point to address will be the development of an internet social network where researchers, students and teachers will share their works, models and experiences (a starting professional network can be found at http://lefil.univ-brest.fr then NetBioDyn group).

KEY TERMS AND DEFINITIONS

Behaviour: A rule that transform or move entities in the simulated environment.

Bdellovibrio: A motile, vibrio shaped, monoflagellated, gram negative bacteria. It is a predator of Photobacterium leiognathi.

Entity: A virtual entity representing a cell or a molecule.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Integrated Development Environment (IDE): A software with an advanced graphical user interface (GUI) aiding the user to create other software applications.

Lysis: The death of an entity representing a cell.

Multi-Agent System: A set of interacting agents (also called entities). In our system, each agent has behaviours to perform simple reactive tasks.

Photobacterium Leiognathi: A bacteria which is bioluminescent and a prey for Bdellovibrio.

ABSTRACT

In this Chapter, a MATLAB-based approach is presented for compression of Electrocardiogram (ECG) data. The methodology employs in three different domains namely direct, transformed and parameter extraction methods. The selected techniques from direct ECG compression methods are TP, AZTEC, Fan, and Cortes. Moreover selected techniques from transformed ECG compression methods are Walsh Transform, DCT, and Wavelet transform. For each of the technique, the basic implementation of the algorithm was explored, and performance measures were calculated. All 48 records of MIT-BIH arrhythmia ECG database were employed for performance evaluation of various implemented techniques. Moreover, based on requirements, any basic techniques can be selected for further innovative processing that may include the lossless encoding.

INTRODUCTION

In current era, patient monitoring systems are gaining importance which results in ever increasing data volume of various biomedical signals such as Electrocardiogram (ECG), Electroencephalogram (EEG) and Electromyogram (EMG). One of the open research problem in biomedical signal processing is the development of efficient data reduction technique (Sabarimalai Sur & Dandapat, 2014). Such techniques rely on maintaining a trade-off between minimization of reconstruction error and maximization of Compression Ratio (CR). ECG monitoring facilitates in providing faster health status of the concerned patient to the health care centre in case of the hostile cardiac behaviour. Cardiac monitoring using ECG signal is the best representative of heart electrical functionality and had proven to be effective in the diagnosis of most of the heart diseases. For continuous monitoring of patient's health status, the ECG signal is recorded for long time durations typically for several hours or few days. The storage of such huge volume of data requires large memory space, for example, a three-channel ECG signal sampled at a frequency of 1 kHz with 11 bits of resolution in three lead system of a particular patient, recorded for 24 h requires 928 MB of memory size per channel without any overhead. Such huge volume of data is also expected to have inter and intra beat correlation or inherent sparsity (Lee, Kim, & Lee, 2011; Ma, Zhang, & Dong, 2015).

So in the present chapter, a brief analysis of algorithms, mathematical background and its simulation implementation using MATLAB, for ECG data compression will be discussed. In order to make the ECG compression technique as a practical tool, this chapter is intended to refer to the MATLAB based routines. Matlab code (.m) of the most common ECG compression methods and algorithms are demonstrated in this chapter.

The performance evaluation of any ECG data compression techniques can be broadly assessed through following six parameters namely 1) Compression Ratio (CR), 2) Percent Root Mean Square Difference (PRD), 3) Percent Root Mean Square Difference Normalized (PRDN), 4) Root Mean Square (RMS) error, 5) Signal to Noise Ratio (SNR), 6) Quality Score (QS). These six qualitative performance evaluation parameters mentioned above are extensively used in literature for accessing the efficiency of any of the compression techniques.

The compression measure CR is equally applicable to both domains where there is difference or same sample resolution in compressed data. The degree of distortion measure in reconstructed ECG signal is primarily computed with respect to the original data, based on the visual as well the qualitative evaluation. The six qualitative performance evaluation parameters mentioned above are extensively used in literature for the comparison purpose (Batista, Melcher, & Carvalho, 2001; Blanco-Velasco et al., 2005; Lee et al., 2011).

The comparison of existing ECG compression methods using the above mentioned performance measures can be carried out, by performing experimentations over most cited Massachusetts Institute of Technology - Beth Israel Hospital (MIT-BIH) database.

Any digital data source has inherent redundancy, if the generated symbols are not equi-probable. The fundamental goal of any data compression approach is efficient data transmission or storage while preserving the significant diagnostic features. The process of data compression seeks to reduce the number of bits of information required to store or transmit digitized ECG signals without a significant reduction in the signal quality (ECG features). Data reduction of ECG signal is achieved by discarding digitized samples that are not vital for rhythm interpretation. For such data reduction, compression techniques are designed, which are classified as lossless or lossy techniques.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The lossless data compression guarantees the integrity of reconstructed data at a compromised CR, typically CR level of 2 to 1 with exact replication of original ECG while the lossy data compression achieves a high compression ratio with varying level of reconstruction error.

For ECG data compression, mostly the lossy type has been applied due to its capability of a high data compression ratio. The efficiency of any compression algorithm can only be evaluated after reconstructing the original signal through the process of decompression. The PRD is used as a similarity measure for the reconstructed and original ECG. The ECG data compression methods can also be broadly divided into three categories namely direct method, transformed method and parameter extraction method.

The direct data compression method analyzes and reduces data points in the time domain. Various direct data ECG compression schemes which includes Turning Point (TP), Amplitude Zone Time Epoch Coding (AZTEC), improved modified AZTEC technique, Co-ordinate Reduction Time Encoding System (CORTES), the delta algorithm and the Fan algorithm. They all have shown their ability for the efficient ECG data reduction.

Typically, AZTEC algorithm has the advantage of high data reduction ratio but suffers from loss of data fidelity due to the presence of discontinuity that occurs in the reconstructed ECG waveform. ASCII based encoding methods are also employed for compression due to its simplicity, which enables them to be used in portable and mobile data ECG data monitoring systems.

The transformed method analyzes energy distribution of the ECG samples by converting the time domain to some other domain, like Fourier transform, Fourier descriptor, Karhunen–Loeve Transform (KLT), the Walsh transform, the Discrete Cosine Transform (DCT) and the wavelet transform etc. This methods falls in category of lossy ECG compression methods as it mostly employs thresholding at some level. The main parameters which needs to be optimized are namely, CR, PRD and threshold value. The transformed based ECG compression method generally consist of following stages, i) pre-processing; for noise removal, ii) transformation; for visualization in other domain, iii) retention of significant coefficients, iv) application of quantization and v) lossless encoding. In the proposed chapter each and every stage was mathematically analyzed and the simulation results has been produced with MATLAB.

The parameter extraction method is based upon dominant feature extraction from the raw signal. The extracted parameter are quantized and then entropy coder is applied for enhancing the compression efficiency. This method includes the processes like vector quantization, peak picking and linear prediction method. There is scope of combining two or more ECG data compression techniques to get better compression efficiency in one or other domain which is an open research problem.

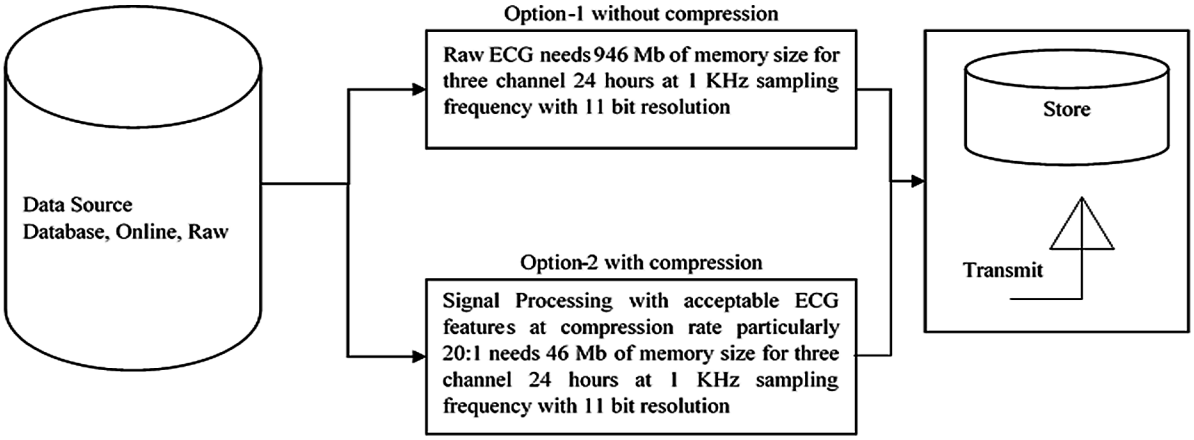
An extensive survey of the various compression methods highlighting their advantages, disadvantages, mathematical analysis and simulation results using MATLAB platform is presented in this chapter proposal thereby facilitating the future research in this direction.

Need of ECG Data Compression

In brief, ECG data compression techniques is the art of signal processing preserving the diagnostic information in a compact form. For any individual under cardiac observation, the ECG data is retrieved continuously online or offline as per prescribed by the cardiac expert. The digitation of ECG data is carried through at the acquisition stage by selecting appropriate sampling frequency and quantization levels. For example as shown in Figure 1, a three-channel ECG signal sampled at a frequency of 1 kHz with 11 bits of resolution in three lead system of a particular patient, recorded for 24 h requires 928 MB of memory size per channel without any overhead. Such huge volume of data is expected to have inter

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. ECG data memory size requirement with and without compression technique



and intra beat correlation or inherent sparsity. For monitoring purpose three lead configuration for ECG acquisition is appropriate. In general for clinical acceptability 12 lead configuration is recommended. This voluminous data can only be handled via appropriate compression technique with varying level of compression ratio and degree of distortion.

Redundancy in the ECG Data

ECG data compression is possible, because ECG, in general, are highly correlated in inter and intra beat which leads to redundancy. High rate of compression can be achieved through reduction in redundancy and correlation present in ECG data. Redundancy can be inferred as repeated intra beat data in ECG as quasi-stationary sense and higher statistical correlation in inter beat ECG represent plateaus.

DATABASE AND PERFORMANCE MEASURE

In the emerging field of medical engineering, research subjects like cardiac arrhythmia detection (Baibars, Kanjwal, & Marine, 2014), heart rate variability (Singh & Singh, 2012), cardiovascular and pulmonary dynamics (Cheng, 2015), artificial intelligence based medical decision support (Hebert, Korabek, & Scott, 2006)and ECG data compression(Jalaleddine, Hutchens, Strattan, & Coberly, 1990; Ma et al., 2015; Sabarimalai Sur & Dandapat, 2014), etc. are of major interest. The Massachusetts Institute of Technology (MIT) supplies some invaluable resources for such research projects. These resources include databases containing recorded physiological signals and software for analyzing, viewing and creating such recordings. In the present study, ECG samples from Arrhythmia Database (Goldberger et al., 2000) (http://ecg.mit.edu) have been taken for investigation of the efficiency of the various methods. The Database contains 48 half-hour excerpts of two-channel ambulatory ECG recordings, obtained from 47 subjects studied by the BIH Arrhythmia Laboratory. The 11-bit resolutions over 10 mV range with a sampling frequency of 360 Hz per sample channel were recorded. To access the compressor efficiency, first 21,600 samples (10 min duration) were used and evaluated with following six data objective compression performance measure metric (Batista et al., 2001; Blanco-Velasco et al., 2005; Lee et al., 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The .mat file can be extracted from (http://www.physionet.org/cgi-bin/atm/ATM) by selecting appropriate database which is MIT-BIH Arrhythmia Database (mitdb). The record number and appropriate time duration can be selected for export signal as .mat file from toolbox provided by website. For typical record 100, 117 and 119 the extracted transposed sample values for different leads are given in Table 1. The total 6, 50,000 ECG samples per lead is presented per record for 30 minutes of duration at 360 Hz sampling frequency. This total number of samples can be calculated approximately as 360×60×30.09 (sampling frequency× second to minute unit conversion factor × time in minutes).

The sample values stated in Table 1 are the benchmark for illustrating different preceding examples in this chapter. The performance measures are

Compression Ratio (CR)

The CR provides information about the degree by which the compression algorithm removes the redundant data. Higher the *CR* less number of bits required to store or transmits the data that can be defined as

$$CR = \frac{B_0}{B_c} \tag{1}$$

where, B_0 is the total number of bits required to represent original data and B_c total number of bits required to represent compressed data along with the side information needed for retrieval of original data.

Percentage Root Mean Square Difference (PRD)

It is a measure of acceptable fidelity and degree of distortion introduced during compression and decompression algorithm. Usually, the clinical acceptability of reconstructed signal after decompression is determined through visual inspection. The numerical evaluation of the level of distortion in reconstructed signal in comparison to original signal can be carried out via PRD measure, defined as

$$PRD(\%) = 100 \times \sqrt{\frac{\sum_{n=1}^{N} (X_s(n) - X_r(n))^2}{\sum_{n=1}^{N} (X_s(n))^2}} \tag{2}$$

where X_r is reconstructed signal with respect to original signal X_s.

Percentage Root Mean Square Difference, Normalized (PRDN)

It is a normalized version of PRD, is PRDN, which does not depend on the mean signal value $\overline{X}$. For any signal, the information lies in its variance. The mean value of the data does not actively contribute to the reconstructed signal fidelity issue. PRDN provides better error estimation in reconstructed signal than PRD.

-	-	-	-	-	-	-
650000	768	1024	1024	1024	1280	768

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$PRDN(\%) = 100 \times \sqrt{\frac{\sum_{n=1}^{N}(X_s(n) - X_r(n))^2}{\sum_{n=1}^{N}(X_s(n) - \overline{X})^2}} \tag{3}$$

Percentage Root Mean Square Difference, Normalized with Respect to Database (PRD_1024)

As for storage purpose, MIT-BIH database adds a 1024 in the original signal. So in order to evaluate the fidelity of reconstructed signal 1024 must be subtracted from the original signal.

$$PRD_1024 = 100 \times \sqrt{\frac{\sum_{n=1}^{N}(X_s(n) - X_r(n))^2}{\sum_{n=1}^{N}(X_s(n) - 1024)^2}} \tag{4}$$

Root Mean Square Error (RMS)

It provides a measure of error in a reconstructed signal with respect to original signal having signal length *N*.

$$RMS = \sqrt{\frac{\sum_{n=1}^{N}(X_s(n) - X_r(n))^2}{(N-1)}} \tag{5}$$

Signal to Noise Ratio (SNR)

SNR, measure of degree of noise energy introduced by compression algorithm in decibel (dB) scale.

$$SNR = 10 \times \log\left(\frac{\sum_{n=1}^{N}(X_s(n) - \overline{X})^2}{\sum_{n=1}^{N}(X_s(n) - X_r(n))^2}\right) \tag{6}$$

Quality Score (QS)

QS is defined as the ratio between the CR and PRD. The QS is a very rational performance indicator when it is difficult to estimate the best compression method while taking into account the reconstruction errors as well. A high score represents a superior compression method.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$QS = \frac{CR}{PRD} \tag{7}$$

All the seven measures are simultaneously used in literature for accessing the efficacy of any ECG compression algorithm. The MATLAB script for calculation for above mentioned performance metric are as follows, which will be used in this chapter for all compression techniques.

If gain (200) and base (1024) are removed before ECG signal processing, then before metric computation both gain and base should be incorporated in reconstructed ECG. Thereby making a fair comparison in the same condition with the original ECG.

Performance Metric Computation

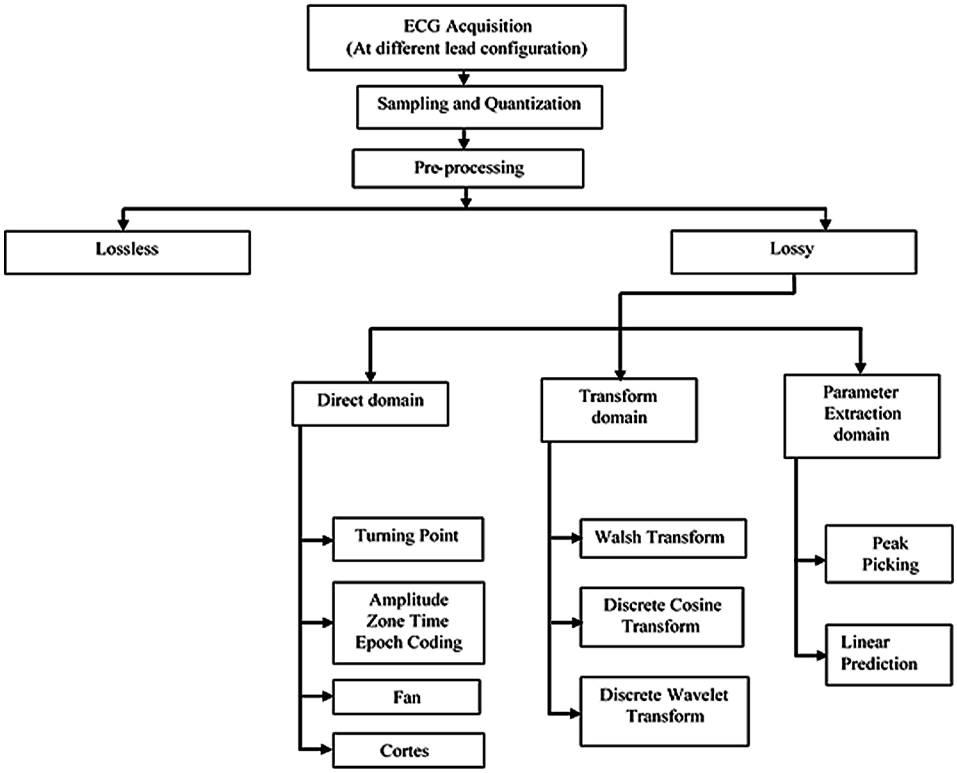
ECG Data Compression Methods

ECG data compression is broadly classified into two types: (i) lossless ECG data compression and (ii) lossy ECG data compression scheme. Lossless ECG data compression is preferred in case of critically ill patient monitoring where each subtle features are needed to be reproduced. Lossy ECG data compression is preferred in case of non-critical patient monitoring conditions and the elderly or regular monitoring purposes. In Lossless ECG compression exact replica of the original signal can be reproduced. But the achieved compression ratio is less than its counterpart i.e. lossy compression scheme. The achieved higher compression ratio in case of lossy ECG compression is at the cost of quality of reconstructed ECG signal. Figure 2, represents the flow chart giving a diversified classification of ECG data compression methods.

Lossless ECG Data Compression Methods

In lossless ECG data compression, the ECG after decompression and compression is identical to original ECG. Every bit of features and other information in reconstructed ECG is preserved. In other words we can state that the reconstructed ECG is exact replica of the original signal. Although this method provides the one of the conflicting requirements of compression, but fails to achieve the higher compression ratio.

Figure 2. Broad classification scheme for ECG data compression methods



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Advantage

- Higher reconstruction signal fidelity.
- Exact replication of original signal is possible.
- Reversible compression.

Disadvantage

- Lower compression ratio.
- Not applicable.

Application

- Critical patient monitoring.

Lossless ECG data compression technique (Horspool & Windels, 1994; Koski, 1997; Sayood, 2010) includes

1. Huffman Encoding
2. LZ Encoding
3. DPCM Encoding

Lossy ECG Data Compression Methods

In lossy compression method reconstructed ECG signal contains degradation with respect to original ECG signal. In this methodology of signal processing perfect reconstruction is sacrificed by the elimination of some amount of redundancies in the original ECG data to in order to achieve a higher compression ratio. Compared to lossless ECG compression method a higher compression ratio can be achieved with varying reconstruction error. For subjective evaluation of the compression scheme these reconstruction errors are not significantly visible. So, lossy ECG data compression methods under certain conditions are regarded as '*visually lossless'*. These certain conditions are preserving the diagnostic features, maintaining the base line. Depending upon the domain of operation on signal the lossy ECG data compression is further subdivided into three groups.

THREE METHODS FOR ECG DATA COMPRESSION

ECG data compression methods can be divided into three different groups namely i) Direct method ii) Transformed domain and iii) Parameter extraction method.

Direct Method

In direct ECG data compression method the digitized ECG samples directly analyzes and compresses the ECG data in the time domain. This section presents a brief overview of the each of basic algorithm

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

along with simulation mechanism especially for ECG data compression. These includes TP, AZTEC, CORTES and Fan algorithm.

Turning Point Method

The basic idea in TP method for ECG data reduction is *to reduce the sampling frequency* of original ECG signal by a factor of two. The maximum possible CR that can be obtained using the TP method is '2' because it preserves one of two samples retaining the slope/turning point information.

The algorithm process three ECG samples at a time. Considering the first sample as reference and then retain one of two remaining samples. The retained sample will become the reference for next two samples. The retention criteria of sample depends upon the magnitude of slope of two samples with respect to reference sample. Whichever sample out of two is having higher magnitude of slope that particular sample is retained other will be dropped for further processing. This process iterates till last sample of the ECG signal is encountered.

In past research (Mueller, 1977) author have concluded that at sampling frequency 200 Hz for ECG data, with 12 bit /sample resolution CR and PRD equal to 2 and 5.3 respectively were achieved. The basic TP procedure for compression is described in Algorithm 1, and reconstruction of ECG data is presented in Algorithm 2.

End of .m Script

An illustration for typical record 119 is given in Figure 3 which shows the original, reconstructed and error signal for 2000 samples. The above mentioned matlab script (.m) files is executed for all 48 records from MIT-BIH database. Table 2 shows the performance measure for typical record 100, 117, and 119 along with the average value for all 48 records. It can be noted that a constant CR equal to 2 and varying values of other performance metrics were obtained using this algorithm. These varying parameter results from the changing complexity in the signal and may violate the nyquist theorem in piece-wise sense.

Advantage

- It retains maximum and minimum points at which the sign of the slope of the signal changes.
- Simple and fast ECG compression algorithm to produce fixed CR of 2:1.
- Iterative application of TP method produces dyadic multiple CR, if there is much higher sampling rate the distortion error may be acceptable.

Limitations

- May violate sampling theorem criteria which results higher degree of distortion in reconstructed signal after repeated application of TP method.
- The retained samples are not equally spaced which may result in localized distortion.

Summary

TP method retains one of two samples through the maximum slope criteria with respect to reference sample point. The algorithm can provide fixed dyadic CR with varying values of reconstruction error. The reconstruction can be accomplished via interpolation between two consecutive samples.

AZTEC

The AZTEC is original developed for rhythmic analysis in real time monitoring of ECG. The basic AZTEC algorithm was first proposed by authors of (Cox, Nolle, Fozzard, & Oliver, 1968) which further improved modified in (V. Kumar, Saxena, & Giri, 2006). In present chapter we provide step by step il-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

lustration of basic AZTEC algorithm with its matlab implementation. The AZTEC algorithm decomposes the signal in terms of plateaus, extremum and slopes. The plateaus and slope detection thresholds are determined empirically. The Algorithm 3 shows the AZTEC algorithm for direct ECG data compression. The combination of plateaus and extremum is called bound.

Algorithm 3. AZTEC algorithm for direct ECG data compression

INPUT:
ecg is the original ECG signal
OUTPUT:
AZTEC is the compressed ECG data
Begin
Plateau detection
Compare the ECG signal sample with previous extrema point and experimentally determined threshold amplitude.
Count the detected consecutive sample which satisfies the above condition
Replace the samples with average value of extrema and name it as Line (L)
Slope detection
Application of experimentally determined threshold for estimating length of plateau
Check for the criteria of the extrema point using the following condition

$$\left\{\left(V(L_{i+1})-V(L_i)\right)\left(V(L_i)-V(L_{i-1})\right)\right\}<0$$

The combined extrema with plateau is called as bound. Except bound left over sample points will fall into the category of slope.
The concept of the time list of slope was devised by (Cox et al., 1968) and is given as

$$\tau(S)=\sum_{i=1}^{m-1}\tau(L_i)$$

The amplitude of slope is determined by

$V(S) = V(L_m) - V(L_0)$

where L_m and L_0 are previous bounds prior to slope.
In order to distinguish the slope and bound, we assign –ve sign to slope time list.
The complete AZTEC can be determined as an ordered pair of time lists and amplitude list.
End

A*	10.65±3.66	0.01±0.01	20.02±19.38	28.31±20.77	0.09±0.09	12.19±4.10	0.83±0.73

A*- for all 48 records average± standard deviation

Advantage

- Higher compression ratio typically in order of 10.
- Applicable for automatic analysis such as QRS detection, having higher slope regions.

Limitations

- The quality of reconstructed signal is very low.
- The reconstructed signal is not acceptable to cardiologist.
- Needs random post processing to resemble the reconstructed signal to original signal.

Summary

The location of important diagnostic features are retained by location of bounds which basically determine the shape of ECG. The AZTEC algorithm keep only extrema (maxima and minima), plateau, and slope. During the reconstruction process plateau and slope are distinguished by introducing a flag of negative sign in time list.

CORTES

The CORTES algorithm (Abenstein & Tompkins, 1982) is the combination of TP and AZTEC method. Depending on the empirically determined threshold value, the length of the lines detected in AZTEC plateaus were retained otherwise the TP data point was saved. If length of the line is less than threshold than in that place of slope operation, TP method was employed. As TP method is efficient in high frequency region and same degree of distortion were added in both high and low frequency regions. Whereas distortion by TP method is tolerated in high frequency region compared to low frequency method. In low frequency region AZTEC algorithm provide low distortion by different length of plateau detection. The interpretation of length of the line is the related with the frequency of the signal, higher the length of the line lower the frequency leads smaller change in the signal and vice-versa. The brief procedure for *CORTES* is described in Algorithm 4.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 4. CORTES algorithm for ECG data compression

```
1:          INPUT:
2:          ecg is the original ECG signal
3:          OUTPUT:
4:          CORTES is the compressed ECG data
5:          Begin
6:          Detect plateau as in AZTEC ECG data compression Algorithm 3.
7:          Apply empirically determined threshold (TH) on the length of plateau
(L)
8:              If L < TH
9:                  TP method (Algorithm 1)
10:              Else
11:                  End
12:           End
```

Advantage

- Better than AZTEC and TP alone.

Limitations

- The quality of reconstructed signal is still low because of unavoidable distortion.

Summary

Cortes method is hybrid combination of TP and AZTEC method designed to preserve ECG features. The QRS feature of ECG is better preserved compared to AZTEC and isoelectric lines are compressed efficiently in comparison to TP method.

Fan

Fan algorithm for ECG data compression is based on finding the region bounded through the empirically determined threshold. The Fan algorithm draws lines between pairs of starting and ending points so that all intermediate samples are within some specified error tolerance, ε. The step-by-step basic Fan algorithm was illustrated by authors of (Jalaleddine et al., 1990; Tompkins, 1993). The brief procedure is presented in Algorithm 5. The visual representation for record number 119 in depicted in Figure 5. In Table 4 performance measure for Fan algorithm on selected and averaged value for all 48 records from MIT-BIH database is represented.

Algorithm 5. Fan algorithm for ECG data compression

1: **INPUT:**
2: *ecg* is the original ECG signal
3: ε error tolerance
4: **OUTPUT:**
5: *Fan* is the compressed ECG data
6: **Begin**
7: X_0=*ecg(1);* Non-redundant permanent sample point or originating point
8: X_1= *ecg(1);* Taking second sample and drawing two lines (U_1, L_1)
U_1- passes through sample point (X_0, X_1+ ε)
L_1- passes through sample point (X_0, X_1- ε)
9: If the 3rd sample X_2 falls within the area bounded by two slopes, generate two new slopes (U_2, L_2) that passes through sample point (X_0, X_2+ ε) and (X_0, X_2- ε)
10: Compare the two pair of slopes and retain the most convergent pair. Which imply lower magnitude of U and higher of magnitude of L is retained.
11: Assign X_1= X_2 and read the next sample into X_2. X_2 always the most recent sample point and X_1 holds the sample immediately preceding to X_2.
12: Repeat the process by comparing X_2 to values of most convergent slopes.
13: If the sample point falls outside the area, save the line length '*len*' & final amplitude X_1, which then becomes the new originating point X_0 and repeat the process.
14: **End**

Published with MATLAB® R2015a

Advantage

- Better than AZTEC and TP alone.
- Simple and faster implementation.
- Higher fidelity of reconstructed signal.

Limitations

- The quality of reconstructed signal is still low because of unavoidable distortion.

Summary

The fan algorithm incorporates the actual sample points which are bounded in the slopes. The three algorithms based on Scan-along polygonal approximation (SAPA) technique closely resemble to Fan algorithm.SAPA-2 proved best result among them. SAPA-2 calculates three slopes between origination sample and actual future sample point. The minor difference between SAPA-2 and Fan is the third slope calculation which is center slope criterion in place of actual sample value criteria.

Transformed Domain

The original ECG samples are subjected to a (linear) transformation in the new domain. The energy compaction property can be further utilized for compression. The basic property of energy compaction is “higher number of samples are clustered in certain region. In current scenario the certain region is near to the origin”. The data compression is achieved in any of domains are only through two ways 1) Thresholding and 2) Quantization.

1. **Thresholding:** There are different approaches for thresholding. When thresholding is applied in transformed domain only significant coefficient whose absolute value is above the threshold is retained. The selection of threshold may be user defined or via optimization algorithm.
2. **Quantization:** The thresholded significant coefficient is represented at lower bit rate through quantization scheme.

Walsh Transform

The Walsh transform amuses the ECG data compression application because it decomposes a signal into a set of orthogonal basis, rectangular waveforms of states are solely either +1 or -1. No multiplier is required and provides only real values as output. It is a asymmetrical and orthogonal transformation.

$$WAL(8) = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \end{pmatrix}$$

The Walsh transform pair with forward and inverse for a signal x(n) of having length N are given by following

$$y_n = \frac{1}{N}\sum_{i=0}^{N-1} x_i WAL(n,i), n = 1,2.....,N-1 \tag{8}$$

$$x_i = \sum_{n=0}^{N-1} y_n WAL(n,i), n = 1,2.....,N-1 \tag{9}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As Walsh transform is symmetric and orthogonal the only difference between forward and its inverse is a multiplication of '1/N' the normalization factor.

The basic application of Walsh Transform in ECG data compression is previously demonstrated by authors of (Kulkarni, Kumar, & Verma, 1997) and its Matlab implementation is also available and explained in its application program. (http://in.mathworks.com/help/signal/examples/discrete-walsh-hadamard-transform.html). The visual representation for record number 119 in depicted in Figure 6. Table 5 and Table 6 represents the performance measure for Walsh transform on selected and averaged value for all 48 records from MIT-BIH database at Th=1 and 0.5 respectively.

Algorithm 6.

```
INPUT:
ecg is the original ECG signal
Define  Th (Threshold)
OUTPUT:
Walsh  transformed coefficient for representation of compressed ECG data
Begin
Take forward Walsh transform by using fwht command
Replace the Walsh coefficient with 0 whosoever is less than the empirically determined threshold
Reconstruct the original signal by using the inverse Walsh transform equation via iwht command in Matlab.
 Compute the performance measure
 End
```

Advantage

- Orthogonal transformation.
- Used power spectrum analysis, useful for characterizing non-linear signals & solving non-linear differential equations etc.

Limitations

- Computationally expensive with respect to wavelet transform.

Discrete Cosine Transform

The DCT is applied to ECG data compression field for improvement in the compression efficiency(Batista et al., 2001; Bendifallah, Benzid, & Boulemden, 2011). Researchers (Lee et al., 2011) have applied, the length of DCT block size should be same as the length of RR interval of ECG to capture the inter beat correlation. The basic formula for DCT is given below for computation of coefficients

$$y(k) = w(k)\sum_{n=1}^{L} X_s(n)\cos\left(\frac{\pi}{2L}(2n-1)(k-1)\right),\ k = 1,2,...,L$$

$$w(k) = \begin{cases} \dfrac{1}{\sqrt{L}}, & k = 1 \\ \sqrt{\dfrac{2}{L}}, & 2 \le k \le L \end{cases} \tag{10}$$

where $w(k)$ is scale factor

- After thresholding the significant DCT coefficient can be further quantized and grouped based on desired requirement.

The Algorithm 7 and its Matlab simulation code is basic implementation of DCT. After empirical estimation, a value equal to 40 was used for thresholding the raw DCT coefficients. Table 7 provide the values of performance measures for selected and average values of all records. The visual representation for record number is 119 in depicted in Figure 7.

```

Published with MATLAB® R2015a

Advantage

- The DCT is falling in the category of orthogonal transform.
- The DCT coefficient generally consists of large amount of near zero values which is main cause of compression.

Limitations

- While DCT operate on real valued input and typically real valued output. Thus there is a need of quantization step in block to achieve compression in same data format.
- Error propagation within the block size arises due to quantization and rounding during reconstruction process.

Discrete Wavelet Transform

The Wavelet Transform is an effective and efficient tool for time-frequency localization. This time-frequency localization is also called as multi-resolution analysis (MRA) representation. The MRA is the basic fundamental approach of the wavelet transform that employed in wide variety of signal processing applications. The localized MRA approach has risen the processing capabilities in stationary and non-stationary domain. Further, it can be successfully applied to the signal feature detection, denoising, and compression. Several reference material for wavelet analysis are available (Daubechies, 1992; Stéphane Mallat, 2009). Wavelet transform is defined in both continuous as well in discrete domain.

The continuous wavelet transform (CWT) is one method of investigating the MRA of data whose frequency content varies with time. CWT maps *x(t)* which is a one dimensional signal to two-dimensional plane formulated by scale and translation defined as.

$$W(s,\tau) = \int x(t)\psi^{*}_{s,\tau}(t)dt \tag{11}$$

where *s* is scale and τ is measure of translation and $\psi^{*}_{s,\tau}(t)$ is the conjugate of mother wavelet formed by orthonormal basis functions. The CWT is computed for the particular scale (variable) by correlating the signal *x(t)* with translated mother wavelet $\psi^{*}_{s,\tau}(t)$. Higher the scale higher the frequency resolution or coarse frequency components and vice-versa. Its reverse is true for time resolution. The *x(t)* can be reconstructed back via inverse wavelet transform (Daubechies, 1992).

The explicit generation of mother wavelet from single wavelet ψ(*t*) is defined through scaling and translation

$$\psi_{s,\tau}(t) = \frac{1}{\sqrt{s}}\psi\left(\frac{t-\tau}{s}\right) \tag{12}$$

The CWT applied on sampled data, with the smooth shifting process over the length of sampled data points, whereas the scaling is defined from the minimum (original signal scale) to a maximum as determined by the user, thus resulting in coarser resolutions in time and frequency domain. This improved resolution demands higher computational time and memory requirement for estimating the wavelet coefficients. The inherent redundancy and difficultly in analytical description of mother wavelet limits the usability of CWT in current scenario. Thus fast algorithm for wavelet coefficient computation is needed. To overcome above mentioned problem Discrete Wavelet Transform (DWT) has been profound. The DWT scales and translates only on discrete steps. In other words DWT is not time or frequency discrete rather than only translation and the scale step are discrete. Definitely it made a trade of between resolution and above mentioned problem but this compromise is widely acceptable.

The intuitively implementation for wavelet transform as the digital filter bank using Eq. 8 and 9 results in DWT defined as follows

$$DWT(m,k) = \frac{1}{\sqrt{s_0^m}}\sum_k x(k)\psi(s_0^{-m}n - k) \tag{13}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As mother wavelet takes various forms depending upon applications, a brief review of their utility for ECG signal processing is available in (Addison, 2005). Most wavelets can be formulated by estimating digital filter coefficients with its impulse response i.e. $\psi(s_0^{-m}n-k)$. The various diagrammatic illustration of forward and inverse DWT as filter banks is available in literature(Al-Shrouf, Abo-Zahhad, & Ahmed, 2003; Hilton, 1997; R. Kumar, Kumar, & Kumar, 2012) which all have the same meaning. The meaning is simple, which deals with the scaling function of the DWT represented as a tree of low and high pass filter bank, within each level only decimated (factor=2) low-pass signal will be transformed further. The subsequent larger scale decomposition results in lower resolution because of the lesser number of samples are available for analysis along with discarded high-frequency components analysis. A dyadic data size is a necessity of filter bank illustration for DWT. which means for *N* decomposition scale the data length must be 2^N. A wide range of literature for ECG data compression using wavelet transform is available with quantization and coding applied after decomposition (Al-Shrouf et al., 2003; Blanco-Velasco, Cruz-Roldán, Godino-Llorente, & Barner, 2007; Djohan, Nguyen, & Tompkins, 1995; Hilton, 1997; Isa, Noviyanto, Jatmiko, & Arymurthy, 2012; Wang & Meng, 2008).

In this Chapter, for ECG signal compression and reconstruction three procedure were adopted. Firstly *N,* level decomposition for given mother wavelet ('haar', 'db2', 'db10', & 'sym8') for input ECG signal was computed. Secondly, thresholding the detail coefficients at empirically or visually determined threshold value and lastly for reconstruction inverse wavelet transform is applied with the help of approximate and modified detail coefficient (exact low pass component and zeros replaced non- significant thresholded detail coefficient with same size) from all levels. The chapter focus is to implement DWT based ECG data compression so we left the quantization and coding part and demonstrated the wavelet based decomposition of ECG signal with its simulation program. The processing of ECG on DWT was operated for dyadic grid and *N=3* was selected for obtaining fixed *CR* by hard thresholding the detail coefficient. Table 8 represents the performance measure for DWT on selected and averaged value for all 48 records from MIT-BIH database over 'haar', 'db2', 'db10', & 'sym8' mother wavelet.

Algorithm 8.

```
INPUT:
ecg is the original ECG signal
OUTPUT:
Wavelet  transformed coefficient for representation of compressed
ECG data
Begin
Take forward wavelet transform by using dwt command
Replace the wavelet coefficient with 0 whosoever is being the part
of high frequency content or details component
Reconstruct the original signal by using the inverse wavelet trans-
form equation via idwt command in Matlab.
Compute the performance measure
 End
```

A*- for all 48 records average± standard deviation

Advantage

- Ability to handle non-stationary data.
- Good localization both in time and frequency domain.
- Better ECG performance measure.
- Ability of automatic removal of outliers.

Limitations

- Functional form representation of many wavelets is difficult.
- The DWT is shift sensitive because input-signal shifts generate unpredictable changes in DWT coefficients.
- The DWT suffers from poor directionality because DWT coefficients reveal only three spatial orientations.
- The DWT analysis lacks the phase information that accurately describes non-stationary signal behavior.

Summary

The formalism of the one-dimensional discrete wavelet transform (DWT) based on different mother wavelet is outlined for ECG data decomposition.

Parameter Extraction Method

The parameter extraction method uses pre-processing tool to obtain a set of set-points or features (typical cycles, extreme locations, etc.) that applied to model the original signal. These features are further quantized using the scalar or the vector quantizer and then some lossless coder is utilized to increase the compression efficiency. Reconstruction of original data is carried out by adopting suitable interpolation scheme. The parameter extraction technique is based on the assumption that the ECG signal is formulated through replication of the number of beats at the frequent rate. Review of some ECG data compression method can be readily found in reference (Jalaleddine et al., 1990; Sabarimalai Sur & Dandapat, 2014). Parameter extraction ECG compression methods mainly classified into prediction models(Al-Shrouf et al., 2003; Arnavut, 2007; Cohen & Zigel, 1998; Nave & Cohen, 1993; Ramakrishnan, 1997). Others are also significant for ECG compression includes scalar/ vector quantization (Cohen & Zigel, 1998; Huang, Wang, & Chen, 2013; Shaou-Gang & Yen, 2001) and template matching method (Paggetti et al., 1994).

In Linear prediction model method the instantaneous sample ($\hat{x}$ (n)) is forecasted by (a) weighted combination past (p) samples.

$$\hat{x}(n) = -a(2)x(n-1) - a(3)x(n-2) - ... - a(p+1)x(n-p) \tag{14}$$

Then, the error among the forecasted and original samples is sent or stored in place of the original samples. The error is quantized using any efficient quantizer (scalar/vector) which is further encoded with lossless encoding. In this process major compression is achieved in two stages first in by reducing the dynamic range and secondly in process of quantization.

The vector quantization is mainly based on the code book creation and transmitting the only codebook number instead of the wide range of samples which are assigned to that particular codebook number. Codebook may be the signal dependent or universal which is available to both of encoder and decoder.

The template matching based parameter extraction method for ECG compression is similar to vector quantization. The template matching for ECG data compression include steps of the beat segmentation, normalization, matching and subtraction with the coding of the residual signal.

The MATLAB code can be made by implementing the any of individual diverse methodology available in the literature.

CONCLUSION

In this chapter, the implementation of different selected techniques for ECG data compression in MATLAB was presented. The implemented ECG compression algorithm may vary with the exact algorithm for particular technique available in the literature due to the focus of this chapter is on the basic methodology of technique rather than pre-or-post algorithm involved with methods. The selected techniques

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

from direct ECG compression methods are TP, AZTEC, Fan, and Cortes. Moreover selected techniques from transformed ECG compression methods are Walsh Transform, DCT, and Wavelet transform. The performance measure for implemented algorithm is also represented. This study seems to be of selection for the appropriate algorithm as needed.

Chapter 50
A Study on Lifetime Enhancement and Reliability in Wearable Wireless Body Area Networks

Saranya Vasanthamani
Sri Krishna College of Engineering and Technology, India

ABSTRACT

The wireless body area network (WBAN) which consists of wearable or implantable sensor nodes, is a technology that enables pervasive observing and delivery of health related information and services. The radio-enabled implantable medical devices offer a revolutionary set of applications among which we can point to precision drug distribution, smart endoscope capsules, glucose level observers and eye pressure detecting systems. Devices with WBAN are generally battery powered due to sensitivity and criticality of the data carried and handled by WBAN, reliability becomes a critical issues. WBAN loads a high degree of reliability as it openly affects the quality of patient observing. Undetected life-threatening circumstances can lead to death. A main requirement is that the health care professionals receive the monitored data correctly in emergency situations. The major objective is to achieve a reliable network with minimum delay and maximum throughput while considering power consumption by reducing unnecessary communication.

1. INTRODUCTION

Wireless technology has advanced to become a vital part of our lives starting from mobile communication to health care departments. Recently, there has been growing interest from system inventors application and researchers on a newly designed type of network architecture usually known as body sensor networks (BSNs) or body area networks (BANs), one made feasible by novel advances on ultra-low-power, lightweight, small-size and intelligent observing wearable sensors. In BANs, sensors are

used to constantly monitor human's functional activities and movements, such as health position and movement pattern. A wireless healthcare application offers and brings many benefits and challenges to the health care sector. These benefits provide a convenient-environment that can monitor the daily lives and medical situations of patients at anytime, anywhere and without limitations. The Figure 1 shows how WBAN provides a wireless connection between these devices and a Personal Digital Assistant (PDA) or a smartphone, which is responsible for the connection with other networks.For example, the obtained data can be forwarded to a hospital server.

1.1 Wireless BSN Scenario

Wireless BSN applications are in great demand in medical care (Movassaghi, Abolhasan, Lipman, Smith, & Jamalipour, 2014; Cavallari, Martelli, Rosini, Buratti, and Verdone, 2014; Davies, Sanjay, & Mohana, 2014), sports and entertainment (Conroy et al., 2009), the military-industrial sector (Kavitha, Balapriya, & Sundrarajan, 2016), and the social public field (Ahmad Dogar & Zafar, 2012; Akyildiz, Su, Sankarasubramaniam, & Cayirci, 2002; Patel & Wang, 2010), and BSNs have gradually become a research hotspot. BSNs is a type of WSN which is formed by physiological factors of sensors placed in the human body or on the body surface or around the body. The key performances it covers are sensors, data fusion, and network communication. It focuses on the advancements in universal health care, disease monitoring, and prevention solution, but also an essential component of the so-called Internet of Things. Its fore most purpose is to make available an integrated ubiquitous computing hardware, software, and wireless communication technology platform, and a vital situation for the imminent improvement of ubiquitous healthcare observing systems (Khan & Yuce, 2010). BSNs initiated from WSNs, so there are many resemblances between them. However, the features are consistently different as of their different

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

application resolutions. Initially, allowing for network deployment, WSNs can be deployed to the unreachable environments, such as forests, swamps or mountains. Several redundant nodes are positioned in the positions indicated above to resolve the problem of node failures, so node density is greater,however, BSN nodes are positioned in, on or around the human body, so the total number of nodes is usually up to a few dozens. Each node confirms the correctness of observing consequences by its robustness (Crosby, Ghosh, Murimi, Chin, & Craig, 2012). Moreover, considering attributes, nodes in WSNs accomplish the similar functions and have the identical properties. The size of nodes is not very critical. Formerly the node is deployed, it will probably no longer need to be relocated. Agreeing to the dissimilar physical signals collected, BSN applications ensure different sensor types (Khan, Hussain, & Kwak, 2009). Furthermore, the necessities of BSN node design are comparatively high. The node dimensions must be small enough, and the nodes must have high wearability and high biocompatibility (Carrano, Passos, Magalhaes, & Albuquerque, 2013). Due to the locations, the nodes are deployed, they will move as the human body moves. Furthermore, considering energy supply, WSNs and BSNs can be battery-powered. The earlier, positioned outdoors, can also be powered by wind energy or solar energy, while the latter can also be powered by kinetic energy and heat (Reddy, Reddy, & Reddy, 2013). Lastly, allowing for data transmission, the transfer rates of WSNs are almost the same, but those of BSNs are different, as the data type and channel task are different among nodes on the body surface and in the BSNs (Khan, Hussain, & Kwak, 2009). Additionally, BSN deployed in the human body are for observing human physiological data, which are subject to user's personal safety and privacy protection issues. Therefore, QoS and the real-time prosperity of data transmission must be considered (Ben Elhadj, Chaari Fourati, & Kamoun, 2012; FCC, 2013; Seyedi, Kibret, Lai, & Faulkner, 2013).

1.1.1 Implanted Node

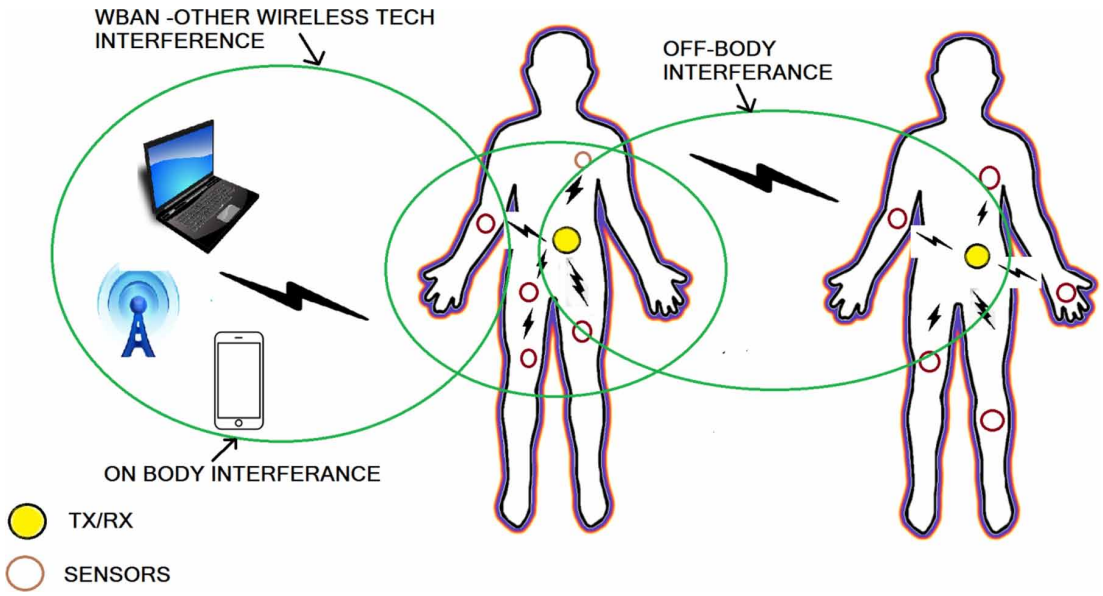
Implanted nodes are used to analyze the health factors with the biosensors which in need to be in the close touching base with the skin, and every now and then even inside the human body. Implantable biosensors are an important class of biosensors constructed on their capability to continuously measure metabolite levels, without the prerequisite for patient intervention and irrespective of the patient's physiological state (sleep, rest, etc.) For example, implantable biosensors symbolize an extremely necessary proposition for diabetes management which presently relies on data obtained by using test strips blood from finger pricking, a practice which is not only painful, but as well is incapable of reflecting the global direction, trends, and patterns related with daily habits.

A startup of a broad research effort predictable at developing implantable biosensors for continuous observing of multiple biologically relevant metabolites, but not wearable sensors.Additional classes of implantable devices which ensure be situated intensively investigated comprise of sensors for nerve stimulation can ease acute pain sensors to the detecting electric signals in brain and sensors to monitor biological analysis in the brain with implanted drug delivery systems for controlled delivery at the site of pain and stress (Tang, Tummala, Gupta, & Schwiebert, 2005).

In the course of the end of the last era, there has been a major increase in the number of various wearable health observing devices, extending from simple pulse monitors, activity monitors, and portable Holter monitors, to sophisticated and exclusive implantable sensors. IWBANs (implantable wireless body area networks) are more desirable than WWBAN (wearable wireless body area network) for numerous advantages. WWBANs have some disadvantages: they limit the mobility of the patients; in accumulation, they can cause skin infections, thus donating poor health conditions. Regardless of the wireless connec-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Representations of implanted sensors



tion is not an essential requirement for observing physiological parameters from implanted sensors. This problem is measured as one of the main incentives for the trend in modern biomedical implanted systems to use wireless technology (Tang, Tummala, Gupta, & Schwiebert, 2005). In Binkley (2003) explored a vision of the near future when one single device will be able to create a WSN with a large number of nodes, which are put on inside and outside the body may be one or the other predetermined or aimlessly, in accord with the application. This visualization can only be achieved over a broad communication standard for wireless telemetry link. Typical hardware and software architecture can support compatible devices, which are predictable to meaningfully affect the succeeding generation of healthcare systems. Certain of these devices can then be incorporated into the wireless body area network, providing novel opportunities for technology to monitor the health status.

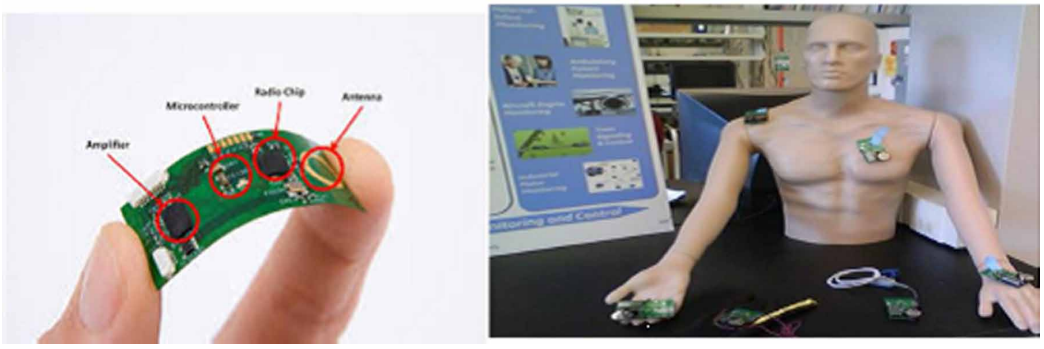
1.1.2 Non Implanted Node

WSN technology offers a wide range of welfares to patients, medical staff, and society through uninterrupted observing in an ambulatory setting, premature detection of abnormal circumstances, vision rehabilitation, and potential discovery of knowledge through data mining of all assembled information. This part shows exactly how to use the planning and mechanism of WWBANs as well as main arrangement enabling unobtrusive, continuous, daily observing of health. In accumulation, this section defines some important implementation issues.

Wearable health observing systems agree the individual follow closely the changes in her or his vital functions and provide feedback for maintaining optimal health status. If integrated into the telemedicine system, such systems can alert medical personnel when serious changes occur. In accumulation with medical centers, patients could be benefited for uninterrupted long-term observing as a portion of a diagnostic practice. We can accomplish optimal maintenance of a chronic condition or can be monitored during the recovery period after the critical event or surgical procedure. Durable health observing can

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Non-implanted sensors nodes



capture the diurnal and circadian variations in physiological signals. These changes, for example, are a very good indicator of cardiac recovery of patients after myocardial infarction (Otto, Milenković, Sanders, & Jovanov, 2006). Long-term observing can also confirm adherence to treatment guidelines or help monitor the effects of drug therapy. Other patients may also benefit from these systems; for example, monitors can be used during physical restoration after hip or knee surgeries, stroke restoration, or brain trauma restoration. The Internet of Things (IoT) is gaining a speedily growing attention in many disciplines, in particular for personalised healthcare. In the meantime, body area sensor network (BASN) under the IoT structure has been widely functional for ubiquitous health monitoring (Wu, Wu, Redouté, & Yuce, 2017; Negra, Jemili, & Belghith, 2016).

The practice of wearable sensors for observing several health-related biometric parameters in daily activities is attracting more interest in recent times. Several individuals are familiar with the use of devices such as wearable heart rate monitors and pedometers for medical reasons or as part of a fitness administration. The architecture includes the major stage to cover the number of wireless nodes of medical sensor that are integrated into WWBANs. Respectively, each sensor node sense, sample, and process one or more physiological signals. For example, an electro cardiogram sensor can be used to monitor heart action, an electromyogram sensor for observing muscle activity, an electro encephalogram sensor for observing brain electrical activity, a blood pressure sensor for observing blood pressure, a tilt sensor for observing trunk situation, and a breathing sensor for observing breathing; and motion sensors can be used to categorize the user's status and to estimate her or his level of activity.

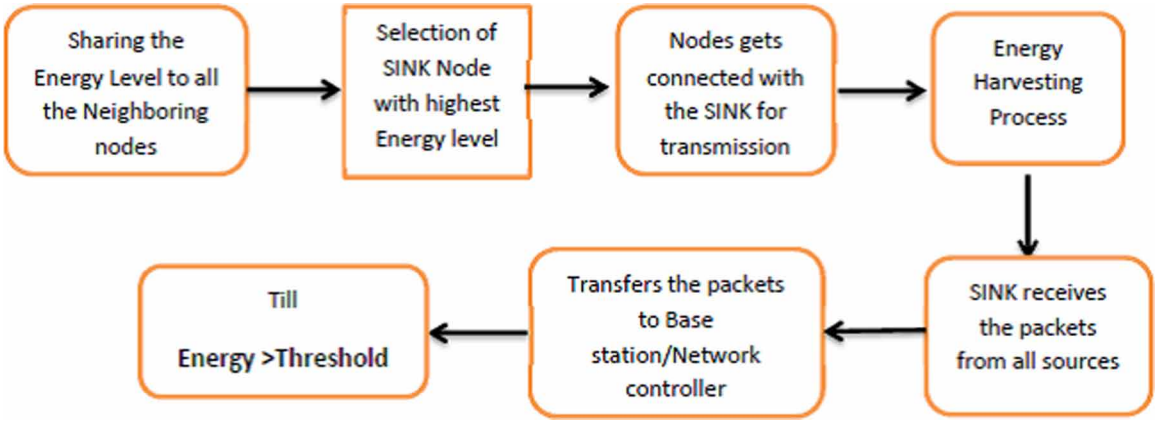
1.2 Topology of the Node Deployment

The deployment of nodes for the data transmission in a network is based on the Energy level of the nodes and the node with the maximum energy is considered as a SINK node.

Initially, the energy level of all the neighboring nodes is analyzed for the selection of a SINK node which holds the highest energy level. After the selection of the SINK, all the other nodes get connected with the SINK till the energy level reaches the minimum threshold level. The packet transmission takes place with the assistance of the SINK acting as an intermediate with the network controller. The same process is repeated till the SINK energy level decreases. Even after reaching the minimum energy level the transmission has to be continued then reelection of another SINK node will to processed for a long-term communication with the same procedure to be continued.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Data communication using SINK



2. LIFETIME ENHANCEMENT METHODS

2.1 Concept of Network Lifetime

In WBANs, energy is consumed mainly on transmission, sensing and unusual energy unused including idle listening, collision, and overhearing. Wireless Body Area Network (WBAN) is a collection of low-power, miniaturized, invasive/non-invasive lightweight wireless sensor nodes that monitor the human body functions and the surrounding environment

2.2 Network Model

WBAN devices are implanted inside the body or might be surface-mounted on the body in a fixed position or else may be accompanied devices which humans can carry in dissimilar positions, in dress pockets, by hand or in bags.Whereas there is a development of tiny devices, in specific, networks consisting of several tiny body sensor units (BSUs) organized with a particular body central unit (BCU).The observing is done in both the places at home and office with these nodes. The development in WBAN technology implements communications on, near, and around the human body and they can transfer information through gateways to reach longer ranges. Through gateway devices, it is possible to connect the wearable devices on the human body to the internet. This way, medical professionals can access patient data online using the internet independent of the patient location.

2.3 Energy Consumption Model

Medical information collected by sensors on the patient's body (WPAN-Wireless Personal Area Networks) is displayed on a bedside monitor. This information is also transmitted to another hospital location for remote monitoring, e.g., a nurses' station) In case of emergency, when the patient is moved from his/her room to the intensive care unit, these communications need to be maintained.

Figure 5. Network model

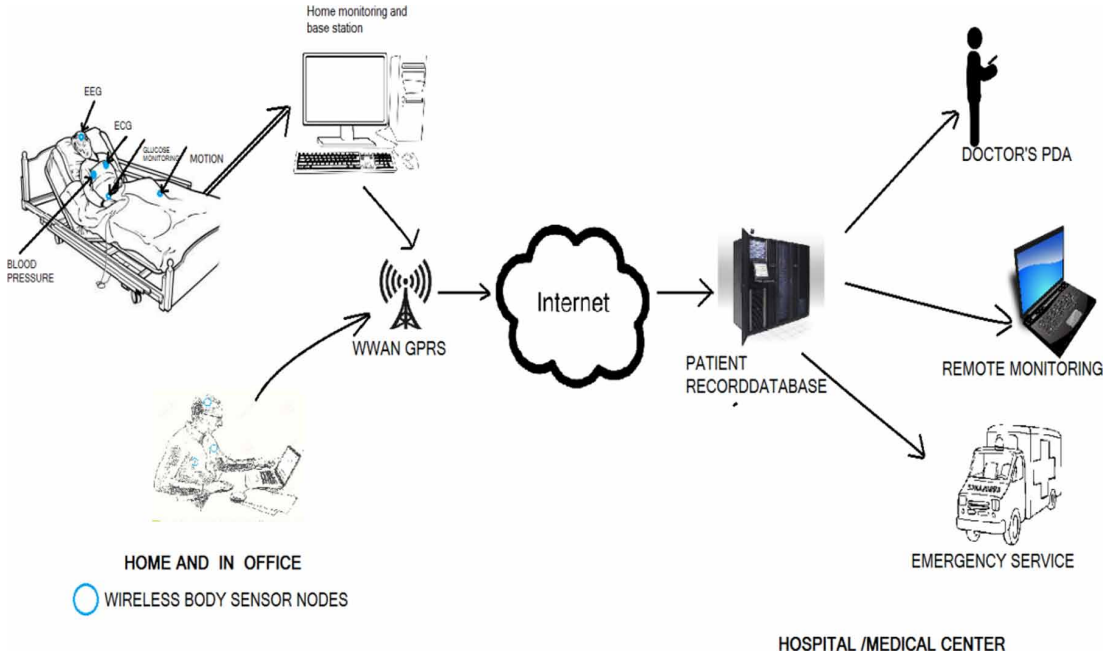

Figure 6. Energy consumption and node deployment using WPAN

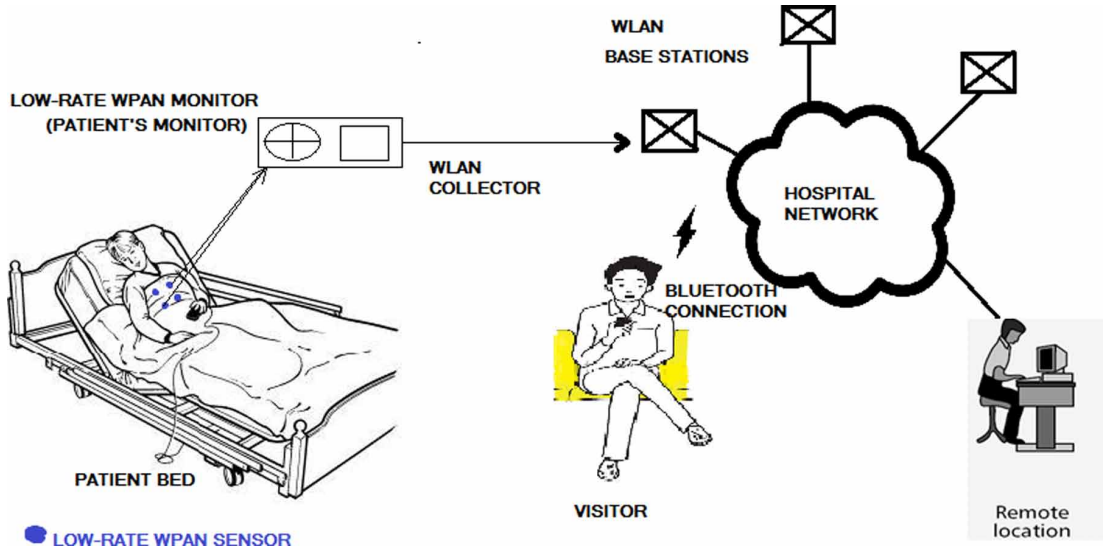


EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$d_{i,j}$: The distance between each pair of sensor nodes and the distance between sensor nodes and the controller.
p_t: The transmission path state (LOS/NLOS-Line of Sight/Non Line of Sight) between each pair of nodes including the controller.
ETX_{elec}, ERX_{elec}, E_{amp}: The energy consumption parameters.
P_L: The packet length in the network.
E_s: The energy storage condition of each sensor node in the network.

The energy cost to guarantee reliable transmission during transmitting and receiving are described in Equations (1) and (2) as follows:

$$Etx_{(PL,d,pt)} = ETX_{elec} * P_L + E_{amp} * P_L * d_{pt} \tag{1}$$

$$Erx_{(k)} = ERX_{elec} * P_L \tag{2}$$

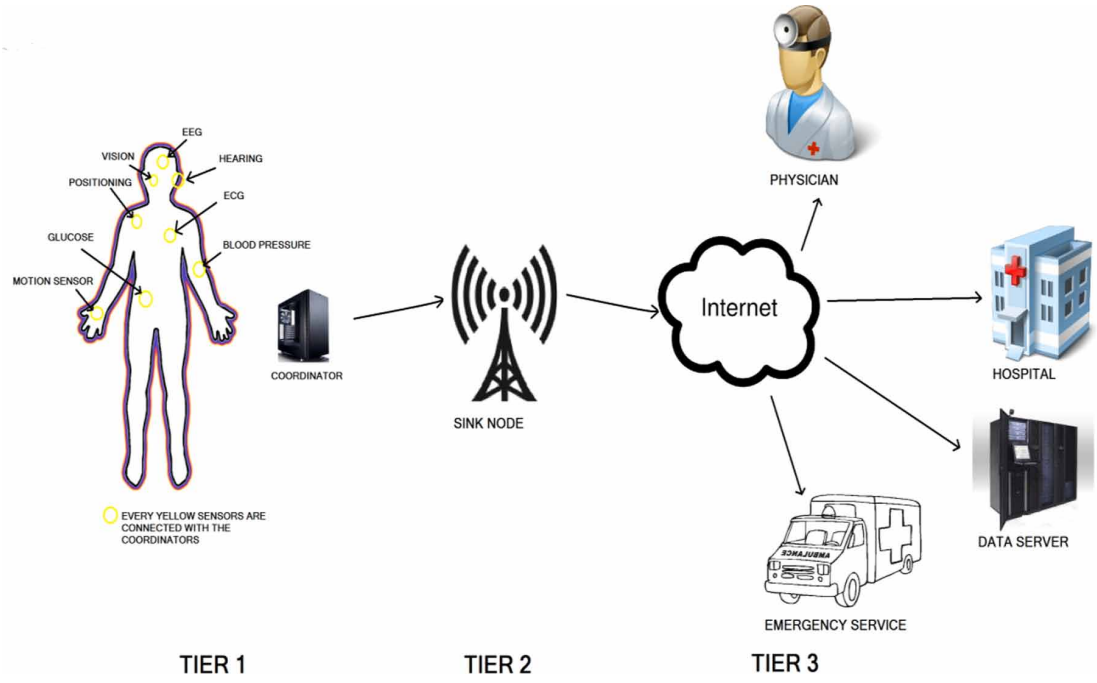
The model takes d n as energy costs due to achannel variation and the path loss in respect with distance d between sender and receiver. Etx represents the transmission energy, Erx the receiver energy, ETX_{elec} and ERX_{elec} the energy the radio dissipates to run the circuitry for the transmitter and receiver, respectively, and Eamp is the energy for the transmitter amplifier. The specific values of these parameters are hardware dependent. In addition, k represents the number of bits sent for the transmission. n is pathloss coefficient related to shadow effect.

The tier 1 of communication in the wireless body area sensor network is based on a number of smart nodes, each accomplished of detecting, sampling, processing, and creating interactive functional signals. Every sensor node obtains initialization guidelines and responds to queries from the personal server. A Coordinator which collects the information from each sensing node and transfers to the SINK node. The tier 2 is the private server that interfaces WBAN sensor nodes, be responsible for the graphical user interface, and communicates with services at the top tier. The private server is classically implemented on a PDA or a cell phone, but instead,it can run on a home private computer. This is predominantly suitable for in-home monitoring of elderly patients. The private server interfaces the WBAN nodes through a network coordinator (NC) that implements ZigBee or Bluetooth connectivity. To interconnect with the medical server, the private server employs mobile telephone networks (2G, GPRS, 3G) or WLANs to reach an Internet access point.

The tier 3, concentrated on a medical server, is enhanced to check hundreds or thousands of discrete users and incorporates a composite network of unified services, medical personnel, and healthcare professionals. Each user wears a number of sensor nodes that are intentionally placed on her/his body. The medical server preserves electronic medical records of enumerated users and delivers several facilities to the users, medical personnel, and informal caretakers. It is the responsibility of the medical server to verify users, receive health monitoring session uploads, design and introduce the particular session data into equivalent medical records, analyze the data patterns, identify serious health variances in order to communicate with emergency caretakers, and forward original directions to the users, such as physician recommended daily workouts. The patient's physician can access the data from his/her workthrough the Internetand observe it safeguard the patient is within probable health metrics (heart rate, blood pressure,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Three tier communications in WBAN



activity), guarantee that the patient is responding to a treatment given by the physician or that a patient has been carrying out the given exercises. A server agent may examine the uploaded data and generate an alert inthe case of a latent medical condition. A larger amount of data collected through these services can also be used for knowledge discovery through data mining. Integration of the collected data into exploration databases and measurable analysis of conditions and patterns could demonstrate the precious information to the researchers trying to link symptoms and diagnosed with chronological changes in health status,physiological data, or supplementaryfactors (e.g., gender, age, weight). It could significantly contribute to monitoring and studying of drug therapy effects for the patients during unavoidable emergency situations.

2.4 Effective Methods

As the total number of sensor nodes in a WBAN is not large, $d_{i,j}$ can be measured manually after the sensor nodes have been deployed as well as p_t, e.g., the transmission path state of each pair of nodes according to the location of each node. Furthermore, the energy consumption parameters are obtained depending on the transceiver types of sensor nodes in the networks. K is identified by the communication protocol and is simply known by WBAN manipulators. E_s can be known by two means depending on two conditions: (A) if the transmit selection is appealed at the network initialization where each sensor node is filled with energy, we can directly achieve the energy storage information from the sensor node form and battery-operated information; (B) if the transmit selection is appealed at a resume from a network recovery, the controller can set a appeal flag in the inspiration frame in order to inform each sensor node to report its residual energy situation in the transmitting time slots. Once all of the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

parameter values are gained, the controller records this information in its memory and has the ability to execute the relay selection scheme. Then, it is illustrated how to implement our relay selection scheme in dual cases. In the principal case where a WBAN is at the initialization stage, the controller will directly execute the relay selection scheme at the beginning of the first frame since it has all values needed to execute the relay selection scheme and load the relay allocation results and the corresponding timeslot allocation in the ideal frame. Then, in the ideal transmission slot, the controller broadcasts the ideal frame to all of the sensor nodes in the network. As each node must listen and receive this ideal frame, all of the sensor nodes in the network will know their transmission strategy and their relay nodes, if needed. In the succeeding case, e.g., a WBAN restarts, where the energy storage condition of sensor nodes is unknown, the controller sets a request flag in the ideal frame at the beginning of the first frame and allocates timeslots for each sensor node in the network to report their energy storage conditions. As a result, in the first frame, sensor nodes send their energy storage information to the controller in their allocated report slots. After the controllers have received all of the report frames, it invokes the proposed relay selection scheme and loads the results and the corresponding timeslot allocation in the next ideal frame, which will be broadcasted in the second frame. Then, in the second frame, each node will know its transmission strategy and their relay nodes. It should be emphasized that the low complexity of the rapid solution in our proposed scheme guarantees that the controller can finish the algorithm in the interval between the point when the controller has received all the energy storage reports to the slot for broadcasting the next ideal frame. Furthermore, it should be noticed that the implementation discussed here does not involve the detailed interaction procedures between the controller and sensor nodes that will be further studied in the future.

3. RELIABILITY

WBANs, which promise significant improvement in the reliability of observing and treating people's health, comprise a number of sensors and actuators that may either be implanted or mounted on the surface of the human body, and which are capable of wireless communication to one or more external nodes that are in close proximity to the human body. Achieving minimal energy consumption, with the required level of reliability is critical for the proper functioning of many wireless sensor and body area networks. Additionally, anyway of the traffic appearances, the methods introduce to understand reliable wireless sensor networks using (occasionally) unreliable components (wireless sensor nodes).

Cooperative communications enable efficient consumption of communication resources, by permitting nodes or terminals in a communication network to cooperate with each other in information transmission. It is a promising technique for yet to come communication systems. The energy efficiency of cooperative systems in wireless body area network (WBAN) to outage the performance of three transmission patterns, specifically direct transmission, single-relay cooperation, and multi-relay cooperation.

At any node *ni*, the reliability estimator module is responsible to measure the average link reliability $\mathrm{LR}_{i,j}$ of link L_{i-j} for neighbor node *nj*. If *N* successful is the number of successful transmissions and *N*total is the number of total transmissions, then the average probability *P*average of successful transmission over a time window δt can be calculated as

$$P_{\text{average}} = N_{\text{successful}} / N_{\text{total}}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. MEDICAL APPLICATIONS OF WIRELESS BODY SENSOR NETWORKS

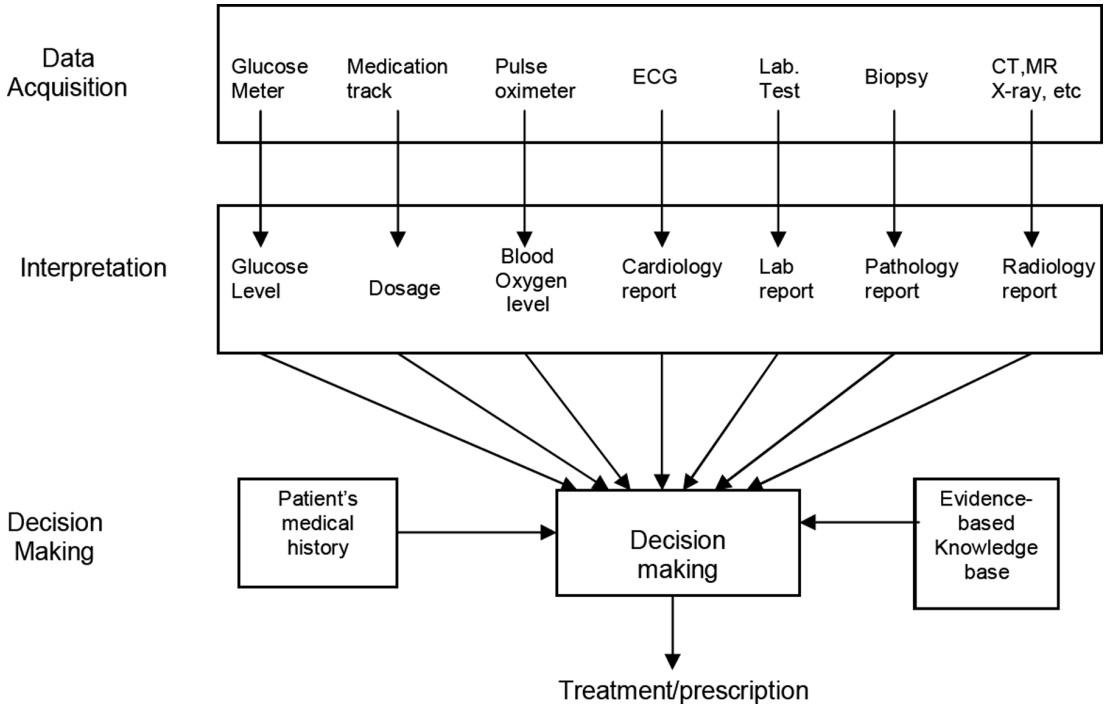
In recent times, the data acquisition begins with the physical property to be measured. Data interpretation and decision making are done based on the data acquisition measured and also treatment is based on the acquisition.

New and improved healing devices in figure 8 are continuously introduced to identify vital signals and present them in an appropriate format for health care supporters. The interpretation can be regarded as a data compression and data conformity process.The general practitioner make a treatment recommendation based on the patient's medical history and current experimental reports by referring the evidence-based database, pharmaco logical handbook, and other resources.

4.1 Energy Consumption and Performance Analysis of WBSN in Healthcare Monitoring

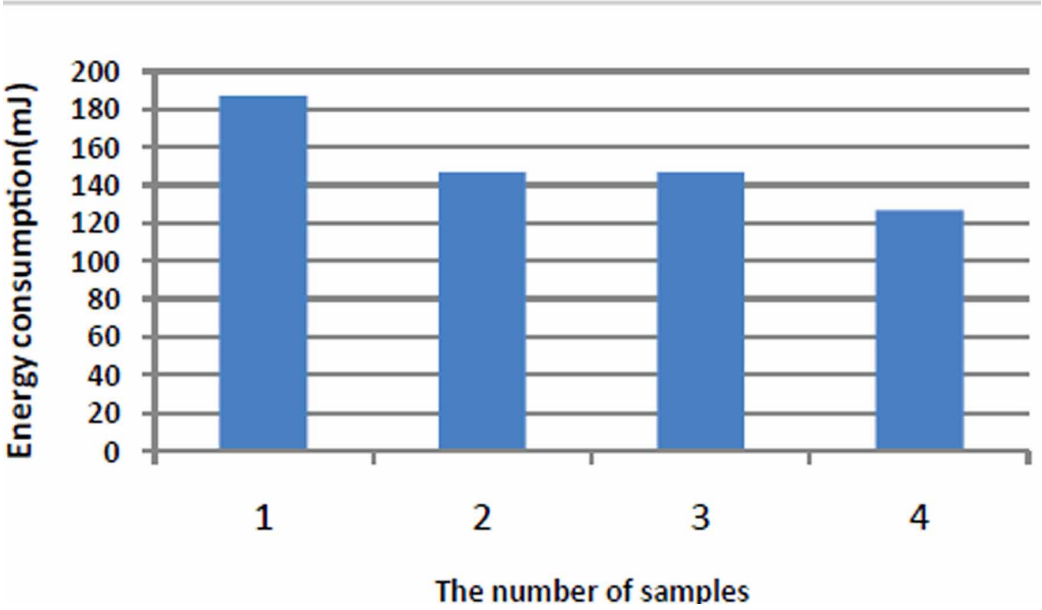
There is a connection between energy consumption and lifetime of the network. A challenge of WBSN is patient eminence of life during the monitoring. So, to provide a quality by reducing energy consumption in a sensor node for the aggregation of sensory data, data packaging and transmitting them to the base station. Therefore, to prolong the lifetime of sensor node when the lifetime becomes short, the patient has to recharge the battery of sensor node in short intervals, and if the patient forget to recharge the battery, it may be dangerous for the patient. Therefore, the burst transmission mechanism is employed to observe the relation between energy consumption and number of samples in a packet.

Figure 8. Applications of WBAN



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Energy consumption for monitoring



4.2 Reliablity of WBSN in Medical Application

The interest in wireless systems for medical applications has been promptly growing. By a number of benefits in wired alternatives, comprises of ease of use, reduced possibility of infection, reduced the possibility of failure, reduce patient uneasiness, improve mobility and low cost of precaution conveyance, wireless applications convey exciting potentials for new applications in the medical market. Portable devices such as heart rate monitors, pulse oximeters, spirometers and blood pressure monitors are essential instruments in intensive care. Integrated wireless technology, these wireless devices could communicate with a gateway that connects to the medical center's network and transmits data to health data stores for monitoring, control, or evaluating in real time or offline after storage.The WBSN provides a reliable updates about the patients to the doctors by using any wirless medium using network routing protocols. The protocols avoides delay and packet loss during transmission

5. CONCLUSION

The essentiality of Lifetime Enhancement and Reliability in Wireless Body Area Network is discussed in this paper.Which describes types of WBAN and the usage of it based on our requirement and patientsproblem. Then the transmission path state of each pair of nodes is located according to the location of each node. Moreover, the energy consumption parameters are acquired depending on the transceiver types of sensor nodes in the networks. Reliability is maintained by the cooperative communication between the nodes. Thus a prolonged network lifetime achieves a reliable network with minimum delay and maximum throughput while considering power consumption by reducing unnecessary communication.

Chapter 51
Pluralistic Tendencies in Healing Abantu Illness in the Contemporary South Africa

Kholekile Hazel Ngqila
Walter Sisulu University, South Africa

ABSTRACT

Ukuhanjwa illness was used as an example to understanding abantu illnesses. With attributional theory ukuhanjwa illness is attributed to spiritual and social causes rather than biomedical causes, whereby causal link is socially constructed between ukuhanjwa illness and entry into the body by familiars. Issues explored included conceptualisation of ukuhanjwa illness. The focus of the chapter is on the reasons for continued pluralistic tendencies in healing regardless of the expectation by the West that people should be focusing on the use of the fast evolving biomedical healing methods. The ethnographic study took place among the Southern Nguni people of OR Tambo District Municipality (ORTDM) in the Eastern Cape, South Africa. Data was collected using qualitative and ethnographic research methods amongst a sample group of 50 participants. The sample was composed of traditional healers, mothers of children who have experienced ukuhanjwa illness, elderly people (male and female), biomedical practitioners and nurses.

INTRODUCTION

The chapter begins by presenting the background for the discussion by outlining the description and identifiable symptoms of *ukuhanjwa* illness; aetiology of *ukuhanjwa* illness; and dealing with illness and disease in order to have better understanding of the illness in question. The chapter has also outlined the focus of the discussion as the rationale for the Southern Nguni people to continue to engage in pluralistic tendencies in healing *ukuhanjwa* as one of the *abantu* illnesses regardless of the expectation by the West that people should be focusing on the use of the fast evolving biomedical healing methods. Ngubane (1977) in Urbasch (2003, p. 11) defined *abantu* illnesses as spiritually caused illnesses which can only be healed using traditional healing methods. Pluralistic approach has been found to be popular

even in other developing countries such as India (Whiting, 1977, p. 249). Dayes (2014) has also noted that people resort to pluralistic tendencies in healing medically unexplained symptoms. The chapter reveals how the Southern Nguni people attach different interpretations and meanings to their illnesses and health experiences as one rationale for people to engage in pluralistic tendencies in healing as their response. The chapter specifically looks deeply into the phenomenon of invisibility of *ukuhanjwa* to the biomedical health system within the context of power relations between the two medical systems – the biomedical and the traditional as another rationale for the use of pluralistic approach in healing *ukuhanjwa* illness. Invisibility has both literal and contextual meanings in relation to *ukuhanjwa*. The invisibility of *ukuhanjwa* to biomedical diagnosis has also been addressed as part of a discourse which needs to be viewed either within its historical, political or cultural setting (Lupton, 2012, p. 2). The chapter has mainly focused on the cultural setting. This discourse also includes the concept of ritual purification, for without such discourse the term is apt to be seen as directly contradicting the literal meaning of the word - pure (Good, 2001, pp. 92-103).

Pluralism is often the result of beliefs that certain illnesses are invisible when using biomedical means of diagnoses. The Southern Nguni people also view pluralistic healing method as the holistic approach in healing *ukuhanjwa* illness – hence this has been discussed under rationale for pluralistic tendencies in healing. The chapter also addresses the perceived source of the healing power as a powerful motivation for continued use of traditional healing methods for *ukuhanjwa* and how it can be linked to pluralistic tendencies in healing.

Lastly, the chapter presents solutions and recommendations highlighting the implications of the Southern Nguni beliefs and cultural practices regarding health, illness and medicine and how those implications relate to the biomedical health sector domination as well as attempts to introduce social change.

BACKGROUND

Description and Identifiable Symptoms of Ukuhanjwa Illness

The Southern Nguni people of OR Tambo District Municipality (ORTDM) in the Eastern Cape of South Africa describe *ukuhanjwa* as an attack on a person, young or old, by familiars (*izilwanyana zokuthakatha*), literally meaning demonic animals used by witches, which penetrate the body through any bodily opening, resulting in certain identifiable and literally visible conditions. These identifiable and literally visible conditions become contradictory to the invisibility which will be explained in the discussion to follow as a contributing factor to the continued pluralistic tendencies in healing what is believed to be *abantu* illnesses.

To name the illness is to diagnose the illness. Once the name is known, the symptoms are understood, the cause is known and the treatment is straightforward. To the Southern Nguni, the illness is known as *ukuhanjwa* from *uku* meaning – to and *hanjwa* meaning - penetrate. Thus, literally - to penetrate and idiomatically - spiritual penetration. This name arose, as do all names for illnesses, from shared experiences and the common worldview of a particular group. The Southern Nguni people make a distinction between two forms of *ukuhanjwa*, namely, the mild and the severe forms of the illness. The mild form manifests itself as red patches on the lips, around the outer lining of the anus and the genitals, as well as a wide open anus. The victim could be a child or an adult since *ukuhanjwa* has no age limit, but is usually a child or infant. The victim is always sleepy and, in the case of babies, their cry is always indicative

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of weariness rather than of pain or discomfort. Indeed, anecdotal evidence suggests that the mild form can present with no pain at all. For Southern Nguni people, only a loud scream is indicative of illness with pain. This form is fairly easy to control and is usually dealt with by the mother or caregiver using traditional medicines.

The severe form of the illness attacks the upper parts of the body as well as the lower parts, with the sinking of the fontanel, the neck losing muscle strength, regurgitation of feeds (*uxakaxa*) and thick saliva from the mouth. Vomiting and diarrhoea are common at this stage. The anus tends to be particularly wide open, to the point where one is able to see up into the intestines. The genitals may also be open. There could be a ring of red patches around the anus and genitals and pus may emit from both the nose and anus of the victim.

The Southern Nguni people of the ORTDM express their fear of severe *ukuhanjwa*, stating that, since it starts in the upper parts of the body with symptoms that could indicate a variety of illnesses, it is very difficult to identify. The most common response of the Southern Nguni when they suspect *ukuhanjwa* is to check the anus of the victim; that is, whether or not it is wide open. They say that, once the victim reaches the stage of losing muscle strength in the neck, there is no way of recovering, and the victim will die.

Aetiology of Ukuhanjwa Illness

The attributional theory as explained by Vaughn, Jacquez and Baker (2009, pp. 64-67) is relevant for contextualising the Southern Nguni conceptualisation of the spiritual causation of *ukuhanjwa*. This illness is attributed to the behaviour of familiars acting on their own, without being instructed by witches. Instead, penetration of the familiars into the bodily openings of the victims is believed to be as a result of their experience of hunger, having nothing to do at that particular moment of their penetration or very hot weather conditions according to the explanation given by the respondents. Another person could argue that although the familiars are believed to cause *ukuhanjwa* illness without the witch's volition, the mere fact that the familiars which have harmed the victim are possessed by a particular witch – that which should be held responsible for all the evil acts of his/her familiars.

Contrary to that thought, the Southern Nguni people consider *ukuhanjwa* illness to be different from other *abantu* illness conditions. Victims regarding *ukuhanjwa* illness are also understood to be blameless with less control over the condition (Foster, 2009, p. 116). Instead people become more concerned about urgent healing and recovery of the victim without worrying about who has caused the illness. In the case of other *abantu* illness conditions witches are blamed for instructing their familiars to cause harm to the victims as a result of enmity or jealousy. In the western, scientifically-defined rationalistic framework, witchcraft might not be recognized as real, but within African communities, it is a reality for most people (Petrus & Bogopa, 2007, p. 2). This points to Barker's (2003, pp. 47-60) statements regarding knowledge and truth. Barker (2003, pp. 47-60) states that knowledge is a matter of perspective, not pure or neutral - attained from a particular point of view. Hence the claim that truth can be viewed as a social commendation rather than an accurate picture of an independent reality, stemming from cultural pluralism as a way of generating shared meanings by different cultural groups (Barker, 2003, pp. 51-60). This conflicts with the biomedical view of itself as representing absolute truth based on empirical evidence – empirical evidence defined from the western perspective. According to Petrus and Bogopa (2007, p. 2), both urban and rural African communities believe that witchcraft exists as a viable and plausible cause for misfortune, illness and death, regardless of whether these things can be scientifically explained or not.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This understanding is applicable to familiars commonly associated with men, such as a certain type of snake called *ichanti*, as well as familiars associated with women, such as a certain type of mouse called *impaka*, or a snake called *irhamba* (puff adder). According to the informants, *ichanti* is known to be invisible to people in its snake form, but takes the form of anything else – such as a horse, or water. Hence the informants could not describe it, other than stating that it is a snake which helps the owner to accumulate wealth. The description of *impaka* indicates something between the *Graphiurus murinus* (woodland dormouse) which has a bushy tail, known to be endemic to South Africa and the *Elephantulus edwardii* (Cape elephant Sengi) which has a very long nose. *Impaka* has both a bushy tail and a long nose, and therefore falls somewhere between the two descriptions. These are the familiars which are believed to be responsible for causing *ukuhanjwa* illness.

Dealing with Illness and Disease

How a person responds to illness and disease depends entirely on his or her worldview. A worldview may be shaped by many factors, some of them contradictory, and may result in an approach which we would call pluralistic. This may be seen as an attempt to reconcile apparently opposing views. People tend to use either traditional, or pluralistic or biomedical healing approaches. Pluralistic healing approach is when the ill-person prefers to use traditional and biomedical healing approaches simultaneously or starts by using traditional healing approach and later use biomedical healing approach as a last resort or starts by using biomedical healing approach and later use traditional healing approach as a last resort. *Ukuhanjwa* is so unique a condition that it tends to be identified as a case for spiritual remedies (traditional healing approach) first and foremost.

One of the most striking aspects of *ukuhanjwa* illness is that, despite the fear which surrounds it and the seriousness of the sickness, the Southern Nguni have developed no particular strategy to pre-empt it. All responses are at the point of attack and immediately afterwards. No long term measures are adopted to prevent it from re-occurring. This seems to be chiefly because the illness is considered fairly rare, and strategies that would probably involve the daily application of an herbal concoction are deemed unnecessary. Apparently, it is not that there is no way of preventing occurrences of *ukuhanjwa*; indeed the same medicines used to cure it could be used to keep it away for the long term. The reality is that people forget, and do not feel a sense of urgency about preventative measures, particularly as these attacks are not common.

The strong smell of the medicines is considered unbearable to the familiars, and is used to repel them, but for a short period of time, just long enough for the person to heal. As soon as the victim is healed, use of the medicine for chasing away familiars is discontinued. The possibility could be that the periods between attacks are just too long, if they recur at all, and the time period is just too long to maintain consistency about the preventative measures. Since it is believed that familiars often loiter around waiting to be summoned and used by their owners, they could be anywhere at any time, and it would imply a very vigilant and daily use of the medicines in order to be sure that one has kept them away.

Regarding cures for *ukuhanjwa*, there are specific traditional remedies, and these seem to work perfectly well – at least in the case of mild *ukuhanjwa*. A teaspoon of a concoction made from the leaves and/or roots of *isivumbampunzi* (*Tulbaghia violacea*), or the leaves *iboza* (*Plectranthus barbatus*) is given as a drink to the victim, and droplets of the same concoction are administered into all bodily openings. For severe *ukuhanjwa*, the Southern *Nguni* people take their guidance from the diviner. In this case it is always a decoction made from the boiled familiar which has attacked the victim. Familiars associated with female witches are the mouse (*impaka*), and the puff adder (*irhamba).*

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In cases where the attack is by *ichanti*, the familiar used by male witches, a special ritual known only to the male owner of this snake needs to be performed. Usually the owner gets to hear of the illness and comes forward voluntarily to offer to heal the child. But the healing has to be performed privately in the presence of the male owner of the familiar and the *ukuhanjwa* victim and in the absence of the caregiver. The involvement of the male owner of the familiar is only at the severe stage of *ukuhanjwa* illness. In consideration of the sample size for the research, chances for survival at the level of severe *ukuhanjwa* illness proved to be less than 50% as out of three participants only one had a child who was successfully healed.

Southern Nguni people are very specific about the ritual space and time of day for harvesting the indigenous medicinal plants. These indigenous medicinal plants need to be ritually pure and have the required maximum healing power, and for this, the place and time for collecting the herbs must be revealed to the diviner by his or her ancestors, through dreams or through consultation of the ancestors by the ordinary person via the diviner. Additionally, collection of indigenous medicinal plants within the premises of the homestead for healing *ukuhanjwa* illness has never been encouraged as the Southern Nguni belief is that their ritual purity and healing power can be weakened by the familiars by walking over them before and after the attack of the victim. The same applies for any person who happens to be treating the ill person - significance of ritual purity of the person performing healing as well as the plants to be used for healing, ritual timing and ritual space have to be highly honoured and observed. The whole healing process of *ukuhanjwa* ends up being ritualised, and no one has ever wanted to deviate from the stipulations that already exist for curing this illness.

RATIONALE FOR PLURALISTIC TENDENCIES IN HEALING UKUHANJWA

Interpretations and Meanings of Illness Experiences

The interpretation of a particular incident or illness depends on the social construction of illnesses in general. An example can be made of an elderly woman who participated in interviews on *ukuhanjwa* when she was 72 years of age. She was a well-educated person with a degree in education and a retired school teacher. She told of how she had developed a small pimple on her leg which she did not take seriously until it developed into a wide circle of black pigmentation. She had not experienced any pain and to her this was significant, and an indication of witchcraft; it being the intention of witches that she would disregard the wound until it caused complete dysfunction of the leg. Her expectation was that a natural illness would be accompanied by pain; the lack of pain was mysterious, indicating the witches' strategy to mislead her so that she would not take action. When advised to visit the biomedical health centre, she refused giving her own interpretation of the cause as a spell she walked over which was set for her specifically by the witches at her younger age so that she would be harmed and fall ill.

Based on her interpretation of the cause, her conclusion was that the biomedical health centre would surely attach an incorrect name to the illness and attempt to heal her, but would not succeed. The true nature of the illness would be medically invisible to biomedical diagnosis.

Her interpretation of the illness led her to decide to apply indigenous medicine to her wound without hesitation. She used the leaves of the sweet potato. She crushed the leaves to extract the juice which she applied directly to the wound on a daily basis for about a week, causing the wound to burst open and release a black fluid. Release of the fluid brought healing. Her interpretation of the experience was that

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the juice of the sweet potato assisted in releasing the spell in the form of the black pigmented fluid. That the wound got healed after the application of the medicine confirmed, in her mind, her initial diagnosis and interpretation.

Invisibility of Ukuhanjwa to the Biomedical Health System and the Southern Nguni Contextual Meaning of Invisibility

According to Liebeck and Pollard (1995, p. 897), visibility refers to being able to be seen or noticed. Applying the term 'invisible', to the symptoms of *ukuhanjwa* could be confusing to the outsider as the symptoms are clearly visible. But the term refers to the whole condition, not only to its symptoms – its causes are included in the term. The biomedical interpretation of the condition varies but includes the suspicion of sexual assault, nappy rash and diarrhoea. The loss of muscle strength in the neck and the sunken fontanel are seen as results of severe dehydration.

When a caregiver takes a child suffering from *ukuhanjwa* to a biomedical centre, she is immediately faced with problems as the tendency is for a biomedical practitioner to separate the cause from the symptoms and see little correlation between the symptoms. The caregiver would be left feeling dissatisfied with the explanation rendered by the biomedical health sector on the illness causation and method of healing that they would receive. Sometimes the victim or the caregiver may just mention the name of the illness *ukuhanjwa* to the biomedical nurse or practitioner without giving a full description of the symptoms. The biomedical practitioner would find the name meaningless as it is not a recognised condition.

In indigenous healing, purity, too, is something that is present but not seen. According to the Southern Nguni people, all indigenous healing methods which deal with spirituality and spiritually-caused illnesses are believed to be ritually pure only if their use lead to successful ritually purification and healing of the ill or polluted person or successfully prevent pollution before it occurs. This is one of the reasons why people who believe in *ukuhanjwa* cannot easily give up their indigenous healing methods – ritual purity is of fundamental importance to them. The very strong smell and taste of indigenous and indigenised medicines used for healing *ukuhanjwa* are believed to be evidence of their ritual purity. The taste and smell contain the power to ward off pollution and to prevent familiars from further polluting the same victim until the process of healing has been successfully achieved. The ill person is not given the medicine for purging but it is supposed to remain inside for cleansing the dirt/impurities from the inside to the outside in order to cool the ill person. According to the Southern *Nguni* people, the contextual meaning of *ukungcola* (dirt/impurities) and *ubushushu* (heat) is pollution. They are the tracks (*umkhondo*) or traces which are left by the penetration of the familiars, and they require ritual purification for cleansing in order to achieve successful healing.

The bitter and biting taste of the indigenous medicines used for the illness in question is believed to have the ability to magically squeeze out pollution from the afflicted parts of the body by means of sympathetic magic. The result is that bodily openings that were harmed and deformed return to their original size. Leclerc-Madlala (2002, p. 93) explains that sympathetic magic is a situation whereby medical conditions are believed to be treatable by substances that are symbolically associated with the condition. It is believed that if the medicine is able to cause the facial muscles to squeeze, then the same response is bound to happen with the bodily openings which have been harmed by the familiars to magically heal and restore their original shape and size.

Holistic Approach in Healing *Abantu* Illnesses

A research report by Ross (2010, p. 46) which stated that for every ten black people, eight use traditional medicine alone or in combination with biomedicine was confirmed in this study as true for the Southern Nguni people of ORTDM. A strong factor influencing the pluralistic nature of help seeking is that people wish to avoid the accusation of not having really tried to find a cure. Since illness is viewed holistically, as spiritual as well as physical, all avenues must be tried.

Another reason mentioned by Eastman (2011, p. 184) is that traditional healers are more easily and widely available as an integral part of the population's social and cultural system. This might not be true for the Southern Nguni people of ORTDM as their behaviour is influenced by their belief system far more than the availability or non-availability of both medical systems. Many urban people, it has been pointed out, will travel for miles to find the right diviner. And many of these same people live in close proximity to biomedical centres.

These pluralistic tendencies are influenced by the belief that healing is not just about the physical body only, but also about spiritual healing – hence, for the Southern Nguni people of ORTDM, the belief system is the chief factor in deciding where to seek help. As Kleinman (2010, p. 86) says, different medical systems employ different explanatory models in an attempt to make sense of disease and give meaning to the individual and social experience of illness. Thus many people will explore all options at their disposal so as to minimize the blame for ill-health or death, since according to their conceptualisation illness and health are defined holistically.

Another reason for the pluralistic tendency in healing is that what is perceived as illness in one culture may not be perceived the same way in another culture. Witchcraft is not recognized in the biomedical health system while for traditional people it is a reality – hence traditional people are open to all options for healing at their disposal.

Eastman (2011, p. 184) confirms that traditional healing together with biomedical healing is widely practiced across social boundaries, as it is not confined to a particular generation or even socio-economic standing. One notices a particular pattern amongst urban people who are assumed to be acculturated. They begin with the biomedical means of healing and later resort to traditional healing methods. Some would immediately engage with both. Their reason for doing this would be their belief that even if the illness starts by being physical, evil spirits or familiars are opportunistic and will attack the victim when he is weakest, so that the ill person confuses spiritual with physical illness. This has also been realised by Farrand (1984, p. 2) and Shoko (2011, p. 290) although Shoko goes on to mention that this pluralistic nature of healing is not only prominent with the urban black people but is also found in the rural areas.

Thinwa (2004) notices the same pattern with urban Tuberculosis (TB) and HIV/AIDS patients, where about 70% adopt a pluralist approach in an attempt to overcome their fear and recover as quickly as possible. Bhana (1986, p. 221) had a similar encounter with Indians who had the same practice of seeking help from both biomedical centres and traditional healers, especially for mental illnesses. The Chinese have established that the same illness can be healed using different methods of healing (Hu, Du, Shen & Xu, 2012, p. 2). Thus the pluralistic tendencies around healing are common and widespread.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Power Relations and Discourses in Illness, Health, and Medicine

Illness, health and medicine are politicised fields in this era of a huge concentration of power in the hands of few. Globalisation has ensured the dominance of a particular worldview and healing system that is inextricably bound to political and economic factors. Hence the interest of medical anthropologists in how health and medical language relate to power (Lupton, 2012, p. 12).

The nature of diseases and their cures, and the process of identifying and labelling diseases, has been dominated by the biomedical health system to the point where it is unable to recognise any other interpretations but its own. It is unable to recognise, name and cure *ukuhanjwa*. Faced with this reality, it strives to treat symptoms, but not the disease itself. The biomedical response to *ukuhanjwa* symptoms is to treat each one individually. They would see the wide open anus as a result of diarrhoea or sexual assault, and advise accordingly. Usually they dispense paracetamol or acetaminophen (the generic name) under the trade name Panado, to bring down the temperature where the *ukuhanjwa* is mild. The traditional approach is to get to the root of the problem and deal with all symptoms at once. It is a truly holistic approach.

According to the Southern Nguni people, biomedical practitioners do not share the name '*ukuhanjwa*' for the condition because they do not recognise the cause as a valid one. To them it is a collection of symptoms without a name – a non-illness. As a non-illness, it cannot be treated effectively. The Southern Nguni way of interpreting the non-comprehension of biomedical practitioners of this condition is that its true nature is invisible to them. They observe that biomedical practitioners cannot provide a medicine or healing method which will simultaneously heal all the symptoms and chase away the evil spirits. According to the Southern Nguni people, the western healing methods heal the physical body whereas traditional healing methods target even the evil spirits, extracting the illness from the deepest parts of the body. Traditional healing methods work on the causes of the illness as indicated that it targets the evil spirits for holistic healing. The enema has to be a small amount, not for purging the victim, but to allow it to cleanse his/her internal organs so that when releasing the bowels it comes out together with the evil spirit and the heat, which resulted from the contact with the familiars, for the victim to cool.

What stands out in this method of healing is that there is no attempt to focus on this or that particular symptom; it is always seen as a collective of symptoms, healed simultaneously. Seemingly, it was originally important for the Southern Nguni people to get the biomedical health sector to understand their illness, and it troubled them that biomedical practitioners continued to dispute its existence. Hence they resorted to the belief that the illness is invisible to the biomedical world. Comparisons between the two approaches would be quite unfair, as they arise from such totally different worldviews. And yet with this particular disease, it does seem that traditional medicine has the upper hand. It has the record of curing from the contextual meaning of the Southern Nguni people, whereas the biomedical approach does not.

Linguistics in medicine, of course reflect the culture from which the medical system arises. The way people speak or the visual metaphors they use often cause confusion, misconceptions and misinterpretations. The pattern of words, figure of speech, concepts, values and symbols (Douglas, 2010, pp. 9-10; Lupton, 2012, p. 2) all contribute to different meanings attached to phenomena, as the case with the phenomenon of cleanliness or purity. The Southern Nguni concept of ritual purity has sometimes erroneously been equated with hygienic cleanliness (Ngqila, 2002), resulting in misunderstandings. To the Southern Nguni, purity and cleanliness in medical matters refer to spiritual cleanness, and the use of anything which brings about this state of spiritual cleanness. This includes appeasing ancestors, warding off pollution and healing the ill. It does not mean sterile, free of germs, clean in the physical sense.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thus we see that different cultural groups develop ways of making sense of illness, health and medicine from their own cultural perspectives, based on historical, political, economic and cultural settings which cannot be compared, as already stated. As a way to rationalise the great disparity that exists between their own traditional methods and biomedical methods, traditional Southern Nguni accept that some healing methods specialise in physical healing while others specialise in spiritual healing. This allows a place for both.

The manifestation of power relations in the field of health and illness can be seen in the way a stronger culture has come to dominate the discourse on health and healing. According to one of the participants (a community member and a nurse), one of the strategies used by the South African government as a way of overpowering those who subscribe to traditional healing methods has been to introduce laws forbidding people from withholding treatment from biomedical health centres to children. This participant acknowledged that adults are still allowed a choice but it is always insisted that they should allow four hours after the use of biomedicine before the application of indigenous medicine. The understanding is that four hours is the lifespan for the functioning of the modern treatment. The biomedical sector does not accept use of traditional medicine at all, such that it is always made to be clear that if a person decides to use traditional medicine, she or he would be using it at her or his own risk and should not blame the biomedical centre. But when it comes to children, the participant insisted that it is a requirement of law that every means possible be made to cure the child biomedically. But it turned out that the protection of children's rights to exclusive medical care (biomedical care) is merely theoretical as, according to the same participant, a particular parent collected her child from the local hospital in preference for traditional medicine because it was after a long while that the hospital had been trying to heal the child without success. The mother of the child arrived at the hospital stating that her child has been attacked by the familiar called *ichanti* (a male snake believed to be for accumulating wealth) and that someone has offered to heal the child and she asked for permission to leave with the child. She explained that the person who offered to heal her child was the owner of the *ichanti* snake. The hospital released the child because the child could not be healed biomedically for a very long time.

The incident confirms what was stated by Mofokeng (2003, pp. 15-16), that some medical practitioners are themselves confused what to advise when they have been exposed to a variety of cultures and experience cultural conflict. In this regard, the nurses had a responsibility to abide by the rules of biomedicine, but because they have been exposed to traditional practices too, they found themselves bending the biomedical rules and releasing the children to their parents. As Levine (2012, p. 86) says, even though biomedicine is accepted as authoritative, its knowledge is not always uniformly shared and practised by all its practitioners. This leads to different diagnostic and therapeutic possibilities, as in the case above (Levine, 2012, p. 86).

This leads to the consideration of ethnocentrism and relativism. Although lip service is paid to the ideas of relativism, with biomedical practitioners encouraged to understand the so-called inferior and weaker cultures, in reality the ethnocentric approach of biomedicine usually swallows up all other considerations. It has already been noted by one of the participants (a community member and a nurse) that the biomedical health centres are clear about what they want to achieve in terms of bringing about social change in the area of illness, health and healing. They would like the wholehearted adoption of biomedical healing methods without any pluralistic tendencies. There are however exceptions in private practice. During interviews in ORTDM, the researcher was told of two biomedical practitioners who attracted a large following by adapting their own healing methods to the needs of people presenting with *abantu* illnesses. These two biomedical practitioners, one a black African man and one a white man from abroad, started working together in Tsolo and later in Mthatha.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

People would travel from all over the ORTDM to these two doctors, because they showed unusual sensitivity to patient's worldviews and understandings of their own conditions. They listened carefully to the language of the local people over a number of years and were able to pick up the terms they used for illnesses. They then indigenised certain biomedicines such as *udupha* (doepa) or *ivimbela* to suit the needs of the traditional people. One of the interviewees from Mhlontlo Local municipality MLM (Tsolo area) under the ORTDM mentioned that she took her children to these practitioners whilst they were still working jointly in Tsolo for all *abantu* illnesses such as *ukuhanjwa,* and their treatments worked. When the researcher visited one of these biomedical practitioners who is currently practising alone in Mthatha, he told of how traditional people who came to him for treatment would adopt the practice they used when consulting diviners: they would sit in front of him and not say a word. His assistant had to explain this to him that when traditional people visit diviners they do not talk, instead it is the diviner who talks, stating the nature of the illness of the patient.

This inspired the biomedical practitioner to purchase a diagnostic machine which takes the place of the diviner as a scanner. The patient sat on the chair and the chair would be able to detect and indicate possible illnesses such as the level of blood pressure, diabetes and others without the patient or practitioner having to say anything. The patients ended up naming the machine as *igqirha* (the diviner). But unfortunately, the biomedical practitioner avoided mentioning the name of the machine and seemingly he is still the only one who has the machine in Mthatha. Even when the researcher tried to inquire about the name of the machine from other biomedical practitioners, they could not tell as they indicated that they have never heard about such machine. The researcher saw the machine which resembled the chair where the patient could sit comfortably for the machine to detect the possible illness. In this regard, the researcher had no choice but to respect research ethics whereby the participant has a right not to divulge the information if he or she feels uncomfortable to do so. These findings contradict the assumption shared by most westerners that people automatically abandon their traditional medicine when acquainted with western medicine (Schott & Henley, 1996, p. 17).

The findings on pluralistic tendencies in healing support what was argued by Gordon (2010, pp. 165-183) and Varga and Veale (1997, pp. 911-924) that people continue using traditional medicine despite biomedicine's hegemonic attempts to prohibit such practices. Hence the biomedical health centres even appear to be contradicting themselves as explained above whereby they would be adamant that they do not promote the use of traditional healing methods while on the other hand they allow adult patients to use their traditional medicine only after four hours after the biomedicine has been applied. Local people have confessed that they continue the use of traditional healing methods in their homes for spiritual healing, despite the prohibitions of biomedical practitioners, as they strongly believe in the existence of spiritually-caused illnesses. Traditional people have demonstrated their scepticism regarding foreign or biomedical healing methods for *abantu* illnesses. This confirms assertions by Perret (2010) and Wedel (2009, pp. 49-64).

In biomedical healing, experimentation and scientific evidence in the laboratory reveal the causes of illness and determine the healing method. With the so-called theological illnesses and metaphysical or traditional healing methods, enculturation ensures the continued belief in the causes and cures of illness over decades and indeed centuries, and this longevity of the practices is evidence enough to sustain their belief system. As one of the participants (a community member and a nurse) revealed that there are even laws which insist on the use of exclusive healing method (biomedical healing method) for children, biomedical healing method seems to be the most popular with governments with political

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

support related to tangible evidence of successes. As far as governments are concerned, there is no place for metaphysical healing methods as their evidence is intangible and undocumented. In this case, it is deemed intangible despite the extended period of continued use and the strong belief systems around illness, health and medicine - hence the categorisation into superior and inferior cultural medicine – ethnomedicine - begins to take shape.

Linking the Source of the Healing Power with the Continued Use of Traditional Healing Methods for *Ukuhanjwa*

There are specific factors which contribute towards the trust and belief that Southern Nguni people have in the power of traditional healing for *ukuhanjwa*. These factors include the person who has recommended the traditional healing method, the bitter and biting taste of the medicinal plants, the very strong smell of the plants and the level of faith and belief that the caregiver has in the methods used.

Researchers have come to a variety of conclusions in relation to the continued use of traditional healing methods. Some of these are refuted by the outcomes of this research amongst the Southern Nguni people of ORTDM. These conclusions include the opening hours of service for traditional healers, whose constant availability is thought to contribute to the loyalty people have for them (Friend-du Preez, Cameron & Griffiths, 2009, p. 345; Ross, 2010, p. 47; Truter, 2007, p. 60). Research for this study suggests that the loyalty people have towards traditional healers and methods has little to do with opening hours, and far more to do with the power of belief, enculturation and conviction about the realities of the spiritual world. Biomedical centres are seen as simply not equipped to deal with the full nature of sickness. One female participant elaborated more on this and indicated that when the hospitals are unable to heal the child and not knowing what to do, they begin to ask questions about the medicine one has given to the child before opting for the biomedical health centre. After realising that they are unable to heal the ill child, the participant stated that they immediately ask the caregivers or mothers to take the child to the place where they started before opting for the biomedical health centre. To the Southern Nguni people, that is a sign indicating that they are also stuck but will not admit to having given up. The participant acknowledged that community members cannot speak openly about their indigenous healing methods to the biomedical health workers and practitioners because they end up being insulted about using their indigenous medicines. Those are some of the reasons which cause them to use indigenous medicine secretly.

Discouraging traditional people to use their own indigenous healing methods in favour of biomedical healing methods, the biomedical health workers have given traditional people the impression that biomedical healing methods are superior and to traditional people, superior means having absolute success in every performance. They are not familiar with the idea that even biomedical healing methods may fail, and that many treatments do not work perfectly the first time. When something that is touted as superior fails to work the first time, they do not think of requesting an adjustment to the dosage, or a different approach. They conclude that the disease is beyond the abilities of the biomedical centre – in effect, invisible to practitioners. It would appear that the idea of trying, adjusting, co-operating with the doctor to observe changes and improvements is not something that has been explained to people. Perhaps it is a mark of the hegemonic tendency of the biomedical health system that in their determination to win the battle against traditional practices, they too assume that their methods will work perfectly and do not consider that healing is sometimes a process, requiring trial and error in some cases.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Friend-du Preez, Cameron and Griffiths (2009, p. 345), Truter (2007, p. 60) and Ross (2010, p. 47)) have also mentioned the issue of staff and drug shortages in biomedical health centres as possible motivations for traditional people to continue with their pluralistic tendencies in healing. The outcomes of this research have indicated that neither shortages of drugs nor of staff are of chief significance, but what is of most significance is the Southern Nguni belief in the invisibility of cultural illnesses to biomedicine.

This brings the discussion back to the link between the perceived source of the healing power and the continued use of traditional healing methods for *ukuhanjwa*. The continued use of these methods has everything to do with the level of belief and faith that caregivers have in the efficacy of these healing methods. Another female participant admitted that Southern Nguni people take the victim of *ukuhanjwa* to the hospital so that they are not viewed as deviants and not because they believe and trust biomedical help. Southern Nguni people believe in indigenous medicine in healing this illness. According to this participant, even the biomedical nurses would go out and pick some leaves to make traditional medicine and apply it to the victim cautioning community members not to tell the doctor that the child has been given traditional medicine – those are nurses who have knowledge about this illness. It is important to note however that belief and faith alone would not have been enough to convince traditional people to continue with the use of traditional medicines. There has to have been evidence of healing with these methods. Thus the faith and loyalty that people show towards the traditional methods of healing for *ukuhanjwa* are backed up by a success rate that cannot be disputed – when it is caught early enough. The fear and alarm that this disease engenders is related to the fact that when noticed and acted upon too late, it invariably leads to death. That is why traditional Southern Nguni mothers always check the anus of their children when a child exhibits unusual sleepiness. Their belief and faith in the efficacy of the healing methods for *ukuhanjwa* is enhanced when the person who recommends the cure – or who recommended it to one's mother or other relative - has a history of positive cures, is trusted and a well-known diviner with an excellent track record.

The spiritual power contained in the plant, as ordained by God and revealed initially by the ancestors, also play their part in making these methods the trusted and apparently successful method that they are. So too does the bitter and biting taste of the plants. These are felt to owe their power to sympathetic magic by which body openings are shrunk back to their original size. Along with taste, the smell is believed to chase away the familiars or evil spirits until the victim has completely recovered as a result of sympathetic magic. The belief is that if the smell is strong enough to affect human beings, then sympathetic magic would make it possible for the familiars to be strongly affected by the smell too.

Ritual timing linked to the application of the healing method for it to work successfully to prevent escalation of the illness to the worst condition. It has always been emphasised that the indigenous healing method should be administered immediately after the illness is recognised and without any further delays for it to work successfully in the case of mild *ukuhanjwa*.

Ritual space is also linked to the maintenance of the healing power in the traditional medicinal plants. Some of the traditional medicinal plants for healing *ukuhanjwa* illness are believed to lose spiritual healing power should they be planted within the home premises – hence they are left to grow in the open fields. The belief is that in the case where these plants are planted within the home premises, familiars cause them to lose spiritual power by walking over them on their way to the victim for spiritual penetration. The same applies to the significance of the ritual space linked to privacy needed by the male owner of the familiar (*ichanti* snake) with the victim for efficacy of the healing method for *ukuhanjwa* illness. Hence no participant has divulged any information relating to the traditional healing method used by the male owner of the familiar – *ichanti*.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The above sources of power have contributed mostly to the strong faith that the Southern Nguni have in the healing methods of *ukuhanjwa*. They would not have attempted to use them if the above sources were lacking. But from an outsider's point of view, one could conclude that continued use of these methods may be attributed to their efficacy and not merely to belief and faith.

SOLUTIONS AND RECOMMENDATIONS

The indications are that the Southern Nguni people of the ORTDM are deeply committed to their indigenous practices regarding *ukuhanjwa,* and are going to continue to consult with their diviners, use their preferred healing methods, and transfer their information on the illness from the present generation to the next.

The biomedical health system needs to pay attention to the interpretations traditional people give to their illness experiences for them to fully understand the point of view of the other person so that points of commonality and divergence can be identified and assessed. They may still experience difficulty in understanding and interpreting healing from a spiritual point of view, thus requiring the input of a traditionalist who would have to indicate if the illness requires spiritual healing, and whether it has been achieved or not. The two systems cannot be compared in a biological way as has been proposed.

Three approaches are used for the illness; the traditional, the biomedical, and the combination of both. This implies that there are three directions which could be taken. The first direction could be that of the biomedical health system being successfully convinced that *abantu* or cultural illnesses do exist and are real – something which might lead to the establishment of an integrated medical system – the Asian model (Baer, 2011, p. 417). The second direction could be that of traditionalists being convinced by the biomedical health system that *abantu* or cultural illnesses exist mostly in their imagination and have no basis in reality – a reality defined by westerners. This may lead to the exclusive medical system (only biomedical system) – the American model (Baer, 2011, p. 417; Levine, 2012, p. 66). The American position often reflects a narrow worldview where everything not familiar is, according to Levine (2012), "dangerous and irrational" (p. 66). The third direction could be that of maintaining the status quo of the inclusive medical system – the British model (Baer, 2011, p. 417) – a tolerant, yet condescending medical system, whereby the South African government extends tolerance to the traditional health system while preventing it from operating at the same level as the biomedical health system. It implies that traditional health care will remain in its lower status and the hegemonic tendency of the biomedical health system will continue. Should this be the case, there are nevertheless certain things listed below that biomedical practitioners can be made aware of, to inform their interactions with patients and improve their possibilities for successful healing.

- In the case of *ukuhanjwa*, despite its severity and possible fatal consequences, no preventative measures are used, despite their availability. This is because the illness is known to occur infrequently, and people can find little motivation to justify the continued alertness and vigilance that such preventative measures would imply. According to the Southern Nguni understanding, once the application of medicines for *ukuhanjwa* is discontinued, the smell is absent and the person is automatically vulnerable and open to attack. And yet no measures are taken to prevent this.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The lack of a systematic way of preventing the illness has implications for health care in the broader sense. One might assume that as long as Southern Nguni people do not notice a threat to their lives, they find little reason to break with habit. For *ukuhanjwa*, sustained action over years would be required to be assured of its prevention, and people are unwilling to take this route. Similarly, they quickly fall away from any long-term practice adopted for prevention. Thus any medical protocol requiring consistency and patience is apt to fail, particularly if it is supposed to be adopted indefinitely with no likelihood of ever stopping. The same way of thinking seems to be evident in the reported resistance to using condoms for the prevention of HIV/AIDS and unwanted pregnancies. Recent reports on TV indicate that instead of increasing, the rate of condom usage in South Africa is dropping, with implications for HIV/AIDS and pregnancy statistics. A lack of consistency also extends to the treatment for HIV/AIDS; getting people to adhere to a long-term treatment regimen is extremely difficult. It has also been observed in the case of tuberculosis (TB), where patients are inconsistent in taking medications, and drop their use as soon as they begin to feel better, despite warnings not to do so.
- Thus, Southern Nguni people have demonstrated a preference for once-off measures, rather than long-term, consistent measures especially preventive measures. Prevention measure for polio, for instance, is dealt with in a more once-off manner, and there would be no requirement for consistency over the long term. Some people even state that there is no preventative measure for *ukuhanjwa*, whereas others confess that there is, it is just that people do not wish to engage with preventative measures. Hence with *ukuhanjwa*, the practice is to respond swiftly and thoroughly, but only for the short term. People do not underestimate the danger; in their view, they believe they are open to attack at any time; the problem is that people lack the ability to maintain consistency for extended period of time in the field of illness, health and medicine. Knowing these facts might enable biomedical practitioners to fully grasp what they are up against – it is not just forgetfulness, but a deep-rooted preference for dramatic, short term measures and a lack of impetus for consistent measures for prevention.
- Ritual and symbolism play a big part in Southern Nguni healing; indeed, an element of ritual is present in biomedical healing, too, and forms a part of all people's experience of healing. For Southern Nguni, there is a ritual time and ritual place for healing to take place and the practices for these things are accepted as uniform, with little deviation ever experienced. The usual experience is that rituals in the biomedical world are completely alien to traditional people. For example, naturalistic illnesses are accompanied by pain and spiritual illnesses are often not accompanied by pain; this is a ritualistic understanding which clashes with the biomedical understanding. Once pain is absent, people begin to seek spiritual solutions and this takes them in a different direction to the way of biomedical healing. Regarding the ritualisation of time and place, and the manner in which medicines should be administered, clashes arise between traditional beliefs and biomedical practices. The issue of symbolism and ritualisation in the biomedical health system is disguised and watered down, but it is present. People have come up with different forms of rituals and symbols in relation to illness and health that calm their nerves and help establish a sense of control. An example can be made of people who believe in the power of injections rather than taking pills. Their belief would be that they will be healed more quickly with an injection. To them the needle has symbolic value; they believe it will bring about a speedier recovery than pills, which have to go through the whole process of being digested before they begin to work, and this process is un-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

seen, time consuming and mysterious. We also see an element of ritual when people are instructed to take medication at certain times of the day and in a certain sequence. This ritual means a lot to the doctors, but is not understood by the traditional patients. For example a patient could be told to take a pill three times a day – in the morning, noon and evening. But when a patient realises that she has forgotten the morning pill, she may decide to take two pills at noon to cover for the morning pill she forgot, without questioning the implications of the timing. For as much as there is a ritual time and place in traditional medicine there is also a ritual time and place in biomedical healing for them to work properly, and these ritual performances may clash, leading to a lot of mis-conceptualisations.

- Ritual actions are apparent too. When a person takes the traditional medicinal plants for *ukuhanjwa*, the face tightens up as a result of the taste, and this is an important factor, indicating that the bodily parts will do the same when the medicine begins to work (sympathetic magic). The same principle applies to the oozing of the black liquid from the wound of the participant who believed that this oozing symbolised the actual healing, the release of poisons, after the application of indigenous medicine prepared from the sweet potato leaves, which had been put into her by witches. The participants' interpretation was confirmed by complete healing that was achieved after a relatively short time. As a result of these experiences with traditional medicines, people could very well expect similarly dramatic and visible evidence of healing when they visit biomedical health centres. They are accustomed to strong tastes, visible evidence and a degree of discomfort when experiencing healing. Slow, steady, consistent and unseen processes negatively impact on the trust of traditional people on the efficacy of biomedical healing methods. In addition, traditional people do not attach a high significance to the ritual timing stipulated by biomedical health centres concerning the application of healing methods. This could be because they are too accustomed to their own ritual timing and spaces, to the extent that they may even apply their own traditional procedures when using biomedicine as an expression of cultural modernity (using modern medicines in a traditional manner, rendering them less effective than planned).
- Southern Nguni people link the source of the healing power to the spiritual power of God in the creation of the bitter, sharp taste of the medicinal plants as well as God's creation of the very strong smell of the medicinal plants used for healing *ukuhanjwa*. The taste and smell indicate God's spiritual power in the features of these plants. Most biomedical physicians, though they may have a personal belief in God, do not ascribe the healing power in plants to God's power and as indicated by Davis-Floyd (1990, p. 277) their view of the human body is mechanistic, viewing the human body as a machine that could be taken apart and put back together to ensure proper functioning.
- There is also the issue of belief in healing methods. To biomedical physicians, the trust they have is in the chemical composition of the medicine and the concept of the source of that strength has little meaning for them. Spirituality has not been significant within the biomedical health sector unlike in the traditional health sector – hence the clash of cultures when it comes to illness, health and medicine. If doctors placed more emphasis on gaining the trust of the patient, that trust would become for the patient the source of the healing power. How people speak about the doctor (his or her reputation), and how he or she handles people as well as his or her methods of healing have to do with the spiritual healing of the patient, and this impacts positively or negatively on the physical healing of the patient. They all contribute to the trust the patient places in the physician.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

> Once trust is placed in a physician, much power will be ascribed to his medicines and methods, and his healing methods will be believed to work. Thus relationship is everything; it establishes a foundation of loyalty and devotion, which will have great implications for how patients adhere to protocols. Such practices could in turn minimise misunderstandings and help establish a common ground for social change and development which would not leave one culture feeling inferior and another, superior.

FUTURE RESEARCH DIRECTIONS

Issues discussed in this chapter are some of the knowledge gaps which need to be filled in order for biomedical practitioners to understand their patients, and perhaps adapt their own practises so as to enjoy greater success in bringing about the health and social change they desire. It could be a matter of finding areas of convergence and divergence between current practice and some of the ideas proposed, so that social change and development may be brought about in a harmonious way. The chapter has certainly not addressed all the issues surrounding illness, health and medicine that are relevant to harmonious social development as the focus was delimited to one *abantu* or cultural illness which has kept the findings and conclusion fairly narrow. A call is extended to other researchers to conduct further research in areas of concern regarding the practice of health, healings and medicine as an attempt to minimise misunderstandings and help establish a common ground for social development which would not leave one culture feeling inferior and another, superior.

CONCLUSION

Belief in a spiritual world and its manifestations in health and illness are generally assumed, by those who hold political and economic power, to spring from less well-developed cultures. The manner in which people conceptualise illnesses and illness causations determined and still continues to determine how they deal with illness and disease. The various approaches are culturally embedded and have less to do with history and development than with enculturation resulting in resistance traditionalism as a manner in which people hold strongly to traditional healing methods despite living in an era of globalisation and rapid change. Traditionalists who still believe in the efficacy of traditional healing methods are found in urban and rural areas, amongst the poor and the elite people and are literate and illiterate – hence the pluralistic tendencies in help-seeking amongst all these categories of people.

The different responses of different cultural groups to issues of health could be what triggered the hegemonic tendencies in the biomedical health system, which is one amongst several cultural healing methods. Its hegemonic tendency is clear, and empowered by the support it receives from governments the world over (Baer, 2011, p. 417). It tends to label the dominated forms of healing as inferior as part of a strategy to effect complete domination and bring about social change. The forces of globalisation on illness, health and medicine, social and political processes are often cited as reasons for the hegemonic tendency of the biomedical health system.

The Southern Nguni contextual meaning of invisibility of *ukuhanjwa* to the biomedical health system, and their conviction that it is a spiritual attack leads them to insist on traditional healing methods for the illness. Where biomedicine is sought, it is used as part of a pluralistic healing approach. The strong belief

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in the efficacy of traditional healing methods for cultural illnesses such as *ukuhanjwa* appears to be as a result of the perceived source of their healing power. This belief and faith in the source of the healing power enables traditional healing methods for this illness to withstand every attempt by biomedicine to undermine and counteract it.

Power relations and discourses existing in the field of illnesses and medicine are usually prompted by the language factor as well as the fact that no cultural group would submit to being made to feel inferior. Hence the traditional people tend to resist allowing extinction of their cultural practices by being placed in the past as history. Occasional failures of biomedical health centres to heal some of the illnesses have created loopholes which are used as reference by traditional people to promote their traditional/ indigenous healing methods. Their interpretation is that biomedical health centres fail to heal such illnesses only because they are invisible to them and are cultural/*abantu* illnesses. All these are attempts by the traditional people to resist the hegemonic tendencies of the biomedical health system. On the other hand, the biomedical health system would insist that their hegemonic tendencies are for the good cause, meaning that of enhancing evolution of culture as well as bringing about social change for the betterment of human health conditions.

Absence of pain to the Southern Nguni people means illness resulting from acts of witchcraft. They generally cannot imagine any other illness which could be without pain other than cultural or *abantu* illness. In the study, the Southern Nguni people gave examples of illnesses they experienced without pain including *ukuhanjwa*. They could even differentiate between different types of cries whereby their contextual meaning of a weary cry was tiredness and the contextual meaning of a loud cry was pain. Hence they linked the weary cry of victims of *ukuhanjwa* with tiredness and not pain.

Although the South African government has lifted laws of apartheid against traditional healing, it seems as if the act is just on paper but not operational according to the desires of the traditional people who would like to see operationalisation of integrated health system encompassing both the traditional and biomedical health system. What seems to be working for now is the inclusive and tolerant health system whereby the biomedical health system remains favoured by the government and recognised as the official and authorised health system. On the other hand, traditional health system is openly used by the traditionalists but the system is still demeaning medical system to the traditionalists as the system keeps the traditional health care in its lower status. The manner in which the Southern Nguni people responded indicated that they prefer the integrated medical system as currently they are still using their traditional or indigenous healing methods secretly. This simply means that, although it is well known that Southern Nguni people use traditional or indigenous healing methods for some of their illnesses, they do not openly admit to such practice to the biomedical health workers and practitioners.

KEY TERMS AND DEFINITIONS

Abantu **Illnesses:** Spiritually caused illnesses which can only be healed using traditional healing methods.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cultural Modernity: Anything which is considered to be modern but still has traces of the culture of a particular group of people. This could be clothes, type of education, types of behaviour, etc.

Indigenised: Anything that is considered to be modern and is used in ways not foreseen by the manufacturer in order to suit the needs of the group of people who use it.

Indigenous: Anything that is endemic to a place or a group who use it in ways it was originally intended to be used.

Invisibility: The Southern Nguni contextual meaning of invisibility of *abantu* illnesses is means the inability of the outsider to link the symptoms of *abantu* illnesses to their causes as understood by the Southern Nguni people in order to be able to prescribe the correct healing method.

Pluralistic Healing Method: The use of traditional and biomedical healing approaches simultaneously or use of traditional healing approach in the beginning and at a later stage use of biomedical healing approach as a last resort or use of biomedical healing approach in the beginning and at a later stage use of traditional healing approach as a last resort.

Ritual Purification: Any method which is used to heal a spiritually-caused illness or cleanse a polluted person so as to prevent illness or misfortune. This cannot be equated with physical cleanliness.

Ritual: Religion in action whereby an act is done in a particular situation in a set precise manner which is the same each time it is performed for the relief of anxiety. The term has also been circularised whereby a ritual becomes any act that is regularly repeated in a set precise manner.

Traditional Medicine: Medicine that is based on theories, beliefs and experiences indigenous to different cultures used in the maintenance of health as well as in the prevention, improvement and treatment of physical and spiritual illnesses. Traditional medicine could be both indigenous and indigenised.

Traditional People: People who still strongly believe in traditional practices irrespective of their level of education (literate or illiterate), location (urban or rural), or status (rich or poor). These traditional practices could be purely indigenous, or indigenised.

Chapter 52
Kinect-Based Limb Rehabilitation Methods

Yongji Yang
Changchun University, China

Zhiguo Xiao

Furen Jiang
Changchun University, China

ABSTRACT

Within the context of health informatics, this article discusses how real-time information of human skeleton movements can be conveniently captured via the use of Kinect-based deep sensor. It highlights an effective action recognition method, using Unity3D to form virtual models of characters and scenes. Kinect somatosensory cameras can now identify one's motion data and provide feedback on the virtual role model to complete the avatar drive. This is to achieve real-time simulation modeling as well as drive operation instructions based on the design and identification verification to complement limb rehabilitation. The hardware of such a health informatics-related system is simple, inexpensive, and highly meaningful in term of augmenting user experience. In conclusion, the suggested approach can contribute significantly towards aiding physical rehabilitation therapy

1. INTRODUCTION

Traditionally, rehabilitation medicine entails the deployment of either man-assisted and/or robot-aided rehabilitation methods to enhance the physical functioning of individuals affected by illnesses or injuries with the goal of minimizing any preventable activity-related impairment. With a growing shortage of medical resources, the rising cost of specialty medical equipment, and its high maintenance costs, a call for new inexpensive means of rehabilitation medicine is highly advocated. One of these innovations is the design of intelligent human-computer interaction (HCI) within the emerging health informatics context.

HCI refers to the transmission of one's ideas to the computer through kinesics (such as gestures, postures, facial expressions, and more) as well as the computer recognition of human action and behavioral feedback. Using HCI to replace traditional rehabilitation methods can effectively resolve the cost and medical resource shortage challenges as it provides the patients with a convenient, inexpensive and effective rehabilitation system. Today, HCI is trending in current rehabilitation research. Yet, temporal variability and the complexity of human action is a key challenge in promoting action recognition. At present, the method of motion parameters collected by wearable sensors, gyroscopes, and accelerometers for the recognition of human body movement is accurate and highly effective (Maekawa, Yanagisawa, & Kishino, 2010; Cao, Cai, & Cheng, 2010), but the wearable sensor reduces the wearer's comfort. In term of visual recognition method, the current study draws on 2D visualization, with the effect often being highly influenced by environmental background, illumination, and occlusion factors.

With the emergence of inexpensive Kinect somatosensory cameras, new opportunities have arisen for action recognition researchers. With the aid of skeletal tracking technology to gather real-time data, these researchers can now collect non-contact 3D human skeleton information, which is hardly influenced by the background illumination. There is also direct use of data based on the key points of Kinect motion recognition method, a method to set the rule to identify joint action between the use of position angle, height and other mobile velocity, acceleration, and the like to define thresholds. Xie Liang et al. (2013), for example, obtained good recognition results by determining the specific posture based on the Euclidean distance and angle between the joints. Such a method is now widely applied due to its ease of use, but it displays low extensibility and a limited recognition in newly defined domains after each new action to be inserted. Another approach is to extract features, then select the appropriate classification for recognition. Raptis et al. (2011), for example, used Kinect to get bone information, transforming it to human angle features from the perspective of the human skeletal structure, which can achieve the classification of dance gesture recognition and the accuracy can be upward of 91.9%. Lai et al. (2012) transform the joints features into 2D features, and the nearest neighbor classifier is used to recognize the hand gesture, which can make the recognition rate to reach 92.25% under the condition of limiting the speed of movement. In this work, we propose using Kinect recognizing skeleton key information, by feature selection, focusing on the temporal and special problems of motion recognition to achieve flexibility, robustness, and high instantaneity. Such an approach can then be used for limb rehabilitation action identification; moreover, this same approach, by binding human skeleton information identified by Unity to the 3D animated character, allows users to practice limb rehabilitation training in a virtual 3D scene as schematically depicted in Figure 1.

Figure 1. Proposed Kinect-based Limb Rehabilitation Method

2. BACKGROUND

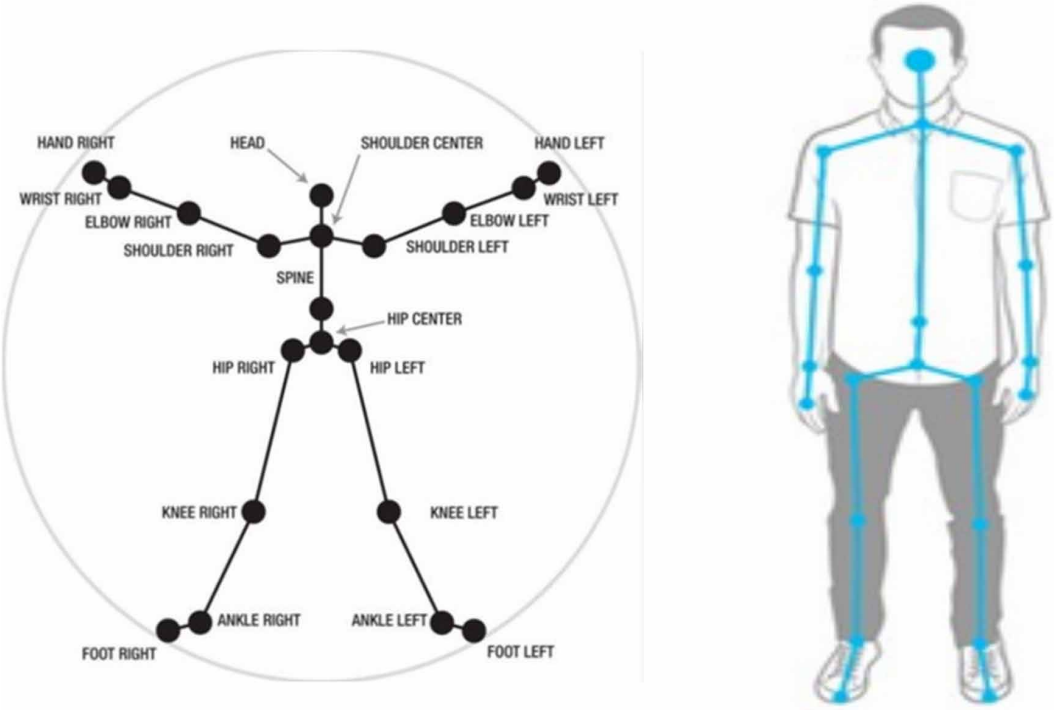
Kinect deep cameras can capture the colored image and deep image of the surrounding scene. In (Lin, Hsieh, & Lee, 2013), the data source used was real-time 3D information obtained from 20 individual body bone joints provided by the Kinect SDK application programming interface (API). Together, the captured information can fully represent a complete and effective body construction in a variety of postures. As shown in Figure 2, the distribution of human skeleton joints captured by Kinect cameras is a depiction of those bone joints that are the posture traits of the body postures. Later, we will discuss more about the matching algorithms for identifying those postures involved in the feature point position below.

Microsoft bone-tracking technology to capture via Kinect for configuring the location of main human joint points and tracking the deep image may be divided into the following three steps (Shotton, Fitzgibbon, Cook, 2013):

Step 1: Foreground Segmentation

Initial stage comprises the use of image-processing technology to achieve human foreground segmentation, which is, analyzing each pixel according to distance to see whether or not the captured image is part of a human body. Accordingly, relevant images of the human body parts are extracted from the depth of the image as a whole through the respective edges according to distance relationship.

Figure 2. The human bone joint points captured by Kinect



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 2: Body Parts Recognition

This stage involves identifying the various parts of the body from the body contours of the image area. Essentially, the step uses hundreds of TB meter training data obtained from Random Forest model for classifying parts of the body. This model can give each pixel a category label and probability value(s) to be associated with the different body parts (such as the head, shoulder, and so on with the entire human body divided specifically into 32 different parts).

Step 3: Joint Points Recognition

The pixels which belong to the same part are combined into one joint point, and the joint location is determined by the Mean Shift local model identification method based on the Gauss kernel function; more specifically, the primary task is to locate the human bone joints accurately from the front and side angles.

Based on the above three steps, researchers can get the bone image data. The current Kinect visual approach can recognize and locate 20 joint points, with 3D information of each joint point. This paper presents a set of real-time contrasting experiments based on Kinect skeleton-based pose identification method from the health informatics perspective as proposed by T. Y. Lin et al. (2013). In this work, a series of experiments, under the same conditions, has been carried out with the method described above and the average time of recognition of each kind of action posture is computed. Compared with the recognition method of TYLin, the average recognition time of each kind of action posture in this method is shorter with the average time for recognition of each action posture recorded as 41.3ms, and the average recognition time of the method being 33.8ms. Altogether, the experimental results show that the proposed method has better real-time performance.

3. ALGORITHM DESCRIPTION

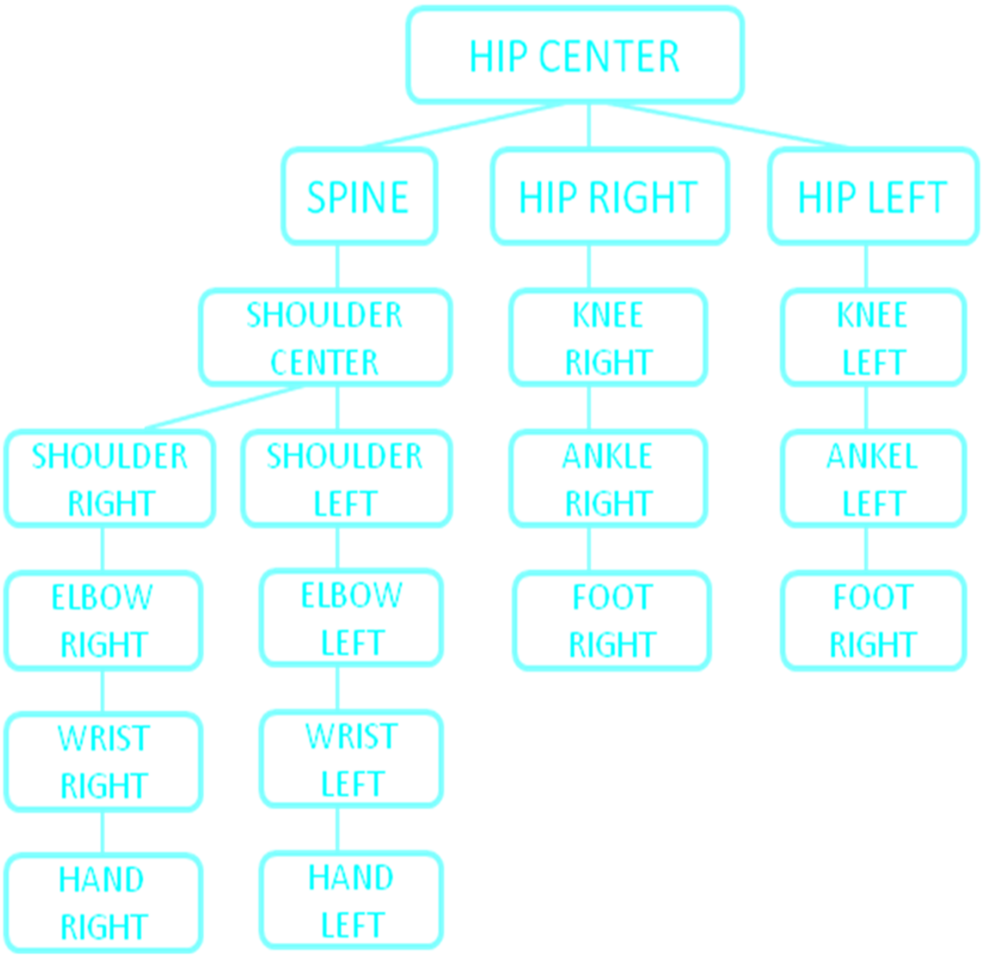
3.1 Skeletal Point Feature Extraction

In human action recognition, the expression of 3D skeletal point is commonly the three-dimensional position coordinates and the amount of rotation of the three axes. The 3D position coordinates are more sensitive in terms of users' size and height and often require additional normalization; moreover, the amount of rotation around the 3 axes is prone to universal lock (Gimble lock). In contrast, the rotation information of the skeletal point highlighted in this paper represents the skeletal point information in space. This is often expressed by quaternion (quaternion) which will effectively avoid the normalization and gimbal lock problems. To define the rotation information skeletal point, you must define the skeletal point coordinates. Here, the center point of the hip is considered the bone coordinate origin of the skeleton, which has no rotation angle. The adjacent bone points extend downward, stratified by about 20 bone points and are representative of the lower nodes. As shown in Figure 3, the adjacent skeletal points have been divided into "parent" nodes, which are the upper bone points versus the "child" nodes, which are the lower bone points.

For all skeletal points detected, we use a 4D vector (x, y, z, w) to describe the spatial information of the skeletal point where (x, y) refer to the skeletal point where the bone coordinate position is set corresponding to the skeletal point of the image location (x_m, y_m); thus, if the hip image position is (x_n, y_n), then $x = x_m - x_n$, $y = y_m - y_n$. Likewise, z is the skeleton point corresponding depth value, whereas w is for the skeletal point and its parent node vector forming an angle with the positive direction of the x-axis; so, if the parent node is skeletal point coordinates (x_1, y_1, z_1, w), then w by formula (1) is calculated as:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Hierarchical Diagram of Human Skeletal Point



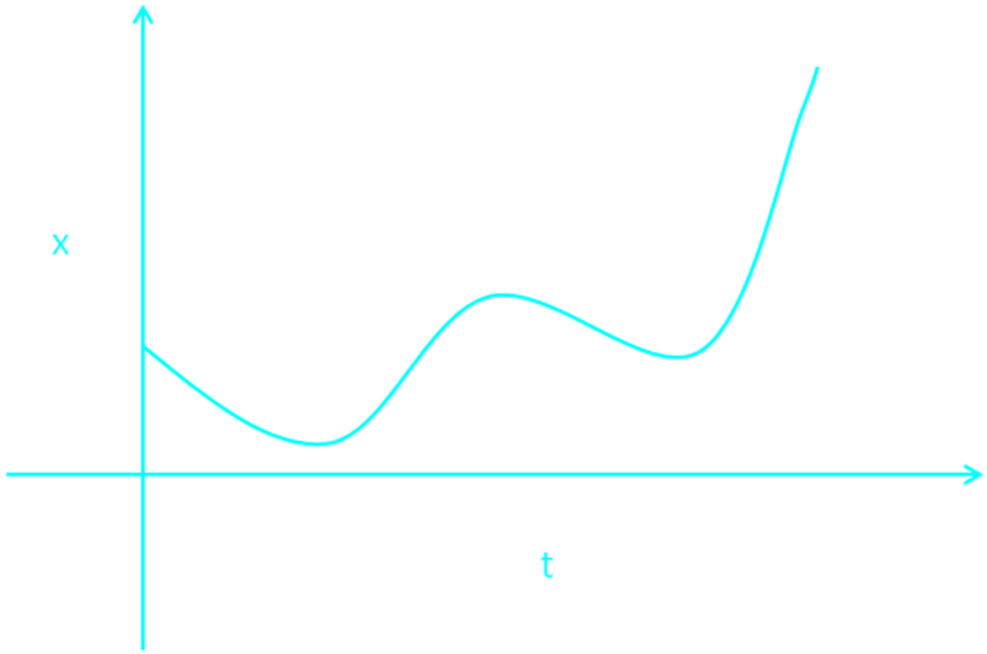
$$w = \arccos \frac{x}{\sqrt{(x_1 - x)^2 + (y_1 - y)^2 + (z_1 - z)^2}} \tag{1}$$

3.2. Weak Classifier Training

The most essential technology in using Kinect to carry out limb rehabilitation training in the health informatics context is to determine whether the body movements are correct and standardized. Hence, the dynamic recognition of human actions needs to be examined closely alongside the changes of skeleton data in a row. Experimental results show that certain action of a skeletal point may be represented as a weak classifier for physical rehabilitation recognition since computation of the parameter of any such skeletal point must follow certain rules. Figure 4 shows changes of x coordinate values when a skeletal point is doing an action. Although the speed of Kinect capturing images is up to 30 frames/s, the changes of the body movement are generally continuous that will not change within a short period of time, and therefore the performance operating characteristics can be fully displayed with 1/s intervals value evalua-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Graph of the x component of the skeletal point over time



tion. Our experiment uses 20s as a period; thus, such a weak classifier characteristic is a 20-dimensional vector. As this features the combination of time segment, it is called space-featured vectors. Given that a skeleton has 20 bone points, each bone point has four parameters, then we can possibly have 80 weak classifiers to fulfill the training.

For categorizing each of the weak classifier, we use SVM (Amami, AyedD, 2013; Yang, Kim, & Park, 2012) to train so as to derive the classification function of each weak classifier. The micro-steps involved are as follows:

1. Define the spatial and temporal characteristics vector set x. A space-time vector set comprises a temporal feature vector information for all skeletal point; that is, a space-time vector set contains 80 20-dimensional vectors, with a time span 20 s, i.e., $x = \{x_1, x_2, ..., x_{80}\}$, each vector xi represents a vector space-time coordinates of a bone point.
2. Take the *nth* currently-to-be-trained recognition action A as temporal and spatial motion vector set, then once again take the *nth* other various types of actions as space-time motion vector set.
3. Train each space-time vector SVM, you can get a total of 80 decision-making functions, thus identify every time and space vector.

After the above training, you will get access to the spatial and temporal characteristics of the vector (Ye, 2014) weak classifiers.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.3. Action Feature Set & Achieving a Strong Classifier

SVM classifier can make classifications of the newly input samples trained by each space-time vectors, but classification accuracy typically cannot meet the demand; hence, using AdaBoost algorithm, weak classifiers can be combined into a strong classifier which can greatly enhance recognition rate (Yim, & Lea, 2014; Chao, Xilu, & Su, 2016). The specific training process is detailed as below:

(1) Getting the training sample

For some action A, we obtain a total of 2n of a series of space-time sample set (x_1, y_1), (x_2, y_2) ... (x_{2n}, y_{2n}), and *nth* samples positive and *nth* samples negative, wherein $y_i \in \{0,1\}$, $y_i = 1$ shows a sample xi which belongs to the action A, negative sample.

(2) Circuit train all groups

$$w_i = 1 / 2n \quad i = 1,2, ..., 2n \tag{2}$$

1. initialized weights w_1, $x = w_x$ where w_1,x is initialized right of the first round of training weights.

For t = 1: T, where T represents a total training of T rounds, t is the current training round number.

2. weight renormalization

$$q_{t,i} = \frac{w_{t,i}}{\sum_{y=1}^{2n} w_{t,y}} \tag{3}$$

where, $q_{t,i}$ is the normalized weights.

3. Each temporal sample set includes 80 spatial and temporal feature vectors, set the *mth* eigenvector to identify, m = 1,2, ..., 80. Since having obtained the corresponding spatial and temporal characteristics of SVM classifier, it is possible to calculate the *mth* feature vectors recognition rate in this group of training samples, wherein the *mth* weighted error rate.

$$\varepsilon_{\int}^{m} = \sum_{i} \left(q_t, h\left(d\right)_{t,i} \right) \tag{4}$$

In formula (4), h (d) t,i is judging result of the *mth* characteristic in Sample i, if it is judged correctly, then $h(d)_{t,i}=0$, if judged wrongly, then $h(d)_{t,i}=1$. Repeat step iii, you can get all the spatial and temporal characteristics of the weighted error rate of *m*.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Select the lowest round of the weighted error vector of the spatial and temporal characteristics.

$$\varepsilon_t = \min\left(\varepsilon_{\int}^1, \varepsilon_{\int}^2, ...\varepsilon_{\int}^m\right) \tag{5}$$

5. Adjust the weight of each group according to vector results:

$$w_{t+1,i} = w_{t,i}\beta_t^{1-e_i} \tag{6}$$

In the above formula, $e_i = 0$ indicates that this group is a correct identification whereas $e_i = 0$ indicates that this group is misclassified, and $\beta_t = \frac{\varepsilon_t}{1-\varepsilon_t}$.

(3) Get a strong classifier

After training of T rounds, a total of T spatial and temporal characteristics obtained as the final classification features, the last strong classifier can then be calculated according to formula (7).

$$C(x) = \begin{cases} 1 & \sum_{t=1}^{T}\alpha_t h_t(x) \geq s\sum_{t=1}^{T}\alpha_t \\ 0 & other \end{cases} \tag{7}$$

Wherein, $h_t(x)$ is the judging result of the *tth* space-time vector of the input actions recorded which is regarded $h_t(x)=0$; s is less than coordinate 1. If it is closer to 1, the recognition-erroneous rate will be reduced; meanwhile, the recognition rate will gradually increase as well as the erroneous rate, and generally the most suitable s is $s = 1/2$.

3.4. The Body Posture Optimization

When Kinect interacts with humans, its infrared sensors need to track every part of the body. In order to achieve higher recognition accuracy, this method requires the users to face the equipment without being blocked. Once obscured, the Kinect system will fail to track the joint points accurately, leading to poor judgments on some parts of the human body. To avoid serious distortion, a good Kinect application not only requires equipment to have clear recognition effect not interrupted by any noise, but can still achieve high recognition accuracy under obscure and noisy environment. In light of this, the authors hereby propose a human bone reconstruction method based on reliability assessment, which can rebuild the defective skeleton pose by means of reliability evaluation and motion database. Several steps are involved: first, the reliability after getting the user's skeleton movement value is calculated and subject is placed as the weight, then similar posture in motion database is extracted. Following this, a natural position space in combination with principal component analysis to satisfy the kinematic constraints is built to finally synthetize natural accurate skeleton measurements. Experimental results show that, when obscured with different degrees, bone reconstruction method based on reliability assessment can still reconstruct movement skeleton of comparatively high quality.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Skeleton reconstruction method is composed mainly of skeleton acquisition, movement reliability assessment, and the building of natural posture space by the use of database structure, skeleton synthesis, and more. Among these, the movement reliability assessment is the most important. Reliability evaluation refers to the objective evaluation of the following three aspects, more specifically, the stability and reliability of the various parts of our body skeleton including:

(1) Behavior reliability
(2) Skeleton reliability
(3) Tracking reliability

- Behavior reliability

Behavior reliability refers to the correctness of the action behavior. When a user's body parts are blocked, the depth image captured by Kinect will mark as if it is impossible to get the accurate location of one's body parts. Due to the lack of the expected target features, positions identified by the method without reliability evaluation are very much unstable (Ji, & Duanyuan, 2016; Zhou, 2015). Therefore, the method should at first weigh the reliability of the user behavior.

Assuming that pi(f), pi(f+1), pi(f+2) are the three consecutive frames tracked body part in 3D space, so, the calculating formula for the displacement is

$$d_i(f) = P_i(f+1) - P_i(f) \tag{8}$$

$$d_i(f+1) = P_i(f+2) - P_i(f+1) \tag{9}$$

The Angle between two vectors can be calculated by the dot product:

$$\theta_i(f) = \begin{cases} \dfrac{d_i(f)d_i(f+1)}{\left|d_i(f)d_i(f+1)\right|} & \left|d_i(f)\right| > d_{\min} \cup \left|d_i(f+1)\right| > d_{\min} \\ 0 \end{cases} \tag{10}$$

The d_{min} is the minimum of the acceptable displacement, when body parts are basically stable, there will not be a big angle change.

Human behavior can be seen as a series of motion sequence. Here, behavior reliability may be defined as:

$$Rb_i(f) = 1 - \frac{\max\left(\min\left(\dfrac{\sum_{f=0}^{f_b}\theta_i(f)}{f_b}, \theta_r\right) - \theta_f, 0\right)}{\theta_r - \theta_f} \tag{11}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Among them, $Rb_i(f) \in [0,1]$, when f_b, the total number of motion frames is detected, θ_f is the smallest rotation angle, θ_r is the smallest unacceptable angle of each frame, repeated experiments show that, when the fb = 3 $\theta_f = 90°$; $\theta_r = 135°$, the effect is better.

- Skeleton reliability

Skeleton reliability refers to the correctness of the skeleton position. When Kinect captures body postures, the user's skeleton size is different from one user to another. Defining two positions for reference, one is T pose, and the other is the standard standing posture. According to the skeleton structure, each part can be connected to many other parts of the body. Assuming that the body parts I were connected to a St of other parts, then for each connection section of s, in the first frame differences f rate can be calculated as follows:

$$d_s(f) = \min\left(\left|l_s\left(f\right) - l_c\right| \Big/ l_c, 1\right) \tag{12}$$

l_c is the length of the related frame part, $l_s(f)$ is the current length of the first frame f s period of skeleton.

Motion reliability is the average period of different proportions all connected, and is defined as:

$$Rk_i(f) = 1 - \sum_{s=0}^{s_t} d_s(f) \Big/ s_t \tag{13}$$

In which, $Rk_i(f) \in [0,1]$.

- Tracking reliability

Tracking reliability refers to whether or not the equipment can trace the body part of the user, as defined by:

$$Rt_i = \begin{cases} 1.0 & \text{Be traced} \\ 0.0 & \text{Not traced} \end{cases} \tag{14}$$

Obtaining the reliability of behavior, skeleton and the state of tracking by the above assessment, the reliability of different body parts can be defined as:

$$R_t = \sum_{f=0}^{f_{total}} \omega(f) \times \min\left(Rb_i(f), R_i\right) \tag{15}$$

In which, $R_i \in [0,1]$, f_{total} is the total number of frames, $\omega(f)$ is f frame gaussian weighting, $Rb_t(f)$, $Rk_t(f)$, $Rt_t(f)$ respectively refers to reliability, motion reliability and tracking reliability. When the body part is not being tracked, it will extract the adjacent frames and reliable data for reconstruction, thereby improving the precision of the identification.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

A natural position space needs to be built for human posture reconstruction, which needs a database also to be built. Database building can use the traditional optical system to capture the right sports movements. In addition to the improvement of the operating efficiency, it can also control the density of the sample position space. The movement database in this paper is from Cameron university (CMU) graphics laboratory. Motion data formats are: ASF - AMC, HTR, BVH, etc. The ASF-AMC data formats are applied here, which can further modify the motion data and bone model as part of additional contributions of the present study.

3.5. Action Identification and Analysis

As a starting point of discussion, we select here five representative body movements from those common actions of the body rehabilitation for experimental research, for example, the right arm lifting, upper limb external rotation, the right leg flat lifting, the right leg side lifting, and squatting. The strong classifier obtained from training is binary classification problems. In order to identify the five different actions, the authors collected 3000 bone data for each bone movement when collecting samples, took 30 consecutive frames of each movement of the bone data as action positive samples whereas other actions as negative samples of this action. Altogether, we now have 100 positive samples obtained for every movement, plus 400 negative samples. The conclusion is that the classifier can distinguish five different actions.

Here, our experimental testing samples are the skeletal human data collected from five persons of different height and size. 6,000 bone data are collected from a single action, which constitutes 200 sample sets, with a total of 1,000 action samples collected. During sample identification, based on the action feature set, sample data are divided by five strong classifiers, whose results are identified and released. If the output of two or more strong classifiers is 1, this means that the sample cannot be identified. The outputs and recognition accuracy of 1000 samples are shown in Table 1.

In order to improve recognition accuracy, the authors correspondingly combine the aforementioned five strong classifiers. A 5-bit binary numbers are used to represent actions. From left to right, they are right arm lifting, upper limb external rotation, right leg flat lifting, right leg side lifting, and squatting. The corresponding bit 1 indicates that the corresponding strong classifier identifies the action, for example, a binary number 01000 represents recognition of the action—the right arm lifting. Overcoming

Table 1. Recognition rate of the first five actions combined

Action	Output the right arm lifting	Output upper limb external rotation	Output the right leg flat lifting	Output the right leg side lifting	Output squatting	Recognition failure	Accuracy rate
the right arm lifting	175	15				10	87.5%
upper limb external rotation	10	172				18	86%
the right leg flat lifting			175	10		15	87.5%
the right leg side lifting			8	178		14	89%
squatting					156	44	78%

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the emergence of the first digit or more than five digits is 1 which will result in recognition failure, we propose action recognizing intensity of the strong classifier P, which holds strong classifier detection rate before P represents a strong classifier training; as such, the higher the detection rate, the greater P is. For example, the binary number 00110, $P_3 > P_4$ indicates the recognition of the action of the right leg flat lifting, otherwise it means recognition of the action of the right leg side lifting. Because the strong classifiers are a few good-weighted weak classifiers intensified, larger action recognition intensity P indicates the weak classifier corresponding to strong classifier identifying the actions or larger weights actions. So, the recognition accuracy of these strong classifiers compared to that intensity of P, is much higher. Experimental results show that the combination, compared with the previous one, has greatly improved action recognition rate. The recognition results of the five combined actions are shown in Table 2.

Compared with Table 1, the recognition accuracy rate of the five kinds of actions in Table 2 has greatly been improved, indicating that the method for identifying human action is very effective. Wherein the recognition rate for the static actions, say, the right arm lifting, squatting, is relatively high because the characteristics of static action is fixed, action characteristic curve is small. The training feature set can recognize this action very well and action recognition efforts can well exclude similar static action interference. As for dynamic movements, say, the recognition rate for upper limb external rotation is relatively low because when the same person or different people do the same action, the rate will be different and the action characteristic curve length will be different. The action characteristic curve length adopted in training and recognition in the present paper is one with a fixed length, and the recognition rate is vulnerable to stretching or compressing of the action characteristic curve length.

Our discussion on the sample training and the identifications of body movements is based on the Adaboost algorithm. Compared with other methodologies, the present methodology puts forward temporal and spatial classification features and uses SVM algorithm to get weak classifiers selecting human action set depending on different human action features, which is simple to achieve and of high operating efficiency. Experimental results show that this method has a high recognition rate. Human skeleton data herein is obtained by Kinect deep sensor. Kinect deep sensor can overcome the influence of light and other environmental factors with relatively low pricing and suitability for human action identification. The use of bone rotation information for action recognition, showing a valid point and the position of the bone change over the bone can provide more data for the physical rehabilitation and action recog-

Table 2. Recognition rate of five combined actions

Action	Output the right arm lifting	Output upper limb external rotation	Output the right leg flat lifting	Output the right leg side lifting	Output squatting	Recognition failure	Accuracy rate
the right arm lifting	192	3				4	96%
upper limb external rotation	4	188				8	94%
the right leg flat lifting			191	4		5	95.5%
the right leg side lifting			3	193		4	96.5%
squatting					194	6	97%

nition which can effectively avoid the normalization and gimbal lock problems and can improve the recognition rate of movements, especially the distinction and recognition between two similar actions. Many difficulties are also encountered during the identification process, such as the selection of action characteristic curve length, and the calculation of curve similarity. Here, we successfully resolved all the above-mentioned problems through demonstrated research and experiments.

4. KINECT-BASED AND 3D VIRTUAL SIMULATION LIMB REHABILITATION TRAINING

Many defects exist in traditional rehabilitation. The introduction of virtual reality (VR), which in addition to real experience and way of thinking, brings the patients into the virtual realm as a complete individual. In such an environment, the patient's visual, auditory and tactile senses can all be fully capitalized. Compared with conventional treatments, VR technology can provide a more realistic, more systematic and natural environment, aside from improved scientific training intensity and more meaningful assessments for patients.

There is many software of 3D environment visualization technology. With the birth of Kinect somatosensory deep cameras, Kinect 3D plug-in software subsequently emerged. Kinect in health informatics context can capture real-time characteristics of the human skeleton, the characters and 3D animated characters are bound to achieve high level human-computer interactions (HCIs). Kinect-Unity-interactive KinectForWindows2.0_Unity.unitypackage plug–in software, the official plug-in of Unity, which can be simply deployed for limb rehabilitation in 3D scenes.

System design is divided into Unity3D scene display module, Unity3D interface module and Kinect data acquisition module. The scene module function can realize the character model to change with the human body captured by the lens. Model binding effect is shown in Figure 5.

As can be seen, the software application allows the setting of a character in the scene, making a character in 3DMax, as well as attaching a character bone, binding in Unity3D, and adjusting the light and sky. Using Unity3D interface modules, the post-Tim script, corresponding with the properties of the front Unity3D, one can achieve bone binding, mirror movement, close-range mode, smoothing and so forth. Additionally, the scene module function can realize the character model to change with the human body captured by the lens. Body parts' binding facilitates the skeleton data acquisition in the Unity3D scene. Many groups of bones are used to represent the various bone nodes in the scene to complete the mapping function of the bones. In transforming the skeletal visualization, we use the four-element approach.

The four-element approach is simply hyper-complex. Four elements are composed of real numbers and linear combinations of *i, j, k*, yielding the formula as follows:

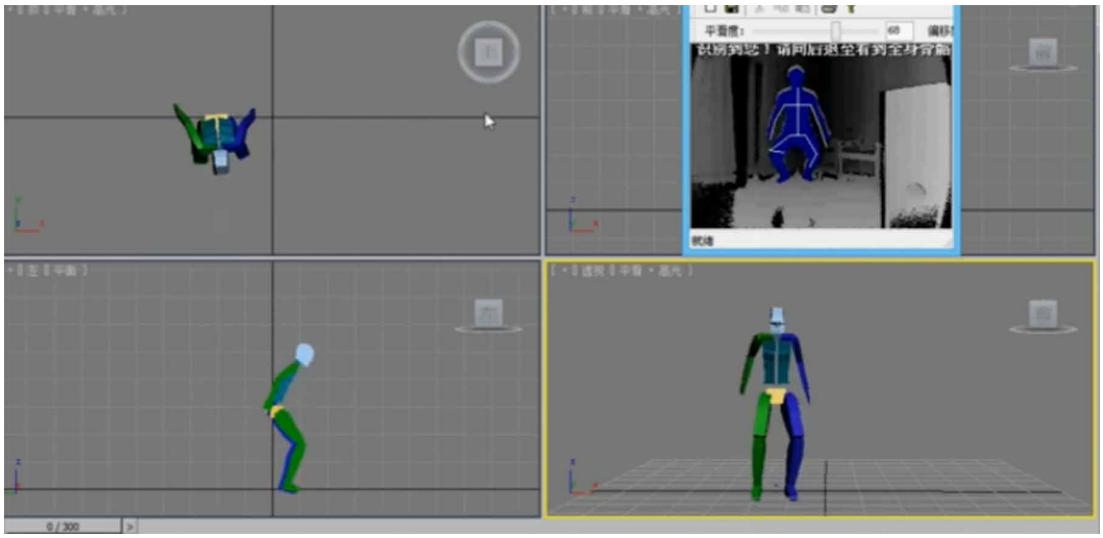
$$i_2 = j_2 = k_2 = -1 \tag{16}$$

$$a + b_i + c_j + d_k = 0 \tag{17}$$

In the computation of the rotation angle, it is worth noting that the four-element Quaternion is used. Quaternion variables are relatively small. Let *x, y, z, w* take values on [-1,1]. The object rotates for two weeks and all its values return to the initial value. The initial value: (0,0,0,1), if it rotates along the y-axis of 180 °, 360 °, 540 °, 720 °, the value taken corresponding to the angle is (0,1,0,0),(0,0,0,-1),(0,-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Human model binding effect



1,0,0),(0,0,0,1); if it rotates along the x-axis of 180°, 360°, 540°, 720°, the value taken corresponding to the angle is (-1,0,0,0), (0,0,0,-1), (1,0,0,0), (0,0,0,1).

No rotation is written by Quaternion. Identify in this way, the bone binding, self-mapping and bone rotation can be achieved.

Kinect data are divided into three parts: device control, bone binding, device image acquisition. The control of the device is mainly reflected in: device starting and initialization, camera angle adjustment, device turning off. Smoothing facilitates free bone rotation, prevents skipped and teleported effects, and is implemented in the bone rotation algorithm.

The final procedure is the test of each module. Limb recognition is the identification of human limbs by mathematical algorithm. Movement identification can be from various parts of the human body, but usually refers to the movement of the head and limbs. You can use Kinect to collect the depth image to do segmentation, confine the range of depth and extract the image within the range. This way of achieving body recognition, as well as recognition speed and accuracy has been greatly improved versus that of the conventional identification methods.

As depicted in Figure 6, here are two games for limb rehabilitation training based on Kinect somatosensory technology and 3D scene technology.

After the scientific research of Kinect-based rehabilitation system, we focus on a comparative survey of the research results and the ways of traditional limb rehabilitation of patients. The investigation results are shown in Table 3:

From the survey results, it is apparent that the limb rehabilitation training method based on Kinect and 3D virtual simulation technology is significantly more efficient than the traditional methods of limb rehabilitation in time use efficiency, training improvements and fun.

improvement of doctor-patient communicative competence	17(85)	3(15)	8(40)	12(60)
preference for this limb rehabilitation	17(85)	3(15)	9(45)	11(55)

5. CONCLUSION

Traditional rehabilitation needs to be carried out in a formal clinical setting such as hospitals. Doctors are basically needed to train patients face-to-face with serious movement disorders.

In contrast, this work proposes a series of upper limb rehabilitation training methods and systems based on Kinect within the emerging health informatics context. It first gathers standardized training actions of doctors, establishes the standard rehabilitation action database, and then identifies and matches exercise postures through joint points and bone data with the help of Kinect equipment. In this context, patients are empowered and can be asked to do the appropriate rehabilitation exercises according to different symptoms, which can be done at home only with the help of inexpensive computer, and other relevant display devices. Such innovations will greatly reduce the workload of doctors.

As well, the exercise interests of the patients trained in the 3D virtual scene can be greatly improved. Doctors can assess the effect of rehabilitation by matching the exercise data of the rehabilitation coach and rehabilitation patients to improve the efficiency and accuracy of the identification operation by AdaBoost algorithm. Experiments show that the model principle is practical, with the platform having commercial value.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In summary, many attempts of Kinect exercise rehabilitation, due to the limitations of Kinect equipment, have been quite limited to date. Oftentimes, there exists error range in skeleton measuring to make the existing skeleton tracking technology incapable in term of expressing human actions, especially human complex continuous actions. Accordingly, in light of advances in health informatics, it is now possible to improve the tracking accuracy of Kinect human skeleton and the algorithm of motion recognition, so as to provide better and more natural human-computer interactions.

ABSTRACT

Ontologies are used to represent knowledge and they have become very important in the Semantic Web era. Ontologies evolve continuously during their life cycle to adapt to new requirements and needs, especially in the biomedical field, where the number of ontologies and their complexity have increased during the last years. On the other hand, a vast amount of clinical knowledge resides in natural language texts. For these reasons, building and maintaining biomedical ontologies from natural language texts is a relevant and challenging issue. In order to provide a general solution and to minimize the experts' participation during the ontology enriching process, a methodology for extracting terms and relations from natural language texts is proposed in this work. This framework is based on linguistic and statistical methods and semantic role labeling technologies, having been validated in the domain of diabetes, where they have obtained encouraging results with an F-measure of 82.1% and 79.9% for concepts and relations, respectively.

INTRODUCTION

In the biomedical context, where the generation of new knowledge is continuous, ontologies have raised interest in the entire biomedical community (Rubin, Shah, & Noy, 2008). Ontologies are used for organizing and sharing biological knowledge as well as integrating different sources of knowledge in order to provide interoperability among different research communities. For example, MEDLINE system, which is based on the MESH medical ontology, is the largest medical knowledge base available over the Internet. Due to the fact that in medical domain new terms are continually emerging, the update and extension of MESH is necessary to avoid its obsolescence. In the last years, ontologies have been applied to several areas such as natural language processing (Paredes-Valverde, Valencia-García, Rodríguez-García, Colomo-Palacios, & Alor-Hernández, 2015), sentiment analysis (Salas-Zárate, Valencia-García, Ruiz-Martínez, & Colomo-Palacios, 2016), bioinformatics (Mayor & Robinson, 2014), business intelligence (Rodríguez-García et al., 2016), recommender systems (Colombo-Mendoza, Valencia-García, Rodríguez-González, Alor-Hernández, & Samper-Zapater, 2015), and cloud computing (Rodríguez-García, Valencia-García, García-Sánchez, & Samper-Zapater, 2014a) (Rodríguez-García, Valencia-García, García-Sánchez, & Samper-Zapater, 2014b), to mention a few.

Nevertheless, building and maintaining long-living ontologies is still a challenge for the scientific community, which requires a considerable human effort and development time. An ontology lifecycle includes several phases such as creation, maintenance, evaluation, consistency checking, etc. and there are several ongoing attempts to address these issues by providing automatic ontology management methods (Petrucci, Ghidini, & Rospocher, 2016). Among them, several ontology learning and ontology evolution methods have been developed.

Ontology learning has been an active research area that has grown according to the needs of creating ontologies in a fast and reliable way. Ontology Learning (also named ontology generation or ontology extraction) is a knowledge acquisition activity that relies on (semi-) automatic methods to transform unstructured (e.g. corpora), semi-structured (e.g. folksonomies, html pages, etc.) and structured data sources (e.g. databases) into conceptual structures (Petrucci et al., 2016).

On the other hand, ontology evolution (also named ontology enrichment) can be seen as the activity of enriching ontologies by adding or modifying concepts and relations. More specifically, in (Stojanovic, Maedche, Motik, & Stojanovic, 2002) ontology evolution is defined as the timely adaptation of an ontology to modified business requirements, to trends in ontology instances and patterns of usage of the ontology-based application, as well as the consistent management/propagation of these change to dependent elements.

Ontology evolution is considered a process due to the fact that a change in the ontology can cause inconsistencies in other parts of the ontology, as well as in other dependent applications (Abcckcr & Stojanovic, 2005), for that reason, the process of ontology evolution contemplates some tasks such as for example resolving the ontology changes, ensuring the consistency of the underlying ontology and facilitating the changes and management of the ontology to the user (Stojanovic et al., 2002).

This paper focuses on the tasks of extracting terms and semantic relationships from natural language texts in order to simplify the process of building and updating the concepts and relationships in biomedical ontologies. The proposed framework is based on linguistic and statistical term extraction methods and semantic role labeling technologies, having been validated in the diabetes domain. Many biomedical ontologies are structurally quite simple, since they consist of only a few relationship types apart from the taxonomical relationship that constitute the backbone of an ontology. One of the main contributions of this paper is the provision of a method for increasing the typology of semantic relationships.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The structure of this paper is described as it follows. In section 2, a summary of the most important ontology learning approaches is explained. Then, in Section 3 the ontology evolution approach is described in detail. Next, in Section 4 an experiment and its results are shown. Finally, some conclusions and future work are put forward in the last section.

RELATED WORK

In the last years, several approaches and tools have been proposed to address the ontology learning and ontology evolution topics. The main advances in the ontology learning are to find and identify ontology elements such as concepts, instances, relations. These elements are mainly identified semi or automatically through approaches based on Natural Language Processing (Sinha, Garg, & Chandra, 2016) (de Azevedo et al., 2014), pattern recognition (Chen, Chen, Leong, & Jiang, 2013), and data mining (Guo, Schwartz, Burstein, & Linger, 2015), among others.

Significant approaches for Ontology learning have arisen from Ontology evolution, which are focused mainly on the management of the evolution process, and versioning comparison. For example, in (Maedche, Motik, Stojanovic, Studer, & Volz, 2002) one of the first methodologies for integral ontology evolution is proposed. Their approach is based on six-phase evolution process, which analyses the causes and the consequences of the changes and ensures the consistency of the ontology and depending artifacts after resolving these changes. This approach was implemented in the KAON ontology management system. Other approach is (Klein, Fensel, Kiryakov, & Ognyanoff, 2002) which affords the topic of ontology versioning for web-based ontologies. The system is based on the comparison of RDF-based ontologies in three different dimensions, meta-data, conceptual relations and transformations between the ontologies themselves. The integration of different ontologies is also afforded in OnEX (Hartung, Kirsten, Gross, & Rahm, 2009). It uses existing ontology versions and identifies the differences between them in order to integrate different versions of the same ontology. The evolution mapping consists of adding, deleting and updating, concepts, relations, and attributes from the last version of the ontology. In (Gil & Martin-Bautista, 2014) they introduce a Systematic Methodology for Ontology Learning (SMOL) from heterogeneous sources through seven phases (Methodology strategy selection, knowledge discovery, query requirements, knowledge selection, knowledge structure construction, knowledge exploration and search, and knowledge structure reorganization) over structured flow. In addition, modification and versioning have been considered for the workflow design of SMOL. Finally, aiming to validate the SMOL methodology an academic case study was carried out. Meanwhile, in (Dinh, Reis, Pruski, Silveira, & Reynaud-Delaître, 2014) a method to recognize the change of patterns between ontology versions is proposed. In order to evaluate the effectiveness of their proposed method, the authors carried out experiments by using several versions of biomedical ontologies, namely SNOMED-CT (SCT), MeSH and ICD-9-CM (ICD9).

However, few studies deal with the automatic evolution of ontologies from texts. For example, in (Zablith, Sabou, d'Aquin, & Motta, 2009) presented the Evolva framework. The authors propose an approach that tries to solve two functionalities, the adaptation of ontologies and change management. Meanwhile, the study presented in (Ottens, Hernandez, Gleizes, & Aussenac-Gilles, 2009), proposed the Dynamo (Dynamic ontologies) tool which used an adaptive multi-agent system to represent the ontology itself and to produce the ontology. In order to evaluate the quality of a taxonomy built with Dynamo, the authors considered a reference taxonomy constructed from a corpus named Astro. The

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

corpus consists of a collection of more than 3000 summaries of scientific articles published in 1995 and 2002 in the journal "Astronomy & Astrophysics". More recently the authors have proposed an improved version named Dynamo MAS (Sellami, Camps, & Aussenac-Gilles, 2013). This tool is based on an adaptive multi-agent system (adaptive MAS or AMAS) that allows building and to evolve ontologies from the text. Lexico-syntactic patterns were used to extract lexical relations between terms. Also, the authors carried out several experiments to evaluate the quality of the system on three corpora, namely Artal (287 bug report documents), Arkeotek (299 rule-based formulation of scientific papers), and Actia (documents that report fault descriptions and repair procedures). Final results showed that the quality of Dynamo-MAS depends on the corpus and initial state of the ontology. In (Benomrane, Sellami, & Ben Ayed, 2016), OntoAMAS, an ontologist feedback tool based on an adaptive multi-agent system (adaptative MAS or AMAS) is presented. OntoAMAS consists of four modules: 1) addition of new documents, 2) extraction and filtering of terms, 3) knowledge interpretation, ontology update, and 4) ontologist interventions. Aiming to evaluate the feasibility of their approach, a set of experiments were carried out, obtaining encouraging results.

Unlike these systems, our proposal is not based on the integration of different versions of the same ontology, but in the acquisition of new concepts and relationships from textual sources. Any seed ontology from the domain under question can be updated and expanded using as input the textual resources available into the scientific literature repositories.

ONTOLOGY EVOLUTION PROCESS

In this work, an ontology is seen as a formal and explicit specification of a shared conceptualisation (Studer, Benjamins, & Fensel, 1998). The Web Ontology Language (OWL) has been used to model the biomedical ontologies to be evolved from natural language texts. In OWL, the following main ontological entities can be distinguished: classes, subclass of relationships, datatype properties (attributes), object properties (relationships), and individuals. OWL provides a formal theory for taxonomy, whereas any other semantic relationship, like partonomy or topology, must be manually defined and implemented using object properties for that.

Our ontology evolution approach deals with the addition and removal of concepts and relationships from a domain ontology. These ontology entities (concepts and relationships) are obtained from natural language texts through two main subprocesses (i) the term extraction process and (ii) the relation extraction process. Once the relevant elements are obtained, the ontology is expanded or modified by using (iii) the ontology evolution module. The main premise of any ontology evolution approach is that the ontology remains consistent after applying a change. In this approach, the consistency of the ontology is checked after each change using and OWL2 reasoner.

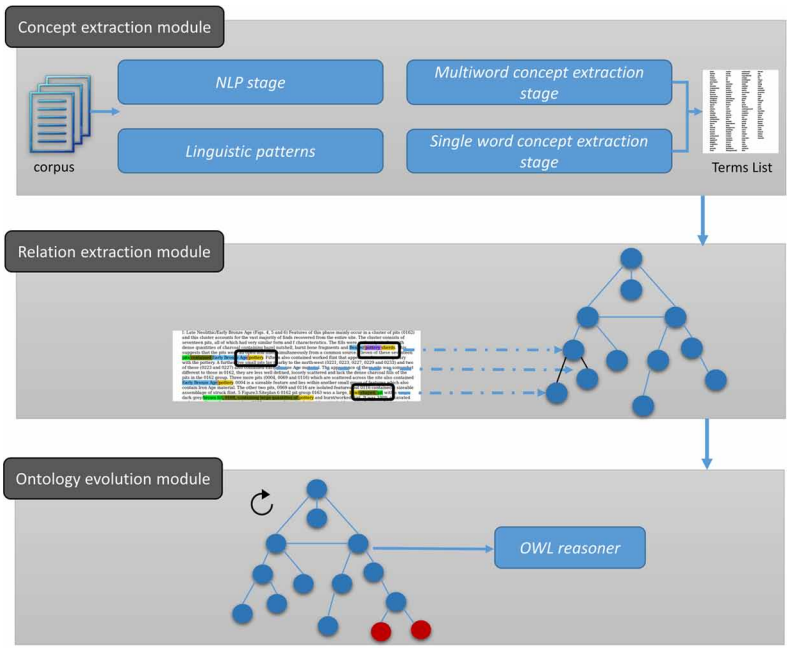
Next, in Figure 1 the main modules of the architecture are described in detail.

Concept Extraction Module

First of all, terms representing concepts are identified. Automatic term recognition denotes the process used to systematically extract pertinent terms and their variants from a collection of documents (Ananiadou & McNaught, 2006). It is assumed that there exist both multiword and single word terms. By taking into account this assumption, two different methods have been implemented: the NC-Value

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. System architecture



algorithm, which allows obtaining the multiword terms candidates to represent concepts, and TF-IDF which has been employed to obtain terms formed by one word. This process can be decomposed into several phases as it is described below.

NLP Stage

The main aim of this stage is the extraction of the morphosyntactic structure of each sentence. For this purpose, the GENIA tagger (Tsuruoka et al., 2005) integrated into GATE has been used. The GENIA tagger analyzes English sentences and outputs the base forms, part-of-speech tags, chunk tags, and named entity tags. The tagger is specifically tuned for biomedical text such as MEDLINE abstracts.

On the other hand, GATE (Cunningham, 2014) is an infrastructure for developing and deploying software components that process human language.

Linguistic Patterns

The candidate terms are identified by means of a hybrid method which uses a series of linguistic patterns in which the morphosyntactic structure of the terms is described. The use of linguistic patterns for identifying biomedical terms is a difficult issue due to the particularities of the biomedical domain, for example, the use of non-alphanumeric characters and acronyms, the complexity of some compound names, such as “granulocyte-macrophage colony-stimulating factor” (Ananiadou & McNaught, 2006). Indeed, terms representing biomedical concepts are usually comprised of multiple words that lead to a more specific meaning as a whole. For instance, “virus” has a more general meaning than “simian immunodeficiency virus”.

peri-kappa B-site	[NN] [NN]
immunoregulatory protein	[JJ] [NN]

In order to address this issue, relevant biomedical patterns have been obtained from some PubMed (United States National Library of Medicine, 1996) abstracts, which were analyzed using GENIA tagger. The most frequent patterns were collected in order to discover new terms.

Table 1 shows some of the morphosyntactic patterns obtained for the biomedical domain as well as some terms matching the patterns.

Multiword Concept Extraction Stage

Once a list of multiword candidate terms has been obtained from the linguistic patterns, it is filtered out by applying the NC-value algorithm presented in (Ochoa, Martínez, Almela, & Valencia-García, 2010). In this algorithm, the system processes context words and split them up according to their grammatical category (i.e., Adjectives, Verbs or Nouns). Both the C-Value and NC-Value algorithms are explained in detail.

C-Value

First, the system arranges the term list and calculates the frequency of occurrence of the candidate term within longer candidates, the frequency of occurrence of that longer candidate term, the length of the candidate term and the total frequency of occurrence of the candidate term in the corpus (see equation 1).

$$C-value = \begin{cases} log_2 \left|a\right| * f\left(a\right) \\ log_2 \left|a\right| * \left(f\left(a\right) - \frac{1}{P(T_a)} \sum_{b \in T_a} f\left(b\right) \right) \end{cases} \quad (1)$$

where:

a is the candidate string;
|a| is the length of the candidate string;
f(a) is its frequency of occurrence in the corpus;
Ta is the set of extracted candidate terms containing a;
P(Ta) is the number of the longest candidate terms containing a;
Sf(b) is the frequency of occurrence of a sub-term of any candidate term b as |a| < |b|.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

NC-Value

In order to obtain an acceptable degree of accuracy in the candidate term list, the NC-value method uses the morphological information from the context of the term under question. The system processes context words and splits them up according to their grammatical category of Adjectives, Verbs or Nouns. With the method developed by (Grefenstette, 2012), a type of weight known as 'context weighting factor' is obtained. It calculates the probability of a context word appearing with a term, as it is formalized in equation 2:

$$weight\left(w\right) = \frac{t\left(w\right)}{n} \tag{2}$$

where:

w is the context word;
t(w) is the number of times that the context word appears with the term;
n is the total frequency of occurrence;
weight (w) is the context weighting factor.

With the weight score obtained, the NC-value may by calculated by using the equation 3:

$$NC - value\left(a\right) = 0.8C - value\left(a\right) + 0.2\sum_{b \in C_a} f_a\left(b\right) weight\left(b\right) \tag{3}$$

where:

a is the candidate term;
Ca is the set of context words for a;
b is a word from Ca;
fa (b) is the frequency of b as the context word for a;
weight (b) is the weight of b as the context word.

In equation 4, the factors 0.8 in the first part and 0.2 in the second part have been assigned after several tests conducted by (Grefenstette, 2012). If the C-value of the candidate term is multiplied by 0.8 and the result of the summation of the individual weight corresponding to the context words is multiplied by 0.2, the NC-value is obtained, which rearranges the list by placing the best candidate terms on the top of the list.

Single Word Concept Extraction Stage

The single word concept extraction is based on the TF-IDF algorithm (Salton and McGill, 1983), which uses the following equation (see equation 4).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\left(tf-idf\right)_{i,d}=\frac{n_{i,d}}{\sum_k n_{k,d}}*\log\frac{\left|D\right|}{N_i} \tag{4}$$

where $n_{i,d}$ is the number of occurrences of the ontological entity i in the document d, $\sum_k n_{k,d}$ is the sum of the occurrences of all the ontological entities identified in the document d, $|D|$ is the set of all documents and N_i is the number of all documents annotated with i.

Relation Extraction Module

In the previous phase, an ordered list with the terms that represent the concepts of the domain has been obtained. For each term, a concept is identified and in this module, the semantic relations between these concepts have to be obtained. Relationships between entities in natural language texts are primarily expressed as verbal relationships or by means of their corresponding nominal form (Friedman, Kra, & Rzhetsky, 2002). The semantic relationship between a syntactic constituent, for example, a noun, and a predicate, for example, verb, is called semantic role. A semantic role defines the role of a verbal argument in the event expressed by the verb (Moreda, Llorens, Saquete, & Palomar, 2011).

For example, in the sentence 'Gene MCOLN1 is mutated in Mucolipidosis type IV', the verb expression "is mutated" express the relation between the events or arguments, which are defined as "Gene MCOLN1" and "Mucolipidosis type IV". Semantic roles and concept labels or tags are also assigned to these arguments. For example, the verb "mutate" expects to have at least two arguments, (i) an initial entity, in this case, "Gene MCOLN1 and" (ii) the final entity, that is, the changed entity, in this case, "Mucolipidosis type IV".

In the biological domain, semantic roles have been used for tasks such as extracting semantic relations and Named Entities (NEs). More concretely, there are some domain-specific projects where semantic roles are defined for biomedical verbs, such as PASbio (Wattarujeekrit, Shah, & Collier, 2004), BioFrameNet (Dolbey, Ellsworth, & Scheffczyk, 2006) and BIOSMILE (Tsai et al., 2007).

In this approach, a framework based on previous works (Ruiz-Martínez, Valencia-García, Martínez-Béjar, & Hoffmann, 2012) is used. This framework attempts to support domain experts in populating ontologies from natural language texts. It allows for several semantic relations to be used and reduces the degree of expert participation during the ontology construction process. It is based on the association of semantic frames from FrameNet with an ontological model created from top-level ontologies. In the BioOntoVerb framework, there are 10 top-level relationships which represented a wide range of biomedical predicates. These predicates relate two ontological concepts on a textual level, although they are constrained to the top-level relationships. For this reason, new predicates have been added, even if they have not a correspondence with top-level relationships.

In Table 2 an excerpt of the relationships described in BioOntoVerb framework is presented.

This module works as follows. First, the concepts obtained in the previous phase are identified in each sentence in the corpus. Then, the verbal expression of the current sentence is found and the system searches if there is any semantic frame that could be applied in order to extract a relationship between the concepts identified in this sentence. If so, a semantic relationship between the two concepts is extracted and included in the domain ontology.

Table 2. An excerpt of the mapped relationships

Ontological Relationship	FrameNet Frames	Lexical Units	Examples in Corpora
caused_by	Cause: A Cause causes an Effect	Cause, Induce, Make, Create, Incite, Provoke, Engender, Instigate, Generate, Produce, Result, Develop	nur77 *may cause* apoptosis by monomer K30p (p13K30) and K34p (p13K34) *result in* a Trp - Arg substitution
located_in	Locating: A Perceiver determines the Location of a Sought_entit	Locate, Situate, Place, Localize, Localized in, Be present In, Localized to, Find	One type, EA / S, *is located in* the upstream promoter region I kappa B gamma - 1 *is found in* both the cytoplasm and nucleus
contained_in	Contain: Container holds within its physical boundaries the Contents	Create, Originates from, Derive from, Generate (inversa), Come from, Develop from, Alter, Transcribe from, Stems from	cytotoxicity of indolocarbazoles *derives from* Top1p p45 mRNA *is transcribed only from* aNF - E2 promoter
transformation_of	Transform: An Agent or Cause causes an Entity to change.	Transform, Modify, Change Transform in/into, Changes in/ into Mutate in/into, Changes into, Converts into, Turns into	I kappa B alpha *is* selectively *modified in* LMP - 1 - expressing B cells GATA sites *have been mutated into* human T lymphocytes

Ontology Evolution Module

The main objective of this module is to manage the evolution of the domain ontology. The main changes in the ontology are mainly the addition and removal of ontological entities, mainly concepts, and relationships.

For this, when a new document is added to the corpus, this module is in charge of launching both the concept and relation extraction modules. If new ontological entities are identified they are inserted in the ontology. On the other hand, if a document is removed the module only will launch again the concept extraction module in order to check if any concept should be removed from the ontology. The relationships are related to the documents from they were extracted, if the document that contained a relationship is removed, then the relationship should be also removed from the domain ontology.

During the evolution process, an OWL reasoner is used to detect inconsistencies in the ontology. If any inconsistency is identified, then the system alerts to the user that an inconsistency has been produced due to an add/remove ontological entity action.

VALIDATION

The methodology described in this work has been validated across the diabetes domain. The study of the results is based on three main scores: precision, recall, and F1-Measure. These measures are the most commonly used for the assessment of statistical extraction systems, and trace their origins back to IR discipline. The precision score is the result of the division between the amount of ontological entities suggested by the system and that are accepted by the expert user, and the total amount of ontological entities suggested. The recall score is the result of the division between the amount of ontological entities suggested by the system and accepted by the expert, and the total amount of ontological entities existing

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in the fragment. Finally, the F-measure score can be interpreted as a weighted average of the precision and recall, where an F-measure score reaches its best value at 1 and worst score at 0.

The experimental corpus in the diabetes domain has 174,568 words distributed into 125 documents. This corpus has been manually processed by domain experts, so obtaining a total amount of 834 concepts or classes and 987 semantic relationships.

As can be observed in Table 3, the system identified 895 concepts and 987 relations, of which the expert accepted a total of 710 concepts and 760 relations.

The results seem promising, obtaining a precision score of 79.3%, a recall score of 85.1% and an F-measure score of 82.1% for concepts detection, and a precision score of 82.6%, a recall score of 77.0% and an F-measure score of 79.7% for relations detection. Therefore, the results show that the system is able to propose several concepts and relations that the experts have manually detected.

Furthermore, a scenario has been defined in order to evaluate the ontology evolution process. In this case of study, 30 new documents were included in the corpus. This corpus was analyzed by the expert user to detect domain concepts and relations. A total of 35 new concepts and 16 new relations were obtained.

The same corpus was processed by the system obtaining 30 new concepts and 12 new relations, of which 26 concepts, and 10 relations were accepted by the expert user. Results are showed in detail in Table 4.

The system obtained good results for ontology evolution process with a precision of 68.4% and 71.4% for concepts and relations, respectively. However, the authors consider that the detection of terms can be improved through the inclusion of other more complex linguistic patterns that allow the detection of some concepts that have not been identified.

Table 3. Evaluation results in the diabetes domain

	Concepts	**Relations**
Relevant concepts and relations	834	987
Concepts and relations identified by the system	895	920
Concepts and relations accepted by the expert	710	760
Precision	0.793	0.826
Recall	0.851	0.770
F-measure	0.821	0.797

Table 4. Results after adding 30 new documents to the corpus

	Concepts	**Relations**
Relevant concepts and relations	35	16
Concepts and relations identified by the system	38	14
Concepts and relations accepted by the expert	26	10
Precision	0.684	0.714
Recall	0.742	0.625
F-measure	0.712	0.666

CONCLUSION

In this paper, an automatic method for acquiring knowledge from biomedical texts has been presented. This approach is based on the use of semantic roles in order to extract semantic relations between concepts.

The proposal supports an incremental evolution by taking into account new text documents. Ontology evolution from free text documents is an important activity for the knowledge engineering community. The approach presented in this work is totally automatic. Another key feature of this approach is that it works not only with taxonomies, but also with multiple semantic relations.

Similarly, (Sánchez & Moreno, 2008) presents a methodology for the detection of non-taxonomic relations from texts. It is based on the identification of the relevant verbs in the text chunks. These verbs are then used as a knowledge basis for learning and tagging non-taxonomic relations automatically and without supervision. Both studies use linguistic patterns for obtaining taxonomic relations.

The authors in (Jiang & Tan, 2010) introduce a methodology which has a similar common ground to ours. The aim of these authors is the development of a high-quality ontology, and for this purpose they use a combination of statistical and lexical-semantic methods.

Further validations of the system are planned by means of its application to texts from different medical domains and by using statistical methods for the analysis of the results obtained. Moreover, the authors intend to extend the system to cover special and temporal relationships (Cuadra, Calle, & Rivero, 2011) and axioms (Terrientes, Moreno, & Sánchez, 2010). The main forecast problem concerning axioms is, however, that the number of participants is a priori unknown. Notwithstanding this fact, the number of axioms present in a text is irrelevant in comparison to the number of other knowledge entities.

It is also planned to include some methods to measure the quality of the acquired ontologies such us the ones presented in (Duque-Ramos, Fernandez-Breis, Stevens, & Aussenac-Gilles, 2011) (Duque-Ramos et al., 2013) and to introduce some methods of question answering in the evolutioned ontologies such as the one presented in (Vila, Mazon, & Ferrandez, 2011).

ACKNOWLEDGMENT

This work has been funded by the Universidad de Guayaquil (Ecuador) through the project entitled "Tecnologías inteligentes para la autogestión de la salud". María del Pilar Salas-Zárate is supported by the National Council of Science and Technology (CONACYT), the Secretariat of Public Education (SEP) and the Mexican government. Finally, this work has been also partially supported by the Spanish Ministry of Economy and Competitiveness and the European Commission (FEDER / ERDF) through project KBS4FIA (TIN2016-76323-R).

Chapter 54
Utilizing Combined Claims and Clinical Datasets for Research Among Potential Cases of Rare Diseases

Kevin J. Bennett

Centers for Disease Control & Prevention, USA

ABSTRACT

With data quality issues with administrative claims and medically derived datasets, a dataset derived from a combination of sources may be more effective for research. The purposes of this article is to link an EMR-based data warehouse with state administrative data to study individuals with rare diseases; to describe and compare their characteristics; and to explore research with the data. These methods included subjects with diagnosis codes for one of three rare diseases from the years 2009-2014; Spina Bifida, Muscular Dystrophy, and Fragile X Syndrome. The results from the combined data provides additional information that each dataset, by itself, would not contain. The simultaneous examination of data such as race/ethnicity, physician and other outpatient visit data, charges and payments, and overall utilization was possible in the combined dataset. It is also discussed that combining such datasets can be a useful tool for the study of populations with rare diseases.

INTRODUCTION

The growth in the use of health information technology (HIT) has been substantial in the United States of America. The percentage of office-based physicians who utilized some form of an electronic health record (EHR) increased from 18% in 2001 to 83% in 2014 (Hsiao & Hing, 2014). Likewise, 96% of US hospitals had an electronic health record system as of 2015, although this percentage was lower for smaller or rural hospitals (68 & 70%, respectively) (Hsiao & Hing, 2014). HIT utilization has also grown across health care sectors, such as in emergency departments (Selck & Decker, 2016) and home health agencies (Mitchell, Bennett, & Probst, 2013). Much of this growth was spurred by the 2009 Health Information Technology for Economic and Clinical Health (HITECH) Act, which gave financial incentives to institutions that adopted electronic medical record (EMR) and other HIT technologies. The HITECH Act introduced meaningful use (MU), which established a set of criteria to ensure that the HIT adopted was clinically useful and eligible for the incentives (Blumenthal & Tavenner, 2010). Part of the MU criteria is to view, download, or transmit patient data electronically (health information exchange – HIE); as of 2015, 33% of providers and 14% of hospitals were able to do this (ONC, DHHS). In addition, up to 80% of hospitals were able to conduct some form of external electronic query of patient data (ONC, DHHS).

Health information also holds promise for health services researchers. By capturing patient, visit, and other data during encounters, researchers are able to get a fuller picture of health care utilization, outcomes, and the factors that affect them both. Data derived from clinically-based HIT systems is limited in its utility for researchers in several ways. First, data can be difficult to obtain unless the researcher has an established relationship with the HIT system owner (i.e., providers or organizations) and a method to retrieve the desired data. Additional difficulties can arise due to limitations or exclusions from the data to protect privacy (ensuring all data is adequately protected and/or de-identified), obtaining patient consent for the use of the data, or ensuring the completeness and appropriateness of the data extracted. Second, there are few HIT-based data sources that are representative of larger populations beyond service areas or insured populations. While larger hospital systems may have a larger service footprint, their data may still only capture their patient population and not be representative of an entire community, or may only capture one segment of care within the care continuum, such as inpatient care or ambulatory care. Third, HIT systems often have separate service lines, meaning that one department may not use the same HIT system or dataset as another department in that same health care system or network. While some institutions are working towards unified HIT systems and datasets (e.g., Veterans Administration, Kaiser Permanente), these are also limited to data from their own enrollees. Finally, data is often collected and catalogued in a manner that serves the clinical care needs of providers and delivery systems, and not the needs of researchers (Miriovsky, Shulman, & Abernethy, 2012; Rosenbloom et al., 2011).

For these reasons, the Healthcare Information and Management Systems Society includes in its definition of an electronic health record (EHR) the need to support ongoing performance measurement as well as support clinical research and evidence based research, facilitated by health information exchange (Handler et al., 2016). Larger databases that include clinical data derived from electronic health records have potential to provide sources of research data, while also providing an opportunity to shift the thinking of how research is conducted, towards a more rapid-based learning model (Abernethy et al., 2010; Etheredge, 2007). This model seeks to capitalize on the clinical content of the data, but the regular updating of such data allows for more time sensitive approaches to research.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is abundant research performed using a variety of data sources, including insurance claims data, surveys, and vital records (i.e., birth and death certificates). These data are utilized to examine a variety of topics, and have resulted in a wide range of findings (Büchele et al., 2016; Faurot et al., 2015; Lauer & McCallion, 2015; Martin, Osterman, & Sutton, 2010; Ross et al., 2000); however, they can be limited. Claims data are useful repositories of individual and organizational information, but often lack key patient and clinical information (such as comorbidities, severity of the diagnoses, lab values, or patient preferences). Other data sources may include more in-depth patient information, but may be based upon patient self-report of conditions, utilization, or health outcomes and therefore may not be reliable (National Center for Health Statistics, 2015; Pierannunzi, Hu, & Balluz, 2013). The ability to utilize data drawn from clinical documentation would be helpful for improving the quality, depth, and explanatory power for health services research by supplementing these administrative sources.

In 2014, a project began that sought to utilize a combined dataset derived from a claims-based dataset and a medical record based dataset for the years 2009-2014. The purpose of this project, described below, was to determine how to link a clinical dataset with state administrative and claims datasets to analyze data on people with potential cases of rare diseases (e.g., Spina Bifida, Muscular Dystrophy, and Fragile X Syndrome). We then sought to describe and compare the characteristics of the individuals identified, and to explore potential research questions and activities that can be conducted using combined data.

METHODS

Dataset Creation

This particular project, funded by the Disability Research and Dissemination Center, focused on individuals with billing codes for one of three rare diseases: Spina Bifida (International Classification of Diseases version 9 (ICD9) 741.xx), Muscular Dystrophy (ICD9 359.0, 359.1, and 359.21), and Fragile X Syndrome (ICD9 759.83). These conditions were chosen for study as they are relatively rare in the general population, and are therefore not widely studied. Individuals were included in each dataset if they had at least one encounter with a diagnosis code including one of these codes. The data are limited, however, in the ability to confirm a medical diagnosis of such diseases without full medical chart review.

Claims and Administrative Data

The Revenue and Fiscal Affairs (RFA) Office[1] is a neutral service entity that warehouses various administrative data from state agencies, which is able to link persons across multiple service providers, locations, and data sources. Through a series of statutes and agreements, state agencies and organizations grant the RFA access to data and data systems. For this project, the RFA provided two sources of data; the first was from Medicaid and State Health Plan Claims, and the second was from Hospital administrative datasets (all described below). The RFA has developed a series of algorithms using combinations of personal identifiers to create its own unique identifier, which enables analysts to link data by person across the multiple sources, while protecting confidentiality of the patients. All data requests were approved by all participating agencies and organizations, including the South Carolina Data Oversight Council and the University of South Carolina Institutional Review Board.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The first dataset included claims for patients with a service coded with one of the above mentioned rare disease billing codes from State Health Plan (SHP) or Medicaid (fee for service) as their insurance provider (hereafter referred to as the SHP/Medicaid dataset).

The SHP is an insurance option, administered by Blue Cross / Blue Shield of South Carolina that is offered to state and local government employees and their dependents. The other dataset is based upon information from the UB-04 billing and HCFA-1500 claim forms, utilized by facilities to bill for their services. These data include diagnostic information (International Statistical Classification of Diseases version 9, ICD-9), types of services received (either ICD-9, Healthcare Common Procedure Coding System(HCPCS), or Current Procedural Terminology (CPT) codes), service dates (admission and/or discharge dates), patient disposition, and other visit information for all inpatient and emergency department visits in the state, regardless of payer (hereafter referred to as the all-payer dataset).

The RFA queried these two data sources for patients with the ICD9 codes as above, and provided two separate datasets (one for SHP/Medicaid, and the other for the all-payer claims data). Race/ethnicity is not included in the State Health Plan data, and is thus not included in the SHP/Medicaid dataset; other information included in this dataset were age group, gender, and information regarding encounters and medications filled.

Electronic Health Records Data

SC is also home to Health Sciences South Carolina (HSSC), which houses the Clinical Data Warehouse (CDW)[2]. HSSC is a statewide research collaborative focused on improving the quality of healthcare delivery, improving health information systems, training the healthcare workforce, and improving patient outcomes. Partners include seven of the state's largest health systems and the state's largest research-intensive universities. This is among the first systems to bring together data from three major research universities and several large health care systems. HSSC created the CDW to facilitate these goals; the CDW aggregates de-identified electronic patient records from these systems to enable providers and researchers to access patient data for research or treatment purposes. The data collected are from electronic health records related to inpatient, outpatient, and emergency department encounters from the affiliated systems.

Using the ICD9 codes described above, individuals were identified as potentially having one of these conditions in the CDW dataset (2009-2014). Information extracted from this dataset included patient demographics (sex, race, ethnicity, and area of residence – rural or urban), visit information (date, visit type (emergency, inpatient, other)), payer (commercial, government, other, self-pay), admission and discharge information, and diagnoses associated with the visit.

HSSC then sent their data file to the analysts at the RFA to merge with the two state-based datasets. To further alleviate privacy concerns, the service dates for all data were shifted randomly, but by a fixed amount across an individual's encounters. The RFA then utilized a proprietary linkage algorithm to match patients from the three sources (CDW, Medicaid/SHP, all-payer datasets). Each person with unduplicated data was assigned a random number generated by an algorithm, referred to as the Unique ID. The algorithm uses personal identifiers that include, but are not limited to: first name, middle initial, last name, date of birth, race, and gender. The dataset was edited (i.e., characters were removed from numeric fields, dates were compared to valid ranges) and standardized (i.e., all characters were converted to uppercase) before being run through the algorithm. All of the identifier fields on a record housed at RFA were compared to records in the CDW data to identify exact or partial matches of individuals. A

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

'MatchType' (a string of characters that represent the match for each identifier field) was then assigned for each potential match. A 'MatchScore' (the rate indicating how often this 'MatchType' yields the same person when compared across multiple rows of data) and a 'FieldScore' (the number indicating the number of the fields that matched) was then assigned to the record. For each individual original record for which there were records with a MatchScore of 90 or greater, a single record was chosen as the actual match based on a match with more specific identifiable fields, such as social security number and date of birth. Once that single record match was chosen, the unique ID number from the matched record was assigned. If no records for a given original record have a MatchScore of 90 or greater, candidates for that original record were then compared to other possible candidates with lower MatchScore values. The process of scoring was then repeated for all records in this pool. The algorithm accounts for misspelling, name changes, and slight differences in the date of birth. An individual's Unique ID remains associated with that individual on all subsequent episodes of services in data captured by RFA, regardless of data source or service provider. Those that had an initial MatchScore of at least 90 were considered strong matches. The remaining were then compared on other characteristics to find additional matches, with a lower limit MatchScore of 60.

The final merged dataset was created using the RFA-generated unique identifier. The demographic variables were then compared and reconciled. In cases of a discrepancy, the assignment was based upon one of the state based datasets (all-payer or SHP/Medicaid).

Health care encounters were matched based upon the patient's ID, the data of the visit, and the setting and categorized into five categories: Inpatient, Emergency Department, Outpatient, Office Visits, and Other. Each dataset included different taxonomies to label their encounters; each utilized Inpatient, Emergency department, and Outpatient while the SHP/Medicaid included both Office and Other categories. To avoid double counting a visit recorded in more than one data source, a stratified matching method was utilized. First, encounters with the same date, by ID, were identified. Next, depending upon the dataset, the category of service was identified (Inpatient, Outpatient, or Emergency Department). Those labeled as 'Office" encounters in the SHP/Medicaid were matched with encounters labelled as "Outpatient" in the CDW data when appropriate. Second, if the date and category matched on two encounters, this was determined to be one visit. Non-matches were designated as different encounters.

Merging the data is simple enough, if done by the unique identifier identified by the matching algorithm described above. In practice, a major hurdle to an accurate merge was in identifying a single encounter as just one encounter, and not confusing the multiple claims associated with an encounter as separate events. For example, a single physician visit may result in multiple claims, associated with tests, labs, or consultations. Multiple claims were merged into a single event for the accuracy of counting encounters. Also, with the merge, the same event could be represented in each of the datasets; thus, care must be taken to match events by date of service, service type, and service location. In addition, professional claims were also added to applicable events (e.g., professional claims associated with an inpatient claim or outpatient surgery).

RESULTS

Description of the Data

The resulting dataset derived from the above process was comprised of 2,637 patients identified within the CDW; 3,074 within the SHP/Medicaid data; and 2,675 from the all-payer data, for a total of 5,308 unique patients. When merged, 8.4% were in both the CDW and SHP/Medicaid; 8.3% were in both the CDW and all-payer; 11.8% were in both the SHP/Medicaid and all-payer; and 14.7% were in all three. Thus, 56.7% of the subjects were found in only one of the three datasets (see Figure 1).

Table 1 displays the demographic characteristics of those in each dataset, compared to those in all three datasets. The all-payer data had a higher proportion of females (56.2%) than the other datasets; the combined data was comprised of 54.2% female. The all-payer data also had the highest proportion that were white (72.9%), compared to 68.1% for the CDW dataset and 54.5% for the combined data (SHP/Medicaid race data were suppressed). The all-payer data skewed older but the combined data skewed towards the 0-17 age group (39.1%).

Table 2 displays the demographic characteristics of the study population by disease. Of these, 61.2% had a code associated with Spina Bifida, 32.7% had a code associated with Muscular Dystrophy, and 6.1% had a code associated with Fragile X. Potential Spina Bifida patients were predominantly female, white, and under the age of 17. Potential Muscular dystrophy patients were predominately male, white, and under the age of 17. Potential Fragile X patients were also predominately male, white, and under the age of 17.

Utilization and Expenditures

Table 3 displays the summary of annual claims, by type and year, for the individuals in each dataset. For the combined data, 22.7% had one or more inpatient visits. This proportion varied by condition; a smaller proportion of those potentially with Fragile X had at least 1 inpatient stay (13.0%) compared to those potentially with Muscular Dystrophy (22.6%) and Spina Bifida (23.8%). This trend remained, with some variations, when annualized (see Table 3). For emergency department visits, 38.3% of the entire sample had one or more visits. This proportion also differed by condition; a smaller proportion of those potentially with Fragile X had one or more visit (26.2%) compared to those potentially with Muscular Dystrophy (36.5%) and Spina Bifida (40.5%). This trend also remained, with some variations, when annualized (see Table 3).

We next examined median annual charges, subset by category of service. For individuals with potential cases of any of the three conditions, combined inpatient visits had an annual median charge of $25,410 and ED visits had an annual median charge of $13,067. Inpatient charges were lower for potential Muscular Dystrophy and Fragile X patients, but higher for potential Spina Bifida patients. The ED charges were similar for Spina Bifida, slightly higher for Muscular Dystrophy, but lower for potential Fragile X patients.

65+	139	4.3	266	15.3	12	3.8	417	7.9

†Proportions differ significantly, $\alpha = 0.05$, by condition

An examination of the primary diagnoses for type of visit was also instructive (see Table 4). For ED visits, commonly cited diagnoses included upper respiratory infections, urinary tract disorders, digestive system disorders, and skin ailments. In addition to those listed above, several diagnoses were unique to the condition: for potential Spina Bifida patients, migraine headaches were the fourth most common primary diagnosis; for potential Muscular Dystrophy patients, schizophrenic disorders were the sixth most common; for potential Fragile X patients, epilepsy was the fourth most common.

For inpatient visits, commonly cited primary diagnoses included urinary tract disorders, live births, pneumonia, and complications from procedures. In addition to those listed above, several diagnoses were unique to the condition: for potential Spina Bifida patients, chronic skin ulcers were the second most common primary diagnosis; for potential Muscular Dystrophy patients, cellulitis and abscesses was the tenth most common; for potential Fragile X patients, Bulbus cordis anomalies and anomalies of cardiac septal closure were the most common primary diagnosis.

DISCUSSION

Using administrative claims and clinical data allowed for a more comprehensive analysis of the experiences of patients with potential cases of selected rare diseases. Each of the datasets used in this project has its relative strengths; the CDW is derived from clinical documentation, the SHP/Medicaid data represents all of the individual level claims for those enrolled in those programs, and the all-payer data represents data from all facilities. In this study, the study population nearly doubled in size due to this combination compared to using any of the datasets alone. In addition, the combined dataset allowed researchers to obtain more comprehensive information about a continuum of care for patients across facilities and provider types. This is particularly useful for those with potential cases of rare diseases, as more complete information about their utilization can now be analyzed.

The use of combined administrative and clinical datasets may have the potential to improve studies of other populations as well, in the following ways:

- Matching visit data across the datasets can help fill in 'missing' information (such as race/ethnicity, visit type, location, prescriptions, lab values);
- Combining facility and professional claims can allow researchers to obtain more complete information for inpatient facility encounters;
- Examining actual laboratory values, not just that the test was performed, might permit researchers to study the linkage between such values and outcomes and/or utilization;

- Expanding information regarding insurance type could lead to more nuanced examination by payer status;
- Providing a more detailed description of the service unit within an inpatient facility can generate a better understanding of the care delivery context for the researcher;
- Identifying comorbidities or complexities in care due to the addition of diagnosis codes and procedure codes from the merged data might improve ability of researcher to make connections;
- Examining the provider classification, such as specialty, associated with the claims could allow for a more comprehensive understanding of what providers these individuals are seeking care from;
- Examining charge data associated with the claim can create a better understanding of health care costs associated with such diseases together with cost-to-charge ratios;
- Utilizing a combined dataset may be helpful to policy makers who are tasked with monitoring health services programs, interventions, and funding as their decisions can be made based upon fuller and more complete information as well as better examinations of the outcomes of such decisions.

There are limitations to these data, however. The CDW data included a large amount of outpatient visit data, but the categorization was vague, making it difficult. Specifically, it is not always possible to differentiate outpatient encounters by type or location (e.g., outpatient surgery vs. ambulatory physician visit). This can be clarified by matching to the SHP/Medicaid visit data, but only for those individuals with information in both sources. If these outpatient claims could be more precisely identified, the utility of that data may improve. Issues regarding the quality of clinical data are not uncommon, and continue to be a barrier to using such data for research (Coorevits et al., 2013; Weiskopf & Weng, 2013).

There were also cases of contradictory information within matched individuals and claims. For example, approximately 1% of the demographic data did not match exactly (i.e., sex, age and race/ethnicity not matching upon merge). When such discrepancies occurred, we relied on data from a state-based source rather than the CDW data. There were also instances where potential matched claims had substantially different service unit categorizations; it was often unclear if these simply represented different claims on the same day, or a discrepancy in classification by the provider. These instances were treated, conservatively, as matches. In addition, there are various reasons why an individual would be presenting one or more of the databases, but not all there, such as seeking care in only one place of service not captured in all three datasets, not having insurance coverage, or even seeking care from out-of-state providers.

Finally, identifying potential cases using ICD9 coding is not perfect. It has been shown that accuracy of administrative data was low when using a straightforward criterion of a single ICD9 diagnosis code for muscular dystrophy. However, accuracy of finding true cases improved substantially with added information in the algorithm (Smith et al., 2017). Future studies may combine medical chart review with administrative data to address the questions of ICD-9 codes validation for rare conditions so that these administrative data sources can be better used for research on rare conditions.

Despite these limitations and difficulties, such a merged dataset represents a useful tool for researchers and policy makers alike. The use of such data has the potential to lead to improvements in population health and service delivery in many aspects.

This analysis was supported by a cooperative agreement from the Centers for Disease Control & Prevention through the Disability Research and Dissemination Center. RFA-R14-002, EMR Rare Conditions. Rare Condition research using a combined Administrative / Clinical Data warehouse.

ABSTRACT

The gene expression analysis is an important research area of Bioinformatics. The gene expression data analysis aims to understand the genes interacting phenomena, gene functionality and the genes mutations effect. The Gene regulatory network analysis is one of the gene expression data analysis tasks. Gene regulatory network aims to study the genes interactions topological organization. The regulatory network is critical for understanding the pathological phenotypes and the normal cell physiology. There are many researches that focus on gene regulatory network analysis but unfortunately some algorithms are affected by data size. Where, the algorithm runtime is proportional to the data size, therefore, some parallel algorithms are presented to enhance the algorithms runtime and efficiency. This work presents a background, mathematical models and comparisons about gene regulatory networks analysis different techniques. In addition, this work proposes Parallel Architecture for Gene Regulatory Network (PAGeneRN).

INTRODUCTION

Bioinformatics is the application of information technology in the field of molecular biology to manage process and analyze both genomic and molecular biological data. Its primary goal is to improve the understanding of biological processes (Nair, 2007). Bioinformatics is a very rich filed of research, in fact it includes so many research areas with diverse applications and according to Srikanth Aluru (2006), the major research areas in Bioinformatics are: Genome annotation (Kelley, MacCallum, & Sternberg, 2000), Sequence analysis (Durbin 1998, Sharif et al. 2015, Sharif et al. 2016, Tharwat et al. 2015), Computational evolutionary biology (Cosmides & Tooby, 1995), Gene expression analysis (Velculescu, Zhang, Vogelstein, & Kinzler, 1995), Analysis of regulation (Janssen, Jones, Jones, & Woods, 1988) and Protein expression analysis (Ghaemmaghami, et al., 2003). In addition, it includes analysis of mutations in cancer (Berrozpe, Schaeffer, Peinado, Real, & Perucho, 1994), Predictions of protein structure (Shortle, 2000), Comparative Genomics (Rubin, et al., 2000), Modeling biological systems (Haefner, 2005), High throughput image analysis (Dowsey, 2005), Protein-protein docking (Dominguez, Boelens, & Bonvin, 2003)and Microarrays (Churchill, 2002).

The microarray is one of the active research fields in bioinformatics. It's a multiplex lab-on-a-chip that assays large amounts of biological material using high throughput screening methods (Culf, Cuperlovic-Culf, & Ouellette, 2006). Moreover, the microarrays experiment (Li & Li, 2008) starts with the sample preparation after that the hybridization, diction step and finally the data acquisition and analysis step. The microarray chips are scanned using special devices called Microarray Scanner. The microarray type depends on the biological material that assays. There are a number of types of microarrays including DNA microarrays (Gasch, et al., 2000), MMChips, for surveillance of microRNA populations (Meenakshisundaram, et al., 2009), Protein microarrays (Stoevesandt, Taussig, & He, 2009), Tissue microarrays (Kononen, et al., 1998), Cellular microarrays (Ma & Horiuchi, 2006), Chemical compound microarrays (Ma & Horiuchi, 2006), Antibody microarrays (Rivas, et al., 2008) and Carbohydrate arrays (glycoarrays) (Culf, Cuperlovic-Culf, & Ouellette, 2006).

The DNA Microarray technology is a high throughput experimental technique that can measure expression levels of hundreds of thousands of genes simultaneously. As an illustration, expression level of the gene is estimated by measuring the amount of mRNA for that gene. A gene is active if it is being transcribed; the more mRNA usually indicates more gene activity (Schena, Shalon, Davis, & Brown, 1995). The DNA microarray has become a useful technique in gene expression analysis for the development of new diagnostic tools and for the identification of disease genes and therapeutic targets for disease such as cancer. In fact, it's the basis for a very efficient screening and diagnosis of disease in an early stage of development. Microarrays could also be expanded into a starting point for developing new treatments for various types of disease.

The analysis of the data resulting from microarrays remains a big challenge for the huge volume of data it produces. In addition, the data analysis process involves various computational tasks (Yang, et al., 2008) and one of the microarrays data analysis tasks is network analysis (Haman & Valenta, 2013). The gene regulatory network (Aluru, 2006)goal is to study the topological organization of the genes interactions. The gene regulatory network analysis techniques can be classified into four main categories: component analysis techniques (Raychaudhuri, Stuart, & Altman, 2000) (Watkins, 2004) (Holter, et al., 2000) (Hyvarinen, Karhunen, & Oja, 2001) (Aapo, 1999) (Liebermeister, 2002) (Liao, et al., 2003) (Chang, Ding, Hung, & Fung, 2008), mutual information based techniques (Romualdi & Chiara, 2011) (Shi, Schmidt, Liu, & Muller-Wittig, 2011), reverse engineering techniques (Jostins & Jaeger, 2010)[44] and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the regression techniques (Gregoretti, Belcastro, Di Bernardo, & Oliva, 2010). In fact, almost all of these techniques are computational intensive and time-consuming. Therefore, parallel algorithms are needed to enhance the techniques performance. The parallelism techniques are categorized as shared memory (Karp, 1988) (Hager & Wellein, 2010) and distributed memory (Hager & Wellein, 2010).Moreover, these two models can be mixed in the hybrid model to take the full advantage of the computing power (Hager & Wellein, 2010).Another form of the distributed computing is cloud computing (Erl, Puttini, & Mahmood, 2013). In addition, the graphic processing unit (GPU) can be used to enhance performance.

This work presents a background, mathematical models and comparisons about gene regulatory networks analysis different techniques. In addition, this work proposes a parallel architecture for gene regulatory network called PAGeneRN (**P**arallel **A**rchitecture for **Gene R**egulatory **N**etwork). This work is organized as follows; the related work that contains gene regulatory network analysis different techniques is discussed in the second. While, the third section provides information about the microarrays, microarrays experiments and the parallelism different techniques. The gene regulatory network analysis techniques are categorized into four categories; component analysis, mutual information, reverses engineering and finally regression techniques. These techniques challenges are summarized in the fourth section. While, the fifth section provides an architecture which enhances the gene regulatory network analysis technique. Besides that, the conclusion is showed in the last section.

RELATED WORK

One of the microarray data analysis techniques (will be discussed in the next section) is the network analysis (Haman & Valenta, 2013)which is a powerful analysis tool to understand real world phenomena and one type of the network analysis is the gene regulatory network, actually, the gene regulatory network focuses on studying gene interactions. This section illustrates the gene regulatory network analysis different techniques, in addition; the gene regulatory network analysis techniques are discussed from sequential and parallel points of view. Furthermore, the applications of gene regulatory network analysis on time series data are discussed.

Gene Regulatory Network

The gene regulatory network aims to study the genes interaction topological organization and gene-to-gene influences. As shown in Figure 1 the gene regulatory network consists of a set of nodes and sets of edges, where the nodes represent genes and edges represent regulatory interactions between genes.

The illustrated example represents a regulatory network in mouse **E**mbryonic **S**tem Cells (ESC) (Zhou, Chipperfield, Melton, & Wong, 2007) the master regulators are Oct4, Sox2 and Nano, where pink nodes represent the main regulators and their protein regulators are represented in yellow. Moreover, the regulatory interactions are illustrated by blue and pink arrows, while, the protein interactions are represented by the orange and green lines. In addition, the arrows from the dashed ellipse indicate that all the regulators inside the ellipse regulate the target.

As illustrated in Figure 2 the gene regulatory network analysis techniques can be classified into four categories: Component analysis techniques, mutual information based techniques, reverse engineering techniques and regression techniques. Furthermore, the component analysis technique can be further categorized into a number of sub-classes. As mentioned before the component analysis of microarrays

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A regulatory network in mouse ESC anchored[1]

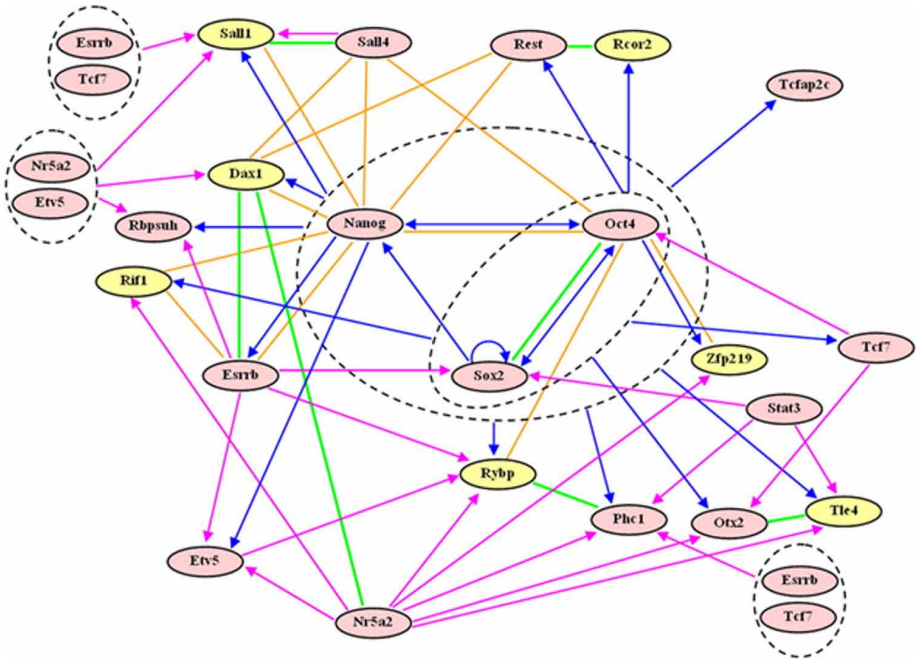

Figure 2. Gene regulatory network techniques

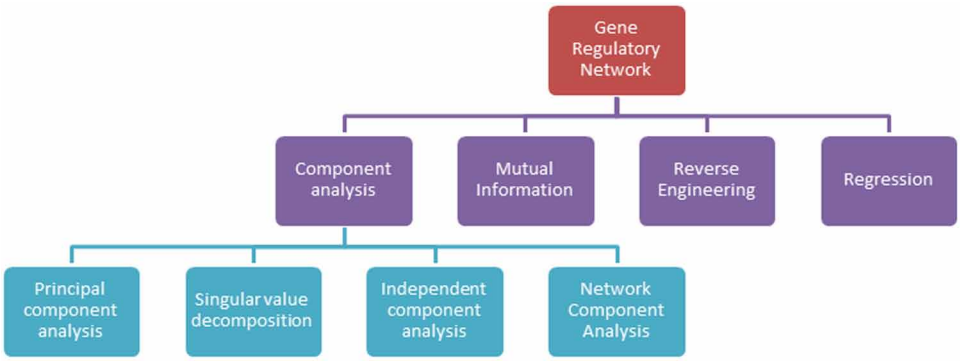

data aims at studying the ways in which gene responses vary under different conditions. While, here the component analysis is a computational technique and aims to build the gene regulatory network. One of the component analysis techniques is the principal component analysis technique (PCA) (Raychaudhuri, Stuart, & Altman, 2000).The PCA is the dimensionality reduction technique which determines the key variables that explain the difference in the data and simplify the data analysis and visualization. In other words, when applying PCA on a data matrix [*A*] of *M* observation in *N* variables; in the case of the gene expression data, the observation are the genes and the variables are the experiment conditions/ samples, it finds new *x* variables which reduce the dimensionality of [*A*], where, the new *x* variables must be orthogonal and mutually uncorrelated. Also, it must take into consideration covering as much as possible the variance in the original variables. These variables are called the principle components. The principle component is a linear combination of the original variable.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Applying the PCA on gene expression data allows scientists to summarize the ways in which gene responses vary under different conditions. When applying the PCA to gene expression data can consider the genes or samples or both as variables. In case of genes being considered as variables, a set of "principle gene components" are created. This principle gene component set illustrates the experimental responses produced by these genes. In the other hand, the PCA creates a set of "principal experiment components" when considering the experiment as variables. This principal experiment component set indicates the experiment conditions that explain the genes behavior. In addition, when the analysis is performed on the experiment and the genes together, it results in a sub-matrix which summarizes the variance in the original data.

The singular value decomposition (SVD) (Watkins, 2004; Holter, et al., 2000) aims to uncover the underlying patters in the gene expression data. Where, the complex gene expression profiles can be captured by a small number of the characteristic modes which capture the temporal gene expression change pattern. Before applying the SVD, the rows and columns must have a zero mean. This is achieved by subtracting the mean values of the data and performing iterative normalization procedures for the rows and columns (Eisen, Spellman, Brown, & Botstein, 1998) . Given the gene expression data matrix [*A*] the SVD states that [*A*] can be written as in Eq. 1. Where the [*X*] is (*M x M*) matrix, [*Z*] is (*N x N*) matrix and [ΣZ^T] is (*M x N*) matrix and the superscript *T* means the matrix transpose. The [*X*] and [*Z*] are orthogonal. The r (the rank of matrix A is no longer than N-1) positive non-zero Eigen-values of [A^TA] are the same as Eigen-values of [AA^T]. The singular values (denoted by S_i) are the square root of these Eigen-values. The [Σ] matrix elements are all zero except for $\sum_{ii} = S_i$ for i= 1, r. The ith column Z_i of [*Z*] is the Eigen-vector of the matrix [AA^T] for i= 1, r. The ith column X_i o of (*X*) is calculated by the formula expressed in Eq. 2. Due to the form of [Σ] the other columns of [*X*] and [*Z*] matrix are irrelevant. As illustrated in Eq. 3, the jth gene temporal variation is expressed as a linear combination of the r characteristics variables. Where, the $Y_i(t)$ is the first r rows of the matrix [ΣZ^T]. It's the characteristic modes associated with matrix [A].

$$A = X\Sigma Z^T \tag{1}$$

$$X_i = \frac{1}{s_i} A Z_i \text{ For i= 1, r} \tag{2}$$

$$A_i(t) = \sum_{i=1}^{r} X_{ji} Y_i(t) \tag{3}$$

The independent component analysis (ICA) (Hyvarinen, Karhunen, & Oja, 2001) (Liebermeister, 2002) is another gene regulatory network analysis technique. The ICA is an unsupervised exploratory analysis technique which models the gene expression data matrix [*A*]using hidden variables [*Y*]as expressed in Eq. 4 and the value of each A_{il} is expressed in Eq.5.The values of [*X*] matrix are the new "independent component" variables. The statistical dependences between the columns of matrix [*X*] must be minimized. As shown in Eq.6 the statistical dependences between variables is computed by mutual information *MI*. Where, Z_k and *Z* is the entropy of the kth variable and the total entropy respectively (Cover & Thomas,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1991). Minimizing the mutual information *MI* is equivalent to minimizing the marginal entropies Z_k since the total entropy *Z* remains constant under the linear transformation. The ICA shows high fraction values around zero; therefore it can identify the approximately sparse components. To avoid this limitation Hyvarinen presented the Fast ICA algorithm (Aapo, 1999). Where, the hidden variables [*Y*] (expressed in Eq. 7) is the product of the *B* and $C^{1/2}$. The $C^{1/2}$ is the linear correlation of the data covariance matrix *C* (Walpole, Myers, Myers, & Ye, 1993). The rotation matrix *R* is initialized to random values and adjusted to minimize the statistical dependence between the independent components. The ICA suffers from the data sensitivity particularly the regulatory variables whose influence of the genes follows the Super Gaussian distribution (Liebermeister, 2002).

$$A = XY \tag{4}$$

$$A_{il} = \sum_{K} X_{ik} Y_{kl} \tag{5}$$

$$MI = \sum_{K} Z_{k} - Z \tag{6}$$

$$Y = RC^{1/2} \tag{7}$$

The gene regulatory network is driven by hidden regulatory signals. Hence, the goal of the gene regulatory network analysis technique is to uncover these hidden signals. These hidden regulatory singles are Transcription Factors (TFs) and are proteins involved in the processes of converting or transcribing DNA into RNA. The traditional computational method such as PCA and ICA ignore the underlying network structure and the decomposition is based on statistical constraints. Hence the provided model may not contain biologically or physically meaningful signals. Furthermore, these dimensional reduction techniques don't address the hidden dynamic reconstruction problems. In addition, PAC and ICA restrict the data to be mutually orthogonal and statistically independent. To avoid these limitations Liao et al. presented the Network Component Analysis (NCA) technique (Liao, et al., 2003). The mathematical model is illustrated in Eq. 4 where [*A*] is the data matrix of size (M x N) and [*X*]is the connectivity matrix of size (M x L) which encodes the connectivity strength (transcription regulation strength) between regulatory signals (TFs) and the output domain (gene expression data). In addition, the single matrix [*Y*] is of size (L x N) where L is the number of the regulatory signals which is much smaller than M. The decomposition of [*A*] into two matrices [*X*][*Y*] is an inverse problem which has no unique solution. Therefore, further assumptions are needed. These assumptions are called NCA criteria which are as follows:

- The connectivity matrix [*X*] must have a full column rank
- The connectivity matrix [*X*] must still have a full row rank when a node is removed which implies that [*X*] must have L-1 zeros
- The single matrix [*Y*] must have a full row rank

The NCA is an iterative algorithm where initial guess of the connectivity matrix [*X*] is formed by setting all the elements corresponding to missing edges between the regulatory layer and the output layer to zero moreover, the remaining elements are initialized to an arbitrary value. In addition, it suf-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

fers from the computational instability and multiple local solution problems. Therefore, Change et al. presented the FastNCA (Fast Network Component Analysis) algorithm (Chang, Ding, Hung, & Fung, 2008). FastNCA is faster than NCA since it is a non-iterative algorithm; furthermore it avoids the NCA limitations. The model of the gene regulatory network is shown in Eq. 4 and Eq.8 illustrates the model with noise. The FastNCA algorithm is illustrated in algorithm 1.

$$B = A + N = XY + N \tag{8}$$

Algorithm 1. FastNCA
Input: [A]: data matrix
Output: Gene Regulatory Network
Step 1: Perform rank-L EYM (Eckart–Young–Mirsky) approximation of *B*by SVD
Step 2: Let $W = U_L$ (left singular vector)
Step 3: Estimate connectivity matrix [*X*]
Step 3.1: For i=1 to L

Re-order rows of W such that the i[th] column of *X* has the form $a_i = \begin{bmatrix} \tilde{a_i} \\ 0 \end{bmatrix}$

Partition $W = \begin{bmatrix} W_c \\ W_r \end{bmatrix}$

Get $[V_0]$ the right singular vectors by applying SVD to W_r
Compute $\tilde{a_i}$ = the left singular vector of $W_c V_0 V_0^T$
Step 4: Estimate the [*Y*] matrix

The regulatory network is critical for understanding the pathological phenotypes and the normal cell physiology. However, the existing computational methods are successful only in the case of lower eukaryotes with simple genomes. Hence, Margolin et al. presented ARACNE (Margolin, et al., 2006) (**A**lgorithm for the **R**econstruction of **A**ccurate **C**ellular Network**s**) which is designed to scale up to the regulatory network complexity. ARACNE is Mutual Information (MI) based on gene regulatory network analysis. That eliminates the majority of the indirect interactions inferred by co-expression. ARACNE computes the MI using the Gaussian Kernel estimator (Beirlant, Dudewicz, Gyorfi, & Van der Meulen, 1997). Another MI estimator is based on B-spline function (Shi, Schmidt, Liu, & Muller-Wittig, 2011) and k-nearest neighbor distances (Kraskov, Stogbauer, & Grassberger, 2004).

Another trend of the gene regulatory network analysis technique is based on the reverse engineering concept. Where, a mathematical model is fitted to the gene expression data. The reverse engineering is the top-down approach in which the data is used to infer the parameter values for the system model. The most of recent reveres engineering techniques are based on expression data from gene expression microarrays. However, most of them don't take temporal spatial aspects of gene expression data into consideration. Nanfack et al. presented the island Evolutionary Strategy (iEs) (Fomekong-Nanfack, Kaandorp, & Blom, 2007) technique. Furthermore, some gene regulatory network analysis techniques are based on the regression algorithms (Gregoretti, Belcastro, Di Bernardo, & Oliva, 2010). Furthermore, there are some researches that focus on the biological point of view such asexploringthe functional and regulatory network of PIP co-modulated genes in human breast cancer. Marie-Anne Debily et al. (Debily,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2009) performed gene expression profiling and network analysis studies on breast cancer cell lines which presented different PIP expression levels. The functional analysis is performed using the Ingenuity Pathway Analysis (IPA) tool. Then, a network analysis technique is performed to investigate the relationship between genes and gene products. These studies proposed that the PIP gene expression is associated with a decrease in cell proliferation, migration potential and increase of apoptotic pathways. Also, they found that the STAT5 (Signal Transducer and Activator of Transcription 5) motif has an important role in a PIP expression regulatory network.

Parallel Techniques

The gene regulatory network computational methods are computationally expensive and time consuming tasks. Since, it is affected by the huge data size. Therefore, parallel algorithms are needed to enhance the techniques performance. Gabrele Sales et al. presented a parallel package called parmigene (**PAR**allel **M**utual **I**nformation calculation for **GE**ne **NE**twork reconstruction) (Romualdi & Chiara, 2011). Parmigene is a parallel R package for mutual information and gene network reconstruction. Parmigene implement the network inference using a minimally biased MI estimator based on the k-nearest neighbor distances (Kraskov, Stogbauer, & Grassberger, 2004). Also, it uses OpenMP to implement gene regulatory network. Table 1 shows the runtime of Parmigene against the minet algorithm (Meyer, Lafitte, & Bontempi, 2008). Parmigene is 12 times faster in MI estimation and 1.3 times faster than ARACNE algorithm (Margolin, et al., 2006). The Parmigene achieved speedups of up to 50 on quad-core system.

Haixiang Shi et al. (Shi, Schmidt, Liu, & Muller-Wittig, 2011) presented accelerated B-spline functions based on mutual information (MI) estimation regulatory network algorithm on GPUs. The B-spline function based on MI estimation is accelerated using the CUDA programming model. Also, a shared memory is used for fast input/output operations moreover, a double precision floating point arithmetic and efficient partitioning schema is used to overcome the GPU device memory limitations. Haixiang Shi et al. accelerated the B-spline function based mutual information (MI) estimations by using the fine-grained model where threads in the same thread block co-operate to compute the MI value for each pair of genes. The achieved speedup is up to 82 on aNvidia Tesla C2050 GPU compared to the multi-threaded version.

Jostins et al. presented synchronous and asynchronous versions of the Parallel island Evolutionary Strategy (piES). The piES is a parallel version of the serial island Evolutionary Strategy (iEs) (Fomekong-Nanfack, Kaandorp, & Blom, 2007) developed by Fomekong et al. The island Evolutionary Strategy algorithm operates on N populations of individuals, each with a population size x. Each population is initialized independently and selection, recombination and mutation are performed only within populations. A migration operation links the population in the serial algorithm; the best individual from each island is copied to a population randomly selected from a uniform distribution. Migration occurs in every m generation.. In the parallel version each population runs on a separate processor. The speedup

Table 1. Runtime of Parmigene against the minet algorithm in minute

No. of Genes	Minet	Parmigene
100	0.02	0.005
1000	4.20	2.21
8799	2120.7	171.8

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of synchronous is 8.7 to 29.2 compared to the sequential piES. On the other hand, the speedup of the asynchronous version is 10.3 to 38.5 since the processors send and receive communication regardless the others' activity which eliminates the waiting time and leads to additional speedups. Table 2 and Figure 3 illustrate the runtime (in minutes) of the synchronous and asynchronous version of piES verses different numbers of the processing nodes.

Gregoretti et al. presented a parallel network identification technique based on the Multiple Regression algorithm (NIR) (Gregoretti, Belcastro, Di Bernardo, & Oliva, 2010). The gene network is described as a system of differential equations where each equation describes the variation in time of the concentration of a particular gene as non-linear function of the concentrations of the other genes. The parallelization of this algorithm depends on assigning different genes to different computing processes equation describes the variation in time of the concentration of a particular gene as a non-linear. The speedup of algorithm is 10.1 to 102.0. Table 3 and Figure 4 show the runtimes of the NIR algorithm verses different numbers of the processing nodes.

Belcastro et al. (Belcastro, et al., 2012) presented a parallel reverse engineering gene regulatory network algorithm based on computing pair-wise Mutual Information between each gene pair. Also, communities within the gene network are discovered using a parallel hierarchical clustering. Network communities are enriched in genes involved in the same biological functions. The algorithm distributes the gene expression data across computing processors which is logically organized in a topological ring. In other words, the processing nodes are named P_0 to P_{p-1} where P_j follows P_i in case of $j > i$. In addition, P_0 follows $P_{p-1.}$ Figure 5 illustrates a ring topology example of 5 processing nodes.

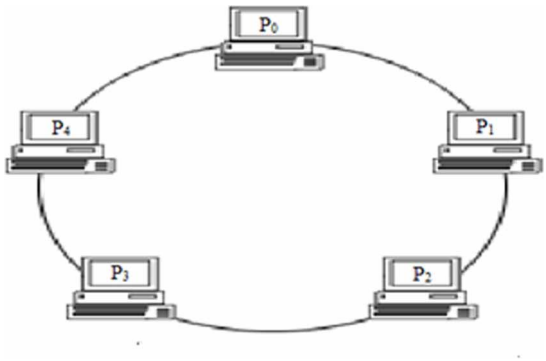
Time Series

There are researches that focus on the regulatory network construction of time series data. The construction of time series regulatory networks is the main problem in molecular biology. The time series is gene expression data measured in different time steps. It's used to identify the intermediate events between perturbation and expression responses. Also, it provides information about the chronological order of regulatory events and it provides information about the gene regulatory network edges direction. One of the time series data analyses is studying the gene response variance under different conditions.

Raychaudhuri et al. applied PCA techniques for time series data (Raychaudhuri, Stuart, & Altman, 2000) where the experiment is considered as variables. As preprocessing steps a natural log transform (Eisen, Spellman, Brown, & Botstein, 1998) is applied to avoid the influence of a gene expression level below and above one. The up-regulated genes have positive expression level while the down regulated genes have a negative expression level. Then, a covariance matrix which measures the experiments contribution in the data set is created. After that, the (n x n); where n is the number of the experiments, the covariance matrix is used to calculate the n Eigen values and their corresponding Eigenvector, where, each Eigenvector defines a principle component. The component can be considered as a weighted sum of the experiments where the weights are the Eigen-vector co-efficient. As shown in Eq. 9, the projection of the i^{th} gene is defined by the j^{th} principle component. Where the C_{kj} is the k^{th} co-efficient of the j^{th} principle component and the P_{ik} is the i^{th} gene expression level in the j^{th} experiment. In addition, the P'

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The ring topology



is the principle component data matrix, where the data is transformed from the original space to the principle component space. The larger Eigen values associated with the Eigenvector, the more contained information. On the other hand, the small Eigen values associated with the Eigenvector are uninformative. The components with less than (70/n)% of the overall variability are discarded. Applying the PCA on time series data is debatable because of the problems with the data point's dependency and the uneven time intervals.

$$P_{ij}^{'} = \sum_{k=1}^{n} P_{ik} C_{kj} \tag{9}$$

The analysis of time series data has many challenges. One being that it is hard to identify the correct sub-set of genes with a clear periodic signature. So, Wichert et al. (Wichert, Fokianos, & Strimmer, 2004) presented two statistical methods for signal detection and gene selection. Also, a statistical test was presented to identify genes relevant for the cell cycle and, a graphical tool is presented to assess whether the data contains periodic transcripts.

The genes co-expression in large data implies co-regulations and gene interactions; however it doesn't provide enough information about interaction directions. In fact, the genetic data helps the scientists to map DNA variations to RNA level variations while as mentioned before; the time series data contains information about the chronological order of regulatory events. So, Yeung et al. (Yeung, et al., 2011) presented a Bayesian model averaging regression algorithm that incorporate external information from diverse data types to infer regulatory networks from the time series and genetics data.

Jianguo et al. presented comprehensive servers for the time series metabolomic data analysis (Xia, Mandal, Sinelnikov, Broadhurst, & Wishart, 2012). The server contains many modules such as quality control, function enrichment and a metabolic path way analysis. The quality control module enables users to evaluate the data quality before conducting any analysis tasks. While the functional enrichment is useful to identify biologically meaningful patterns. Moreover, the metabolic path way analysis module is useful to analyze the pathways and visualize organisms.

METHODOLOGY

The traditional genetics experiments that manipulate single genes or monitor the effects of a single gene in different experimental conditions are valid methods of gathering data about genes. However, they unearth very little information about other genes or how genes may interact with the collective gene product in a living organism. A useful technique that effectively transforms a living cell from black box into a transparent box is the Microarrays. They allow one to identify the genes that are expressed in different cell types, to learn how their expression levels change in different developmental stages or disease states and to identify the cellular processes in which they participate. This section illustrates the microarrays and the microarrays data analysis techniques. Besides that, the different parallelism techniques are discussed.

Microarrays

The DNA Microarrays technology is a high throughput experimental technique that can measure expression levels of hundreds of thousands of genes simultaneously. In fact, expression level of the gene is estimated by measuring the amount of mRNA for that gene. Actually, the procedure of a DNA microarray experiment includes multiple steps from sample preparation to data analysis (Figure 6), among which hybridization is a central process. Where, the sample that contains the targets to be investigated is added to the DNA chip to allow their binding to the probes fixed on the chip, resulting in a characteristic binding pattern representing the levels of gene expression of the sample. The sample itself is labeled prior to the hybridization and the mostoftenused labels are fluorescence labels that allow detection of the binding event. After the hybridization, the chip is washed and then fluorescence intensities on the chip are read and recorded by a scanning or imaging device. Raw data reflecting the fluorescence intensities are statistically analyzed and often shown by fold changes as compared to control (Li & Li, 2008).

The first step in microarrays experiment is the sample preparation where a microarray is prepared either specifically for the genes of interest or for all of the genes in the organism of interest's genome. This is done by synthesizing a complementary probe to the mRNA for each gene. Namely, the most common technique for doing this is to use robotic systems to individually synthesize thousands of probes, with one spot containing thousands of oligonucleotide probes for a single gene. After that, you can extract the mRNA from cells you wish to analyze, this mRNA represents all of the expressed genes in those cells and then the mRNA is labeled with a fluorescent dye. The second step is Hybridization where both the experimental and the control mRNA are simultaneously washed over the microarray. Whenever the probes on a given spot interact with a complementary mRNA strand, the two will hybridize, thus binding the mRNA to the microarray. After a certain period of time the remaining solution is discarded and the microarray is gently rinsed. In the third step; Dictation, the microarray is scanned optically using Microarrays Scanner and the ratios of red to green are computed. Since red represents the control mRNA and green represents the experimental mRNA, the colors on each spot will reflect how the expression of each gene was changed by the manipulation of the experimental condition. Often a new image of the microarray is formed almost exactly the same as the original, with the exception that now green means a reduction in expression and red means an increase in expression. The final step is the data acquisition and analyses of the red: green ratios which are analyzed mathematically for relationships among the genes (Cheung, et al., 1999).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The analysis of the data resulting from microarrays remains a big challenge for the huge volume of data it produces. In fact, the data analysis process involves various computational tasks (Yang, et al., 2008). As shown in Figure 7 the microarrays data analysis process starts with a sub-set extraction. In this step, the dataset is filtered to extract the differentially expressed genes, (discriminator genes) which are the genes with significantly different expression into two defined groups of microarray experiments. The output of this step can be the input of other analysis tasks such as component analysis, clustering and network analysis. The aim of a gene expression search is to find a set of genes that have similar expression patterns with a target gene. Actually, when the function of a target gene is unknown, inspecting the function of genes with expression patterns similar to the target gene may reveal the function of the target gene. On the other hand, when the function of the target gene is known, we can have an insight into how similarly/dissimilarly genes are expressed in given conditions.

The microarrays data clustering aims to organize genes where those with similar expression patterns are grouped together to identifying biologically relevant groups of genes. While, the aim of component analysis is studying the ways in which genes responses varies under different conditions. Moreover, network analysis (Haman & Valenta, 2013) is a powerful analysis tool to understand real world phenomena. There are two types of regularity network, gene regularity network and PPI (protein-protein interaction) network. The gene regulatory network or genetic regulatory network (GRN) is a group of DNA segments which interact with each other through their RNA and protein expression products in an indirect way.

Figure 6. Workflow of a DNA microarray experiment

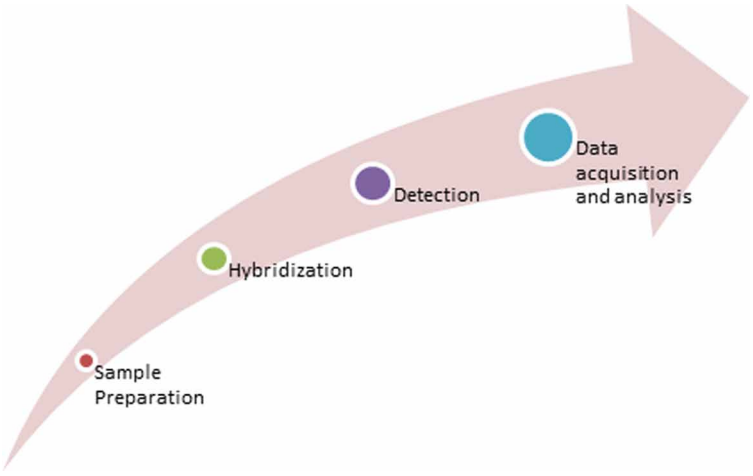

Figure 7. Microarrays data analysis tasks

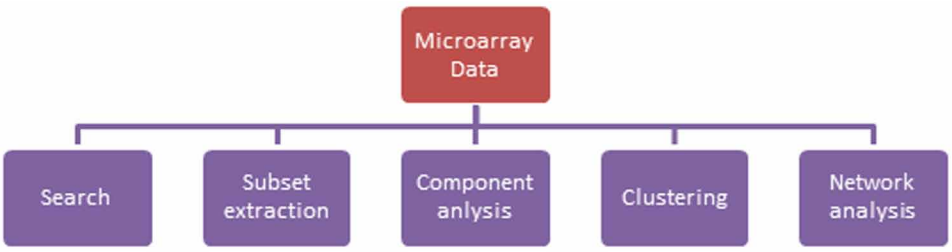

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Also, they interact with the other substances in the cell, actually, these interactions governing the gene transcription rates into mRNA. On the other hand, the protein-protein interaction network plays a key role in understanding the protein docking process and the cellular system working method, due to the huge size of data sets produced by microarray technology, analysis tasks are usually computationally intensive and time-consuming. Therefore, it requires high-performance computing power.

Parallelism Techniques

In the past decades it was believed that program execution time was improved by creating faster and more efficient processors to deal with the growing massive volumes of the data. However, parallel computing was introduced to execute programs in parallel instead of sequential executions (Kumar, Grama, Gupta, & Karypis, 2003). The program is divided into tasks and the independent tasks are executed at the same time on different processing nodes. In this way, the parallel computing concept succeeded to minimize the cost of building expensive hardware since it benefits from the computing power of different processors instead of increasing the computing power of one processor. Parallel computing models are categorized into two areas: Process interaction and problem decomposition. The process interaction focuses on how the processes communicate with each other. While, the problem decomposition focuses on how the program is divided into independent tasks.

The problem decomposition is classified into two trends: Task parallelism and data parallelism. On one hand, the task parallelism focuses on the decomposition of the program into independent tasks which are executed simultaneously. While, the data parallelism focuses on performing operations on a dataset. Where, a set of tasks will operate on separate partitions of the data independently. In the shared memory model, the data will be shared between the processes while in the distributed memory the data will be divided between the memories of the processes.

The process interaction is categorized into two main categories; shared memory architecture (Karp, 1988) (Hager & Wellein, 2010) and the distributed memory architecture (Hager & Wellein, 2010) (also called message passing architecture). As shown in Figure 8-a, in the distributed memory architecture the memory is distributed and the processes communicate by sending messages. These communications can be asynchronous or synchronous. On the other hand in the shared memory architecture, the memory is shared among all the processes and the processes communicate implicitly by updating shared variables (Figure 8-b). The shared memory model requires protection mechanisms such as locks, semaphores and monitors to control concurrent access. Sometimes, the two architectures can be merged together to benefit from the full computing power of the hardware, this architecture is called hybrid architecture as shown in Figure 8-c. In this case, the computational tasks are distributed among the processing nodes and each node executes its own task on a number of threads.

Another form of the distributed memory architecture is cloud computing (Erl, Puttini, & Mahmood, 2013) where groups of remote servers are deployed (Figure 8-d). The main advantage of cloud computing is that the user focuses only on the business core instead of being involved in the hardware management. The deployment model of cloud computing is classified into three categories private, public and hybrid. In the private cloud the infrastructure is operated for a single organization. On the other hand, in the public cloud the infrastructure is rendered for public usage, while, the hybrid model is a collection of the private and the public cloud models.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The graphic processing unit (GPU) (also called visual processing unit (VPU)) can be used to enhance the performance. The GPU is an electronic circuit used to accelerate image creation and manipulation for the output unit's and it's more efficient than the CPU (central processing unit) because of its parallel architecture. The famous GPU programming language is CUDA (Compute United Device Architecture) (Sanders & Kandrot, 2010) and OpenCL (Open Computing Language) (Gaster, Howes, Kaeli, Mistry, & Schaa, 2012). As shown in Figure 9 the CUDA execution model consists of a grid where the grid is a set of blocks and each block is a set of concurrent threads and each thread has a unique ID. The threads in the same block communicate through the per block shared memory, in addition, the threads in the same block are synchronized using barriers. The threads in different blocks have no direct communication and cannot be synchronized directly. CUDA supports two types of parallelism, the coarse-grained and fine-grained. In the coarse-grained, a large number of threads run independently in parallels, whereas in the fine-grained, the threads located in the same thread block co-operate simultaneously on some shared memory space. As illustrated in Figure 10 the OpenCL execution model consists of Index space which consists of a set of work groups. Each workgroup contains a number of independent work items.

CHALLENGES

One of the microarrays data analysis tasks is the gene regulatory network. The gene regulatory network aims to study the genes interactions topological organization and gene-to-gene influences. Where each gene is represented as a node and regulatory interactions between genes is represented as edges. The gene regulatory can be classified into four categories; component analyses, mutual information, reverse engineering and regression techniques. One of the component analysis techniques is the principle component analysis (PCA) technique (Raychaudhuri, Stuart, & Altman, 2000). The PCAis a dimensionality reduction technique which determines the key variables that explain the difference in the data and simplify the data visualization and analysis. The PCA assumes that the data is orthogonal which is not always valid in biological data. Another trend is the singular value decomposition (SVD) technique (Watkins, 2004) (Holter, et al., 2000)which aims to uncover the underlying patters in the gene expression data. Where, the complex gene expression profiles can be captured by a small number of the characteristic modes which capture the temporal gene expression change pattern. SVD suffers from the noise sensitivity also some results aren't meaningful. In addition, another trend is the independent component analysis (ICA) which may provide multiple local solutions. To avoid the limitations of PCA, SVD and ICA Liao et al. presented the Network Component Analysis (NCA) technique (Liao, et al., 2003).Although that, it is computational expensive and provides multi-local solutions. In addition, Change et al. presented the FastNCA (Fast Network Component Analysis) algorithm (Chang, Ding, Hung, & Fung, 2008) which is faster than NCA. However, the FastNCA is a sequential algorithm.

The regulatory network is critical for understanding the pathological phenotypes and the normal cell physiology. Mutual information (MI) based techniques is another trend for the gene regulatory network analysis.Margolin et al. presented ARACNE (Margolin, et al., 2006) (**A**lgorithm for the **R**econstruction of **A**ccurate **C**ellular Network**s**) which is designed to scale up to the regulatory network complexity. ARACNE computes the MI using the Gaussian Kernel estimator (Beirlant, Dudewicz, Gyorfi, & Van der Meulen, 1997). Another MI estimator is based on B-spline function (Shi, Schmidt, Liu, & Muller-Wittig, 2011) and k-nearest neighbor distances (Kraskov, Stogbauer, & Grassberger, 2004). The drawback of the MI based techniques is biased to the mutual information estimation method.

Figure 9. The CUDA execution model

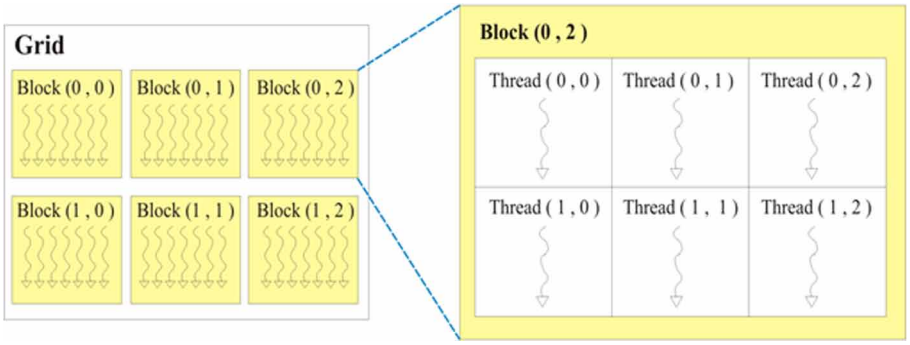

Figure 10. The OpenCL execution model

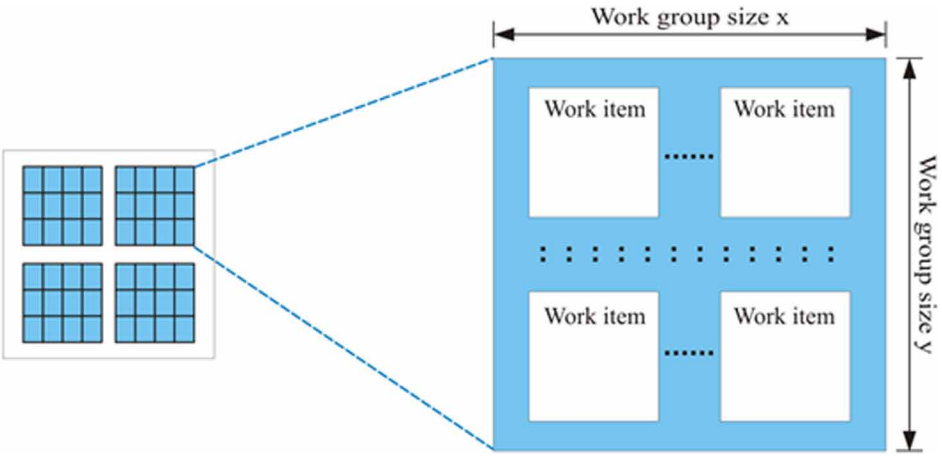

Another trend of the gene regulatory network analysis technique is based on the reverse engineering concept. Where, a mathematical model is fitted to the gene expression data. The reverse engineering is the top-down approach in which the data is used to infer the parameter values for the system model. The reverse engineering techniques assume that the data is linear which is always valid in the biological data. In addition, In addition, these techniques don't take the temporal spatial aspects of gene expression data into consideration.

The regression based techniques is another trend of the gene regulatory network analysis techniques. Where, the gene network is described as a system of differential equations where each equation describes the variation in time of the concentration of a particular gene as non-linear function of the concentrations of the other genes. The drawback of these techniques is the noise sensitive. Furthermore, the commons drawback of these techniques is the computational expensive where the techniques runtime is affected by the size of data. The drawbacks of the gene regulatory analysis techniques are summarized in Table 4. Since, almost all of these techniques are computationally intensive and time-consuming, parallel algorithms are needed to enhance the techniques performance.

PROPOSED ARCHITECTURE

The gene expression data analysis plays important role in understanding the gene functions and relationships. One of the gene expression data analysis tasks is the gene regulatory network which aims to study how the genes interact with each other and the gene-to-gene influences. Moreover, the regulatory network is critical for understanding the pathological phenotypes and the normal cell physiology. Unfortunately, most of the recent techniques are effected be the huge data size. Therefore, this work proposes solution for gene regulatory network using a high performance technique to enhance both the speed and the efficiency called PAGeneRN (**P**arallel **A**rchitecture for **GeneR**egulatory **N**etwork).In fact, the parallel techniques can be divided into two categories based on the parallelism type. Some algorithms are functionality paralyzed where each processing node executes different task simultaneously. On the other hand, other algorithms are data paralyzed where each processing node execute the same function on a chunk of the data simultaneously.

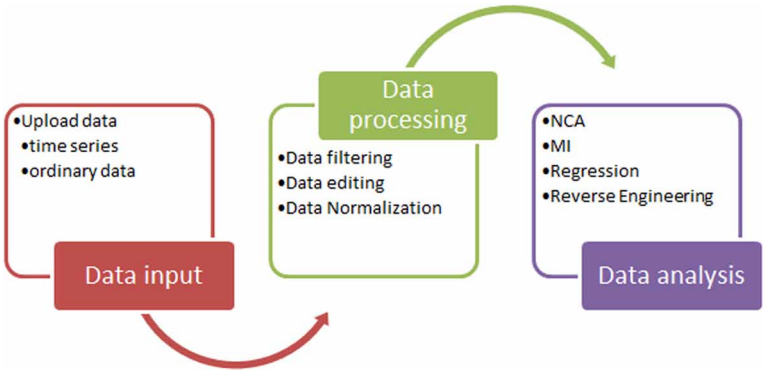
The proposed architecture (PAGeneRN) will combine the two different parallelism methodologies (data and functionality parallelism model) to take the full advantage of the high performance computing power. In addition, the proposed algorithm will use the computational power of the GPUs. Furthermore, a complete gene regulatory analysis framework is proposed. As shown in Figure 11 the proposed framework consists of three main modules data input, data processing and finally the data analysis module.

The Data input module enable user to input the data to the system. The data may be ordinary gene expression data or time-series. The next module is the data processing which aims to transform the raw data into cleaner data through set of procedures such as filtering and data editing. In other words, the data processing module has different options such as data filtering, data editing and data normalization option. Data filtering option enables user to remove empty or low quality data points from the dataset. On the other hand, the data editing option enable user to delete/edit data points. While, the data normalization is important for the biological data analysis where some techniques assume that the data is normally distributed. Also, data normalization reduces the systematic bias in the data. The last module is the data analysis module which is the core module. The data analysis module consists of different parallel gene regulatory network analysis techniques.

The data analysis module consists of a parallel version of the FastNCA algorithm (Chang, Ding, Hung, & Fung, 2008) (illustrated in algorithm 2 and 3). Where, the master processing node will distribute the data among the worker node. Where each worker will take a chunk of the data of size N/P (N is data

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Proposed architecture modules



size). In addition, the framework will contain Mutual information based technique where the mutual information estimated using the cubic B-spline. In addition, the framework will contain parallel version of regression and reverse engineering techniques. Moreover, these techniques can be combined with the genetic information to avoid the meaningless results problem.

Algorithm 2. FastNCA parallel version – master node
Input: [A]: data matrix
Output: Gene Regulatory Network
Step 1: Perform rank-L EYM (Eckart–Young–Mirsky) approximation of *B* by SVD
Step 2: Let W = U_L (left singular vector)
Step 3: Estimate connectivity matrix [*X*] in parallel
Step 3.1: Send chunk of the data for each processing node
Step 3.2: Collect data from the processing nodes
Step 4: Estimate the [*Y*] matrix
Algorithm 3. FastNCA parallel version – worker node
Input: [W]: left singular vector matrix
Output: Connectivity sub matrix [*X*]
Step 1: Parallel for i=1 to L

Re-order rows of W such that the i[th] column of *X* has the form $a_i = \begin{bmatrix} \tilde{a_i} \\ 0 \end{bmatrix}$

Partition $W = \begin{bmatrix} W_c \\ W_r \end{bmatrix}$

Get [V_0] the right singular vectors by applying SVD to W_r
Compute $\tilde{a_i}$ = the left singular vector of $W_c V_0 V_0^T$
Step 2: Send connectivity sub matrix [*X*] to the master node

CONCLUSION

The gene regulatory network is one of the microarrays data analysis tasks which aims to study the gene-to-gene influences and genes interactions topological organization. Where each gene is represented as a node and regulatory interactions between genes is represented as edges. Many researches focused on the gene regulatory network analysis. This work presents a background, mathematical models and comparisons about the gene regulatory networks analysis different techniques. The gene regulatory is classified into four categories; component analyses, mutual information, reverse engineering and regression techniques. Furthermore, the component analysis techniques are categorized as principle component analysis (PCA), singular value decomposition (SVD), independent component analysis (ICA) and network component analysis (NCA) technique. The PCA and Mutual information based techniques suffers from assuming that the data is orthogonal and linear respectively. On the other hand, the SVD technique sometimes provides non-meaningful result also it suffers from the noise sensitivity. Furthermore, the ICA may provide multiple local solutions. However, the NCA avoids the problems of the PCA, SVD and ICA techniques, it is a computational expensive. In addition the mutual information based techniques is biased to the mutual information estimation method. Furthermore, the regression technique is noise sensitive. This paper also proposes PAGeneRN (**P**arallel **A**rchitecture for **Gene R**egulatory **N**etwork) gene regulatory analysis architecture which uses a parallel model to enhance the technique performance. The proposed architecture consists of three main modules: Data input, data processing and the data analysis module. The Data input module enable user to input the data to the system. While, the data processing aims to transform the raw data into cleaner data through set of procedures such as filtering and data editing. Furthermore, the core module is data analysis module which consists of different parallel gene regulatory network analysis techniques.

Chapter 56
Research Perspectives on Functional Micro and Nano Scale Coatings:
New Advances in Nanocomposite Coatings for Severe Applications

ABSTRACT

Research topics related to the production of nanocomposites are the most important directions of development of new semiconductor engineering, ensuring high nanocomposites obtaining useful properties in the scope of biophysical characteristics, biomedical and piezoelectric applications. We present two case studies as Hydroxyapatite are in medical applications and aluminum nitride as acoustic wave sensor. Hydroxyapatite, is the main inorganic structure of the tooth enamel and bone and is a biomaterial that is commonly used in biomedical applications that involve bone substitution, drug delivery and bone regeneration because of its excellent biocompatibility, high bioactivity and good osseoconductivity. Since the past decade. Aluminum nitride (AlN), an electrical insulating ceramic with a wide band gap of 6.3 eV, is a potentially useful dielectric material very important in fields such as optoelectronic and micro electronics.

INTRODUCTION

In recent years, there has been a breakthrough in the research of new materials with increasingly complex structures with properties of ionic and electronic conduction (Morkoc, 2013). Such materials have applications in important areas of technology as components of many optoelectronic devices - among the new materials studied highlights the metal nitrides - and hydroxyapatite nanostructured films fabricated by RF magnetron sputtering for biomedical applications (Zhang, 2013).

In general, semiconductor nitrides are the group of inorganic compounds consisting of nitrogen and other more electropositive element, except for halogens and hydrogen. Nitrides of elements such as boron, titanium, zirconium, aluminum, and silicon are hard, stable at high temperatures, and are resistant to chemical agents. At a much smaller scale, coatings are used in numerous electronic products (both consumer and industrial electronics) and biomedical products.

Currently, our society is increasingly immersed in nanotechnology. They are shown, two approaches to nanocoatings applications that impact our daily lives. In section 1, a new method of magnetic confinement of plasmas RF hydroxyapatite has shown to produce a high crystalline quality for biomedical applications. In section 2, aluminum nitride nanostructures grown via pulsed laser deposition - PLD that has been used as substrates for the manufacture of acoustic wave devices - SAW are highly demanded by the telecommunications industry.

1. HYDROXYAPATITE NANOSTRUCTURED FILMS FABRICATED BY RF MAGNETRON SPUTTERING FOR BIOMEDICAL APPLICATIONS

Hydroxyapatite - HA ($Ca_{10}(PO_4)_6(OH)_2$),(Morgan, Wilson, Elliott, Dowker, & Anderson, 2000) is the main inorganic structure of the bone and enamel teeth and also is the main bioceramic that is commonly used in biomedical applications that involve drug delivery, (Hollister, 2005; Vallet-Regí & Ruiz-Hernández, 2011) bone repair and bone regeneration due its excellent properties of osteoinduction, osteoconduction and osseointegration (Astala & Stott, 2008; Paul & Sharma, 2006). Since past decades, the HA has been used as a bioactive coatings to improve the osteoconductivity of metallic implants for the orthopaedic applications. Metals as titanium and alloys have not the bioactive capacity, different deposition techniques to produce calcium phosphate (CaP) coatings has been developed to improve the osseointegration, osteoconduction and osteoinduction of the metallic implants (Dos Santos et al., 2010; Macaskie et al., 2005; Socol et al., 2004; Ueda, Narushima, Goto, Taira, & Katsube, 2007; Wang et al., 2006; Wen, Xu, Hu, & Hodgson, 2007).

Chemical and physical deposition processes are used to synthesize HA as coatings over a metallic surface, these deposition techniques are: biomimetics, (Uchida, Oyane, Kim, Kokubo, & Ito, 2004) sol-gel routes, (Melde & Stein, 2002; Padilla, Roman, Carenas, & Vallet-Regı, 2005; K. Zhang, Francis, Yan, & Stein, 2005) electrochemical deposition,(Liu, Savino, & Yates, 2011; Narayanan, Seshadri, Kwon, & Kim, 2008; Wang, Eliaz, & Hobbs, 2011) and others,(Li, Hong, Yu, & Qi, 2010; Li & Qi, 2008) as well as plasma spray, (Dong, Khor, Quek, White, & Cheang, 2003; Ellies, Nelson, & Featherstone, 1992; Khor, Dong, Quek, & Cheang, 2000) Pulsed Laser Deposition (PLD), (Carradò, 2011; Joanni et al., 2004) Ion and Electron Beam Deposition (IBD, EBD),(Jeong, Choe, & Eun, 2011; Rabiei et al., 2006) Electron Cyclotron Resonance deposition (ECR)(Akazawa & Ueno, 2013, 2014) and Radio Frequency Magnetron Sputtering (RF-MS) (Akazawa & Ueno, 2014; Boyd, Meenan, & Leyland, 2006). The chal-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

lenge is produce a thin, dense, adherent, stoichiometric and crystalline HA coating over the implant surface, thus the HA coatings will be stable in a biological environments,(Bauer, Schmuki, von der Mark, & Park, 2013) and not to degrade along the time when inside of the human body. Besides, all deposition techniques has been adapted to produce thin coatings with thickness less than of 500 nm to improve the adhesion to the substrate and to preserve the original topography of the metallic implants (Akazawa & Ueno, 2013). Nevertheless, it is difficult produce a thin HA coating without the formation of undesirables amorphous calcium phosphate phases (ACP) (Ferro, Barinov, Rau, Teghil, & Latini, 2005; Hahn et al., 2011; Surmenev, 2012; Yonggang, Wolke, Yubao, & Jansen, 2007; Zhang, 2013). Usually, CaP coatings are commonly treated at temperatures up to 900º C to transform the amorphous phases (ACP) in a HA structure (Akazawa & Ueno, 2013; Surmenev, 2012; S Zhang et al., 2007). In addition, these thermal treatment may produce undesirables phases mainly as tricalcium phosphate (α,β –TCP) and calcium oxide (CaO) and induces the crack and release of the coatings (Jeong et al., 2011; Surmenev, 2012; S Zhang et al., 2007). The tricalcium phosphate ($Ca_3(PO_4)_2$) is a CaP material with a dissolution rate greater than the hydroxyapatite and the CaO is a material that produce high toxicity levels when in contact with proteins and cell of the body.

On the other hand, to optimize the properties of osteoinduction, osteoconduction and osseointegration of the hydroxyapatite materials (in bulk) is necessary functionalize the chemical-structure with adequate quantities of ions substitutions as for example: Zn^{2+}, Sr^{2+}, Mn^{2+}, Mg^{2+}, Fe^{3+}, $(CO_3)^{2-}$, $(SiO_4)^{4-}$ and F^- by Ca^{2+}, $(PO_4)^{3-}$ and $(OH)^-$ (Miao et al., 2008; Pereiro et al., 2012; Surmeneva et al., 2013). In processes of coatings fabrication by chemical deposition is possible functionalize the HA structure with many other ions substitution, controlling mainly the stoichiometry and crystallinity but not the density, roughness, adhesion and thickness (Kim & Choe, 2011; Surmeneva et al., 2013). The physical deposition using plasma processes, produce a functional HA structure is not very common due to the complication of tune the plasma properties and control the deposition parameters to form this complex structure ($Ca_{10-m}M_m(PO_4)_{6-n}X_n(OH)_{2-q}Z_q$). In addition, several studies have shown that the Radio Frequency Magnetron Sputtering technique (RF-MS) have potential for applications in biomedical implant, that due to the use of a stable plasma along the time it could produce a nanostructured coatings with low surface roughness of high density and show good adhesion to the substrate (Nelea, Morosanu, Iliescu, & Mihailescu, 2003; Snyders et al., 2008; Snyders et al., 2007). Nevertheless, inadequate sputtering processes may produce low temperatures, energies and diffusion in the plasma that may inhibit the growth of a nanocoatings with a correct stoichiometry and high crystalline order (Kim & Choe, 2011; Nelea et al., 2003; Shi, Chen, Yu, & Zhang, 2008; Snyders et al., 2007; Van Der Wal et al., 2006).

In other works is possible observe that the thermodynamic properties of the plasma is the main responsible of coating formation (Han, 2009; Shaginyan, Han, Shaginyan, & Musil, 2006). About this, is very important understand know control and tuning the thermodynamic properties of the plasma for each plasma configuration or geometry. In this section is discussed the production of a high crystallinity and stoichiometric nanocoatings of hydroxyapatite and functionalized hydroxyapatite with fluorine ions obtained from the tuning of a highly magnetically confined plasma by orthopedic implant applications (Hong et al., 2007; López et al., 2013; López et al., 2015; Mello et al., 2007).

1.1. Deposition Techniques of CaP Coatings by Biomedical Applications

1.1.1. Plasma Spray

Plasma spray is the first commercial deposition technique to fabricate coating of CaP on metallic implants due the low cost and practicality. This technique consists in produce a plasma jet from a discharge at high frequency together with a gas injection (Khor et al., 2000). The gases commonly used in this process to produce the plasma jet are: the acetylene, butane and argon, which these gases limits the plasma temperature. After ignition of the plasma jet is aggregate the CaP powder. The plasma produces the ionization of the CaP particles that later are ejected to the substrate to form the coating. With this deposition technique is possible obtained CaP coatings with high hardness, low fracture strength, low coefficient of thermal expansion, high porosity, thick, low adhesion between coating and substrate (Khor et al., 2000). To produce HA coatings for this technique is commonly observed additional CaP phases as: TCP and CaO (Dong et al., 2003; Ellies et al., 1992). In addition, the crystallinity, density, thickness and roughness of the coatings are difficult to control producing not adequate mechanical properties[55] that in implant applications are not efficient.

1.1.2. Sol-Gel Deposition

This chemical deposition technique is extensively used for deposit CaP coatings over metallic implants mainly due to control of the HA stoichiometry and low cost (Guipont et al., 2010; Padilla et al., 2005; K. Zhang et al., 2005). The technique consist in polymerize an organometallic in an alcohol or water solution (Sol) together with an acid or base solvent (Gel) up to produce the bioceramic (Belabbes, de Carvalho, Schleife, & Bechstedt, 2011; Schwertfeger et al., 1994). With this technique is possible produce coating, fibers and powder (Schwertfeger et al., 1994). In coatings fabrication the process can form particles size of HA equal and less than the production by plasma spray (S Zhang et al., 2007). Commonly, deposition of HA and HA substituted with other ions may produce thick, porous and cracked coatings with weak adhesion and to form amorphous phases at room temperature (Chung et al., 2006; Jallot et al., 2005; Kim & Choe, 2011; Layrolle, Ito, & Tateishi, 1998; Tredwin, Young, Neel, Georgiou, & Knowles, 2014; S Zhang et al., 2007).

1.1.3. Electrodeposition

Several works has been performed using this technique to produce HA coatings. The mainly characteristics of these CaP coatings are low temperature processing, thick coatings ($\Lambda \approx 50$ μm), cracked, non-dense, high crystallinity, easy to coat complex parts, control of the composition and microstructure and long time to depositions. The technique involve the deposit over a metallic substrate by electrolysis controlling: the composition into the aqueous environment, the temperature, length between electrodes, voltage and current applied on the metallic substrate.(Dos Santos et al., 2010) From this technique is possible produce microcrystals of HA (5 μm of size) oriented along the *c* axis of the HA structure (Dos Santos et al., 2010; Zhang, 2013).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1.1.4. Pulsed Laser Deposition

The technique involve in ionize the particles of a target from the use of a pulsed laser of high energy density. The most used laser to deposited CaP films is the KrF ($\lambda = 248$ nm), (Carradò, 2011; Socol et al., 2004) (Iliescu, Nelea, Werckmann, & Mihailescu, 2004; Pelletier, Carradò, Faerber, & Mihailescu, 2011; Rau et al., 2010) but others are also used as: Nd:YaG ($\lambda = 355$ nm) and ArF ($\lambda = 193$ nm)(Jedynski, Hoffman, Mroz, & Szymanski, 2008; Mróz, Jedyński, Prokopiuk, Ślósarczyk, & Paszkiewicz, 2009; Saju, Reshmi, Jayadas, James, & Jayaraj, 2009).

When the laser beam of high energy strike the target surface the firsts micrometric layers may absorbed this energy producing a high atomic and molecular vibration, dissociating the atomic bond and consequently producing the ionization and ablations of atoms, radicals, clusters and agglomerates of particles that will be deposited over a substrate. The PLD technique may reproduce HA coatings with the same target stoichiometry, as well as, can reduce the thickness up to 50 nm. Commonly, these films produce a combination of crystalline and amorphous phases with high roughness and porous but with a better adhesion between substrate and coating (K. Zhang et al., 2005; Sam Zhang, 2013; S Zhang et al., 2007). In addition, is common perform a threat thermal *in-situ* on the substrate (TT ~ 350° C - 600° C --> 350 °C - 600 °C) to induce a formation of only crystalline HA phase (Surmenev, 2012; Surmenev et al., 2011).

1.1.5. Radio Frequency Magnetron Sputtering (RFMS)

This is the principal physical deposition technique to produce CaP nanocoatings (Akazawa & Ueno, 2013, 2014; Boyd, Duffy, McCann, Cairns, & Meenan, 2007; Feddes, Wolke, Jansen, & Vredenberg, 2003; Padilla et al., 2005; Snyders et al., 2007; Surmenev, 2012; Surmenev et al., 2011; Van Der Wal et al., 2006; Xu, Long, Sim, Diong, & Ostrikov, 2005; Yamaguchi, Tanaka, & Ide-Ektessabi, 2006). This technique consist in ionize an inert gas, commonly argon (Ar), producing a plasma which is confined by a magnetic field generated by the magnetrons. The Ar ions of the plasma are accelerated in direction to the cathode\target striking the target surface and consequently producing the pulverization of the target atoms and finally the deposition of these atoms over the substrate surface.

Most of coatings produced at room temperature by RFMS are composed by a lower crystalline order (some only of amorphous phase) and non-stoichiometric ($Ca/P \neq 1.67$). Threat thermal at $T > 500°$ C --> 500 °C (*in-situ* and *ex-situ*) are necessary to induce the crystallinity of the coatings and transform the ACP to HA coating (Boyd et al., 2007; Boyd et al., 2006; Ozeki, Aoki, & Masuzawa, 2010; Snyders et al., 2008; Snyders et al., 2007; Van Der Wal et al., 2006; Van der Wal, Wolke, Jansen, & Vredenberg, 2005). Nevertheless, in some cases the heat processes endanger the coating stability and the adhesion between coating and substrate.

On the other hand, all works using this technique has tried adjusting the deposition parameters for to get the fabrication of unique phase of crystalline and stoichiometric HA coatings. In this direction were produced and characterized CaP films using bias at high voltage and heaters at high temperatures on the substrate holder, which make the deposition system more expensive and difficult to operate. Despite the large number of publications on this theme, few studies has been carried out over the mechanisms of CaP films formation. Most of the research is limited to the knowledge of the relationship between the structural characteristics of the films with the deposition parameters such as: power density, voltage, gas pressure, and target - substrate distance, deposition time (rate), bias and temperature applied to the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

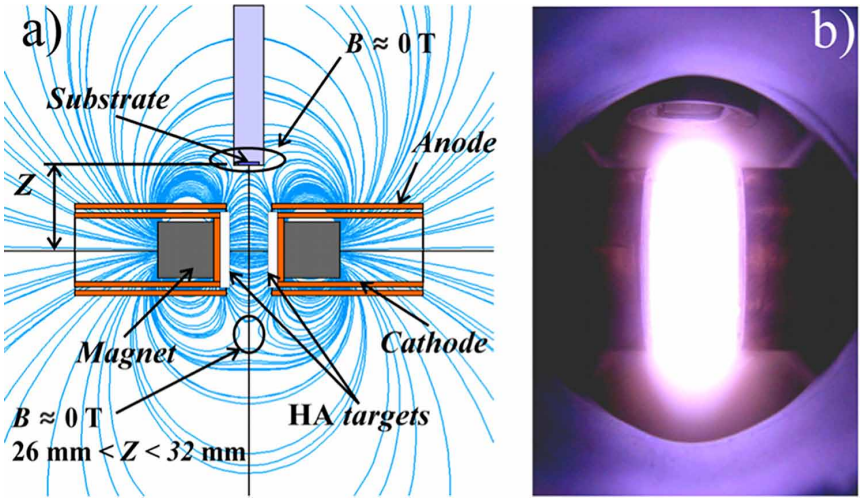
substrate (Surmenev, 2012; Surmenev et al., 2011; Surmeneva et al., 2013; Sam Zhang, 2013). In the case of physical vapor deposition techniques (PVD), have not still detailed studies involving the influence of the thermodynamic properties of the plasma with the films properties deposited on different substrates (Surmenev, 2012; Surmenev et al., 2011; Surmeneva et al., 2013).

1.2. Right Angle Magnetron Sputtering System (RAMS)

This sputtering system was adapted from the conventional magnetron sputtering geometry. This system exhibited two magnetrons positioned face-to-face (*in-axis*) with a substrate holder kept in a floating electric potential positioned in right angle to the magnetrons (*off-axis*). This modification was called right angle magnetron sputtering (RAMS) (López et al., 2013; Mello et al., 2007; López et al., 2015). The two magnetrons of the RAMS system work at 13.56 MHz of radio frequency (RF). The magnets into the magnetrons are composed for NbFeB (grade N42) and produce a high intensity magnetic field ($\mathbf{B} \approx 0.15$ T) which confined the plasma inside the central region of HA targets, as observed in Figure. 01 (López et al., 2013).

The high magnetic confinement of the plasma increases the ionization rate, the diffusion processes and the plasma temperature of the argon (Ar), oxygen (O_2) (5 mTorr and 1 mTorr, respectively) and the atoms that conform the targets (Ca, P and H). The substrates are positioned at distance of $\mathbf{Z} = 29$ mm from the center of the plasma bulk (see Figure. 01) which in this position there have a plasma trapped between magnetic mirror. The substrate holder was maintained electrically insulate with the RAMS chamber, producing a potential of 2 V relative to the ground, approximately. This floating potential and the deposition of ions (Ca^+, PO^-, O^-, H*) induces a great mobility of these species (ions and electrons) over the substrate surface, increasing the ions diffusion in the film growing as well as producing crystalline thin films conformed by HA nanodomains (in lower deposition time) that along the time the heat delivered by the plasma produces crystalline coatings of HA at room temperature (Figure 1).

*Figure 1. (a) Scheme of the RAMS system showing the magnetic field (B) and the substrate position region (**Z**) where the **B** ≈ 0 T. (b) Picture of the interior of the sputtering chamber showing the confined plasma glow at 120 W of RF power and at Ar and O_2 gas pressures of 5 mTorr and 1 mTorr, respectively López et al., 2013;*

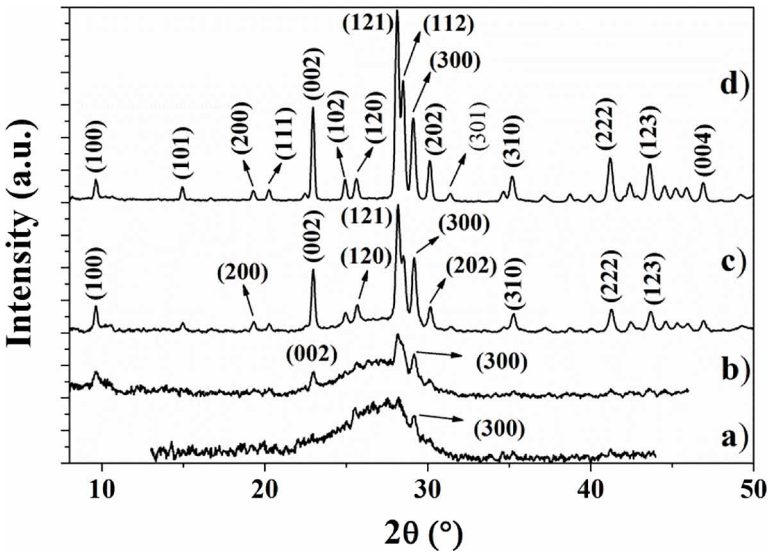


EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1.3. HA Coatings Fabricated by RAMS System

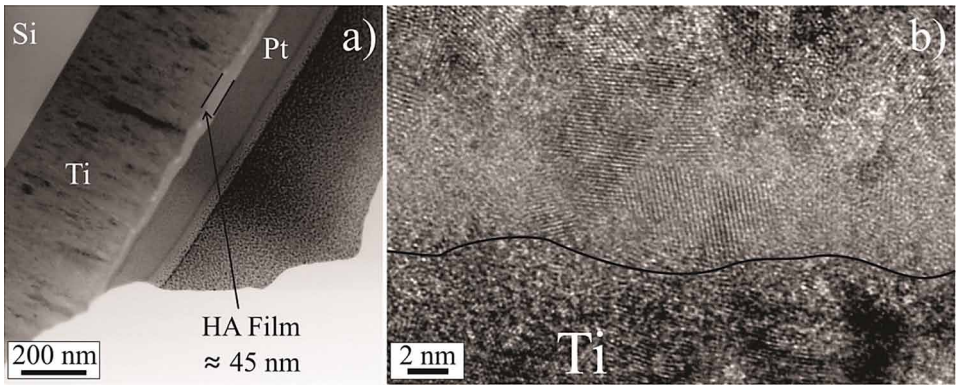
Commonly, there have a routine to coatings preparation which consist in associate the structural characterization (stoichiometry, crystallinity, adhesion film to substrate, roughness and texture) with the deposition conditions as: height between substrate - target, working pressure of argon and oxygen gases, bias potential on substrate holder, *in-situ* thermal treatment on substrates and RF power delivered to magnetrons (Surmenev, 2012; Sam Zhang, 2013). Other alternative is study, understand and control the thermodynamic properties of the plasma to form the coating with adequate physical-chemical properties and to propose new models of materials formations. For this, adequate knowledge in plasma technology and plasma processing must be taken in consideration as well as diagnose the plasma from adequate probes to measure the kinetic and dynamic of the electrons and ions in the discharge. The method most used to diagnose the plasma is from the Langmuir probe, which is possible characterize the thermodynamic properties of the electrons in the plasma discharge such as: density (n_e), temperature (T_{eff}), plasma potential (V_p), average kinetic energy ($< \varepsilon >$), diffusions (Γ) and energy delivered to film formation (E_D). (Chen & Smith, 1984; M. Lieberman & Lichtenberg, 2005; M. A. Lieberman & Lichtenberg, 1994; Shun'ko, 2009) With the RAMS system (using crystalline and stoichiometric and non-stoichiometric HA targets) was possible obtained stoichiometric (Ca/P = 1.68 ± 0.08) and crystalline (120 nm of crystallite size) nanostructured HA thin films (thickness less than 540 nm) with smooth roughness of 2 nm from the tuning of electron plasma properties in: $n_e = 2.0 \times 10^{15}$ m^{-3} and $T_{eff} = 11.8$ eV (Figure. 2 and Figure. 3) (López et al., 2013).

*Figure 2. GIXRD (λ = 0.13775 nm) patterns at a grazing incidence of $\Phi = 0.5°$ for the films that were fabricated with thicknesses and deposition times of (a) 90 nm – 30 min, (b) 135 nm – 45 min, (c) 225 nm – 75 min and (d) 540 nm – 180 min. The HA thin films were made at a deposition rate of 3 nm/min (**Z** = 29 mm) with a plasma power of 120 W and gas pressures of 5 mTorr and 1 mTorr for argon and oxygen*
López et al., 2013



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. (a) Image obtained by scanning transmission electron microscopy - STEM (bright field imaging) - for the sample that was prepared by FIB showing the CaP thin film region with a thickness of 45 nm between the Ti and Pt films. (b) HRTEM of the CaP thin film showing many HA crystalline nanodomains. The thin film was fabricated at 120 W of RF power, Z = 29 mm, deposition time of 15 min, deposition rate of 3 nm/min and gas pressures of 5 mTorr and 1 mTorr for argon and oxygen, respectively
López et al., 2013



From these results was possible to propose a growth model of stoichiometric and crystalline HA film produce at room temperature. This growth model associates the plasma temperature at $T_{eff} = 11.8$ eV and the total energy to form one HA unit cell, since ions deposition of Ca^{+}, O^{-}, H* and PO^{-} to formations of CaP aggregates, formations of CaP clusters precursors (possible Posner clusters), formation of a HA nanodomains and formation of crystalline films of HA (López et al., 2013). The energy of formation of these CaP clusters (precursors of the HA structure) were compared from a simulation made by *ab initio* in vacuum environment as proposed by other authors (Kanzaki, Treboux, Onuma, Tsutsumi, & Ito, 2001; Louis-Achille, De Windt, & Defranceschi, 2000; Treboux, Layrolle, Kanzaki, Onuma, & Ito, 2000).

The fabrication of a controlled crystallinity and stoichiometry of HA nanocoatings (at room temperature) produced without heat treatment (*in-situ* or after deposition) and bias is only possible from the knowledge and the control of the plasma properties, which will have a high efficiency in orthopedic implant applications.

1.4. Functionalized HA Coatings by Incorporation of Fluorine Ions and Fabricated by RAMS System

HA targets with ionic substitution of OH^{-} by F^{-}, ($Ca_{10}(PO_4)_6(OH)_{2-x}F_x$, where x = 0.6) was synthesized and produced to fabricated FHA films with the finality of functionalize the film surface and produce an increase of the physic-chemical stability, increase the resistance to dissolution by acid, reduce the bacterial proliferation and increase the bioactivity, as reported by other works (Louis-Achille et al., 2000; Montazeri et al., 2013; Sam Zhang, 2013).

To produce FHA films with excellent crystallinity (in all film thickness as shown in the Figure. 04 and Figure. 05), excellent stoichiometry with adequate introduction of fluorine ions in the HA structure (Ca/P = 1.68 ± 0.04 and F/Ca = 0.12 ± 0.004), low roughness (R_{RMS} = 2 nm) and good reproducibility in different substrates surfaces, the deposition conditions was maintained at ***Z*** = 29 mm (height between

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

substrate and magnetrons, as observed in the Figure. 01), RF power of 110 W, deposition time of 180 min and deposition rate of 3 nm/min. In this condition the plasma parameters showed an electron density and temperature of: $n_e = 1.2 \times 10^{15}$ m^{-3} and $T_{eff} = 9.0$ eV, respectively (López et al., 2015).

Finally, these results are evident that the right angle magnetron sputtering (RAMS) have a great potential to fabricate crystalline and stoichiometric nanocoatings ($\Lambda < 500$ nm of thickness) at room temperature of HA and FHA with adequate control of the fluorine incorporation and without the use of heater and bias on the substrate holder.

Figure 4. TEM images of 540 nm thick FHA film produced at 110 W RF power, 180 min and Z = 29 mm. The gas pressures of Ar and O_2 were 5.0 mTorr and 1.0 mTorr, respectively. 2. ACOUSTIC WAVE NANO DEVICES ALUMINUM NITRIDE OBTAINED BY PULSED LASER DEPOSITION

Semiconductors nitrides of group III-V (GaN, InN AlN) alloys have been considered for many years as ideal for manufacturing semiconductor optoelectronic devices for the performance limit blue-ultraviolet (UV). The main appeal of these materials is the fact that these have a direct energy gap covering a wide range of energies from 1.9 eV (red) InN, to 3.4 eV (UVA) of GaN, to 6.2 eV (UVC) of AIN (Strite & Morkoç, 1992). Maruska *et al.* (Maruska & Tietjen, 1969) fabricate in the decade of the 60s the first GaN crystal thin film by epitaxy techniques hydride vapor phase. The main applications of these materials relate to emitters / detectors radiation devices in the blue-ultraviolet range. Today, most optoelectronic devices on the market operate at wavelengths from infrared (IR) to green.

2.1. Structural Properties of Nitride Semiconductors (Group III-V)

These nitrides crystallize according to three types of structure: Wurtzite ((hexagonal close packing)), also called (*α-AlN; α-GaN and α-InN*); zinc-blende (cubic), denoted as (β-*AlN,* β-*GaN and* β-*InN*) and rock salt structure ((Sodium chloride, NaCl Structure). The first two are the most common; the Wurtzite structure is the most stable at room temperature while the zinc-blende is metastable. The Wurtzite type structure consists of two hexagonal compact packages (HCP), two types of atoms interconnected along the axis direction of hexagonal symmetry, with a spacing of 5/8*c*. The Wurtzite zinc-blende structures are similar in that each metal atom (Group - III) is coordinated with four non-metallic (Nitrogen) and vice versa. In fact, they only differ in the sequence of stacking of planes diatomic N-Metal. Wurtzite structure in sequence in the direction <0001> is *ABABAB* while in the zinc-blende type *ABCABC* stacking is in the direction <111>. When having both structures similarity relates to appear zincblende type inclusions in layers with Wurtzite structure, especially in areas in which has stacking faults (Levinshtein, Rumyantsev,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Shur, 2001; Maruska & Tietjen, 1969; Morkoc, 2013; Ruterana, Albrecht, & Neugebauer, 2006). The lattice parameter of the three binary (GaN, AIN, InN) for the different structures is shown in Table 1.

The lattice vibrations (phonons), observable in the nitrides with Wurtzite structure by Raman spectroscopy, are related in Table 2.

2.2. Aluminum Nitride Applications in Acoustic Wave Sensors

The relationship between the surface acoustic wave (SAW) designed on thin films of aluminum nitride (AlN) grown on Si_3N_4 substrates by using a Pulsed Laser Deposition and optical properties has been widely studied due to their low net mismatch and thermal stability (Cressler, 2005). Moreover the dependency of both properties with a temperature of deposition. Aluminum nitride, an electrically insulating ceramic with a wide band gap of 6.3 eV, is a potentially useful dielectric material very important in fields such as optoelectronic and microelectronics. For instance, it can serve as the dielectric gate with high voltage and high power electronic devices; AlN is also being investigated as a substitute for the silicon dioxide buried layer in silicon-on-insulator (SOI) substrates due to its low thermal expansion coefficient, high breakdown dielectric strength, and high chemical and thermal stability (Clement, Vergara, Sangrador, Iborra, & Sanz-Hervás, 2004; Jiang, Shen, Ogawa, & Guo, 2003; Yamashita, Fukui, Misawa, & Yoshida, 1979). Moreover, metal nitrides based on AlN are of high interest because of their electrical, optical and acoustical properties (Clement et al., 2004). Their hardness and thermal coefficients of expansion

Table 1. Lattice parameters and energy gap of nitrides of group III-V at room temperature

	Lattice Parameters (Å)	**EG (300K) (eV)**
β-AlN	$a = 4.38$	5.11 (theoretical)
α-AlN	$a = 3.112$ $c = 4.982$	6.2

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

are comparable to that of Si. AlN is used for acoustic wave devices on Si (Clement et al., 2004), optical coatings for spacecraft components, heat sinks in electronic packaging applications, as well as electroluminescent devices in the wavelength range from 215 nm to the blue end of the optical spectrum. Some optical properties near the fundamental band gap of AlN have been reported by Yamashita et al. (Yamashita et al., 1979) since 1979.

Several theoretical studies have been well documented in the past, (Jiang et al., 2003; Levinshtein et al., 2001) however, reliable experimental data has been reported just recently because both the sample quality and the spectroscopic techniques have only been substantially improved in recent years. Precise knowledge of the optical constants is particularly important in view of the use of AlN thin films in optical filters and light emitting laser diodes since they also show temperature dependence. Similar to the section 1.1.4 for the HA, Pulsed Laser Deposition (PLD) is largely applied for processing thin films and other structures. The highly no equilibrium nature of the PLD process is attractive for the synthesis of stoichiometries thin films of various metal nitrides, carbon nitrides, oxides and oxynitrides from the corresponding bulk targets. PLD appears to be a suitable method to transfer stoichiometrically complex monolayer structures from AlN ceramic structures to substrates.

Thus, from AlN stoichiometries films, many infrared (IR) measurements presented in the literature were used to estimate the film quality. The IR-spectra provided important information about the composition, homogeneity, crystallinity and the residual stresses present in the films. Moreover, the ellipsometry and reflectance measurements have been used to determine the refractive index in many AlN compounds, since the ellipsometry and reflectance are sensitive and non-destructive techniques used for studies of optical properties and microstructures of surfaces and thin films (Caicedo, Pérez, Caicedo, & Riascos, 2013; Pérez, Riascos, Caicedo, Cabrera, & Yate, 2011a; Rosenberger, Baird, McCullen, Auner, & Shreve, 2008; Zhuang et al., 2009). Additionally, single-chip front-end RF modules incorporating Surface Acoustic Wave (SAW) filters are a matter of intense research. At present, these modules are fabricated by bonding single crystal piezoelectric SAW devices onto integrated circuits. Thin films of polycrystalline Aluminum Nitride (AlN) are promising materials for the integration of SAW devices on Si_3N_4 substrates due to their good piezoelectric properties and the possibility of deposition a low temperature compatible with the manufacturing of Si integrated circuits. AlN thin films of sufficient quality for SAW applications can be a obtained by the PLD technique (Pérez et al., 2011a).

2.3 X-Ray Photoelectron Spectroscopy (XPS) Analysis

The XPS survey spectrum of AlN thin film grown at 300 ºC is shown in Figure 6. The peaks at 534.4 eV, 397.3 eV, 124.4 eV, and 73.9 eV correspond to O1s, N1s, Al2s, and Al2p binding energies, respectively. Calculation of the peak areas of deconvoluted spectrum (Figure 7) without O1s contribution gives an atomic ratio of Al:N = 0.392: 0.588, which is similar to the stoichiometry of $Al_{0.40}N_{0.60}$ (Caicedo et al., 2013). The core electronic spectra carry the information about the chemical composition and bonding character of the Al–N films. The integral of N1s, Al2s, and Al2p spectra corrected by relevant sensitive factors can evaluate the concentrations of Al, and N elements in the Al–N films. The corresponding integral of the deconvoluted peaks can also be used to estimate the bond contents, which are described by the following formula:

$$C_i = \Sigma(A_i/S_i)/\Sigma(A_j/S_j) \quad (1)$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

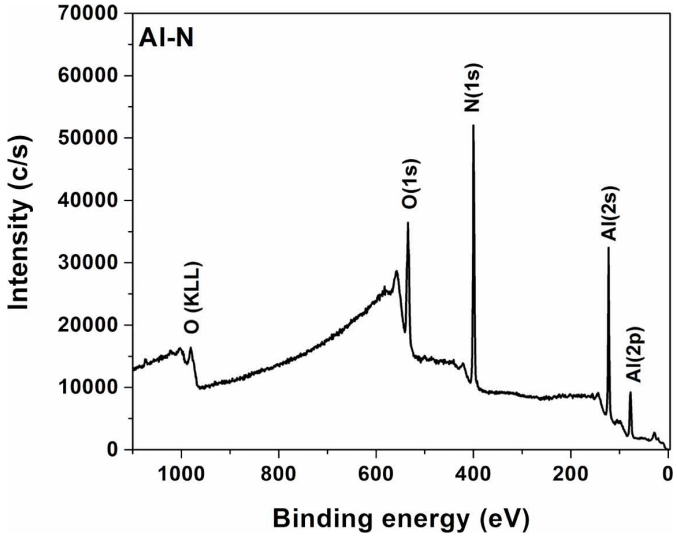
Where **-*S*** is the sensitivity factor, ***A*** is the integral of deconvoluted peaks, and ***C*** is the atomic content. The numerator is the sum of the integral of one sort of bond; the denominator is the sum of the integral of all types of bonds decomposed from the whole peak of N1s, A2s, and Al2p in the sample. The atomic concentrations of Al, N and O elements of XPS analysis of the coating deposited at 300 °C are listed in Table 3. For all the Al-N films obtained, the O concentration is less than 3 at.%. We can speculate that the majority of the oxygen at the surface of the non-treated sample (which is smooth and almost perfect) is chemically bonded into alumina-dominated oxide- nitride material.

The high-resolution spectra of Al2p, and N1s were recorded from AlN films, as shown in Figure 7(a), the Al2p peak is composed of a shoulder separated by 1.7 eV with intense peak. The XPS spectrum of Al2p can be fitted well by two Gaussian functions. The value of the binding energy obtained for the Al2p peak was 73.9 eV and the higher value for Al2p was 75.6 eV, respectively. According to the literature(Mahmood et al., 2003; Pérez Taborda, Riascos Landázuri, Jiménez García, & Caicedo Angulo, 2010; Taborda, Caicedo, Grisales, Saldarriaga, & Riascos, 2015) for the Al2p peak, the first one (73.9 eV) and the second one (75.6 eV) can be assigned to Al–N and Al-O bonds.

The appearance of the peak at 73.9 eV clearly shows that Al has reacted with N; therefore, it can be assigned to Al-N. In Figure 7(b), N1s peak is composed of spin doublets, each separated by 2.9 eV. The XPS spectrum of N1s, well fitted by two Gaussian functions, depicts the N1s spectrum with values at 397.3 eV and 400.2 eV characteristics for N-N and Al-N bonds, respectively.

The XPS results demonstrated that Al atoms bonded to N in the form of nitride, taking into account that the elemental concentration of the Al-N film was obtained by adjusting the laser incidence on Al target, and the N_2 as a working gas. In this specific case, it was found that amounts of Al (N) in the AlN film were maximum at the current establishment of process conditions and the ratio of Al and N in the film was about for 2:1. In general, formative Al (N) phase indicates that the aluminum and nitrogen activity and activation energy provided by the present deposition conditions are enough for the formation of an Al-N thin film. Although the surface temperature of the substrate during deposition of Al-N

Figure 6. XPS survey spectrum of Al-N coatings deposited on Si_3N_4 at 300 °C, where different elemental signals show



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

film is around 300 °C, the substrate lies in a high-density plasma region and a high ion-to-atom ratio of aluminum and nitrogen, thus behavior can induce to the formation of Al-N phase at the low temperature below 300 °C. Moreover, the correlation between temperature deposition and chemical properties due to the reduction of oxygen concentration when the increase of deposition temperature, this behavior was associated with high surface energy activity generated by high surface temperatures that induce more nitrogen reaction.

The concentrations in these depth profiles were obtained by curve fitting of high-resolution XPS spectra and measurements of the XPS peak areas. In order to see the effects of increasing the substrate temperature during the growth of thin films which would serve AlN buffer for Mo SAWs. The dependence of aluminum and nitrogen in the deposition temperature is shown in Figure 8 which represent various chemical states as described in the section 2.3 XPS in Table 3 and Figure 8.

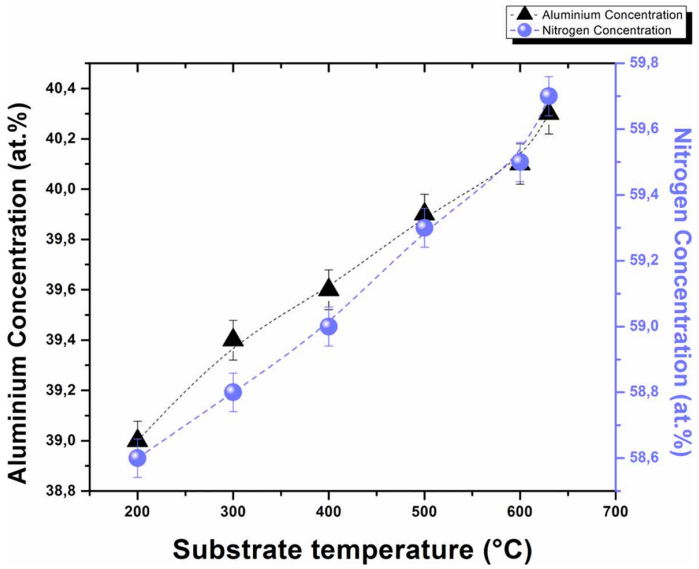
Figure 8. Temperature dependence at the concentrations of Al and N for AlN films



2.4 Surface Analysis of AlN Films via Atomic Force Microscope

Nevertheless, most of the energy in the propagating surface acoustic waves is contained in the region within one wavelength below the surface, so they are very sensitive to the surface state and are affected by any change, such as residual stresses and the level of roughness. Moreover, authors such as C. Zhuang *et al.(Zhuang et al., 2009)* have shown that at the same frequency and in the small roughness limits (RMS ≪ wavelength), the SAW velocity increases according to the decrease in the RMS roughness. Figure 9 a-c shows a 5μm × 5μm image for AlN films deposited with different deposition temperatures. The general trend in the AlN films with the decreasing temperature exhibits a decrease of the grain size and roughness. In Figure 9 obtained from AFM drops observed of which are characteristic of the PLD technique and are occasioned by the release of particulates from the Aluminum target at impact with the substrate, such generate imperfections on the surface of the films also shows micro drops on AlN surface generated by PLD energy deposition corresponding to high laser fluency. Moreover, the correlation between roughness and grain size with deposition temperature is shown in Figure 10 The quantitative values were extracted from the AFM images by means of statistical analysis Scanning Probe Image Processor (SPIP®). Each data point in the plots represents an average over AFM images. The corresponding error bar was obtained by a standard deviation of the values (Mahmood et al., 2003; PEREZ TABORDA et al.; Pérez Taborda et al., 2010; Taborda et al., 2015; Zhuang et al., 2009).

Figure 10 shows the grain size and roughness values for the AlN films, thus, in this case, a decreasing tendency in surface measurements was observed when the deposition temperature was increased. The lower grain size and roughness values obtained in this study by the Al–N films deposited on silicon substrate represented a decrease of grain size around 42% and roughly 31%, compared to that obtained from the Al–N films deposited at 200 ºC. This fact is relevant since the continuity of the surface is important for optical and electrical SAW devices (Kar & Bose, 2011; Raole, Mukherjee, & John, 2005).

Figure 9. AFM images for AlN films grown onto Si_3N_4 substrate with different deposition temperatures: (a) 200 ºC, (b) 400 ºC and (c) 630 ºC.(Caicedo et al., 2013)

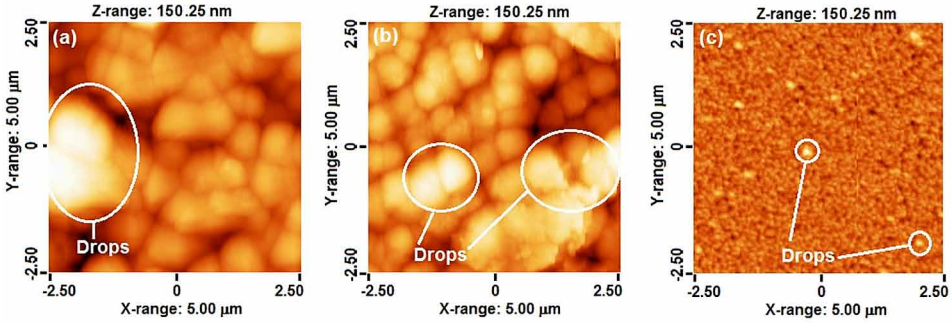

Figure 10. Surface measurements obtained via AFM and SPIP® analysis for AlN films with a total thickness of 150 nm: Correlation between grain size and roughness with deposition temperature

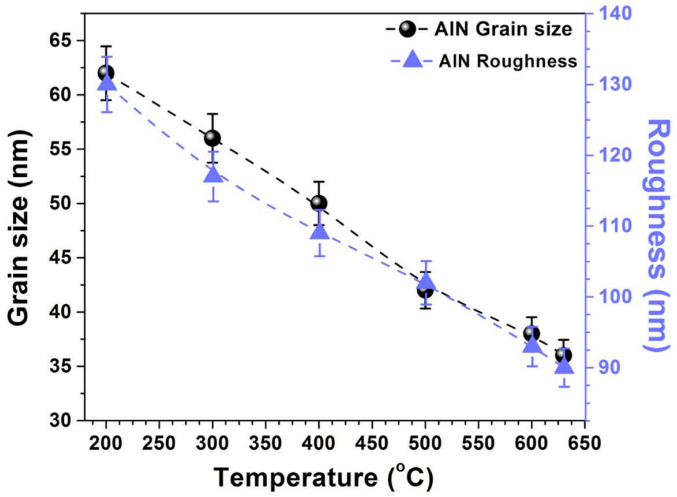

The variation of grain size and roughness (Figure 10) obtained in the Al–N films suggest that thermal activation generated by the increasing in the deposition temperature on surface substrates modifies the superficial morphology by increasing the energy associated with atoms on the substrate surface and/or the growing film surface which produces a relative reduction of grain size and roughness.

2.5 Dominant Wavelength and Color Purity Analysis

The reflectivity measure is the fractional amplitude of the reflected electromagnetic field while reflectance refers to the fraction of the incident electromagnetic power that is reflected at an interface. The reflectance is thus the square of the magnitude of the reflectivity. The reflectivity can be expressed as a complex number as determined by the Fresnel equations for a single layer, whereas the reflectance is always a positive real number.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Additionally, reflectivity is distinguished from reflectance by the fact that reflectivity is a value that applies to thick reflecting objects. When reflection occurs from thin layers of material, internal reflection effects can cause the reflectance to vary with surface thickness. Reflectivity is the limit value of reflectance as the surface becomes thick; it is the intrinsic reflectance of the surface, hence irrespective of other parameters such as the reflectance of the rear surface (Kar & Bose, 2011; Touati, Hadjoub, & Doghmane, 2006; Zayats et al., 2008). On the other hand, the dominant wavelength (of a color stimulus) is defined as: "*the wavelength of the monochromatic stimulus that, when additively mixed in suitable proportions with the specified achromatic stimulus, matches the color stimulus considered*" (Kar & Bose, 2011). The AlN films have been compared with pure aluminum because the mirror finish aluminum has the highest reflectance of any metal in the 200–500 nm and the 3000 –10000 nm (far IR) regions, while in the 500 –700 nm visible range it is slightly outdone by AlN and silver, but in the 700 –3000 nm range (near IR) it is slightly outdone by, gold, and copper materials.

The reflectance spectrum or spectral reflectance curve is the plot of the reflectivity as a function of wavelength as can be seen in Figure 11 Therefore, all the deposited films appear highly reflective with white and aluminum colored. Figure 11a. shows the optical reflectance spectra of the AlN single layers obtained at different deposition temperatures. The reflectance of the aluminum and the eye sensibility are shown for comparison. The spectra of the samples show high reflectance for long wavelengths, near to 33% for the AlN films deposited with 200 °C and close to 23% of AlN films deposited with 630 °C. These values of reflectance at these wavenumbers are in good agreement with previous reports for AlN films (Zhuang et al., 2009). A clear decrease in reflectivity for short wavelengths is seen, characteristic of a system with high free-electron density with a reflectance edge below 550 nm due to a screened plasma resonance. The white and aluminum colors of the AlN films are a result of the steep plasma reflection edge that occurs in the visible region where the reflectivity minimum is around 560 nm. The color purity refers to the degree of purity present at a color; therefore in a pure color do not exist any achromatic effect within its composition, which can vary its capacity for reflection. One of the three dimensions of color refers to the color purity that a surface can reflect. When the tone is full and is not mixed with an achromatic effect (brightness), this presents its maximum saturation or purity. On the other hand, if a particular color is combined with an achromatic effect, or with its complement (luminosity), it suffers a loss of purity or neutralization. The color purity changes with the temperature of deposition, at ranges from 0.63 to 0.66 for AlN films, away from the color purity of pure aluminum (0.90), hence confirming that the films are less white compared with the aluminum. Color coordinates of AlN single layer films are shown in Figure 11b.

Reference coordinates of pure aluminum are shown for comparison in that Figure 12. The results of color measurement indicate that all films reflect a hue slightly shifted far to the white as compared to aluminum reflectivity and with similar color purity. Likewise, dependence is observed the high dependence on reflectance percentages when the deposition temperature is varied from 200 to 630 °C. Figure 12a exhibits one constant region for wavelengths ranged from 760 to 800 nm; in those regions it is possible to appreciate the effect of deposition temperature on changes in the reflectance values. Figure 12b shows the decreasing of reflectance when the temperature is increased, which indicate that temperature promotes the absorbance in the AlN deposited via PLD. The last behavior changes in optical properties (reflectance) can be related with changes generated by the reduction of grain size and reduction of surface roughness when the depositing temperature is increased producing an activation surface energy observed from AFM images.

Figure 11. Dominant wavelength and color purity results (color online): (a) Optical reflectance of AlN films deposited onto Si_3N_4 (100) substrates at the different deposition temperature, also aluminum optical reflectance and eye sensibility were also plotted as the references. (b) Chromatic diagram, in the x, y coordinates, of the reflectivity for AlN films. White coordinates of an achromatic point are located at (1/3, 1/3)

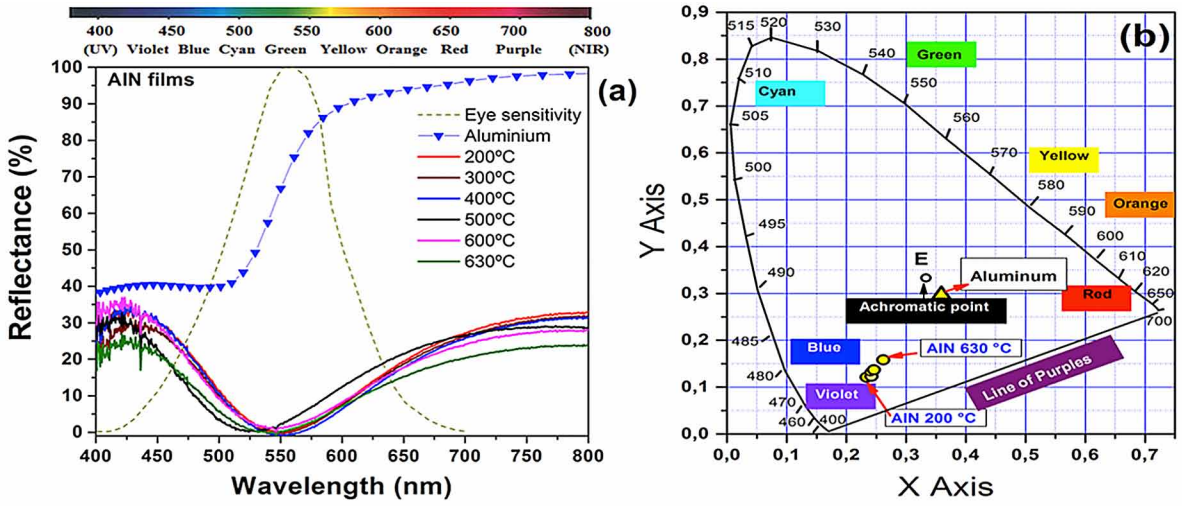

Figure 12. Temperature-Reflectance dependence (color online): (a) Reflectances of AlN films deposited onto Si_3N_4 (100) substrates at the different deposition temperature from 760 to 800 nm wavelength, (b) reflectance as function of deposition temperature

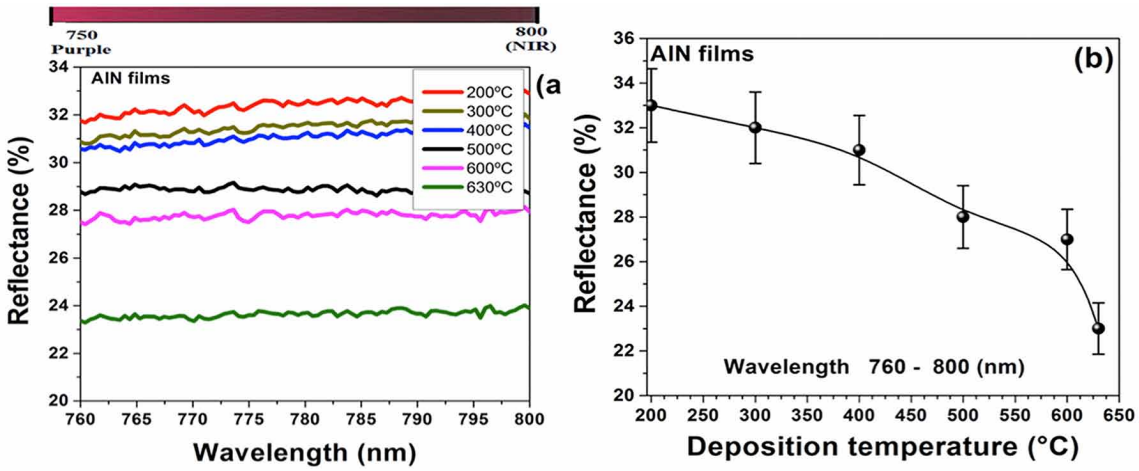

From the reflectance spectra it is seen a weak but clear effect of deposition temperature on the optical properties. As the temperature is decreased, the reflectance of the films tends to be higher in the near infrared region. So, dominant wavelength and color purity have been calculated from the reflectance spectra of all films by using the *java-optics* software (Table 4). The dominant wavelength was varied for all the samples, from 562 to 570 nm, and a little close to that of pure aluminum reference (574 nm)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In. Figure 13a it can be observed the influence of deposition temperature on color purity. This graph shows the increase of purity values towards color gray purity. Figure 13b shows the differences in the dominant wavelength for all AlN films deposited with different deposition temperatures.

The wavelength is an important optical characteristic for different materials. When the wavelength is changed it is possible to observe that natural color is changed. This modification on optical properties is associated to changes generated by the reduction of grain size and reduction of surface roughness observed in AFM images. Moreover, the changes in chemical composition of AlN films observed in XPS spectra show that oxygen concentration is reduced when the temperature deposition is increased. Therefore, the low oxygen concentration induce changes in the energy bands generating changes at optical properties (color purity and dominant wavelength). Finally, the purity color dependence in AlN films with temperature obtained demonstrates the possibility of some purity color control.

SEM images was carried out to quantitatively study the surface morphology of our samples in relation to an increase on deposition temperature in AlN films grown onto Si_3N_4 (100). Figure 14 Shows SEM micrographs for AlN films with a random distribution of microparticles or micro drops that were analyzed on these surfaces in agreement with AFM images. Accordingly, the deposition temperature

Table 4. Optical properties for AlN films deposited onto a Si_3N_4 substrate

Deposition Temperature (°C)	Dominant Wavelength (nm)	Color Purity	Axis X	Axis Y
200	562	0.63	0.234	0.121
300	567	0.63	0.242	0.123
400	569	0.63	0.240	0.132

clearly affects the reduction of micro-drops; this can be possible due to great surface mobility when the temperature was varied from 200 to 630 °C. This surface mobility reduces the possibility that the micro-drops are anchored on the surface when arriving with high energy on AlN film. Otherwise, the high superficial temperature that produces surface diffusion of micro-particles or micro-drops, which can decrease the overall number of particles. The magnification image showed in Figure 15 exhibits that molybdenum lines are continuous, without any interruption or short circuit. After electrical measurements, it was possible to deduce an insulator behavior for our AlN structures, a good prerequisite for using them as surface acoustic wave (Mo/AlN/SAW) devices.

2.6 Applications: Frequency response of Mo/AlN SAW devices

Authors as Hadjoub *et al.* (Hadjoub, Touati, Doghmane, & Doghmane, 2008) been reported improvement in the Rayleigh Velocity (VR) by decreasing the thickness of the films and substrates used Si_3N_4 with a velocity of 5694 m/s value very next to that of VR (SiC) = 6810 m/s. These values are referred to substrates for fast VR (Al_2O_3) = 5680 m/s, VR (Si) = 4710 m/s, VR (SiO_2) = 3410 m / s, VR (Ti) =

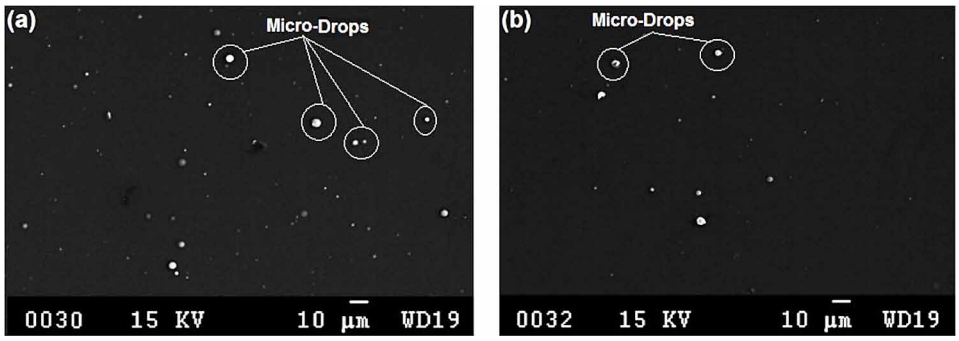

Figure 15. SEM micrographs showing the interdigital structure of Mo coating on AlN films obtained by PLD: (a) general interdigital structure, (b) magnification images where it is possible to observe the width and distribution of lines that conform the interdigital device

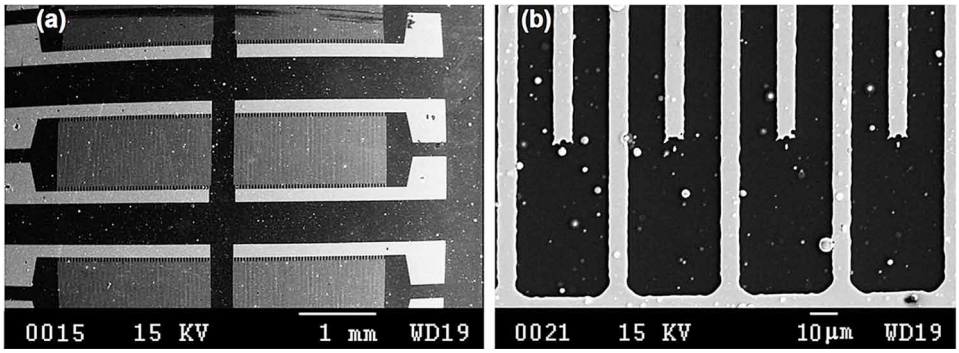

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2960 m/s and VR (W) = 2670 m/s, reported in the literature (Caicedo, Zambrano, Aperador, Escobar-Alarcon, & Camps, 2011; Drafts, 2001; Hashimoto & Yamaguchi, 2001; Kao, Cheng, & Chen, 2002; Paduano, Weyburne, Jasinski, & Liliental-Weber, 2004). It clearly shows the importance of using substrates with good speed of Rayleigh and compatible with existing silicon technologies so that in our case Si_3N_4 because VR is 20% higher than that of Si.

Recently, some authors (Caicedo, Zambrano, Aperador, Escobar- Alarcon, & Camps, 2011; Drafts, 2001; Hashimoto & Yamaguchi, 2001; Kao, Cheng, & Chen, 2002; Paduano, Weyburne, Jasinski, & Liliental-Weber, 2004) have reported the relation between the h/λ and V_{SAW} by experiment or theory, where h is AlN thickness, λ is wavelength, and V_{SAW} is SAW velocity. The relationship between the thickness and the wavelength this $h/\lambda = 0.004$. The frequency response characteristics of Mo/AlN SAW devices fabricated using the different deposition conditions, such as, 200 ºC, 400 ºC and 630 ºC, have been measured, of which results are shown in Figure 16 a-d. As can be clearly seen by comparing the wide-frequency scan spectra of those three devices (which are plotted in the insets of Figure 16c, by using the AlN buffer layers the center frequency was shifted from approximately 0.618 GHz Figure 16a to higher frequencies of 0.621 GHz (Figure 16b) and 0.625 GHz (Figure 16c). This indicates that the AlN buffer layer could be used as high phase velocity substrate in the fabrication of high-frequency SAW devices, as with Molybdenum.

Additionally, in Figure 16d that the insertion loss was reduced by the use different deposition temperatures of AlN buffer, by using the AlN buffer layers the center frequency was shifted from approximately 0.618 GHz (Figure 16a) to higher frequencies of 0.621GHz (Figure 16b) and 0.625GHz (Figure 16c). This indicates that the AlN buffer layer could be used as high phase velocity substrate in the fabrication of high-frequency SAW devices. In addition, it appeared in Figure 16c that the insertion loss was reduced by the use of AlN buffer. To examine in more detail the dependence of insertion loss on the deposition condition of AlN-buffer, the insertion loss has been measured for all the fabricated SAW devices.

The results are plotted in Figure 15 as a function of temperature deposition of AlN films and the estimated quantitative values are also listed in Figure 16. As can be seen in Figure 17, for SAW devices, fabricated using the sputtered-AlN buffer with Mo channel the insertion loss was exactly correlated with the corresponding temperature value for all AlN films.

This can be identified by comparing the results obtained from the device with AlN films deposited on silicon nitride substrate. For the above devices, the temperature deposition was increasing systematically, as already shown in Figure 17. Moreover, the device with AlN deposited to 630 ºC revealed the relatively large insertion loss in relation to frequency value (0.625 GHz). This may be attributed to the relatively low surface roughness (90 nm) AlN film used in Mo/AlN device considering that the surface roughness of AlN film may also be associated by the surface morphology and deposition temperature of AlN buffer layer, the results shown in Figure 16d. confirm that frequency response characteristics (insertion loss) can be affect by reduction of oxygen concentration, reduction of grain size, roughness, and decreasing with reflectance of AlN films together with increase of color purity and dominant wavelength thin this sense, the property of AlN buffer may strongly govern the characteristic of SAW device using the Mo/AlN system. (Caicedo et al., 2013)

The direct relationship between increased frequency and speed in SAW devices, all this related to the morphological qualities of roughness and grain size favor in increased rate of velocity. The resonance frequency of an SAW is determined by the equation $f = V/k$, where f is the resonance frequency, V is the phase velocity of the acoustic wave and k is the acoustic wavelength, which in turn is defined by the electrode pitch in the *interdigital transducer* (IDT). The reflected signal of the Rayleigh mode in AlN

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 16. Frequency response characteristics of fabricated Mo/AlN SAW devices with different deposition temperatures (a) 200 ºC, (b) 400 ºC, (c) 630 ºC and the insertion loss by the use different deposition temperatures of AlN buffer for (a), (b) and (c)

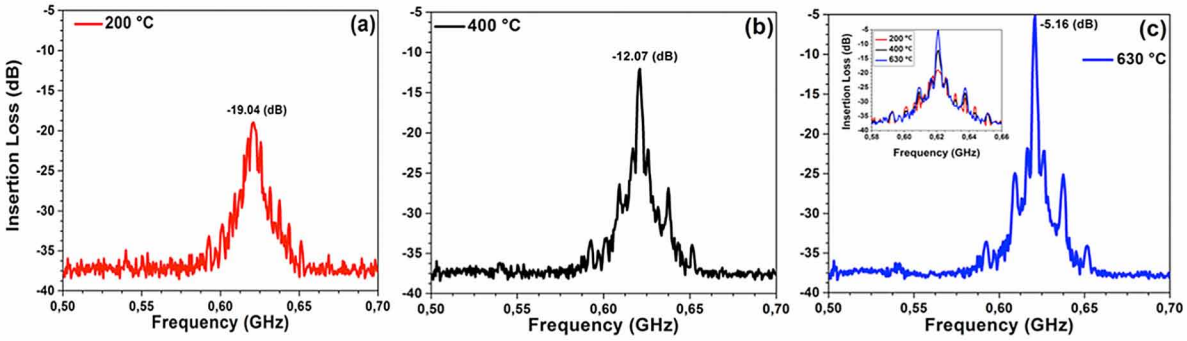

Figure 17. The measured insertion losses of fabricated Mo/AlN SAW devices, as a function of the temperature values from the deposited AlN films

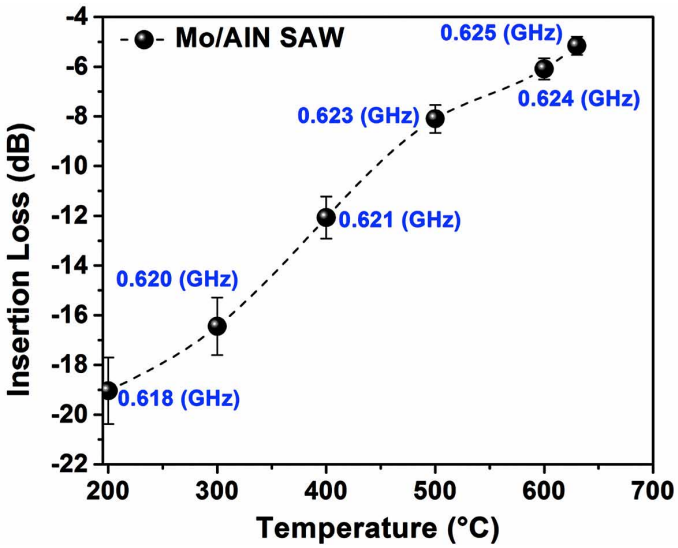
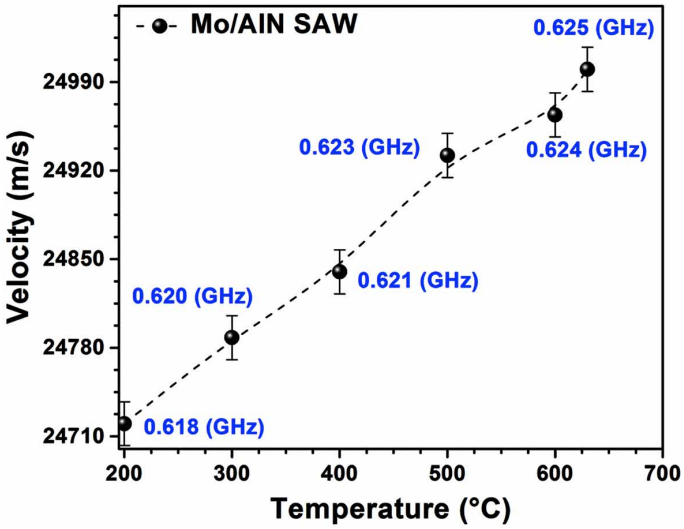


films deposited to highest temperatures (630ºC) is observed to be much stronger than that of the AlN films deposited to lowest temperatures (200 ºC) and the phase velocity of AlN films deposited to (630 ºC) is much higher. For The Mo/AlN SAW devices, the measured resonant frequencies of the Rayleigh mode waves ranges from 0.618 GHz to 0.625 GHz corresponding to phase velocities of 24720 m/s to 25000 m/s, indicating good repeatability and reproducibility (Pérez et al., 2011a).

Thus, the lowers deposition temperature of the substrate, generate a perturbation of the acoustic velocity that is related to a change in frequency of the oscillator circuit. In the Figure 17 is shown as before said to improve velocity with increased temperature of the films deposited during the growth of AlN and were used as substrates for SAW devices Mo. Figure 18 Acoustic wave velocity as a function of deposition temperature in Mo/AlN/Si_3N_4 system.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Acoustic wave velocity as a function of deposition temperature in Mo/AlN/ Si3N4 system



Take the last behavior is possible to observe that the quasi-static electric field associated with the SAW interacts with the charge carriers of the film. The SAW velocity is, therefore, dependent on the AlN thin film conductivity changes. These velocity changes can easily be interpreted as a shift in the resonant frequency, when the SAW delay line is incorporated in an oscillator conFigureuration. The effect of temperature is one of the easiest parameters that can be sensed because almost all physical and chemical effects depend on temperature (Kar & Bose, 2011; Morkoc, 2013).

In certain applications, the effect of temperature should be minimized in order to avoid any interference with other effects. For acoustic wave sensors, the temperature effect induces dimensional dilatations and small changes in the mechanical and electrical properties. Two kinds of interaction can thus be measured: *(i)* shift of the acoustic wave velocity due to intrinsic changes of material properties (elasticity and density) (this is the case for almost all SAW devices using metal-nitrides materials with low thickness) (Aissa et al., 2015; Caicedo et al., 2013; Clement et al., 2004; Jung, Lee, Kim, & Park, 2004; Trang et al., 2007) and *(ii)* for acoustic devices for which the resonant frequency or the velocity is dependent on the dimensional values (Lamb wave devices, thickness and shear mode), temperature can affect changes of both material properties and boundary conditions(Kar & Bose, 2011; Taborda et al., 2015).

2.7 Correlation Between Optical Properties and Acoustic Wave Velocity in Mo/AlN SAW Devices

In Figure 19 shows the relationship between optical properties (reflectance), acoustic wave velocity and deposition temperature in AlN films. In Figure 19 it is clearly shown that the reduction of grain size, reduction of reflectance and the increase of the color purity when the deposition temperature decreases, is associated with an increasing of frequency response, due to the increase of acoustic wave velocity, produced by energy activation at the higher deposition temperature. From this correlation, it is possible to determine that one merit index associates to an acceptable reflectance and acoustic wave velocity at the same temperature deposition.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Is observed a direct relationship between the roughnesses of the AlN thin films and increasing the deposition temperature, the AFM results show a decrease in roughness with increasing temperature in the deposit. Figure 19b shows a clear correlation between the roughness and the Rayleigh velocity, obtaining the highest velocity for the samples grown at a higher temperature of 630 °C to deposit are the lower roughness.

Therefore, the AlN films deposited around 450 ºC offer the best synergy for optical and acoustic properties with good reflectance and an acceptable acoustic wave velocity. Furthermore, the nanometric grain size and in thickness of such thin films AlN/Si_3N_4 a low surface roughness (≤120 nm), the nucleation side is characterized by a relatively small grain size (≤70 nm), which can be decreased with increased substrate temperature improving processes nucleation, hence enhancing the propagation of elastic waves as shown in Table 5.

The morphological properties of AlN are highly dependent on their polarity, since the nitrogen, finished films typically have a greater roughness than the finished aluminum, but instead its crystal quality is better. Initial reservoir conditions greatly affect the polarity of the material obtained (Levinshtein et al.,

Figure 19. Correlation between optical properties (Reflectance) and acoustic wave velocity in Mo/AlN SAW devices. In Figure 19b. There is a correlation between roughness and Rayleigh velocity as a function of temperature deposit AlN thin films

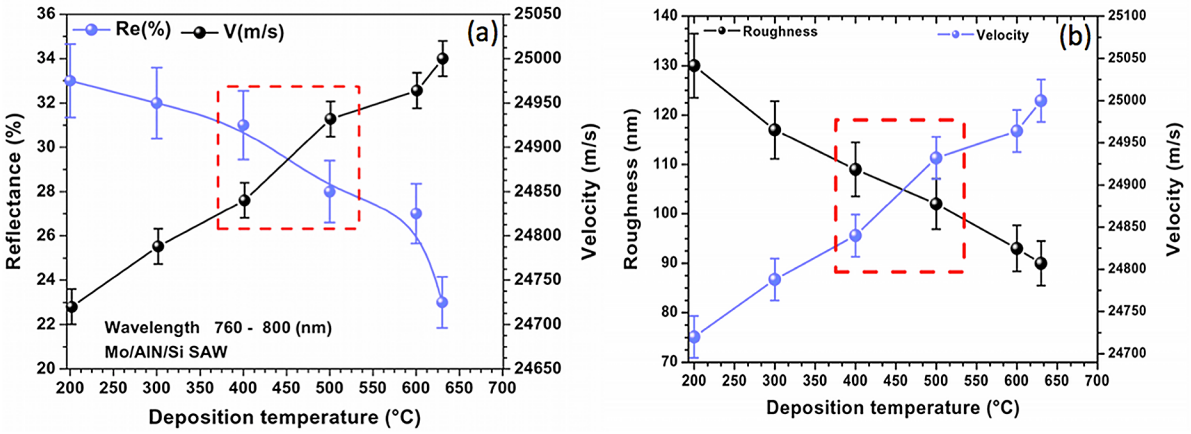


Table 5. Influence of the substrate temperature of AlN thin films on the morphological properties - roughness and the velocity of sound on the SAW

Temperature Substrate (ºC)	Insertion Loss (dB)	Frequency (Ghz)	Grain Size (nm)	Roughness (nm)	SAW velocity (m/s)
200	19,04	0,618	62	130	24720
300	16,45	0,620	56	117	24788
400	12,07	0,621	50	109	24840
500	8,1	0,623	42	102	24932
600	6,09	0,624	38	93	24964
630	5,16	0,625	36	90	25000

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2001). Although in principle it might be thought that all the material has the same polarity, however, is possible that their areas in which the crystals have different polarities. This may explain why the lower the roughness (due to increased substrate temperature during the deposit) on AlN films has favored an increase in the velocity of the waves in the SAW devices.

CONCLUSION

The method of plasma diagnosis by tuning the formation energy of materials formation as HA films may lead to propose and confirm experimental and theoretical models. It was demonstrated that knowledge of the plasma geometry and the corresponding energetic characteristics was a necessary pre-condition for controlling the film stoichiometry and crystallinity adequate for biomedical applications. Furthermore, the knowledge and control of plasma properties is more important than the use of heater and bias used in the conventional sputtering systems.

Likewise, investigated the role of deposition temperature in determining the optical properties of AlN films and the frequency response characteristics of Mo/AlN/Si_3N_4 SAW devices, due to AlN films were grown on Si_3N_4 (100) substrates by PLD using an Al target in N_2 as working gas. The temperature deposition was varied from 200 °C to 630 °C to analyze their effect on the optical and morphological properties of the films. X-ray photoelectron spectroscopy (XPS) confirmed the formation of the binary films. The study revealed that temperature deposition has a marked influence on the chemical and physical nature of all the AlN thin films (oxygen concentration grain size and roughness). For piezoelectric films with a smooth surface, a decrease in the RMS roughness can lead to an increase in its SAW velocity. The evidence is increased with decreasing speed of the roughness and grain size with increasing substrate temperature. It was found a decrease in the reflectance of 10%, an increasing of color purity of 4.5% and dominant wavelength around 1.5% with temperature deposition between 200 - 630 °C. Furthermore, the deposition temperature clearly affects the reduction of micro-drops; this can be possible due to great surface mobility when the temperature was varied from 200 to 630 °C. The SAW propagation velocity is strongly dependent on deposition conditions. The Rayleigh mode and can be obtained with h/λ ratio larger than 0.004. The reflection signal amplitude and phase velocity of Rayleigh wave have been increased with increasing of deposition temperature. Finally, it was possible to design an interdigital structure with Mo circuit on AlN films like an insulator, which can be used as surface acoustic wave (SAW) devices.

Recently authors like Aissa et al.(Aissa et al., 2015) have achieved a breakthrough in obtaining high quality thin films of AlN. The films were deposited by dc magnetron sputtering (dcMS) and high power impulse magnetron sputtering (HiPIMS) deposition techniques. In both cases of films deposited by dcMS and HiPIMS, the XRD results showed that the obtained films are oriented, with full width at half maximum rocking curves of around 1°. Raman spectroscopy revealed higher residual stress relaxation in the AlN epilayers grown by HiPIMS compared to AlN grown by dcMS, highlighted by a blue shift in the E2 (high) Raman mode. The SAW measurements indicated an insertion loss of AlN-SAW devices of about 53 and 35 dB for the AlN films deposited by dcMS and HiPIMS respectively. Even though the values of the insertion loss of the as-deposited AlN thin film by HiPIMS are a little bit inadequate for real applications, these frequency-response characteristics, manifestly, show the potential for high-frequency applications of AlN thin films deposited on Silicon substrates at room temperature.

Chapter 57
Optimal Intervention Methods for Markovian Gene Regulatory Networks

Mohammadmahdi Rezaei Yousefi
The Ohio State University, USA

ABSTRACT

A central problem in translational medicine is to provide a framework for deriving and studying effective intervention methods to elicit desired steady-state behavior for a gene regulatory network of interest with Markovian dynamics. Heretofore, two rather different external control approaches have been taken. The first optimizes a subjectively defined cost function while modeling treatment constraints; therefore, desirable shift of the steady-state mass is a by-product. The second approach, on the other hand, focuses solely on the steady-state behavior of the network and provides the maximal shift achievable. Although both approaches are optimal with respect to their objectives, the choice of which to use depends on the treatment goals.

INTRODUCTION

In order for a cancer treatment to be successful one must account for the patient's condition, the nature of the disease, its dynamics, the effect of antitumor drugs or radiation, the duration of effect and side effects. Each of these is a major field in the medical community, and a vast amount effort has been devoted to their characterization. Typically, the main objective of many treatment schemes is to find the right dose schedules while maximizing the benefit to toxicity ratio for a large portion of the patient population (Simon & Norton, 2006). To this end, treatments usually involve some kind of protocol and several drug candidates acting on various gene products with the aim of mitigating undesirable gene functions in cancer-related genetic pathways. Cancer therapies, for example chemotherapy, are usually administered in cycles, where each cycle begins by delivering a drug that kills cells which divide rapidly. The drug is effective for some period, on both normal and tumor cells, after which there is usually a rest period

allowing the body to recover from the adverse effects of the drug (Brunton, Chabner, & Knollmann, 2010). To maximize the chance of eradicating a tumor, one should deliver the most effective drug at a sufficient dosage over as short a time as possible (Simon & Norton, 2006). However, since the toxicity of a drug could be intolerable to the patient, we desire a therapeutic method that acts very rapidly and with high efficiency so that a large percentage of tumor cells die or shift into a mode where they can no longer proliferate. The method should, at the same time, prolong patients' lives with reasonable quality during and after treatment.

The duration of effective response for a given set of drugs depends on many factors that may vary among a patient population or even in a population of cells within an individual. Achieving an acceptable success rate is tied to three key factors: (1) building accurate models for the underlying dynamical system governing the cancer and the drug response; (2) forcing cancerous cells to either initiate cell death or terminate differentiation as early as possible; and (3) choosing a suitable intervention strategy according to the states of the tumor and patient at the beginning of each therapeutic cycle (Yousefi, Datta, & Dougherty, 2013).

A gene regulatory network (GRN) refers to a class of models describing the multivariate functional relationships among a cohort of genes or their products. From a graphical perspective, genes are nodes in this network and edges describe regulatory relationships between genes. A GRN can be alternatively viewed as an input-output system, where the inputs are signals from signaling pathways or transcription factors, and the outputs are gene expression levels at a given time (Huang, Tienda-Luna, & Wang, 2009). A regulatory network should be able to predict the behavior of the collection of genes of interest under different conditions and perturbations (Dougherty & Shmulevich, 2012; Pe'er & Hacohen, 2011). These networks aim to model cellular control and how abnormal cell functions result from one or several breakdowns in the regulatory mechanisms, making them an important part of translational medicine (Dougherty, Pal, Qian, Bittner, & Datta, 2010).

Building a model for the underlying GRN is the first step toward designing optimal intervention. There has been a considerable amount of work on developing models and inference methods that provide accuracy, robustness, adaptivity and a system-level view, including Bayesian networks (Friedman, 2004), signed directed graphs (Kyoda, Baba, Onami, & Kitano, 2004), Petri nets (Chaouiya, Remy, & Thieffry, 2008; Matsuno, Doi, Nagasaki, & Miyano, 2000), differential equations (De Jong, 2002), stochastic differential equations (Chen, Wang, Tseng, Huang, & Kao, 2005; El Samad, Khammash, Petzold, & Gillespie, 2005), Boolean networks (Kauffman, 1969) and probabilistic Boolean networks (PBNs) (Shmulevich, Dougherty, Kim, & Zhang, 2002). Each modeling paradigm has its own strengths and weaknesses. For example, Bayesian networks are descriptive and require a large number of samples for inference. Boolean models are predictive, but they are very simplistic and come short when a more refined characterization of a regulatory process is needed. Although ordinary differential equations can capture quantitative molecular or physical details of the system, predictions are usually accurate only when the number of molecular species involved is large. When regulatory molecules are produced in small concentrations, fluctuations in the number of molecules have a significant impact on the process dynamics, and therefore a stochastic differential equation model is more appropriate (Cao & Samuels, 2009; Shmulevich & Aitchison, 2009).

Modeling GRNs via Markovian dynamical networks, such as PBNs, has received much attention recently because they are simple and can capture uncertainty, intrinsic or extrinsic, due to measurement noise in the data, latent variables or stochastic interactions among genes or gene products at different levels. Another feature of PBNs, which makes them attractive for studying intervention methods that affect

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the dynamics of a GRN, is that they can be represented as finite-state Markov chains. Each state in the resulting Markov chain represents a *gene activity profile* (GAP) and state transitions are made according to a *transition probability matrix* (TPM). To be self-contained, this chapter will give a review of PBNs.

The set of all GAPs constitutes the state space of the network, which can be then partitioned into two disjoint sets of *desirable* and *undesirable* cellular states according to the expression levels of a given set of genes. An undesirable state can be associated with a phenotype representative of a cancerous state; for example, cell growth in the absence of growth factors is undesirable (Faryabi, Vahedi, Chamberland, Datta, & Dougherty, 2008). Once a model for the underlying GRN is assumed and desirable and undesirable states are identified, the goal in optimal intervention design is to find therapeutic strategies (control policies) associated with some predefined objective functions such that the evolution of the network is optimally steered from undesirable states to desirable ones (Datta & Dougherty, 2006; Dougherty et al., 2010; Dougherty & Datta, 2005). This problem has been extensively studied within two basic intervention approaches in the context of PBNs, namely structural intervention and external control.

Structural intervention, in its simplest form, involves a one-time change in the regulatory pathway of interest. Given a cancer-related network and a collection of potential structural interventions, the objective is to single out the one resulting in a maximally desirable alteration in the steady-state of the network (Qian & Dougherty, 2008; Shmulevich, Dougherty, & Zhang, 2002; Xiao & Dougherty, 2007).

External control, on the other hand, is generally based on changing the expression status of a set of specific genes or gene products, called the *control* genes, at each decision epoch. The first proposed intervention approach in the context of PBNs was to determine an optimal single-gene perturbation to the network based on first-passage times in Markov chains (Shmulevich, Dougherty, & Zhang, 2002). Attention, later, turned to dynamic-programming-based finite-horizon (Datta, Choudhary, Bittner, & Dougherty, 2003) and infinite-horizon external control methods (Pal, Datta, & Dougherty, 2006). This chapter will be solely focused on external control methods, and will utilize the rich theory of stochastic optimal control.

Decisions regarding possible interventions are usually assumed to be made at every state transition of the network (Datta et al., 2003; Pal et al., 2006). To model dosing constraint, a cyclic approach to intervention may be implemented in which there is a sequence of treatment windows and treatment is allowed only at the beginning of each window (Vahedi, Faryabi, Chamberland, Datta, & Dougherty, 2009). These protocols ignore an important practical aspect of therapy: Due to biological and microenvironmental variability within tumor cells, the action period of an administered drug can vary among a population of patients, so that treatments may have an unknown duration of action. Accounting for this practical modeling assumption introduces an acyclic structure in the intervention protocol. Furthermore, in practice, a physician might monitor a patient at every stage of treatment and decide whether to intervene or not, and if the decision is to intervene, then the patient's body will be under the influence of the drug for some duration, usually followed by a recovery phase. Based on a recently proposed model for tumor growth inhibition, we will first characterize the variability of the length of drug action. Then, we will present a unified approach to both cyclic and acyclic intervention models for PBNs. We accomplish this by placing the problem in the general framework Markov decision processes with partially controlled decision intervals (White, 1978), also known as *semi-Markov* models (Bertsekas, 2005), with an infinite horizon discounting cost objective function. We present a methodology to devise optimal solutions for this class of sequential-decision-making problems and locate optimal intervention policies for synthetically generated gene regulatory networks, and a mutated mammalian cell-cycle network.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Usually, optimal intervention methods are defined relative to a cost value that is assigned through a subjective process. Thus the long-run effect of such methods on a PBN becomes a by-product of the optimization procedure. Since a patient's phenotype is associated with the steady-state behavior of their underlying gene regulatory network, from a practical perspective, it is advantageous to define optimality directly in terms of long-run behavior, which in turn would relieve the physician or biologist from the burden of having to define a subjective cost function (Dougherty et al., 2010; Yousefi & Dougherty, 2013). To address this, we will formulate optimization on the steady-state distribution of PBNs to maximally alter undesirable phenotypes. In addition to desirable and undesirable states, there may exist some "ambiguous" states that are either unrelated to the condition of interest or not fully understood, and thus bear some perceived risk. The framework is flexible enough to account for such cases, where we put constraints on the amount of mass we are willing to accept at different types of states. We will demonstrate the performance of optimal policies using synthetically generated networks as well as a real mammalian cell cycle network and a metastatic melanoma network.

There are other approaches for the control of biological systems. For example, an integrated approach to modeling and control of biological systems has been presented in (Julius et al., 2008), where the authors propose a stochastic hybrid model of the lactose regulation system of *E. coli* bacteria. The dynamics of this model can be further abstracted into a much simpler two-state continuous-time Markov chain, which then can be used to design a feedback controller that drives a certain amount of bacteria to an induced state by manipulating some chemical concentration in the environment (Julius et al., 2008). A recent approach to controlling GRN dynamics has been proposed in (Zañudo & Albert, 2015), where an asynchronous updating scheme for a Boolean network is considered as the model. By integrating the structural and functional information available in the network, the authors propose a procedure to find control targets that directly stabilize the expression or activity of a few select components so that the cell dynamics are driven towards a desired fate or away from an undesired fate. The utility of this approach is demonstrated on a leukemia signaling network and a network controlling the differentiation of T helper cells (Zañudo & Albert, 2015). We refer the interested reader to (Iglesias & Ingalls, 2010; Queinnec, Garcia, Niculescu, & Tarbouriech, 2007) for more examples on the application of control theory in biology.

MARKOVIAN GENE REGULATORY NETWORKS

A "good" model for a GRN should be able to predict the behavior of the main processes, pertinent to the phenotypes of interest, that occur inside a cell or within a population of cells under different conditions and perturbations (Dougherty & Shmulevich, 2012; Pe'er & Hacohen, 2011). It should also identify cellular control mechanisms that lead to normal and abnormal cell functions. Although one can construct complex regulatory models that describe genetic interactions at a fine grain level, this would require a precise understanding of the underlying biological processes and extensive amounts of experimental data to infer the model. Due to these limitations, we may need to move toward coarser models that incorporate uncertainty, rather than complexity, at different levels.

PBNs, as a class of Markovian networks, model uncertainty in gene activity in a GRN (Shmulevich, Dougherty, Kim, et al., 2002). They are essentially a probabilistic extension of a class of rule-based models for the GRNs known as the Boolean networks (Kauffman, 1969). We will first give a brief re-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

view of Boolean networks and then describe a class of PBNs we will be using throughout this chapter. We will also discuss how PBNs can incorporate external intervention inputs, and address two types of controlled PBNs that are central in our study of network intervention.

Boolean Networks

A Boolean network assumes a regulatory graph representing multivariate interactions among a set of genes or gene products. An interaction is specified by a directed edge starting from a predictor gene and ending at an influenced gene. Every gene that is directly connected to another gene may serve as its predictor. A Boolean regulatory rule defines how the predictors of a gene determine its expression level. We restrict ourselves to binary levels, where it is assumed that the expression of each gene is quantized to two levels: zero or one. Zero corresponds to an unexpressed (OFF) gene and one corresponds to an expressed (ON) gene. The mathematical theory extends directly to networks with discrete-valued nodes. We now formally define a Boolean network.

Definition 1: A Boolean network is fully characterized by a set of n nodes, $V=\{v^1,v^2,\ldots,v^n\}$, (representing genes $\{g^1,g^2,\ldots,g^n\}$ or their products) and a collection of Boolean functions $F=\{f_1,f_2,\ldots,f_n\}$ describing the functional relationships between the nodes. Each Boolean function f_i: $\{0,1\}^j \rightarrow \{0,1\}$ determines the value of node i at time $t+1$ given the value of its predictors at time t by

$$v_{t+1}^i = f_i(v_t^{i1}, v_t^{i2}, \ldots, v_t^{ij_i}), \tag{1}$$

where $\{v_t^{i1}, v_t^{i2}, \ldots, v_t^{ij_i}\}$ corresponds to values of j_i predictors of gene g^i, $\{g^{i1},g^{i2},\ldots,g^{ij}\}$, at time t. In a Boolean network, all genes are assumed to update synchronously, so that the network evolves according to a genome-wide GAP, $\mathbf{v}_t = (v_t^1, v_t^2, \ldots, v_t^n)$ at each time t, forming a *state space* of size 2^n. One may alternatively convert each $\mathbf{v}_t$ to a decimal value by $x_t = \sum_{i=1}^{n} 2^{n-i} v_t^i$, where $x \in \mathcal{S} = \{0,1,\ldots,2^n-1\}$ is a *state*. Given an initial state, a Boolean network will eventually enter and stay in a set of states called an *attractor cycle*. The set of states leading to an attractor cycle is known as a *basin of attraction (BOA)* (Dougherty et al., 2010). Once we have a state space, we can identify phenotypes as the attractors of a Boolean network. We label states as being *desirable* or *undesirable* depending on the type and severity of the phenotype they are associated with. The set of desirable and undesirable states are denoted by $\mathcal{D}$ and $\mathcal{U}$, respectively.

Probabilistic Boolean Networks

Due to latent variables, unknown interactions among genes and measurements noise, one may introduce uncertainty into a Boolean network by allowing a collection of several contextual regulatory functions, instead of a single F, as well as random perturbation of the nodes at every time epoch (Shmulevich, Dougherty, Kim, et al., 2002). The resulting model is a PBN formally defined below.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Definition 2: A probabilistic Boolean network is characterized by a set of n nodes, $V=\{v^1,v^2,\ldots,v^n\}$, and a set of m constituent Boolean networks, $\mathbf{F}=\{F^1,F^2,\ldots,F^m\}$, called *contexts*, a selection probability vector $S=(s^1,s^2,\ldots,s^m)$ over $\mathbf{F}$, a network switching probability q and a random gene perturbation probability p. Random switching and gene perturbation are assumed to be mutually exclusive.

At any time point, with probability q, the network evolution may switch from a constituent Boolean network to another according to the selection probability vector. It is assumed that the probability of switching to a new constituent network is independent of the current network, and in particular the current network may switch to itself. In addition, with probability p, the current state of each gene in the network can be randomly flipped. The PBN is said to be *context-sensitive* if $q<1$, the interpretation being that there are latent variables outside the network whose changes cause the model network to behave stochastically (Brun, Dougherty, & Shmulevich, 2005). If $q=1$, the PBN is said to be *instantaneously-random*, the interpretation being that the uncertainty in the PBN arises from uncertainty in model inference (Shmulevich, Dougherty, Kim, et al., 2002). With sufficiently small perturbation probability p, the long-run behavior of a PBN will reflect the attractor structures within the context Boolean networks (Brun et al., 2005). Throughout this chapter, we assume instantaneously random PBNs.

Transition rules of any instantaneously random PBN can be modeled by a homogeneous Markov chain, whose states are the GAPs of the underlying regulatory network (Shmulevich, Dougherty, Kim, et al., 2002). Let $\{Z_t \in \mathcal{S},\ t=0,1,\ldots\}$ denote the stochastic process of the state of a PBN. For all $t=0,1,\ldots$, originating from state $x \in \mathcal{S}$, the successor state $y \in \mathcal{S}$ is selected randomly according to the TPM $\mathcal{P}$, whose (x,y) element can be calculated readily from the following equation:

$$\left[\mathcal{P}\right]_{xy} = p_{xy} = P(Z_{t+1} = y \mid Z_t = x) = (1-p)^n \sum_{l=1}^{m} s^l 1_{F^l(x)=y} + 1_{D(x,y)\neq 0}(1-p)^{n-D(x,y)} p^{D(x,y)}, \quad (2)$$

where $D(x,y)$ denotes the Hamming distance of x and y in their binary representations. Due to random gene perturbation, the equivalent Markov chain is ergodic and has a unique invariant probability vector, π, equal to its steady-state distribution.

Controlled PBNs

We assume that PBNs admit external control inputs that may take their value from a set of actions specifying the type of intervention on a set of genes (or their products), which directly influences the dynamics of the GRN of interest. We refer to these genes as the *control genes*, and discuss two types of control inputs that have been used in the literature. One can easily extend the theory to other arbitrary control inputs as long as they influence the network dynamics. We assume there is a finite set of control actions, $\mathcal{A}$, where each element $a \in \mathcal{A}$ specifies a control input that effects the expression level of a control gene, g^c, for some $c\in\{1,2,\ldots,n\}$. Since a decision maker might resort to random mechanisms for taking actions, we assume that the actions are permitted to be random. Let $\{A_k \in \mathcal{A}, k=0,1,\ldots\}$ denote the stochastic process of actions taken.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The first, and simpler, class of control inputs are called *binary* inputs, where one allows for choosing decisions from a set $\mathcal{A}=\{0,1\}$ at every transition (or decision epoch) of the process. The control action a=0 results in no-intervention, while a=1 toggles the current state of the control gene. The TPM for the controlled network under a binary input is denoted by $\mathcal{P}(a)$ and defined as

$$\left[\mathcal{P}(a)\right]_{xy} = p_{xy}(a) = P(Z_{t+1} = y \mid Z_t = x, A_t = a), \tag{3}$$

which is the probability of going to y at time t+1 starting from state x and taking action a at time t. Let $\tilde{x}$ have the same binary representation as x except with bit v^c flipped. For a=1, we have

$$\left[\mathcal{P}(1)\right]_{xy} = p_{xy}(1) = P(Z_{t+1} = y \mid Z_t = x, A_t = 1) = P(Z_{t+1} = y \mid Z_t = \tilde{x}) = p_{\tilde{x}y}, \tag{4}$$

where $p_{\tilde{x}y}$ is defined in (2). Thus, the control action a=1 replaces the row corresponding to the state x by the row corresponding to the state $\tilde{x}$ in the original TPM of the underlying Markov chain. For a=0, we simply have $\mathcal{P}(0) = \mathcal{P}$ from (2).

The second class of control inputs are referred to as *persisting effect* inputs, which find application in the intervention models, where the decision maker is not allowed to make decisions at every transition of the network, but only at certain time epochs. Furthermore, once a decision is made it may last for several time epochs until the next decision epoch. To model this effect, one can assume that the external control forcibly sets the expression of the control gene to a certain level. A simple and common choice for $\mathcal{A}$ then would be {0,–1,1}, where 0 indicates no-intervention, and -1 or 1 indicate that the control gene is externally set to 0 or 1, respectively. The network evolves without alteration when a=0, i.e., the transition rules are found from (2). However, for $a\in\{-1,1\}$ the network evolves according to its underlying regulatory functions, but at the same time the control gene is forcibly kept at a fixed state. Hence, depending on the choice of control, some of the states become *accessible* while the others become *inaccessible*, where only transitions between accessible states are permitted. Hence, in the presence of intervention, we will have a PBN with restricted transition rules.

We define $\mathcal{S}_a$ as the set of accessible states when an action $a \in \mathcal{A}$ is in effect. Consequently, the set of inaccessible states for an action $a \in \mathcal{A}$ is $\mathcal{S} \setminus \mathcal{S}_a$. For example, assuming that g^1 is the control gene, which corresponds to the most significant bit in the binary representation of the states, we get

$$\begin{cases} \mathcal{S}_0 = \mathcal{S}, \\ \mathcal{S}_{-1} = \left\{0, 1, 2, \ldots, 2^{n-1} - 1\right\}, \\ \mathcal{S}_1 = \left\{2^{n-1}, 2^{n-1} + 1, \ldots, 2^n - 1\right\}. \end{cases} \tag{5}$$

During a *control phase*, when the network is completely under the influence of a control input $a\in\{-1,1\}$, only transitions between states in $\mathcal{S}_a$ are allowed. Therefore, all the probability mass of possible transitions from an inaccessible state to an accessible state would be absorbed by its corresponding accessible state. We denote the TPM of the controlled network during this phase by $Q(a)$, given by

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\left[\mathcal{Q}(a)\right]_{xy} = q_{xy}(a) = \begin{cases} p_{xy} + p_{x\tilde{y}}, & \text{if } x, y \in \mathcal{S}_a \\ 0, & \text{if } x, y \notin \mathcal{S}_a \end{cases} \tag{6}$$

where $a \in \{-1,1\}$ and p_{xy} is defined in (2). For $a=0$, we have $\mathcal{Q}(0) = \mathcal{P}$.

Next we address two types of transient phases, *uncontrolled-to-controlled* and *controlled-to-uncontrolled*, and find the TPMs during these phases. These transient effects last for only one time epoch until the network enters or leaves the controlled phase. When uncontrolled, the network can start from any original state in $\mathcal{S}$; however, under the control action a it must arrive at a state in $\mathcal{S}_a$ following the transition rules of the controlled network. Using a similar argument as in the control phase, we can calculate the TPM of the network in the uncontrolled to controlled transient phase, denoted by $\mathcal{R}(a)$, as

$$\left[\mathcal{R}(a)\right]_{xy} = r_{xy}(a) = r_{\tilde{x}y}(a) = \begin{cases} p_{xy} + p_{x\tilde{y}}, & \text{if } x, y \in \mathcal{S}_a \\ 0, & \text{if } y \notin \mathcal{S}_a \end{cases} \tag{7}$$

where $a \in \{-1,1\}$ and p_{xy} is defined in (2). For $a=0$, we have $\mathcal{R}(0) = \mathcal{P}$. During the controlled to uncontrolled transient phase, the control action transitions from being effective to ineffective; therefore the state must originate in $\mathcal{S}_a$, depending on the control action taken earlier, but then may transition to any state in the full state space, $\mathcal{S}$. Hence, the network transition probabilities follow that of the original TPM, $\mathcal{P}$.

Cost-Dependent Control

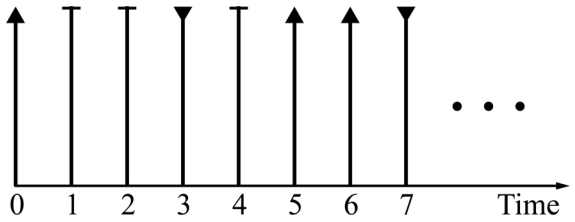
Optimal cost-dependent finite- and infinite-horizon intervention methods assume that there is a bounded cost function associated with every state and control decision pair. Although the choice of cost function is subjective and depending on the treatment goals, typically one assigns non-negative costs to an intervention decision and/or if the next state is an undesirable state.

It has been argued that short term control methods are not always effective as they do not change the steady state behavior of the PBN (Pal et al., 2006); therefore, infinite-horizon methods are preferred, unless one specifically is interested in temporarily changing network dynamics. Optimal infinite-horizon control policies can be formulated relative to two different objective functions: the expected total discounted cost and the expected average cost. Whereas the latter is only concerned with the long-run behavior of the network, the former puts more emphasis on short-term effects of the intervention decisions, although both will change the steady-state behavior of the PBN.

One of the earliest and simplest control methods permits making decisions, at every epoch, to intervene or let the PBN follow its uncontrolled transition rules (Datta et al., 2003; Pal et al., 2006). The optimal control methods for both types of objective functions are stationary, meaning that they are independent of time and only dependent on the state of the network. We refer to this class of control models as *one-transition* models. Figure 1 depicts an example.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Intervention is allowed at each time epoch. Blunt arrows stand for no-intervention; normal arrows stand for up-regulation; reverse arrows stand for down-regulation.

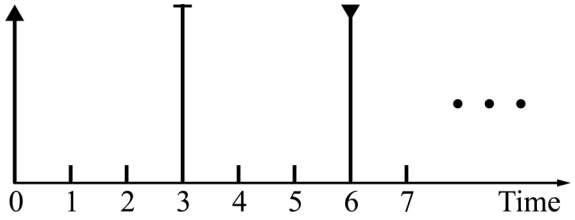


Generalizing the class of one-transition methods in order to account for dosing constraint in chemotherapy, (Vahedi et al., 2009) defines cyclic strategies in which treatment windows are assumed to be every W time epochs. A one-time decision is allowed only at the beginning of each treatment window; thereafter, the network evolves for W–1 epochs without any intervention effects. Similar cost functions as to those in (Pal et al., 2006) are considered and the goal is to minimize the expected total discounted cost. Optimal control methods for this problem are stationary. Figure 2 shows a schematic of this *W-transition* intervention model.

The effect of external intervention, specifically those of antitumor drugs, on tumor cells have been extensively analyzed in the pharmacology literature (Cojocaru & Agur, 1992; de Vladar & González, 2004; Himmelstein & Bischoff, 1973). The pharmacokinetics and pharmacodynamics (PK/PD) of a given drug are separately modeled and then linked together to arrive at a model for the time-course *concentration-effect*. In short, PK uses mathematical models to explain and predict drug concentration in the body (for example, in the blood stream or the tumor site) over time. PD, on the other hand, links the effects of a drug and its mechanism of action to the drug concentration level or the total integrated effective concentration during the course of treatment (Simon & Norton, 2006). It is common to use differential equations (e.g. multi-compartment models) for PK, which in many cases are fairly accurate. However, modeling PD is more challenging as the time-course effects of a drug are not easy to measure. PK/PD linking, with the objective of determining how much variability in drug effectiveness is attributable to measurable drug concentrations, can be done via several functions, including linear models, sigmoid-E_{max} models, etc. (Dayneka, Garg, & Jusko, 1993).

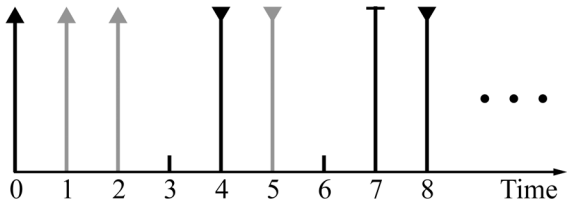
The W-transition policy ignores the drug's duration of action, and the fact that persistent effects exists and must be accounted for in the intervention model. To alleviate this limitation, we build upon recent work for tumor growth inhibition in response to a given drug, where a measure for the duration of ef-

Figure 2. Intervention is only permitted at the beginning of each window of W=3 epochs. Thereafter, the network evolves freely with no intervention for W–1 time epochs. Blunt arrows stand for no-intervention; normal arrows stand for up-regulation; reverse arrows stand for down-regulation.



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. The drug, once administered, has an action period with a random length, followed by a recovery phase. For example, at epoch 0, the decision is to up-regulate. The drug has a persistent effect of length three epochs (shown by the shaded bars). Similarly, at epoch 4 the decision is to down-regulate, but now the drug effect lasts two epochs. The recovery phase is one epoch. Blunt arrows stand for no-intervention; normal arrows stand for up-regulation; reverse arrows stand for down-regulation.



fective response as a function of parameters is provided (Magni et al., 2008; Magni, Simeoni, Poggesi, Rocchetti, & De Nicolao, 2006). In the new intervention model, the duration of drug action, following each application, is assumed to be random. The randomness is attributed to biological variability among tumor cells, which results in different action periods for a drug. Figure 3 shows an example of this intervention model, referred to as the *random-length* intervention model, where the effect is persistent over a random number of consecutive epochs.

This framework includes several special cases of intervention models:

1. **One-Transition:** Decisions are allowed at every epoch, and drug effect vanishes immediately.
2. ***W*-Transition:** Decisions are allowed at every W epochs, and drug effect vanishes immediately.
3. **Cyclic Control with Fixed-Length Duration of Action:** Decisions are allowed at every W epochs, and drug effect vanishes after $L \leq W$ epochs.
4. **Acyclic Control with Fixed-Length Duration of Action:** Similar to the cyclic model, but when the control decision is *no intervention*, the next decision is made immediately at the next epoch.

We will present the optimal intervention policy for this new intervention model. Our formulation uses the theory of MDPs with partially controlled decision intervals, where given the current state and the action taken, the time interval between successive decisions can be random with a known probability distribution (White, 1978). Similar to the cost function defined for the one-transition model, a predefined cost at each stage is applied when a control action is taken and/or the next state is in the set of undesirable states. The objective is to devise a control strategy that minimizes the expected total discounted cost.

Standard Discounting Cost MDP

We will first review basic MDPs corresponding to the one-transition model. For t=0,1,… denoting the time, let $Z_t \in \mathcal{S}$ and $A_t \in \mathcal{A}$ be a controlled Markov chain, where $\mathcal{S}$ is a finite set of all possible states the Markov chain can occupy, and $\mathcal{A}$ is the set of all possible actions available to the decision maker. The TPM of this chain is defined by

$$p_{xy}(a) = P(Z_{t+1} = y \mid Z_t = x, A_t = a). \tag{8}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

A *control policy*, $\mu=\{\mu_t\}$ for $t=0,1,\ldots$ is sequence of instructions for taking actions that steers the dynamics of the process. Let $\{z_t\}$ and $\{a_t\}$ be the sequence of observed states and actions, respectively. We allow for μ_t to be a function of the entire history of the system up to time t, denoted by $h_t = (z_0,a_0, z_1,a_1,\ldots,z_t,a_t)$. Once h_{t-1} is available then some action $a \in \mathcal{A}$ is chosen with probability $\mu_t(a \mid h_{t-1}, z_t)$, where $\mu_t(a \mid h_{t-1}, z_t) \in [0,1]$, and

$$\sum_a \mu_t(a \mid h_{t-1}, z_t) = 1. \tag{9}$$

Let $\mathcal{M}$ be set of all control policies μ. The transition probabilities, $p_{xy}(a)$, the initial state $Z_0=x$ of the Markov chain and any given policy μ determine a unique probability distribution, P_x^μ, over the space of all trajectories of states and actions [derman1970finite]. We denote by E_x^μ the corresponding expectation relative to P_x^μ. Let $g : \mathcal{S} \times \mathcal{A} \times \mathcal{S} \to \Re$ be the immediate cost function, which is assumed non-negative and bounded for all x, a, and y. Given a discount factor $\lambda\in(0,1)$ and an initial state x, the goal is to find a control policy minimizing the expected total discounted cost defined by

$$J(x,\mu) = \lim_{N\to\infty} E_x^\mu \left\{ \sum_{t=0}^{N} \lambda^t g(Z_t, A_t, Z_{t+1}) \right\}. \tag{10}$$

The discount factor guarantees convergence of (10) (Derman, 1970). The optimal cost function, J^*, is defined as

$$J^*(x) = \min_{\mu\in\mathcal{M}} J(x,\mu), \tag{11}$$

for every $x \in \mathcal{S}$ and a policy μ^* yielding the minimum is called an *optimal policy*. It turns out that one need not consider the entire set $\mathcal{M}$ when searching for the optimal policy; instead it suffices to restrict the search to the set of stationary and deterministic policies, denoted by $\mathcal{M}_D$. Policies, μ_t, in $\mathcal{M}_D$ are the same for all $t=0,1,\ldots$, depend only on the current state, and at each state are equal to one for a single element in $\mathcal{A}$ (Derman, 1970). These three conditions imply that μ^* is a single-valued mapping from $\mathcal{S}$ to $\mathcal{A}$. On the basis of the principles mentioned above, one can formulate requirements to minimize the expected cost over an infinite horizon in terms of a functional equation for the finite horizon case. The resulting optimal policy tells us which action to take at each decision epoch, given the state. The functional equation takes the form,

$$J_{k+1}(x) = \min_a \left\{ \tilde{g}(x,a) + \lambda \sum\nolimits_y p_{xy}(a) J_k(y) \right\}, \tag{12}$$

for $k=0,1,\ldots$ and $x \in \mathcal{S}$, where $\tilde{g}(x,a) = \sum_y p_{xy}(a) g(x,a,y)$. Note that, in the above equation, k does not index forward time; rather, it indicates the number of remaining time epochs. In this new reformulation, $J_{k+1}(x)$ is the minimal expected discounted cost over $k+1$ remaining epochs when the initial state is x and the cost at the final epoch is $J_0(x)$, which is assumed to be bounded for all $x \in \mathcal{S}$.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Starting from state x and by choosing action a, we will move to state y at the beginning of the next epoch with probability $p_{xy}(a)$. Now that the chain is at state y, all decisions for the remaining k epochs are assumed to be optimal. Thus, by definition, the optimal expected discounted cost for these k epochs will be $J_k(y)$ relative to the beginning of the k^{th} epoch. Since this is looking one step ahead, it will be discounted and, therefore, we get a cost of $\lambda J_k(y)$. But at epoch $k+1$ we do not yet know y, so we must take the expected value of $\lambda J_k(y)$ relative to y. The immediate expected cost at the $k+1^{\text{st}}$ epoch is $\tilde{g}(x,a)$ and hence, given x and a, the term on the R.H.S of (12) is the optimal expected discounted cost at epoch $k+1$.

Moving to the infinite-horizon domain, and inspired by (12), one can apply the dynamic programming mapping, $\mathfrak{T}$, transforming any function $J : \mathcal{S} \to \Re$ into a new function $\mathfrak{T}J : \mathcal{S} \to \Re$, defined by

$$(\mathfrak{T}J)(x) = \min_a \left\{ \tilde{g}(x,a) + \lambda \sum\nolimits_y p_{xy}(a) J(y) \right\}, \tag{13}$$

for $x \in \mathcal{S}$. We can determine the optimal policy with the help of the following theorems, resulting in an iterative algorithm called *value iteration*. Proofs of these statements can be found in (Bertsekas, 2005).

Theorem 1.1 (Convergence): For any bounded function $J : \mathcal{S} \to \Re$ and all $x \in \mathcal{S}$, the optimal cost function satisfies

$$J^*(x) = \lim_{N \to \infty} (\mathfrak{T}^N J)(x), \tag{14}$$

where $\mathfrak{T}^N$ is the composition of the mapping $\mathfrak{T}$ with itself N times.

Theorem 1.2 (Bellman's Optimality Equation): For all $x \in \mathcal{S}$, the optimal cost function J^* satisfies

$$J^*(x) = \min_a \left\{ \tilde{g}(x,a) + \lambda \sum\nolimits_y p_{xy}(a) J^*(y) \right\}. \tag{15}$$

Furthermore, J^* is the unique solution of this equation in the set of all bounded functions.

Theorem 1.3 (Necessary and Sufficient Condition for Optimality): A stationary and deterministic policy μ is optimal if and only if $\mu(x)$ attains the minimum in Bellman's optimality equation for every $x \in \mathcal{S}$.

The first part of Theorem 1.2 says that $J^* = \mathbf{T}J^*$. In other words, J^* is the fixed point of $\mathbf{T}$. Theorem 1.1 states that J^* can be iteratively found by successively computing $\mathfrak{T}J, \mathfrak{T}^2 J, \ldots$ for any bounded initial cost function J. The convergence of this algorithm is guaranteed due to discounting, where the limit is J^*. Hence, the value iteration algorithm can be continued until some stopping criterion is reached. The last theorem assures that the resulting optimal policy is stationary and deterministic.

Discounting Cost MDP with Partially Controlled Decision Intervals

In a standard MDP, the time index and decision epochs are the same. However, for a MDP with partially controlled decision intervals decision epochs might include multiple time units (White, 1978). Define $\mathcal{L} = \{1, 2, \ldots, K\}$, for a fixed $K \geq 1$, to be the largest time interval between two consecutive decisions epochs. Let t=0,1,… index the decision epochs. We denote by $L_t \in \mathcal{L}$ and $\{l_t\}$ the sequences of random variables representing the length of the time intervals between consecutive decision epochs and the corresponding observed values, respectively. We assume $L_0 \equiv 0$. The transition probabilities for the Markov chain with partially controlled decision intervals are characterized by

$$p_{xy}^{l}(a) = P(L_{t+1} = l, Z_{t+1} = y \mid Z_t = x, A_t = a), \tag{16}$$

for any t=0,1,…, where $Z_t \in \mathcal{S}$ is the sequence of random states, $A_t \in \mathcal{A}$ the sequence of actions, and $\{z_t\}$ and $\{a_t\}$ are the corresponding sequences of observed states and actions, respectively. $p_{xy}^{l}(a)$ is the probability that if we start at a state $x \in \mathcal{S}$ and the decision maker takes an action $a \in \mathcal{A}$, the next call for a decision will take place $l \in \mathcal{L}$ time epochs later and we arrive at state $y \in \mathcal{S}$.

We define a *control policy* μ to be a sequence $\{\mu_t\}$ of instructions for taking actions at each decision epoch t. Each μ_t may be a function of the entire history of the system up to decision epoch t, which we define by

$$h_t = (l, z_0, a_0, l_1, z_1, a_1, \ldots, l_t, z_t, a_t). \tag{17}$$

Once we have h_{t-1}, we will choose an action $a \in \mathcal{A}$ with probability $\mu_t(a \mid h_{t-1}, l_t, z_t) \in [0,1]$, such that

$$\sum_a \mu_t(a \mid h_{t-1}, l_t, z_t) = 1. \tag{18}$$

Denote the set of all control policies μ by $\mathcal{M}$. Similar to the standard MDP, the transition probabilities, $p_{xy}^{l}(a)$, the initial state, $Z_0 = x$, and the policy, μ, determine P_x^{μ} over the space of all trajectories of the states, actions and decision epochs. Let E_x^{μ} denote the corresponding expectation operator. We define $g(x, a, l, y) : \mathcal{S} \times \mathcal{A} \times \mathcal{L} \times \mathcal{S} \to \Re$ to be the immediate cost function over a decision epoch of length l when a transition from state x under control a to state y is made in l subsequent periods. We assume g is non-negative and bounded for all tuples (x,a,l,y). The objective function is the expected total discounted cost, defined by

$$J(x, \mu) = \lim_{N \to \infty} E_x^{\mu} \left\{ \sum_{t=0}^{N} \lambda^{\left(\sum_{m=0}^{t} L_m\right)} g(Z_t, A_t, L_{t+1}, Z_{t+1}) \right\}, \tag{19}$$

for every state $x \in \mathcal{S}$ and $\mu \in \mathcal{M}$, and the goal is to minimize it over the space of policies $\mathcal{M}$. (White, 1978) formulated the following equivalent functional equation for $k \geq K-1$ and all $x \in \mathcal{S}$:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$J_{k+1}(x) = \min_a \left\{ \tilde{g}(x,a) + \sum_y \sum_l \lambda^l p^l_{xy}(a) J_{k+1-l}(y) \right\}, \tag{20}$$

$$\tilde{g}(x,a) = \sum_y \sum_l p^l_{xy}(a) g(x,a,l,y), \tag{21}$$

and $\lambda \in (0,1)$. The functions $J_k(x)$ are assumed given and bounded for all $1 \le k \le K-2$ and $x \in \mathcal{S}$. In, $J_{k+1}(x)$ is the minimal expected discounted cost beginning in state x with $k+1$ remaining epochs and $\tilde{g}(x,a)$ is the immediate expected cost at state x and for control action a. If the next decision epoch happens l time epochs later and leads to arrival at state y the minimal expected discounted cost (relative to that point in time) is $J_{k+1-l}(y)$, which when discounted to the present time by a factor λ^l, and when averaged over the joint distribution of y and l, gives the required result by minimizing over all actions $a \in \mathcal{A}$ (White, 1978).

We define the dynamic programming mapping, $\mathfrak{T}$, by

$$(\mathfrak{T}J)(x) = \min_a \left\{ \tilde{g}(x,a) + \sum_y \sum_l \lambda^l p^l_{xy}(a) J(y) \right\}, \tag{22}$$

for all $x \in \mathcal{S}$. Finding the fixed point of the mapping $\mathfrak{T}$, and the minimizing control action at each state x, gives the control policy minimizing the objective function (19). The following three theorems provide the solution to this problem.

Theorem 1.4 (Convergence): For any bounded function $J : \mathcal{S} \to \mathbb{R}$ and all $x \in \mathcal{S}$, the optimal cost function satisfies

$$J^*(x) = \lim_{N \to \infty} (\mathfrak{T}^N J)(x). \tag{23}$$

Theorem 1.5 (Bellman's Optimality Equation): For all $x \in \mathcal{S}$, the optimal cost function J^* satisfies

$$J^*(x) = \min_a \left\{ \tilde{g}(x,a) + \sum_y \sum_l \lambda^l p^l_{xy}(a) J^*(y) \right\}. \tag{24}$$

Equivalently, $J^* = \mathfrak{T}J^*$, and J^* is the unique solution of this equation in the set of all bounded functions.

Theorem 1.6 (Necessary and Sufficient Condition for Optimality): A stationary and deterministic policy μ is optimal if and only if $\mu(x)$ attains the minimum in Bellman's optimality equation for every $x \in \mathcal{S}$.

Proofs of these statements can be found in (Yousefi, Datta, & Dougherty, 2012). Similar to the standard MDP, the value iteration algorithm can be used to find the optimal policy.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Random-Length Intervention Model

Successful treatment, both at the individual level or the population level, requires modeling uncertainties in the underlying dynamical system corresponding to the tumor, its interaction with the drug, and the costs associated with the treatment (Heppner, 1984). For each treatment cycle, samples must be taken from patients to determine the state of the tumor. Depending on the state, a decision must be made as to what type of intervention is necessary. An intervention at the beginning of a treatment cycle usually implies administering an antitumor drug that initiates the process of tumor growth inhibition.

As a special case of the finite-dimensional growth model, (Magni et al., 2008, 2006) propose a semi-empirical tumor growth inhibition model that exhibits good prediction for tumor growth for *in vivo* experiments. Once the effect of the drug on the dynamics of an unperturbed tumor is modeled, under some simplifying assumptions, they show that, in a single treatment window, tumor growth is delayed. The extent of this effect approximately depends on the proportionality constant of a *damage* function, which models the desirable effect of the drug on the tumor cells, the tumor growth rate at early stages of development, and the integral of the drug concentration-time curve. We denote by T_e the length of the drug effect on tumor cells over a single treatment window. Taking into account the variability of response to the antitumor drug within a population, we assume a four-parameter beta distribution for T_e,

$$T_e \sim \mathrm{Beta}(\alpha, \beta, \underline{T}_e, \overline{T}_e), \tag{25}$$

defined on the interval $(\underline{T}_e, \overline{T}_e)$, where α,β>0 are two real numbers characterizing the shape of this distribution. The parameters of this distribution may be set after consulting with pharmacologists and drug developers.

Assuming PBNs as our reference model for the overall dynamical behavior of tumor cells in the population and external control inputs with persisting effect with $\mathcal{A}=\{0,1,-1\}$, we denote by $T_e(a)$ the length of the window during which the corresponding control gene, directly affected by the drug, will be invariant depending on the type of intervention action $a \in \mathcal{A}$. We also assume that there is a fixed-length rest window of length $T_r(a)$, following $T_e(a)$, to let the side effects of the drug gradually subside. In addition, in the case of no-intervention, i.e. a=0, the next decision will be called after $T_r(0)$ units of time have elapsed since $T_e(0)$ is zero. Note that transitions in a PBN occur in discrete time, while $T_e(a)$ and $T_r(a)$ are continuous-time quantities. A simple resolution would be to construct a probability mass function over a discrete set of levels for these variables. We denote the discretized variables by $\overline{T_e(a)}$ and $\overline{T_r(a)}$.

We define a cost function over the set of control actions and the set of states a PBN may occupy. The total cost for the entire course of treatment is obtained by accumulating the discounted cost incurred at each transition of the network. The discounted cost emphasizes that obtaining a response at earlier stages is favored over later stages. The cost functions directly reflect our objectives; hence, they should be assigned by physicians in conjunction with pharmacologists according to their understanding of the treatment objectives.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

To solve the optimal intervention problem for this particular model, we need only calculate $p_{xy}^{l}(a)$ and $\tilde{g}(x,a)$ for every *x,y,a,* and *l*, and use the mathematical machinery for the MDPs with partially controlled decision intervals. To this end, we first define $\mathcal{L}_{w}(a)=\left\{0,1,2,\ldots,W(a)\right\}$, where *W*(*a*) denotes the maximum length of response to the intervention action *a*, and we define

$$\mathcal{L}(a)=\left\{l: l=\overline{T_{e}(a)}+\overline{T_{r}(a)}\,\text{and}\,\overline{T_{e}(a)}\in\mathcal{L}_{w}(a)\right\}. \tag{26}$$

The probability mass function of $\overline{T_{e}(a)}$ is defined as $P_{l_{w}}(a)=P\left(\overline{T_{e}(a)}=l_{w}\right)$ for all $l_{w}\in\mathcal{L}_{w}(a)$ and $a\in\mathcal{A}$. Note $P_{l_{w}}(a)\geq 0$ and $\sum_{l_{w}}P_{l_{w}}(a)=1$. Thus, the total length of each treatment cycle (drug action and rest together) is a discrete random variable whose probability mass function is $P_{l}(a)=P_{l_{w}}(a)$, for every $l\in\mathcal{L}(a)$ and $a\in\mathcal{A}$.

One structural constraint of the problem is that if no intervention occurs, i.e. $\overline{T_{e}(0)}=0$, then the next decision epoch will be called deterministically $\overline{T_{r}(0)}$ time epochs later on. Thus, we have $P_{l}(0)$=1 for $l=\overline{T_{r}(0)}$. Another structural constraint is that if any intervention occurs we have $\overline{T_{e}(a)}\geq 1$, meaning that $P_{l}(a)$=0 for $l=\overline{T_{r}(a)}$ when $a\in\mathcal{A}\setminus\{0\}$. Therefore,

$$p_{\mathbf{ij}}^{l}(0)=\begin{cases}p_{\mathbf{ij}}^{\left(\overline{T_{r}(0)}\right)}, & \text{if } l=\overline{T_{r}(0)}\\ 0, & \text{otherwise}\end{cases} \tag{27}$$

$$p_{xy}^{l}(a)=P_{l}(a)\sum_{x'}r_{xx'}(a)\sum_{x''}q_{x'x''}^{\left(l-\overline{T_{r}(a)}-1\right)}(a)p_{x''y}^{\left(\overline{T_{r}(a)}\right)}, \tag{28}$$

for all $a\in\mathcal{A}\setminus\{0\}$ and all $l\in\mathcal{L}(a)$. The terms p_{xy}, q_{xy}, and r_{xy} are found from (2), (6) and (7), respectively, and a superscript (*n*), as in $p_{xy}^{(n)}$, denotes the transition probability of going from state *x* to *y* in *n* epochs.

In our setting, the immediate cost function $\tilde{g}(x,a,l,y)$ is also an expected discounted cost accumulated over the entire window. Let $g_{xy}(a)$ denote the one-transition cost function, which depends on the current state *x*, next state *y* and control *a*. We assume that $g_{xy}(a)$ is non-negative and bounded for all $x,y\in\mathcal{S}$ and $a\in\mathcal{A}$, and postulate the following structure for it:

$$g_{xy}(a)=\begin{cases}C+c(a), & \text{if } y\in\mathcal{U}\\ c(a), & \text{if } y\in\mathcal{D}\end{cases} \tag{29}$$

where *c*(*a*)=*c* for all $a\in\mathcal{A}\setminus\{0\}$ and zero otherwise. It is straightforward to show that

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\tilde{g}(x,a)=\begin{cases}\sum\limits_{m=0}^{\overline{T_r(0)}-1}\lambda^m\sum\limits_y p_{xy}^{(m+1)}g_{xy}(a) & \text{for } a=0\\ \sum\limits_{l\in\mathcal{L}(a)}P_l(a)\tilde{g}(x,a,l) & \text{for } a\in\mathcal{A}\setminus\{0\}\end{cases} \tag{30}$$

$$\begin{aligned}\tilde{g}(x,a,l)=&\sum_y r_{xy}(a)g_{xy}(a)+\sum_{m=1}^{l-\overline{T_r(a)}-1}\lambda^m\sum_{x'}r_{xx'}(a)\sum_y q_{x'y}^{(m)}(a)g_{x'y}(a)\\&+\sum_{m=l-\overline{T_r(a)}}^{l-1}\lambda^m\sum_{x'}r_{xx'}(a)\sum_{x''}q_{x'x''}^{(l-\overline{T_r(a)}-1)}(a)\sum_y p_{x''y}^{(m-l+\overline{T_r(a)}+1)}g_{x''y}(0),\end{aligned} \tag{31}$$

for all $l\in\mathcal{L}(a)$. Substituting $p_{xy}^{l}(a)$ and $\tilde{g}(x,a)$ from, and, respectively, into and using the value iteration algorithm one can find the optimal control policy.

Simulation on Networks

To illustrate the effectiveness of our approach, we run several simulations on both synthetically generated PBNs and a PBN corresponding to a mammalian cell cycle network. Throughout, we choose the following values for the parameters:

$$\text{Cost function parameters:}\begin{cases}\lambda=0.95\\ C=2\\ c=0.1\end{cases}\quad\cdots\quad\text{Drug effect parameters:}\begin{cases}W(-1)=W(1)=W\\ W=10\\ \overline{T_r(a)}\equiv\overline{T_r}\in\{1,2,5,10,20\}\\ T_e(-1)=T_e(1)=T_e\\ T_e\sim\text{Beta}(10,30,0,10)\end{cases}$$

We also discretize the beta distributions into ten levels. The resulting discrete distributions are shown in Figure 4.

We evaluate six intervention strategies, each based on different assumptions and constraints:

M1 (One-Transition): Decisions are made at each time epoch and the drug duration of effect is assumed to be 1;

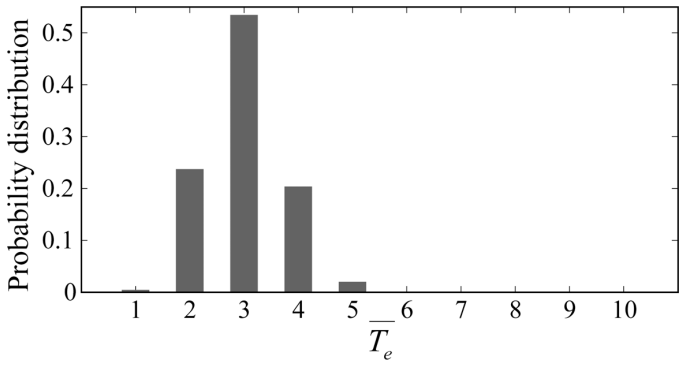
M2 (Cyclic $(W+\overline{T_r})$-Transition without Drug Effect): Decisions are made at every $(W+\overline{T_r})$ time epochs and the drug duration of effect is assumed to be 1;

M3 (Acyclic $(W+\overline{T_r})$-Transition without Drug Effect): Decisions are made at every $(W+\overline{T_r})$ time epochs if $a\in\{-1,1\}$ and $\overline{T_r}$ time epochs otherwise. The drug duration of effect is assumed to be 1;

M4 (Cyclic $(W+\overline{T_r})$-Transition with Drug Effect): Similar to M2 but the drug response is modeled with fixed length of *W*;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Quantized beta distributions for $\overline{T}_e$ with T_e~Beta(10,30,0,10)



M5 (Acyclic $(W + \overline{T}_r)$ -Transition with Drug Effect): Similar to M3 but the drug response is modeled with fixed length of *W*;

M6 (Random-Length Drug Effect): The drug is correctly modeled with a random-length effect, and we allow for a rest period of length $\overline{T}_r$.

We refer to the optimal policies derived for each model by the name of that model. Once control policies are found, we apply them with the random-length drug effect (M6) serving as the true model. Note that M1-M5 policies are suboptimal for this model. Hence, our simulation will show how much, relative to the suboptimal policies, one can improve upon when using the optimal policy.

Synthetic Networks

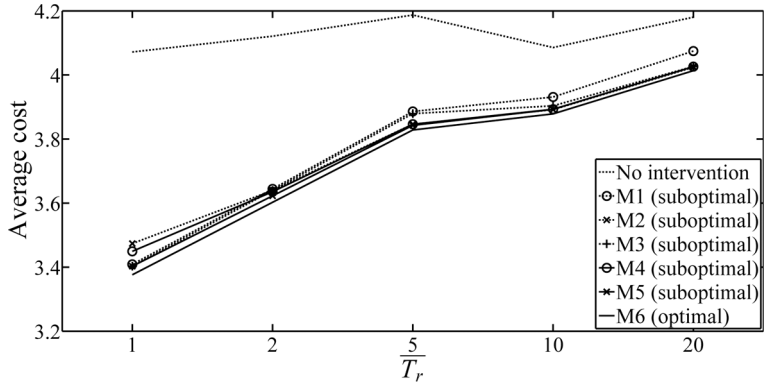
We consider instantaneously random PBNs with seven genes. We also assume each PBN consists of four equally likely constituent Boolean networks with the maximum number of predictors for each Boolean function set to three. When generating Boolean updating functions for each gene, we set the output of each Boolean function, for each input, to one with a small probability, which itself is drawn randomly from a beta distribution with mean 0.1 and standard deviation 0.01. The gene perturbation probability is set to p=0.01. Once BNs are generated, we compute the TPM of each PBN. We define undesirable states, $\mathcal{U}$, as those for which the least significant bit in their binary representation is one, and assume that the control gene is the most significant bit of states.

For each set of simulation parameters, we generate 2900 random PBNs. For each randomly generated PBN in a set of simulations, we find the optimal policies for M1-M6, implement them on the M6 model by simulating the intervention processes over a time-course of length 1500 time epochs, and accumulate the discounted cost incurred at each state-control pair observed. We repeat this process 50000 times, each with a random (uniformly generated) initial state, and compute the expected total discounted cost.

Figure 5 shows the effect of different values for $\overline{T}_r$ on the expected total discounted cost, averaged over 2900 random networks. In this case, $\overline{T}_e$ will most likely take on values from {2,3,4} as shown in Figure 4 which indicates a relatively small variability in the length of drug response. We observe that M6 is optimal on average with a small margin compared to the suboptimal policies.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Average cost of different policies across 2900 random PBNs for $\overline{T}_r \in \{1, 2, 5, 10, 20\}$



Although suboptimal policies appear to perform similarly to the optimal one on average, there are networks for which the optimal policy clearly outperforms the suboptimal ones. We quantify the amount of reduction in the cost, for each random network, achieved by the optimal intervention policy relative to the suboptimal ones via the following formula:

$$\Delta(\mu) = 100 \times \frac{J(\mu) - J(\mu^{\mathrm{M6}})}{J(\mu)}, \tag{32}$$

where $J(\mu)$ denotes the expected total discounted cost when a policy μ is used and $J(\mu^{\mathrm{M6}})$ denotes the expected total discounted cost when under the optimal policy, M6. Because the networks are randomly generated Δ will also be random. We graph the empirical complementary cumulative distribution function (CDF) of Δ for different suboptimal polices when $\overline{T}_r \in \{1, 5, 20\}$.

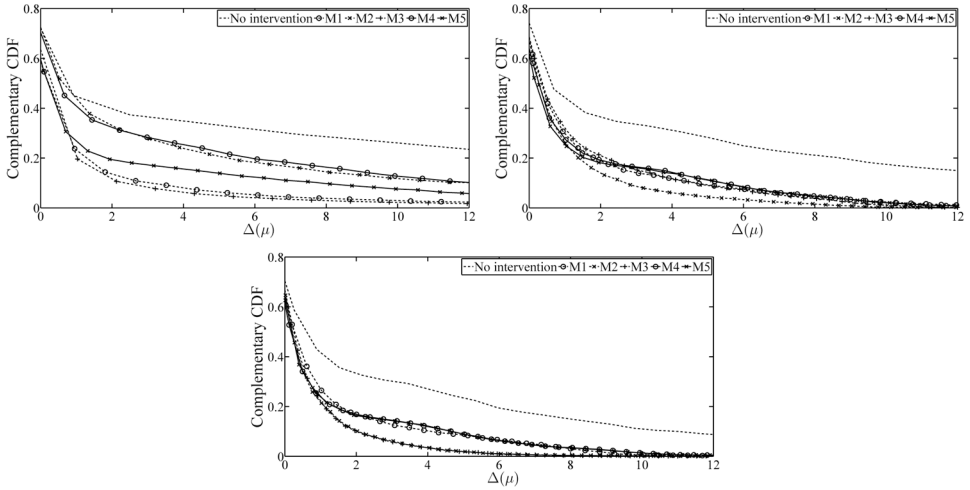
The complementary CDF graph in Figure 6 reveals a high probability that the optimal policy noticeably outperforms others. Interestingly, we observe very little improvement over the M2 and M3 policies for larger $\overline{T}_r$. In this case, $\overline{T}_e$ is likely to be much smaller than $\overline{T}_r$, so that the policies resulting from M2 and M3 may induce similar cost compared to M6.

Real Network

This network models normal biological processes that occur during the mammalian cell cycle, whose disruption can lead to uncontrolled cell proliferation. It was originally constructed in (Faure, Naldi, Chaouiya, & Thieffry, 2006) to provide a logical framework for comparing different strategies to explore the dynamical properties of the core mechanisms controlling the mammalian cell cycle. The network has ten genes (or proteins), CycD, Rb, p27, E2F, CycE, CycA, Cdc20, Cdh1, UbcH10 and CycB, and the regulatory relationships are assumed to be Boolean. Table 1 summarizes these regulatory functions. Three key components in this network are Cyclin D (CycD), retinoblastoma (Rb) and p27. Extracellular signals, under normal conditions, coordinate cell division with overall growth by controlling the activation of CycD. The tumor suppressor protein, Rb, plays a central role in the negative control of the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Empirical complementary CDF of the improvement over different intervention policies across 2900 random PBNs: (Top-left) $\overline{T}_r = 1$ *; (Top-right)* $\overline{T}_r = 5$ *; (Bottom)* $\overline{T}_r = 20$



cell cycle and in tumor progression (Giacinti & Giordano, 2006). Rb is active in the absence of certain cyclin-dependent kinases. When present, however, these cyclins inhibit Rb through phosphorylation. p27 is also active in the absence of the cyclins. An active p27 blocks the action of CycE or CycA and, hence, Rb can also be active even if the cyclins are present, resulting in a mechanism that stops uncontrolled cell division.

This Boolean network can also be used to study the consequences of various mutations. For instance, a possible mutation of p27 (always OFF) may introduce detrimental effects on a cell's normal regulation (Faure et al., 2006). A situation can arise, where both CycD and Rb might be inactive and cell division occurs repeatedly in the absence of any growth factor. This suggests labeling the states in which both Rb and CycD are down-regulated, under a mutated p27, as undesirable. Table 2 presents the Boolean functions of this mutated cell cycle network. The network consists of nine genes, CycD, Rb, E2F, CycE, CycA, Cdc20, Cdh1, UbcH10 and CycB, ordered from the most significant bit to the least significant bit in the binary representation. Depending on the state of the extracellular signal, which determines CycD being ON or OFF, we obtain two contexts. We first build an instantaneously random PBN where these two contexts described above are equally likely. We assume that the gene perturbation probability is 0.01, and define $\mathcal{U}$ to be those states for which CycD and Rb are simultaneously down-regulated. This reflects the undesirability of cell growth in the absence of growth factors. We also choose E2F as the control gene.

Similar to the synthetic networks, we find the M1-M6 policies and apply them to the M6 intervention model. We implement a similar procedure for estimating the expected total discounted cost, but with a small difference where we iterate the time course simulation 250000 times, each with a random initial state, and set the length of the time course simulation to 2500 time epochs. Figure 7 shows performance comparison results for each intervention policy based on the expected total discounted cost for different sets of parameters. The performance results are consistent with the results obtained from simulations on the synthetic networks.

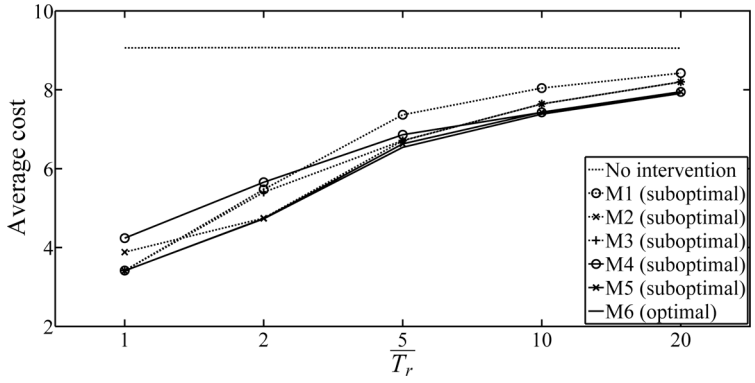
Figure 7. Average total discounted cost of control policies derived from different intervention models for the cell cycle network and $\overline{T}_r \in \{1, 2, 5, 10, 20\}$



Cost-Independent Control

In the previous section, we assigned a large cost to undesirable states and aimed to minimize the long-run discounted cost of being in these states. In systems biology, it is common to model phenotypes as the steady-state behavior of the underlying regulatory network. Thus, from a practical perspective, in many cases our primary interest may be to optimize the long-run occupation of undesirable states, and not to minimize a subjective cost function. Direct optimization has been addressed to some extent in (Qian & Dougherty, 2012; Qian, Ivanov, Ghaffari, & Dougherty, 2009), where the authors propose several classes of greedy stationary policies to reduce the mass corresponding to undesirable states and increase the mass corresponding to desirable states in the steady state distribution, subject to some constraints.

In this section, we will review these suboptimal methods and present an optimal solution to the maximal phenotype alteration problem. Our solution provides an optimal policy with a computational complexity equivalent to solving a linear program (LP) optimization problem. We also address a generalization of this optimization procedure, where the amount of mass moved to some ambiguous states may be constrained. This constrained optimization is especially important in therapeutic methods since one would like to avoid introducing new probability mass to states associated with unknown phenotypes as much as possible (Qian & Dougherty, 2012).

Suboptimal Phenotype Alteration

Consider an instantaneously random PBN with a single control gene g^c and a binary control input. One of the earliest suboptimal methods for maximally altering the long-run behavior of a PBN is a greedy algorithm based on *mean-first-passage-time (MFPT)* (Vahedi, Faryabi, Chamberland, Datta, & Dougherty, 2008), which locates a policy in $\mathcal{M}_{\mathrm{D}}$ based on the heuristic that reaching desirable states and leaving undesirable states as soon as possible is preferable. One of the advantages of this algorithm is that it is model-free and can be directly designed from time-course data without having to infer the TPM of the network.

Suppose that up-regulation of the gene g^1 is undesirable. The TPM of the uncontrolled PBN can be partitioned into four sub-matrices as follows:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\mathcal{P}(0) = \begin{pmatrix} \mathcal{P}_{\mathcal{D}\mathcal{D}} \mathcal{P}_{\mathcal{D}\mathcal{U}} \\ \mathcal{P}_{\mathcal{U}\mathcal{D}} \mathcal{P}_{\mathcal{U}\mathcal{U}} \end{pmatrix}. \tag{33}$$

One can compute the MFPS vectors $MFPT_{\mathcal{D}}$ (the MFPTs from each state in $\mathcal{U}$ to any state in $\mathcal{D}$) and $MFPT_{\mathcal{U}}$ (the MFPTs from each state in $\mathcal{D}$ to any state in $\mathcal{U}$) by solving the following system of linear equations (Kemény & Snell, 1960):

$$\begin{cases} MFPT_{\mathcal{D}} = e + \mathcal{P}_{\mathcal{D}\mathcal{D}} MFPT_{\mathcal{D}} \\ MFPT_{\mathcal{U}} = e + \mathcal{P}_{\mathcal{U}\mathcal{U}} MFPT_{\mathcal{U}} \end{cases} \tag{34}$$

where *e* is a column vector of 1's with the appropriate length (with *n* genes, *e* has 2^{n-1} elements). We denote by $\mu_{\text{MFPT}} : \mathcal{S} \to \mathcal{A}$ the control policy derived from the following procedure: choose a number γ. For every $x \in \mathcal{U}$, if $MFPT_{\mathcal{D}}(x) - MFPT_{\mathcal{D}}(\tilde{x}) > \gamma$, then $\mu_{\text{MFPT}}(x)=1$; otherwise, $\mu_{\text{MFPT}}(x)=0$. Using this rule, one reduces the expected time to reach the desirable states. Analogously, for every $x \in \mathcal{D}$, if $MFPT_{\mathcal{U}}(\tilde{x}) - MFPT_{\mathcal{U}}(x) > \gamma$, then $\mu_{\text{MFPT}}(x)=1$; otherwise, $\mu_{\text{MFPT}}(x)=0$. Thus, the expected time until a passage to undesirable states is increased. The tuning parameter γ is set to a large when the ratio of the cost of control to the cost of the undesirable states is higher so that the control is applied less frequently; otherwise, under no constraints on the control frequency, we set γ=0 (Vahedi et al., 2008).

Another greedy method for solving this problem is called a *basin of attraction (BOA)* control policy, which belongs to the set of stationary and deterministic policies (Qian et al., 2009). For any state *x*, let $\mathcal{L}^j(x)$ be the set of attractors for the basin containing a state *x* in the *j*th constituent Boolean network, keeping in mind that a state *x* belongs to exactly one basin of attraction in each constituent Boolean network. Let

$$\mathcal{B}(x) = \bigcup_{j=1}^{m} \mathcal{L}^j(x) \tag{35}$$

be the union of attractors for the basins of *x* over all of the constituent Boolean networks. For each constituent Boolean network, we calculate the minimal distance of each state in $\mathcal{S}$ to states in $\mathcal{D}$ or in $\mathcal{U}$, and denote their weighted average, with respect to the Boolean networks selection probabilities, by $d_{\mathcal{D}}$ and $d_{\mathcal{U}}$, respectively (Qian et al., 2009).

A BOA control policy, $\mu_{\text{BOA}} : \mathcal{S} \to \mathcal{A}$, is derived via the following algorithm for every $x \in \mathcal{S}$. Suppose $x \in \mathcal{U}$. If $\mathcal{B}(x)$ does not contains any desirable attractors and at the same time $\mathcal{B}(\tilde{x})$ contains desirable attractors, then $\mu_{\text{BOA}}(x)=1$. By this, the network moves to $\tilde{x}$ in which the likelihood of arriving into desirable attractors is increased. If both or neither of $\mathcal{B}(x)$ and $\mathcal{B}(\tilde{x})$ contain desirable attractors, then $\mu_{\text{BOA}}(x)=1$ if $d_{\mathcal{D}}(x) > d_{\mathcal{D}}(\tilde{x})$, $\mu_{\text{BOA}}(x)=0$ if $d_{\mathcal{D}}(x) < d_{\mathcal{D}}(\tilde{x})$, or otherwise, $\mu_{\text{BOA}}(x)=0$. Now, suppose $x \in \mathcal{D}$. If $\mathcal{B}(x)$ contains undesirable attractors and at the same time $\mathcal{B}(\tilde{x})$ does not contain any undesirable attractors, $\mu_{\text{BOA}}(x)=1$, so that the chance of entering undesirable attractors is reduced. If both or neither of

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$\mathcal{B}(x)$ and $\mathcal{B}(\tilde{x})$ contain undesirable attractors, then $\mu_{\text{BOA}}(x)=1$ if $d_{\mathcal{U}}(\tilde{x}) > d_{\mathcal{U}}(x)$, or $\mu_{\text{BOA}}(x)=0$ if $d_{\mathcal{U}}(\tilde{x}) < d_{\mathcal{U}}(x)$. Otherwise, $\mu_{\text{BOA}}(x)=0$ (Qian et al., 2009).

A third algorithm, the *steady-state distribution (SSD)* control policy, is based on the theory of rank-one perturbations of regulatory functions, where one can readily calculate the exact shifted stationary mass (Qian & Dougherty, 2008; Qian et al., 2009). Let π and $\mathcal{Z} = [I - \mathcal{P}(0) + e\pi]^{-1}$ be the steady-state row vector and the fundamental matrix of the unperturbed network, respectively, where *I* is the identity matrix *e* is a column vector of 1's with the appropriate dimensions. The perturbed steady-state distribution can be computed by:

$$\hat{\pi}^{x} = \pi - \frac{\pi_{x}(\mathcal{P}_{x}(0) - \mathcal{P}_{\tilde{x}}(0))\mathcal{Z}}{1 + (\mathcal{P}_{x}(0) - \mathcal{P}_{\tilde{x}}(0))\mathcal{Z}^{x}}, \tag{36}$$

where $\mathcal{P}_{x}$ is a row in $\mathcal{P}$ corresponding to the states *x*, $\mathcal{Z}^{x}$ is a column in $\mathcal{Z}$ corresponding to state *x*, π_{x} is the stationary mass at state *x*, and $\hat{\pi}^{x}$ is the steady-state vector after we flip the control gene at state *x*.

A SSD control policy, .., is found via the following procedure. For every pair of states *x* and $\tilde{x}$, compute $\pi_{\mathcal{U}} = \sum_{y\in\mathcal{U}} \pi_{y}$, $\hat{\pi}^{x}_{\mathcal{U}} = \sum_{y\in\mathcal{U}} \hat{\pi}^{x}_{y}$ and $\hat{\pi}^{\tilde{x}}_{\mathcal{U}} = \sum_{y\in\mathcal{U}} \hat{\pi}^{\tilde{x}}_{y}$. If $\pi_{\mathcal{U}} \le \min(\hat{\pi}^{x}_{\mathcal{U}}, \hat{\pi}^{\tilde{x}}_{\mathcal{U}})$ then $\mu_{\text{SSD}}(x) = \mu_{\text{SSD}}(\tilde{x}) = 0$; otherwise, if $\hat{\pi}^{x}_{\mathcal{U}} \le \hat{\pi}^{\tilde{x}}_{\mathcal{U}}$, then $\mu_{\text{SSD}}(x)=1$ and $\mu_{\text{SSD}}(\tilde{x}) = 0$, and if $\hat{\pi}^{x}_{\mathcal{U}} \ge \hat{\pi}^{\tilde{x}}_{\mathcal{U}}$, then $\mu_{\text{SSD}}(x)=0$ and $\mu_{\text{SSD}}(\tilde{x}) = 1$.

When deriving the SSD control policy, all beneficial one-row perturbations are found independently. However, one can also iteratively find a state and corresponding control action having a one-row perturbation resulting in the largest reduction of undesirable mass. This is the *conservative steady-state distribution* (CSSD) control policy. We begin by assigning no control to all states. At each iteration, one selects a state $\underline{x}$ and corresponding control action at state $\underline{x}$ with a maximal reduction in undesirable mass. The algorithm runs iteratively until intervention at any additional state actually increases the stationary mass of undesirable states. One can theoretically guarantee that the located control policy will always induce undesirable stationary mass less than or equal to that of the uncontrolled network (Qian et al., 2009). By construction, μ_{CSSD} is a stationary and deterministic policy. Table 3 presents the algorithm, where π and $\mathcal{Z}$ denote the steady-state distribution and the fundamental matrix of the unperturbed network, respectively.

None of the control policies discussed thus far check if there is an introduction of mass at states representing complications or harmful side effects to healthy cells, even though these states are labeled as desirable. It is therefore prudent to restrict the shift of mass to only those states associated with known healthy phenotypes. To meet this new criterion, we partition $\mathcal{D}$ further into two categories of .., representing known healthy states, and $\mathcal{D}_{\text{A}}$, representing *ambiguous* states where we have little or no prior knowledge and thus may lead to complications or damages (Qian & Dougherty, 2012).

The goal is now to find a control policy that shifts the undesirable probability mass as much as possible and at the same time keeps the ambiguous probability mass of each state below certain level. The *constrained SSD (conSSD)* and *constrained CSSD (conCSSD)* control policies aim to find such (suboptimal) policies (Qian & Dougherty, 2012).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. CSSD control policy algorithm (Qian et al., 2009)

Set $\underline{\pi}=\pi$ and $\underline{\mathcal{Z}} = \mathcal{Z}$; Assign the set of states with no control to the set of all states: $\mathcal{O} = \mathcal{S}$;
Repeat
Δ=0;
For all states $x \in \mathcal{O}$ do
Compute $\Delta\pi_{\underline{u}} = \underline{\pi}_{\underline{u}} - \hat{\underline{\pi}}^{x}_{\underline{u}}$;
If $\Delta\pi_{\underline{u}} > \underline{\Delta}$ then
$\underline{\Delta} = \Delta\pi_{\underline{u}}$; Assign the best state to control: $\underline{x}$=x; $\underline{\pi} = \hat{\pi}^{x}$;
End
If $\underline{\Delta}$>0 then
$\mu_{\text{CSSD}}(x)$=1 and $\mu_{\text{CSSD}}(\tilde{\underline{x}}) = 0$; $\mathcal{O} = \mathcal{O} \setminus \{\underline{x}, \tilde{\underline{x}}\}$; Update $\underline{\mathcal{Z}}$ for the rank-one perturbed network accordingly (refer to (Qian et al., 2009) for the updating equation);
Until $\underline{\Delta}$=0;

We denote by $\mu_{\text{conSSD}} : \mathcal{S} \to \mathcal{A}$ and $\mu_{\text{conCSSD}} : \mathcal{S} \to \mathcal{A}$ the conSSD and conCSSD control policies, respectively. The algorithms presented in Table 4 and Table 5 are similar to those of SSD and CSSD, respectively, except that they take into account an upper-bound, $\delta \geq 0$, on the long-run probability mass of ambiguous states after control. This will represent the maximum amount of risk one is willing to accept with regard to introducing probability mass at an ambiguous state while implementing the intervention policy. In practice, expert medical knowledge would be employed to identify the set $\mathcal{D}_{\text{A}}$ and upper bound δ (Qian & Dougherty, 2012). As a consequence of adding this stringent criterion, it is expected that these constrained control policies become less effective in terms of shifting the undesirable mass.

Optimal Phenotype Alteration

We now find optimal intervention policies with respect to the objectives and constraints. As we will see, the problem of maximal phenotype alteration is a special case of constrained MDPs (Altman, 1999). Therefore, we begin with a brief review of MPDs, where we focus on the average cost objective function. In general, the decision maker minimizes one objective function subject to constraints on possibly one or more additional objective functions. The basic components of a constrained MDP with average cost are the same as those of discounted cost, but with additional cost functions. Therefore, we adopt the same notations, and only define a new immediate cost function as $r : \mathcal{S} \times \mathcal{A} \times \mathcal{S} \to \Re^{D}$, which is a D-dimensional non-negative and bounded vector corresponding to D constraints. We also denote the TPM of the controlled chain by $\mathcal{P}(a)$, and assume that the chain is ergodic under any deterministic policy. For an initial state $x \in \mathcal{S}$ and a control policy $\mu = \{\mu_1, \mu_2, \ldots\} \in \mathcal{M}$, the infinite-horizon expected average costs are defined by

$$G(x,\mu) = \limsup_{N\to\infty} E^{\mu}_{x} \frac{1}{N+1} \sum_{t=0}^{N} g(Z_t, A_t, Z_{t+1}), \tag{37}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$R_d(x,\mu) = \limsup_{N\to\infty} E_x^{\mu} \frac{1}{N+1} \sum_{t=0}^{N} r_d(Z_t, A_t, Z_{t+1}), \text{ for } d = 1,2,\ldots,D. \tag{38}$$

Given $C_1, C_2, \ldots, C_D \geq 0$, we can formulate the optimization problem in its most general form for any initial state $x \in \mathcal{S}$,

$$\begin{aligned} &\min_{\mu\in\mathcal{M}} G(x,\mu) \\ &\text{subject to } R_d(x,\mu) \leq C_d \text{ for all } d = 1,2,\ldots,D. \end{aligned} \tag{39}$$

All policies that satisfy the constraints are called feasible. Let $G^*(x)$ denote a solution of (39). A feasible policy μ^* is optimal if $G^*(x) = G(x,\mu^*)$, for all $x \in \mathcal{S}$. Although, the search space $\mathcal{M}$ is infinite (possibly uncountable), we consider a set $\mathcal{M}_S \subset \mathcal{M}$, of stationary policies without loss of optimality. $\mathcal{M}_S$ includes those policies for which μ_t is time invariant (not dependent on t) and only a function of z_t for any t. In other words, the probabilities that a control policy μ assigns to different actions only depends on the current state observed and not the time. Note that the set of stationary and deterministic policies, $\mathcal{M}_D$, is a subset of $\mathcal{M}_S$.

It can be shown that may be transformed into a LP with its dual being (Altman, 1999):

$$\begin{aligned} &\min_{\{\nu_{xa}\}} \sum_x \sum_a \nu_{xa} g(x,a) \\ &\text{subject to } \begin{cases} \sum_x \sum_a \nu_{xa} r_d(x,a) \leq C_d, \text{ for all } d = 1,2,\ldots,D \\ \sum_a \nu_{xa} = \sum_y \sum_a \nu_{ya} p_{yx}(a), \text{ for all } x \in \mathcal{S} \\ \sum_x \sum_a \nu_{xa} = 1 \\ \nu_{xa} \geq 0, \text{ for all } x \in \mathcal{S},\ a \in \mathcal{A} \end{cases} \end{aligned} \tag{40}$$

where $g(x,a) = \sum_y p_{xy}(a) g(x,a,y)$ and $r_d(x,a) = \sum_y p_{xy}(a) r_d(x,a,y)$ for each d=1,2,…,D. Letting $\left\{\nu_{xa}^*\right\}$ be a minimizing argument of (40), one can recover an optimal stationary policy $\mu^* \in \mathcal{M}_S$ by

$$\mu^*(a \mid x) = \frac{\nu_{xa}^*}{\sum_a \nu_{xa}^*}. \tag{41}$$

If D>0 and is feasible, then μ^* requires randomization (choosing between the actions in $\mathcal{A}$ through a randomized mechanism) in at most D states (Altman, 1999; Ross, 1989). However, if there are no constraints on the expected average cost criteria, i.e., D=0, then there is no randomization and $\mu^* \in \mathcal{M}_D$.

In our maximal phenotype alteration problem, we desire an intervention policy that optimally shifts the long-run probability mass of undesirable states towards desirable states, without introducing new mass at ambiguous states. This objective essentially concerns the long-run expected frequencies of observing undesirable states which is encoded in the variables $\{\nu_{xa}\}$ marginalized over the actions, i.e., $\left\{\sum_a \nu_{xa}\right\}$.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Let $\bar{\mu}(x) \equiv 0$ denote the stationary and deterministic control policy of *no-intervention*. For any policy $\mu \in \mathcal{M}_{\mathrm{S}}$, the amount of *shift* in the aggregated probability of undesirable states is defined as

$$\Delta\pi_{\mathcal{U}}(\mu) = \pi_{\mathcal{U}}(\bar{\mu}) - \pi_{\mathcal{U}}(\mu), \tag{42}$$

where $\pi_{\mathcal{U}}(\mu) = \sum_{x\in\mathcal{U}} \pi_x(\mu)$ and $\boldsymbol{\pi}(\boldsymbol{\mu})$ is the steady-state row vector of the controlled Markov chains governed under policy $\boldsymbol{\mu}$. In general, $-1 \le \Delta\pi_{\mathcal{U}}(\mu) \le 1$ and our goal is to maximize it subject to some constraints on the elements of $\boldsymbol{\pi}(\boldsymbol{\mu})$, which are usually in the form of $\boldsymbol{\pi}_x(\boldsymbol{\mu}) \le \boldsymbol{\gamma}_x$ for every $x \in \mathcal{D}_{\mathrm{A}}$ and constants $\boldsymbol{\gamma}_x \ge 0$.

First, note that maximizing $\Delta\pi_{\mathcal{U}}(\mu)$ is equivalent to minimizing $\pi_{\mathcal{U}}(\mu)$. Now, let the immediate cost functions g and r_d be defined as

$$g(x,a,y) = \begin{cases} 1, & \text{if } x \in \mathcal{U} \\ 0, & \text{otherwise} \end{cases} \tag{43}$$

$$r_d(x,a,y) = \begin{cases} 1, & \text{if } x \in \mathcal{D}_{\mathrm{A}} \\ 0, & \text{otherwise} \end{cases} \tag{44}$$

for any action $a \in \mathcal{A}$, any state $y \in \mathcal{S}$ and all d. Using these cost functions, we will count the number of visits to states in $\mathcal{U}$ and $\mathcal{D}_{\mathrm{A}}$. Thus, for a policy $\mu \in \mathcal{M}_{\mathrm{S}}$ and an initial state x, equations (37) and (38) provide in the steady-state mass of undesirable and ambiguous states, respectively. The constrained maximal phenotype alteration problem can thus be formulated as

$$\min_{\{\nu_{xa}\}} \sum_x \sum_a \nu_{xa}$$
$$\text{subject to } \begin{cases} \sum_a \nu_{xa} \le \gamma_x, \text{ for each } x \in \mathcal{D}_{\mathrm{A}} \\ \sum_a \nu_{xa} = \sum_y \sum_a \nu_{ya} p_{yx}(a), \text{ for all } x \in \mathcal{S} \\ \sum_x \sum_a \nu_{xa} = 1 \\ \nu_{xa} \ge 0, \text{ for all } x \in \mathcal{S},\ a \in \mathcal{A} \end{cases} \tag{45}$$

Once the solution $\left\{\nu^*_{xa}\right\}$ is found, one can recover the optimal stationary policy using (41). If there are no ambiguous states, then the optimal policy is stationary and deterministic. We refer to this policy as the *optimal unconstrained (UC)* policy and denote it by μ^*_{UC}. If there are $|\mathcal{D}_{\mathrm{A}}|$ ambiguous states then the optimal policy may not be deterministic; however, it belongs to $\mathcal{M}_{\mathrm{S}}$ and requires randomization in at most $|\mathcal{D}_{\mathrm{A}}|$ states. In this case, we call this policy *optimal phenotypically constrained (PC)* and denote it by μ^*_{PC}.

Simulation on Networks

We test our method on synthetically generated networks and a real network modeling metastatic melanoma.

Synthetic Networks

For phenotypically constrained problems and for any PBN, we define $\mathcal{D}_{\mathrm{A}} = \{x \in \mathcal{D} : \pi_x \leq 1/2^n\}$, where π is the steady-state vector of the uncontrolled network. We also set $\gamma_x = \max_{x \in \mathcal{D}_{\mathrm{A}}} \pi_x$ for all $x \in \mathcal{D}_{\mathrm{A}}$.

We synthetically generate 2500 instantaneously random PBNs with seven genes and report both the average performance across all networks as well as the empirical complementary CDF of

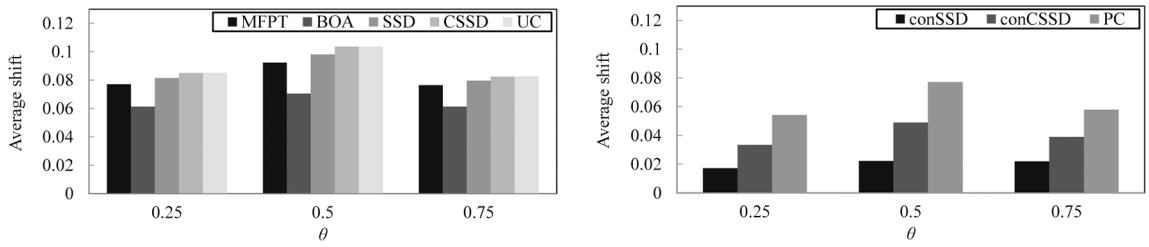
$$\Delta(\mu) = \Delta\pi_u(\mu^*) - \Delta\pi_u(\mu) = \pi_u(\mu) - \pi_u(\mu^*). \tag{46}$$

Here, $\Delta(\mu)$ quantifies the gain made by using an optimal policy, μ^*, over a suboptimal one, μ. Clearly, $0 \leq \Delta(\mu) \leq 1$. For each network, we calculate $\Delta(\mu)$ for all six suboptimal policies discussed earlier in this section and both optimal policies, for both the unconstrained and constrained problems, separately.

We assume that each PBN is generated from four equally likely constituent Boolean networks with the maximum number of predictors for each Boolean function set to three. We assume that the probability that each Boolean regulatory function takes on the value 1 is a random variable whose values are taken from a beta distribution with mean $\theta \in \{0.25, 0.5, 0.75\}$ and standard deviation 0.01. This quantity controls the dynamics of a randomly generated Boolean network. We also assume a random gene perturbation probability of 0.001. We define undesirable states, $\mathcal{U}$, to be those for which the most significant bit in their binary representation is zero, and assume that the control gene is the most significant bit of states.

Figure 8 shows the shift in the probability mass of undesirable states induced by the optimal and suboptimal policies, defined in (42), averaged across all PBNs for each values of θ. These graphs clearly illustrate the optimality of μ^*_{UC} and μ^*_{PC} compared to their suboptimal counterparts. Among the unconstrained suboptimal policies, μ_{CSSD} yields the best results. However, μ_{conCSSD} does not induce as much shift as μ^*_{PC}, which is due to the fact that the search space of the conCSSD policy belongs to the class $\mathcal{M}_{\mathrm{D}}$ of policies, whereas μ^*_{PC} belongs to the larger class $\mathcal{M}_{\mathrm{S}}$. It is worth noting that the amount of average shift induced by μ^*_{PC} is significantly less than μ^*_{UC}, which can be attributed to the additional constraints imposed on the optimization problem.

Figure 8. Average shift for different policies across 2500 random PBNs with seven genes: (Left) unconstrained policies; (Right) Phenotypically constrained policies



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9 presents the empirical complementary CDF of $\Delta(\mu)$ for different suboptimal interventions. The graphs indicate that μ^*_{UC} and μ_{CSSD} induce similar amounts of shift with a high probability. It is also evident that μ^*_{PC} outperforms μ_{conCSSD} with a (realistically) significant probability; for instance, with probability 0.1 using μ^*_{PC} may yield an improvement of more than 5% over μ_{conCSSD}.

Real Network

It has been demonstrated that by manipulating the concentration level of the Wnt5a protein secreted by a melanoma cell line, one can directly affect the metastatic status of the cell as measured by standard *in vitro* assays for metastasis (Bittner et al., 2000; Dissanayake et al., 2008; Weeraratna et al., 2002), which suggests that reducing the WNT5A gene's action could reduce the risk of a melanoma metastasizing. Therefore, it is desirable to down-regulate WNT5A as much as possible through appropriate intervention mechanisms (Datta et al., 2003; Qian & Dougherty, 2008).

We use a Boolean network composed of ten nodes extracted from a set of 587 genes (Kim et al., 2002). The Boolean regulatory relationships between these genes/proteins are presented in Table 6. Note there is a single context when we construct a PBN from this network. We label states with an up-regulated WNT5A as undesirable. We set the gene perturbation probability to 0.001. We assume that up-

v^9	synuclein	$\left(\overline{\text{WNT5A}} \textbf{ AND } \overline{\text{MART1}} \textbf{ AND } \overline{\text{STC2}}\right) \textbf{ OR } \left(\text{RET1 } \textbf{AND } \overline{\text{MART1}} \textbf{ AND } \text{STC2}\right) \textbf{ OR } \text{MART1}$
v^{10}	STC2	$\overline{\text{S100P}}$

regulation of WNT5A is undesirable, and set ambiguous states in $\mathcal{D}$ to non-attractor states of the Boolean network, so that the control policy will not introduce new attractors. For the control genes, we choose each gene in the network, except WNT5A, as the control gene, in turn.

The aggregated probability mass of undesirable states for the uncontrolled network is $\pi_{_U}(\overline{\mu}) = 0.1711$. Table 7 shows the shift made by all control policies based on different control genes. The maximum shift induced by μ^*_{UC} occurs when either MMP3 or PHOC are the control genes. However, the maximum shift for μ^*_{PC} occurs when MART1 is the control gene, which is an immunogen that the body sometimes recognizes and attacks via the immune system (Dissanayake et al., 2008; Qian & Dougherty, 2012).

CONCLUSION

Modeling tumor heterogeneity and the degree to which tumor cells respond to antitumor drugs are crucial to developing optimal cancer treatment. Using a recently proposed model for tumor growth inhibition, we have characterized uncertainties associated with drug response at different levels and built a probabilistic model for the entire intervention process. While accounting for practical effects arising from therapeutic constraints, we assumed PBNs as our model for GRNs and derived optimal control policies with random-length duration of treatment effectiveness. This was accomplished by taking a unified approach in the framework of finite-state MDPs with partially controlled decision intervals and

infinite-horizon discounted cost. This framework is general enough to include several other, simple but practical, intervention models. We presented a simulation study on randomly generated instantaneously random PBNs and demonstrated that optimal intervention policies outperform suboptimal ones with a significant probability. We also showed the effectiveness of optimal intervention policies on mutated mammalian cell cycle regulation.

Although the control policies derived from this procedure are optimal, their optimality is relative to subjective cost functions defined by consulting physicians or biologists. We resolved this issue by addressing optimality directly relative to the long-run behavior of the underlying network and phenotypes of interest. We utilized a linear programming approach to optimally move the steady-state mass of undesirable states toward desirable states. We provided a simulation study on synthetic PBNs with different dynamical properties and a metastatic melanoma network, where we demonstrated the superiority of optimal methods over several suboptimal approaches.

Besides the approaches presented here, many additional methods have been proposed: (1) to constrain the intervention so as to limit the expected number of interventions (Ching et al., 2009; Faryabi et al., 2008); (2) to deal with biological model uncertainties via robust intervention policies (Pal, Datta, & Dougherty, 2008, 2009; Yousefi & Dougherty, 2014); (3) to address unpredictable effects of a drug on multiple off-target genes (Yousefi & Ivanov, 2013); (4) to address asynchronicity of updating rules in gene networks (Faryabi et al., 2008); and (5) to mitigate the computational burden from complex gene networks (Akutsu, Hayashida, Ching, & Ng, 2007; Faryabi, Datta, & Dougherty, 2007; Ivanov, Simeonov, Ghaffari, Qian, & Dougherty, 2010; Ng, Zhang, Ching, & Akutsu, 2006; Vahedi et al., 2008).

Although the applicability of many of the discussed approaches may appear to hinge on first demonstrating the validity of PBNs as a model for GRNs, these approaches are not restricted to PBNs. In fact, the main assumption underlying most of these approaches is that the dynamics of GRNs can be well-approximated by Markovian stochastic processes. This assumption is not restrictive once we realize that the class of Markovian models encompasses a large body of both deterministic and stochastic dynamical models of GRNs (Kim et al., 2002; Goutsias & Jenkinson, 2013). As long as we can characterize the joint probability distribution of the stochastic process of interest and have a well-defined objective func-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion, with reasonable assumptions on the intervention model, we can derive either an analytical or an approximate solution to various intervention problems. The question now is whether inferring the joint probability distribution is possible, both computationally and experimentally. To answer this question, we must first answer two even more fundamental questions: (1) what assumptions are we willing to impose on the form of this joint probability distribution? and (2) what types of data, and how much, do we need to collect to achieve an accuracy, in terms of model prediction error, within a desirable range? Nonetheless, it is this author's belief that methods for optimal or approximate intervention will play an important role in the near future when the medical community is ready to adopt model-based design of intervention strategies for cancer treatment.

Chapter 58
Human–Data Interaction in Healthcare

Federico Cabitza
Università degli Studi di Milano-Bicocca, Italy

Angela Locoro
Università degli Studi di Milano-Bicocca, Italy

ABSTRACT

In this chapter, we focus on an emerging strand of IT-oriented research, namely Human-Data Interaction (HDI) and on how this can be applied to healthcare. HDI regards both how humans create and use data by means of interactive systems, which can both assist and constrain them and the operational level of data work, which is both work on data and by data. Healthcare is a challenging arena where to test the potential of HDI towards a new, user-centered perspective on how to support and assess "data work". This is especially true in current times where data are becoming increasingly big and many tools are available for the lay people, including doctors and nurses, to interact with health-related data. This chapter is a contribution in the direction of considering health-related data through the lens of HDI, and of framing data visualization tools in this strand of research. The intended aim is to let the subtler peculiarities among different kind of data and of their use emerge and be addressed adequately. Our point is that doing so can promote the design of more usable tools that can support data work from a user-centered and data quality perspective and the evidence-based validation of these tools.

INTRODUCTION

Twenty-five years ago, medical informatics was defined as "dealing with the storage, retrieval and optimal use of biomedical data" (Shortliffe et al. 1990). At that time, little emphasis was put on the practices of data production, that is on how medical practice, and single stories of illness, care and recovery are represented, accounted and "datafied" in some valid and reliable manner. However, these practices, which include policies, rules, habits, conventions, tools and techniques, have always been intertwined with and affected by the available ITs, as well as by the expectations of the stakeholders on how to make sense

and use of health-related data. Different perspectives on these expectations, and on what valuable health data are, lead to manifest chasms between primary use and other uses of health information, as often discussed in the specialist literature (Fitzpatrick and Ellingsen, 2013). To try to cross these chasms, we need to create the suitable language to describe the differences and give some operational definitions.

We distinguish between three different macro-types of data and the related processes in which these data are either produced, processed or consumed: namely, primary data, which come from a broad range of sources and are produced within a caring process to make its unfolding seamless and smooth (Berg, 1999); secondary data that are derived from the primary data for purposes different than care, like accounting and medical billing (Abdelhak, Grostick, & Hanken, 2012); and tertiary data, that are produced from the secondary data for any unanticipated need of the potential consumers of health services (see Figure 1).

To illustrate this tripartition, an analogy from the agriculture domain can be drawn (Locoro, 2016): primary data are like the produce of the land, which farmers grow for themselves as well as the external market. Secondary data are the product of a transformation of these primary data, like the one performed in food industry where vegetables are cleansed and chopped. Tertiary data are further transformed from secondary data to make them more easily consumable, that is suitable for and conveyed to a broader population of consumers in terms of information services, like fresh-cut vegetable products can be seen as the service to have vegetables already ready-to-eat.

The definitions mentioned above shed light on the relationship between data and their uses, which cannot be overstated. The tripartition that we propose reflects the different uses and practices in which data are produced and consumed and it calls for a specific area of research focusing on how to support people in interacting with their data of concern and in gaining insight from them: Human-Data Interaction (HDI).

BACKGROUND

As rightly noted by Hornung et al. (2015), the expression HDI is neither specific nor new. On the one hand, humans have always interacted with data, that is they have inscribed, read and communicated data in terms of simple marks, more complex symbols and any kind of meaningful signs[1]. On the other hand, this interaction has predominantly been mono-directional until interactive systems have allowed users to get access to data according to their peculiar and situated needs. In the computing literature, the expression has been used since the 1990s, e.g., by Kennedy et al. (1996), to address the needs of the users in the context of data intensive settings and hence "the problem of delivering personalized, context-aware, and understandable data from big datasets" (Cafaro, 2012). More recently a number of authors have tried to define Human-Data Interaction, by focusing on different aspects: Elmqvist (2011) and Cafaro (2012) focused on the material and embodied aspects of interaction; Crabtree and Mortier (2015) prefer to assimilate HDI to "the management and use of personal data in society at large" where *personal* here means that data are either "about individuals" or are delivered in terms of "personalized experiences". In particular, Elmqvist (2011) defines HDI as "the human manipulation, analysis, and sense making of large, unstructured, and complex datasets" and Cafaro sees HDI systems "as technologies that use embodied interaction to facilitate the users' exploration of rich datasets". We agree with Hornung et al. (2015) and Crabtree and Mortier (2014) in regard to the fact that "HDI does not only refer to embodied interaction, but to all kinds of interaction" and that "HDI should investigate 'data that affects people' ".

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

These reflections highlight the twofold meaning of HDI that we clarify in what follows. HDI is both a phenomenon and a research field that focuses on this phenomenon. As a phenomenon that is an object of research, we propose to see HDI as the class of actions where, on the one hand data are produced, processed and exploited by humans; this encompasses, at the two extremes of the action spectrum, both the "datafication" of facts, that is the process by which portions of the reality of interest are translated into the domain of words, symbols and numbers (through coding, classification, and measure[2]); and what we call data telling, that is the creation of accounts and stories that human can tell according to the data they make (a) sense of. On the other hand, HDI also regards actions in which humans are affected by data, that is in which their interpretations, opinions, beliefs and decisions are made by, or better yet according to, data.

Moreover, as a research area focusing on this kind of interaction it lies at the intersection of data science, data visualization and human-computer interaction. Researchers involved in HDI study how humans record and use data by means of Information Technologies; and design interactive systems that allow humans to retrieve and explore complex data sets in order to gain value in their learning, insight in their decisions, and feedback in their action. Considering HDI a distinct research field, although deeply grounded in the intersection between data visualization and human-computer interaction means to highlight the typical tenets of HCI about the centeredness of users in successful design and the importance to consider "complex contextual factors including the systems of beliefs, values and norms of the involved people" (Hornung et al. 2015) when designing systems by which humans can explore and interpret data according to their skills, competences, desires and needs. Moreover, it also means to borrow from HCI the attitude to evaluate the impact of these systems on the people life and investigate systematically "data production, collection, processing and use [by] focusing on the social impact they provoke" (Hornung et al. 2015).

In this chapter, we mainly focus on HDI as an evidence-based approach to the design of ICT systems. Our main contribution is a tripartite conceptual framework to help practitioners separate the concerns and address design related aspects peculiar to primary and tertiary data type, data work and data users. Three studies are also presented to exemplify the typical approaches within HDI and the related framework to the design, development and evaluation of healthcare supporting technologies. In particular, the first case refers to the heuristic evaluation of data visualization prioritization, the second one to a user test on data customization for citizens, and the third case to a research through design of a data visualization tool.

INTERACTION AS KEY TO UNDERSTAND HEALTH DATA

In this section we discuss how to consider interaction central to characterize and distinguish among the roles of health data, as an alternative to top-down, and abstract ways to classify them: in short we propose an analytical framework where considering who is going to use health data, and why (that is for what objective in what task) is more important than investigating the intrinsic attributes of data to understand how to better manage them (Strong, et al. 1997).

In virtue of these primary concerns, we distinguish between primary, secondary and tertiary (health) data. For a straight metonymy, we intend primary data as entangled with the primary use of data, by definition; secondary data with secondary use(s); tertiary data with tertiary uses. The "primary use" of health information is "to use it to directly support patient care", both by aiding medical decision-making and by ensuring continuity of care by all providers, that is both interpretation of medical signs (represented

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

by data) for decision making, and coordination among the actors involved "around" the patient (Berg, 1999). Secondary use regards both other uses of the same data collected for the primary use within the administrative domain, and the generation of derivative data for other aims than care, like billing and reimbursement, performance and care quality evaluation, resource planning and management, service design and public policy making. Tertiary use regards the heterogeneous uses through which tertiary data are put to the test of users' life: this can encompass the publication and dissemination of valuable indications for the citizens and the taxpayers about the available healthcare services, so as to orient them in the choice of the best healthcare provider (or just the closest one to their shelters – cf. Cabitza et al. 2015b); the policy makers and facility or agency manager, to facilitate the monitoring of suitable outcome and performance indicators and to enable the benchmarking and comparison of care facilities; as well as the researchers and epidemiologists to make sense of the great numbers of "similar" patients that are treated and detect trends and patterns of treatment appropriateness and efficacy.

On a more general level, three concepts characterize uses and data in each of these three ambits: primary use is related to what has been often called "data work" (Bossen et al. 2016). Secondary uses with data storing and processing. Tertiary uses with data value. Data storing and processing are self-explanatory concepts in computer science and regard the set-up of efficient data bases and the automation of accurate procedures by which to structure data, run searches and extract complex reports for disparate purposes. As secondary data and secondary processes usually entail little interaction by humans and these are always IT specialists and consultants who have always considered usability a relative concern, we will focus on the primary and secondary domains, and hence on data work and data value.

Data work is quite never defined in the specialist literature; although it is often mentioned, it is a slippery notion. We see it as a modern (but not at all recent) coinage after the word paperwork, of which it represents an abstraction, with respect to the medium of data representation; but also an extension, with respect to what people manage as data of their interest (besides accounting and resource management). As such data work is not only "working on data", typically producing new data in accounting for and recording a faithful representation of the work done; but also that portion of work that can be accomplished only by relying on some accurate data, i.e., "working by data". These two kinds of work are usually so deeply intertwined that distinguishing between them is useless and probably wrong: in the healthcare domain, the studies by Berg (Berg, 1999), for instance, clearly show that clinicians record data on the patient record not only to accumulate data for archival reasons (and for many other secondary uses), but also to coordinate with each other, articulate the resources around a medical case, and take informed decision in a written, distributed communication with themselves and the other colleagues taking care of the same patient. In healthcare, data work regards the additional effort paid by caregivers in making the record a "working record" (Fitzpatrick 2004), that is a resource capable of keeping disparate competencies and roles bound together and connected around the same cases over time and space.

On the other hand, tertiary use of tertiary data regards the concept of data value, that is how to exploit data to achieve some relevant goal for the user (even just to be informed about something), so that we can say that the user finds value in the data (also: she finds data valuable), or she gains value to some aim. Whether value is already in the data or rather it is created by an active stance of its consumers looks like an idle question: in a HDI perspective, value is the result of interacting with data and being capable to exploit them by tertiary users, that is lay people moved by unpredictable motives and toward unanticipated aims. In other words, on one hand data have got value if they are true and have been made accessible and comprehensible; on the other hand, their value lies in the comprehension itself, in the acquisition of true information, in learning notions, techniques, practices, and in the resulting knowledgeable behav-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

iors, in their turn producing some positive effect, on either the single person or her community[3]. Thus, data value can be defined as the potential of data (for its intrinsic qualities) to enable processes of value creation by someone for anyone (either herself, or the others) in some given context.

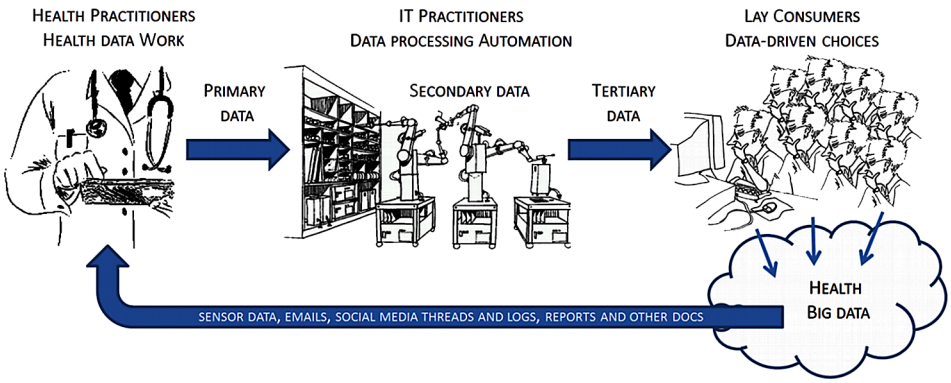
HDI CONTRIBUTIONS FOR THE QUALITY OF INFORMATION

While this tripartition is general enough to be applied in any domain where many different roles partake to the generation and transformation of data in the same supply chain, so to say, from the practitioner working in the field, to the final consumer of information services, its application to healthcare can be justified for its role in addressing the problem of the still relatively low quality of the data of patient records (Liaw et al. 2013), both in regard to completeness, accuracy and timeliness (Cabitza & Batini, 2016). Indeed it allows, on one hand, to highlight differences, separate concerns, and identifying ambits of use that are irreducible to one another; on the other hand, it allows to see the (existing) "seams" between these ambits (Berg and Goorman 1999) and therefore to address cooperation and interoperability without reckless neglect.

In regard to this latter point, it is time to acknowledge that chasms between primary and other uses exist and they go beyond the usual tension between clinical vs. administrative purposes because it is the concept of "adequate quality" that should be adopted to assess care-oriented data; likewise, crossing the chasm between the secondary and tertiary domains requires more than merely making secondary data more open and accessible, because also the end consumers' readiness to access, comprehend and exploit them, as well as their unpredictable purposes, are to be considered. Thus, the challenge to bridge the chasms mentioned above can be seen in terms of the problem of reusing primary data, which is "always entangled with the context of its production" (Berg and Goorman, 1999), in different contexts (either secondary or tertiary ones).

As Berg and Goorman note, reuse is possible only if data are made "transportable", that is sufficiently disentangled from their context of production; and this can occur only if specialized additional work is performed on data. So it is not a matter of improving, automating or changing current data work, but rather to invest on new and different data work, and corresponding new organizational roles (e.g., data nurses).

Figure 1. The three kinds of data and ambits proposed for HDI in healthcare



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In regard to the separation of concerns, our distinction between primary, secondary and tertiary data is quite different from other frameworks discussed in the Data Quality literature: for example, the one inspired by the manufacturing domain (Shankaranarayan et al., 2003) which distinguishes between raw data, component data items, that is semi-processed information and information products, which are composed out of these items. Primary data are not necessarily raw (Gitelman, 2013), because they are meaningful to and usable by the primary consumers that generated them. On the other hand, secondary and tertiary data are unfinished information products: the former ones are resources for specialist work (both clerical and managerial) within specific organizational boundaries and processes, while tertiary data result from the enactment of information services conceived for the non specialist and the external consumers, that is for the public. The distinction introduced by Shankaranarayan and his colleagues focuses on an incremental definition of the information product, and is often mentioned in regard to how Data Quality (DQ) can be assessed, monitored and continuously improved (e.g., Wang, 1998)

Differently from the Information Product perspective, our tripartite perspective focuses on the different roles that produce and consume different information products that can be considered "definitive" only in relation to their context of use. Consequently, a HDI approach to DQ issues grounds on the interpretation of quality of data as their "fitness for use" (Wang & Strong, 1996). Our proposal is aimed at detecting and taking the differences from the various uses in healthcare seriously (Bossen et al. 2016).

According to our metaphor, secondary data and secondary data-centered processes are like industrial processes, that need standardization to achieve regularity and efficiency and that involve relatively few people with specific skills and motives, like the competent and trained operators of assembly lines at the shop floor of plants. This is why HDI regards secondary data and processes only marginally, and to a much greater extent the primary and tertiary contexts. In primary settings, HDI addresses the challenges of fitting "data work" to work, that is of reconciling the articulation of cooperative activities performed by knowledgeable experts with their effort in continuous recording relevant events and information about what has been carried out, and often also of why and how. On the other hand, in the broader ambits of tertiary use, HDI deals with the manifold challenge to design data structures, visualization controls and interaction affordances, for both unintended uses and unanticipated needs, for both the practitioners without particular e-literacy and numeracy, and lay people from the general public.

We would argue that quality of information should not be assessed irrespective of the distinction between primary / secondary / tertiary uses, that is, by adopting the same metrics and methods in a context-independent manner: on the contrary, data used in care processes should be evaluated on the basis of the efficacy they enable appropriate and timely action (fit to use), also on the basis of work conventions and tacit knowledge that are difficult to bring back to the usual dimensions of accuracy, completeness and consistency (Gregory et al., 1995). This is in line with the idea to measure the quality of primary (health) data in terms of appropriateness and as a function of the health outcome they help to achieve. Bad quality should not be related to completeness, timeliness or, even, accuracy, since health practitioners can perfectly make sense of "bad" data and to some extent they even expect them (Bossen et al. 2016); but rather to "information failure" and its impact, that is the number of times data work is either direct or indirect cause of adverse event or near misses (Pipino & Lee, 2011). Despite the authorities that advocated for more research on this concept (Pipino & Lee, 201; Cabitza & Batini 2016), information failure (or error) is still under-researched and a taxonomy of cases to guide analysis and comparison still missing, for instance one that could distinguish between cases in which wrong or late decisions were carried out with accurate and timely data, respectively, and the other way round, a right and timely interpretation has been based on wrong and obsolete data, and so on[4].

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly, further research is needed for the evaluation of the quality of tertiary data: this is highly correlated with the quality of the information services conceived for the general public, which should be evaluated in terms of the extent to which data are "informative" and can be appropriated by consumers and appreciated in their lives (i.e., according to its social value), that is if they affect decisions for the better.

This is where HDI can fit in and be a novel way to address long-standing problems of low quality that neither incentivizing structures nor sanctions seem to solve completely. Indeed, HDI covers three phases: design, development and evaluation of the systems by which to extract information and support knowledge in data-intensive application domains. As HDI approaches operate at the upper layer of the well known ISO-OSI standard, i.e., the application layer, or, better yet, the data visualization layer, the scope of HDI is not to tackle which data are to be shown in terms of ethical or security issues (which are tasks usually delegated to the lower layers of the ISO-OSI pillar, such as model and control layers, e.g., a database, a middleware, and so on), but how data are to be shown instead, e.g., in terms of ergonomic and usability issues. The scope of an HDI approach is mainly that of the design, development and evaluation of data visualization interfaces. In particular, HDI regards the user-centered elicitation of better requirements of configuration, adaptation and appropriation of big data analytics cockpits and dashboards to optimize usability and the user experience, i.e., efficiency, effectiveness and satisfaction; the application of End-User Development techniques and tools to allow end-users tweak the tools by which data are extracted and visualized; and user-centered methodology for the assessment and continuous improvement of the quality of the interaction of the humans with their data of interest, so as to reduce both information overloading and information funneling/complacency (Parasuraman and Manzey, 2010), and improve awareness. This also includes the exploration of new techniques toward better interactive visualization environments and above all better data-telling, that is the capability to build and share stories that can explain data and facilitate correct interpretations (e.g., in medical domain by adopting a natural frequency approach - Hoffrage et al., 2002) and to allow, instead of curbing, the social exchange within a community of data-users of multi-perspective, sound and viable interpretations around the data that are supplied by the computational systems to inform decision making and knowledgeable action.

Summarizing, HDI can contribute in addressing the reconciliation of needs in health data production and use by providing methods and techniques that investigate the following two research strands:

1. The design of interfaces that could promote mutual awareness between data producers and consumers: on the one hand, by increasing commitment and awareness of consequences in the producers of the primary data; and, at the same time, by raising awareness in the secondary consumers of the contextual and social nature of primary data and hence of their limitations. This can be achieved, for example, by endowing the interfaces by which data are collected and presented with specific affordances that adapt to the context according to specific business rules in order to convey the so called "awareness promoting information" (Cabitza and Simone, 2012); this can be done also by means of simple visual clues like text highlighting or side messages, which do not impose any behavior to the data producers but help their interpretation.
2. The design of interactive visual interfaces that could support the understandability of data analytics. The transformation of data into information services does not necessarily require a massive processing of data but rather the application of state-of-the-art human interaction techniques to develop interactive infographics and highly tailorable dashboards that enable user-friendly online analytical processing and hence the transformation, even by end users (Lieberman, Paternò, Klann, & Wulf, 2006), of secondary data into socially valuable information.

AN HDI APPROACH TO FOSTER EVIDENCE-BASED DESIGN

The phrase evidence-based design is not totally new but still not really common, especially in the computer science literature and there is little wonder that also recently (Ammenwerth & Rigby, 2016) it has been applied to the fields of informatics that are closer to medicine and healthcare. In fact, the parallel with the approach to medical practice known as "Evidence-Based Medicine" (EBM)(VV.AA., 1992) is not coincidental, and indeed, it constitutes a sort of natural extension of that methodological empirical attitude to the design of computerized tools that can have an impact on medical decision and care quality. Shortly speaking, an evidence-based approach to IT design requires to back up any claim of utility or usability of a particular solution or tool with empirical studies that collect data from real users (including the perceptions of domain experts) and undertake standard statistical tests and group comparisons (Longhurst et al. 2013). Even more than this, an evidence-based approach must consider findings from the field of work in combination with the expertise of IT practitioners and the needs and wishes of the intended prospective users (e.g., patients and shopfloor doctors and nurses). Especially this latter aspect is typical in the Human-Computer Interaction field, and we also proposed it for studies accomplished within the HDI field (Cabitza et al., 2016).

To give more concreteness to the notion of HDI and evidence-based design, in the rest of this chapter we will report about three small-scale user studies in the domain of health information. The common element of these studies is the collection of empirical "proofs" (that is evidence) about solutions that were designed to increase the perceived value of interfaces and data visualization tools in the healthcare sector. To our knowledge the most relevant of the similar initiatives is the "Visualizing Health" project (http://www.vizhealth.org/), developed by the University of Michigan and the Robert Wood Johnson Foundation. In this project, which is subtitled "a scientifically vetted style guide for communicating health data", the involved researchers compared tens of different styles by which to communicate risk-related information in order to select the best ones for the general public according to a series of empirical tests involving real users. The main finding, which we also back up, is that when it comes to presenting health information, there is no single "best" graphic, as this depends on the intended goal and, in a subtler way, on what matters most to the intended users of the diagrams and infographics (Cabitza et al. 2015b). This calls for an evidence-based approach to this kind of evaluations, which must be tailored to specific groups of people (e.g., practitioners, patients) and contexts of use (Solomon et al. 2016).

Figure 2. The ranking of data item in radiology; items are enumerated according to their fine-grained ranking within the macro-category of priority level. Levels are established according to statistical testing.

DATA ITEM IN THE MAIN PAGE OF THE RADIOGRAPHER	LEVEL OF PRIORITY
Patient ID, Exam Date, Birth Date, Radiographist Name.	HIGHER
Level of urgency, Name of the patien, Time of execution, Patient Gender, Responsible Radiologist, Access number, Alert, Body section, DICOM ID, Patient fiscal code, Modality Type, Referring facility.	PROBABLY HIGHER
Ordering Radiologist, Exam description, Phone number, Room ID, patient's current address, patient's municipality, how the patient arrived, cost center.	PROBABLY LOWER
Patient nationality, Patient height.	LOWER

EXAMPLES OF USER STUDIES IN HEALTHCARE HDI

In this section we will report about three small user studies we accomplished under the tenets of HDI for an evidence-based design of data visualization tools for the healthcare sector. This is also aimed at showing that an evidence-based approach can be adopted also for small software development projects and without the need of relevant budgets. In particular, the first study regards primary data in radiology work, in terms of the identification of what data the practitioners should be required to record for their primary aim, and what data they deem less useful to this aim. The second study regards the value of tertiary data about hospital quality and availability, as this is evaluated by citizens that would need to gain information about the hospitals of their catchment area to choose where to go according to their needs and preferences. We will just outline the first two studies and give some more details of the third one, which regards the acceptance of an innovative system of data visualization for aggregate patient data by a sample of general practitioners (family doctors).

The Radiology User Study

In this study, we asked 15 expert technicians from different radiology facilities of Northern Italy to indicate the usefulness for their work of 31 information items on an ordinal scale, from 1 (negligible) to 6 (essential). The items regarded either the assessment of patients, their management for the execution of digital imaging examinations, or the preliminary evaluation of radiographic media, and they were collected by considering the Italian guidelines for quality assurance in teleradiology (Working Group for Quality Assurance in Diagnostic and Interventional Radiology, 2010).

The aim of the study was to rank those items from the most useful to the least, so that the interface of their information system could be optimized. Here, the concept of optimization should be interpreted as follows: either in terms of having the radiological information system display and require only those data that the radiographers considered certainly useful for their job; or, at least, in terms of a system that would not urge the users to fill in the low priority fields as mandatory data that block the application unless radiographers insert them. The online questionnaire platform displayed the 31 items in different order to minimize order bias and the task was carried out as part of an assignment of a first Level Master degree class on IT management for radiographers.

We then applied an original ranking method, discussed in (Cabitza et al. 2015a) by which we classified each item in one of four levels of priorities (see Figure 2). An informal interpretation of the result could consider the first group (see the green block in Figure 2), i.e., Patient ID, patient birth date, exam date, operator name, radiographer name (if these latter are not the same) as those items that cannot be missing in the radiographer screen, and that indeed need to be emphasized at the interface level (e.g. by being rendered at a proper font size) and double checked by the operators involved to avoid potential mistakes and adverse events. The second group of items (including the name of the patient, the ordering radiologist, the access number) are data of lower priority but still very important, that radiographers should consider mandatory to fill in. Conversely, low priority items like patient nationality and patient height (see the red block in Figure 2) could be considered those that should not be imposed to the data work of radiographers, nor displayed irrespective of the specific examination, as these unnecessary items could contribute to clutter the user interface and hide more relevant information.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In our future work, we will perform the same user study in different groups of users of the radiological information system, like the medical radiologists and the administrative clerks, so as to make the interfaces adaptive according to the role logged in, and have the systems display awareness promoting information (Cabitza & Simone, 2012) about the different perception of utility (if any) by different worker categories. For instance, let us assume that the administrative clerks in a given hospital would consider the indication of the cost center and the billing address of the patient essential data items for their paperwork; in this case, radiographers, who conversely attach a low priority to these items (see Figure 2), could be notified that these data are important for someone else in the same facility (e.g., by means of some iconic indication or by a warning message at the end of the work shift) and be made aware (see above) of the data-related needs of other professionals that are connected by the same patient case.

The Open Data Study

In this second study, we collected 330 complete questionnaires from a population of citizens living in an urban area and aged 18 or older. To this aim, we invited personal friends and acquaintances, all of the colleagues of our university department, and the students of two master classes from the same university. Sample representativeness was achieved by weighting the response set by both age and gender according to the latest national census. The respondents had to evaluate the utility of 11 information items in different scenarios of urgency and serious health conditions. The information items had been selected from those that can be conveniently extracted from some of the most important big open healthcare data sets available in the USA, in Canada and in Italy (taken, respectively, from healthdata.gov, www.cihi.ca and dovesalute.gov.it).

The sample exhibited (statistically) significant appreciation for three information items above all the others: the hospital ranking by number of admissions for the pathology of interest; the ranking by average wait time for the pathology of interest; and the ranking of facilities by their reaching time from one's place. The rankings evaluated the least useful were the rankings produced according to either the perceived level of care quality by all the hospitalized patients, or by the percentage of patients that had to be hospitalized again within six months since the first discharge. While the latter information is quite technical, perhaps too much to be appreciated by a sample of lay people, the former indication came unexpected and quite puzzling.

All of the collected indications are useful to design healthcare portals that show their users a minimal set of items with the highest potential to satisfy the users' needs, on default of other information, leaving the other items accessible on demand. Interestingly, we detected significant differences in the perception of information usefulness between different user profiles. For instance, male respondents attached more importance than women to the ranking based on georeferenced information. Not surprisingly, expert users considered the ranking by number of admissions for the pathology of interest more important than people self-declaring non-expert. We also probed the sample preferences for different ways to display the same information, either by simple and essential tables or by richer and more appealing infographics. Also in this case we detected a statistically significant difference between females and males, as the former ones found infographics to be clearer and more intuitive than men; and between young respondents and the elderly as the former ones, quit unexpectedly, found the tabular form more clear than the latter ones. These differences suggest that the usability of a healthcare portal can be maximized even considering basic profiling information and user satisfaction can be improved by asking the user only a few data, like gender and age.

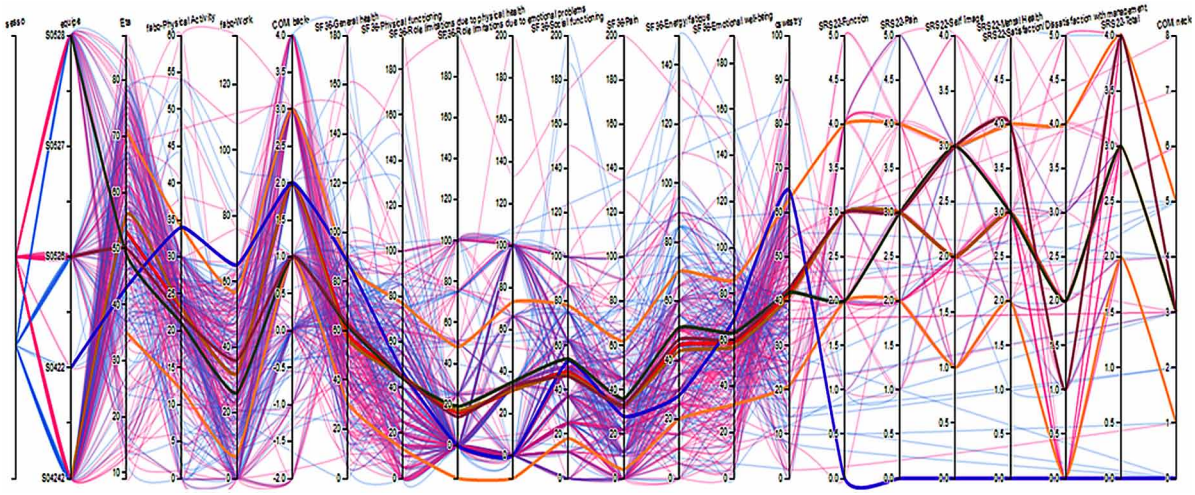
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The General Practice Study

We will focus now on the third user study that in some way integrates the research question of the former two studies regarding perceived utility with one of the central issues for the HDI field of whether interactivity improves the perceived value of data. Thus, the first research question is: What health open data are perceived as *more useful* in general practice (if any)? The second one is: Would visualizing these open data by means of *interactive* (that is browsable, zoomable, etc.) maps make these data to be perceived as *more useful and usable*? To further investigate this latter question we addressed it also in case of innovative visualizations, like in the case of diagrams displaying *parallel coordinates* (Inselberg, 2009) (see Figure 3). Thus, in particular, we wondered whether this kind of tools are effective means to represent patient data at various levels of description and to help GPs understand population trends, discover (frequency-based) normal and abnormal conditions, and detect correlations between multiple conditions.

To these above aims, we conceived a short questionnaire to be administered as a Computer-Aided Web Self-Interview (CAWI). This questionnaire consisted of four sections, which were to be rendered each in a different Web page: in the first page, the platform presented a list of 13 datasets that the authors had previously selected among the health open datasets made available on the DatiOpen.it platform (http://www.datiopen.it/en), which is one of the biggest Italian open data portals collecting more than 2,000 thousand datasets. In particular the respondents were asked to choose at least one dataset (and at most three) that they could want to consult in an online and customized "visual dashboard" supporting their own professional practice. In the second page we further selected 6 datasets for their suitability to be mapped into a georeferenced map like the one depicted in Figure 4.a, and asked the doctors to evaluate the degree of *utility for their profession* of each dataset on a six-value ordinal scale, from 1 (not useful at all) to 6 (very useful).

Figure 3. The parallel coordinate diagram shown to the user panel; the thick red and orange lines indicate the average values and standard deviations respectively. Blue lines represent single male patients. Pink lines female patients.



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Then, we asked the doctors to imagine to be able to interact with the map, so that they could browse the map by dragging, and zooming in and out at the desired level of visualization (e.g., province, city, neighborhood if possible) and get a *heat map* like the one depicted in Figure 4.b. We then asked whether visualizing the above datasets on such a browsable map would make the data more useful or not (on a 5-value scale ranging from 1 "the data would be much *less* useful" to 5 "the data would be much *more* useful", passing through a middle value 3 "it wouldn't make almost any difference"). Finally in the third section, the questionnaire displayed a parallel coordinates diagram like the one depicted in Figure 3. We asked to indicate on a six-value ordinal scale the degree of informativity of such a way to represent patient data (from 1 not informative at all, to 6, very informative).

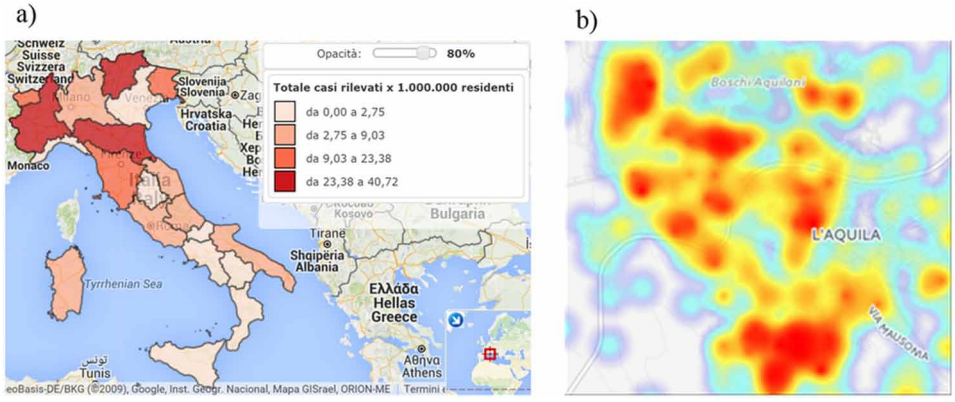
The questionnaire was left open for two weeks after the invitation had been sent to potential respondents. In this time lapse no reminder was sent. When we closed the survey, 29 GPs had accessed the questionnaire; 23 of them had completely filled in every item of the questionnaire in an average time of 5.9 minutes (SD=2.6 minutes). In this respondent sample, 5 out of 10 have been family doctors for more than 30 years, 9 out of 10 for more than 20 years; no respondent had less than 10 years of work experience so that we can consider the sample composed of experts in the Family Medicine domain.

The majority of the respondents (65%) claimed to be competent in Information Technology (IT) but neither experts nor enthusiasts. These latter ones were, respectively, approximately one third and one fifth of the sample. We detected a statistically significant and moderately negative correlation between age and IT expertise (-.49, p=.018), as it could be expected.

The respondents were asked to choose the three most useful datasets to be visualized on a personal dashboard for their daily practice by selecting them out of a list of 13 data sets. These had been selected for their popularity in terms of number of downloads from a comprehensive collection of Italian health open datasets . The sets chosen more frequently by the respondents were:

1. Regional distribution of the percentage of elderly people involved in the program of Integrated Home Care (in Italian: Assistenza Domiciliare Integrata).
2. Number (and details) of the Rehabilitation facilities for the elderly (in Italian: Istituti di Riabilitazione Extraospedaliera per Anziani).
3. Inpatient care average length of stay.

Figure 4. The static map (on the left, a) shown to the general practitioners; the heat map (on the right, b) resulting from interacting with the map depicted on the left



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

These datasets were selected by approximately one third of the sample (38%, 33% and 30% respectively). The other datasets collected much fewer preferences, with the "number of cases affected by pneumococcal disease by year" that was not chosen by any respondent.

In regard to the utility of data sets to be displayed on a georeferenced map, we got statistical significance for two sets only, which were considered useful for general practice, namely:

1. Number of registers on exposure to carcinogens (.5 vs. .95, p=.000).
2. Hospitalization rates, by regime, patient genre and region (.26 vs. .74, p=.035).

For the other data sets we did not get statistical significance: however, the "number of medical prescriptions delivered" can be considered the least appreciated information set (.64 vs. .36).

We also asked whether putting all of the above datasets into an interactive map, instead of a static one, would change the perceived utility of the datasets themselves. The majority claimed mapping data would make a difference, and that in so doing the datasets would be more useful (.83 vs. .17, p=.003, one third of the GPs even claiming that the data "would be much more useful"). The ranking of relative utility of mapping open data sets is reported in Table 1.

As a visualization aid to the comprehension of patient data and their correlation on multiple dimensions, parallel coordinates, like those depicted in Figure 3 and 5 were found to be highly informative: the responses were positive for the majority (.64 vs. .46, p=.286). Furthermore, almost every GP involved in the user study claimed that the interactive version (see Figure 5) of the diagram was much more informative than the static view (.96 vs. .04, p=.000, 60% "much more informative").

The characteristics of the respondent sample, in terms of work experience and attitude towards Health IT suggest that the respondents can be considered representatives of a population of real domain experts and that the potential (positive) bias introduced by the IT enthusiasts should be low. Besides the results reported above, the questionnaire also allowed the respondents leave free text comments in order to suggest datasets and applications to be considered in further studies, give advice on potential improvements to the visual tools presented, and more generally share remarks with the research team.

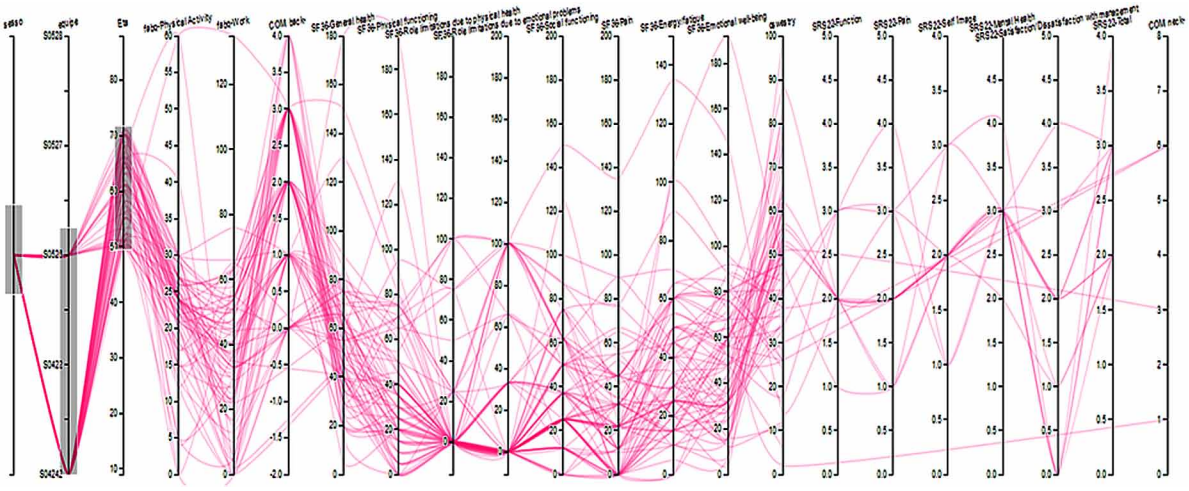
In particular, we report two comments that suggested relevant improvements to the Parallel Coordinate (PC) dashboard. One GP suggested to implement PCs indicating explicitly central tendency parameters on their axes (wherever applicable), like means and medians, standard deviations and interquartile ranges,

Table 1. Open datasets to be visualized in maps ranked by perceived utility

Dataset	Priority level$^{(sig.)}$	Perceived utility$^{(sig.)}$	Median
Carcinogen exposure registers	Higher$^{(*)}$	Positive$^{(***)}$	5
National Drug Consumption	Uncertain$^{(NS)}$	Positive$^{(NS)}$	4
Home care patients	Uncertain$^{(NS)}$	Positive$^{(NS)}$	4
Hospitalization rate	Uncertain$^{(NS)}$	Positive$^{(*)}$	4
Incidence of invasive diseases	Uncertain$^{(NS)}$	Positive$^{(NS)}$	4
Incidence of occupational diseases	Uncertain$^{(NS)}$	Positive$^{(NS)}$	4
Number of prescriptions	Uncertain$^{(NS)}$	Negative$^{(NS)}$	3

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The parallel coordinate diagram shown in Figure 3 after having interacted with it; in particular three specific ranges of data have been specified to filter the patient data to be highlighted: more precisely, female patients treated by two specific medical teams (equipe) and between 70 and 50 years of age



both at the level of the single GP patient set, and (if available) at the regional and national level. This doctor noticed how the bundle of lines, in virtue of their variable thickness at the intersection with the different coordinates, would nicely and visually represent the frequency distribution of the values within the subject population. Another GP suggested to allow the user to switch from a cross-sectional view (i.e., the default one) where each line represents the current conditions of a single patient, to a longitudinal view. In such a view, the current conditions would be represented as a highlighted line, while the bundle of the other lines would represent the different conditions that the same patient exhibited in the past, as these are recorded on the medical record of the GP or in the patient's health record.

We are aware of the limitations of this study. For instance, the fact that the involved doctors had to imagine the novel interaction, by looking at static pictures of how the visualization tools would change according to their actions. However, giving doctors real dashboards with which to interact and ask about their perceptions would have been problematic for the impossibility to give them a uniform training and to check remotely their interaction with the tool to evaluate. Using an interactive prototype would have implied a training phase of all the doctors involved in the experiments, and a physical presence during the usage of the interactive prototype to observe and record the experiment for further examination. A uniform training phase could have being achieved by preparing a video animation to show how to use the interactive prototype, but we could not do it due to two main reasons: (i) the lack of human resources that should also be present during the experimental sessions, and hence the impossibility to control the experiment adequately; (ii) the dread that the respondents, acting remotely without our presence, could assess the video animation and not the interactive prototype. However, we believe that studies like the present one, where interactivity is simulated in terms of its effects, could be useful anyway in a preliminary phase of development, where to understand if endowing visual tools with some kind of interactivity would be worth the effort.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

FUTURE RESEARCH DIRECTIONS

In light of the evidence collected in this study, we can conclude that designing for a better interactivity of open data platforms for general practice is worth further efforts. From the HDI perspective, this conclusion was desirable; although it might also seem easily predictable, nevertheless that conclusion could not be taken for granted in a committed *evidence-based approach* to Health IT design (Rigby et al. 2013, Longhurst et al. 2013, Cabitza et al. 2016). For this reason, our studies are just a small but necessary contribution in the research agenda outlined in the Introduction and that we advocate as future research directions of an increasing number of researchers in the health informatics, data science and human computer interaction fields. These future researches should be aimed at gaining feedback and design-oriented indications from both caregivers and patients to improve their experience in interacting with the next data visualization tools to come.

CONCLUSION

In this chapter we have proposed a tripartite perspective to health data by which to distinguish between primary data, i.e., the content of health records that clinicians and nurse produce and consume in their decisions and treatments; secondary data, i.e., the content of structured data bases, data warehouses and the reports that automated procedures produce and display on interactive data visualization tools (or dashboards) to support the tasks of clerical and managerial roles (including policy makers); and tertiary data, i.e., particular content that has been selected and optimized in terms of clarity, understandability and appeal, in one word usability, to be offered online for the general public and hence for unanticipated needs and aims. The distinction has been proposed to separate concerns and differentiate agendas. The one-size-fits-all approach to data quality improvement simply does not work (Pipino et al. 2002), nor solve the still present problems of low use of and low satisfaction for the Electronic Health Record (Cabitza et al. 2015a). Moreover, such a simple separation of concerns also allows to emphasize the concept of "use and reuse" of health data (Berg and Goorman, 1999), which is important to keep in mind when setting quality requirements and imposing ideal data model to health practitioners and their patients.

Human Data Interaction (HDI), as a research approach, can provide alternative methods to address these challenges, which are becoming more and more urgent especially in our current age of increasing opportunities and threats regarding the "datafication" of medicine and the consequent production of health big data (Murdoch & Detsky 2013). In particular, HDI approaches would focus on evaluating how ICT supports data (producing) work by relieving doctors and nurses from form-filling, coding and other administrative tasks; and on evaluating the usability and the user experience related to interacting with tertiary (health) data, to understand the actual value these convey in decision making and information-intensive tasks. Put it in another way, through HDI a design approach more sensible to relieving doctors from administrative tasks should become the primary concern behind ICT systems for supporting healthcare practices. It goes without saying that there is not an ultimate solution to achieve this goal, and HDI is no exception. Nevertheless, HDI may promote an attitude and awareness to cognitive ergonomics aspects, to usability studies applied to healthcare information systems, and so on. The HDI perspective is aimed to let emerge that doctors should not work with data as information *per se* (e.g., by forcing them to fill a form of a database table full of tedious completeness constraints aimed to achieve an intrinsic data quality), rather they should use their time to work and reflect *upon* data, in order to enhance their

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

daily work, practices and decisions. As a final consideration, HDI may be considered as an approach through which nothing is advisable *a priori*, unless it is packed-up with an evidence-based design and empirical evaluation. HDI cannot be directly connected to better outcomes, but to trace back all of the ICT recommendations and solutions to the evaluation of their impact in daily practices in terms of outcome efficiency and effectiveness, rather than in terms of intrinsic characteristics of a data system *per se*.

KEY TERMS AND DEFINITIONS

Data Visualization: A visual representation of a (subset of) dataset. Also, the scholarly discipline addressing how to design, implement and deploy this kind of representations.

Data Work: A class of working activities that regard the production, arrangement, management and interpretaton of data to perform other work tasks adequately.

Evidence-Based Design: A design approach that integrates the empirical and user-centered validation of alternative solutions to choose which ones to implement and how to, in order to increase the odds that the overall final system will be found to be usable (efficient, effective, satisfactory) by the users and be appropriated in their practices.

Human-Data Interaction: a discipline that addresses the phenomenon of how users make value out of datasets by interacting (i.e., querying, filtering, zooming, etc.) with an either textual or visual representation of those data.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Open Data: Those non-personal data that, made available by some institution, organization or association, anyone can freely access, use, modify, and share for any purpose, subject, at most, to requirements that preserve attribution and openness.

ENDNOTES

1 We concur with Hornung et al. (2015) that data are "artifact-mediated representations of phenomena that need to be given meaning by people and that serve some purpose".

2 To this respect, datafication is a process of both dis-closure of the representable reality, as well as the closure of what is (willingly or unaware) left tacit behind. Datification constructs facts, but it can also entail the (irreversible) destruction of context, through the emergence of text out of human experience.

3 Obviously we are aware that the value of something, and hence also data, can be appraised differently than by adopting a consumer-oriented perspective, which regards what in classical political economy is denoted as "use value". Value can be a function of the resources involved or consumed to get the data (mainly by primary users), to verify and cleanse them, and make them fit to interoperable formats typically in secondary processes); or, simply, a function of how much someone is going to pay to obtain them (cf. the idea of economic value, that is so common in this age of splendour of online advertising). These different perspectives reflect different conceptions of the idea of value, as it has been formulated in centuries of economic and theoretical speculation (see (Dobb, 1975) for a classic review of those conceptions).

4 Other interesting cases regard the failure to detect relations between either right data or inconsistent ones; the failure to get the right implication from right data or, the other way round, success in detecting right relations and inferring right implications from wrong data. It is important to distinguish between all of these cases in understanding the root causes of information failures and understand how to minimize the odds of their occurrence.

ABSTRACT

Biological interaction mainly depends on the interactions of various genes and genomes. To identify actual meaning of interactions we have to find out the facts and reasons for these interactions. Gene analysis allows to verify such environment. Gene annotation means to identify the exon regions in metagenomic samples. The de Bruijn graph plays significant role in gene prediction and next generation sequencing (NGS). Apart from that, Eular Path of de Bruijn graph introduced generalized gene annotation for translational and splicing signals, exon introns separation and coding regions. set of graph reduction rules have used to build a de Bruijn graph. Accurate solution for large scale sequencing, trims space complexity and generates optimal gene annotation have tested.

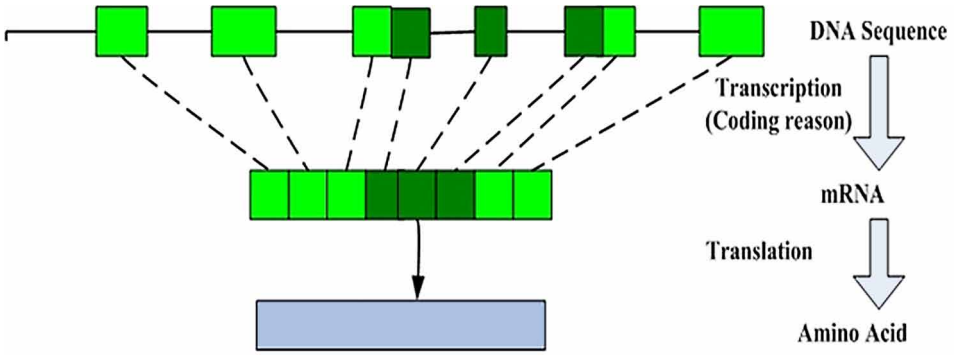
INTRODUCTION

The approach that specifies or categorized the genetic substance from environmental collections is called metagenomics. This process is important due to its uniqueness on data clustering facilities. I.e. the system permits to organize huge molecular data into a small area. By imposing metagenomics concept, various vital and unique molecules with pivotal activities and applications have been determined. The populations and demand of foods and daily necessary goods are increasing day by day. To fulfill the demand of daily commodities as well as medical support, metagenomics will play very important role. Lot of companies are willing and investing in this sector to clear the unknown genetic information. So metagenomics gene analyses will dominant in enzymes processes, medicines, agriculture, ecology and new generic products. Metagenomics ensure to supply new molecules and novel enzymes with dynamic activities and provide factors from set of enzymes from the cultivable microorganisms. Apart from that, the uses of metagenomics are used to uncovering novel biocatalysts from nature, bioremediation and xenobiotic metabolism.

DNA sequence consists of four nucleotides A, G, C and T. These sequencing efforts generate a large amount of raw data as the DNA sequence of a eukaryote is often longer than a hundred million base pairs. The genome of human has 3.2 billion (appx) base pairs. The annotation of these sequences of biological data is needed as a computation tool for gene finding. Locating the genes is not only helpful but also a prerequisite for further analysis, such as the characterization of the function of the gene product, determining the phylogeny of different species or understanding gene regulation. But the problem of finding genes in a genomic DNA sequence is difficult and high space complexity.

Metagenomics, the investigation of crude bacterium under the study of genomic substances gathered precisely from natural data sets, has been applied to analyze the shape, activities, and mechanical interactions of small communities. Various analysis permit us to know about different microbes in multiple areas (Ley et al., 2008; Rusch et al., 2007; Wu et al., 2011), their composite architectures of the communities they built (Huttenhower et al., 2012), and the pivotal encounter they maintain on the associated environment (Tyson et al., 2004). It important to analyze the various bacterium interactions

Figure 1. The central dogma is a framework for understanding the flow of genetic information. It states that DNA makes RNA, and RNA makes protein (amino acid.)In transcription process DNA convert into RNA specially mRNA(messenger RNA) and in translation RNA convert into protein(amino acid).



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

however, human metagenomics interactions are very essential to utilize the meaningful result due to its impact on mankind need as drugs, foods and diseases identifications (Qin et al., 2012; Behre C.J, et al., 2013; Greenblum et al., 2011).

In the age of information superhighway, numerous metagenomic analyses are based on gene-centric processes and as well as new aim to cluster the complete genomic shape of the association by virtue of shotgun metagenomics. Mathematical analysis based on shotgun sequencing impact helped to mapped database to a orthologous gene groups such as KEGG (Kanehisa et al., 2012), COG (Tatusov et al., 2003), EggNOG (Powell et al., 2012), M5NR (wike et al., 2012) to investigate similarities to genes or proteins with real and annotated activities. It is important to know that the biological activities among similar genes are work together in contrast, with taxonomic identify resulted in the experimental analysis. BLAST is frequently used to mapped to obtain greater score values on sequence alignment and annotations (Dalevi et al., 2008). This annotation mechanism and the measurements of the data set alignment that mapped individual activity is a an important part in computational metagenomic research and it helps to identify the functional shifts related with disease, as it is the basis of general genomic of analyses.

An important hypothesis afterwards, this annotation process and the key to properly saving the absolute structures of the metagenome alignment where small genome sequencing input holds abundant information to precise map to the exact activity. By considering different annotation rules and assumptions that each input will be directed to either its gene of or to an orthologous gene from an efficient distant genome annotated with the same function. These rules for future assumption that input initiating from intergenic regions or from orthology collection with unknown activity will not be properly mapped to any of the active annotated genes in our database. These considerations are vital for both estimation as well as identifying the presence or absence of gene groups. Now-a-days, but, no details and systematic studies has not checked this analysis on a broad scale, nor have rules for this annotation system been regulated. The shortage of such systematic analysis produce the results sketched for different metagenomics studies are very difficult to quantify and compile and challenges any steps to compare research outcomes.

Microarray data set is a collection of chemically coated glass, nylon membrane or silicon. A microarray is a small chip (made of chemically coated glass, nylon membrane, or silicon. It comprises of millions of information for metagenomics genome or DNA sequence analysis. Metagenomics based research or microarray engineering organized an environment to measures automated process to check up the expressions and interactions of genes in all respects as drug design, disease investigations, protein-protein interactions and sequence analysis. But, very large data set in genes and biological network creates computational complexities in efficient data handling. To overcome the overcome the difficulties, classification and clustering techniques help optimize data processing. Subgroups help to organize the data set separately and consecutive ways. This clustering process is important for better data processing. Various clustering algorithms have been contributing the better data processing. A microarray based computational algorithm (Jiang et al., 2004) leveled data set into three distinct parts that helps to maintain group based data separation. But unsupervised data management produces some pitfall of this algorithm. Total number of groups and subgroups were unknown it becomes problematic for very large data processing. Microarray DNA sequence and gene analysis plays an important role towards the generations of drugs and diseases investigations. This system allows thousand of small DNA molecules in a small storage area. In current time, microarray data processing is very important in the field of Computational Biology. Consequently, microarray image processing enables proper information generation in gene annotations (Karim et al., 2011). Moreover, complete or global metagenomics processing opens verification techniques for gene expressions interactions. Formal and basic approaches of measuring gene study focused on a specific

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

factor that led a limited area of biological data processing as well as information generation. Due to limitations, lots of vital biological changes were lost or misjudged. In this regards global data processing are very much efficient to cover all the facts related to the overall data set (Fryer et al., 2002).

In addition, de bruijn graph runs much faster and requires less memory space than most of compared methods, and exhibits competitive CPU time. The performance of optimized de bruijn graph is even comparable with the other gene assembler in both sensitivity and accuracy. Reduced de bruijn graph also runs much faster for gene annotation.

BACKGROUND

De-Bruijn graph is a directed graph that crates edges among all existing nodes in such a way that $P = (p1, p2, p3, \ldots, an)$ to $Q = (q1, q2, q3, \ldots, bn)$ with Q being a left sided part of P, or $q1 = p2$, $q2 = q3$. The critical benefit of this graph is that it mathematical tools that helps to remove assembly faults and get optimal solutions. Transcription assembler iterative De Bruijn graph approach (T-IDBA) (Peng et al., 2011) is an modified approach of iterative de Bruijn graph that rearrange positive genome segments from large sets of irregular data set of genes. Velvet (Zerbino at el., 2008) is a complete tool that quickly manage de Bruijn graph to curtail false reads and cut the redundant input sequences in genome segments. Velvet is a strong and efficient and simple dBG-oriented assembler. ABySS (Simpson et al., 2009) is a parallel and cluster based a measurement which is used to employ storage space for large-scale data volumes using the de Bruijn based classification. This package support and indicate the K-mer graphs and strongly connected graph calculation for a certain amounts of nodes that requires large storage area. AllPaths (Butler et al., 2008) is another de Bruijn Graph based assembly tool which can manage large amounts of genome sequencing. It is expandable in both prototype and real data sets. Apart from that, this package holds an algorithm that is used to read corrected input genome sequences. An organized research paper (Sonia and Sarwar, 2015) on Next Generation Sequencing has narrated the graph based approaches for genome assembly. MIRA3 is an organized framework of overlap layout consensus (OLC) under greedy algorithms (Zang et al., 2000). It is a tedious assembler that can read and manage older errors by the support of OLC and greedy mechanisms. Mosaik (http://bioinformatics.bc.edu/marthlab/Mosaik) is a history oriented sequencing process that aligns parallel sequencing in an exact analysis using Smith–Waterman algorithm with the help of hash-based table for shorter sequence reads. Another OLC-based automated tool is Newbler (Margulies et al., 2005) which is massively re-arranged by the famous 454 Life Science in gene sequencing and analysis. The starting point of this tool is used to sequence the DNA or RNA without the support of pairwise alignments where the sequence lengths were near about 120 bp. This automated computational tool has been updated that can organize the pairwise alignments as well as distinct alignments. From 2005, OLC was introducing for two basic ways as, OLC could build unitigs from input data and second it constructs huge contigs from unitigs. The pivotal benefits of Newbler are uses of sequence reads coverage and reduced matching errors. Graphlet degree vectors (Sonia and Sohel, 2014) are tinny strongly connected level graph under a large graph network. It supports to verify the gene annotations as well as interactions.

The research area of finding the protein coding genes in a eukaryotic genomic sequence by computational methods has become competitive. Most of the estimated 30000-40000 human genes code for proteins. Cells make a protein molecule from a DNA sequence containing the gene (Figure 1). First, a copy of a contiguous region of DNA is larger than actually coding part. This process is called transcription.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Out of this sequence the introns are spliced out and the result is the concatenation of the exons, so called messenger RNA (mRNA). The number of exons varies in per gene. Some genes consist of only one exon and therefore do not contain introns. The human muscle protein constitutes the other extreme. It consists of 178 exons. In human, it is estimated that there are on average nine exons in per gene (Brown, 2002). In metagenomic analysis is defined as the classification of microbial genomes via the direct isolation of genomic sequences from the environment without prior cultivation (Handelsman, 2007).

The whole genome of an organism sequence is assembled and then genes are predicted. In metagenomic, a single genome cannot be assembled and therefore, it is a challenge to predict genes within these short sequences (Hoff et al., 2009). Accurate gene annotation for environmental samples is needed so that genes can be classified to their correct functions, and it paves the way for functional studies in metagenomic. In the chromosomes the DNA sequence is found in a double stranded sequence, where each nucleotide in one strand is opposed by a complementary nucleotide in the other strand. A(Adenine) is the complement of T(Thiamine) and vice versa. In the same way C(Cytosine) and G(Guanine) are complementary bases. As the sequence of nucleotides of one strand is fully determined by the sequence of nucleotides on the opposite strand, we only need to know the sequence of one of the strands. Usually two neighboring genes (regardless whether they are on the same strand or on opposite strands) are separated by an inter-genomic region, but exceptions to this organization are known. In the human mitochondrial genome the coding regions (sic) of the genes ATP8 and ATP6, which are on the same strand, overlap by 46 nucleotides (the reading frames in the overlapping region are different). An example of a gene lying within another gene is the human neurofibromatosis type I gene on chromosome 17, which has three short genes on the opposite strand within one of its introns. Each of these internal genes has introns itself.

LITERATURE OVERVIEW

Bridger (Chang et al., 2015) is a software package that calculates the genome arrangements with the help of de novo transcriptome assembler where Cufflinks based methods are employed to decrease drawback of ongoing de novo assemblers. Justification of this tool are made with real data sets of human, and mouse RNA. It reduces the errors of false positive selections and operates substantially faster and holds much less storage areas than most existing assemblers. Consequently, Bridger restricted the sensitivity and accuracy with Cufflinks. However, this process is not fit for handling overlapped sequences. VirAmp (Yinan et al., 2015) is an integrated assembler that comprised with the techniques of existing assemblers as well as web-based interactive interfaces. This assembler supports multiple pipeline environments for data set classifications. This package also enables representations of large number of data set into a single platform. The interactive interface is the key advantages of this tool. However, this tool is also not free from overlapped genome sequencing and it takes more time to handle interconnected genome sets. ClusDCA (Wang et al., 2015) is ontology based automated environment that relocate information among all data set that has unique activity to mitigate the overfitting difficulties for sparsely annotated functions. To depict interconnected data, ontology based method takes more time due to absence of mapping. A mapping based analysis overcomes the difficulties where a reads mapping algorithm utilize short reads onto a de Bruijn graph of assemblies (Yuzhen et al., 2015). The prime consideration is a hash table that organizes the relationship of k-mers (mer: from Greek meaning "part") to enable faster mapping of reads to the graph. This is a reference-centric technique to metatranscriptome assembly that utilizes graphs of metagenome assembly as the reference. The experiments however notice that, this process has

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

missed mapping of shorter fraction of multi-edge-spanning reads. While there is a sequencing defect in classification of k-mer, this algorithm is unable to detect the location of the error.

Accurate gene annotation for sample data is needed so that genes can be classified to their correct functions. Gene prediction programs can be categorized into two different groups. First, the ab initio programs that employ training set with known annotation for training the parameters of their models, are widely used in gene prediction (Mario et al., 2003). There are a large number of gene-finding programs of this kind, e.g. GENIE,(Martin et.al., 2000) GENSCAN, (Christopher, 1997) GENEID, (Gens et al., 2000) and GLIMMER (Arthur et al., 2007).Other gene prediction program known as similarity-based programs, use external information about the input sequence to predict genes. Some popular similarity based programs are GENEWISE,(Ewan et al., 2004) AGenDA (Leila, 2003) and the well known BLAST which searches the input. Open Reading Frame (ORF) is a conventional approach in gene prediction which began with a start codon and end with in-frame stop codon (Hoff et al., 2009). Generally, genes in prokaryotes are 1000-bp in length on average (Xu et al., 2006). Due to the short sequence length of metagenomic, they contain incomplete ORFs that lack start and/or stop codon, thus conventional ab-initio programs cannot be applied to metagenomic. Similarly, homology-based approaches for gene predictions rely on databases that only contain known, and thus a limited set of genes. Therefore, both of these categories do not work well for metagenomic fragments which are about 700 bp less than 400 bp when produced by Sanger and next generation sequencing, respectively (Mardis, 2008).Sequence similarity search has been proved useful in many cases, it is seen that only a fraction of newly discovered sequences have identifiable homolog in the current databases. Proteins might have already included representatives of most ancient conserved regions (ACRs, regions of protein sequences showing highly significant similarity across phyla) and that new sequences not similar to any database sequence are unlikely to contain ACRs (Green et al.,1993). The proportion of vertebrate genes with no detectable similarity in other phyla is estimated to be 50%.This is supported by a recent analysis of human chromosome 22 where only 50% of the proteins are found to be similar to previously known proteins. Therefore, recent tools have emerged to address these problems for metagenomic reads. Three programs are widely used for this purpose: Orphelia (Hoff, 2009), MetaGene (MG) (Noguchi et al., 2006), Meta Gene Annotator (MGA) (Noguchi et al., 2008), and Gene-Mark (Besemer et al., 1999). We demonstrate a memory efficient technique for metagenomic large scale data. We used bipartite graph and Euler path for finding gene from large DNA data set.

ARCHITECTURAL APPROACH

The structure of this work is built based on gene annotation (Figure 2).Our method works based on three phases: Data collection, Graph generation and Gene Annotation. The sample data are the data set of DNA nucleotides of human, plants or micro organ. Sample data are character of set of DNA nucleotide data stream. In graph generation phase divided into sub phases: generation of signed graph and graph reduction. In graph generation phase, we generate a undirected sign graph with multiple edges and loop. Graph reduction rules are used for graph rewriting. Basic reduction rule for graph rewriting technique is used for specification and generation of graph optimization.

After graph optimization we performed gene annotation. In next phase, gene annotation process is applied with euler path by using optimize de Brujin graph. We transform de Bruijn graph into series of equivalence sub graps. Euler path of every sub graphs represent the sub solution of the problem. Euler

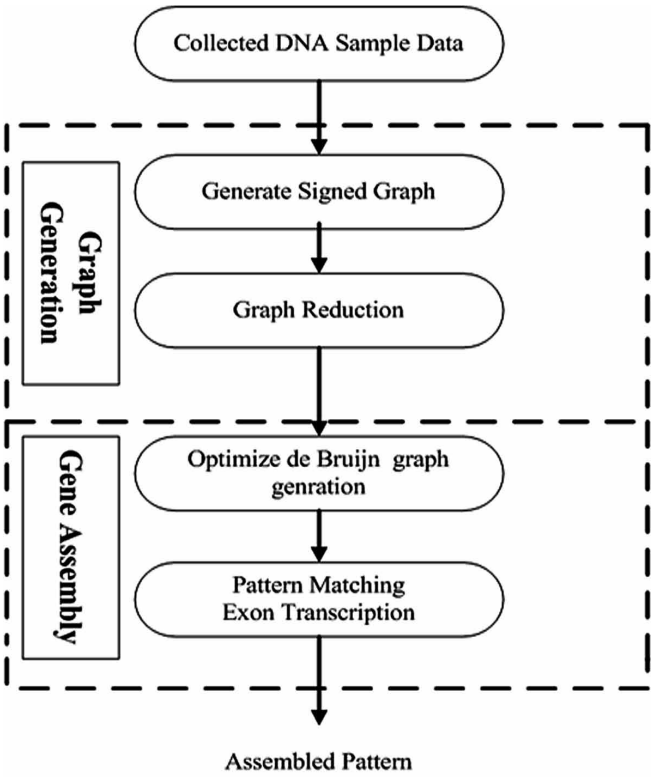
Figure 2. Semantic view of the proposed methodology for genome assembly; our architecture has two phases: graph generation and genome assembly. In graph generation phase, an optimized de brujin graph is generated and genome assembly phase different type sequence are assembled (i.e. Exon separation or Genome fragmentation etc.).



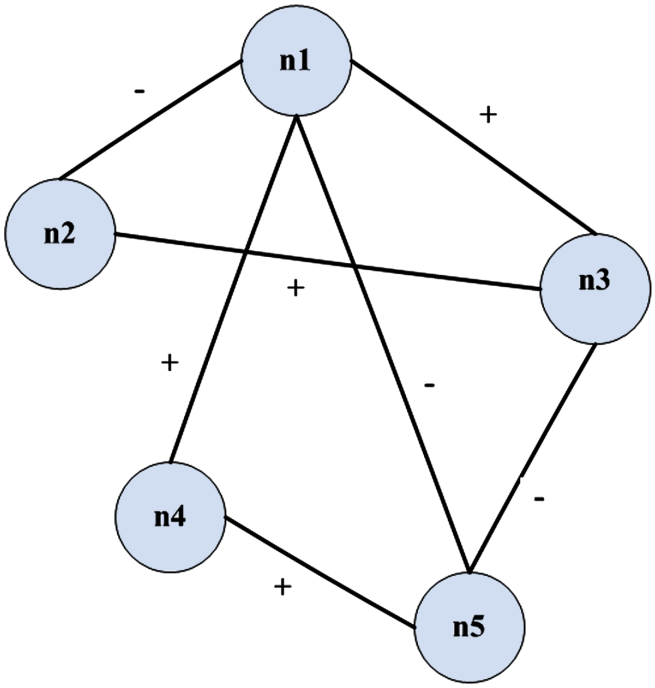
path is an efficient algorithm that is solved in a linear time. To combine the every solution of sub graphs represent the solution of gene annotation. In exon transcription, we marked initial and stopping sites in optimize de Brujin graph and find out euler path from intial site to stopping sites. Initial and stopping site indicates the exon annotation region.

SIGNED GRAPH

In this section we have introduced basic notations for signed graph. Let G=(V,E) be a finite undirected graph with multiple edges and self loop. The number of |υ| the vertices, is called the order of G and the connected number of |e| is called the degree of G. We write υ ϵ G if υ is vertex and e ϵ G if e is edge of G. The neighborhood of a vertex υ is $N_G(\upsilon)=\{u|(\upsilon,u)\ \epsilon\ G\}$.The vertex υ is isolated if $N_G(\upsilon)=0$.If a vertex has exactly one neighbor, it is denoted as a leap. We called G is discrete graph if all vertices are isolated. A subset A⊆G is stable if there is no edges (υ,u) with υ,u ϵ A. Graph A is complete if any two vertices of G are adjacent.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. A simple signed graph with positive or negative edges; an edge will negative if edges is connected with negative nodes and edges are positive if edges are connected with positive nodes.



A signed graph G=(V,E,ϕ) consists of vertices and edges (V,E) together with a labeling function ϕ:V→{+,-} of vertices V.A vertex υϵG said to be positive and negative if φ(υ)=+ and φ(υ)= - respectively. We let

$$G^{+} = \{\upsilon | \varphi(\upsilon) = +\} \text{ and } G^{-} = \{\upsilon | \varphi(\upsilon) = -\} \tag{1}$$

We say that a signed graph is negative if all its vertices are negative (Figure 3). Also, an edge $e=\{u,\upsilon\}$ is called negative, if $\upsilon,u \in G^{-}$.

If G and H constitute a two signed graph and its two disjoint vertex sets are V(G) and V(H), let $G \oplus H$ be their disjoint union, the vertex set of $G \oplus H$ is $V(G) \cup V(H)$ (Figure 4a) and its edge forms,

$$E(G \oplus H) = E(G) \cup E(H) \tag{2}$$

The complete connection $G \otimes H$ has the vertices set and the edge set is (Figure 4b)

$$E(G \otimes H) = E(G) \cup E(H) \cup \{(\upsilon, u) \mid \upsilon \in G, u \in H\} \tag{3}$$

We used undirected sign graph for graph analysis and transformation which are performed in graph reduction technique. It is more compatible and easy in graph analysis in which enlarging graph by joining new edges with information and reduction by deleting edges or replacing sub graphs.

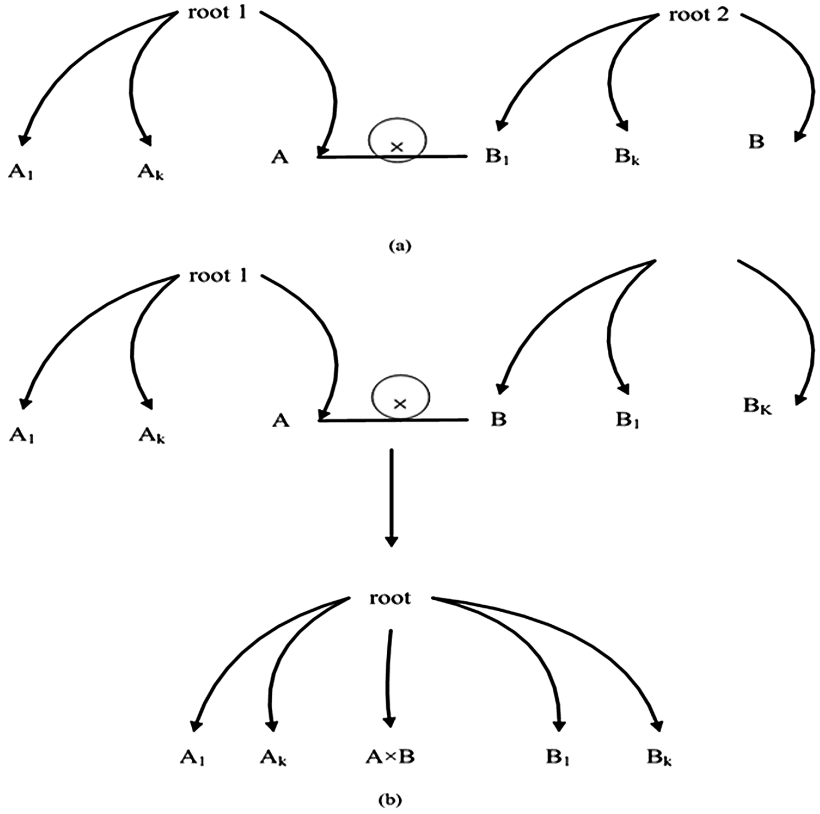
Figure 4. Two basic operations of signed graph: (a) And operation for two disjoint graph where two vertices convert into one vertex (b) complete operation for disjoint graph where two disjoint graph convert into one graph



GRAPH REDUCTION RULE

There are three basic fundamental operations of reductions rule for signed graph. The molecular operations are translated into following operations:

Let u and v be two vertices:

1. The negative graph rule for v is applicable to G if $\upsilon \in G^-$ and it is isolated in G. The result is the signed graph $nr_{\upsilon}(\upsilon)=G-\{\upsilon\}$. The number of vertices is $|nr_{\upsilon}|=\{\upsilon\}$.
2. The positive graph rule for v is applicable to G if $\upsilon \in G^+$. The result is the signed graph $nr_{\upsilon}(\upsilon)=G-\{\upsilon\}$. The number of vertices is $|nr_{\upsilon}|=\{\upsilon\}$.
3. The double rule for $v \neq u$ is applicable to G if $\upsilon, u \in G^-$ and $e=\{\upsilon,u\} \in E(G)$. The result for signed graph $dr(\upsilon) = G - \{(u,\upsilon), E', \varphi'\}$ where φ' is obtained to $G-\{u,\upsilon\}$ and E' obtained from complementary of E.

In basic reduction rule, graph rewriting technique is used for specification and generation of graph optimization. Graph analysis and transformation are performed by graph rewriting technique. Analyzing graph means enlarging graph by joining new edges with information and graph transformation means

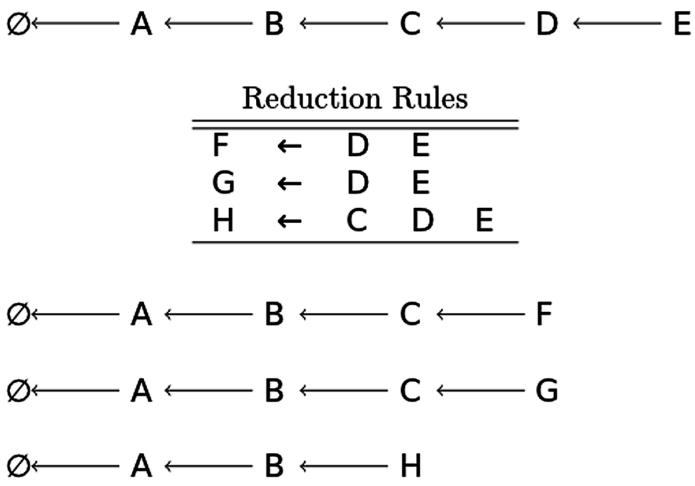
Figure 5. Graph reduction rule with termination point; in graph reduction rule it reduces the edges (paths) . A,B,C,D,E are nodes of the graph and Φ is termination point. D and E nodes are reduced by F or G.C,D and E nodes can also replaced by H. Here termination point indicates the ending point or pattern in transcription region. Replacement nodes reduce the graph complexity.



reduced into the graph rewriting by deleting and attaching sub graphs. In reduction rules we delete or replace two or more nodes by another node (Figure 5).

In graph reduction rules, node D and E are rewritten by F (Figure 5).Here D and E nodes can correlate with F, redundant nodes D and E are replaced by F. Node C,D and E are rewritten by new node H. Reduced edges are encrypted with new edge. Termination by edges accumulation and termination by edges subtraction is used for graph termination process. When, we reached to null point (Φ) that indicates the termination (Figure 5).

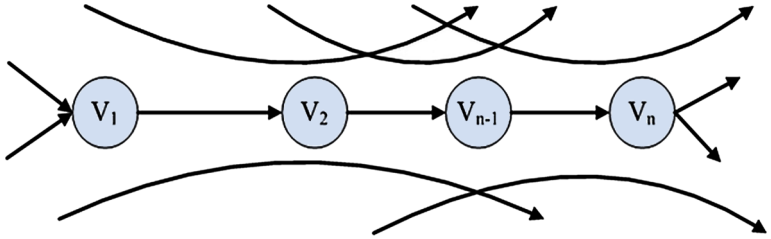
OPTIMIZE DE BRUJIN GRAPH

A sets of reads S={s_1…….s_n},define the de Bruijn graph G(S_1) with (l-1) vertices.An (l- 1) tuple v∈S_{l-1} is joined by directed with l-edges. If S_l contains l-tuple for which the first (l-1) nucleotides coincide with v and last (l-1) nucleotides coincide with tuple w. Each l-tuple from S_l corresponds to an edge in G. If S contains the only sequence S_1, then this sequence corresponds to a path visiting each edge of the de Bruijn graph. A de Bruijn can substitute every edge by k parallel edges, where k is the number of times the edge is used. If S contains the only sequence S_1,this operation creates k parallel edges for every l-tuple repeating k times in S_1.Euler path is an efficient algorithm that is solved in a linear time.

In de Bruijn graph, a vertex v is called a source if indegree(v) =0,a sink if outdegree(v)=0 and branching vertex if indegree(v).outdegree(v)>1.A path v_1.....v_n in the de Bruijn graph is called a repeat pattern if indegree(v_1)>1,outdegree(v_n)>1 and indegree(v_i)=outdegree(v_i)=1,for 1≤i≤n-1.Repeat pattern starts with v_i node and $v_{n,}$ are called exits from a repeat (Figure 6). An Eulerian path visits a repeat some times by visiting entrance and exit nodes. An Eulerian path covers a repeat if it contains an entrance into and exits from repeat by using end node. Every covering read-path reveals some information about the gene annotation between entrances and exit.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. The overlapping pattern with repeated vertices and edges.v_1 ..... v_n are repeated vertices in an overlapping graph. It is difficult to find out the read -length and contigs. Euler path gives the optimal solution for overlapping pattern. This overlapped graph divided into two sub graphs.



To solve the Euler path for gene annotation, we have transformed the both graph G and path P into new graph G_1 with path P_1.This is called equivalence if it exits one to one correspondence in (G, P) and (G_1,P_1).We transform de Bruijn graph into series of equivalence transformation:

$(G,P) \rightarrow (G_1,P_1) \rightarrow (G_2,P_2) \rightarrow \ldots\ldots\ldots \rightarrow (G_k,P_k)$

To combine the every solution of sub graphs represent the solution of gene annotation (exon/introns separation), Euler path solution is used. We describe a simple equivalence transformation that solves the Euler path problem where graph G has no multiple edges. We consider two cases of transformation; one is x-y detachment and another one is x-cut. Let $x=(v_{in},v_{mid})$ and $y=(v_{mid},v_{out})$ are two consecutive edges of graph G and $P_{x,y}$ be the collection of all paths of P that includes all sub paths. $P_{\rightarrow x}$ defines as a collection of paths from P that end with x and $P_{y\rightarrow}$ as a collection of paths from P that starts with y. Then x,y-detachment is a transformation that adds a new edge $z=(v_{in},v_{out})$ and deletes the edges x and y from G (Figure 7a).This detachment transformation alters the systems of path P as follows:

1. Substitute z for x,y in all path from$P_{x,y}$.
2. Substitute z for x in all paths from $P_{\rightarrow x}$.
3. Substitute z for y in all paths from $P_{y\rightarrow}$.

Every detachment reduces the number of edges in G and reduces the complexity of Euler path problem. Consider a fragment of graph G with 5 edges or 4 paths y_3-x,y_4-x,x-y_1 and x-y_2 (fig-7b).For graph fragmentation n edges or paths, it will be y_n-x,y_{n-1}-x,….y_1-x. In symmetric situation, x is tangle (repeated pattern) and there is no available information to relate any of paths y_3-x and y_4-x to relate another paths x-y_1 and x-y_2. An edge x=(v,w) is removable if

1. It is only incoming edge v and only one outgoing edge w.
2. x is either the initial or the terminal edge for every path P containing x.

An x-cut transformation P into a new system of paths by simply removing *x* from all paths in $P_{\rightarrow x}$ and $P_{x\rightarrow}$ without affected graph G itself (fig-7b).If x is a removable edge then x-cut is an equivalent transformation. Detachment and x cut proved to be powerful technique to build a simple de Bruijn graph and reduce fragments for all genome.

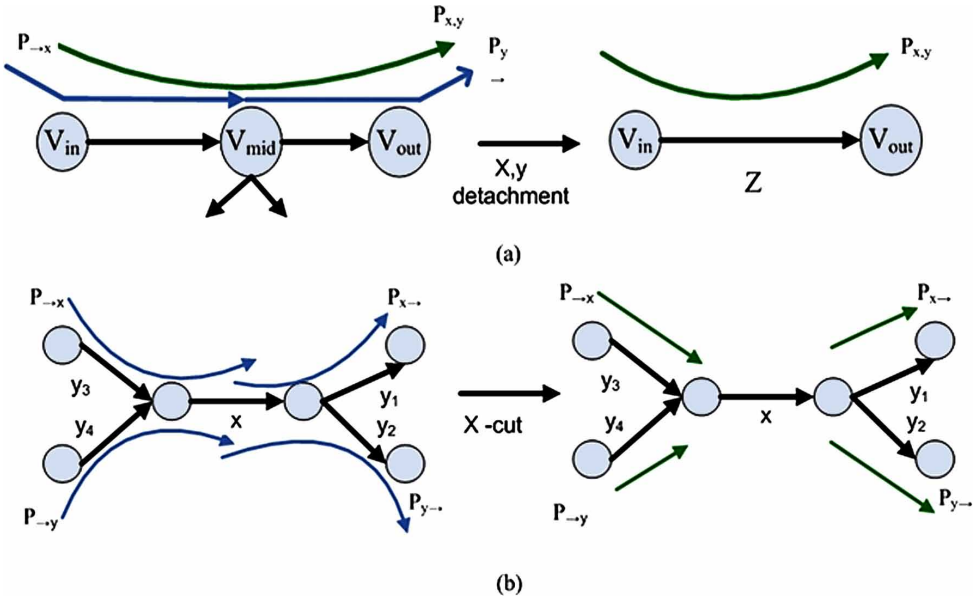
Figure 7. Equivalent transformation for Euler path; blue indicates the overlap paths and green line indicates equivalent paths.(a)X,Y –detachment which alters the systems of path for overlapped graph. In every detachment reduces the number of edges and reduces the complexity of Euler path. (b) X-cut which divide the overlapped graph into two or more sub graphs.



GENE ANNOTATION

De Bruijn graph is used for gene Annotation (Exon Intron separation) and next generation sequence assembler. It reduces computational effort by breaking read (sort sequence) into smallest part of DNA. Reads are called k-mer where the parameter k denotes the length of bases for these sequences. De Bruijn graph capture exon separation with considering exon initial and stop sites using k-mer (Figure 8).Construct a de Bruijn graph for exon introns where separation consists of the following steps:

1. **Structure of k-Spectrum:** Reads are divided into overlapping sequence of k. Every k-mer consists transcription and stopping site in exon chain.
2. **Node Generation:** Every (k-1) node generates for k-spectrum. In de Bruijn graph, exon initial site is marked as initial node (source), ending node (sink) represents stop site of exon chain and intermediate node serves donor and acceptor site for exon transcription.
3. **Edge Construction:** A directed edge is created from x node to y node if there exists k-mer such that its prefix is equal to x node to y node. Overlap path are reduced to euler path simplification which described in section 4.1.To traverse marked source node to sink node we had indentified the exon chain from whole DNA sequence.

By reducing whole data set into k-mer overlaps the de Bruijn graph reduces the high redundancy in short read data set. In exon annotation, imitation sites start with ATG and termination site with TAA or TAG or TGA. Another donor and acceptor site generates the internal node in de Bruijn graph. Initial and

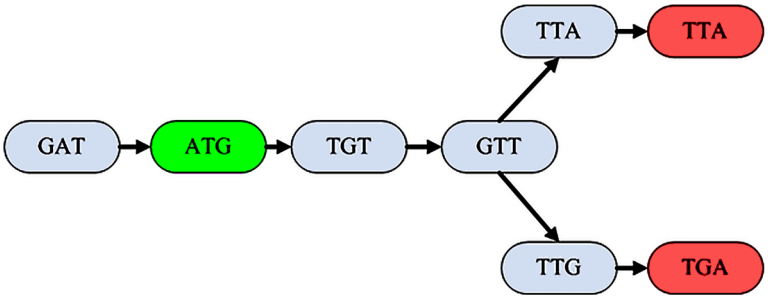
Figure 8. The length of overlap k-1=2; green node indicates initial site and red node indicates termination site respectively. Black line indicates the order of k-mer. Two braches indicates the separate genome annotation and possible ways of exon chaining.



stopping site indicates the exon annotation region (Figure 8). By converting the set of reads into edges of the de Bruijn graphs, the annotation problem becomes equivalent to finding an Euler path graph. To reduce the exponential distinct Euler path, heuristics are usually applied to construct the graphs. The graphs are filtered of erroneous occurrences and nodes are unambiguously connected by edges which are merged together.

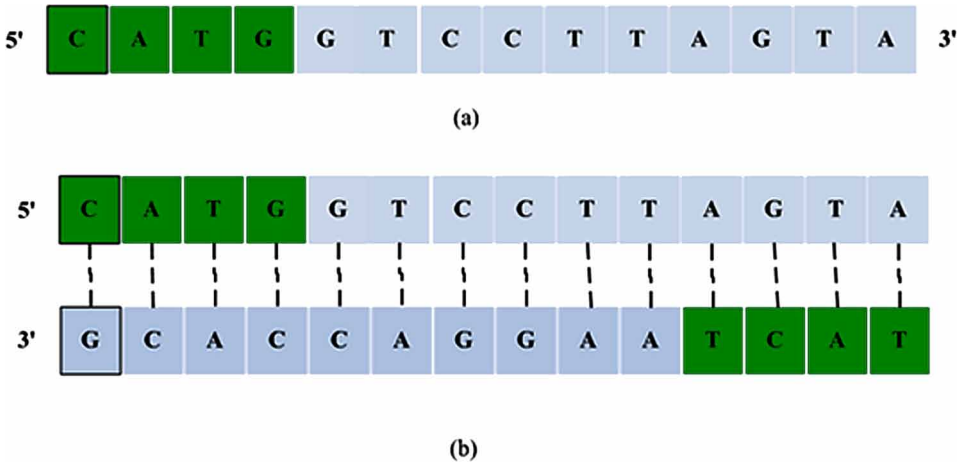
GENOME FRAGMENTATION

All sequencing platforms produce explanation of the target DNA molecule in the form of reads sequences of single-letter base pairs. (Miller et al., 2010). An example of a single-end read and a paired-end (Figure. 9a & Figure 9b). Genome assembly is two groups:

- **De Novo:** It is an assembly tools for DNA sequence. Contigs is A group of overlapping clones representing regions of the genome; the contiguous sequence of DNA created by assembling these overlapping chromosome fragments. In genome assembly scaffold is used to describe the first complete sequence assembly, to which new reads are aligned. Once have a scaffold you don't depend on de novo assembly anymore but can find a region to which any given new read is most similar and subsequently look for genetic variation.
- **Mapping/Reference:** In genomics complete genomes provide an outstanding resource for future sequencing projects. However, generating finished genomes is an exclusive and laborious endeavor. In some cases, the returns of finishing a genome are not worth the cost particularly when draft genomes can provide enough information for robust assembly process. Draft genomes contain a large number of unordered sequences of various lengths called contigs. Contigs can be joined into more contiguous sequences called scaffolds using paired-end reads. While a set of contigs/scaffolds can be useful for a wide variety of projects (gene annotation, gene expression profiling, etc.), contig order provides vital information in comparative genomics and analyses of specific genomic regions. Typically, a rough ordering of contigs can be accomplished by mapping contigs to a closely related reference genome.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Example of DNA fragment read (a) single end (b) double end; single end read indicates the single DNA sequence fragmentation and double end read fragment the multiple sequences. Double end read reduces the time complexity than single end.



As a result of the de novo assembly stage, a set of scaffolded contigs is accessible. Besides ordered contigs, scaffolds also contain gaps of estimated length separating the contigs. Scaffolds are also often called supercontigs. Low risk assemblies consistent with almost all of the detectable pair-wise read overlaps are called unitigs.Sequence alignment is the procedure of comparing two or more sequences by searching for a series of individual base pairs or base pairs patterns that are in the same order in all sequences. In most cases, the sequences cannot be aligned perfectly due to their mismatch. In an optimal case, mismatch base pairs and gaps are placed, in order to match together as many identical or similar base pairs as possible.

Sanger's method is most popular sequence fragment assembly algorithms were focused on creating multiple overlapping alignments of the reads to produce a layout assembly of the data. The alignment is used to read the consensus sequence, from which the DNA sequence is incidental. The described method was called the overlap-layout-consensus approach (OLC). OLC approach is one of the two typical approaches of the de novo DNA assembly, and is effectively used during the assembly of long, high-quality reads. Another very important, and currently most utilized approach in combination with Next Generation Sequencing (NGS) data, is based on the de Bruijn graph. This approach was commonly known as short read assemblers. Unlike the computationally expensive step of determining overlap amongst reads, the de Bruijn graph is constructed from fixed-length subsequences. If the sequence length is m then that have a perfect (m-1) suffix to (m 1)-prefix overlap. In de Bruijn assembler include Euler, AllPaths and Velvet methods.

Both the OLC and the de Bruijn approaches are graph based. Another type approaches also do exist. They include greedy search methods i.e. dynamic approaches such as Taipan (Schmidt et al., 2009).Errors in assembly can occur for two main reasons: Firstly, incorrect or incomplete information provided to the assembler. The real-world WGS data that contains errors can induce the following problems in overlap and de Bruijn graphs (Miller et al., 2010):

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Bubbles:** Bubbles are generated when two paths start and end nodes are same. Bubbles generated by causes of errors or biological variants. Dijksatra's and breath first algorithm is used the best path and remove such error.
- **Spurs:** Spurs are short, dead-end divergences from the main path. They are induced by sequencing error toward one end of a read. They can be induced by coverage dropping to zero. Possible causes include sequencing errors toward one end of a read, and low coverage.
- **Converging and Diverging Paths:** Reverse definition than for the bubbles, two paths converge into one, that later diverges again into two separate paths. Possible causes are repeats in the target or source genome.
- **Cycles:** Cycles are paths that converge on themselves. They are induced by repeats in the target. For instance, short tandem repeats induce small cycles.

Although sequencing technology has greatly enhanced, still no sequencing platform can produce sufficient data to assemble a complete genome from a single experiment. One of the key problems in shotgun sequencing is caused by repeats in genome sequences. Repeats, in cases when they are longer than fragment reads, persuade problems during the overlap phase of assembly. As a result, assemblies result in fragmented contigs, separated by gaps. Repeat caused fragmentation is more pronounced in the NGS technology. Assemblies containing gaps are called draft assemblies, while the process of filling the gaps is called finishing. Finishing involves obtaining missing sequences, improving low quality regions, resolving miss assemblies and ordering scaffolds. In order to fill gaps, further sequencing is usually required, either by amplifying and sequencing fragments spanning gaps, or by resequencing the entire DNA.

OVERLAP-LAYOUT-CONSENSUS APPROACHE

Let $N = \{n_1, n_2, \ldots\ldots n_m\}$ be a set of non-empty strings over an alphabet. An overlap graph of G is a complete weighted directed graph where each string in N is a vertex and the length of an edge between vertices x and y. The construction of the overlap graph is the first step of the OLC approach. General process of this approach consists of three main phases from which it derives its name:

1. **Overlap:** An overlap graph is created by joining all the reads by their respective best overlapping reads. This step is similar to the greedy approach.
2. **Layout:** The overlap graph is analyzed and simplified with the application of graph algorithms to identify the appropriate paths traversing through the graph and produce an approximate layout of the reads along the genome. The ultimate goal is a single path that traverses each node in the overlap graph exactly once.
3. **Consensus:** Multiple sequence alignment of all reads covering the genome is performed, and the original sequence of the genome being assembled is contingent through the consensus of the aligned reads.

A very important observation is that the identification of a path that traverses every node in the graph only once is a computationally difficult Hamiltonian path problem. The problem is also known as the Travelling Salesman Problem and is NP-complete.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The evolution of assembly Overlap-Layout-Consensus (OLC) and de-bruijn graph (DBG) algorithms are widely used OLC generally works in three steps: first overlaps (O) among all the reads are found, then it carries out a layout (L) of all the reads and overlaps information on a graph and finally the consensus (C) sequence is inferred. It is an intuitionist assembly algorithm. In the OLC algorithm, the identification of overlap between each pair of reads is explicit; typically by doing all-against-all pair-wise reads aligning. As a result, the OLC algorithm constructs a reads graph, which places reads as nodes and assigns a link between two nodes when these two reads overlap larger than a cutoff length. The nodes number is equal to the reads number, increasing linearly with sequencing depth and the links number will increase by a logarithmic scale.

DBG is an anti-intuition algorithm, working by first chopping reads into much shorter k-mers and then using all the k-mers to form a DBG and finally inferring the genome sequence on the DBG. The DBG assemblers were initially successful on small genomes such as bacteria, and were then extended to large genomes. In the DBG algorithm, the overlap relationship between neighboring k-mers is established implicitly. This process is completed by chopping all the reads into k-mers and simultaneously recording their neighboring relations. DBG algorithm constructs a k-mer graph that places k-mer as nodes and assigns a link between two nodes when these two k-mers are neighbors on the genome.

EXON TRANSCRIPTION

As exons are not independent, by splicing exons together to assemble a gene one can further eliminate false exon predictions by imposing translatability (i.e. adjacent exons must maintain the open reading frame). The main difficulty in exon assembly is the combinatorial explosion problem: the number of ways *N* candidates' exons may be combined grows exponentially with *N*. The key idea of computational feasibility comes from dynamic programming (DP), which allows finding "optimal assembly" quickly without having to enumerate all possibilities. We can limit possible errors by assuming each entry with a correct annotation that should satisfy:

- The initiation site is ATG.
- The donor site is GT.
- The acceptor site is AG.
- The stopping site is either TAA or TAG or TGA.
- No stop codon interrupts the open reading frames.
- The length of coding regions is a multiple of three.

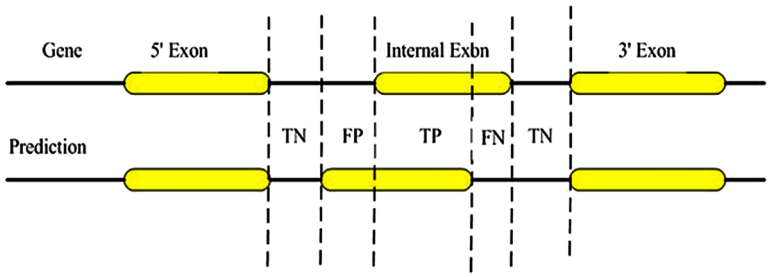
In pattern reorganization, the performance of a prediction system can be measured by the following statistics: true positive (TP), true negative (TN), false positive (FP) and false negative (FN). The internal exon prediction measurement on the nucleotide base pair in different level (Figure 10).

The accuracy of a prediction system is measured by sensitivity (SN), specificity (SP) and correlation co-efficiency (CC) as follows:

$$SN = \frac{TP}{TP + FN} \tag{4}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Measurement of Exon prediction comparing with predicted data set; True Positive (TP) indicates exon region consist both gene and predicted gene, True Negative (TN) indicates exon region not present both gene and predicted gene, in False Positive (FP) exon region is found in predicted pattern but not in real gene.



$$SP = \frac{TP}{TP + FP} \tag{5}$$

$$CC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FN) \times (TN + FP) \times (TP + FP) \times (TF + FN)}} \tag{6}$$

RESULT

We experienced our gene analysis method on three data sets which are adh222, h178 and sag178 (Table 1). Adh22 is a single sequence of Drosophila melanogaster and 2.9Mb long. It is a well characterized sequence from the Adh22 region and has been used in the Genome Annotation Assessment Project(GASP). In the update version std1 contains 38 genes with a total of 111 exons and std3 contains 222 genes with a total of 909 exons. The genes lie on both strands. Both the authors of GENIE and of GENEID have used these two annotation sets for testing their programs. H178 is a set of 178 human genomic sequences with one complete gene each. Each contains one gene and a little neighboring DNA. The sequences are from EMBL, were compiled by[GAA+00] and have also been used by the author of GENSCAN for evaluation [YLB01]. The mean sequence length is 7169 bases. This set is known to contain three annotated genes which are very likely, if not known to be wrong. But we kept them for reasons of comparability. sag178 is a set of 43 sequences with 178 human genes. These sequences were also taken from [GAA+00]. The mean sequence length is 177 kilo bases (shortest 70, longest 282 kilo bases) and each sequence contains average 4.1 genes.

We measured the gene prediction accuracy with the sensitivity and specificity. A predicted exon is considered correct if both splice sites are at the annotated position of an exon. A predicted gene is considered correct if all exons predicted are correctly and no additional exons are predicted. Predicted partial genes were counted as predicted genes. For each data set these measures were computed globally. For comparing we choose GENESCAN and GENEID. We took GENSCAN as it is the most commonly used gene prediction program and as it is considered one of the best programs for humans. Our method considers memory efficient which is considering GENESCAN. We used GENEID (version 1.1) as there

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

is a special Drosophila parameter set available for it and as it uses a different approach not modeling the lengths. GENEID first finds splice site candidates, then exon candidates are using the splice site candidates and then genes using the exon candidates.

By combining both measures we use the f-measure, a good indicator of overall precision and recall of the algorithm. F-measure (Figure 11) indicates the positive predictive value of a data set.

$$F - measure = \frac{2 * SP * SN}{SP + SN} \tag{7}$$

Internal exon prediction is important for gene prediction. Internal exons also have flanking splicing boundaries: the acceptor splicing sites at the 5´ end and the donor sites at the 3´end. Potentially all of the selected donor site and acceptor site candidates can be paired to form exon boundaries. The number of internal exons in a gene is one less than the number of introns. In our learning data set, there are only 125 internal exons. When we paired 348 selected donor site candidates and 607 selected acceptor site candidates, we had got another set of 314 pseudo exons, The final internal exon prediction combined all the features of donor sites and acceptor sites, with the in-frame hexamer preferences and the log of exon length. The optimal discriminate function had the performance in Table 2.

Table 1. Accuracy result on training data sets

Table 2. Internal Exon measurement based on sensitivity, specificity, coefficient co-relation

Measurement	Total Number	Accuracy		
		SP	SN	CC
Base Pair	145	94.1%	87.2%	92.1%
Exon	325	91.0%	87.1%	87.1%

The Sensitivity and Specificity measure the estimate of the program capability of detecting reads that contains gene. Coefficient indicates the accuracy of gene detection. The Genome Analyzer can generate paired reads with a length of 150 bp and more. There are, however, alternate technologies such as sequencing that produce longer unpaired reads. In this experiment, we investigate the influence of read length on an assembly.We simulated paired reads of 150 bp length (with a 450 bp fragment size) and 400 bp unpaired reads from the E. coli genome and human chromosome 20, respectively. All reads were simulated as error-free and at 50× base coverage. We used Velvet with a k-mer size of 31 to assemble all four data sets.

The contig sizes for each assembly. The assemblies using the 150 bp paired reads yield far larger contigs as compared to the 450 bp single read assemblies (Table 3). This is in part due to the way a de Bruijn graph assembler such as Velvet works: the reads are split into smaller pieces, the k-mers. In this experiment, we used a k-mer size of 35 which is the maximum for Velvet . Therefore we compared in principle k-mers of length 35 with and without pairing information. The strong impact of read pairs as opposed to single ended reads is evident (Figure 12).

To examine how long inserts can improve the assembly we sequenced E. coli with different base pair size(6kb to 10 kb). All of the de novo assemblers that we tested have the ability to use long-insert size (Table 4). Table 4 shows results obtained using De Brujin graph with a variety of long insert libraries.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Effect of read length for different E.Coli sample with different base pair

Sample	N50 Contig Size	Largest Contig	Genome Coverage
E. coli, 150 bp pe	122,776 bp	326,886 bp	97.07%
E. coli, 450 bp sr	21,405 bp	127,976 bp	96.27%
Chr. 20, 150 bp pe	56,744 bp	401,312 bp	89.59%
Chr. 20, 450 bp sr	2,214 bp	23,423 bp	91.05%

The 6 kb inserts already help bridge most of the repeats in E. coli if combined with the short insert sequence, and result in an assembly with an N50 of 1,403,330 bp. The two largest contigs cover a region of 2,348,095 bp, which corresponds to 68% of the E. coli genome. The rest of the genome is contained in smaller contigs (Figure 12).

The use of graph reduction rules to store a de Bruijn graph is straightforward and memory efficient. The expected false positive rate can be tuned based on desired memory usage, yielding a wide range of possible storage efficiencies . Optimized de bruijn graph is more efficient in time and space than the other assembler tools. We find out optimal euler path by using optimized de bruijn graph for gene annotation

Table 4. Effect of insert size for different super contig

Inserts	Reads (bp)	Coverage	N50 Super Contig	Largest Super Contig	Genome Coverage
200 bp	2×75	50×	94 kb	224 kb	98.88%
200 bp	2×75	50×	1.1 Mb	1.9 Mb	97.17%
200 bp	2×75	50×	4.2 Mb	4.2 Mb	98.59%

Figure 12. Genome accuracy analysis by using de brujin graph for four data set (E.coli, 150 bp pe, E. coli, 450 bp sr, Chr. 20, 150 bp pe, Chr. 20, 450 bp sr); we find better accuracy for E.coli, 150 bp.

CONCLUSION

In this research, we have observed that graph theory gives better accuracy than other two models. Our method is a robust that continuously vacant the memory storage, especially the proposed algorithm truly stands out when the data set of DNA segments are increased. In fact, our simulation result indicates that is more accurate in large data set. It performs relatively well on the task of assembling exons to genes because programs with a similar exon level accuracy often have a lower gene level accuracy. This means those programs more often combine the exons to a wrong gene structure for example by splitting or joining genes. With the growing number of sequenced species, the possibilities of finding approximate possible exons and genome assembly by cross-species alignments of homologue genomic sequences also increase. This leaves the task of assembling possible exons or pattern to genes. In future, we shall consider this concept for finding possible introns analysis.

KEY TERMS AND DEFINITIONS

De Brujin Graph: A generalized de Bruijn graph is a directed graph, where an edge exists from all nodes of form $V=(v_1, v_2 \ldots\ldots v_n)$ to $U=(u_1 u_2 \ldots\ldots u_n)$ with U being a left-shifted version of V, or $u_1=v_2$, $u_2=v_3$,.....$u_{n-1}=v_n$.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

DNA Fragmentation: DNA fragmentation is the breaking of DNA molecules into smaller pieces. Fragmentation of DNA is an early step in next generation sequencing workflows, as well in the creation of DNA inserts for expression libraries.

Euler Path and Circuit: An Euler path is a path that uses every edge of a graph exactly once. An Euler circuit is a circuit that uses every edge of a graph exactly once path.

Exons: A segment of a DNA or RNA molecule containing information coding for a protein or peptide sequence.

Gene: A linear sequence of nucleotides along a segment of DNA that provides the coded instructions for synthesis of RNA which, when translated into protein, leads to the expression of hereditary character.

Gene Annotation: Annotation is the process by which relevant information about these raw DNA sequences is added to the genome databases. This involves describing different regions of the code and identifying which regions can be called genes.

Gene Assembly: Genome assembly algorithms are sets of well defined procedures for reconstructing DNA sequences from large numbers of shorter DNA sequence fragments.

Genome: The total amount of genetic information in the chromosomes of an organism, including its genes and DNA sequences.

Introns: A segment of a DNA or RNA molecule that does not code for proteins and interrupts the sequence of genes.

Metagenomic Gene: Metagenomics is the study of a collection of genetic material (genomes) from a mixed community of organisms. Metagenomics usually refers to the study of microbial communities.

Signed Graph: A signed graph is a graph in which each edge has a positive or negative sign. Formally, a signed graph Σ is a pair (G, s) that consists of a graph $G = (V, E)$ and a sign mapping or signature s from E to the sign group $\{+,-\}$.

Chapter 60
Healthy 3.0:
Healthcare Digital Dimensions

ABSTRACT

Over the past few years, healthcare practice has evolved to include new forms of information and communication technologies, and healthcare providers have begun to leverage IT solutions and the internet to reach consumers in transformative ways. There is a common thought both in business and academia that the technology adoption process is a key component of success and allows firms to achieve and sustain competitive advantages. Therefore, this research attempts to reinforce the assessment of ICT impacts on healthcare, analyzing it from two different perspectives: 1) firm performance, which is measured as a combination of induced and intangible benefits beyond the traditional financial benefits; and 2) healthcare providers' acceptance and adoption of ICT tools. To assess the first perspective, a structural equation model was applied to a large database sample covering firms from 17 European countries. The results reinforce the importance of induced and structural benefits in firms' overall performance. The second perspective was analyzed only for the Portuguese healthcare providers sample. These results can be a starting point for rethinking the healthcare models emphasizing the perspectives of Healthy 2.0 and considering that patients' technological pattern evolution will lead to Healthy 3.0 in the short term. Nevertheless, some questions remain unanswered regarding the impacts of the ICT acceptance process on overall benefits; therefore, future research will focus on this domain.

INTRODUCTION

It is no longer enough to consider the impact and role of information and communication technologies (ICTs) at firm and industry levels. Much has been written about these matters (Inklaar, O'Mahony, & Timmer, 2005; Jennings, Clifford, Fox, O'Connell, & Gardner, 2015; Pilat, 2004; M. B. Tiago & Tiago, 2013; Van Ark, Inklaar, & McGuckin, 2003), but the vast technological changes that occurred require that the scope of these researches be broadened.

Traditionally, and taking into account the results found in previous studies, the impact of ICT can be perceived as detailed in: 1) the contribution of ICT investment to capital intensity; 2) the contribution of the technological adoption model to a firm's performance; 3) the spillovers of rapid innovation by the use of ICT; 4) the competitive and dynamic effects of ICT on a firm's turbulence in terms of entry, exit, and the mobility of market shares of incumbents; and 5) the empowerment of strategic dimensions through the use of ICT tools (Fracolli et al., 2014). Nowadays, there needs to be the added consideration of the role and impact of ICT in the communication flows of the firms, regardless of internal or external context. In these contexts, the web developments influenced the flows of information creation and sharing. Additionally, the initial Web evolved into Web 2.0, reflecting a gradual growth in terms of popularity and resources and the emergence of new tools that meet users' need for interactivity with information (Tekli et al., 2013).

ICT-related sectors are often characterized as high-tech and knowledge-intensive industries, since they rely deeply on the use of ICT tools to leverage an internal innovation process When approaching other service sectors, the impacts of ICT adoption are perceived as lower (I. Chang, 2007). There has been much discussion of the role that recent advances in ICTs could play in improving health service systems in developing countries, as well as other services industries with traditionally lower levels of technology connected to healthcare (Hadgkiss & Renzaho, 2014).

Drawing on the existing literature, this chapter attempts to analyze: 1) the impacts of ICT in healthcare services firms' performance; 2) the adoption and acceptance of ICT patterns of physicians and nurses; and, 3) to unveil some of the trends in the healthcare sector driven from ICT use in European countries. Therefore, a conceptual model was developed for understanding and investigating the different contributions achieved by the adoption of ICT in this sector.

The data used in this research came from the 2006 e-business watch survey, covering 834 health services firms in 17 countries (Belgium, Bulgaria, Czech Republic, Denmark, Finland, Greece, Spain, France, Hungary, Ireland, Italy, Latvia, The Netherlands, Norway, Poland, Sweden, and the UK). The survey was enlarged with data gathered in Portugal regarding physicians' and nurses' use of technology-based systems.

In general, our findings support the conceptual framework presented and the results obtained can be used as a support tool in ICT decision makers' processes, since it clearly states the overall benefits of ICT successful implementation as well as presents the global performance impacts achieved with an integrated IS framework. Some useful preliminary insights are produced, however, leaving a considerable number of issues for future research, including the possibility of extending the research to include new tools and perspectives.

This chapter is organized in the following manner. The next section summarizes the literature related to the adoption of ICT tools by healthcare firms. The third section of the chapter formalizes the major points presented in the conceptual model and translates them into hypotheses. In the fourth section,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the methodology is applied and the results are presented. The fifth section offers concluding remarks about the some of the major issues, controversies, and problems, as well as suggests solutions and future research paths.

BACKGROUND

In the mid-1980s, information and communication technologies have achieved a dominant role, leading to several changes in the internal organizational environment, regardless of the sector. In today's competitive global context, such technologies act as an imperative in two ways: 1) reducing the uncertainties related to production and services processes (Henderson et al., 2012), as well as supporting administrative tasks (Dewett & Jones, 2001; Sheng, Chang, Teo, & Lin, 2013) and subsequent achievement of sustainable competitive advantage (McKee, Varadarajan, & Pride, 1989); and 2) narrowing the distance between providers and customers, allowing a continuum of information flow that enhances overall service quality (Darkins, Foster, Anderson, Goldschmidt, & Selvin, 2013; Egea, González, & Menéndez, 2015; Kumar, Novak, & Tomkins, 2010; McGowan et al., 2012).

These changes impel rethinking firms' strategies concerning the digital domain: as IT investments that need to be performed to enhance performance; and, as a daily tool between service providers and clients that needs to be spread out and regulated.

A review of the existing literature related to information and communication technologies and IS impacts on organizational performance may enable a more effective implementation of these tools and how organizations can take advantage of their application (Bayo-Moriones, Billón, & Lera-López, 2013; Eder & Igbaria, 2001). According to the results of several research studies, such as the papers of Papastathopoulos, et al. (2007) and Peansupap and Walker (2005), there are two main reasons that tend to influence greatly the way firms handle the acceptance and implementation of ICTs: the level of investment involved and failure rates or past experiences of failure associated with the implementation of ICT applications.

More, the debate regarding the use of ICT seeks to determine which firms' characteristics enhance the adoption of ICT and enhance their impact on organizational performance (Dewett & Jones, 2001; Liao, 2003). In this sense, the literature suggests as adoption enablers' firms' characteristics, strategy commitment and external environment. This concept has stimulated the study of the elements and drivers of adoption of ICT/IS use in recent years (Bayo-Moriones et al., 2013; Bayo-Moriones & Lera-López, 2007; Liao, 2003; Liu & Liu, 2008; Papastathopoulou et al., 2007; Schillewaert, Ahearne, Frambach, & Moenaert, 2005; Wild & Griggs, 2008; Yi & Hwang, 2003 ; Zhu & Kraemer, 2002; Zhu, Kraemer, & Dedrick, 2004).

Information technology has become a common asset in health services industry in the past four decades and has gained widespread usage (Rahimi & Vimarlund, 2007). Thus, it's hard to picture health care services with absence of information and communication technology tools (I. Chang, 2007; M.-Y. Chang, Pang, Tarn, Liu, & Yen, 2015; Hung, Hung, Tsai, & Jiang, 2010). Nevertheless, the evaluation of the outcomes, the benefits and inhibitors associated with IT-based systems in medical informatics is still a challenge.

Nowadays, it is clear that ICT offers tremendous opportunities to improve daily-base activities in healthcare sector. One of the main reasons for the growing importance of IT in this sector relies on the fact that IT is consider to be an enabler to handle the enormous amount of information related to patients.

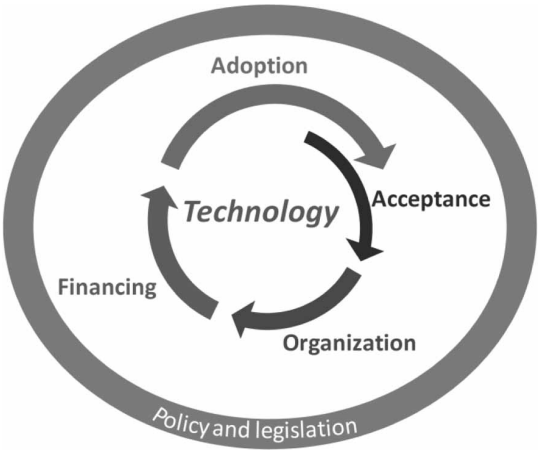
Figure 1. ICT adoption dimensions in healthcare sector



The identified determinants, which would influence the future implementation of electronic healthcare systems, can be classified into six major categories: (1) Technology, (2) Acceptance, (3) Organization, (4) Financing; (5) Adoption; and, (6) Policy and Legislation (see Figure 1).

The use of *technology* in health services can be observed in regular operations such as electronic patient records access, decision support systems which helps clinical actions, among others (Ammenwerth, Gräber, Herrmann, Bürkle, & König, 2003; Buntin, Burke, Hoaglin, & Blumenthal, 2011; Egea et al., 2015). The following table presents some of these applications and the research made around them (see table 1).

After summarizing all these works that analyze the use of digital tools on healthcare, it seems very cliché to define the concept of healthcare, but the panoply of definitions and uses found in literature impels us to do so. Therefore, in this work "Health care" is considered as the broad concept, which encompasses diagnosis and treatment of patients, education of staff, patients and the general public, and administrative activities (Fischer & Soyez, 2015).

From the results of multiple studies, it can be seen that information technologies such as electronic patient records, electronic health records, e-prescribing, decision support systems, electronic management of chronic disease, and bar coding of drugs and biological products can reduce health care costs and medical errors (Ammenwerth, Schnell-Inderst, Machan, & Siebert, 2008; Bates et al., 1998), as well as improve the communication between all stakeholders (Lau, 2011; McGowan et al., 2012). However, implementation of these information technologies has lagged in most European nations as well as the United States, leaving a question unanswered: *if the adoption of ICT has so many positive contributions, why it's use still so reduce and controversial?*

The quest for revealing this answer leads us to the second dimension – *acceptance* – and to its four different domains: social and ethical barriers; interoperability of systems; technology organizational environment and end-users acceptance.

ICT adoption and especially internet use is rapidly changing the landscape of health information (Ahmad et al., 2006; Sharma, Kilian, & Leung, 2014). Nevertheless, the potential arise from this electronic elements is far bigger then what is been explore. The full capacity use is still constrained by social and ethical barriers.

Lau (2011)	Web 2.0 Tools
McGowan et al (2012); Fischer and Soyez (2015)	Social media applications
Costa Fabricio F Costa (2013)	PatientsLikeMe social network
Egea et al. (2015)	Adoption of Internet technologies by physicians

The work of Fabricio F. Costa (2013) added to this field by incorporating the technology as a catalyst and enhancer of healthcare over time (see Figure 2).

Since web 2.0, big data start to be used and in these processes the primary stakeholders in the decision of, and the impact of, are the patients, the researchers, and the other healthcare providers. Additionally, it can be considered in the participations of payers and other regulators. With web 3.0, genetic, genomic and other "OMICS" information tends to be integrated to help services providers to deliver a person-driven healthcare.

Thus, as mention by Jensen et al. (2009) and reinforce by Fabricio F. Costa (2013) and Brothers and Rothstein (2015), clients' questions regarding data privacy and security led to smaller rates of implementation of electronic health systems. By one hand, the legal frames in different countries constrain

Figure 2. IT and Medical evolution

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the use and electronic diffusion of patients' records. By other hand the patient and the physician have ethical and personal concerns regarding the adoption of these tools, especially when these enable the access by third parts (Brothers & Rothstein, 2015).

Lucas (2008) examining the adoption of ICT in developing countries uncover some of the potential problems related to the technology environment of each business unit. To this author in the short term is quite easy to have goods results driven from the adoption of ICT. Nevertheless, this initial small-scale success aren't guarantee of sustainable large-scale benefits or even long term success. The main reasons for this septic framework are related to robustness of sophisticated electronic equipment; the availability of technical staff to operate, maintain and support the equipment adopt; the complexity of hardware and software failures; the adequate training programs; the proper funding to finance routine operating expenses, maintenance costs and the frequent needs for upgrades; and the end-users commitment and knowledge regarding the system benefits and applications.

The second dimension is related to interoperability of the information systems, since healthcare providers use information systems with several different types of data and user interfaces (Macedo & Isaías, 2009) and standardized output is need. Until recently, IT products available for healthcare providers were mostly designed for large organizations and were costly. And, as Brannigan (1985) suggested, the major problem with IT acquisition is not the initial decision process, but the complete final analyses of adequacy of the system to the health care providers needs. Technical verification and validation are important keys during system development, but their validation after implementation is critical.

The fast and growing adoption, combine with the need to evaluate the outcome of the investment, include the "technology assessment" as a crucial element of health policy (Fischer & Soyez, 2015). Thus, back in 1990, in a conference held in Montpellier, Flagle et al. (1991) stated out the importance of (1) ''develop a dialogue between the fields of medical informatics and Health Technology Assessment''; and (2) ''to issuing recommendations about the methodological requirements for evaluating Health Information Systems''.

As research in other fields suggests, the adoption and acceptance of ICT tools requires a set of human, organizational and technological conditions. Since the seventies, research on information systems has contribute to a better understanding of the advantages related to the use of IS and the facilitators factors of an ICT acceptance process (Hadgkiss & Renzaho, 2014; Pilat, 2004). The work of Davies (1989) brought some light to his matter, introducing a new framework of analysis – Technological Acceptance Model and since then several studies have been conducted analyzing the adoption of technologies by end users (T. C. Davis et al., 1993). On his model, Davis examines the mediating role of perceived ease of use and perceived usefulness in their relation between systems characteristics (external variables) and the probability of system use (an indicator of system success). An update version of his research -TAM2- has presented several years later and the overall results explain almost 40% of systems use. In both works the emphasis has been set on end users performance. This model has been test in healthcare sector (M.-Y. Chang et al., 2015; Hu, Chau, Sheng, & Tam, 1999; Raitoharju, 2005) and the results pointed to the fact that individual impacts are often neglected when evaluating ICT initiatives as well as the IT stress as a factor of IT acceptance.

Another approach is to analyze the customization of the systems to healthcare providers' main characteristics. Considering the strong push for clinical leadership in the development and procurement of information technology in health care, it's surprising the lack of clinical input acknowledge by IT system' developers (Heathfield, Pitty, & Hanka, 1998).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The lack of participation and commitment to the system implementation and outcome continuous to be consider the major factor in the failure of information technology in health services (Lucas, 2008). More recent work has built on the practice perspective recognizing the importance of contextual environment in ICT adoption. Existing work practices may shape and be shaped by the introduction of new ICTs (Egea et al., 2015; Hadgkiss & Renzaho, 2014).

Back in the earliest nineties, Tornatzky and Fleischer (1990) present a framework which assess technological and organizational environment through three key dimensions - the organizational context, technological context and the surrounding context. Since then, the TOE model has been widely used, since it helps to understand the technological path of the firm.

Papastathopoulou (2007) and Peansupap and Walker (2005), present two other strong reasons that tend to influence greatly the way firms handle the acceptance and implementation of ICTs: the level of investment involved and failure rates or past experiences of failure associated with the implementation of ICT applications. These ideas introduce us in to the fourth dimension: *financing*.

Despise the reports revealing that electronic medical records provide financial benefits by helping to reduce costs and improve revenues, few formal cost-benefit analyses have been performance (Jennings et al., 2015). Wang et al (2003) analyzed the results obtain by organizations during a 5 year period driven from the adoption of ICT. According to these authors the healthcare firm had two majors costs associated with this implementation: systems cost, which are related to system implementation, support and maintenance; and induce cost, which are related to the process of converting paper-base operations in digital operations. These two domains had an overall cost of almost $50.000, which was lower than the benefits achieved of $86.400. The benefits obtained in the process were found to be especially savings in drug expenditure, reduction of cost in radiology and decreasing of billing expenditure costs. Similar conclusions were found in the work of Ruland and Ravn (2003), Hillestad et al. (2005) and Lapointe and Rivard (2006). However, traditional financial and accounting methods of evaluation are not totally suitable in this case, because there are some intangible, indirect and even strategic benefits related to IT implementation that need to be considered (Grembergen & Amelinckx, 2002).

Looking at the healthcare sector, back in the 70s, among others authors, Ware, Davies and Stewart (1977) suggested the increasing importance of customer/patient satisfaction with medical and healthcare services. Almost four decades after those statements, patients' satisfaction remains a critical aspect; however, as services literature notes, the need for employees' satisfaction is a driver for customers' satisfaction, since the healthcare service outcome is dependent on their performance (Anderson, Fornell, & Rust, 1997). Several studies conducted to measure patients' overall satisfaction confirm the importance of physicians and nurses in this process (Jennings et al., 2015).

The fifth dimension comprises the *adoption* of different healthcare information technologies to improve the quality of healthcare services. In this sense, improving the quality of care and customer satisfaction are key factors that need to be considered and that can push healthcare providers to adopt more ICT tools (Hung et al., 2010). These tools can improve services quality, since it changes the model of health services delivery (Jennings et al., 2015). Some examples of such services include educating patients about their diseases, online follow-ups, monitoring of symptoms, and clarifying doubts about diseases. To support these new services, adoption healthcare providers can exploit different IT applications.

Innovative companies found that Web 2.0 collaborative applications could be introduced in their current or new implementations of intranets, bringing them advantages in internal communication with employees. Given the characteristics of blogs, RSS and wikis, they are the most used Web 2.0 tools to facilitate communication, collaboration and sharing of internal information.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Several studies have examined the Web 2.0 intranets tools (Lai & Turban, 2008; Richter, Stocker, Müller, & Avram, 2013) and the outcomes of their use:

- Wikis: Collaboration, audit, internal training, knowledge management;
- Blogs: in-house training, communication, sharing, definition of social responsibility, knowledge management;
- RSS: News, information and knowledge management.

At a macro level, these information flows can promote inward sharing, outward sharing, inbound sharing and outbound sharing (Drapeau & Wells, 2009; Murphy, 2010). Looking at the inward sharing in healthcare organizations, the mere fact that providers belong to small groups who work together within the organization improves their subjective wellbeing, and allows them to share knowledge easily between colleagues to gain expert status, to collect feedback and to improve overall job satisfaction (Murphy, 2010).

The outbound level and the outward sharing have gained relevance in the past decade with the explosive growth of the Internet, which stimulated social behaviour exchanges and consequently modified human daily activities, habits and interactions. Online communities explore the ubiquity of the web and bring people together from all over the globe, allowing them to share knowledge and promote a collective dialog (Budden, Anthony, Budden, & Jones, 2011; Kumar et al., 2010).

In this context, healthcare institutions were forced to adopt a user-centric model that doesn't focus on diseases, but on the user as an involved member of the decision-making process, with capabilities to choose between different health options and preventive health behaviors. As a result, the "P4 Medicine" model seeks to change the medicine perspective from reactive to proactive, aiming to maximize individual health rather than just treat the causes of disease. The P4 in this model stands for: predictive, preventive, personalized, and participatory (Fabricio F Costa, 2013).

On the second and fourth P, the use of social networks leverages the doctor/patient interaction, allowing the sharing of information among patients as the network (Fabricio F Costa, 2013). A good example is the PatientsLikeMe social network.

The potential of social networks and other Web 2.0 tools to establish new health services cannot be ignored. These services are known as Healthy 2.0, which reflects the use of social media by health professionals and patients in order to customize treatments and promote health education (Sharma et al., 2014).

Several studies analyzed the adoption of social networking to mediate the communication flows between organizations and patients, and unveiled the most common applications: health information and dissemination campaigns, and tele-assistance and monitoring. But these studies also revealed that social networks are been used by patients as a community in order to share and search information and experiences with peers, to keep and search medication information, and to use an interactive medication database (Fabricio F Costa, 2013; Dhillon, Wünsche, & Lutteroth, 2013; Sharma et al., 2014).

More, this approach leads to the use of OMICS and other big data driven-content, but also requires a human-IT approach that enhances the adoption and use of technology by all stakeholders (Fischer & Soyez, 2015).

So, the question that remains unanswered is: if technology enables healthcare providers' to deliver a high quality service, why some many are reluctant to engage in a more digital service? This question finds a partial answer in the legal domain, since some of the inhibitors found in the literature are related with legal risk and privacy concerns (Classen et al., 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The last dimension cover refers to *policy and legislation* and finish what can be consider as the cycle of adoption of ICT in healthcare (see, Figure 1). In this domain there are no general rules and guides, since it's deeply associated with national health systems policy and they differ from one country to another. Nevertheless, there are some common points that need to be considered: patients' privacy rights and their legal protection (Jensen et al., 2009); security standards which allow a common language between players (Gritzalis, 1997); and, clinicians activity rules and structure (Buntin et al., 2011).

The Council of European Professional Informatics Societies, back in 2005, produce a report considering the Standardization for ICT Security and one of the sections was devoted to analyze the ICT security standards for healthcare applications. The authors advocate that Health informatics standards were essential to achieve the goals of e-Health in Europe, supporting interoperability between systems and patient information exchange between health organizations and protecting patients and clinicians' privacy rights. Pirnejad et al. (2007) suggested that the first steps in establishing an international application with adequate data protection safeguards rely in building an Inter-organizational communication network (IOCN) in healthcare with appropriated strategies safeguarding security measures. For instance, in the European case the directive "CEN EN14484 (2003) International transfer of Personal health data" covered data protection and established specific terms of exchange data with third countries.

Although healthcare researchers and information system investigators have studied ICT adoption to some extent, there are still few conceptual bases available to assess the global information and communication technology contribution to overall healthcare business success. There is also limited data regarding the combined acceptance and adoptions of these ICT tools by physicians, nurses and patients. When analyzing these assessments with a business-value approach, weaknesses assume a major role. Therefore, the next section attempts to minimize these gaps.

CONCEPTUAL FRAMEWORK AND HIPOTHESES

In the last three decades information technology in health care has existed and has gained widespread usage (Ammenwerth et al., 2004). Nevertheless, there are also hazards related with information technology in health care driven from the challenges and innovations adoption process and measurement.

For more than a decade it is widely believed that broad adoption of electronic medical record (EMR) systems will lead to major health care savings, reduce medical errors, and improve health care services (Marques, Oliveira, Dias, & Martins, 2011). However, the measurement of ICT impacts covers the assessment of the quality, value and their applications in the health care environment, the improvement of health information applications and the enabling of an evidence-based health informatics practice.

Thus, as it happens in other industries, the cost-benefits evaluation of IT implementation cannot be performed only base in traditional financial and accounting methods. Literature review revealed some intangible, indirect and even strategic benefits related to IT implementation that need to be considered, most of them common in IT domain (Grembergen & Amelinckx, 2002). Thus, there is undoubtedly a need to develop a better comprehension of ICT healthcare adoption impacts on global results.

The application of IT literature in this subject may shed some light on the measurement of the success of these initiatives (Romano Jr & Fjermestad, 2001). Yoon et al. (1995) suggested a framework based on five levels: business profitability, improved decision performance, level of system usage, perceived benefits and user satisfaction. The work of Eder and Igbaria (2001) analyses the impact of ICT on business performance and stressed that there are some indirect effects which need to be consider. More

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

recently, Bayo-Moriones and Lera-López (Bayo-Moriones et al., 2013; 2007) suggested that the positive impacts identified are not limited to increased productivity and reduced costs, influencing intermediate performance measures such as process efficiency, quality of services, organizational improvements, knowledge flows and customer satisfaction.

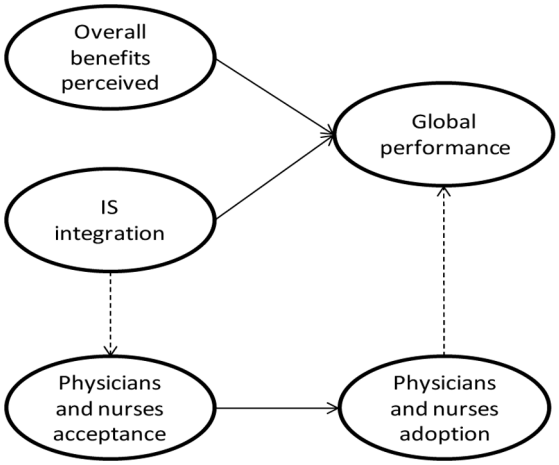
These last elements (quality of services, knowledge flows and customer satisfaction) can be improved by technology, but as mentioned previously, are dependent on end-user acceptance and adoption (I. Chang, 2007; Holden & Karsh, 2010; Jennings et al., 2015). From previous works, three sets of players need to be considered when adopting an HIS: patients (Hall & Dornan, 1988; Norum, Grev, Moen, Balteskard, & Holthe, 2003; Scalone et al., 2008); nurses (Abbott & Coenen, 2008; Verdegem & Verhoest, 2009) and physicians (Egea et al., 2015; Hunt, Haynes, Hanna, & Smith, 1998; Van Der Meijden, Tange, Troost, & Hasman, 2003; Verdegem & Verhoest, 2009).

In order to improve the success of information technology implementations, different models grounded in behavioral science or using theories that identify conditions and determinants of success are used (M.-Y. Chang et al., 2015; Hadgkiss & Renzaho, 2014; Heathfield et al., 1998; Holden & Karsh, 2010; Hunt et al., 1998; Mathieson, 1991; Norum et al., 2003). Nevertheless, as IT literature has evolved, these models have been tested separately and in a more-or-less restricted set of IT implementation procedures. In the healthcare setting, user behavior is influenced not only by the end-user personal framework, but also by a multifactor structure at the group, organizational and patient level. In this context, the defining of suitable multi-level intervention has been overlooked and this is the gap that the current research attempts to fulfill.

For this purpose, a significantly modified version of the original TAM was used, integrating the concepts presented by King & He (2006), and considering the relationships among the three main TAM variables—perceived ease of use, perceived usefulness and behavioral intention to use—and considering the three sets of players.

The research model, as shown in Figure 3, illustrates an examination of the productivity flows considering not only the operational process but also intangibles domains, which affects healthcare systems adoption and results. This framework also identifies metrics that can be used to measure the intangibles benefits. Each perspective is evaluated according to the appropriate metrics.

Figure 3. Conceptual Model



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The primary research question to consider is this: What are the benefits engages in performance, considering it as global productivity increasing, trough the implementation of ICT? And what is the impact of operational process (integrated IS) on global productivity performance? Besides measuring the convergence of a technological approach with a business value approach, our aim is to discover the direct nature of the impact of intangible benefits in healthcare firms' outcome.

The model is validated by using a structure equation model to test the hypotheses. The measurement model is done by using Confirmatory Factor Analysis (CFA). We will see later that the observable variables (indicators) we selected are measures of latent variables (factors). We assume that IT process and benefits driven from organization acceptance of IT have a direct effect on successful IS application. Therefore, we assume that the healthcare productivity performance gains are explained not only by the standard use of information systems, but also by the perceptions of organizational, technical and productivity gains.

Two sets of postulates were put together: first, considering as a theoretical base for the development of these postulates the literature on information systems and healthcare fields that evaluates the factors impacting healthcare performance; and, second, considering as a theoretical background the models related to technology adoption and acceptance.

The first is subdivided into three subsets and measures the impact of the three different kinds of benefits; following the results found by other researchers and bringing to HIS the measurement of intangible benefits already consider in other IT domains. The induce benefits are consider as all the benefits arise in terms of security, efficiency, reliability and staff satisfaction driven from the adoption of ICT. The financial benefits reflect the financial gains resulted from ICT implementation. The structural benefits consider the gains obtained from process modifications and operational cost reductions.

The second hypothesis seeks to confirm the inference that there is a positive impact of overall benefits on global healthcare productivity and consequently on healthcare firms' performance. The third hypothesis sought to identify a positive impact of the interoperability and integration of IS on global productivity performance, as an agent driving the optimize adoption and use of ICTs.

Another set of three questions was defined for each different set of players, based on the conceptual model present by King & He (2006). Therefore, the fourth hypothesis considers that the perceived ease of use of the implemented system impacts positively the acceptance of global HIS. The fifth proposition considers that healthcare providers' perception of the ICT usefulness impacts positively the acceptance of HIS. The last hypothesis advocates that behavioral intention, driven from personal past experiences and expectations, impacts positively HIS acceptance.

DATA TREATMENT AND RESULTS

To validate the first set of assumptions, data was collected from a sample of 834 European healthcare firms in a total of 17 countries (Belgium, Bulgaria, Czech Republic, Denmark, Finland, Greece, Spain, France, Hungary, Ireland, Italy, Latvia, The Netherlands, Norway, Poland, Sweden and UK) and covering seven dimensions of analysis: (1) ICT infrastructure and e-business software systems; (2) automated data exchange; (3) e-standards and interoperability issues; (4) Innovation activity of the company; (5) ICT skills requirements and ICT costs; (6) ICT impacts, drivers and inhibitors; and (7) background information about the company.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Initially we used a set of descriptive statistics that allowed for a greater sensitivity to the data (Sekaran, 2006). Such descriptive statistics also acted as guide for the multivariate statistics later on performed (Hair, Anderson, Tatham, & Black, 1998). Some notes about the sample used.

Distribution of firm size, measured by the number of employees, shows that almost half of the firms are micro- and small-size firms (around 50.7%). Around 99% of the firms in the sample have access to Internet and from those 28.7% use a wireless access. The importance of having ICT department at firm structure was measure and 49% of the sample currently employs ICT practitioners. The importance give to the lack of ICT department was measure by their impact on global ICT strategy and management (37.5% considers it a great deal), in ICT network architecture (56.4% considers it a huge concern), in ICT security (52.1% consider important) and maintenance (35.4% consider it important).

When asked about the IT solutions adopted by their firms, the highest percentage of respondents refers the use of pharmacy management system, as we can observe in the following figure 4.

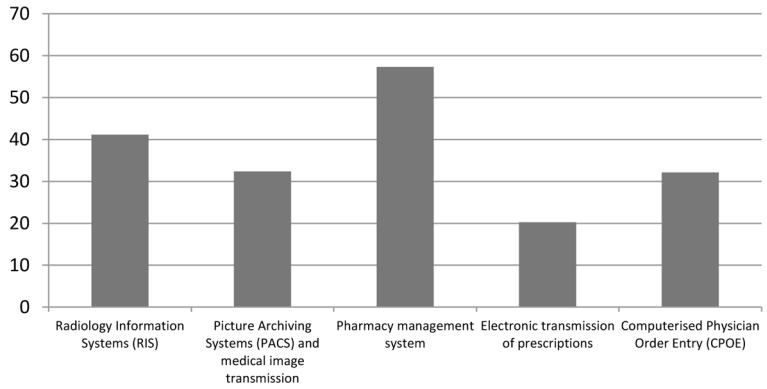
The model was estimated by the Maximum Likelihood method in the AMOS package. The model goodness of fit may be considered acceptable according to the values of some goodness-of-fit index, although the chi-square test statistic ($\chi 2 = 626{,}4$; df =321; p-value = 0,000) is significant, implying a bad fit. However, as is well known, this test has serious limitations — namely its dependence on the sample size and on the number of indicators. In general, for large sample sizes the chi-square statistic is significant, and in the present case the sample size is quite large (n = 834) (Hair et al., 1998). For that reason, it is usual to evaluate the goodness of the fit by a set of index, also presented in Figure 4.

After global model fit has been assessed, the numerical results were evaluated in order to test their support of the research question. The numerical results can be obtained directly from the path coefficients of the structural model presented in Figure 5. We refer to standardised coefficients that account for scale effects and serve as indicators of the relative importance of the variables.

The measures for global model fit included in Figure 5 suggest that our model fits the underlying data well (Hair et al., 1998) and all the paths were statistically significant.

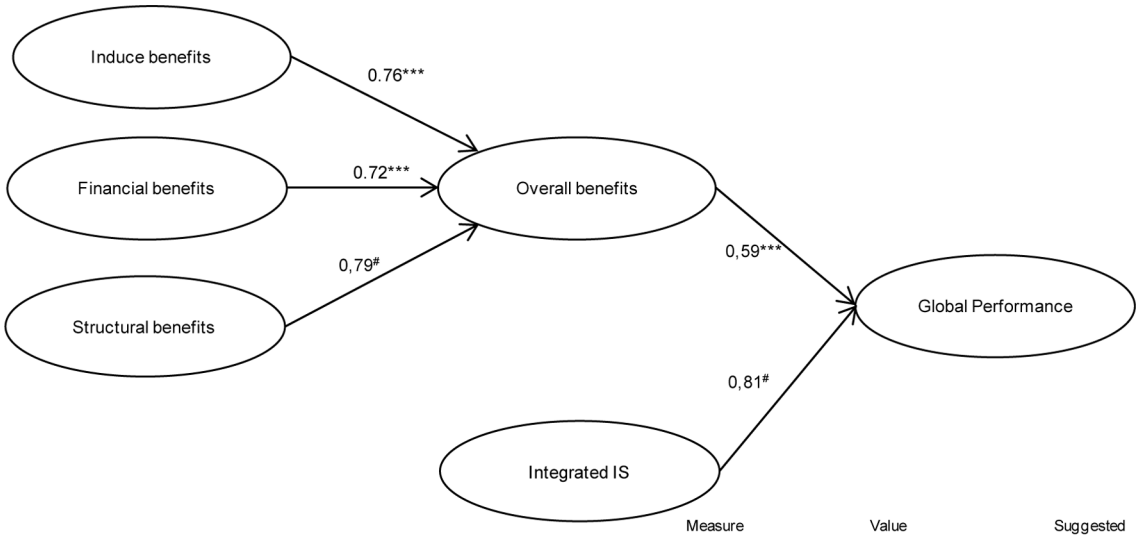
Our findings generally support the conceptual framework previously presented. The three dimensions used to compose the overall benefits achieved trough ICT adoption are all significant and validate trough the confirmatory factor analysis performed. Induce benefits, financial benefits and structural benefits explained 76 percent, 72 percent and 79 percent respectively regarding the variance in the overall benefits construct. As a result, hypothesis H1 is not rejected. A reference needs to be made regarding the relative similar value achieved in terms of financial benefits, reinforcing the perspective token in this research.

Figure 4. Percentage of adoption of different HIS



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Structural equation model and estimation results (model 1)



The results also allow concluding that the overall benefits contribute with 59 percent to global performance, so hypothesis H2 is not rejected.

The indirect effects existent in the model were also assessed. From those arises the strong relationship between interoperability of HIS and reduction of cost.

On the other hand, the results show that the construct "integrated IS", which is related to the interoperability between HIS present in the firm, contributes with 81 percent to global performance, implying that our hypothesis H3 is confirmed. A last note needs to be made relative to the value achieved in this path, which is greater than the relationship found between overall benefits and global productivity.

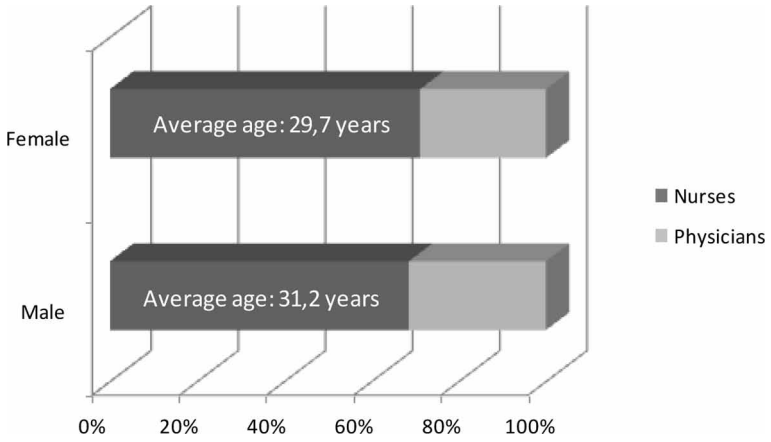
To validate the second subset of assumptions, data was collected from a sample of Portuguese physicians and nurses, covering four dimensions of analysis: 1) perceptions regarding the ease of use of current systems, 2) perceptions regarding impact of use, 3) behavioural intention to use ICT tools, and 4) past experience and demographics. Taking into consideration that the TAM will produce different results if the users being questioned have a) used the technology being tested previously and b) had a choice in whether to use the technology, the questionnaire will target healthcare providers with experience in the use of HIS.

Again, we used a set of descriptive statistics that allowed for a greater sensitivity to the data. As shown below, the sample has a higher representation of nurses, and in both profiles, the average age is quite low. This reflects the higher propensity of the millennial generation to use ICT tools, since the sample only gathered the data of individuals who actually used technology (see Figure 6).

All physicians use a computer at the hospital or clinic where they operate, other than the EMR, but only 23% report using it in private clinic. Looking closely at the perceived ease of use of electronic patient records, female physicians present a more positive perception of this tool: 50% consider EPR

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

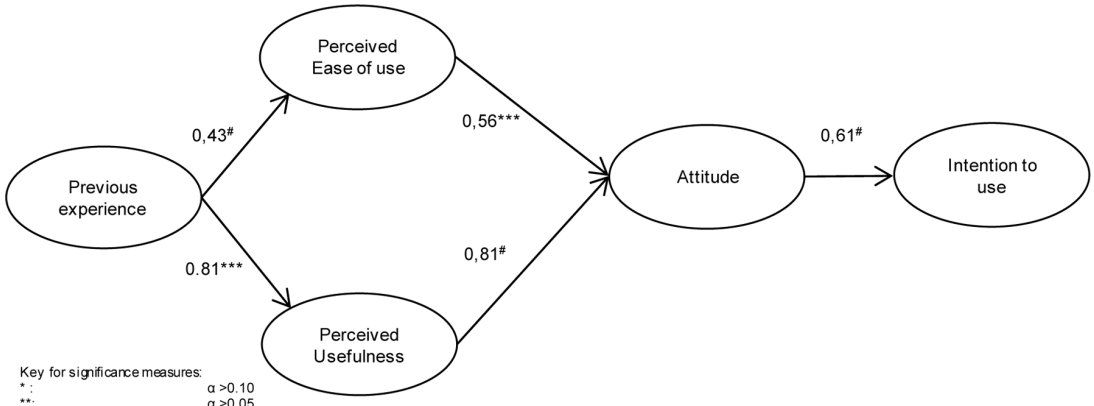
Figure 6. Demographic profile of healthcare providers' using ICT tools



very easy to use. Since there seems to exist a significant difference between female and male physicians (Gefen & Straub, 1997; Lu, Yu, Liu, & Yao, 2003; Venkatesh & Morris, 2000), the analysis was performed based on perceived gender differences. All nurses refer to using a computer for their daily records and show evidence of having a longer experience in doing so (average time of usage: 5 years). Regarding the physician-patient relationship, physicians are not convinced that the use of EMR improves the quality of medical care received by patients (44.7%), but 65.8% believe that it helps them perform better. Looking at nurses' answers, 56% believe that EMR does not improve the quality of medical care received by patients.

A second structural model was estimated by the Maximum Likelihood method in the AMOS package. After global model fit was assessed, the numerical results were evaluated in order to test their support of the research question. The numerical results can be obtained directly from the path coefficients of the structural model presented in Figure 7. We refer to standardised coefficients that account for scale effects and serve as indicators of the relative importance of the variables.

Figure 7. Structural equation model and estimation results (model 2)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

When performing multi-group analysis, the sample size of the groups being compared should be roughly equal. Since, in our sample, the number of nurses was larger, it wasn't possible to perform a multi-group analysis.

Once more, our findings, in general, support the conceptual framework. The dimensions used to compose the perceived ease of use and perceived usefulness are all significant and validate with the confirmatory factor analysis performed. Previous experience with the use of IT systems explained 43 and 81 percent of perceived ease of use and perceived usefulness, respectively. These results unveil some difficulties with the adoption of the technology and found that support of the attitude toward using ICT tools was positively correlated with intention behaviour. A note needs to be made relative to the value achieved in perceived usefulness and attitude towards use, which is greater than the relationship found between perceived ease of use and attitude.

DISCUSSION AND CONCLUSION

The digital era bring with it enormous challenges that healthcare firms can embrace, especially if we consider the facilities associated with the gathering of information about customers, suppliers, markets, and supply — and the easy processing of information regarding processes, and services, which can also be easily spread to the clients and other publics.

Even though academic researchers and practitioners alike praise information and communication technologies adoption (M.-Y. Chang et al., 2015; Hadgkiss & Renzaho, 2014; Marques et al., 2011), perhaps the most significant gap in the literature is the lack of large-scale empirical evidence showing that ICT makes a difference to the overall performance of the firm and determining which factors are critical to leverage overall performance.

The goal of the current study was twofold: 1) to identify the nature of the relationship between overall performance and these benefits, as well as the relationship with interoperability of HIS; and 2) to determine if the individual's acceptance of a technology is determined by its perceived usefulness and perceived ease of use. For this purpose, a set of propositions were developed: the first relies on exploring the nature of the benefits that can be achieved during the implementation and use of ICT tools; the second is based on the relationship between these benefits and healthcare performance; the third relies on the fact that most healthcare firms use more than one HIS, and for that reason, interoperability between all the systems can be crucial to global performance; the fourth and fifth predict that ease of use and usefulness will influence an individual's attitudes toward, intention to use, and acceptance of the technology. Therefore, our aim is to develop a new interpretation that offers fresh insights and understanding.

Given the nature of relationship between variables that is consider, the use of structural equation model is suitable. Based on the results of our two models, we can draw the following conclusions:

- Bayo-Moriones and Lera-López (2007) reported that the positive impacts occurred in an organization were not limited to increased productivity and reduced costs, but also influencing intermediate performance measures. The present work reinforces these ideas in the healthcare sector, presenting induces benefits achieved from ICT adoption.
- When comparing our results with the ones found by Egea et al. (2015), who also study European healthcare providers relationship with technologies, a positive trend seems to appear. This might be a sign that Europeans are more willing to adopt technologies which is fairly positive if con-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

sidering the downturn economic context and that those TI-solutions are quite effective in lower-resource settings.

- Our results confirmed some prior research regarding the relationship between interoperability of HIS and global performance (Macedo & Isaías, 2009; M. B. Tiago & Tiago, 2013), since we found a strong relationship between these constructs. In addition, indirect effects were also found, especially between interoperability of HIS and reduction of cost, which is an important dimension of global performance.
- Even though prior research on HIS field does not consider the intangible benefits of an adoption of ICT, we can empirically show that induce benefits influences the composition of total benefits. It means that this tendency, already observed in other IS domains, needs to be considered when evaluating the outcome of ICT investments.
- We validate the construct of global healthcare performance integrating measurement metrics besides the financial and accounting, following the path introduce by the work of Grembergen and Amelinckx (2002) and already tested in other domains (Maria Teresa Borges Tiago, Couto, Tiago, & Vieira, 2007; M.T.B. Tiago, Couto, Tiago, & Vieira, 2008).
- Our results also point to the existence of relevant benefits driven from structural processes which suffer improvements from the adoption of ICT, in line with Eder and Igbaria (2001), that had suggested the impact of some indirect effects on firms performance due to the use of ICT.
- The most surprising fact is, however, related to the relative contribution of financial benefits to total benefits. Since this is the most common dimension of analysis adopted by firms, we were expecting to find here the biggest contribution of all three dimensions. But, regardless your expectation, the impact found was strong but the smallest of all three.
- When looking at the results of the second sample, gender and age differences were found in terms of ICT adoption and benefit perceptions, which was already suggested in previous works (Gefen & Straub, 1997; Lu et al., 2003; Venkatesh & Morris, 2000).
- In the work of McGowan, et al (2012) focusing on social media usage by physicians, the authors stated that the frequency of usage is influenced primarily by positive attitudes toward the technology, perceiving that the technology is easy to use, and perceiving the technology to be useful to achieve better performance outcomes. Similar results were found in our sample.
- Our results also point to a lower relationship between perceived ease of use and attitude. These results might reflect the minimal training and customization of the IT systems used in the healthcare facilities in the sample.
- Our results didn't allow us to conclude if there was statistical evidence that physicians' and nurses have different behavior intentions regarding ICT. However, looking at the data we can infer that regarding to ICT acceptance and adoption the outcomes are not significantly different, which is quite unique when compare with the results from other studies regarding cost and quality of service provided by nurses and physicians (Jennings et al., 2015).

We caution readers to consider that the induce benefits and structural dimensions of HIS await future research and that the conclusions presented are related to the present samples used. For these reasons they cannot be generalized.

Issues, Controversies, Problems

It is often stated that healthcare is lagging in the rear of others sectors of our society when it comes to the adoption and use of ICT. If we look carefully at healthcare organizations strategic choices in terms of investment in this area, we still notice that the investments are consider as pilot projects and are disperse and with reduce or none IS architecture. This limited investment in ICT has been a rational choice since the measurement of the gains is still scarce. Besides, compensation mechanisms, public recognition and pressure, and consumer demand have not created a strong enough incentive for healthcare organizations to accept the financial costs and face up to the non-financial obstacles to ICT implementation.

However, the fast growth of web-based platforms that facilitate online social behavior has significantly modified the nature of human activities, habitats, and interactions (T. Tiago & Veríssimo, 2014). And service providers that neglect ICT investments are clearly loosing focus on consumer, regardless of the industry.

One of the major challenges concerning the ICT adoption is end users' acceptance. But who are these end users? Until a few years, the healthcare sector was focused on internal stakeholders. With the evolution of both medical and IT fields, the focus shift and started to integrate external stakeholders too.

From an internal perspective, if it is a common domain to recognize related to ICT adoption the reduction of medical errors, delays and misdiagnosis. But, it's also common to find references to the reduction of human relation or contact between physicians, patients and nurses. Thus, if for some this is a benefic consequence of ICT, for others, it is a lack of conformity that is damaging the outcome of the service. In short, if healthcare providers were rewarded for safety and quality results, they would be more likely to invest in ICT and promote an IT culture inside healthcare services stakeholders.

From a patient perspective, there is a wide range of benefits that can be achieved from the use of ICT, such as efficiency, convenience, richer and participate information, and social network application. As previously mentioned the Healthy 2.0 model answers to some of the challenges that the healthcare sector faces (Fabricio F. Costa, 2013). Again, this model relies on the end-user's acceptance and adoption, meaning that healthcare providers need to be motivated to adopt a digitally active posture.

Considering that for patients and relatives, through information communication technologies have a number of benefits including efficiency, convenience, richer and participative information, and accessibility, is relatively common to find these participants on social networks and in search motors looking for answers. With semantic web, big data and new OMICS technologies have been targeted, since it can enable a more efficient, low-cost and large-scale generation and analysis of biomedical data and personalize IT-driven healthcare service.

Especially considering that in the near future information sharing among the various health-specific social networks, and with the generic social networks (Facebook, Twitter), using Web 3.0 technology will improve the patient/provider relationship in all 4P's, paving the way for the development of new IT tools, such as Healthy 3.0.

However, the adoption of a Healthy 3.0 scenario requires that healthcare providers consider that the information and the digital sharing are trustworthy and valid. Additionally, it requires that they are ready to adopt these technologies and ultimately embrace them as a format for providing new services and lifelong learning.

In the meantime, governments and national service entities try to develop mechanisms through policy and legislation to minimize the effects of these inhibitors' and promote ICT standardization and capable pathways within the national service frameworks.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In essence, the ICT adoption process reveals six dimensions that need to be consider in order achieving success and points out to the importance of three major players in the process: physicians, patients or clients and nurses. If all these stakeholders are awareness of the benefits of ICT to the entire organization, the acceptance of ICT will be easier and the financial and productivity gains are greater. Thus, we can consider that the success of these initiatives relies on developing an ICT environment inside and outside the healthcare firm.

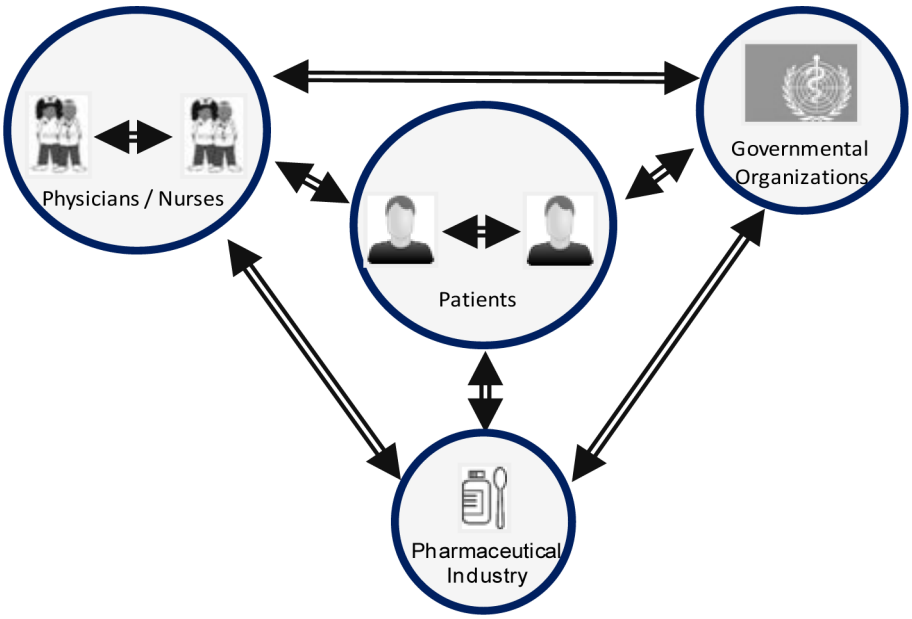
Solutions and Recommendations

Our comments are given with Portugal as main background for the healthcare sector together with a global understanding of the healthcare systems in other European countries and the USA. So, looking at the model present in this study several considerations can be made.

The first suggestion we make is related with acknowledge by all stakeholders the total benefits and not only the financial benefits of ICT implementation. In order to overall acknowledge of induce and structure benefits, a communication strategy needs to be set considering the three different major players: clients, physicians and nurses and their contact points with ICT. For instance, the communication with the last two publics can be executed trough training and public recognition of the outcomes. The success of this process relies on multiple actors' structure, as present below (see Figure 8):

Therefore, our suggestions included reinforcing harmonization activities between the existing entities of a national health system (NHS), starting with the clear identification of the players and their specific needs, followed by the development of specific ITS base on the identified needs. Afterwards, a certification procedure for e-health standards and adoptions should be promote, considering that such a process would allow interoperability of systems and the increasing of end-user orientation.

Figure 8. Healthy 3.0: healthcare digital dimensions



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Since the orientation should be focus on the end-user several actions should take place. Regarding health services clients, the emphasis needs to be on demystifying the concerns related to privacy and security. In this process, communication plays a crucial role and needs to reflect the organizations' commitment in leverage digital technologies to provide better, ubiquitous and less expensive services to customers.

The other two types of end-users should sense the support of their board, which is clear when auscultation during ITS development and implementation occurs; training and customization of ICT tools is provide; and global and personal efforts are recognize and compensate.

With the adoption of this matrix the intangible benefits can be identify and enlarge and interoperability of systems is assured. Nonetheless, to promote an easier acceptance process by inside players, the start timing and executive commitment is critical. This should be combined with the use of a team of expert innovators that will have as goals educate and promote the development of an IT culture.

FUTURE RESEARCH DIRECTIONS

This research produces some useful insights, leaving still a number of issues for future research. One of these issues is related to the possibility of extending the study in order to consider an inclusion of some dimensions of the technological acceptance model, such as technological personal readiness. Similarly, this study could be expanded covering the views and expectation of the three main players consider in this work: physicians, nurses and clients. The analysis of their perspective on this matter can reinforce some of the conclusions achieved, challenge some of the outcomes of this work and certainly contribute to a deeper understanding of healthcare IS evolution and prospective.

Another path to follow regards the new ways of healthcare delivery, the new public and their solicitations. This will require additional IS functionalities, been an interesting field for future research.

CONCLUSION

The results generated some interesting findings. First, the data support our conceptualization for the global benefits construct. Within global benefits elements, all have a positive impact on the maximization of firms ICT-driven benefits and consequently global performance. Secondly, the findings allow us to conclude that induce benefits have a positive indirect impact on global productivity. Thus, financial and intangible benefits appear to greater than what was usual accounted, paying back the initial investments made by the healthcare firms. Nonetheless, the size of the effect for this relationship was smaller than would be expected.

According to these results, the concept of integrated systems as an important dimension of overall results equation is reinforced. So, managers should consider the use of HIS competencies to improve everyday services process. Namely, taking advantage of the benefits such as reducing structural and operational costs, increasing employees' motivation and satisfaction, improving services quality as pointed out by others researches.

More, healthcare providers should be motivated to adopt ICT tools as an important opportunity to engage customers and perform a high-quality service.

KEY TERMS AND DEFINITIONS

Healthy 3.0: Adoption of Web 3.0 technology-based tools to improve the patient/provider relationship.

HIS Measurement: Methods to evaluate outputs and outcomes of the use of IT-based systems in medical informatics.

ICT Acceptance: Individual and firms 'attitudes regarding technology and their intention to use.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ICT Induce Benefits: Intangible benefits achieved by the adoption and use of ICT in healthcare.

ICT Performance: ICT can give significant boost productivity gains of a firm, which can be measure through financial and non-financial metrics.

ICT ROI: Financial accountable benefits driven from the value gains and cost reduction.

ICT Support: Technical and training support in daily basis and board commitment to ICT use, measure by recognition of efforts and compensation.

Chapter 61
Informed Consent in Healthcare:
A Study Case of Genetic Services

Bo Yu
George Mason University, USA

Duminda Wijesekera
George Mason University, USA

Paulo Costa
George Mason University, USA

ABSTRACT

Informed consents, either for treatment or sensitive information use/disclosure, that protect the privacy of patient/participant information subject to law that in certain circumstances may override patient wishes, are mandatory practice in healthcare. Similarly, for protecting and respecting research participants, informed consents are also prerequisite for human subjects research. Although the healthcare industry has widely adopted Electronic Medical Record (EMR) systems, consents are still obtained and stored primarily on paper or scanned electronic documents. Integrating a consent management system for different purposes into an EMR system involves various implementation challenges. A case study, informed consent for genetic services, is used to show how genetic informed consents placed new challenges on the traditional ethical standards of informed consent, and how appropriate consents can be electronically obtained and automatically enforced using a system that combines medical workflows and hierarchically, ontologically motivated rule enforcement. Finally, this chapter describes an implementation that uses the open-source software-based addition of these components to an open-source EMR system, so that existing systems do not need to be scrapped or otherwise rendered obsolete.

INTRODUCTION

The healthcare industry seeks quality improvement strategies to provide standardized, safer and more efficient patient services as well as medical research, focusing on patient safety, quality of care, risk management, data security and privacy preservation. The term "informed consent", first used by a California appeals court in 1957 (Cal. App. Ct. 1957), has become a vital ethical doctrine in medical practice. The American Medical Association states that "obtaining informed consent is an ethical obligation of the practice of medicine and a legal requirement per statute and case law in all 50 States" (O'Leary, 2010). In healthcare domain, informed consent has been considered one of the effective strategies to achieve the above goals. Herein the authors focus on three different categories: consent for medical treatment; consent for sensitive medical information use and disclosure; and consent for human subjects research.

In the last several decades, evolving computer-based Information Technology (IT) in healthcare has changed how computing systems support healthcare service delivery, with examples including Electronic Medical Record (EMR) systems and Personal Health Record (PHR) systems. The U.S government plays a major role in promoting healthcare IT, including EMR systems. The healthcare industry has adopted EMR systems widely. Nonetheless, nearly all EMR systems do not have an integrated electronic informed consent management system to support obtaining and automatically enforcing, patients' or participants' informed consents during treatment or medical research. In current practice, nearly all medical or research facilities use paper-based informed consent forms. The common approach used for managing informed consent forms in EMR systems is to scan paper consent forms and store them in electronic media, thereby restricting it to basic record keeping. Scanned consents are difficult to use by electronic information systems during medical processes, which makes caregivers responsible for enforcing the consents the same way it was done before introducing the EMR systems. Advanced automated features such as consistent enforcement of informed consent pursuant to statutes, regulations and guidelines are missing. In addition, hospitals spend on average $80,000 per year (Anonymous, 2007) scanning consent forms to perpetuate an inefficient, less than perfect consent system that results in subpar enforcement in the form of wrong or inapplicable consents. Failure to obtain informed consent is a top-ten reason for generating medical malpractice claims; "a properly completed consent form would have prevented 45% of errors on surgery wrong sites" (Compbell, 2004). Furthermore, studies concerning enforcement of medical informed consent in existing EMR systems reveal that no EMR systems support dynamically obtaining, and automatically enforcing, patients' informed consents when implementing medical processes. Consequently, a mechanism to implement and enforce e-consent is needed.

Informed consents in healthcare are governed by statutes and regulations that change over time. For example, a medical lawsuit that establishes precedent may trigger a new or amended statute or regulation or alter how a law is interpreted. Nevertheless, studies on consent laws are scarce, perhaps because ever changing laws would cause such studies to have a short shelf life. Issuing proper medical consent demands to evaluate all consent rules and to determine the type of consent to be obtained from the appropriate consent provider. Yet, no implementation method or modeling changes to consent laws are available that govern specific institutional practices (Beauchamp, & Childress, 1989). Consent is rendered unreliable without adhering to corresponding changes in laws. Moreover, consent statutes and regulations are complex. At times, ambiguous and complex laws (e.g., precedent changing interpretations of the law that, due to ambiguity, is subject to multiple interpretations) result in having gaps between user's understanding and the mechanized enforcements. Thus, a methodology for acquiring proper consent based on evolving law must be able to accommodate the dynamism inherent in changing regulations.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Authors' approach incorporates a medical consent management component into an existing EMR system to obtain and automatically enforce dynamically e-consent by using workflow technologies. More specifically, the authors use ontology-based knowledge representation and reasoning mechanisms to obtain required informed consents based on requester role, request purposes, each unique patient situation to ensure compliance with consent laws pertaining to the applicable sub-discipline. This technique also enforces protection of patient privacy in EMR systems. A case study, informed consent for genetic services, is used to show authors' work.

Following this Introduction, Section 2 describes informed consent in healthcare domain; Section 3 provides a case study, to show detailed models of authors' approach; Section 4 displays an implementation and, finally, Section 5, entitled "Conclusion," summarizes the proposed EMR system and briefly identifies future improvements.

MEDICAL INFORMED CONSENT

Categories of Consent

As mentioned above, medical informed consent has become the bedrock of medical practice. It majorly falls into three categories:

Treatment Consent

Patient safety, quality of care is the first major concern in practice medicine. Currently, every provider must obtain consent from a patient or guardian before commencing treatment, terminating treatment and choosing among alternative treatments. Nonetheless, the forms of treatment consent are various. In some cases, the patient or legal guardian must consent and/or sign a document memorializing that consent has been given. And yet, in most care providing entities, the patient showing up or requesting diagnosis or treatment constitutes default consent.

Informed treatment consent– either expressed or derived– is an important aspect of proper medical treatment, including but not limited to undertaking alternative treatments or terminating treatment. That process includes providing an unbiased risk/benefit analysis; explaining alternative treatments in a way that the patient understands, accurately communicating the care provider's understanding of the appropriateness of the treatment; advantages and disadvantages of obtaining the treatment or not obtaining it; and available alternatives (Appelbaum, & Thomas, 1995). The informed aspect of consent requires care receiver's awareness of he/she is willing to consent without undue influence by caregivers, insurers, or other involved actors.

Another requirement is caregiver acknowledgment that the patient and/or guardian have the mental capacity to consent. This makes psychiatric consents and consent given under anesthesia particularly difficult. Many federal, state and local governments have developed laws and regulations, and healthcare organizations have developed guidelines, for obtaining and memorializing informed treatment consent. Traditionally, the care seeker or his/her legal consent holder sign consent forms.

Much literature shows that researchers focus their research on different informed treatment consent requirements. For the standards of disclosing treatment benefits, risks, and alternatives, Studdert, D. M., et al. (2007) analyzed geographic variation in informed consent law. Authors in (Boonstra, & Nash,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2000; Bourgeois et al., 2008; Buchanan, 2004; Grisso, & Appelbaum, 1998; Holder, 1987) assessed patients' decisional capability to assent to treatment. In (Fisher, 2002), authors described four psycho-legal standards, communicating a choice, factual understanding, appreciation of the situation, and rational manipulation of information, all used to evaluate a patient's competence in giving consent. However, to date, this aspect of consent lacks a widely accepted standard.

Advances in medicine and technologies bring new challenges to treatment consent. For example, advantages in genetics being adopted as medically acceptable indicators to provide preventive and pre-emptive treatment for hereditary diseases. Gene therapy inserts genetic material into patients' targeted cells to treat disease. Up to date, gene therapy has been used to treat cardiovascular disease and cancer. Thomas Wirth (Wirth, Parker, & Ylä-Herttuala, 2013) made projections that "Gene therapy… will sooner or later be part of the standard care for a variety of different diseases". Unlike common treatment, informed consent delivers explicit risks/benefits of treatment to help patients in making a decision; it has been very difficult to determine precisely immediate benefits from gene therapy. Without full awareness patients' interests and choice may become compromised. Therefore, the contents of automatically generated consent forms should be dynamic, clear and explicit to the individuals.

Although less research has been devoted to managing treatment consent in EMR systems compared to protecting identifiable patient information, many researchers continue to improve consent treatment management. See for example, papers "Informed consent for clinical treatment" (Hall, Prochazka, & Fink, 2012) and "Informed Consent for Medical Treatment and Research: A Review" (Del Carmen, & Joffe, 2005) that introduced the basic concepts of informed treatment consent and made several practical suggestions for processing treatment consents effectively. However, none of those suggestions or analysis provides approaches to obtain dynamically or enforce automatically informed treatment consent in EMR systems. Even though, many healthcare organizations have attempted to include electronic consent management in their EMR systems. Veterans Administration Medical Centers use iMedConsent™ (VHA HANDBOOK 1004.05, 2005) that supports electronic access, completion, signing and storage of informed consent forms and advanced directives. iMedConsent has two parts: Software application and clinical content library. iMedConsent generates consents on each procedure without workflows, so the system is limited; it neither dynamically gains informed consents at the point of providing treatments nor enforces consents on medical procedures.

Some medical treatments are procedure-oriented, established by specialty boards as practice standards consisting of activities that caregivers must complete. Required informed treatment consents are embedded in some of those activities, which is an important factor that can change the medical treatment workflow. Standardized treatment procedures, documented in guidelines, usually require multiple checks. However, current EMR systems do not truly support and enforce pre-defined treatment workflow in run-time. To surmount this challenge, the authors proposed using workflow technologies to develop a Workflow-based EMR system in authors' previous work "Building Dialysis Workflows into EMRs" (Yu, & Wijesekera, 2013).

Authors' Workflow-based EMR system provides procedural choreography for treatment regimens using a Workflow Management System (WfMS). Authors' Workflow-based EMR system directly controls the progression of predefined and prebuilt care procedures that comply with local and national standards and policies; and also by providing flexibility that caregivers may need to continue treatment when, in their judgment, superior care compels moving to the next or alternate methods. Inability to obtain consent in emergencies is an example of an exception to a predefined workflow. Authors' system is also well suited to study healthcare delivery safety and quality care issues: Workflow logs perform an

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ongoing audit trail to satisfy accountability requirements and can also be used to improve the workflow. Furthermore, to enforce consent requirements, EMR systems must conditionally grant permissions upon prior receipt of valid, appropriate consent. Therefore, a Consent Management System (CMS) should be introduced in existing EMR systems. By leveraging the fact that medical consents accompany medical procedures, the best way to implement a CMS is by incorporating a medical consent management component into a Workflow-based EMR system. Without changing the Workflow-based EMR system architecture, the authors treat a CMS as an additional component of WfMS. Informed consents obtained by authors' CMS are stored in the EMR as part of patient medical records. The authors also designed additional user interfaces for users to issue missing but required treatment consents. See authors' paper "Consent-Based Workflow Control in EMRs" for more information (Yu, Wijesekera, & Costa, 2014).

Privacy Consent

Patient privacy is the second major concern in consents. In general medicine, informed privacy consent, provides the proper opportunity and knowledge for patients and/or research participants to understand and decide how the medical community can use and share their identifiable medical information. The Health Insurance Portability and Accountability Act (HIPAA) defines Protect Health Information (PHI) as "information that identifies the individual or for which there is a reasonable basis to believe can be used to identify the individual" (Federal Register, Vol. 78, No. 17, 2013, pp1689). HIPAA and other healthcare-related privacy laws mandate how patients' PHI may be used and disclosed. Every medical entity/provider must obtain a patient or guardian's informed consent before sharing and/or using patient PHI except for specified purposes of use and disclosure, such as treatment, for public health activities. In authors' previous work, the authors analyzed HIPAA in a great detail. However, HIPAA only governs covered entities.

Similar to treatment consent for genetic diseases, studies of, and methodologies for, protecting privacy of genetic information have lagged behind scientific advances. The harms of wrongly releasing or misusing genetic information are more than the physical harm, but so-called "psychosocial" harms (Strouse, 2005), which may cause societal discrimination (uninsurability, unemployability), even breakdown of family relationships. Prince et al. describe three practical genetic counseling cases that illustrate genetic discrimination (Prince, & Roche, 2014). The fundamental covenant of protecting patient privacy is embodied in patient-doctor privilege. Compromising genetic information privacy may stigmatize someone as carrying a genetic marker for a disorder or disease. Many researchers have suggested adopting traditional information protecting methodologies to protect patients' confidentiality. Yet, unlike other clinical datum, genetic information is unique and traceable to an individual or group of individuals who share a genetic inheritance (Mascalzoni, et al., 2008, & Gostin, Hodge, 1999). For example, certain genetic information of an individual may not only precisely identify him/her as high risk of certain hereditary disease(s), but also indicate that his/her relatives may have the same risks due to a hereditable gene. Consequently, traditional methodologies for privacy protection, such as de-identification, are not as well suited to the new area. Informed consent complied with proper privation laws tailored for genetic research and clinical usage constitutes a strong basis for ensuring appropriate genetic privacy.

In the past decade, consent management has received considerable attention from researchers, healthcare organizations, and publications proposing different ways to improve electronic consent management. Especially, most of those e-consent approaches focus mainly on sharing medical data, privacy, and security aspects (Grimson, Stephens, Jung, Grimson, Berry, & Pardon, 2001; Saranummi,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2005). For example, "eConsent: The Design and Implementation of Consumer Consent Mechanisms in an Electronic Environment," Coiera and Clark (2004) provided guidelines for designing an e-consent system. Another relevant work is by Ruan C. and Yeo S.S. (2009) that used a UML Model to design an e-consent system. They first identified various parts necessary to specify the e-Consent rules about patient record protection, then used UML to model the properties required by an e-consent system to make the associated patient record protection rules explicit and verifiable. That theoretical work was neither used to design nor implement an e-consent system that works with an EMR.

Rusello G. et al. (2008) proposed a consent-based healthcare management workflow where patients can control disclosing of their medical data based on workflows that are related to inter-institution transfers such as consults. Others have proposed e-consent management to be integrated with EMR or electronic health records systems (Bergmann, Bott, Pretschner, & Haux, 2007; O'Keefe, Greenfield, & Goodchild, 2005; Sheppard, Safavi-Naini, & Jafari, 2009; Win, & Fulcher, 2007). Win et al. (2002) in their paper "Implementing patients consent in electronic health record systems" expressed patient consent using an interface-based approach. Regarding enforcement of privacy consents in existing EMR systems, Bhatti, R. and Grandison, T. (2007) quoted several reports about healthcare privacy, concluding that IT system security mechanisms to enforce patients' consents for privacy were under-utilized and often bypassed. As mentioned in authors' previous works, privacy consent has a lot in common with treatment consent. Nevertheless, they are different in the following aspects:

1. **Issues/Objects are Dealt with Differently:** For privacy consent, patients decide how to use or disclose their identifiable medical information; by contrast, for treatment consent patients decide what should be done to their body.
2. **Who is Covered:** In privacy consent, HIPAA covers the medical information in what are known as covered entities. These are health providers/hospitals/health plans/healthcare clearing house and the like. Non-covered entities, such as private pharmaceutical factories have to abide by state privacy laws and organizational policies.
3. **The Type of Consent Affects the Government's Ability Override Patient Wishes:** The patient does not solely control consent regarding sharing of a patient's identifiable information. This type of consent also depends on the purposes of use and disclosure and a hierarchy of controls applies to the final decision. For example, HIPAA or state law can override a patient who rejects sharing his/her identifiable medical information that relates to a "Serious Threat to health or safety (OCR, 2003, pp 8)" Pursuant to an individual's right to be free of unwanted bodily invasion, patients have more power when deciding their treatment procedures. Consequently in normal care, providers must execute valid treatment consents.

The differences between the two categories of informed consents preclude using the same methodology to obtain informed consent for protecting privacy, especially because privacy rules that reflect public policy may override patient wishes. Thus, the additional factors of governmental override add complexity to protecting privacy for information sharing management in EMR systems. In HIPAA, the purpose of using and disclosing PHI provides a good example; it requires additional components for managing and enforcing this kind of consent in EMR systems in different levels. The traditional authentication strategy, like Role-based Access Control (RBAC), is insufficient (Al Faresi, Wijesekera, & Moidu, 2010). Authors' approach combines patient consents with the hierarchy privacy rules of regulation to determine the correct subsequent actions.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Participating Research Consent

Protecting and respecting participants of human subject research is the third major concern in healthcare domain. In most cases, informed consent for participating in human subjects research is a prerequisite. Participation in research allows researchers to generate and analyze new data or use their old data/samples. Traditional medical research may be well designed within a fixed time. The participants are informed with sufficient information about the study purpose, the procedures used in the study, and potential risks and benefits, etc. and the participants have the right to withdraw their consent at any time.

Contemporary medical research, especially biomedical research, provides many challenges to the currently accepted ethical standards of informed consent in both categories (Mascalzoni, et al. 2005; Knoppers, 2005; Petersen, 2007)

One challenge of designing consent for participating biomedical research and consent for performing a medical treatment is: in general medicine, clinicians seek patients' permission to perform planned procedures and/or to use their medical information for treatment. The patients are knowledgeable about the risks/benefits of performing procedures. Correspondingly, the benefits or risks of participating a genetic study may not be foreseen at the time of consent. As stated in (Strouse, 2005; The Presidential Commission for the Study of Bioethical Issues, 2013), obtaining informed consent in biomedical research settings present differences in required techniques and approaches when compared to clinical practice. In addition, informed consent is a process rather than an occurrence at the one-point action. Another challenge of consent for reusing sensitive medical data or samples in research is: in general medicine, patients reasonably consider that their medical information constitutes their own private information and, hence, are unwilling to either share or have divulged such information beyond participated study, as well as they, are easily able to withdraw such consent at any time. Conversely, the new genetic researches based on the enormous existing data or samples around the world, and may develop over time, which cause re-consent or completely strike out widely shared genetic data is impossible. The fundamental ethical principle of research consent may no longer be suitable. Irrespective of the purpose of research, methodologies for respecting participants and preventing them from both emotional distress and social risk have not, however, kept pace with rapid medicine and technique advances.

Hence, it is no surprise that some genetic medical practices and biomedical research are performed without obtaining appropriate informed consent. For example, researchers may entice participants to participate in a proposed study without providing them with the proper informed consent forms. To address this issue, some researchers advocate different methodologies such as using overly stringent policies to protect participants from harm, and to encourage trust in the research study itself. Obtaining written informed consent of testing to produce genetic data is such an example. But this approach potentially risks limiting scientific innovation (Hallinan, et al., 2015) Genetic research advances also benefit public health (Khoury, & Dorman, 1998). One of the evidences is breast cancer 1 (BRCA 1), where a gene mutation that can be used for general population to predict and prevent from disease (Struewing, & Abeliovich, 1995). Other researchers have proposed a new, open-consent model for medical and scientific genetic research (Lunshof, et al., 2008) or open-access policies for genetic data sharing (Kaye, et al., 2009) in order to achieve research goals quickly. Some researchers disagree on these proposed divergent methodologies and question if such policies may result in a new threat to research participants. Without the consensus of ethical and legal framework for biomedical research consent may result in a perceived breach of the patient's right to privacy and erosion of the ever-sacred principle of researcher/doctor-patient confidentiality (Petronio, 2012; McGuire & Secko, 2009; Beskow, 2010). The authors

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

balance the power of research goads and individual interests by implementing and enforcing related laws and organizations guideline in authors' designed prototype consent management system, for example, by recommending the conditions to apply a waived research consent by the federal "common rule" in federally funded research; guidelines for broad consent given by the Council for International Organizations of Medical Sciences (CIOMS, 2006). Additionally, the nature of genetic research may not promise short-term benefits to the participants and considerable risks in the research must be as part of participating research consent forms.

Components of Consent Forms

Due to the absence of an agreed upon views on the components of medical consent forms, the contents of consent forms may vary greatly. Nonetheless, many studies explored this issue and proposed various recommendations on the essential content of informed consent. Carmen Ayuso et al. (2013) proposed ten minimum elements of information to be included in all informed consent forms for whole-genome sequencing (WGS) in the clinical setting. They did so after searching and reviewing applied documents from 554 documents in the Pubmed-Medline and Embase, such as Scope, Benefits, Risks, Voluntary, Alternative test, Future use, Incidental findings, etc. The authors also examined many paper-based consent forms and found that they include a large number of attributes. As shown in authors' previous work, the authors found 21 attributes in eight dialysis consent forms. Authors' examinations have led to categorizing the consents as follows:

1. **Informed Consent Giver:** The person with the legal right to make health care or participating decisions, such as parents or legal guardians of minors, healthcare proxies, healthcare providers or third parties.
2. **Disclosed Information:** At a minimum, includes procedure (treatment procedure for treatment consent, data usage for privacy consent, research procedure for research consent, and so on), benefits, risks and alternative procedures.
3. **Patient's Decision:** Includes the decision (deny or accept) by providing all required conditions and attributes such as signatures, date, etc.

Consequently, consents are based on all input variables, such as consent giver, treatment specification, related consent rules, and the like. Usually, they are represented in the physical forms in writing, electronic forms in the computer applications, or in some other legally acceptable manner. Hence a well-designed consent form should be obtained when activities require it. In authors' prototype system, electronic consent forms are automatically generated based on the collected attributes and regulations and enforced to obtained as practice workflow demands.

The various rules generated from laws, organization policies or sub-discipline medical guidelines affect each component of consent. Therefore, to be valid, informed consent must comply with state and federal laws and regulations applicable to medical sub-disciplines, as well as depend on some specific situations such as treatment type, research type, facility location and the purposes of use and disclosure of sensitive patient information for medical information sharing consent.

Consent Rules

As stated above, the relationship between consent components and governed rules are expounded below:

1. Informed consent giver component is governed by a competency rule; that is there to validate that the patient has sufficient maturity to grant informed consent;
2. Disclosed information component is governed by information or disclosure rules. An essential component is the concept of autonomy that allows competent adult persons and emancipated children to make their own decisions based on the understanding of given information. Nonetheless, the scope of the disclosure of required information is still debated, especially in genetic consents.
3. Patient's decisional component is governed by decisional capability rule, which is for evaluation of patient competency for understanding information about the procedure or using/sharing medical data and the ability to provide a rational, voluntary agree or deny decision. In (Fisher, 2002), authors described four psycho-legal standards of:
    a. Communicating a choice,
    b. Factual understanding,
    c. Appreciation of the situation, and
    d. Rational manipulation of information that is used to evaluate patient competence in granting consent.

However, no widespread consensus exists on how the decisional capacity of treatment consent should be measured.

Consent statutes and regulations are complex. Authors' previous work (Yu, Wijesekera, & Costa, 2014) showed the complexity of determining patient competency for treatment consent. One of the issues is that each state has its own laws defining minors, at times differing by treatment type. Various statutes and regulations and laws governing informed consents change over time. For example, a medical lawsuit that establishes precedent may trigger a new or amended statute or regulation or alter how a law is interpreted. Nevertheless, studies of consent laws are scarce, perhaps because ever changing laws would cause such studies to have a short shelf-life. Yet, no implementation method or modeling changes to consent laws are available that govern specific institutional practices (Beauchamp, & Childress, 1989). Consent is rendered unreliable without adhering to corresponding changes in laws. Even more, at times ambiguity adds to complexity (e.g., precedent changing interpretations of the law that, due to ambiguity, is subject to multiple interpretations). This causes breakdowns between concepts that people use and data that computers interpret. Thus, a methodology for acquiring proper consent based on evolving law must be dynamic.

Issuing proper medical consent demands to evaluate all consent rules and to determine the type of consent to be obtained from the appropriate consent provider as well as allowing exceptions to achieve the flexibility. For example, an incapacitated patient (perhaps temporarily due to injury or medication) may be considered not to possess a sound mind or may have been determined not to have the mental capacity (such as developmental disorders or clinically determined mental impediments) needed to provide legally binding informed consent. Similar exceptions exist with respect to children or young adults, who may not be considered mature to provide consent (Appelbaum, & Grisso, 1995).

System Architecture

Authors' system architecture (shown in Figure 3) consists of the following components: (1) User Interface (UI) for EMR system users, (2) EMR's Runtime System, (3) WfMS ─ Workflow Management System - a runtime system that enforces medical treatment workflow, (4) CMS ─ Consent Management System, and (5) corresponding databases.

1. **UI:** Enables interactions between EMR systems and EMR system users (usually refer to people, such as members of the treatment team and quality care team that may want to review the logs, etc.)
2. **EMR System:** Provides clinical functions, including the display of patient demographic information, vital signs, medication, lab order/results, etc.
3. **Workflow Management System:** Designs and executes workflow models, consisting of a workflow editor, workflow runtime engine and other components such as a workflow task handler that enforce the completion of a specific task.
4. **Consent Management System:** Evaluates and obtains appropriate patient's consent form, if needed. It contains different consent services, such as Patient Privacy Consent Management Service (PPCMS) and Patient Treatment Consent Management Service (PTCMS).
5. **Related Databases:** WfMS' databases contain healthcare and medical research workflow specifications composed of tasks describing processes and WfMS' data; while EMR systems' databases contain patients' or research participants' medical records and other EMR systems' data.

As stated, previous work describes the details of the developed consent management and workflow-based EMR design. The enhanced Workflow-based EMR system includes:

A CMS connected to WfMS that contains different consent management services, such as treatment consent management service, privacy consent management service, participating research management service, and so forth. The authors describe two of main consent management services below:

1. A PTCMS that contains a Treatment Consent Management System (TCMS) and Treatment Consent Rule Management System (TCRMS), which ensure treatment consents comply with treatment consent laws and policies. TCMS generates the appropriate informed treatment consent forms automatically and obtains the consent before passing to the next task.
2. A PPCMS contains a Privacy Override Privilege Management System (PoPMS) and a Privacy Consent Rule Management System (PCRMS). When an entity requests using or disclosing protectable patient information through the EMR system, the sub-component, the PoPMS in the system will check the requester, which may be a government agency, patient, covered entity, business associate or a researcher. Then PoPMS retrieves the purpose of disclosure and use of sensitive medical information based on federal, state privacy rules or organization policies. For example, in HIPAA, without any stated purposes, a patient or his/her authorized representatives is allowed to require this patient's PHI. In this situation, the request is assigned as "required disclosure" by default. If the request is an "authorized use" and disclosures, the request will trigger PCRMS to obtain a patient's informed privacy consent, which when given by the patient can be used for disclosure. In this design, the Ontology Service (OS) plays a role in obtaining valid consent forms. OS includes an ontology editor (to edit terms and rules), a rule set that codifies treatment or privacy consent

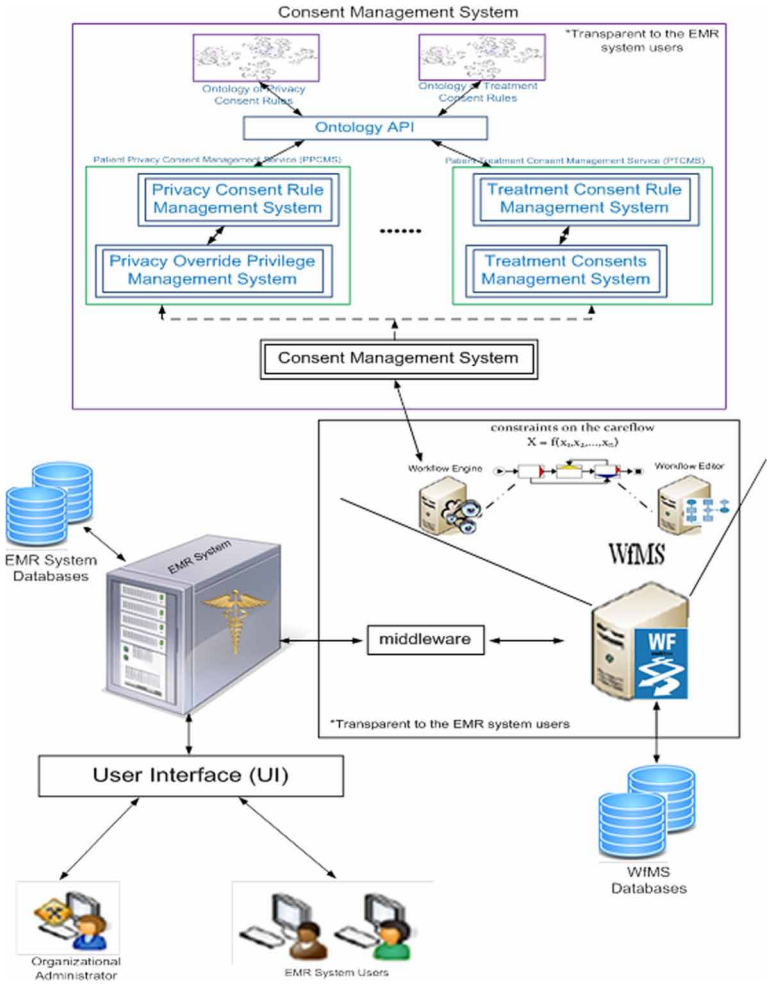
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

laws and a reasoner that derives components of the consents that are displayed as consent forms by the EMR system. PCMS returns the final decision made by privacy rules with the highest override privilege to the EMR system. For authorized uses and disclosures request, the decision is shown on a patient's valid privacy consent.

Similar in design to the TCMS, PoPMS can retrieve or generate the valid informed privacy consent forms automatically and passes the patient's decision of sharing his/her sensitive medical information. The Enhanced Workflow-based EMR System Architecture is shown in Figure 1.

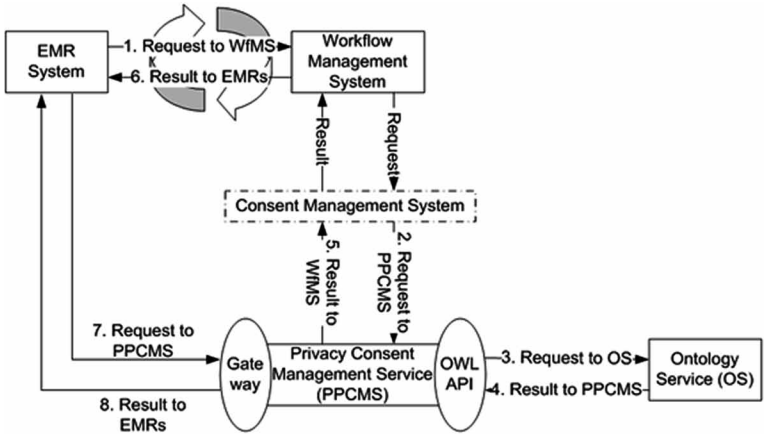
Informed consent is managed by the combination of WfMS and CMS. Based on the kind of consent required, corresponding consent management service is triggered. Following, the authors use PPCMS as an example to show how does the system work. PCRMS must be able to ascertain the consents, if any, are missing, but are required for making the final decision; if so, they must be obtained prior to disclosure. See, Figure 2 for the interaction among the WfMS engine; the EMR systems; and PPCMS and OS.

Figure 1. Workflow-based EMR system with consent management architecture



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Interactions between the WfMS; the EMR system; and PPCMS and OS per session



Step 1 EMR System → WfMS: When a requestor starts to request an individual's sensitive medical information in an EMR system or the request is issued during other workflow tasks, a "launch case" event request with workflow specification I.D. or name is sent to WfMS engine; WfMS engine enables the work item(s) based on control flow defined in the workflow specification and input data. If the enabled work item(s) do not request consent service, then go to Step 8. Otherwise,

Step 2 WfMS → CMS: If a procedure/step needs to check patient's informed privacy consent, the CMS is triggered. Furthermore, base on requested consent type, a corresponding consent management service is triggered, PPCMS in this case.

Step 3 PPCMS → OS: PPCMS uses OWL API to connect to the OS with patient's information and other required consent information.

Step 4 OS → PPCMS: OS retunes the results reasoned based on the rules to the PPCMS.

Step 5 EMR System → PPCMS: This additional step is triggered only when informed consent is required. EMR system requests the PPCMS to the kind of the privacy consents should be issued.

Step 6 PPCMS → EMR: System Similar to the previous step, except this step is triggered only if the consent service is called. PPCMS returns the answers to EMR System.

Step 7 PPCMS → WfMS: PPCMS passes results to CMS, then the CMS forwards results to WfMS, the WfMS decides if procedures should continue or be aborted based on the workflow specification.

Step 8 WfMS → EMR System: WfMS sends a notification to EMR system. The available work item(s)/ step(s) will notify EMR system users via UI. Then, the interactions between WfMS and EMR system are repeated.

In the next section, the authors use informed consent for genetic services as a case study to show how genetic informed consents placed new challenges on the traditional ethical standards of informed consent. It also illustrates how appropriate consents can be electronically obtained and automatically enforced using a system that combines medical workflows and hierarchically, ontologically motivated rule enforcement.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CASE STUDY ON GENETIC SERVICES

In authors' previous works (Yu, Wijesekera, & Costa, 2014), the authors mainly address the consent for medical treatments, with a focus on informed consent for procedure-oriented treatment regimes. A preliminary study convened jointly by the National Institute of Health (NIH) and the Center for Disease Control (CDC) (Clayton, 1995) presents the risks and ethical issues involved in collecting and storing tissue samples for genetic tests in a research setting. Herein, the authors present a unique approach, which is based on the premise that acceptable genetic service regimes are captured in workflows to automatically obtain or generate (when needed) the deferent types of informed consent for clinical usage (collectively called *genetic services*) and genetic research. Moreover, the authors combine genetic privacy laws and policies relevant to informed consent with an encompassing and customizable genetic services workflow to show consent enforcement for ensuring appropriate genetic information privacy.

Background

Genetic studies comprehensively utilize genotypic and phenotypic data (Ritchie, et al., 2015). Studies have shown that preventive care, in which genetic services and researches play an important role, costs significantly less than treatment upon disease onset (Németh, et al., 2013). Examples include genetic mutations causing certain kinds of breast cancers (BRC-1 and BRC-2), ovarian cancer, sickle cell anemia, behavior disorder, β-thalassemia, left ventricular noncompaction cardiomyopathy and Alzheimer's disease, etc. Those genetic advances have encouraged some genetic services to become medically acceptable common practice to provide preventive and preemptive treatment for hereditary diseases. Concurrently, rapid advancement of genetic research continues to lengthen the list of predictable diseases (Rehm, et al., 2016). Many of those achievements are produced by researches using large sets of stored genetic information and samples. As stated in (Kerath, et al., 2013), the utilization of existing biobanks' stored information has become the cornerstone of human genomic and epigenomic studies. The concept of open access in the field of genomic research is expressed in the Bermuda Principles and the Fort Lauderdale Agreement, which have been widely applied in North America and the UK for funded genetic research. Sharing genetic data is vital for maximizing the use of such information to benefit patients and the general public. However, concern for ensuring genetic privacy is growing.

Genetic exceptionalism is defined in a paper (Gostin, & Hodge 1999) as "*the societal practice of treating genetic data as different from other types of health data for the purposes of assessing privacy and security protections*." The Federal Government and some states enacted several genetic-specific legislations to protect the genetic privacy and prevent discrimination. For example, HIPAA considers genetic information to be confidential medical information and regulates healthcare providers. In spite of Gostin & Hodge (1999) argued this definition is flawed in the light of two reasons:

1. Strict protection of genetic data threatens the accomplishment of public goods;
2. There is no clear demarcation separating genetic data from other medical data.

The majority of scholars agree that genetic information has its particular characteristics from other medical data. Some researchers say that *genetic information is essentially familial in nature and is referred to as the Genetic Information is Familial Thesis (GIFT)* (Liao, 2009), sharing such information will benefit related groups of individuals. Yet, others, who advocate the view of humans possessing the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

rights of *do not want to know* (Sherlock, 2009, & Liao, 2009), disagreed with the familial approach in their literatures. Sharing such data introduced new challenges. Inter alia, related regulations are many. For example, some countries have regulations to enforce sharing such information among family members (Lucassen, & Kaye, 2006, & American Society of Human Genetics Social Issues Subcommittee on Familial Disclosure, 1998) and others do not. Both research and clinical uses of genetic information pose ethical issues on medical consent:

- **Ethics:** Privacy involving genetic information differs from traditional medical informed consent. For example, protecting patients' private information is an important medical ethics and legal obligation. The key point is that the healthcare industry's current level of privacy and confidentiality is not yet entirely suitable for genetic privacy in both clinical medical practice and biomedical research. Genetic privacy consent has not been linked-up to applicable laws as part of an EMR workflow that enforces appropriate consent as a predicate to using genetic information in research and clinical practice. Protecting patient privacy in the context of genetic information leads to other equally unique types of challenges.
- **Legal Issues:** Requirements differ based on the usage. For example, generating data requires written informed consent that meets strict requirements, whereas sharing genetic data for research may have a less stringent opt-out consent. Genetic information can be traceable not only to individuals but also identify data owner's relatives and makes family trees susceptible to stigma (Roach et al., 2010). Therefore, genetic privacy has been proposed as categorical privacy that differs from traditional individual-centered concepts of privacy in literature (Lunshof, 2008). Furthermore, genetic privacy laws vary from state-to-state and may be inconsistent with and be more or less stringent than federal law.
- **Social Implications:** Societal views are often reflected in law and/or organizations' policies, so societal implications are likely inextricably intertwined with laws and policy governing genetic privacy and what constitutes informed consent.

As a solution, the authors provide an encompassing framework consisting of workflow-enforced genetic privacy as well as biomedical consent management consistent with state and federal genetic privacy laws such as a statute, regulation, and precedent. These missing regulations presented issues for the authors' prototype implementation that have been resolved by having default rules.

Related Work in Context

EMRs play a vital role in sharing medical information among participating actors based on their usage scenarios. In addition, using EMRs for genetic services present a unique set of challenges (Mascalzoni, 2008). Belmont et al. (2009) highlighted the privacy, ethical and legal issues of handling genetic data in EMRs. Additional, Scheuner et al. (2009) conducted a case study to verify if existing EMR systems meet genetic information needs. This study, involved results, and conclusions gathered from discussing 56 patient's electronic medical records within10 EMR specialists, 16 medical geneticists, and 12 genetic counselors, shows an overall lack of support for functionality, structure, and tools for clinical genetic practice. A more recent study on the state of EMRs supporting genomics for personalized medicine again identifies the designing of the structure of data as a challenge (Ullman-Cullere, 2011). The authors also identified genetic services workflow management as a priority area that needs further

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

research, development, and testing. The authors, too, observed that current EMR systems for genetic services still cannot support the ability to obtain/generate informed privacy consents and enforce them in EMRs (Yu et al., 2015).

Some researchers suggested that the proper legislation on generating and using genetic information is pivotal to improving genetic privacy (Gymrek et al., 2013). In 2013, HIPAA (45 C.F.R. §160.103) Omnibus Rule included genetic information as PHI to be regulated under the privacy portion of HIPAA. Nonetheless, states may have different definitions of genetic information. The combination of Federal privacy laws and state laws from many states form a fragmented regulatory and statutory landscape for permissible information sharing and consent management. Indeed, significant regulatory gaps create additional burdens in providing automated ways to obtain and generate information consent in EMRs.

As mentioned, an informed consent management system in genetics is needed. To the best of authors' knowledge, to date, there is no such system implemented in EMR systems that can accommodate the rapid advancements of genetics research and the evolving nature of the genetic privacy landscape. To comply with different genetic privacy laws under various circumstances in clinical practice and genetic research is challenging. EMR systems evolved with differing architectures to satisfy different requirements at different stages of technology development. Many treatises (Locatelli, Restifo, Gastaldi & Corso, 2012; Shortliffe, & Cimino, 2006; Wickramasinghe, & Geisler, 2008) have detailed EMR system evolution. Today, EMR systems are indispensable. Because medical organizations have over two decades adopted costly EMR systems ($25M-$45M per large hospital and $8B for the Defense Health Agency), medical organizations are understandably reluctant to switch to new systems. Consequently, a strategy of integrating a genetic consent management with existing EMR systems may provide a solution that the authors advocate.

Proposed Approach

Authors' solution to the issue is to enhance an existing EMR system with a workflow management system to choreograph predefined procedures, as the authors have prototyped using open source solutions. Although there will be other components that drive the EMR systems, EMR users will not notice a difference in interaction by using authors' solution.

During the time that genetic services have been around sub-disciplines or education papers have also defined de-facto workflows for some genetic services. For example, The Genetic Counseling Definition Task Force defines Genetic counseling as "The process of helping people understand and adapt to medical, psychological, and familial implications of genetic contributions to disease." However, the authors were unable to find a documented and modeled comprehensive workflow. Therefore, the authors need to create a genetic services workflow model. The authors describe a genetic services workflow specification in the next section.

High-Level Genetic Services Workflow

The methodology used to generate a genetic services workflow involves the following steps:

1. The authors interviewed genetic researchers to get their individual practice workflows.
2. The authors collected the paper-based documents used to record events and data that are associated with the workflows.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, the authors combined (1) and (2) to generate a more comprehensive workflow. The authors describe the high-level workflow process first; then describe its one of sub-processes genetic counseling with the requesters involved in the processes separately and show an embedded consent management system.

The high-level genetic services, modeled using a workflow editor is shown in Figure 3. The shown workflow covers the high-level view of the genetic services consisting of multiple requested genetic services, as shown in Figure 1, the leftmost node with a right-pointing green arrow inside a circle is the starting point of the workflow, and the rightmost circle with a filled red square ends the workflow. Atomic Task (using a single box in Figure 3, as (1: Submit Request) denotes "a single task to be performed by a human participant or an external application"; Composite Task (using a double box in Figure 1, as (4B: Do Genetic Counseling) represents "A container for another workflow process (also called a sub Net)"; The starting point is the process of receiving different request for a genetic service by different requestors, such as care providers, researcher, etc. When genetic service or genetic information using/sharing, the consent management system is triggered automatically in authors' design. Details follow.

"Do Genetic Counseling" Sub-Workflow

The continuous workflow that the authors call "do genetic counseling," named *4B: Do Genetic Counseling,* has two composite tasks in *Do Genetic Counseling* sub-workflow, *Pre-test Genetic Counseling,* and *Post-test Genetic Counseling,* as shown in Figure 4 and Figure 5. This sub-workflow is based on a presentation on clinical genetic counseling from Stanford University's Clinical Genomics program (Merker, 2014). In addition to the previous presentation, the authors used another presentation by O'Daniel et al. (2012) on Genomic Medicine for additional details. Here the authors provide a detailed documentation and overview of the Genetic Counseling workflow. The following list provides the details of the individual tasks involved in the process of providing genetic counseling to a patient or care provider.

Figure 3. High-level genetic services workflow

Figure 4. Pre-test genetic counseling

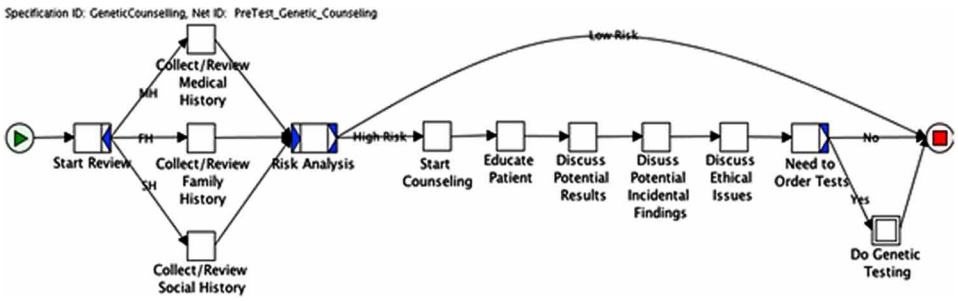

Figure 5. Post-test genetic counseling

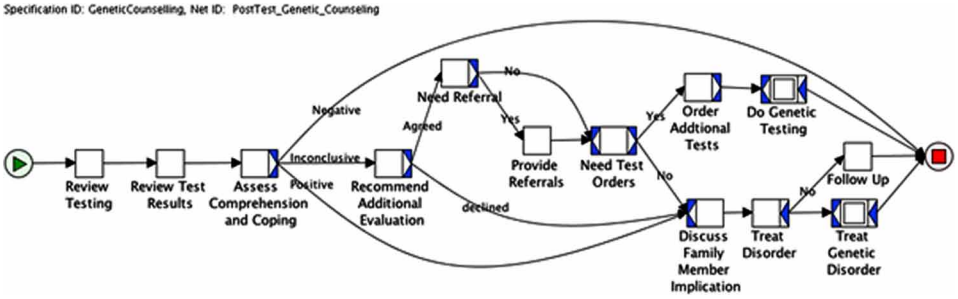


1. Collection of Medical Records, Family History, and Social History:
   a. **Require Genetic Counseling:** A case originates with a physician's referral for genetic counseling. Alternatively, a patient self-requests genetic counseling after learning of a manifestation of a genetic disorder in a family member.
   b. **Patient Walk-ins:** Upon arriving at the genetic counselor's office, a self-requests patient is asked to provide social and family history. Concurrently, the Genetic Privacy Consent is obtained. Additionally, if copies of medical records are provided, they are recorded in the system. In authors' workflow model, the patient is presented with a detailed family and social history questionnaire to assess the risk of a suspected hereditary disease. Authors' workflow produces a questionnaire on suspected Hereditary Cancer Syndrome based on forms developed by the Virginia Women's Center (Virginia women's center website).
   c. **Physician's Referrals:** When a physician refers a patient for genetic counseling, the patient is asked to sign release forms for medical records (Genetic Privacy Consent) from the referring physician (if not already provided). If not, and the patient brings in copies of medical records, they are recorded in the system.
   d. **Review Requirements:** Information collected from the patient is reviewed for completeness. If any, missing information is collected from the patient, patient's primary care physician or public sources of ancestry information. This is shown in the "*Collect More Information*" task in the modeled workflow (Figure 4). When all of the information (to the best of patient's knowledge) is collected, one or more of following people review the collected information: Genetic Counselor, Molecular Pathologist, and/or Medical Geneticist. Next, check for the amiability of genetic test to answer the questions posed by the patient or the referring physician.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Pre-Test Counseling:** Once an insurance or payment authorization is obtained, the patient meets with a genetic counselor for pre-test counseling. The genetic counselor performs the following sub-tasks for pre-test counseling:
    a. An informed consent is obtained for counseling, i.e., Genetic Counseling Treatment Consent. As a part of this informed treatment consent, the counselor provides the patient with information about the expected risks and benefits of this process.
    b. The family, social, and medical history provided by the patient is reviewed.
    c. The counselor discusses the expected range of results and their impact on the patient and his/her relatives. Additionally, the counselor discusses other potential incidental findings that may be in the report. Incidental findings are those findings in the test results that are not associated with the primary reason for conducting the test, but indicative of other recognizable genetic disorders. The counselor also discusses ethical issues that could arise from conducting or disclosing these test results. Before ordering the tests, any questions or clarifications from the patient are answered. At this moment, the counselor will obtain a doing lab consent, which belongs to the Medical Treatment Consent.
    d. If applicable, consent for sharing information or using their samples for current or future possible research purposes (Participating Genetic Research Consent) is collected.
3. **Lab Work:** Blood or tissue samples are collected from the patient for genome sequencing. Generally, one tube of blood is collected for sequencing. An additional tube may be collected for confirmatory studies. Another tube of blood may be collected from the patient with appropriate consent for research purposes. The blood and tissue samples are then sent to a laboratory for sequencing, and the sequenced genetic information is returned to the genetic counseling team. The authors do not model the workflow for genome sequencing in the laboratory in this chapter.
4. **Post-Test Counseling:** Once the sequencing results are reported back to the genetic counseling team, a draft report is prepared. This draft report is reviewed by a review team consisting of Genetic Counselors and/or Medical Geneticists, Physicians, and/or content experts. Once reviewed, the final report is uploaded into the EMR and is ready for the patient. Ideally, this report should be delivered electronically to the EMR. When the patient meets the counselor to discuss the test results, the following sub-tasks are performed:
    a. The counselor reviews the test results with the patient. Once the review is complete, the counselor assesses the comprehension and coping skills of the patient.
    b. If the additional evaluation or referral for treatment (e.g. prophylactic mastectomy) is warranted, referrals or orders are placed by the genetic counselors. Alternatively, the patient may decline the recommendations of the genetic counselor. If the recommendations are declined, it is recorded in the EMR and if needed, a second opinion is scheduled.
    c. The counselor finally discusses implications of the findings on related family members. At this point, the genetic counselor may recommend the patient to inform related family members personally about the test results and treatment options by providing templates. Alternatively, they may obtain consent (Genetic Privacy Consent) to disclose test results to affected family members.
    d. Lastly, if required, the counselor may schedule follow-up appointments.
5. **Disclosure and Other Consents:** At the end of the genetic counseling process, the care provider may be required to obtain consent to retain samples and/or genetic information (sequencing results) and genetic test reports based on state and federal regulation. Additionally, the care provider may

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

require additional disclosure consents to share information with other individuals or entities as required by law. If consent to retain genetic samples and test information is denied, they must be destroyed and/or purged from the EMR records. Once these housekeeping tasks are complete, the genetic counseling workflow comes to an end.

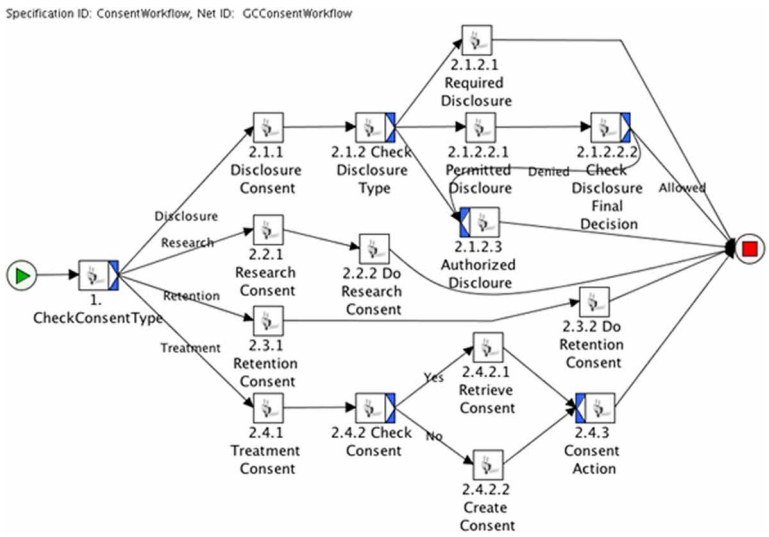
Consent Management in the Genetic Counseling Workflow

As discussed earlier, there are various types of informed consent required for Genetic Counseling, which mainly include treatment consent; genetic information use/disclosure consent, so-called genetic privacy consent; genetic research consent; and retention consent. If a proper workflow in not enforced for genetic counseling in the EMRs, it may leave healthcare providers and/or health-care organizations open to lawsuits. Existing laws limiting genetic information disclosures do not generally consider ethical issues involved during the disclosure process. Ethical issues present an abstract concept that needs to be carefully considered by genetic counselors on a case-by-case basis. Additionally, an organization's ethical guidelines may regulate disclosure of genetic information, which upon disclosure may tangibly affect a third party.

In this section, the authors describe how the authors enforce all of the required consents in the genetic counseling workflow. The authors describe the enforcement of disclosure consent in this work. Other types of consent may be enforced in the workflow very similar to the disclosure consent.

When a task requires consent in the genetic counseling workflow, the consent management system is invoked to manage the consent requirements. The authors also adopted workflow technologies to model the consent management processes as a workflow specification, shown in Figure 6. In the case of information disclosure consent, the consent must comply with federal and state laws, as well as organization policies.

Figure 6. Genetic consent management workflow



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In developing authors' prototype, the authors studied genetic-related privacy laws in great detail. At first, the authors examined the papers and publications (Rothstein, 2014; & American Health Information Management Association, 2013), which focused on the federal genetic privacy laws. There are four major federal laws for genetic information sharing as shown below:

1. Genetic Information Nondiscrimination Act of 2008 (GINA) (2008). GINA regulates employers and health insurance companies but not healthcare providers who use genetic information. GINA protects individuals from discrimination based on genetic conditions. However, GINA does not apply to federal government employees or employers with fewer than 15 employees.
2. HIPPA (45 C.F.R. §160.103). The 2013 Omnibus Rule included genetic information as PHI to be regulated under the privacy portion of HIPAA. However, HIPAA only mandates a portion of genetic information requestors such as covered entities.
3. The Common Rule applies only to institutions that perform federally funded research on human subjects; private research institutions may voluntarily agree to comply with federal standards. Among other issues, the Common Rule sets out explicit standards for informed consent by research subjects, although an ethics board may waive these requirements.

Although these laws guide establishing policies for genetic information sharing, none of them absolutely protects genetic privacy. In addition to federal laws, many state laws and institutional polices add to the informed consent management.

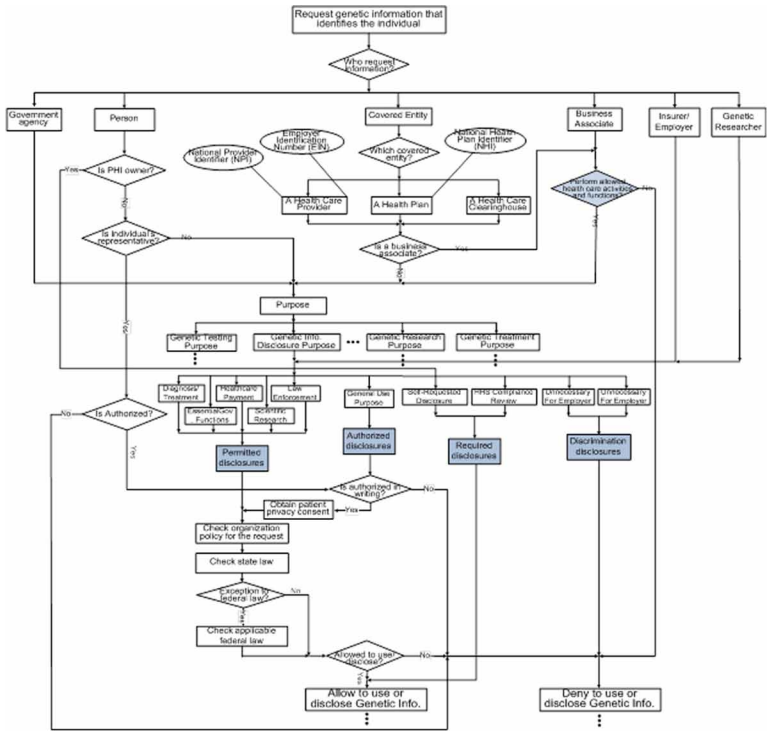
Now the authors are reviewing genetic privacy laws from states that apply to genetic privacy in published literature (Mulholland, 1998; & National Conference of State Legislatures, 2008) and online resources. Many states have their own genetic privacy laws with different levels of requirements to protect genetic privacy.

For example, California has a more strict genetic privacy law while some states such as Alabama do not have any regulations specific to genetic data. Furthermore, the genetic information use and sharing of genetic services will vary based on the types of the requestor (such as genetic counselors, researchers), and the purpose (such as diagnosis, research, payment). Without an understanding of informed consent, it is problematic to make consent information semantics explicit and hence discoverable automatically in a software system.

Computer science defines "Ontology" as "the explicit specification of a conceptualization" (Gruber, 1995) or "explicit formal specifications of the terms in the domain and relations among them (Noy, & McGuinness, 2001)." Consequently, ontologies can be used to model a domain of discourse as a set of representative primitives, such as classes, object properties, data properties and relationships between them. Many papers present reasons to use ontologies to formulate shared vocabulary (knowledge) of a given healthcare domain of interest (Gruber, 1993), to ensure interoperability within the various healthcare domains (by ontology matching). Ontologies have been used to represent actionable knowledge in biomedicine (Dang, Hedayati, Hampel, & Toklu, 2008; Garde, Knaup, Hovenga, & Heard, 2007; Matos, Campos, Braga, Palazzi, 2010; Rosse, & Mejino Jr, 2003; Yu, 2006) due to their ability to capture domain knowledge in a formal yet simple and incremental manner, as well as their easy and powerful application in reasoning processes (Valls, Gibert, Sánchez, & Batet, 2010). Other healthcare fields include decision support and information integration. Thus, the authors developed a medical treatment consent ontology as a preliminary notation to formalize the predicates used in creating consent rules.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Structure of the hierarchy overrides privilege to override the privacy disclosure decision



The rules used to model treatment consents are of the form "predicate$_1$(x_{11},x_{12},..,x_{1n}),… …., predicate$_m$(x_{m1},x_{m2},,,x_{mk}) → predicate(y_1,…y_p)" where the predicate instances stated left of the arrow symbol → are taken as the body of the rule and read as a conjunction of predicate$_1$($_{x11}$,x_{12},,,x_{1n})/\,…,/\ predicate$_i$(x_{i1},x_{i2},,,x_{ij})/\,…., /\predicate$_m$(x_{m1},x_{m2},,,x_{mk}) and the consequent is predicate(y_1,…,y_p). The intended meaning is that if the conditions specified in the antecedent hold, then the conditions specified in the consequent also hold. The authors show patient maturity evaluation rules for each state based on its consent laws as a case study in authors' published paper (Yu, Wijesekera, & Costa, 2014). In (Yu, Wijesekera, & Costa, 2014), the authors used open source software for implementing authors' framework YAWL Management System as the workflow management system and OpenMRS as authors' EMR system, Ontology Web Language (OWL) to describe authors' consent ontology, implemented using Protégé and applied Pellet as tour ontology reasoner. Similar techniques are used to obtain valid genetic privacy consents in addition to the privacy disclosure decision made by the highest override privilege as shown in Figure 7. As a result, additional task, which applied checking disclosure decision privilege rules, is added to genetic privacy consent service workflow.

Implementation

The authors developed a functioning prototype that addresses many aspects to develop an automated and integrated informed genetic information consent system. The prototype collages the data gathered during interactions with the medical provider with the application laws, regulations and policies to address the privacy issues specific to genetic information. The first component of implementing the genetic

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

privacy enforcement gathers the required information from an EMR system. This foundation allows the rules to be seamlessly integrated with the operations of the medical facility and maximizes the use of existing data to reduce additional data entry. The authors extended an open-sourced EMR by adding a tab to launch the consent workflow management system for an EMR system user. The workflow gathers additional information regarding aspects of the tasks being performed and then executes the path based on the purpose for accessing the genetic information (Disclosure, research, or treatment).

Once all the required information has been gathered from either the EMR database or from the users by invoking workflow-based prompts, the workflow management engine calls consent management system whenever an informed genetic consent is required. When a corresponding consent service is triggered, it implements an ontology described below to reason if the requested access is permitted or if not a consent form is required to generate. The access evaluation is done at each level in the hierarchy that is applicable to state, federal genetic privacy laws, and organization policies. By definition, federal laws are at the top of the hierarchy followed by state laws, local laws and then organizational policies. The hierarchical structure dictates how conflicts between laws and policies can be resolved based on the decisions made at each level. (For example, Federal Laws set a number of restrictions on the use of genetic data in research. Unless explicitly allowed in the Law, an organization cannot write conflicting policies.) The workflow engine evaluates the results from each level to return an overall decision as to whether access is allowed along with incorporating any other requirements that must be enforced (such as retention periods, written consent, de-identification, etc.)

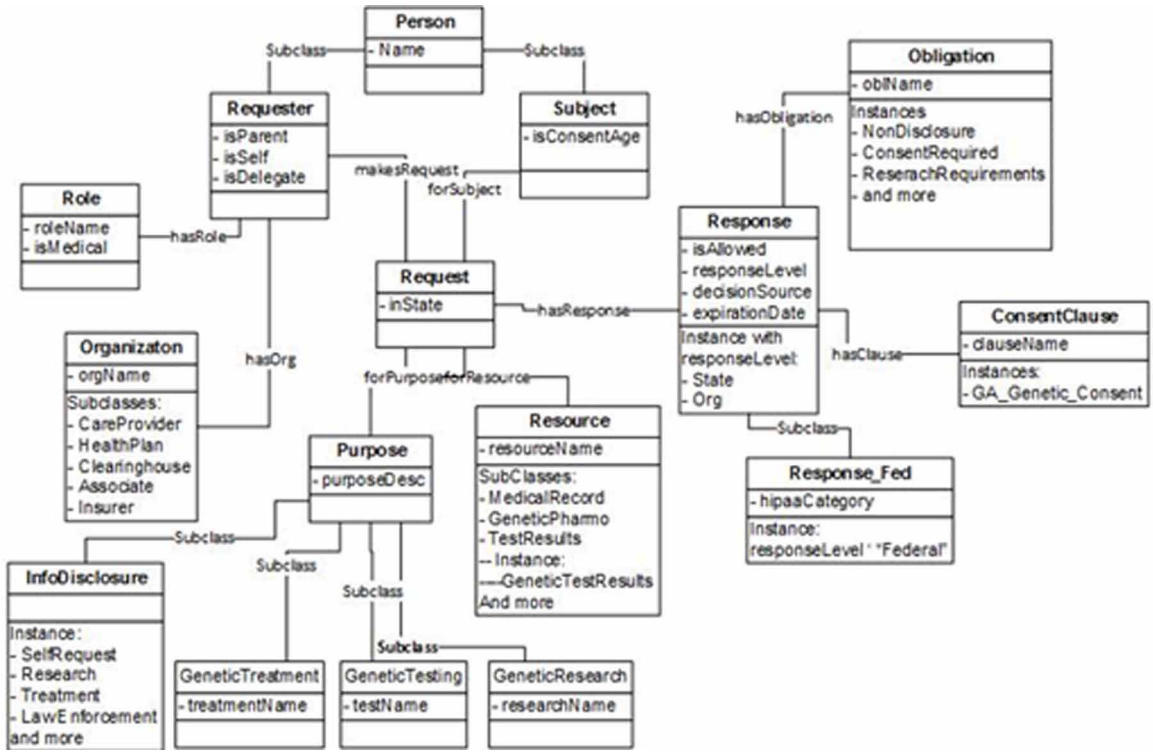
In order to support the consent service, the authors developed an ontology to capture the various aspects of enforcing privacy laws and policies. As shown in Figure 8, the ontology has four major entities:

- **Requester:** The person making the request to access the medical information including their role, associations with a specific organization, and information about this organization,
- **Resource:** The part of the electronic medical record being requested along with information about the subject (or patient)
- **Request:** Details on the purpose for requesting the information. The four specific purposes applicable to genetic information are disclosure, research, testing and treatment. The prototype currently implements the information disclosure component with the applicable specific instances for Self-Request by the Patient, Law Enforcement, etc.
- **Response:** The results of the reasoner applying the appropriate rules along with a list of any obligations that must be enforced by the EMR and specific consent clauses that are needed for the associated approvals. (A subclass for Federal Responses allows information about HIPAA-specific requirements to be gathered.)

The ontology diagram shown in Figure 8 contains some main properties and instances used in authors' work so far. The ontology is implemented using the Protégé platform with the laws (Federal and State), and the organizational policies are enforced using DLQuery and the Pellet reasoner. The predicate used in each rule uses the Request instance with the associated properties to gather additional information on the Requester and the Resource. The appropriate Response instance (Federal, State or Organization) receives the outcome of the rule regarding whether access is permitted or denied the specific law or policy that generated the result, and the appropriate obligations and clauses.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. The ontology diagram



The Override property implements the hierarchy of Federal/State laws and organizational policies described above. The override property is set as a meat-rule implementing a more strict law being evaluated that permits a looser law or policy to provide a different answer or supplemental information. So, if a Federal law permits access but has a clause where a state or organization can set a different policy to deny access, the override property in the Federal response is set to "True." Alternatively, the organizational policy might still permit access but add more clauses to the consent agreement that must be signed.

For example, HIPAA permits access to medical records even genetic data for treatment. In Georgia, there are additional obligations and consent requirements when the resource being accessed is from genetic testing. The Response structure allows both sets of answers to be passed back to the workflow engine for further evaluation and execution.

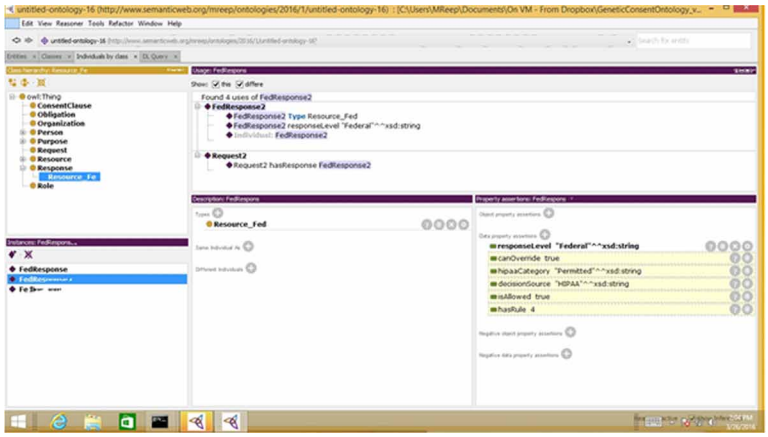
As an example of the implementation of obligations and overrides, the first DLQuery checks for the Federal law for access to the genetic Test Results for Treatment. The response is set to provide the corresponding information for the associated HIPAA category for Permitted, and therefore other laws can override the decision.

makesRequest(?r, ?req), forPurpose(?req, ?pur), purposeDesc(?pur, "Treatment"), hasResponse(?req, ?res), responseLevel(?res, "Federal") -> isAllowed(?res, true), canOverride(?res, true), hipaaCategory(?res, "Permitted"), decisionSource(?res, "HIPAA"), hasRule(?res, 4)

The next part of the example below shows the DL Query for the related request which sets the location in Georgia and that the rule can be executed if the Federal response allows an Override. The State response then allows access but with an additional obligation for a Consent Agreement and the agreement must have text specific to Georgia.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

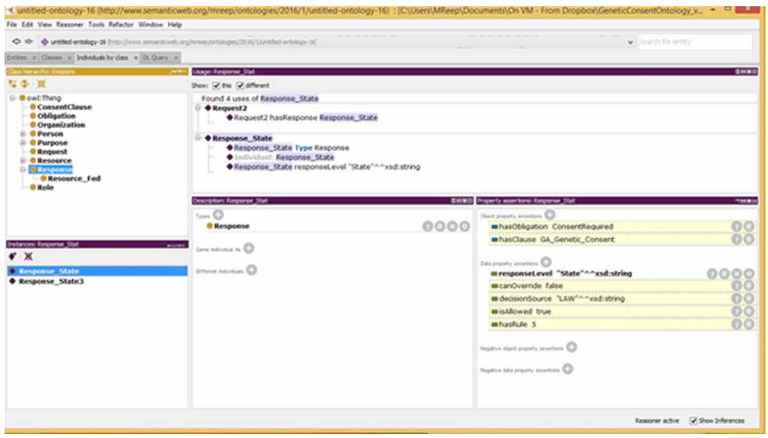
Figure 9. Outcome of the decision of accessing genetic data using Pellet reasoner



isSelf(?r, false), makesRequest(?r, ?req), inState(?req, “GA”), forResource(?req, ?resource), forPurpose(?req, ?pur), purposeDesc(?pur, “Treatment”), resourceName(?resource, “GeneticTestResults”), hasResponse(?req, ?res), responseLevel(?res, “Federal”), canOverride(?res, true), hasResponse(?req, ?resst), responseLevel(?resst, “State”), oblName(?obl, “ConsentRequired”), clauseName(?clause, “GAGeneticConsent”) -> isAllowed(?resst, true), canOverride(?resst, false), decisionSource(?resst, “GA_LAW”), hasObligation(?resst, ?obl), hasClause(?resst, ?clause)

Once the reasoner has evaluated the rules, the workflow engine will retrieve the Response, Obligation and Clauses instances through Java API calls to Protégé in order to enforce the results. The first part of the enforcement determines if access to the requested resource is allowed or denied. In order to consolidate the responses into one answer, first the Federal response is checked and, if an override is permitted, the state level is evaluated followed by the organizational level. If the consolidated response is determined to be a denial, then the EMR workflow ends with a message and information on the law or policy that generated the denial is provided. If the consolidated response is to allow the requested

Figure 10. Outcome of the decision of accessing genetic data using Pellet reasoner



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

access, the workflow displays information on the required obligations and requests acceptance to these conditions for data access. If consent is required, the applicable genetic privacy consent form will be retrieved for granting consent by legal consent giver. The workflow ends with access decision being provided to the requested genetic data.

Finally, the authors describe security issues, which are important considerations for any EMRs:

- **Access Control:** The medical team as a whole provides the required services to a patient who visits the medical center, from acceptance of a patient to the end of the treatment at the facility. Each team member plays a designated role in providing care with a set of assigned duties that are choreographed with each other, forming workflows. The team together provides the care planned for the patient. The authors used a role-based access control model to provide confidentiality.

Furthermore, enforced informed treatment consent and privacy consent can be viewed as more complex access controls with more complex rules.

- **Accountability:** To monitor the quality of care and be consistent with continuous improvements, an EMR system must enable auditing capabilities. HIPAA requires logging all PHI requests and the system actions for auditing. Authors' workflow-enforced EMR system with consent management allows the quality care team to review both procedures and outcomes from workflow logs and EMR system logs and consent logs, which provide an audit trail that satisfies accountability requirements.

CONCLUSION

Adding an executable consent-enforced service into workflow-based EMR systems to manage informed consent at runtime includes not only all benefits provided by workflow enforced EMR systems (Yu, & Wijesekera, 2013), but also provides significant benefits to medical practitioners and patients by reducing medical malpractice and potential medical treatment errors caused by missing informed consents (Yu, Wijesekera, & Costa, 2014). This work also improves the patient-caregiver relationship, risk management, decreases malpractice costs, enhances audit capabilities and fosters continuous care process improvement. Another advantage of authors' approach is the protection of patients' privacy by authors' EMR system. Additionally, this system can accommodate changes to policies and standards.

Solving the new consent management challenges in the area of genetic service, authors' approach allowed a single consent management system to handle different consent services based on the procedures' purposes. Authors' approach stores all genetic consents in the EMR system. Gaining consents and dealing with exceptions are recorded in the workflow management system. Thus, these records are readily available for quality of care audits and reviews.

Finally, using ontological techniques in a consent management system and creating a consent ontology enable keeping current of each State's evolving consent laws. Failure to track consent law changes closely and in near-real time is a sure recipe for failure.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Authors' work introduces an inspiring framework to extend existing EMR systems to avoid treatment errors caused by deviation from standardized treatment workflow and potential breach of privacy, or "psychosocial" harms to the individuals, as well, the many serious negatives that flow from lack of proper, informed consent.

Authors' ongoing work will expand this EMR system to automatically generate required consent rules from revised or newly enacted laws so that the operational EMR quickly reflect these changes, to allow patients to revoke consents and to appoint or re-appoint consent holders. This research path also includes further developing the evaluation rule repository to cover other more specific treatment scenarios.

KEY TERMS AND DEFINITIONS

Consent Ontology: An ontology of consent.
Electronic Medical Record (EMR) System: An electronic system that manages medical data.
Genetic Counseling: Counseling related to genetic issues.
Genetic Services: A set of services that generates or uses genetic data.
Medical Informed Consent: A decision and permission to perform a procedure in medicine.
Participating Research Consent: A decision and permission to participate in medical research.
Privacy Consent: A decision and permission to use and disclose information.
The Health Insurance Portability and Accountability Act (HIPAA): The federal laws to protect patients' PHI for covered entities.
Treatment Consent: A decision and permission to treat medically.
Workflow Management: A management system for executing workflows.

Chapter 62
Towards User Authentication Requirements for Mobile Computing

Yaira K. Rivera Sánchez
University of Connecticut, USA

Steven A. Demurjian
University of Connecticut, USA

ABSTRACT

The emergence and ubiquity of mobile computing has placed powerful capabilities in one's hand providing a wide range of applications such as email, calendar, photos, browsers, social network, communication, shopping, health and fitness, games etc., which were once restricted to traditional platforms. Such applications on a single mobile device raise critical security issues related to managing identity, re-authenticating users that stay active for long periods of time, protecting sensitive PII and PHI against access and misuse, insuring secure transactions, and protecting the physical device. This chapter explores user authentication requirements for mobile computing by: evaluating alternative user authentication requirements in order to make recommendations on their usage in authentication; identifying authentication methods used in mobile healthcare applications; and proposing a set of requirements for user authentication to handle the situation when a user seeks to be securely authenticated across a set of applications that are placed into context within a framework.

INTRODUCTION

Mobile computing platforms have greatly increased in the marketplace. By the end of 2013, globally, 6% of the population owned a tablet and 22% owned a smartphone (Jeggenstuen, 2013). In the United States, by the end of 2014, there was a 63.5% penetration rate (eMarketer, 2013). Such growth leads to the reduction of traditional desktop and laptop sales (Gartner, 2014). As individuals rapidly change the ways they access data and information, there is a profound impact on the way that users must be

authorized and authenticated. Accessing data and executing apps on a mobile platform is substantially more dynamic than traditional computing on laptops and desktops. A mobile device user may have a myriad of open applications including email accounts (corporate, Gmail, yahoo, etc.), browsers, social network apps (Facebook, Twitter, LinkedIn, etc.), communication apps (Skype, Snapchat, SMS, etc.), shopping apps (Amazon, JCPenney, Walgreens, etc.), health and fitness apps (CVS Health, Microsoft HealthVault, MyQuest, etc.), games, etc. In such a setting, users are often logged onto and authenticated to all of these apps simultaneously and move among them throughout the day, providing them with the ability to store, exchange, and view both personally identifiable information (PII) and personal health information (PHI). The drawback is the need for users to be authenticated on each individual application and often re-authenticated during sessions that can last for long periods of time. The challenge in this situation is to deliver a means for user authentication for mobile computing in order to provide a more seamless experience for users.

As a result, for a user to manage his/her personal information in several domains, we need to find a secure means while maintaining their privacy. Therefore, the challenge is a need to provide a cohesive means of user authentication that can cross all of these different domain boundaries with high availability of data, while still providing the necessary level of security and privacy. Our approach to such a challenge is to identify existing frameworks, standards, types of access control, and authentication methods that can identify requirements for user authentication for mobile devices and applications that would then be able to interact and share information with other mobile, cloud, and computing applications for a given domain. In the case of healthcare, health information technology (HIT) systems have emerged (e.g., electronic medical records (EMRs), practice management systems (PMSs) and personal health records (PHRs)), due to the American Recovery and Reinvestment Act (ARRA) of 2009 (U.S. Department of Education, 2010), all which must adhere to the Health Insurance Portability and Accountability Act (HIPAA) (HHS.gov, 2013) for the security, availability, transmission, and release of a patient's medical information. Note that an EMR is the primary means for making patient information electronically available to medical providers for healthcare. This wide adoption of HIT allows individuals to track their own health data independent of their provider. For example, the fitness market has exploded with wearable fitness devices that link to mobile applications, e.g., Apple has a new HealthKit app (Apple iOS 9, 2014) that utilizes a dashboard to manage health and fitness data while Google has the Fit fitness tracker (Real IT Experts, 2013). Both have pushed strongly into the smartwatch market to track activity, heart rate, blood pressure, etc. (Kelly, 2014) and these and other apps must be able to securely exchange HIPAA protected information back and forth with mobile applications for both patients and medical providers. In such a scenario, the same information is stored in different ways in diverse HIT systems and other applications, and this information must be staged back and forth to a mobile device and be protected from theft and misuse while simultaneously allowing a user to share the data with authorized medical providers and others, such as family members.

In support of this, the main focus of this work is to identify the requirements and capabilities that are needed to support user authentication that allows a person utilizing a mobile device to gain access to protected information from multiple input sources (cloud services, other users, other apps, etc.), with the health care domain as a test-bed. This chapter identifies and explains user authentication requirements for mobile computing that offers a high degree of security assurance and that is able to facilitate the aforementioned discussion on the access, usage, and sharing of information among users. In order to support user authentication in mobile computing there are key security concepts to be considered. In terms of *credentials*, mobile applications have long used passwords as a main means of access, with recent OS

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

mobile operating system updates providing support for fingerprints and the proposal of single-sign on in a mobile setting (Yu, Wang, & Mu, 2012). *Risk-based authentication* (Abe, Itoh, & Takahashi, 2007) offers the potential to assess the risk via a geographic location log, the app being accessed, the time of day a user typically logs into the app, a device's IP address, etc.; such geographic information may be useful when users stay logged on for long periods of time. With respect to *biometrics*, one approach has proposed the tracking of graphical touches on a mobile device's screen (pressure, intensity, and touch) as a means to authenticate a user's identity (Zhao, Feng, & Shi, 2013). Other techniques include: *multi-factor authentication* (Bhargav-Spantzel et al., 2007), which would allow a mobile device to authenticate using something that a user knows (e.g., username/password, PIN, image, etc.), possesses (e.g., token or certificate), or is (e.g., fingerprint, retina scan, etc.); *user profiling* (Jeong & Choi, 2012), which discovers patterns in large quantities to establish if the user is who he/she says he/she is by tracking the way that he/she utilizes his/her mobile device, and deviations of behavior may indicate a problem; and, utilizing keystroke in conjunction with handwriting-based analysis (also multi-factor) to achieve a higher degree of confidence in the authentication process and user identity (Trojahn & Ortmeier, 2013).

The chapter explores user authentication requirements for mobile computing, accompanied by a case study of its usage for the aforementioned health care scenario by: investigating and presenting work by researchers in the area; by identifying what has been done in security for authentication, in general, and for the mobile case, to identify gaps of work that exist in trying to streamline the authentication process; by examining various mobile applications in the healthcare domain to understand their authentication approaches; by identifying and discussing limitations of the varied authentication approaches with regards to the sharing and exchange of information; and, by analyzing the approaches in terms of what they utilize in order to do user authentication. The end result of the chapter is an explanation and identification of user authentication requirements for mobile devices and applications that must securely interact with numerous devices and systems to support security assurance for a domain, which in our case will be demonstrated in healthcare.

The remainder of this chapter has 6 sections. In the *Background and Motivation* section, we state why healthcare has been chosen as a test bed, and review HIT systems and applications including Electronic Medical Records (EMRs) and Personal Health Records (PHRs) along with a scenario on futuristic needs in terms of secure access to health data. The *Security Concepts Impacting Mobile Authentication* section explores the security concepts needed to understand the different components of user authentication, focusing on three main authentication factors: knowledge factors, possession factors, and inherence factors. The *Authentication in Mobile Healthcare Applications* section presents several existing mobile healthcare applications, focusing on their respective methods of authentication to provide access to a user. The *Authentication Requirements in Mobile Computing* section identifies and discusses a set of five requirements: long-term mobile application sessions; beyond two-factor authentication; advanced threats and hacking; multiple and simultaneous authentication; and, lost or stolen device. These five requirements are then placed into context through the presentation of a framework that demonstrates their interactions. Then, the *Future Trends* section identifies approaches that are emerging and may impact authentication, such as: the increase of multi-factor authentication in mobile devices (from both Google and Apple) (Beranek, 2014), the concept of continuous authentication (Schaffer, 2015), new approaches for mobile security (like VIP Access (Symantec, 2013)), and new mobile operating systems for mobile devices (e.g., Firefox OS, Tizen, and Ubuntu) (Boxall, 2013). Finally, the *Conclusion* section finishes this chapter.

BACKGROUND AND MOTIVATION

As previously stated, we will focus on identifying and explaining user authentication requirements utilizing a healthcare setting as base. We chose the healthcare domain since improper disclosure of data can have serious impact on patients, which can include personal embarrassment, prejudice, ostracization from family and community groups, death, as well as issues with insurability (Rindfleisch, 1997). Moreover, a report made by Ponemon Institute (2009) revealed that the cost of data breaches in the majority of the industries (e.g. communications, retail) per lost or stolen record averages approximately $154 per record (see Figure 1) (Ponemon Institute, 2015) . Nevertheless, in the healthcare industry, the cost per lost or stolen record could be as high as $363 per record, which is more than double the cost to manage a data breach in other industries. We consider that utilizing a healthcare setting as basis is an appropriate and informative manner to present the main focus of the chapter; note that the proposed requirements can be applied to other domains as well.

To start the discussion, we define various concepts that will appear frequently throughout the chapter and present a case scenario to have an idea of how security can be applied to these concepts. We divide the presentation into two parts. First, we review health information technology (HIT) systems utilized by patients, medical providers, hospitals, etc. Then, we provide a plausible, and at times, futuristic scenario for the usage of mobile devices and their applications, in general, and as related to health care.

Figure 1. Per capita cost by industry classification.

Health IT Systems Concepts

To highlight the need for authentication, consider the usage and management of personal health information in the healthcare domain. In the last several years, various HIT systems have emerged such as: electronic health records (EHRs), practice management systems (PMSs) and personal health records (PHRs) (Rouse, 2015). Such automated and interoperable systems are utilized to help reduce errors and lower costs, in comparison to paper-based systems. An EHR contains health information about an individual patient, which can be shared throughout different healthcare settings (Stricker, 2010). Such data can include the demographics, medical history, and allergies of the patient. A PMS can be defined as applications and tools utilized in health care institutions in order to keep track of all the operations these do such as patient billing and medical data processing (Codjia, 2010). Finally, we have electronic medical records (EMRs), which are mainly utilized by organizations that deliver care (e.g. hospitals and clinics) to manage records. Usually, the terms EHR and EMR are utilized interchangeably.

The emergence of the systems described above and of other HIT systems is mostly due to the American Recovery and Reinvestment Act (ARRA) of 2009 (U.S. Department of Education, 2010) to assist the United States economy to recuperate from an economic recession by allocating $787 billion to different areas, with $150 billion to healthcare industry, of which $36 billion was allocated to states to focus on doing HIT adoption including EMRs, PHRs, and Health Information Exchange (HIE). All of the systems must adhere to the Health Insurance Portability and Accountability Act (HIPAA) for the security, availability, transmission, and release of a patient's medical information. Also, in order for practitioners to obtain incentives for implementing EHRs in their medical offices, they must follow several requirements. These are described under the Meaningful Use stage 1 and stage 2 criteria (CMS.gov, 2015). Meaningful Use Criteria are utilized to certify the capabilities of EHRs in order to improve the quality, safety, and efficiency of care, to engage patients in the care process, and to maintain privacy and security of patient health data. EHRs and EMRs in the United States are required to meet Stage 2; Stage 3 objectives were recently released by Centers for Medicare and Medicaid (CMS) (Centers for Medicare & Medicaid Services, 2015). This wide adoption of HIT allows individuals to track their own health data independent of their provider. In addition to the Health IT systems described above, there exist many mobile applications that can be utilized to track a patient's well being, to manage their health data, among many other features. Also, the fitness market has exploded with wearable devices that link to mobile applications, e.g., Apple has a new HealthKit app (Apple iOS 9, 2014) that utilizes a dashboard to manage health and fitness data while Google has the Fit fitness tracker (Real IT Experts, 2013). Both have pushed strongly into the smartwatch market to track activity, heart rate, blood pressure, etc. (Kelly, 2014). As more applications store healthcare data in different systems, it becomes difficult for users to obtain their data seamlessly. As a result, we are faced with numerous issues for user authentication for mobile applications that must be addressed for the user to access his/her data in a more secure and seamless way.

Futuristic Case Scenario

Consider that accessing data and executing apps on a mobile platform is substantially more dynamic than traditional computing on laptops and desktops. A mobile device user may have a myriad of open applications including email accounts (corporate, Gmail, Yahoo Mail, Hotmail, etc.), browsers (Chrome, Safari, Opera, Firefox, etc.), financial management apps (banking, insurance, investment, etc.), social

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

network apps (Facebook, Twitter, Instagram, LinkedIn), communication apps (Skype, Snapchat, SMS, etc.), shopping apps (Amazon, Barnes & Noble, JCPenney, Home Depot, Walmart, etc.), loyalty programs to encourage product usage (Starbucks, Dunkin Donuts, eBates, etc.), health and fitness apps (CVS Health, Microsoft HealthVault, MyQuest, Apple Healthkit, Google Fit, Fitbit, etc.), video-streaming (YouTube, Netflix, HBO GO, Hulu, Vudu, etc.), games, etc. In such a setting, users are often logged onto and regularly stay authenticated to all of these apps simultaneously and move among them throughout the day keeping sessions open (logons active) for long periods of time, providing them with the ability to store, exchange, and view information that ranges from the least confidential (video streaming) to sensitive personal information (PII and PHI). The drawback is the need for users to be authenticated on each individual application and often re-authenticated during sessions that can last for long periods of time. Therefore, one of the challenges in this scenario is to provide a means for identifying and explaining user authentication requirements for mobile computing in order to provide a more seamless experience for users.

Suppose we have a set of IT applications, systems, and databases for a particular domain, and there will be mobile applications for different classes of users that are interested in both reading/writing data in one or more of these IT Apps, Systems, DBs (ITASDB). Each of the ITASDB has some sort of public API or cloud services that facilitate access and usage. For example in the case of health care, there would be cloud computing services to facilitate access to EHRs, PHRs, pharmacy systems, imaging and testing laboratory results, etc. What unique type of infrastructure would be necessary to allow a mobile application to easily interact with one or more ITASDB via cloud services where what they interact with can shrink and grow over time? What do we have to do in order to allow mobile apps (which may be the user or may be the app itself) to register in such a way as to get access to ITASDB initially and then change over time? And once registered, can they easily get access to cloud services in order to perform the appropriate and relevant read/write operations? In a health care scenario, it would be reasonable in the very near future for a person to manage medical and fitness information to: get information from HIT systems, fitness apps, etc., for a complete integrated view of health and personal data; and, share information from the mobile applications to various stakeholders such as family members (elder care), personal trainers or nutritionists, and medical providers.

SECURITY CONCEPTS IMPACTING MOBILE AUTHENTICATION

This section reviews several key security concepts to allow the reader to understand their usage and impact in regards to authentication. We focus on *user authentication*, which is the process that is performed to determine if a user is whom he/she says. There are three main authentication factors that we emphasize, which can be utilized to verify a user's identity: knowledge factors, possession factors, and inherence factors. Table 1 summarizes the factors in terms of: definition, examples, and advantages/disadvantages. In addition, Table 1 provides information on two-factor/multi-factor authentication, which consists on the combination of two or more of the previously mentioned authentication factors.

While there has been an increase in usage of biometrics and multi-factor authentication, there has also been research and development endeavors that have identified the potential pitfalls and have proposed the inclusion of user profiling and risk-based authentication for mobile security frameworks. Recall that *user profiling* consists of discovering patterns or correlations in large quantities to establish if the user is who he/she says he/she is, where the way that a user utilizes his/her mobile device would

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Main Authentication factors.

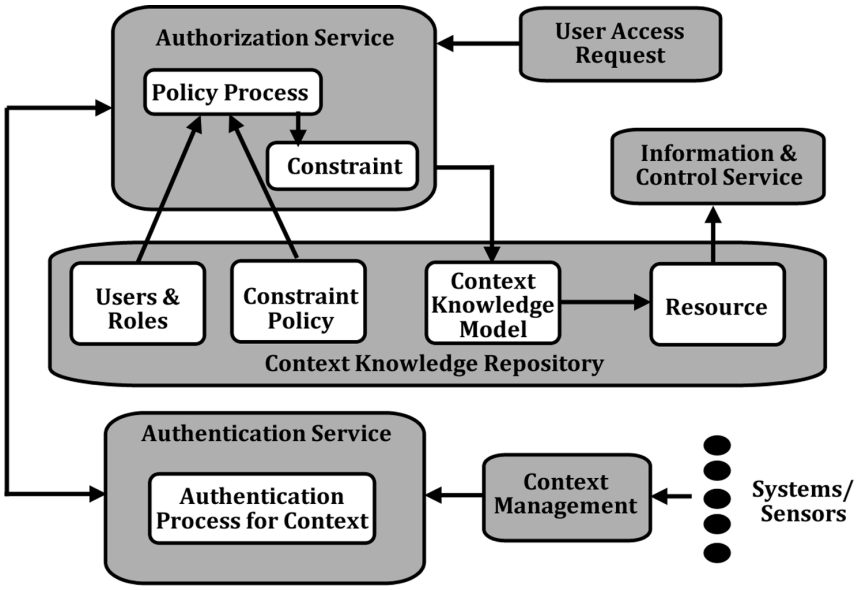
	Knowledge Factors	Possession Factors	Inherence Factors	Two-Factor/ Multi-Factor
Definition	Information that only the user knows.	Something the user has.	Things that the user is.	Combination of two (or more) authentication factors.
Examples	Username, Password, Personal Identification Number (PIN)	Tokens, Public Key Infrastructure (PKI), Digital Certificates, Digital Signatures, X.509 Certificates	Biometrics	Password along with a token
Advantages	• Low cost. • Users are very familiar with them.	Enhance security without the need of hard-to-remember passwords.	• Ideal for accessing high-security systems. • Difficult to duplicate.	• Stronger security than if you used only one factor to authenticate. • Can be inexpensive.
Disadvantages	• Subject to attack. • Could be stolen. • Often forgotten. • Vulnerable to users that set easy-to-guess passwords. • Vulnerable to users that reuse their password on multiple accounts.	• Extra cost associated with a token. • Fraudulent use could allow improper disclosure of highly sensitive data.	• Need for complex additional hardware/ software to support biometric. • Potential high cost. • Potential to misuse the collected data. • Application obtaining data on the user that was not supposed to be accessible.	• Users can disable this feature. • Could create inconvenience for the user.

be tracked, and deviations of behavior may indicate a problem. The general idea of the approach can be seen in Figure 2 taken from (Jeong & Choi, 2012), which has proposed a method to provide security for mobile resources that reside in the cloud. This process begins with the user utilizing various systems/ sensors in order to enter his/her credentials. Then, this information gets processed through the means of several policies to determine the information/resources the users are allowed to access. *Risk-based authentication* consists of having different levels of authentication in a system and depends on the level of security the data that the user is trying to access has, and the way that the system policies are set up based on a risk score threshold. For example, suppose a system has been set up with a set of security policies. If a user is in a location that he/she frequently visits with his/her smartphone and is attempting to access high-level security data, then the system will utilize a basic method of authentication (such as a username/password combination) since the user was identified properly (the risk score was low). On the other hand, if the location of the user is not recognizable by the system and neither is his/her device, the system will opt to utilize more advance methods of authentication such as multi-factor authentication (the risk score was high).

Another biometric approach is *Keystroke Dynamics-based Authentication (KDA)* (Hwang, Cho, & Park, 2009; Changa, Tsaib, & Lina, 2012), which is a behavioral biometrics and can be seen as an approach used to analyze the way that a person types text on a keyboard/touchscreen. KDA can be utilized as part of a mobile user authentication method. For example, a user is trying to get authenticated in a mobile application and for this, he/she needs to enter his/her username/password combination. In this case, in addition to verifying the correct input, the system will analyze the way that the user entered the data based on factors such as the time he/she took to enter the credentials, and any other patterns found

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Platform for Authentication service.



using the smartphone's sensors. The work of Hwang et al. (2009) evaluated the way that KDA could be utilized in mobile devices via a framework from their paper, as shown in Figure 3. The framework contains three phases: the enrollment phase, the classifier phase, and the authentication phase. In the authentication phase, the user enters his/her credentials and the keystroke pattern gets analyzed. If the distance between the prototype and the pattern is lower than an established threshold then the user is legitimate, otherwise, an impostor. An interesting effort also in the KDA seeks to offer a more generalized typing authentication based approach that leverages biometric information that can be gleaned from the actual typing habit of the user (Feng, Zhao, Carbunar, & Shi, 2013), which would be stored electronically. The approach, called Typing Authentication and Protection (TAP), has two stages, which are shown in Figure 4: at logon, there would be an analysis to match the typing with the expected pattern of the user, while, after logon, the typing behavior of a user would be continuously checked with a variation from the expected having the potential to raise an alert.

The next approach, a *voice biometric* (Authentify, 2006), is realized as a numerical representation of the sound, pattern, and rhythm of an individual's voice, and is considered to be a secure approach due to the fact that, similar to fingerprints, such patterns are unique to each individual. To use a voice biometric, a user must perform a two-step process of enrollment and authentication, as shown in Figure 5, and taken from (Li, Tian, Yang, Shi, & Zhang, 2009). When a user enrolls, his/her biometrics are stored in the database, e.g., a voiceprint for the voice biometric. At a later point in time, whenever a user attempts to access a mobile application, in order to authenticate himself/herself, he/she needs to speak a phrase. The mobile device captures this phrase, extracts its features (such as sound and rhythm), and tries to match these with the voice prints/features that are stored in the database for that particular user. If the features stored in the database are similar to the features obtained from the user to a certain extent (higher than a threshold), then the user can access the application, if not, then he/she will be denied access. Another

Figure 3. Three steps of the KDA framework.

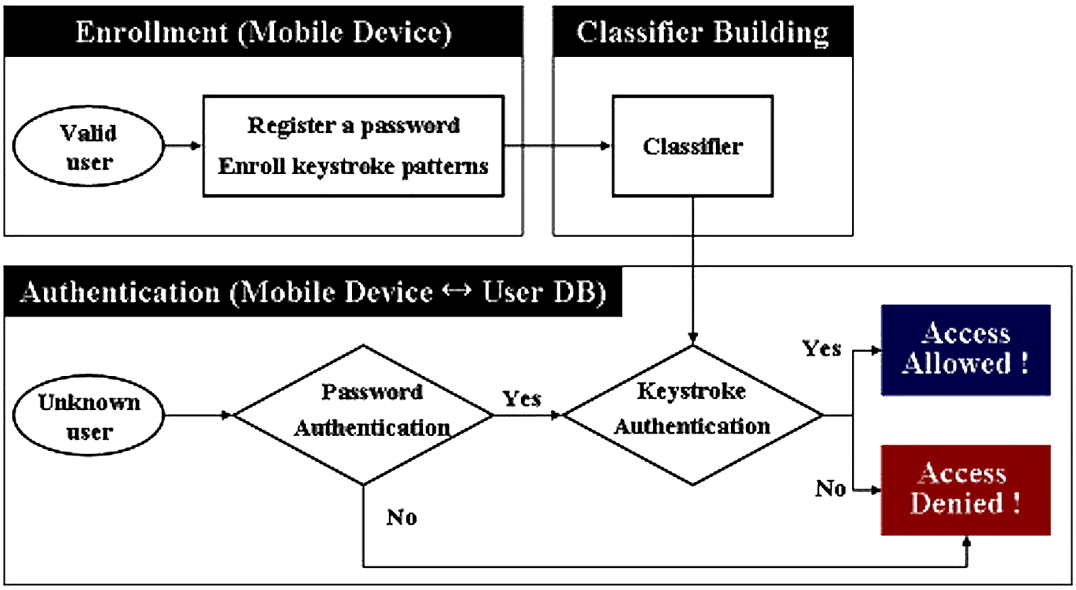

Figure 4. Two stages of the TAP framework.

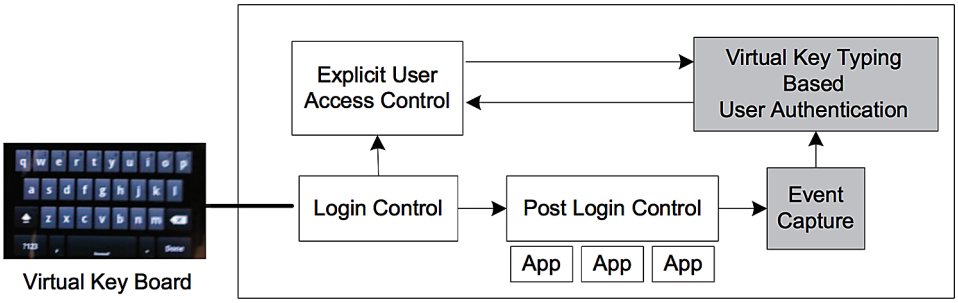

research work related to the voice biometric approach in (Baloul, Cherrier, & Rosenberger, 2012) utilizes speaker recognition techniques to create a challenge-based method for mobile authentication in order to avoid security threats such as replay attacks.

Lastly, there has been an effort that considers the role of biometric when utilized within a *multi-factor authentication* context. Such a framework proposed in (Siddiqui, Abdullah, Khan, & Alghamdi, 2014) is comprised of a three-factor cloud-based user authentication method. The framework contains four phases: a registration authority phase, a smart application activation phase, a login phase, and a password phase. Authentication occurs in the login phase, where the user enters his/her username/password combination along with his/her fingerprints with the use of his/her mobile camera. Once these credentials get validated, if they are correct, then the system will send a one-time password (OTP) to the user's mobile device based on the calculation of a timestamp for further authentication. There are two ways that the system can reject the user at this point: if the timestamp sent with the OTP has an incorrect format, or if the result of the current timestamp minus the timestamp sent by the user is greater than an expected

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

interval. Otherwise, if the user entered the right OTP along with a valid timestamp, then the system will grant access to the user. This process is shown in Figure 6 as excerpted from Siddiqui et al. (2014). Another effort of note (Aronowitz et al., 2014) is very ambitious in combining a policy manager along with three different and sophisticated biometric techniques in one multi-model approach: *chirography*, which is based on an analysis of the touch of a user on a mobile device screen that is combined with both facial and voice recognition. The block diagram for the approach is shown in Figure 7.

AUTHENTICATION IN MOBILE HEALTHCARE APPLICATIONS

This section presents several mobile healthcare applications focusing on the respective methods of authentication to provide access to a user. The objective of this section is to evaluate the authentication

Figure 5. Enroll model and matching of biometric system

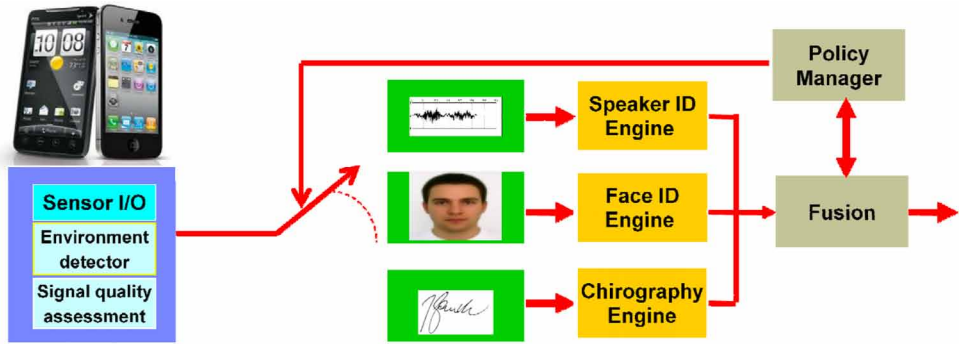
Figure 7. Multi-modal biometrics authentication system



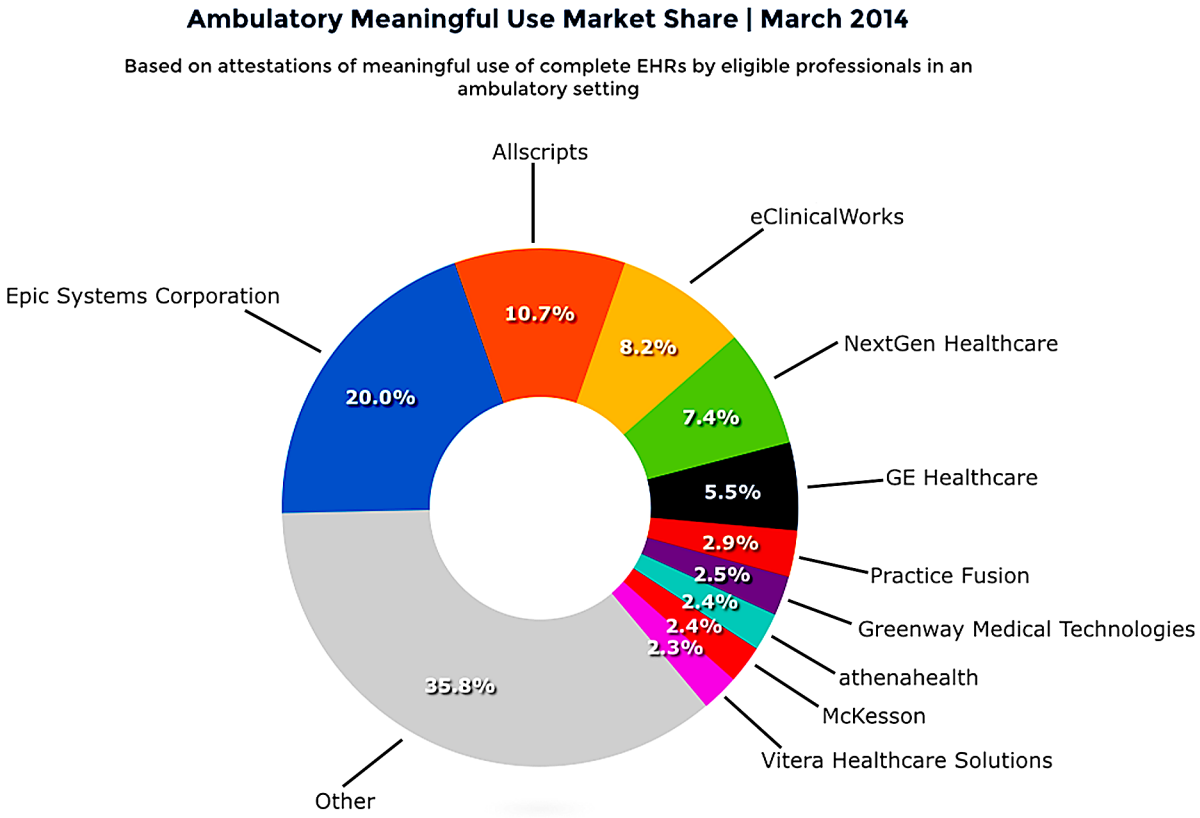
methods mobile healthcare applications utilize. The HIT market, in particular regarding electronic health records (EHRs), is diverse and extensive, with a reported 179 vendors supplying EHRs to 4,634 hospitals (Health IT, 2015) but is dominated by 10 products (McCormack, 2014), as shown in Figure 8. For the purposes of this paper, we focus on the "Top Ranked Virtualized & Native Mobile EHR Applications" (Black Book Market Research firm, 2014). From this list of top EHRs, we have selected the following representative set that was chosen based on their usage of advanced authentication techniques: drchrono, Allscripts Wand for Professional EHR, Kareo, Practice Fusion, and Greenway Healthcare PrimeSUITE.

The EHR drchrono (drchrono Security, 2015) is a collection of web-based, iPad, and Android tools with strong security capabilities that allow medical providers to perform tasks associated with viewing medications, allergies, and chart history of their patients and can be utilized to add patients, schedule appointments, among other features. In addition, patients that arrive at the medical practice can be given iPads for patient check-in, replacing the clipboards that are historically utilized. drchrono is HIPAA compliant (Online Tech, 2011) and meets industry-standard security practices, and authenticates users by utilizing a username/password combination along with a code that the user has to enter every time he/she logs in. This achieves *two-factor authentication* via the Authy app (Authy, 2015), where a combination of two factors is employed: a username/password (what a user knows) in conjunction with the mobile device itself (what a user has). Such a code is sent to the user's mobile phone and changes every 20 seconds. The app for drchrono also utilizes the auto-logoff feature, which automatically logs off users that are logged into the account but have been inactive for a certain period of time. In addition to this, drchrono utilizes a digital certificate in order to verify that the user is authenticated correctly and is in the correct site. Two-factor authentication is one of the key technologies that can provide an additional layer of protection to sensitive health care data (drchrono, 2013). Note that drchrono now offers fingerprint scanning on Apple mobile platforms to further control access to information. Lastly, there is the mobile application "drchrono EMR/ EHR" (drchrono Inc, 2015) for iOS platforms. The various drchrono products and applications are all certified stage 1 Meaningful Use criteria. Programmatically, drchrono provides a rich API and SDK to allow third party applications to be built that leverage the security capabilities while offering new ways to access health information.

The second EHR, Allscripts Wand for Professional EHR (Allscripts, 2014), provides a robust EHR with mobile anytime access, clinical decision support, and to track for patients during a visit, health reminders, medication management, potential allergies/interactions, ordering labs, procedures, medications, and so on. From a mobile perspective, Allscripts Wand offers a mobile client for both iPads and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Market Share of EHRs



iPhones, providing the medical provider with secure access to the Allscripts Professional EHR from remote locations. The corresponding Allscripts Remote app offers similar capabilities for Android devices. Like drchrono, Allscripts offers the ability for biometric two-factor compliant authentication through the BIO-key company (BIO-key, 2013) augmenting the username/password combination with fingerprint scanning and recognition. Allscripts Wand is intended to give medical providers flexibility through the usage of an iPad that travels with the physician as he/she moves around the medical facility to check on active patients, prep for new patients, and handle access when outside of the medical practice (nights, weekends, etc.).

The third EHR is Kareo (2015), which is available as a full-featured web-based and cloud-based solution whose 2014 edition is certified for Meaningful Use stages 1 and 2. Kareo provides both web-based, and iPad and iPhone based capabilities that support: patient registration/scheduling; a dashboard for medical providers with a schedule of the day's appointments, ability to approve prescription refills, review lab results, etc.; and a patient chart, documentation, and ordering functions for the actual appointment. At this time, patients are only provided with a web-based patient portal. Kareo was designed by doctors for doctors to be intuitive and provides features such as note-taking capabilities, one-click access to a patient's chart, shortcuts for the top 120 primary care conditions, while ensuring that all of the clinical information presented in the EHR is reliable and can be accessed fast. As for security features, Kareo has automatic backups of data and it provides customers with the option for them to setup their own password complexity policy for the patient portal. This meets PHI and HIPAA compliance and also allows

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

permissions to be set on a patient-by-patient basis to protect patient privacy. In addition, if a user tries to login many times and is unsuccessful, the Kareo patient portal will lock out the user's account until administrative action can be taken. At the present time, Kareo does not support two-factor authentication.

The fourth EHR, Practice Fusion, like Kareo, is a web-based cloud computing solution that is both web-based and iPad-based, but not currently supporting iPhone and Android. Practice Fusion has features such as: electronic prescribing, medical charting, scheduling, unlimited support, a personal health record for patients (Practice Fusion, 2009), and is HIPAA and Meaningful Use stage 1 and 2 compliant (Practice Fusion, 2013). According to Practice Fusion, the EHR contains solid user authentication and utilizes user login time windows to determine when a user logged on to the system, automatically logs out the user if he/she has not been utilizing the application for a certain amount of time, and enforces the use of strong login passwords. Also, Practice Fusion contains well-defined user roles and access levels. In addition to this, the data that belongs to each of the practices is kept separate for each organization in order to maintain privacy and confidentiality. The data sent between the users and the Practice Fusion servers is encrypted during transmission using SSL/HTTPS, and utilizes ultra-secure tokens (64-byte hexadecimal strings). For the newer iPads, fingerprint authentication for enabling the mobile device is supported, but the technology has not been integrated as a two-factor authentication with Practice Fusion.

The final EHR, Greenway Health PrimeSUITE (Greenway Health, 2015), is also a web-based and cloud-based solution that is HIPAA and Meaningful Use stage 1 and 2 compliant. In terms of mobile support, PrimeMOBILE offers the ability for medical providers to utilize Apple, Android, or Windows devices, making it among the most platform-versatile EHRs. However, the patient portal that is provided, PrimePATIENT, is web-based. Note that while Greenway PrimeSUITE does not yet support two-factor authentication, third party hosting vendors can provide that capability (iTELAGEN Healthcare IT Redefined, 2015). In fact, one vendor offers PrimeSUITE access through any computer or mobile platform/device that provides tunneled SSL as well as two-factor authentication (MDS Medical, 2014).

The mobile healthcare applications we chose as part of our analysis and, that are within the top ten EHRs, provide different security mechanisms to authenticate users. Table 2 depicts some of the main factors we are evaluating to consider whether an application is highly secure or not. These factors are: the authentication mechanism used, the policies/methods utilized to keep the credentials secure and, if it contains an auto log off feature, which we consider its crucial in environments where many users access a mobile application on the same mobile device. In the Background and Motivation section, we discussed the three main authentication factors and the way that two or more of these could be combined in order to have a two-factor/multi-factor authentication approach. Even though this type of mechanism is becoming increasingly popular in systems that contain highly sensitive data, only two of the EHRs evaluated (drchrono and Allscripts Wand for Professional EHR) contain this feature (note that Greenway Healthcare PrimeSUITE relies on third-party vendors to have two-factor authentication). The authentication method commonly utilized in the evaluated mobile applications is the username/password combination mechanism. While some of the EHRs utilize this mechanism in combination with another authentication mechanism to provide two-factor authentication (drchrono and Allscripts Wand for Professional EHR); others do not provide a second authentication factor and provide password policies (Kareo) or enforce the use of strong passwords (Practice Fusion) instead. We can also notice that biometric methods are utilized in three of the EHRs we presented (drchrono, Allscripts Professional, PrimeSUITE). What all the EHRs had in common in terms of securing the authentication process was the fact that all of them include the auto log off feature. This is strongly required in mobile applications that contain highly sensitive data since it logs out the user after a certain period of inactivity in the session.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Main Authentication features in evaluated mobile applications

	Username/ Password	Password Enforcement/ Policy	Digital Certificates	Biometric Authentication	Two-factor Authentication	Automatic log off
drchrono	✓	✓	✓	✓	✓	✓
Allscripts Wand for Professional EHR	✓			✓	✓	✓
Kareo	✓	✓				✓
Practice Fusion	✓	✓				✓
Greenway Healthcare PrimeSUITE	✓			✓	✓	✓

While all the evaluated EHRs contain authentication mechanisms to provide a secure mobile application for users, each one of them has drawbacks. For instance, all of these have an option that involves a username/password combination. Some have mechanisms to ensure that the password is strong (drchrono, Kareo, and Practice Fusion), while others suggest users to have a strong password but do not enforce this requirement (Allscripts Professional and PrimeSUITE). In addition, the EHRs that enforce passwords do not offer two-factor authentication. Thus, if the user's password is guessed, then there is no other method to ensure that the user who entered the password is who he/she says he/she is.

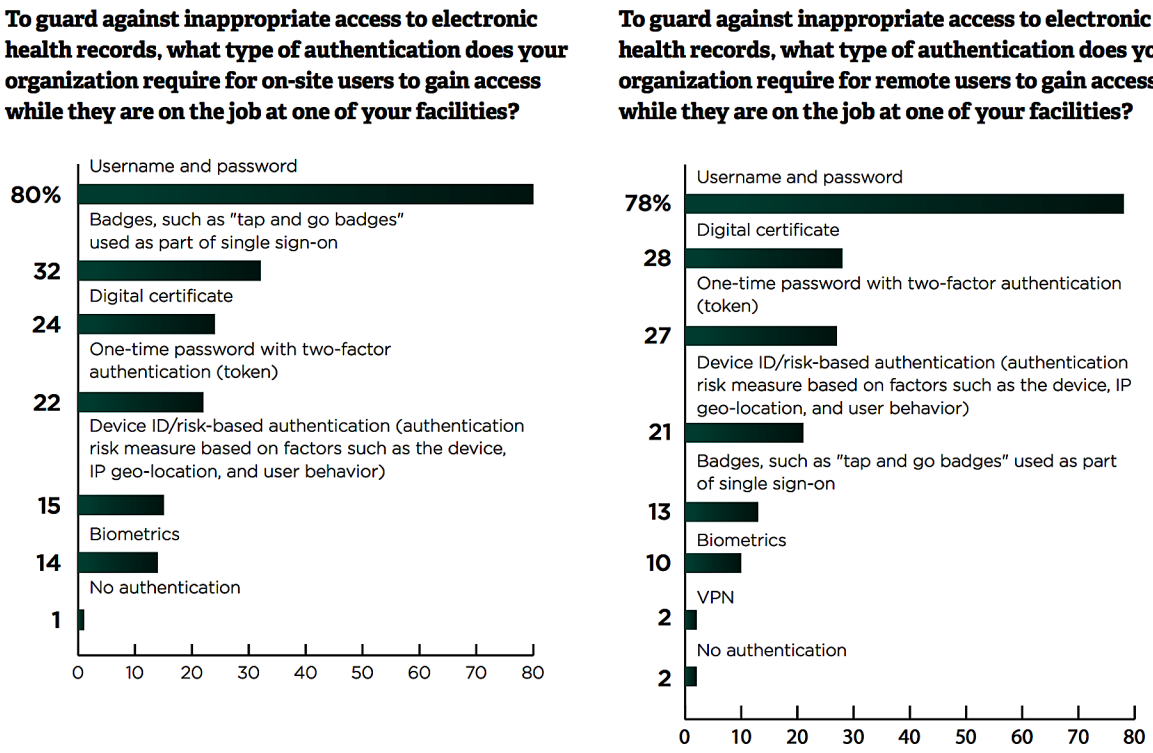
To complete the discussion, we highlight the *Healthcare Information Today* survey (Information Security Media Group, 2015), which contains answers to various questions on the way that healthcare entities manage regulatory compliance to the steps that are been done in order to secure health data. One question of particular note is relevant to the main purpose of this chapter, related to the authentication mechanisms healthcare organizations utilize to protect EHRs. The left side of Figure 9 shows (in percentages) what are the authentication mechanisms users utilize when they are inside the healthcare facility they work in and, the right side of Figure 9 shows (in percentages) what are the authentication mechanisms users utilize when they are outside the healthcare facility they work in and need to access EHRs. By looking at the results shown on Figure 9, we can see that the dominant method to secure EHR data is a username/password combination while methods that can be more suitable to protect this data (e.g. two-factor authentication and biometrics) are not generally used.

AUTHENTICATION REQUIREMENTS IN MOBILE COMPUTING

The objective of this chapter is to enumerate and explore the requirements for user authentication as it relates to mobile computing. We have identified some requirements on the critical areas that have to be addressed in order to achieve secure user authentication in support of the diverse needs of mobile computing, particularly as related to high security concern areas such as health care. In order to determine these, we took into consideration the limitations of the evaluated mobile applications in the previous section as well as the concerns expressed in the work presented by other researchers and that we briefly discussed throughout the chapter. There are five specific requirements identified to date, including: long-term mobile application sessions; beyond two-factor authentication; advanced threats and hacking;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Dominant user authentication methods in EHRs



multiple and simultaneous authentication; and, lost or stolen device. Each is reviewed in turn. To complete the discussion, these five requirements are juxtaposed into a framework that demonstrates the way that the requirements interact with one another via a three-phase process of device security, authentication process, and application security.

The first requirement, *long-term mobile application sessions*, deals with the unique nature of mobile applications in terms of the length and duration of a session under the control of a username/password logon. When one starts a session with a mobile app, and provides his/her username/password credentials, most apps assume that the user wants to store that information within the app so that subsequent logons no longer require providing that information. Some applications that involve payment or other charges require the user to re-authenticate often with just a password re-entry in order for the purchase to proceed or even just an acknowledgement to use a particular account, which utilizes the stored prior username/password combination. In fact, many applications retain the username/password information for long periods of time, and even remember this information after the application is closed and reopened. From a mobile authentication perspective, this could be a potential problem, particularly if a device is lost or stolen. Suppose that a user has a pharmacy app, a personal health record app (e.g., Microsoft HealthVault or Web MD), and a patient portal app (e.g., the Kareo patient portal from the prior section), all of which have HIPAA sensitive information on current prescriptions (pharmacy app), personal health data (PHR), and pending appointments or ordered medical tests (portal). If these apps do not re-authenticate, then they would be vulnerable to both access to PHI as well as potential malicious misuse if the mobile device is lost or stolen. For health care and other sensitive mobile applications, there is a need for the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

long-term mobile application sessions to be curtailed in some manner, perhaps timing out the application akin to the way that sessions are terminated in browsers, or by frequent or period re-authentications. The recommendation that we make for this requirement is to suggest that health care and other sensitive mobile applications remove the long-term storage of username/password in an app, so that each time the application is closed, this information is erased.

The second requirement, *beyond two-factor authentication*, involves the need to perhaps go beyond the concept of two-factor authentication in order to arrive at an even stronger process to authenticate, particularly in regards to health care and other sensitive mobile applications. The area of multi-factor authentication is targeting the need to go beyond just two factors. One of the most interesting aspects of mobile computing is the fact that the devices continue to have more powerful processing power, high resolution, advanced cameras and features, and additional capabilities via a wide range of sensors. There is an opportunity to exploit all of these features with authentication techniques that are compute-intensive such as encryption or utilizing the camera and processing for retinal scanning/recognition or facial recognition as a means to improve the security. The recommendation that we make for this requirement is that there should be a movement towards multi-factor authentication with the intent to take advantage of the growing computing and processing capabilities of mobile devices for more secure authentication. An example of an approach that goes beyond two-factor authentication is demonstrated in Siddiqui et al. (2014) as shown in Figure 6.

The third requirement, *advanced threats and hacking*, has the need to be aware of the widespread attacks that are underway against all types of computing infrastructure across a wide range of domains. In the health care area, one of the major health insurers in the United States, the health insurer Anthem, was the target of a major cyber attack in February 2015 (Anthem, 2015) and there have also been attacks on major retailers (Target and Neiman Marcus) and financial institutions such as JP Morgan Chase (Finkle & Hosenball, 2014). In addition, in the health care domain, there was a recent attack at the Children's Hospital in Boston, MA, and such an attack has the potential to directly impact patient care (Farrell & Wan, 2014). Further, there is a major assessment at the national level that has been undertaken (Clapper, 2013). There has also been a marked increase in mobile cyber attacks (Ruggiero & Foote, 2011; RT, 2014). In terms of mobile computing, these advanced threats and hacking have the potential to disrupt the way that we utilize mobile devices in all of our activities, with a clear impact on health, e-tailing, and financial applications. These attacks are nefarious since they don't involve a direct assault on the information on a mobile device, but instead target sensitive PHI and PII that are stored in the systems mobile applications are interacting with. As a result, our recommendation for this requirement is that there needs to be a realization that the systems that mobile applications utilize be more secure for these indirect attacks. For instance, the mobile application could enforce a multi-factor authentication approach as the one mentioned in the previous requirement (Siddiqui, Abdullah, Khan, & Alghamdi, 2014)

The fourth requirement, *multiple and simultaneous authentication*, focuses on the need for user authentication, in which a user of a mobile device is attempting to access a set of related systems through a single application. For example, consider a mobile application for a patient portal for one of the medical systems in the prior section of this chapter, that allows a user to do a number of simultaneous tasks including: request a prescription refill or its status which interacts with the HIT systems of a specific pharmacy; schedule an appointment for a blood test which interacts with the HIT system at a particular testing laboratory; review past medical examinations and data such as blood pressure, cholesterol, etc., that accesses your data in the EHR of your medical provider; and, store and access fitness data stored in the HIT systems of a fitness vendor. A mobile application with such breadth requires username/password

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

authentication with multiple systems either simultaneously or in some sequence. In such a situation, does the authentication check get sent to multiple systems in parallel? Or in a sequence where it has to be successful at one system before authenticating the next system in a chain? From a mobile computing perspective, the issue is the appropriate way to handle the need for multiple HITs authentications in a simultaneous manner with the same credentials. One danger in automating such an authentication process would be that if the mobile device has been taken over (by either another user or via an attack), such a chained authentication process would mean that multiple systems accessible to the mobile application would all be vulnerable. The recommendation for this requirement is to in fact mandate that multiple and/or simultaneous authentications be severely limited, even at the expense of aggravating the end user, in order to insure that the potential exposure of PHI and PII are limited.

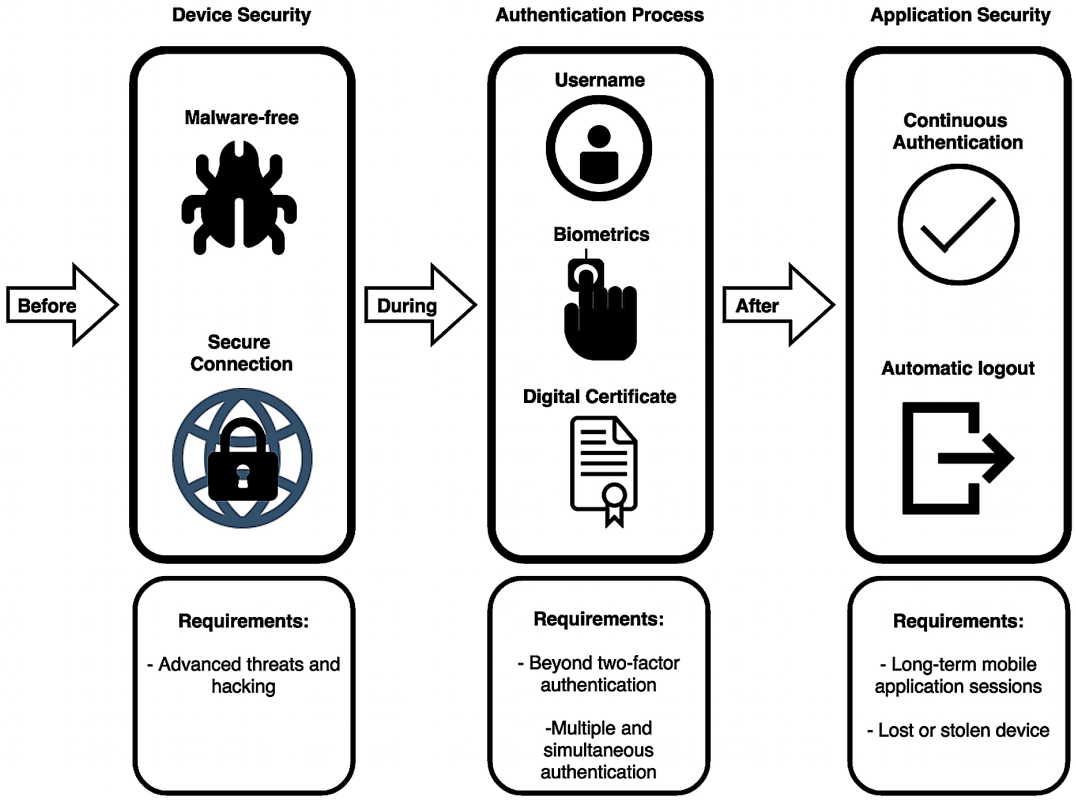
The final requirement, *lost or stolen device*, considers the case where a user's device is misplaced or stolen. This could affect many applications whose sessions are running at the time if the device does not have a strong authentication method (e.g. has an easy-to-guess pattern to unlock the device) or doesn't have an authentication method at all. For example, consider the case in which a person is utilizing his/her device to view his/her medical record and that even when the application is closed by the user, it remains in session for 10 minutes before the user is automatically logged out. If the device lacks a proper lock and the application is still running, then the person who stole the device could gain access to the user's confidential information, and maybe, obtain the permissions needed to modify or corrupt the stored PHI. This clearly indicates a strong requirement to insure that the user's private data will not be compromised in this situation. Taking this into consideration, our recommendation would be to implement a more secure mobile authentication approach to unlock a device. A research work that attempts to secure a mobile device (Sun, Zhang, Zhang, & Zhang, 2014) proposes a two-factor authentication approach, which consists of a user drawing on arbitrary regions on the touchscreen of his/her smartphone in order to unlock it, with the user being authenticated based on the geometric properties of the curves he/she drew, in addition to his/her behavioral and physiological characteristics. Our recommendation for this requirement is to consider that approach as well as to leverage other multi-factor and simultaneous approaches that that compromising PHI or PII can be mitigated when devices are lost or stolen.

The five requirements as presented in this section can be collected into a framework that can be applied to mobile applications that contain highly sensitive data to provide a secure authentication process. This is illustrated by the framework in Figure 10 which has a three phase process of device security, authentication process, and application security, shown from left to right; note that under each phase, the relevant five requirements per phase are indicated. The *device security phase* consists of the requirements utilized before user authentication takes place. In this phase, when the user opens the application and before he/she is given permission to log in, the mobile application will verify if the mobile device does not contain malware and if it's connected to a secure network (e.g., WAP or WEP connections). The device security phase satisfies the third requirement previously mentioned (*advanced threats and hacking*).

The *authentication process phase* contains the requirements that are used during the user authentication process. This phase covers the authentication process of the mobile application and consists on a secure authentication approach such as multi-factor authentication (depicted in Figure 10), which consists of the user's username, of a user's biometric trait (e.g., fingerprint, voice recognition) and, of a digital certificate that contains information about the user's device and determines if the mobile application is trusted. In addition, the authentication process phase supports the case when a mobile application connects to more than one system to retrieve information that is displayed in it, utilizing the concept of single sign-on (SSO), which consists of granting access to several systems with only one set of credentials. The

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Proposed process involving requirements



authentication process phase covers the second and the fourth requirements described (*beyond two-factor authentication* and *multiple and simultaneous authentication*). After the authentication process phase completes we need to keep verifying if the user is who he/she says he/she is. This is accomplished in the *application security phase* for the requirements that are applied when the user is authenticated. This phase handles this situation by continuously verifying the user's identity with methods such as KDA. In addition to this, the application security phase contains the automatic log off method, which consists of terminating the session of the mobile application if the user is inactive for a certain period of time or if any anomalies are detected in the user's behavior while he/she is utilizing the mobile application (e.g., change of keystroke patterns, sudden change of locations, sudden change of actions, etc.). Once the application logs out, the personal information of the user will be erased from the mobile device (if any was stored during the session). This final application security phase satisfies the first and fifth requirements described (*long-term mobile application sessions* and *lost or stolen device*). Note that the methods presented in each of the phases could be modified in order to provide different security methods.

FUTURE TRENDS

This section identifies and reviews approaches that are emerging and may impact authentication in two different areas. First, we explore the emerging technologies for biometric and multi-factor authentica-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion, as applied to mobile platforms, which includes continuous authentication in order to keep verifying the user's credentials after he/she gets authenticated and while the session is active. Then, we review the new mobile operating systems for mobile devices that include Firefox OS, Tizen, Ubuntu Touch for Mobile, and Jolla Sailfish. Over the past few years, a general consensus has coalesced towards the likely predominance in the very near future of widespread adoption and usage of biometrics authentication and multi-factor authentication for user authentication in mobile devices/applications (Whittaker, 2013; Beranek, 2014; Reisinger, 2014; Coplan, 2014; Zaibak, 2014). In addition to this, in the Background section of this chapter, we reviewed several research efforts (Siddiqui, Abdullah, Khan, & Alghamdi, 2014; Jeong & Choi, 2012; Maiorana, Campisi, González-Carballo, & Neri, 2011) that evaluate biometric and multi-factor authentication approaches and propose ways in which they could be implemented to obtain a more secure and user-friendly mobile user authentication scheme than what the market offers these days. Our objective in this section is to explore these methods in greater detail and their application to mobile computing in the future from a more technological perspective.

Biometrics methods have begun to be adopted for mobile devices. Mobile network maker Ericsson conducted a survey, which consisted on asking 100,000 people of over 40 countries what were their thoughts about biometric smartphones. Seventy-four percent of respondents said that such device would "become mainstream" throughout 2014 (Beranek, 2014). We can say this prediction became fairly true in September 2013 when Apple released the iPhone 5s, which includes a fingerprint reader with the purpose of modifying the way users authenticate to the system and/or to applications, and to improve user usability. In addition to this, in April 2014, Samsung released the Samsung Galaxy S5, which contains a fingerprint scanner as part of the security package of the mobile device. Further, on May 2014 Samsung Senior Vice President Rhee In-jong reported that his company is exploring ways to increase the utilization of biometrics in their mobile devices to incorporate "iris detection" into the smartphones that will scan a user's eye to determine if the iris matches what the device has on-file (Reisinger, 2014). Also, besides fingerprint scanning and "iris detection", other biometric factors that are currently being considered are facial recognition, voice biometric, and vein. One effort (Beranek, 2014) postulated that the biometric method that will likely be utilized on upcoming authentication schemes would be voice biometrics since it is considered to be less invasive than iris detection and fingerprint scanning. In addition, in 2014, CA technologies joined the Fast Identity Online (FIDO) Alliance in order to create a novel authentication model for mobile applications (Coplan, 2014). Instead of seeing authentication as a one-time event, this effort seeks to implement a continuous authorization system based on dynamic contextual-based intelligence. The approach is that a system needs a certain level of intelligence in order to generate a risk profile, and needs to be able to coordinate the authentication process over a session. The approach would eliminate password-based mobile authentication to be replaced by techniques that employ context and behavioral analytics, and combine multiple sources of credentials and intelligence that triangulates context against risk. Currently, the literature suggests that continuous authentication will become one of the preferred methods to do user authentication in mobile applications that contain highly sensitive data (Qualcomm, 2015; Zeltser, 2015). The main idea behind such a method is to continuously verify the user's identity in a transparent way (without interrupting the user's session) by looking at the interactions that the user has with the application. For this, we can utilize biometrics, keystroke patterns, and sensors that the smartphone contains (e.g. accelerometer). If the mobile application detects an anomaly in the context that is being evaluated, then it could ask the user to validate his/her identity or, it could close the session.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Concurrent with the aforementioned biometric authentication, there are emerging technological solutions that have begun to appear for use with mobile devices. First, the two major mobile platforms, Android and iOS, are offering multi-factor authentication (MFA) and biometrics authentication applications in order to serve as an additional method of authentication for users to gain access to some of their accounts, namely, "Google Authenticator (GA)" (Google, Inc., 2015), and "Eye Verify Biometric Data Tool" (EyeVerify LLC, 2015). All of these mobile applications are available on both Android and iOS platforms: the first one serves as a multi-factor authenticator, and the second one serves as a biometric authenticator. Basically, these mobile applications add another level of security to user accounts that support such authentication methods. In addition, there are more global approaches to mobile security that apply to multiple devices. For example, Symantec, a world leader in PC-based, cloud, and mobile security solutions offers Validation & ID Protection (VIP Access (Symantec, 2013)) for all mobile platforms (iOS, Android, Windows, Blackberry, etc.) that provides a unique security code for when logging onto participating online financial and merchandise web sites. VIP works for both mobile and desktop devices and is available on the stores for the aforementioned platforms. Similar to Symantec's approach, VASCO (2015) a leader of providing two-factor authentication and electronic signature solutions to financial institutions, has created DIGIPASS for Apps (VASCO, 2014), which is available on almost any mobile device platform (includes major platforms such as iOS, Android, Blackberry, and Windows). This is an SDK that provides enhanced security for mobile applications by allowing users to establish two-factor authentication (supports PIN and fingerprint biometrics features) and electronic signing into their mobile applications. Moreover, the SDK provides a risk-scoring feature, which consists of embedding platform and context elements into the authentication process in order to strengthen the security of the application.

Finally, we discuss several new operating systems for mobile devices. These are Firefox OS (Mozilla, 2015), Tizen (2014), Ubuntu Touch (Ubuntu, 2015), and Jolla Sailfish (Sailfish, 2015). All of these are open-source, Linux-based mobile operating systems, and they have many similarities as well as features that make them unique. Since all of these are relatively new to the mobile market, some lack detailed information on the way that user authentication is handled and have limited material on other relevant security features. Nevertheless, we provide a general idea of each system and its available security features.

Firefox OS was released in 2013 and is a Linux kernel-based open-source operating system available for smartphones, tablets and smart TVs. In terms of implementation, all of the applications are web applications; nevertheless, the application's pedigree or provenance determines in which category the web application is. The applications can be classified into three categories: *certified applications* that come preinstalled in the device; *privileged applications* that the application market has vetted meaning that they have passed through a process that checks that they cannot perform malicious actions; and *web applications*, which are basically webpages that are accessible through a mobile browser. The majority of third-party applications are in this last category and contain the least available permissions due to the fact that the marketplace does not revise the applications that fall in it. As for security, Firefox OS implements it on several layers (Gadyatskaya, Massacci, & Zhauniarovich, 2014). One of the layers provides application sandboxing using Discretionary Access Control (DAC), and another layer implements the permission system utilizing Mandatory Access Control (MAC). As a result, the application sandboxing prevents applications from having access to the data of other applications. To achieve this, each application contains a unique low-privilege user ID (UID). This approach can prevent attacks from malicious websites, but the amount of overhead that is created can be significant since for two applications that utilize the same data or share a great part of the data, each needs its own copy. As for permissions, the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

mobile OS can deny, allow, or prompt default actions. Similar to Android, an application must specify the permissions needed in a manifest file. In addition to these security features, Firefox OS enforces a content security policy, which is utilized to ensure that the content shown on the page is the one that is supposed to be there. This prevents attacks such as cross-site scripting. Moreover, the Firefox OS includes the capability of allowing an application to request two sandboxes, one for itself and one for any website it accesses, in order to prevent the application from attacks by a website's contents.

Tizen OS was released on 2012 as an ordinary Linux distribution. In terms of applications, it supports mobile website, hosted, and packaged applications. *Mobile website applications* open in a mobile device's web browser, *hosted applications* are client applications that store and access their resources on a remote server, and *packaged applications* are the ones whose have all of their resources in their package. The latter two applications can be published in the Tizen store, and packaged applications are the only ones that have access to the Device API. Similar to Firefox OS, each application contains a manifest file. However, instead of each application having a unique UID, there are only two UIDs: root and app. Therefore, a DAC mechanism cannot be utilized to separate app data (do sandboxing). As an alternative, Tizen OS utilizes the Simplified Mandatory Access Control Kernel module, which manages access to resources via simple rules in the form {subject, object, permission}. In addition to providing sandboxing, Tizen OS provides the ability for applications to interact with one another. Developers can establish private communication between their applications by utilizing application or data control mechanisms. Tizen OS refers to permissions as privileges, of which there are three types: *public privileges* which are available to all applications; *partner privileges* which are only for companies registered as trusted partners in the Tizen store; and, *platform privileges* which are only available for developers working for the Tizen consortium. The privilege level is identified by verifying the signatures that come with the application, of which there are two, a developer signature and/or distributor signature. The developer's signature can be utilized to grant additional permissions to applications that contain the same signature, and the distributor's signature is utilized to sign a system application in order to assure that the application is safe to run, and belongs to the Tizen store by default. Similar to Firefox OS, Tizen has cross-site scripting options for apps that want to restrict the sources of web content, and it can also limit the webapp navigation to a domain list by specifying such in the manifest file. Lastly, a unique security feature of Tizen OS is that the developer has the ability to encrypt the device's application resources (i.e. HTML, JavaScript) in order to protect such from plagiarism.

The next OS, Ubuntu Touch was released in October 2013, with an announcement in September 2014 that was recently released in Europe. In terms of data security for mobile applications, the Ubuntu Touch has an approach called Application Confinement (Ubuntu Developer, 2014) that makes sure that the applications only have access to the files that belong to them. In order to share content between applications, Ubuntu Touch provides a Trusted Helper service called the Content Hub that is still in development. In addition to this security feature, the OS has a trust model (Ubuntu Developer, 2013) to determine which applications can be trusted and which can't for purposes of granting permissions. The applications that are not trusted by the OS are the ones that run in a restricted sandbox, and applications that are published in their app store. These cannot access features such as user data, privileged APIs, sensitive APIs, or another application's data without the user's permission. The applications that are trusted by the OS are the ones that come installed with the device. Since these trusted applications are not under confinement, they have permissions such as: being able to access resources or data available in the user's session, and limited access to system services and data as defined by the OS. Permission to sensitive data can be granted or denied to applications published in the app store when a user is trying

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to install them. As a result, the user can be aware of which permissions the application needs to have access to and based on this, make a decision on whether to install it or not.

The last OS is Jolla Sailfish OS. Even though its release was made on November 2013, the operating system main page contains limited information related to its security features. Nevertheless, on March 2015, Jolla announced that it will be teaming up with SSH Communications in order to create a high-security version of Sailfish OS (Lomas, 2015). The version is targeted to be utilized by government officials, and for corporations that need a secure mobile solution. However, anyone who wants a more secure mobile solution for his or her personal use will also be able to acquire the product.

Finally, we note that there are several secure mobile solutions that are currently out in the marketplace. Two of these are the Blackphone (Silent Circle, 2015), and the Tor mobile operating system (O'Neill, 2014). Blackphone was launched on June 2014, and its operating system, PrivatOS, can be defined as a combination of a fortified Android operating system along with a set of applications designed to provide users absolute privacy. Tor was announced on February 2014 based on Tor's The Amnesic Incognito Live System (TAILS) approach, which is an anonymous operating system for PCs. The applications, which can be downloaded free with Tor, will provide strong anonymity to the user, and features such as encrypted voice, video, text messaging, and security features that can disable location tracking. The system will be available on stock Android and Ubuntu products.

CONCLUSION

This chapter has provided a detailed discussion of alternative user authentication methods with an aim towards identification and explanation of user authentication requirements for mobile computing, supplemented by a discussion of its potential usage in a healthcare application. In support of this work, the *Background* section reviewed the health care domain, its systems, and the usage of information, coupled with a discussion of a future potential usage of mobile devices and their applications, in general, and as related to health care. In terms of authentication, the *Security Concepts Impacting Mobile Authentication* section explained concepts such as user/password identification, PKI/certificates, biometrics, and multi-factor authentication. Using these two sections as a basis, the *Authentication in Mobile Healthcare Applications* section explored the specific authentication methods for actual health information technology systems (e.g., drchrono, Allscripts Wand for Professional EHR, Kareo, Practice Fusion, and Greenway Healthcare PrimeSUITE) that have requirements to simultaneously access and protect data. This set the stage for the discussion in the *Authentication Requirements in Mobile Computing* section, which proposed and explored five requirements (long-term mobile application sessions; beyond two-factor authentication; advanced threats and hacking; multiple and simultaneous authentication; and, lost or stolen device) that identify needed capabilities that currently transcend traditional authentication methods. These five requirements were then collected into a framework that demonstrates their interactions and had a three-phase process for: device security, authentication process, and application security. To complete the chapter, the *Future Trends* section identified approaches that are emerging and may impact authentication including continuous authentication, the increase of multi-factor authentication in mobile devices (Google and Apple), new mobile operating systems (Firefox OS, Tizen, Ubuntu, Sailfish), approaches for mobile security (like VIP Access), and secure mobile OSs (Blackphone and Tor).

KEY TERMS AND DEFINITIONS

Biometrics: Technologies utilized with the purpose of analyzing human body characteristics (e.g., fingerprints, voice patterns, facial patterns).

Chirography: New biometric method, which is based on obtaining what a user writes on a multi-touch screen with his/her finger.

Continuous User Authentication: Authentication method that continuously authenticates a user through the means of some of his/her biometric traits.

Health Information Technology (HIT) Systems: Electronic systems that are utilized with the expectation that they will lower costs, improve efficiency, and reduce errors, in addition to providing better care and services for consumers in the healthcare domain.

Inherence Factor: User authentication method based on things a user is, which can include traits of the user such as fingerprints and eye retina.

Keystroke Dynamics-Based Authentication (KDA): Behavioral biometrics approach used to analyze the way that a person types text on a keyboard/touchscreen to verify a user's credentials.

Knowledge Factor: User authentication method based on things a user knows which can include having knowledge of a phrase/pattern utilized to unlock a device.

Mobile Computing: Devices that allow people to access software/data regardless of their location.

Multi-Factor Authentication (MFA): Method that uses two or more authentication factors (knowledge factors, possession factors, and inherence factors) in order to verify if a person is who he/she says he/she is in a place, system, etc.

Possession Factor: User authentication method based on items that a user has with him/her, which can include hardware device such as tokens.

Risk-Based Authentication (RBA): Method that provides different levels of authentication in a system depending on the confidentiality of the data the user is trying to have access to, and on a risk score threshold.

User Authentication: Process done to verify if a person has access to a certain place, system, application, etc.

User Profiling: Method that consists of discovering patterns in large quantities to establish if the user is who he/she says he/she is by tracking the way that he/she utilizes his/her mobile device, and deviations of behavior may indicate a problem.

Chapter 63
Perceptions of Play:
Using Play-Doh to Enhance the Student Experience in Bioscience Higher Education

Gemma Lace-Costigan
University of Salford, UK

ABSTRACT

Playful and kinaesthetic learning approaches are used in numerous early years (birth to 5 years old) learning environments, however studies in HE STEM disciplines are uncommon. This study aimed to explore the use of Play-Doh in an undergraduate anatomy module as a method of enhancing engagement. 63 students attended the 'kinaesthetic play' lecture, where students worked in teams to make a variety of epithelial cell types using Play-Doh. Before and after the activity, students were asked to 'choose one word to describe how you feel'. Before the activity, 48.3% of responses were negative (E.g. confused, worried, childish). However, after the activity not a single negative response was recorded. 98% of students reported that they enjoyed the activity and 84% reported that the activity increased their understanding. This data suggests a utility for kinaesthetic playful practice in STEM teaching. Overcoming initial student perceptions towards alternative teaching practices is a challenge to be considered during session design.

INTRODUCTION

The concept of playful learning is well researched and has formed the foundation of early years educational teaching methods (Piaget, 1999, Kangas, 2010, Broadhead et al, 2010). Engagement of adult learners through playful practice has been demonstrated in a few studies (Rice, 2009; Nerantzi et al, 2015), however there is relatively little research into the role and potential for playful learning methods in higher education (HE), particularly in STEM subject teaching including biological and biomedical science. Defining 'play' for an adult learner is difficult but in 1999, Henricks proposed that play could be considered an experience that has intrinsic (rather than extrinsic) motives, so that someone would choose to participate in that activity for the experience of participation alone and that learning is not the primary driver of participation. Henricks also postulated that the process of play was more impor-

tant than the end result and play should involve some degree of active engagement. When students are completely captivated by a playful activity, Csikszentmihalyi (2013) proposed a state of mind called 'flow' where deeper learning can be achieved in both adults and children. Incorporating playful learning activities in adult learning environments therefore has the potential to increase learning whilst enhancing student experiences and satisfaction which has been reported to occur as a consequence of 'flow' (Csikszentmihalyi, 2013).

Learning models that incorporate kinaesthetic elements such as the VARK (visual, aural, read/write, kinaesthetic) model developed by Neil Fleming, have been well described across numerous subject disciplines (Fleming & Mills, 1992). VARK learning style assessments are still used in HE in an attempt to enable learners with the information that will allow them to make informed choices about the way they select learning materials, study and prepare for exams. Within the biological and biomedical science disciplines, students are often encouraged to contextualise their learning through kinaesthetic means such as active participation in laboratory practical experiments or anatomy dissections. 'Learning through doing' or experiential learning (described by Kolb, 2014) is therefore a common practice within STEM teaching/learning. However, the kinaesthetic learning activities used often lack a creative dimension and often involve following step by step protocols to achieve a desired end result. There are limited opportunities for creative or explorative learning within some of the common kinaesthetic activities associated with science teaching and this may restrict the amount of deeper learning that can occur. There are countless texts describing the importance of providing opportunities for creativity within learning environments (Beghetto, 2015; Cropley, 2001; Mayer, 1989). However, it is unclear if these kinds of activities would be enjoyable or beneficial to HE STEM students, particularly those studying on biological or biomedical science programmes.

The field of cognitive psychology has generated a multitude of research describing how to increase engagement and promote learning. It is known that memories are enhanced during emotional arousal (Dolcos et al, 2004) and for a long time neurobiologists have researched the cellular basis of 'emotional learning' (LeDoux, 1992). Understanding that a student is more likely to remember a specific lecture (and associated content) if an emotional response is instigated during the lecture is something that can be exploited by academics when designing teaching sessions. Historically, individual students may have been targeted with questions during traditional lectures, or asked to stand in front of peers and take part in a demonstration which would most likely trigger a fear or an 'adrenaline' response in the participating student. The activation of a fear response may induce avoidance behaviours (LeDoux, 1992) which may lead to decreased lecture attendance. Whilst this method may have been successful in promoting increased attention in lectures (and memory of them afterward), this may not always have led to positive student experiences. With mental health issues such as anxiety on the increase in undergraduate student cohorts (Williams et al, 2015), it may be time to try and promote more positive emotional responses in lectures.

There are a number of challenges posed by teaching STEM subjects, for example, having to teach large cohort numbers. The need to teach large numbers of students at any one time may restrict the kind of learning environments available for use, for example, teaching may be restricted to the use of large lecture theatres with static furniture. Issues associated with 'crowd control' may deter academics from trying more adventurous and novel teaching styles. Teaching staff may also be required to cover a significant amount of complex course content in a relatively short period of time and the requirements of accrediting bodies may mean the curriculum lacks flexibility. Many STEM students may begin to feel overwhelmed by the volume and complexity of course material that is covered in a single teaching session. Additionally, research has reported that 59% of students find lectures boring half the time and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Play-Doh has a distinct and recognisable appearance, texture and smell

30% find lectures boring most of the time, with the use of PowerPoint slides being largely attributed to this effect (Mann & Robinson, 2009). In order to facilitate active learning and a deeper understanding of the more difficult (or tedious) course content it is vital that educators explore more novel methods of engaging students within the traditional lecture theatre environment whilst assessing the success of these more alternative approaches to teaching.

As described previously, there is evidence that both playful learning practice and kinaesthetic learning models have been successful in promoting engagement and learning in HE. Research has also demonstrated that learning is more likely to take place during a state of heightened emotional arousal (Dolcos et al, 2004) and so designing learning activities that stimulate a sense of happiness, creativity and nostalgia may be used to enhance learning of some of the least interesting/stimulating areas of a STEM programme. Play-Doh is a type of popular modelling clay that has been on the market since the 1950's and is sold in approximately 75 different countries worldwide (Walsh, 2005). For decades, children have played with this product in their own homes and also have been exposed to it in schools and other learning environments. Play-Doh has a distinct appearance, smell and texture that would be recognisable by most individuals born after the 1950's and it could be predicted that the use of this medium could trigger feelings of happiness and nostalgia whilst adding a creative and tactile element to a learning activity (Figure 1).

This study aimed to explore and evaluate the use of Play-Doh in a 'kinaesthetic play' lecture in an attempt to increase engagement and student enjoyment during a two hour histology lecture focusing on epithelial tissue.

METHODS

Study Sample

This study was performed at the University of Salford with L4 students enrolled on the BSc (Hons) Biomedical Science (IBMS) programme which is offered by the School of Environment and Life Sciences. This programme is accredited by the Institute of Biomedical Science (IBMS) and so much of the curriculum content is inflexible to ensure that graduates have covered the key learning material for graduate biomedical science practice. The most recent National Student Survey reported 90% overall student satisfaction with this programme and that 91% of students were employed or in further study within six months of graduating (Which? University, 2016). Common careers for biomedical science graduates have included employment as NHS biomedical scientists, research scientists, industry scientists and employment as medical writers. Other graduates have gone on to study for MRes, MSc, PhD, Medicine, Dentistry and Teaching qualifications.

121 students were enrolled on the L4 Human Anatomy module which is a lecture based module delivered over two semesters. 2.3% of these students were international students, 60.3% were female and 18% were classed as mature students. The group was ethnically diverse and included 29% Asian/ Asian British Pakistani students, 23.3% White British students, 12.2% Black/Black British African student and 7% being of Asian/Asian British Indian origin.

Kinaesthetic Play Lecture Design

In the first semester of the L4 Human Anatomy module the teaching and learning focus was on gross anatomy and was delivered by a single member of staff via traditional lecture methods in a large lecture theatre. In the second semester, the focus shifted to tissue histology and was again delivered by a single (different) member of staff, Dr Gemma Lace-Costigan (GLC) in the same lecture theatre. The lecture theatre capacity was sufficient to seat 130 students and was divided into two equal seating blocks (separated by stairs with additional stairs at the end of each block), with each block being organised into rows of 8-10 seats. Entry points were located at both the front and the back of the room.

In the first lecture delivered by GLC, students were advised that different teaching methods would be used in an attempt to enhance learning and promote engagement. As per the University of Salford academic regulations (University of Salford, 2016), lecture notes were made available at least twenty-four hours before the lecture, however students were informed that details regarding some of the planned learning activities would be removed to ensure an element of surprise and originality to the sessions.

The kinaesthetic play lecture was the fourth lecture to take place in the series of 8 lectures delivered. Out of the 121 students enrolled on the module, 63 students attended the kinaesthetic play lecture. Before the start of the lecture, each seating space had a single sticky note placed on the desk which was to be used to collect the study feedback. At the start of the session students were informed that the content delivered in the first half of the session would be used to allow all students to participate in a competition later on in the lecture. Students were then given a traditional lecture (via PowerPoint) describing the role, types and features of different types of epithelial tissue. Once the subject material had been delivered, students were informed that the competition was about to start. The students were presented with the following information on a PowerPoint slide: ‘Working with the students in your row, you have 10 mins to create each of the following cell types; simple squamous epithelia, simple ciliated columnar epithelia,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

simple cuboidal epithelia, stratified cuboidal epithelia. Label in detail. Don't forget the 'general' features of an epithelial cell'. Students were given the opportunity to ask any questions about the activity and then before the activity started a new slide was displayed which directed the students to use their sticky notes to anonymously complete the following task; Choose ONE word to describe how you feel about taking part in this activity. Once this was completed the competition instructions slide was projected once again and students were asked a second time about any activity queries and a small pot of Play-Doh was given to each student. Once all queries were answered a timer was started and the activity began. During the activity, the academic in charge (GLC) walked around the room, encouraging participation and asking/answering student questions. All students present took part in the activity. After 10 minutes, all students brought their entries down to the front of the room for formative assessment. The work was primarily assessed by GLC but students were also invited to leave feedback for their peers with respect to the accuracy of the models and labelling. It was reinforced that models would not be assessed based on their artistic merit but instead on evidence of understanding the structure of the various epithelial cells. The entries were discussed as a group and a small prize (a choice of chocolate or stationary) was awarded to the team that produced the best models. The students were then asked to complete the following task; choose ONE word to describe how you feel AFTER taking part in the activity. Students were also asked to rate (1-strongly agree, 2-agree, 3- undecided, 4- disagree or 5- strongly disagree) the following statements; 1) I enjoyed that activity and 2) That activity increased my understanding of epithelia. The feedback was collected and the lecture then continued using traditional PowerPoint delivery.

Data Analysis

Of the 63 participants, 58 fully and correctly completed feedback sticky notes. 5 sets of feedback were not utilised in the study due to missing ratings or use of full sentence responses rather than a single word response.

A basic language analysis was performed by inputting the responses into WordClouds.com to assess the frequency of responses for each question and to generate a visual summary of responses. This site generates word clouds allowing the visualisation of text inputs so that the most frequently occurring words appear in larger font, whereas the less frequently occurring words appear in a smaller font. Each response was categorised as being optimistic/positive, neutral/ambiguous in meaning or pessimistic/negative.

A register was taken at the end of the session and this was used to explore the relationship between kinaesthetic play lecture attendance and overall module exam performance via an unpaired T-test.

Results

All attending students participated in the learning activity (100% engagement) with each individual student producing one of the four epithelial cell types required. In order to submit a competition 'entry,' each team had to submit all four epithelial cell types. When there were more than four members in each team, additional cells were made to ensure all individuals could create something as demonstrated in Figure 2.

After being presented with the learning activity students were ask to 'Choose ONE word to describe how you feel about taking part in this activity' (Figure 3A). After participating in the learning activity students were then asked to 'choose ONE word to describe how you feel AFTER taking part in the activity' (Figure 3B). Figure 3A highlights that before the activity, the most common responses were 'excited,' 'confused' and 'shocked'. However, after the activity, the most common responses were 'happy,'

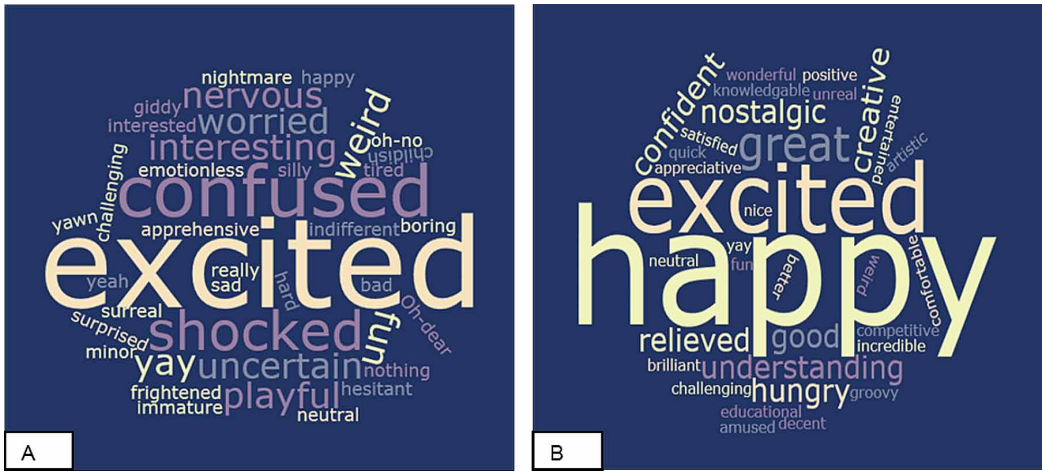
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The kinaesthetic play lecture activity

'excited' and 'great'. The full range of student responses can be visualised in Figure 3, where the most commonly reported words appear in a larger font size within the word cloud and the least commonly reported words being reported appearing in a smaller font size.

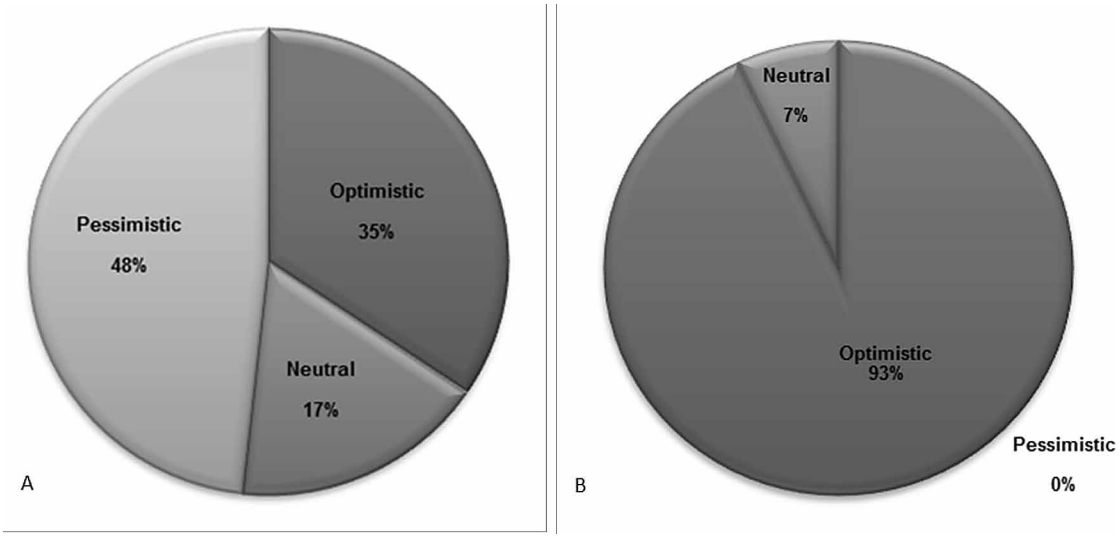
When asked to 'choose ONE word to describe how you feel about taking part in this activity' before the activity took place, 48% of responses used language that was negative/pessimistic, 35% that was positive/optimistic and 1% of responses were neutral or ambiguous in meaning (Figure 4A). The most popular three negative/pessimistic words were 'confused,' 'shocked' and 'worried' and a number of students also reported feeling 'nervous,' 'apprehensive,' 'frightened' and also selected words such as 'nightmare,' 'immature,' 'childish' and 'boring'. The most common three optimistic words were 'excited,' 'interesting' and 'playful' and other responses included 'fun,' 'yay,' 'giddy' and 'happy'. The most frequently selected neutral/ambiguous words were 'weird,' 'indifferent' and 'emotionless'. Overall, the top three responses were 'excited' which was interpreted as being a positive/optimistic response, and 'confused' and 'shocked' which were deemed negative/pessimistic responses.

Figure 3. Perceptions of play A) before the activity B) after the activity (Word cloud created at word-clouds.com)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Language analysis of responses A) before the activity and B) after the activity

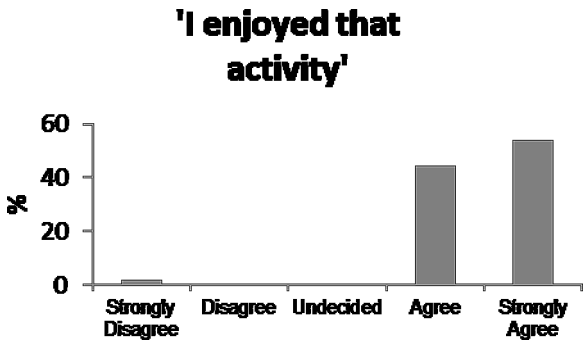


When asked to 'choose ONE word to describe how you feel AFTER taking part in this activity,' 0% of responses were negative/pessimistic, 93% were positive/optimistic and the remaining 7% responses were neutral or ambiguous in meaning (Figure 4B). The most commonly selected positive/optimistic responses were 'happy,' 'excited' and 'great' and other responses included 'understanding,' 'nostalgic,' 'confident' and 'creative'. The most frequent neutral/ambiguous responses were 'hungry,' 'neutral' and 'weird'.

When participants were asked to consider the statement 'I enjoyed that activity,' 54% of participants reported to 'strongly agree,' 44.4% reported to 'agree,' 1.6% reported to 'strongly disagree' and no students selected to 'disagree' or were 'undecided' (Figure 5). Overall, 98.4% students therefore reported enjoying the activity.

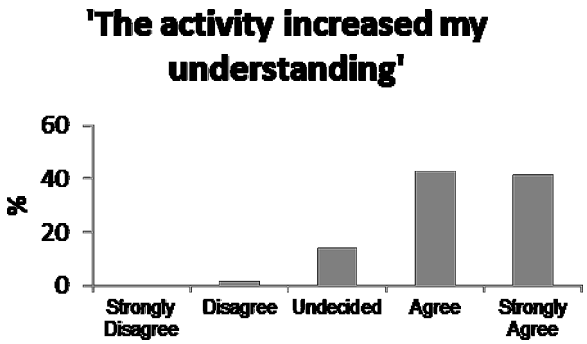
When participants were asked to consider the statement 'The activity increased my understanding of epithelia,' 41.3% students reported that they could 'strongly agree,' 42.9% reported to 'agree,' 14.3% were 'undecided, 1.6% reported to disagree and no students chose to 'strongly disagree' with the statement. Therefore 84.2% of students felt the activity increased their understanding of epithelia (Figure 6).

Figure 5. Student ratings of the statement 'I enjoyed that activity'



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Student ratings of the statement 'The activity increased my understanding of epithelia'



Out of the 121 students enrolled on the module, 63 students attended the playful lecture. The group of students that attended the session achieved a mean exam result of 70.1% whereas the student group which did not attend the lecture attained a significantly lower exam mark of 60.1% ($p<0.05$). Access to the full lecture series attendance records were not available and so marks could not be adjusted to compensate for regular lecture non-attendance.

CONCLUSION

Designing engaging and interactive lecture sessions that enhance deep learning is a challenge taken on by academics across different discipline areas worldwide. Kinaesthetic learning activities and playful learning practice has been shown to be successful in a number of disciplines, yet these methods are poorly explored in HE STEM subjects. Teaching to large numbers of students within the constraints of a traditional and static lecture theatre can be intimidating at times, and educators may be cautious with respect to introducing kinaesthetic and playful learning activities due to issues associated with 'crowd control'. Modern day Universities strive to increase student satisfaction as well as exam performance and some academics may feel there is a risk associated with deviating from the normal modes of educational practice. More research is needed to explore the potential use of alternative teaching methods with larger student groups within traditional lecture hall environments in HE STEM disciplines.

Academics whom are keen to appease their students may be concerned that the incorporation of kinaesthetic and playful learning activities may be considered patronising or childish by adult learners. In this study, Play-Doh was used as a learning material and this particular medium is a popular toy that is also used in early years' education. After being briefed about the learning activity, the initial responses from students regarding taking part in the kinaesthetic play activity were mostly negative/pessimistic (48.3% of responses), with only 34.5% of students giving a positive/optimistic response. Many of the responses given were anxious responses (for example 'confused,' 'shocked,' 'uncertain,' 'worried,' 'nervous,' 'apprehensive,' 'frightened') indicating students were being pushed out of their learning comfort zones. The Learning Zone Model of learning (Senninger, 2000) describes how students can be encouraged to learn by venturing out of their comfort zone but without being pushed into their 'panic' zone. It would be interesting to note the impact on the responses if the students were given advanced warning of the class activity in future sessions, thus removing the element of surprise and not pushing students into their

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

'panic' zone. However, by doing this you would introduce the risk of students harbouring any negative preconceptions simply not turning up to the session. Though the majority of teaching on the BSc (Hons) Biomedical Science Programme at the University of Salford is centred around traditional lectures, lab classes and tutorials, less traditional approaches such as flipped-learning, workshops, poster/oral presentation sessions, problem based learning, seminars etc are also increasing being incorporated within the programme. However, the majority of these alternative teaching practices are utilised at L5 and L6 where the class sizes are smaller and the subject material is more specialised. Increasing the variety of teaching styles and learning activities right from the start of L4 may be useful to modify student expectations so that alternative learning activities are not perceived as threatening, intimidating and without pedagogical benefit. Encouraging and inviting students to step out of their learning comfort zones whilst being mindful that certain activities may hinder learning due to negative emotional reactions is likely to enhance both learning and student learning experiences (Senninger, 2000).

A number of the responses collected before the learning activity indicated that students perceived the activity to be childish or unsuitable at the HE level. Responses such as 'immature,' 'childish' and 'silly' reinforce the importance of explaining the significance of the activity with respect to its potential to enhance learning. If a student does not consider a learning activity meaningful and worthy of their time and effort, they are less likely to fully engage and commit to the interaction (Fredricks et al, 2004). Making students aware of the success of other adult associated playful learning initiatives such as 'Lego Serious Play' (James, 2015; Nerantzi et al, 2015), games-based learning approaches (Whitton & Moseley, 2012) and the use of augmented reality to enhance scientific laboratory skills (Akçayır et al, 2016) may be effective in demonstrating the significance of such playful approaches. By carefully explaining the underlying pedagogical principles associated with playful/kinaesthetic learning activities and how this relates to achieving intended learning outcomes, one might expect to reduce some of the initial negative/pessimistic perceptions evoked.

It is extremely interesting to note that while 48.3% of the responses were negative/pessimistic before the activity, this value dropped to 0% after the activity with 93% of students giving positive/optimistic responses. Many of the responses indicated a level of enjoyment (for example, responses included feeling 'happy,' 'excited,' 'great,' 'incredible,' 'positive,' 'brilliant,' or the word 'fun') and a number of students reported the feeling of nostalgia. Creativity was also a theme amongst responses (for example students reported feeling 'creative' and 'artistic') and a significant number of responses indicated that the students felt they had learned from the activity (responses included the words 'understanding,' 'knowledgeable' and 'educational'). The lack of negative/pessimistic responses after the learning event demonstrates that once the learners had experienced the learning activity first hand, those negative feelings were extinguished. The source of those original negative feelings may have been due to the association between Play-Doh, childhood memories and early years' educational experiences and a misalignment with their expectations of adult learning methods in University. The kinaesthetic play lecture would have been the first and only exposure to a creative and tactile learning activity whilst in a large group teaching session in HE and some level of scepticism is not unexpected. Students come into HE with certain preconceptions of how, when and where learning will take place. It would have been interesting to compare enjoyment levels before the introduction of the playful learning activity to how students perceived the lecture with an incorporated kinaesthetic playful element. It would also be interesting to follow up with those students in the future to see how their perceptions change with time. It is only natural for a student to relate back to their own personal experiences of education or media portrayals of University life and in a culturally and ethnically diverse population such as cohort being described in this study, these preconceptions may

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

vary significantly. These findings again reinforce the significance of increasing student awareness of the success of other adult learner associated playful learning practices (such as 'Lego Serious Play') and the scholarship associated with these methods. By seeing these learning activities as part of a research informed approach, students in HE may have less negative preconceptions about participation. It is an extremely significant finding that despite almost half of the cohort originally having negative thoughts and feelings associated with the kinaesthetic play activity, after the activity the majority of the group gave positive feedback. It could therefore be postulated that increased exposure to alternative teaching styles (and understanding of the underlying pedagogies) may be more likely broaden the minds of learners in HE so that similar activities are not viewed so negatively when presented in the future. It would have been useful to conduct a series of pre-activity and post-activity interviews to allow a more detailed exploration of student perceptions of kinaesthetic playful practice in bioscience HE. However, given the large cohort size, this would have proved logistically difficult and so a follow up study targeting smaller group sessions in bioscience HE might be useful in dissecting out what underlies some of the negative preconceptions of playful practice.

This study aimed to explore whether HE STEM students would appreciate and enjoy a more artistic and tactile learning activity, despite the subject area conventionally not being associated with creative learning approaches. 98.4% of the students that participated in the kinaesthetic play lecture reported that they enjoyed the activity which demonstrates more creative learning activities should not be overlooked simply because they do not traditionally sit within STEM teaching methods. The increasingly collaborative nature of academia means that science and art fusion projects are on the increase therefore enabling students to think about science creatively is likely to increase employability. Encouraging students to express scientific understanding through artistic means may help consolidate their learning, since many biological/biomedical students may in fact learn through kinaesthetic learning methods (Kolb, 1994). There exists a catalogue of historical research describing different learning styles and preferences (Honey & Mumford; 1982, Kolb, 1981; Myers-Briggs, 1980; Schmeck, 1998) however more modern approaches celebrate the complex and individual nature of learning and how learning preferences may be dynamic rather than static. It is therefore important for educators to provide a variety of learning activities that so that students can explore which learning methodologies work best for them and their individual learning requirements at any given stage of their learning journey.

Using Play-Doh as a learning tool served to inject some creativity within a traditional lecture based learning environment, allowing students to individually participate in the learning activity whilst also working as part of a team. A wide variety of literature is available to support that many students 'learn through doing' (Kolb, 2014) and since each student would be individually producing a Play-Doh model, each student would therefore be actively involved in the session. By immersing themselves in the tactile and sensory task of making different epithelial cells, the student was creating their own, personal experience and memory of the kinaesthetic play lecture which would facilitate their learning through active participation. Additionally, each individual formed part of a team so even though parts of the activity were being performed in solitude, there was a collaborative slant on the activity. When students work well with others and experience a sense of connection whilst undertaking a learning task, engagement has been reported to increase (Wentzel, 2009; Deci & Ryan, 2000). Introducing a competitive element to the activity (via offering a small reward for the most accurate Play-Doh creation) increased the motivation of the student to participate through the desire to win and/or receive an award. The use of competitive activities to enhance motivation and learning has been described in numerous publications (Brophy, 2013; Weiner, 1990). Other studies have reported how cooperative learning techniques (which involve

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the use of activities where students work together on tasks to receive rewards or recognition) have been used successfully in primary and secondary school education (Slevin, 1980). Games participation is a classic example of how reward and 'winning' can be used to motivate engagement and newer pedagogical research approaches provide evidence to support the use of games to enhance teaching and learning (Whitton, 2011; Moseley & Whitton, 2012). It would be interesting to note if the results would have been different if the competitive element of the activity was removed. The kinaesthetic play activity used in this session combined using active participation, collaborative learning with a competitive element, which ultimately resulted in enhanced positive/optimistic feedback after the activity. Though team activities can be logistically difficult to manage in a traditional lecture hall environment, this study demonstrates that they are a worthwhile effort and useful in enhancing engagement, promoting student satisfaction and enhancing learner experiences.

A large number of responses after the activity were highly emotive (for example, students reported feeling 'happy,' 'excited,' 'nostalgic,' 'satisfied' or responded with the word 'fun') and previous research has demonstrated that in situations of heightened emotional arousal, learning and memory formation becomes more effective (Dolcos, 2004; LeDoux, 1992). The students who attended the lecture attained significantly higher marks in their exams compared to those who did not attend the lecture however these results should be interpreted with caution. It must be considered that only ~10% of the exam questions were associated with the kinaesthetic play lecture content and the non-attending students may have generally had poor attendance to the full lecture series. In future sessions, a before and after activity test could be delivered using a platform such as Kahoot. This would enable an exploration of how these kinds of tactile and playful activities may enhance understanding of the course content in a traditional lecture environment. It should be recollected that the main aim of this study was to assess the utility of using Play-Doh based kinaesthetic playful activities to enhance student engagement and enjoyment rather than to increase student exam performance, though it is known that a relationship between engagement and performance exists. Enhancing student learning should be the primary objective of a teaching activity and 84.2% of students felt the activity enhanced their understanding of the subject area and the other study findings support the notion that they had fun whilst learning.

Since 100% of the students present in the session actively participated in the learning activity, with 98.6% of students reporting that that they enjoyed the activity and 84.2% reporting they felt the activity increased their understanding of the subject, it can be concluded that kinaesthetic playful learning activities using Play-Doh can be used in increased student engagement, enjoyment and understanding. Engaging large numbers of HE students in creative, playful and kinaesthetic learning activities can be logistically challenging but ultimately beneficial to the learner. This research demonstrates that despite having some initial negative perceptions about kinaesthetic learning practice, students ultimately enjoy these alternatives to traditional lecture based delivery styles and report that they feel their understanding of the subject area has been enhanced. Kinaesthetic playful practice therefore has the potential to be used at different levels of education across a variety of different discipline areas, including within HE STEM teaching.

Chapter 64
Pre-Implementation Case Studies Evaluating Workflow and Informatics Challenges in Private Primary Care Clinics for Electronic Medical Record Implementation

Calvin Or
The University of Hong Kong, China

ABSTRACT

Despite the potential benefits of electronic medical records (EMRs), their implementations have failed in a number of instances because of misfit between the technology design, work practices, workflows, and clinicians' needs. To promote effective design and implementation of an EMR system, the present pre-implementation study modeled the clinical workflow processes in private primary health care clinics and identified the associated gaps, weaknesses, and informatics challenges in the processes. Systematic field observations were performed to collect workflow data. Forty-three health care professionals (16 physicians and 27 clinical assistants) of fifteen private primary health care clinics were studied. The results, presented in a workflow diagram, demonstrate step-by-step details of the clinical work processes, their gaps and weaknesses, and possible improvement opportunities offered by the application of EMR. The workflow model provides important implications that may be applicable to other health care settings that plan to implement EMRs.

INTRODUCTION

An initiative that focuses on implementation of an electronic medical record (EMR) sharing system in both public and private health care sectors in Hong Kong has been launched. Though potential benefits of EMR are evident, it has been a challenge to gain buy-in for the technology from private doctors (Hong Kong Legislative Council Panel on Health Services, 2009) which provide more than 70% of outpatient consultations for the population. Many of them continue to use paper-based medical records; for the few that use electronic records, most do not have data sharing capabilities (Hong Kong Legislative Council Panel on Health Services, 2009). Non-adoption of EMR is a significant concern for patients and health care organizations because its adoption is a prerequisite for benefits of the technology to be realized.

Extant literature has indicated that slow adoption or abandonment of a health information technology (IT) is likely to occur when the technology impedes routine clinical practices or when the design of the technology is not compatible with the users, tasks, or external environment (i.e., misfit between the technology and its sociotechnical system elements) (Lorenzi, Riley, Blyth, Southon, & Dixon, 1997; C. K. L. Or et al., 2009; Tan & Or, 2015, in press). For EMR systems, in particular, their implementations have failed in a number of instances because of misfit between the technology design, work practices, workflows, and clinicians' needs (e.g., Ash & Bates, 2005; Chin, 2006; DesRoches et al., 2008; Sicotte, Denis, & Lehoux, 1998). According to the sociotechnical theories and models for (health) technology implementation (Hendrick & Kleiner, 2000; C. Or, Dohan, & Tan, 2014; Sittig & Singh, 2010), to address the issue of misfit one of the necessary initial steps is pre-implementation workflow and work system assessment since it facilitates understanding of the characteristics and needs of the end-users and work units (McGowan, Cusack, & Poon, 2008; C. Or, Wong, Tong, & Sek, 2014; Samuels, 2008). By understanding the characteristics and needs, practitioners can design the technology in a way that can enhance the technology-user-workflow integration. Indeed, studies assessing workflow and work systems largely via observations for health IT implementation and adoption exist. For instance, Dykes et al. (2005) conducted an observational analysis of workflow to determine how primary care providers interacted with an EMR system. Their analysis led them to establish new adoption and training strategies that resulted in improvement in the adoption of some of the system features. Or et al. (2014) performed field observations and interviews to understand why a clinical information system of a nursing home was abandoned and how work tasks were performed in order to identify factors affecting the implementation of the system. Unertl et al. (2009) modeled the workflow, information flow, and work practices of ambulatory clinics providing chronic disease care by using observational and interview data. Their study led to the development of guidelines for health IT design to support chronic disease care.

The present study aimed to scrutinize pre-implementation clinical workflows in private primary health care clinics in order to address the following questions: 1) what were the major clinical activities in the private primary health care clinics in Hong Kong and the associated gaps and weaknesses as well as informatics challenges in the clinical process; and 2) what would be the focuses when developing an effective EMR system for the gaps, weaknesses, and challenges.

METHODS

Grounded in the theory of sociotechnical analysis of work system (Hendrick & Kleiner, 2000), this study used a direct field observation method to analyze the workflows and possible improvement opportunities.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The method was adopted because it allowed us to understand how work activities and issues occurred in real situations (Hendrick & Kleiner, 2000). As mentioned earlier, previous studies have demonstrated the use of observations to examine workflows and work systems. Based on the Systems Engineering Initiative for Patient Safety (SEIPS) model of work system and patient safety (Carayon et al., 2006), the observations focused on interactions among the individuals (i.e., health care professionals, patients and other caregivers), clinical tasks, technology, work environment, and organization. A health informatician with nursing background (KW) and a human factors researcher (IC; see the acknowledgments) were trained and took part together to observe a total of forty-three health care professionals (16 primary care physicians and 27 clinical assistants (CAs)) of fifteen clinics. The two researchers stood in a non-interfering area, such that doctor-patient encounters were not disturbed. After the observations, the researchers asked the health care professionals follow-up open-ended questions for seeking clarifications about work procedures and rationale behind actions. Those fifteen clinics were selected because they were a private primary care clinic, had not had any EMR sharing system in place or only had basic computer applications (e.g., Microsoft Excel) for data management, and were readily available for participation. Based on prior studies (Flick, 2006; C. K. L. Or et al., 2005; Poon et al., 2006; Samuels, 2008; Unertl et al., 2009), observational data of this present study was translated into a workflow diagram whereby the clinical workflow challenges were analyzed and elucidated.

RESULTS

Table 1 presents the characteristics of the study sample. Figure 1 illustrates step-by-step details of the care delivery processes, starting with patient registration and continuing through patient discharge.

In summary, CAs first check in patients upon their arrival. For a new patient's registration, the CA requires the patient to write down his/her demographic information on a piece of paper and to present his/her Hong Kong identity (HKID) card or passport as proof of identity. The CA also collects the patient's health insurance information and then verifies his/her insurance eligibility status and coverage

Table 1. Study sample characteristics

	Physicians (N=16)	**Clinical Assistants (N=27)**
Males/females	14/2	0/27
Mean age (SD)	47.5 (11.2) years[†]	34.1 (11.8) years
Experience in medicine Mean (SD) Range	 21.8 (11.3) years[†] 5-40 years[†]	 10.7 (9.8) years 0-40 years
Self-reported experience level in using computer None Beginner Competent Expert	 0 7 (43.8%) 9 (56.2%) 0	 0 11 (40.7%) 16 (59.3%) 0
Had experience using health IT (e.g., barcoding and standalone patient record systems)	10 (62.5%)	7 (25.9%)

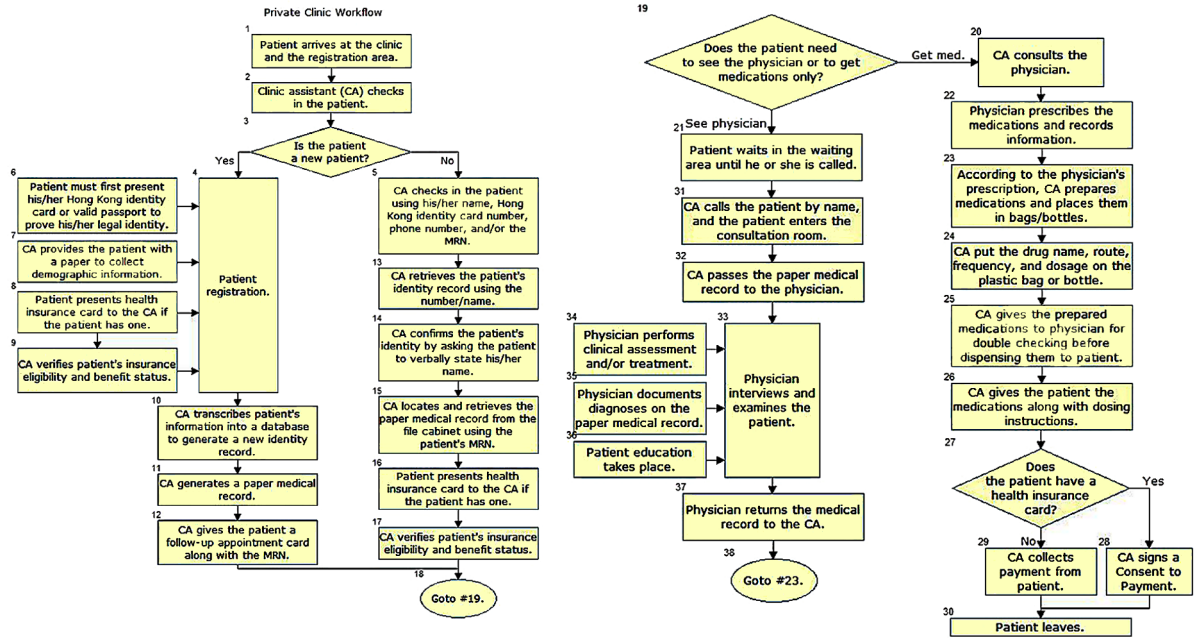
Figure 1. Primary care workflow processes observed in private care clinics



type by calling the insurance company, using an insurance verification card reader, or through the company website. Following that, the CA manually transcribes the demographic and insurance information into an identity record that is maintained in either a paper notebook or an electronic database (e.g., an Excel spreadsheet). The CA also generates a paper-based medical record and a medical record number (MRN) for the patient (a MRN is a unique, clinic-specific number allowing identity records to be linked to medical records). For patients who visited the clinic before (old cases), they present their MRN to the CAs for registration. With a MRN, CAs can directly retrieve patients' paper-based medical records. If patients fail to provide their MRN, CAs must first search and retrieve the patients' identity records in order to obtain their MRNs before being able to locate the medical records.

Next, the CA put the patient into the consultation room for medical consultation. Meanwhile, the CA passes the patient's medical record to the physician and collects the record of last patient for preparing medications. As was observed, the physician's work involves generation and examination of different pieces of information (e.g., medical records, sick leave certificates, attendance certificates, receipts, health insurance reimbursement claim forms, and/or other medical records and diagnostic test reports brought by patients from various hospitals or health centers). Tools and technologies such as glucometers, stethoscopes, otoscopes and oximeters are used and discussions are held with patients and their family members. For each patient, the physician documents the patient's diagnosis, progress, treatment, vitals and prescriptions in a paper chart.

Sometimes patients only request to refill medications. In this case, CAs pass the patients' medical records to physicians, who review the patients' diagnosis, progress, and prescription history, and writes the prescription. CAs dispense medications accordingly and place them in bags or bottles with labels containing the patient's full name, drug name and route, dosage and frequency of intake, and safety instructions. This labeling can be completed by computer printing or by hand. Following that, the physician

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

cross-checks the medications and drug labels before the CA gives the medicines to the patient. When discharging patients, CAs collect payment from patients and for those having health insurance they also need to sign an insurance reimbursement claim form.

DISCUSSION

To the author's knowledge, this is the first study exploring in detail the clinical workflow process and informatics challenges in the private health care sector in Hong Kong—a less studied population. Many previous health IT implementation initiatives did not examine workflows and work systems prior to the implementation partly perhaps because the practitioners might believe that the technologies would automatically fit the existing work system and thus be accepted and used by users when they were implemented. This study identifies and highlights the major clinical workflow issues through the effective use of workflow and work system analysis and provides new practical insights into critical design aspects that should be addressed in the development of the EMR sharing system. More specifically, the workflow model of this present study is useful for health care organizations to evaluate design flaws in a primary care work system as well as for health informatics practitioners to develop an effective EMR system for the system design problems. As can be seen from the foregoing, there are gaps, design weaknesses and challenges in the current work system, workflow and information flow.

Overall, the process of collecting and managing patients' data is cumbersome and disorganized, entails considerably inefficient work tasks, and is vulnerable to effective information transfer and communication. First, in new patient registration, the use of scraps of paper is a frequently observed method to collect patients' information. To maintain the information, the CA creates an identity record in either an electronic or paper format by manually copying the patient's information on papers into a computer database or paper notebook, respectively. Clearly, the use of scraps of paper is an unreliable way to secure patients' data. Also, the process of manual transcription of data from one form to another can be a source of error.

Furthermore, a paper medical record and an associated MRN are also created for each patient to maintain clinical data. During old case patient check-in, the CA must first obtain the MRN from the patient and use the number to locate the patient's identity record for verifying their identity and the paper medical record for physician charting. However, as was observed, not all patients were able to recall or had their MRNs with them at the time of check-in. As a result, the CA was unable to instantly locate any of the records. Instead, the CA used other information of the patient (e.g., name, phone number, and/or HKID/passport number) to search for the identity record for the MRN. It is especially troublesome for clinics using paper-based identity records because CAs need to manually search through the paper notebook to obtain patients' MRNs. The search process is time-consuming as CAs need to flip and scan through pages of records, whereas search through an electronic database is less tedious and quicker. All the aforementioned information gathering, generation and retrieval mechanisms that consist of several inefficient and redundant steps make the care service delivery process disorganized, time-consuming and error-prone.

It is also of great concern for the clinicians to handle many different types and pieces of information from various sources and to maintain various records stored in different places in the clinics. At another instance, it was observed that the CA was unable to find the paper medical record in the file cabinet for a patient as the record was misfiled after the previous visit. The record was found only after the CA went

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

through a long series of checking and searching. Using multiple records to maintain data is unreliable and is likely prone to errors. To avoid multiple and duplicate data entry or filing, it is suggested that an EMR system be designed to enable the clinicians to acquire and manipulate all patient information (including demographic, insurance, medical, lab test and others) in one record system and to access the records by using a single, unique identification number, such as an identity card or passport number.

Information transfers between physicians, CAs, and patients are primarily by paper records and notes written on pieces of paper as it is handy. Moreover, CAs are required to walk back and forth between their work area and the consultation room when transferring documents and notes. It is suggested that EMRs can eliminate this cumbersome and time consuming step by offering an easy-to-use and fast-response mechanism that allows an efficient information transfer and communication among the physicians, CAs, and patients.

The handling of patients' health insurance information and payment reimbursement documents also makes the workflow inefficient. In case of patients having an insurance plan, CAs needs to use different tools to identify and verify patients' insurance eligibility and coverage. It is suggested that an EMR system that enables full access to updated information on patients' insurance coverage and/or that performs automatic eligibility checks should simplify the verification process.

To promote EMR adoption and implementation, a critical key is that system features and functions should match the users' needs (Karsh, Holden, & Or, 2011). To achieve this, system developers must identify the required functionality within the EMR. The present study observed that physicians were engaged in various work tasks during patient encounters. Based on the observations, an EMR system should at least have the ability for the physicians to extract patients' data from the system, such as medical history and laboratory test results; document patient diagnoses, progress, and results; record treatments provided; order laboratory tests; prescribe medications; access clinical and teaching materials; compose sickness certificates and substantiation of attendance and services; prepare billing documents, such as reimbursement claim forms and receipts; and provide electronic signature on notes and documents. The observations also suggested that the EMR system should allow the CAs to easily print medication labels directly off the machine and attach them to the drug bags and bottles as this can help reduce clerical and labeling errors caused by handwriting. On the other hand, without this information about what the physicians and CAs need in their work, it would be unlikely to develop an EMR system that would just fit the needs; as a result, the use of such system is likely to be ineffective and inefficient, and the system can eventually be abandoned.

This study has certain limitations that need to be addressed in future research. The generalizability of this study should be considered in light of the fact that it was conducted on a sample of physicians and CAs of only fifteen private primary care clinics. Further studies with a larger sample size covering clinics with different specializations are needed as workflows of specialist care could be different. The author also acknowledges that the study sample is limited to a single region. However, it has been suggested that findings from studies of this type are most relevant to jurisdictions with similar technical capabilities, geographical characteristics, historical background, socioeconomic development, or cultural identity to Hong Kong, such as Shanghai, India, Singapore and other (former) British colonies with similar health care systems (Leung, Yu, Wong, Johnston, & Tin, 2003). There were some methodological challenges we encountered in the study that might have limited the amount of data we could collect. For instance, some clinics that were invited to participate in the study were not observed because they were not available. Also, in few cases, during the data collection, the researchers were asked to leave

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the consultation rooms as the patients did not want to be observed during the consultations. However, despite the limitations, our study provides some useful baseline knowledge and significant insights into an EMR design and implementation.

CONCLUSION

This present pre-implementation study scrutinized and identified everyday clinical activities, workflows, information flow, and the stakeholders' needs in private primary health care clinics that enabled us to recognize the inadequacy of the workflow processes and to acquire a thorough insight into what to focus on when developing and implementing the EMR system. Using the knowledge about the workflows and needs can help ensure the EMR system to include effective functions and features and consequently increase the harmony among the system design, the care processes, and the users' characteristics. This harmony is an essential step to promote EMR acceptance and adoption. In general, this study leads to the following important implications for health IT implementation. Poor fit between health IT design, workflows, and work practices can lead to unintended adverse consequences, such as work practices interruptions, additional workload, and technology rejection. To improve fit pre-implementation assessments of existing workflows and user work patterns and behaviors are necessary.

Clinical Relevance Statement

Workflow and work system assessment prior to health IT implementation is critical as the workflow knowledge can facilitate understanding end-user and work system needs and thus can help increase the harmony between the technology design and the care processes.

Conflict of Interest Statement

The author declares that they have no conflicts of interest.

Protection of Human Subjects

Approval of the institutional review board of the University of Hong Kong was received, and written informed consent was obtained from participants.

ACKNOWLEDGMENT

This study was supported in part by the Hospital Authority of Hong Kong/the University of Hong Kong, contract research project RCGAS-NA100001 C. Or (PI) and the Hong Kong Research Grants Council, Theme-based Research Scheme (Grant # T32-102/14-N; PI: F. Chen). The author is grateful to the physicians and clinical assistants for their participation and thank Katie Wong, RN; Irene Cheung; Ellen Tong, RN; and Antonio Sek, MD for their assistance on data collection and experimental design.

Chapter 65
Extraction of Protein Sequence Motif Information using Bio-Inspired Computing

Gowri Rajasekaran
Periyar University, India

Rathipriya R
Periyar University, India

ABSTRACT

Nowadays there are many people affected by the genetic disorder, hereditary diseases, etc. The protein complexes and their functions are detected, in order to find the irregularity in the gene expression. In a group of related proteins, there exist some conserved sequence patterns (motifs) either functionally or structurally similar. The main objective of this work is to find the motif information from the given protein sequence dataset. The functionalities of the proteins are ideally found from their motif information. Clustering approach is a main data mining technique. Besides the clustering approach, the biclustering is also used in many Bioinformatics related research works. The PSO K-Means clustering and biclustering approach is proposed in this work to extract the motif information. The Motif is extracted based on the structure homogeneity of the protein sequence. In this work, the clusters and biclusters are compared based on homogeneity and motif information extracted. This study shows that biclustering approach yields better result than the clustering approach.

INTRODUCTION

Protein Sequence

Proteins (Vincent, Bernard, & SinanKockara, n.d.) are present in every cell of the organisms. They are involved virtually almost in all cellular activities. They are responsible for the various metabolic activities, nutrition transportation, regulations and etc. They exist as single chain molecule, as a three dimensional

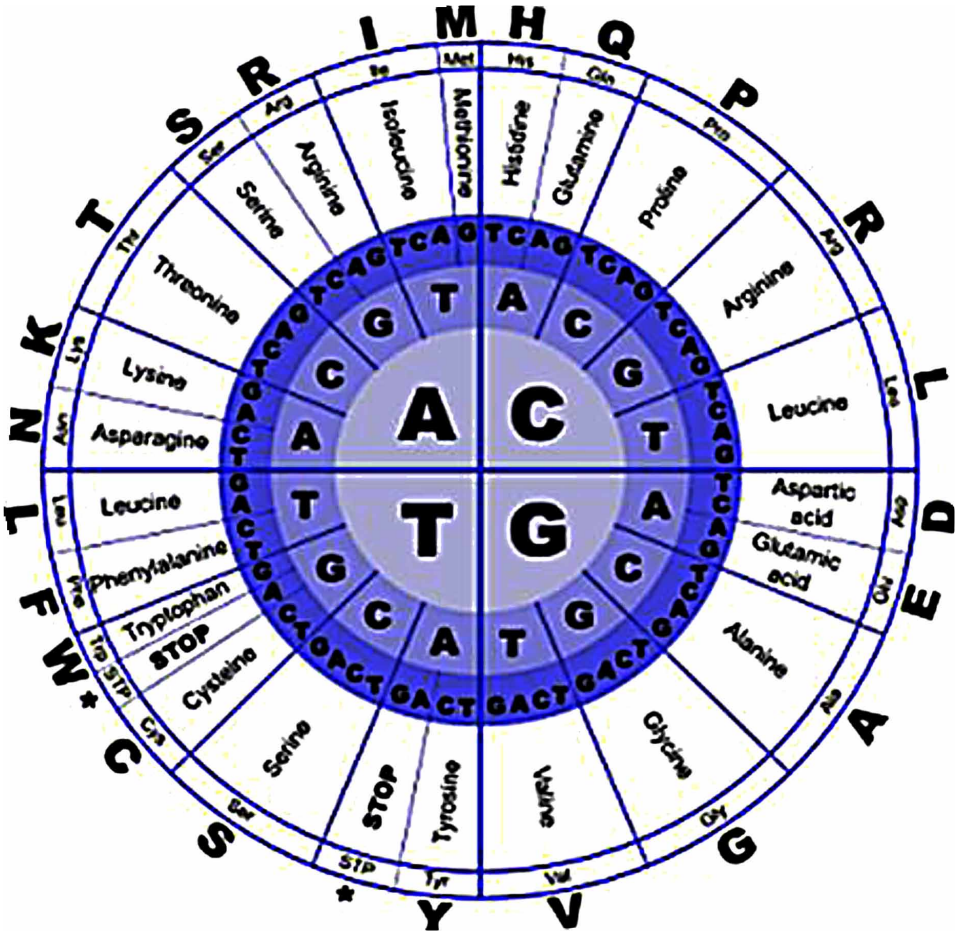
Figure 1. The IUPAC code for PROTEIN from DNA code



structures or even in the bundle or complex forms. The protein plays a vital role in cellular processes. The protein consists of twenty amino acids. They possess different characteristics such as hydrophobic, hydrophilic, polar, non-polar and etc. It is the great challenge to the bioinformatics that to find which combination of proteins are responsible for what kind of activities. The structure and function discovery of proteins in living organisms is vital role in understanding the background of various cellular processes. It is helpful in treating various diseases, in detecting the drugs to peculiar diseases.

The irregularity in the proteins can be found if their actual functionality and their protein complex are known. The biologist will interpret the functionality of the protein complex based on their chemical properties.

These significant protein complexes of various organisms are discovered using the computational techniques. Protein complexes are an assembly of proteins that build up some cellular machinery; commonly spans a dense Sub-network of proteins in a protein interaction network. The gene expression would not help much in detecting the functionalities of the gene. Protein sequence can be generated from the DNA/mRNA sequence that codes for the protein are shown in the Figure 1. The four basic amino acid combines to form the protein that is shown. The 20 different amino acids that are present in the protein sequence along with their chemical name are listed in the Table 1.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Amino acid codes

1-LETTER	3-LETTER	DESCRIPTION
A	Ala	Alanine
R	Arg	Arginine
N	Asn	Asparagine
D	Asp	Aspartic acid
C	Cys	Cysteine
Q	Gln	Glutamine
E	Glu	Glutamic acid
G	Gly	Glycine
H	His	Histidine
I	Ile	Isoleucine
L	Leu	Leucine
K	Lys	Lysine
M	Met	Methionine
F	Phe	Phenylalanine
P	Pro	Proline
S	Ser	Serine
T	Thr	Threonine
W	Trp	Tryptophan
Y	Tyr	Tyrosine
V	Val	Valine
B	Asx	Aspartic acid or Asparagine
Z	Glx	Glutamine or Glutamic acid

As the protein sequences are in the form of long amino acid sequence, the repeated protein groups are not found manually. These protein groups are denoted as motifs. The protein structure is of many types secondary, tertiary, quaternary, 3 fold and so on. The secondary structures are used in this work. The structural similarity of the detected protein complexes is used to extract the homologous complexes. The functionality of proteins is discovered by various methods like sequence-motif based method, homology based methods, and structure based methods. The motifs can be extracted from the clusters that are generated by various computational techniques.

Roles of Proteins

The proteins[1] are responsible for various activities of the biological system. They present in various parts of the human body. The Figure 2 shows the basic roles of protein in the human body. Besides this, the protein also has various other roles. The motifs are helpful in predicting these functionalities of the protein. The proteins are present in

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Blood**: The hemoglobin protein carries oxygen in our blood to every part of our body.
- **Hair and Nail**: Protein called alpha-keratin forms our hair and fingernails, and also the major component of feathers, wool, claws, scales, horns and hooves
- **Muscles**: Muscle proteins called actin and myosin enable all muscular movement- from blinking to breathing to rollerblading.
- **Cellular Messengers**: Receptor proteins stud the outside of your cells and transmit signals to partner proteins on the inside of the cells.
- **Cellular Construction Workers**: Huge clusters of proteins form molecular machines that do your cells' heavy work, such as copying genes during cell division and making new proteins.
- **Brain and Nerves**: Ion channel proteins control brain signaling by allowing small molecules into and out of nerve cells.
- **Enzymes**: Enzymes in our saliva, stomach, and small intestine are proteins that help you digest food.
- **Antibodies**: Antibodies are proteins that help defend your body against foreign invaders, such as bacteria and viruses.

Clustering

Clustering (Berkhin, 2002) is one of the known data mining technique used to group similar kind of data elements. It is used to discover similar patterns from a sea of data. The similarity among objects in the same cluster is greater than in different clusters. It is one of the unsupervised learning algorithms. The clustering (DEIB, n.d) is helpful in intrinsic grouping the unknown data based on our objective. It is a main task of exploratory data mining (Wikipedia, n.d.), and a common technique for statistical data analysis, used in many fields, including machine learning, pattern recognition, image analysis, information retrieval, and Bioinformatics. The motif information is extracted using various techniques like clustering with K-Means, hybrid K-Means, Self-Organizing Maps, etc., in the literature. As all these areas are dealing with the unclassified data, the clustering is well suited to these kinds of research areas. The clusters can be found based on various similarities between the data, such as intra distance and inter distance of the clusters. The quality of clusters will be evaluated based on our objective.

There are a number of problems with clustering. Some of them are as follows.

- Current clustering techniques do not address all the requirements adequately (and concurrently).
- Dealing with large number of dimensions and large number of data items can be problematic because of time complexity.
- The effectiveness of the method depends on the definition of "distance" (for distance-based clustering).
- If an obvious distance measure doesn't exist, we must "define" it, which is not always easy, especially in multi-dimensional spaces.
- The result of the clustering algorithm (that in many cases can be arbitrary itself) can be interpreted indifferent ways.

Biclustering

Biclustering (Madeira & Oliveira, 2004) is another data mining technique. It is also named as Co-Clustering, Two Way Clustering. It generates biclusters of different sizes and characteristics. The process of grouping data based on both the rows (segments) and columns (amino acids). Biclustering is useful for Bioinformatics and many other research areas. It is NP-Complete.

The major difference (Berkhin, 2002; Madeira & Oliveira, 2004) between the clustering and biclustering are as follows.

1. Clustering applied to any one of the dimensions of the dataset, but biclustering applies to both dimensions.
2. Clustering derives the global model, biclustering derives the local model.
3. Biclustering groups more similar patterns than the clustering process.

Contribution

The contributions of the thesis are as follows.

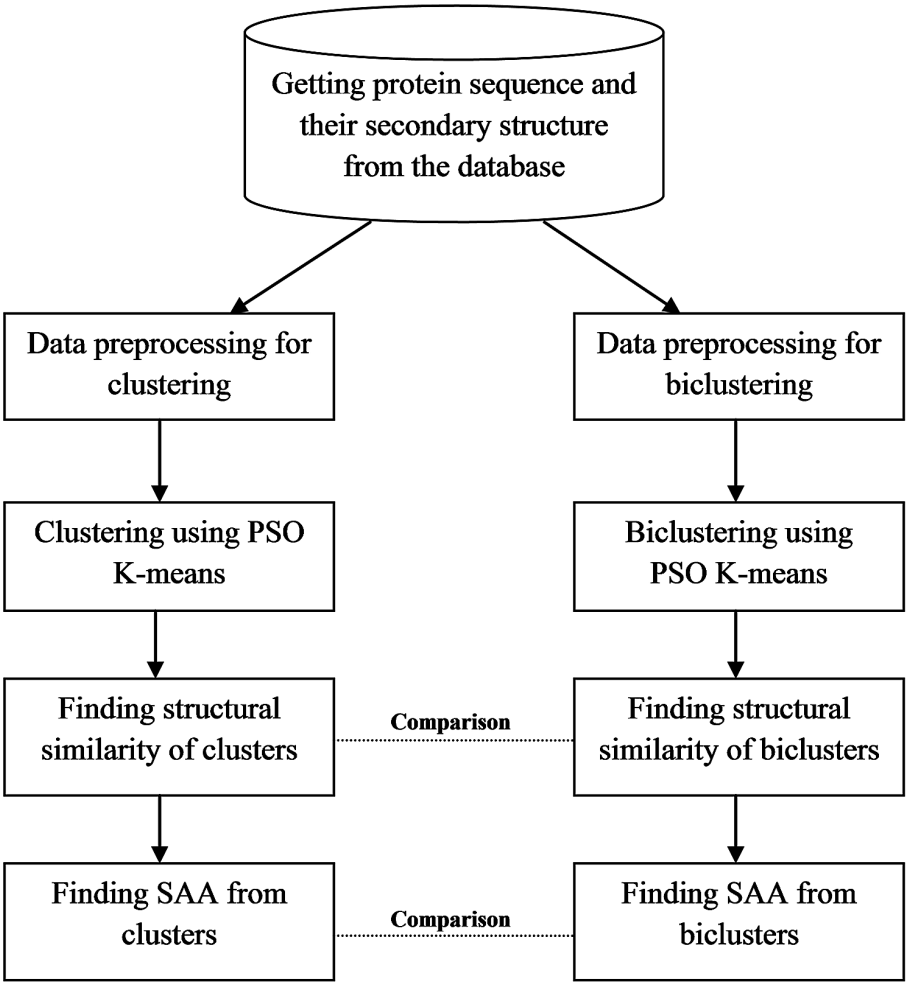
1. Studying various methods of extracting protein motifs from the literature.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. The proposed work is to extract the motif from the protein by clustering the given protein sequence with PSO K-Means.
3. The proposed work is to extract the motif from the protein by biclustering the given protein sequence with PSO K-Means.
4. Comparison between the quality of the clusters and biclusters based on structural similarity.
5. Comparison between significant amino acids extracted from clusters and biclusters.
6. The overview of the proposed work is shown in the Figure 3.

The protein sequence is extracted from the databases that are available for the protein sequence and motifs such as BLOCKS (Pietrokovski, Henikoff, & Henikoff, 1996), PROSITE (Bairoch, 8ucher & Hofmann, 1996), PISCES (Wang & Dunbrack, 2003) and so on. The protein sequence is preprocessed for both clustering and biclustering processes. The clusters and biclusters are compared based on their structural similarity, extracted significant amino acids and protein motifs extracted.

Figure 3. Overview of the proposed work



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

In this work (Zhaoa-Xing-Ming, 2005), they have proposed a novel approach for extracting features from motif content and protein composition. They have used Support Vector Machine (SVM) along with the combination of Genetic Algorithm (GA) and Principal Component Analysis (PCA) for extracting the protein motif.

In this work (Fujiwara & Konagaya, 2008), they have proposed a methodology for protein extraction in their work, they have used the Hidden Markov Model (HMM) to detect the protein motifs from the proteins with motifs unidentified. They train the HMM with test samples of protein motifs of various categories to detect the protein motifs as similar to the trained dataset.

In this work (Chen, Pellicer, Tai, Harrison, & Pan, 2009), the authors have proposed a novel efficient granular computing models for protein sequence motif and structure information discovery. The protein sequence motifs are extracted using the granular computing with the Fuzzy improved K-Means model and Fuzzy greedy K-Means model.

In this work (Cheng, Hudson, Kim, Crawford, Wright, & Che, 2011), they have defined another method for protein sequence motif extraction using Decision Forest. They have used the decision forest combined with fuzzy logic and granular computing to get more efficient results than their previous work.

In this work (Vincent, Bernard, & SinanKockara, n. d.), the authors have proposed a biclustering algorithm for extracting the protein motifs. They obtained the clusters using Fuzzy Greedy K-Means (FGK) model along with the Granular Computing. They used Cheng and Church methodology to shrink the clusters in order to get high quality biclusters.

In this work (Elayaraja, Thangavel, Ramya, & Chitralegha, 2011), the authors have devised a method for motif extraction process using the rough K-Means. They have used Rough K-Means to yield the better results than simple K-Means in their work, "Extraction of Motif Information from Protein Sequences using Rough K-Means" in 2011

In this work (Elayaraja, Thangavel, Chitralega, & Chandrasekhar, 2012), they have further suggested another method for motif extraction process using the SVD in addition to the rough K-Means in order to attain better results. Their work is "Extraction of Motif Patterns from Protein Sequences Using SVD with Rough K-Means Algorithm" in 2011

In this work (Chang, 2012), they have suggested a method for Protein Motif Extraction Using Neuro-Fuzzy optimization in 2002, they attempted to improve the speed and flexibility of protein motif identification. They proposed an algorithm to extract both rigid and flexible protein motifs and to detect consensus pattern, or motif, from a group of related protein sequences.

In this work (Chen, KripamoyAguan, Yang, Wang, Pal, & Chung, 2011), they have suggested a method for the discovery of Protein Phosphorylation Motifs through Exploratory Data Analysis, they proposed an F-Motif algorithm for motif extraction using clustering methods in 2011.

The various works in the literature show that the different hybrid methods were used for extracting the Motif Information. Those methods are any combination of Support Vector Machine (SVM), hidden Markov Model (HMM), Neural Networks, Fuzzy system, Rough set, Clustering technique and so on. Some authors were used optimization technique to improve the extraction process, such as Genetic Algorithm (GA). From the literature, it shows the combination of optimization technique can improve the results. The PSO is one of the best optimization techniques that does not stuck with local optimum. The

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

clustering technique is better suits for unidentified data. The biclustering further improves results than the clustering process, the combination of PSO with clustering and biclustering on protein sequences is proposed and yield better results. This proposed work is further discussed in the following chapters.

METHODS AND MATERIAL

The protein motifs are extracted using various data mining techniques. In this study, clustering and biclustering technique are used. The K-Means algorithm is used for this clustering process. The PSO K-Means algorithm is proposed for the protein sequence to extract motif information.

K-Means

The K-Means (Ahmadyfard & Modares, 2008) algorithm is one of the simplest, ever using and known clustering algorithms. It is suitable for many research areas. K-Means is one of the simplest unsupervised learning algorithms that solve the well-known clustering problem. It is numerical, unsupervised, non-deterministic and iterative clustering method.

The given dataset is partitioned into k clusters. The data points are assigned randomly to the clusters resulting in clusters that have roughly the same number of data points. This algorithm works faster for the larger dataset. It produces the tighter clusters than hierarchical clustering. The simple K-Means algorithm is shown in the Figure 4.

Particle Swarm Optimization

Optimization is the process of determining the best possible or desirable solution. There are a number of nature inspired optimization algorithms that imitate the natural behaviors. Swarm intelligence (2006) is devised based on the collective behavior of the decentralized and self-organized system of the natural swarms. The particle swarm optimization (AshaGowdaKaregowda & SeemaKumari, 2013) is one of the swarm intelligence techniques. It is a stochastic optimization technique. It is a population based method that is designed based on the birds flocking behavior. Selecting the initial population is decided based

Figure 4. Simple K-Means algorithm

1. Select k objects from the search space represented by the objects that are to be clustered. These are initial cluster centroid.
2. Assign each object to the group that has the closest centroid.
3. When all objects have been assigned, recalculate the positions of the centroid.
4. Repeat Steps 2 and 3 until the centroid no longer move. This produces a separation of the objects into groups from which the metric to be minimized can be calculated.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

on the problem criteria. The steps involved in PSO algorithm are given in the Figure 5. The number of individuals in the population is decided based on the objective of the problem. The particle at each time interval updates its position and velocity based on its own best position achieved so far and the global best position achieved by any one of the particles in its swarm. The random terms are used to weigh the acceleration of the particle. The best position is evaluated based on the objective function of the problem. The basic particle swarm optimization algorithm (Vora, 2013; Riccardo, James, & Tim, 2007) is in 0.

The velocity of the particle is updated based on equation 1, here the first term is based on the velocity of the previous iteration t, second term is cognition part, based on the local best position of the particle and the third term is social part, based on the global best position of the particle. The w represents the inertia weight of the previous velocity of the particle; it is calculated using the equation 2. The c1 and c2 are constant values chosen randomly, the R1 and R2 are random numbers where R1, R2 [0,1].

$$vel_{ij}\left(t+1\right) = wv_{ij}\left(t\right) + c_1 R_1\left(pbest_{ij} - x_{ij}\left(t\right)\right) + c_2 R_2\left(gbest_{ij} - x_{ij}\left(t\right)\right) \tag{1}$$

where,

$$w = W_{max} - \frac{W_{max} - W_{min}}{iter\left(max\right)} - iter\left(x\right) \tag{2}$$

The w_{max} is the initial weight of the particle and w_{min} is the final weight of the particle. The position of the particle at each iteration is updated using the equation 3 based on the updated velocity of the particle.

$$x_{ij}\left(t+1\right) = x_{ij}\left(t\right) + v_{ij}\left(t+1\right) \tag{3}$$

Homology Secondary Structure of Proteins

HSSP (Homology-derived Secondary Structures of Proteins) (Reinhard, Antoine & Chris, 1996) is a derived database merging information from three- dimensional structures and one- dimensional sequences of proteins.

HSSP file of any protein sequence will contain the following parts:

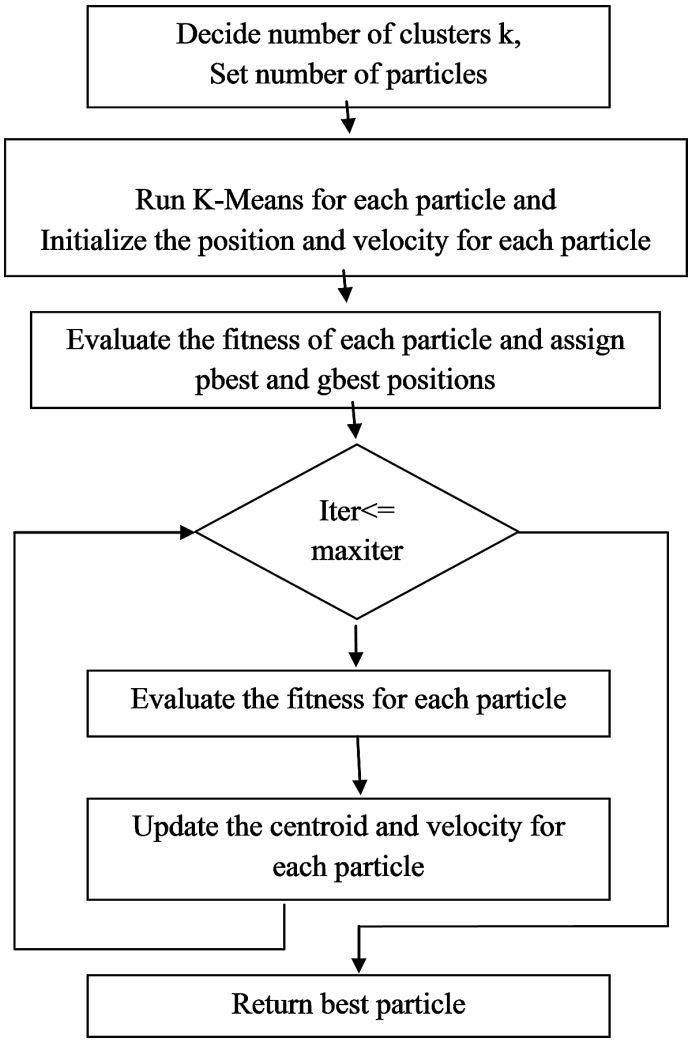
- Header information
- Protein sequence
- Alignment information
- Sequence profiles

Distance Measure

The city block distance (Vincent, Bernard, & SinanKockara, n. d.; Elayaraja, Thangavel, Chitralega & Chandrasekhar, 2012) is suitable for this type of data. Since this measure deals with n-dimensional data element, it is suitable for this type of sequence profiles. The distance measure is calculated using the equation 4.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Particle swarm optimization algorithm



$$\text{distance} = \sum_{i=1}^{R}\sum_{j=1}^{A} V_k(i,j) - V_c(i,j) \tag{4}$$

where R is the number of residues and A is the number of amino acids (20). The Vk(i,j) is the value of the profile matrix in row i and column j of segment k. The Vc(i,j) is the value at row i and column j of the centroid of the cluster c.

Cluster Validity Measure

The clusters detected by each particle are evaluated for their fitness. The intra cluster distance (Ahmadyfard & Modares, 2008) is used as the cluster validity measure. The intra distance of the cluster shows how close the elements of the cluster are placed. The average intra distance value of each particle is calculated. The particle with the minimum distance is taken as the best particle.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{intra distance} = \sum_{i=1}^{n} \text{distance}(A_k\left(i\right), \text{cent}_k) \tag{5}$$

where distance(A_k(i),cent$_k$) is calculated using the city block distance as defined earlier in the equation 5.

Bicluster Validity Measure

The biclusters detected by each particle are evaluated for their fitness. The Mean Square Residue (MSR) (Madeira & Oliveira, 2004) value is used to validate the biclusters of each particle. The particle with minimal MSR value is considered as best particle. It is calculated using the equation 6.

$$\text{MSR}\left(b\right) = \frac{1}{\left|I\right|\left|J\right|} \sum_{i\epsilon I,\ j\epsilon J} \left(b_{ij} - b_{iJ} - b_{Ij} + b_{IJ}\right)^2 \tag{6}$$

Where MSR(b) is the mean square residue of a bicluster b with I rows and J columns, b_{iJ} represents the column average and b_{Ij} represents the row average.

Structural Similarity Measure

Similarity measure for the protein sequences is calculated based on the secondary structure of the protein sequence. A cluster's or bicluster's average structure (Vincent, Bernard, & SinanKockara, n.d.) is calculated using the equation 7.

$$\text{Structural similarity} = \frac{\sum_{i=1}^{ws} \max\left(P_{i,H},\ P_{i,E},\ P_{i,C}\right)}{ws} \tag{7}$$

Where ws is the window size and $P_{i,H}$ shows the frequency of occurrence of helix among the segments for the cluster in position i. $P_{i,E}$ and $P_{i,C}$ are defined in a similar way. If the structural homology for a cluster or bicluster exceeds 70%, then it can be considered as structurally identical. If the structural homology for the cluster or bicluster is between 60% and 70%, then it can be considered weakly structurally homologous.

PROPOSED METHOD: MOTIF EXTRACTION USING PSO K-MEANS

PSO K-Means

Initially the numbers of groups (k) have to be given data. This will differ for different dataset. The k value plays vital role in the K-Means, the k value that suits the given dataset can be estimated by the trial and error process. Then decide the number of particles to perform our clustering process to find the optimal result. The initial velocity and position of the particle can be set based on the objective.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Each particle will cluster the source data into k clusters. The centroid of their clusters is taken as the position of that particle. Initially, each particle will take the random position and random velocity. Then the fitness of each particle is calculated. Then for each particle the pbest position is evaluated, the velocity and position of each particle are updated until the termination criteria are met. The gbest position is updated at each iteration. The various steps involved in PSO K-Means is shown in the Figure 6.

Clustering Using PSO K-Means

The K-Means algorithm is one of the simplest, ever using and known clustering algorithms. K-means algorithm highly depends on the initial state and converges to the local optimum solution. So the optimization method is used to obtain the optimum result of the K-Means algorithm. PSO (Kunik, Solan, Edelman, Ruppin & Horn, 2005) is ideal for identifying the global optimal cluster i.e. global significant amino acid. This method suffers from local minima problem which can be eliminated by the optimization technique like PSO (Youcheng et al., 2012; AshaGowdaKaregowda & SeemaKumari, 2013)

The number of particles is set as per the user's need not greater than 100. It is set in order to overcome the complexity of the computation. The initial velocities of each particle are set to random values. The position of each particle is the cluster centroid. The number of cluster taken is fixed for each particle. The cluster intra distance is taken as the fitness in the PSO algorithm ($Fitness_{clus}$) using equation 8.

$$Fitness_{clus} = \frac{\sum_{k=1}^{K}\sum_{i=1}^{n} P_{ik} - P_{ibest}}{K} \tag{8}$$

The particle with minimum fitness value is taken as the best particle. In the equation 4.1K represents the number of clusters, P_{ik} is the position of the i^{th}particle in the cluster k, P_{ibest} is the personal best of the i^{th}particle and n is the number of particles. The various steps involved in PSO K-Means are shown in theFigure 6.

The pseudo code for psokmeansprocedureis given in theFigure 7. the preprocessed sequence (A), number of clusters required (k) and number of particles (n) to generate are given as input to the this procedure. The procedure kmeans(A, k) is used to cluster the given dataset A into k clusters for each particle with different centroid. The max_iter is the maximum number of iterations to be performed. The evaluateFitness(pop_i) is used to evaluate the fitness value of the i^{th} particle using the equation 4.1. The evaluatePBest(p_{besti}) is used to find the local best (pbest) position of the i^{th} particle. The updateVelocity(vel_i)

Figure 6. Steps in PSO K-Means

1. Generate the initial population by choosing number of individuals in the population.
2. For each particle initialize the parameters like velocity and position.
3. While the iteration <= iteration max or termination condition
    a. Evaluate the fitness of each particle position and Update the 'pbest' and 'gbest' positions.
    b. Update the particle velocity and position using eq. 1 & 3.
4. End

Figure 7. Pseudocode for PSO K-Means procedure

```
Procedure psokmeans
Input :
        A   //preprocessed dataset
        n   // number of particles
        k   // number of clusters
Output :
        gbest   //global best particle
start procedure
        for each particle i
                // call kmeans for each particle
            pop_i=kmeans(A,k)
            pbest_i=evaluateFitness(pop_i)
            vel_i=rand val
        end for
        gbest=pbest_1
            //initialize gbest with pbest of first particle
        while iter<=max_iter
            for each particle i
                evaluateFitness(pop_i)
                pbest_i = evaluatePBest(pop_i)
                vel_i = updateVelocity(pop_i)
                updatePosition(pop_i)
            end
            gbest=evaluateGBest(pbest)
        end while
        return gbest
end procedure
```

procedure is used to update the velocity of the i^{th}particlein the current iteration. The updatePosition(pop_i) procedure is used to update the position of the i^{th}particle in the current iteration. The global best (gbest) value is evaluated at the end of each iteration using evaluateGBest(pbest) procedure.

Biclustering Using PSO K-Means

Biclustering is viewed as an optimization problem with the objective of finding the biclusters with minimum MSR and high volume. PSO is ideal for identifying the global optimal bicluster i.e. global optimal sequence motif. This method suffers from local minima problem which can be eliminated by the optimization technique like PSO. A Biclustering (Das & Idicula, 2010; Rathipriya, Thangavel & Bagyamani, 2011; Cui & Potok, 2005) algorithm along with Particle Swarm Optimization (PSO) technique for protein sequence is proposed. The main objective of this algorithm is to identify the minimal subset of amino acids with coherent in their presence in the sequences. These biclusters have low MSR value, where MSR value is the quality measure of correlation between various residues and amino acids. PSO is initialized with initial biclusters which is obtained by using PSO K-Means on both the dimensions of the normalized protein frequency matrix A. This result in faster convergence compared to random particle initialization of the PSO and it also maintains high diversity in the population. Each particle of PSO (Rathipriya, Thangavel & Bagyamani, 2011; Thangavel, Bagyamani & Rathipriya, 2011) explores a possible solution. It adjusts its flight, according to its own and its companions flying experience.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The personal best (pbest) position is the best solution found by the particle during the course of the flight. This is denoted by the pbest and the optimal solution is attained by the global best (gbest). BPSO updates iteratively the velocity of each particle towards the pbest and gbest. For finding an optimal or near optimal solution to the problem, PSO keeps updating the current generation of particles. This process is repeated until the stopping criterion is met or maximum number of iterations is reached. The MSR is taken as the fitness of the bicluster ($Fitness_{bic}$) using the equation (9).

$$\text{Fitness}_{\text{bic}} = \frac{1}{|I||J|} \sum_{i \epsilon I, j \epsilon J} \left(b_{ij} - b_{iJ} - b_{Ij} + b_{IJ} \right)^2 \tag{9}$$

Where fitness is the mean square residue of a biclusterb with I rows and J columns, b_{iJ} represents the column average and b_{Ij} represents the row average.

The pseudo code for psokmeansbic procedure is given in the Figure 8 9. the preprocessed sequence (B), number of row clusters (rk) and column clusters (ck) required and number of particles (n) to generate are given as input to this procedure. The procedure kmeansbic(B, rk, ck) is used to cluster the rows of given dataset B into rk clusters and cluster the columns of given dataset B into ck clusters, then combines the row clusters and column clusters into sub-clusters known as biclusters for each particle with different centroid.

The max_iter is the maximum number of iterations to be performed. The evaluateFitness($popbic_i$) is used to evaluate the fitness value of the i^{th} particle. The evaluatePBest($pbestbic_i$) is used to find the local best (pbestbic) position of the i^{th} particle. The updateVelocity(vel_i) procedure is used to update the velocity of the i^{th} particle in the current iteration. The updatePosition($popbic_i$) procedure is used to update the position of the i^{th} particle in the current iteration. The global best (gbestbic) value is evaluated at the end of each iteration using evaluateGBest(pbestbic) procedure.

Experimental Analysis

The proposed work is implemented in MATLAB 2012, the system has 3 GHz Intel core processor, 2GB RAM and Windows7 Operating System. This section discusses the experimental analysis of each step involved in this proposed work.

Protein Sequence Dataset

In this empirical study, more than 2710 protein sequences are taken from the Protein Sequence Culling Server (PISCES) (Wang & Dunbrack, 2003) as the dataset. In this database, none of the sequences shares more than 25% sequence identity.

The frequency profiles from the HSSP is constructed based on the alignment of each protein sequence from the protein data bank (PDB) where 300 sequences are considered as homologous in the sequence database. The Sliding windows with nine consecutive residues are taken. Each window contains one sequence segment of nine continuous positions. In addition, all the sequences are considered homologous in the sequence database. Secondary structures are also taken from DSSP. DSSP is a database of secondary structure assignments for all protein entries in the PDB. The various parameters used in our work are listed in the Table 2. The 30 sample protein sequences are taken and it is converted into 10,635 segments.

Table 2. List of parameters

Number of sequences	30
Number of segments	10,635
Number of residues	9
Number of clusters	50-100
Number of biclusters	Row clusters: 50-100 Column clusters: 3-5
Number of particles	30-100

Sequence Representation

Each sequence is represented using sliding window (Vincent, Bernard & SinanKockara, n.d.; Elayaraja, Thangavel, Chitralega & Chandrasekhar, 2012). A sliding window contains residues as rows and amino acids as columns. In this study nine consecutive residues are taken. Normally, twenty Amino Acids are used to represent the protein sequence. The size of each sequence differs from the other. In order to make

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

all the sequence of same size and to convert the categorical data into numerical the following steps are performed. First arrange the one-dimensional sequence data into two-dimensional by taking the HSSP profile frequency values of every nine consecutive residues as one segment. Now each segment will be in the size nine by twenty. This preprocessing step is shown in the Figure 9. The secondary structures of the protein sequence are collected from the DSSP database. There are eight classes in secondary structure which is mapped to three classes the following conversion model: assigning H, G, and I to H (Helices), assigning B and E to E (Sheets), and assigning all others to C (Coils).

These sliding windows are used for clustering process, whereas for biclustering each window is normalized to a single row. For this purpose, the normalization techniques like average value, difference between max and min value and most frequent value can be taken. Now the data become two-dimensional with each row representing a segment and the column represents the average composition of the 20 Amino acids in that segment. This preprocessing step is shown in the Figure 10.

RESULTS AND DISCUSSIONS

The result of both the clustering and biclustering process using PSO K-Means model as proposed in this work are tabulated and interpreted below. The comparison between the clustering and biclustering process is performed based on their secondary structure similarity is discussed. The significant amino acids of the protein sequence are extracted and visualized using logo representation. The motifs detected for the given sequences are taken as superset for the significant amino acids and their interpretation is also tabulated.

Structural Similarity Comparison

The clustering technique is quite inefficient when compared to the biclustering process. This is proven from the secondary structure similarity value. The number of clusters (Vincent, Bernard, & SinanKockara, n. d.) with higher similarity value generated by our model is less when compared to the number of biclusters generated.

The Table 3 shows that biclustering can detect the biclusters with more similarity value. So the biclustering technique is better when compared to the clustering technique for protein motif extraction process. The structural similarity value is calculated using the equation 7. The clusters or biclusters with similarity value greater than 70% is taken as highly homologous and with a similarity greater than 60% and less than 70% is taken as a weakly homologous sequence. The Figure 11 is the plot with the number of clusters and biclusters with structural similarity as given in the Table 3. From this figure, it is clear that the biclustering model can detect more homologous sequence than the clustering model.

Sequence Motif Representation

The PSO K-Means Biclustering Model is chosen to improve the cluster quality which extracts the motif information efficiently without converging to the local minima. The Figure 12 and Figure 13 are the sequence logo representation of the cluster 1 and 2. Similarly the Figure 14 and Figure 15 are the logo representation of the bicluster 1 and 2.

The logo representations of the clusters and biclusters show that the biclusters are more conserved to specific amino acids than the clusters. The horizontal axis shows the positions and the vertical axis shows the bits of amino acids. The PSO K-Means-Biclustering Model is chosen to improve the cluster quality

Table 3. Comparison between clustering and biclustering based on secondary structural similarity

Number of clusters= 147 *Number of biclusters=147 (49× 3)*		
Structural Similarity Value Above	**Clusters**	**Biclusters**
75%	23	35
70%	40	54
65%	69	75
60%	76	89

because it clusters the columns of the data matrix in addition to clustering the rows. The corresponding amino acid sequence columns that are purged by the PSO K-MeansBiclustering Model (Motif) (Vincent, Bernard, & SinanKockara, n. d.) are shown to be either the full or the partial superset of the significant amino acids (SAA): amino acids with appearing frequency greater than 8%. Table 4 and Table 5 illustrate the SAA and Motif relationship for the entire nine positions of the bicluster 1 and 2. Thus, biclustering are proven to have the potential to select meaningful amino acids that biologists are interested in.

CONCLUSION

The motif information is extracted using this PSO-K-Means model efficiently than simple K-Means. The results show that the PSO-K-Means Biclustering Model is capable of preserving more original data points and obtaining better cluster quality. The biclustering model can detect the highly homologous sequences than the clustering model. The motifs extracted are helpful for biologist for their further research works on new protein sequence. This will be an apt computational process for the biologists handling the two dimensional sequences. It reduces the computational cost when compared to the computations on multi-dimensional sequence analysis.

The future enhancements will be performed as follows:

- Select different number of residues
- Use any criteria for selecting the number of clusters
- Combine granular computing technique with this technique further
- Use some other optimization techniques like BCO, ACO etc.,
- Prediction of biological functionality of the extracted motifs

KEY TERMS AND DEFINITIONS

Biclustering: The process of grouping data based on both the rows (segments) and columns (amino acids)

Bio-Inspired Computing: Bio-inspired computing is a field devoted to tackling complex problems using computational methods modeled after design principles encountered in nature

Clustering: Grouping similar kind of data elements. It is used to discover similar patterns from a sea of data. The similarity between the objects in the same cluster is greater than that of the different clusters.

Protein Motif: Motifs are the patterns that present repeatedly in the sequence which are responsible for various cellular processes

Protein Sequence: Sequence of Amino Acids responsible for various cellular activities of the biological systems

PSO: Particle Swarm Optimization is one of the swarm based optimization technique. It is devised based on the bird flocking behavior

Significant Amino Acids (SAA): SAA represents the protein pattern that present in the set of protein sequences that shows the dominant characteristic present in that Protein group.

ABSTRACT

Breast cancer is considered as one of the life-threatening disease among woman population in developing as well as developed countries. This specific study reports on classification of breast thermograms using probabilistic neural network (PNN) with four statistical moments features mean, standard deviation, skewness and kurtosis and two entropy features, Shannon entropy and Wavelet packet entropy. The CLAHE histogram equalization algorithm with uniform and Rayleigh distributions were considered for contrast enhancement of breast thermal images. The asymmetry detection was performed by applying bilateral ratio. A total of 95 test images (normal = 53, abnormal = 42) was considered. Simulation

study shows that CLAHE -RD with wavelet entropy features confirms the existence of symmetry on the right and left breast thermal images. An overall classification accuracy of 92.5% was achieved using the proposed multifeatures with PNN classifier. The proposed technique thus confirms the suitability as a screening tool for asymmetry detection as well as classification of breast thermograms.

INTRODUCTION

Medical thermography is found to be a promising tool for early breast cancer detection and provides a scope of developing computer aided diagnostics tool for the biomedical engineering community. The high metabolic changes are reflected in the form of high temperature in the localized region through infrared thermal images and this property is well exploited for the clinical breast cancer interpretation (Kontos et al., 2011; Amri et al., 2016). The inherent relation between the radiation from the human skin and surface temperature has a huge influence in the level of skin's blood perfusion. This property is being exploited for infrared thermal imaging and the effect of angiogenesis, inflammatory, etc. is well captured by this imaging procedure. It has the ability to showcase the changes in the vascular process referred as neoangiogenesis (Nishida et al., 2006). The increase in surface temperature in the cancerous regions can be well exploited using this imaging procedure. The active and inactive blood vessels in and around the breast region can be well mapped through this thermographic imaging. It further detects the newly formed or activated blood vessels with distinct appearance. Due to its ability to detect changes at the cellular level, study reveals that the thermographic imaging test can detect activity 8 to 10 years before any other test. This makes the IR imaging based thermography as the potential candidate to detect the metabolic changes before the actual formation of the tumor (Moghbel et al., 2011; Bhowmik et al., 2015; Amri et al., 2016; Garduño-Ramón et al., 2017).

Several attempts have been made towards the detection of breast cancer using thermography imaging technique. Kuruganti & Qi (2002) performed asymmetric analysis in breast cancer detection. The hotspot cancerous tissue due to temperature variation was recognized by this approach. Initial segmentation was performed using Hough transform. The test images were obtained from Bioyear Inc. with a sensitivity of 0.05 degrees Celsius.

Mahmoud Zadeh et al. (2015) have applied the extended hidden Markov model for optimal segmentation of breast thermal patterns. The proposed method was able to recognize semi hot regions into distinct areas. The computational burden was less compared to other segmentation procedures reported in the literature. A specific study on breast cancer detection using rotational thermography was reported (Francis et al., 2014). The proposed work showed a significant improvement on detection of breast cancer compared to the traditional thermography procedure. Textural features were extracted to distinguish cancer and non-cancerous tissues from breast thermo grams. Acharya et al. (2010) have showed the effect of textural features with support vector machine classifier for breast cancer detection using infrared thermal images. An overall classification accuracy of 88.10% was attained based on the database obtained from General hospital, Singapore. Bhowmik et al. (2015) have shown a specific study on analysis of hybrid intelligent techniques using breast thermography the detection of breast cancer. A specific study by making use of higher order statistics for breast thermograms was reported (Acharya et al., 2014). Ramakrishnan & Suganthi have investigated the effect of Gabor wavelet transform for breast thermogram images (Ramakrishnan & Suganthi, 2014).

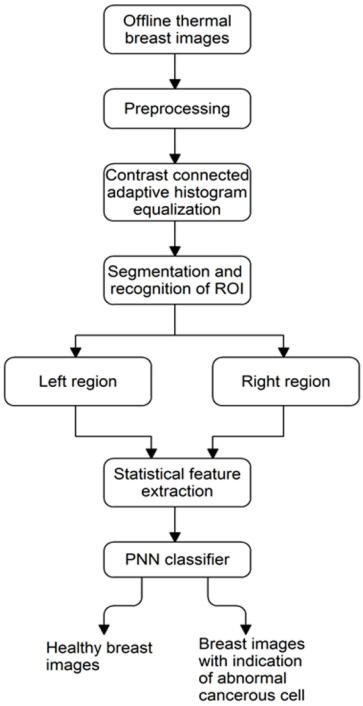
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This specific research study investigates the classification of breast thermograms for cancer detection using the thermal breast images collected from Indian women ethnic group. The pilot study was carried out to develop automated screening algorithm for breast cancer among Indian woman. The proposed scheme employs CLAHE with Rayleigh distribution for contrast enhancement followed by extraction of statistical moments and entropy features. The semi-automated region of interest detection helps in identifying the symmetry/asymmetry nature of the acquired breast thermograms. Later probabilistic neural network was applied for classifying the normal and abnormal breast thermograms. Ductal carcinoma was considered as the abnormal for the proposed study. Further the study was restricted to lateral position of the thermograms for the investigations.

PROPOSED BREAST THERMOGRAM CLASSIFICATION SCHEME

Figure 1 shows the flow diagram of the proposed breast thermogram classification technique. The breast thermal images were captured using the FLIR IR camera using the standard protocol with appropriate ethical clearance. The acquired offline images were filtered and grayscale image processing was performed. In order to enhance the image, Contrast-Limited Adaptive Histogram Equalization (CLAHE) mapping to two variants, uniform and Rayleigh distributions was applied. Canny edge detection with gradient operator was introduced to segment the image and appropriate ROI was selected through semi-automated technique from right and left breast regions.

Figure 1. Proposed breast thermogram classification scheme



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Four statistical moments such as, mean, standard deviation, skewness and kurtosis along with two entropies, Shannon's entropy and Wavelet packet entropy were applied and these significant features later was collectively fed to a probabilistic neural network model for classification of normal and abnormal breast images. In order to locate the existence of asymmetry between the left and right breast regions, a parameter referred as bilateral ratio was applied. The performance of the proposed model was evaluated in terms of sensitivity, specificity and classification accuracy.

STUDY SETUP

Figure 2 shows the screening setup of breast thermography. The subjects were requested to sit in a comfortable position and were asked to undress up to waist to ensure smooth recording of the image under controlled room temperature (22° C). Due ethical clearance was obtained and subject consent form were collected before the commencement of the procedure. The camera was arranged at a distance of 1.5m from the subject. Only frontal postures were considered for the analysis in this pilot study. The database was based on the breast thermograms collected from Indian ethnic women of age group 24-58.

Being a non-invasive screening technique, breast thermogram images cannot be compared directly to recognize the normal and cancerous cells. The asymmetry analysis indicates the presence of cancerous cells. It is well known fact that the red and white regions in the breast thermograms indicate the hot spots; green region as moderate temperature and blue regions as cold regions. The temperature distribution plays a very crucial role in breast region analysis. Figures 3 and 4 show the typical normal and abnormal images. For this specific study, 53 normal and 42 abnormal breast thermal images were collected.

GRAY SCALE PROCESSING

The thermal images were filtered using second order Butterworth filter and gray scale level processing was applied. In order to improve the contrast of the image, a variant of histogram equalization referred as contrast Limited Adaptive Histogram Equalization (CLAHE) was applied. To select the best region of interest, two different mapping was considered: Uniform and Rayleigh distributions (Erturk, &Konyar.,

Figure 2. Screening setup of breast thermography

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Typical normal images

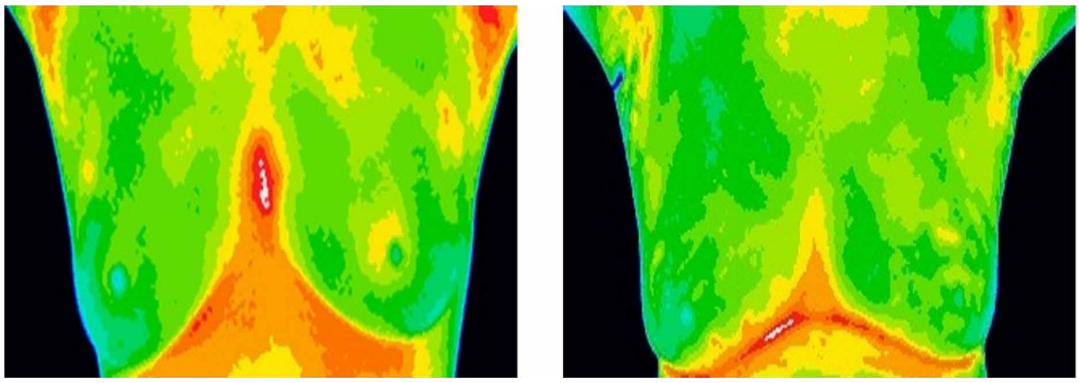


Figure 4. Typical abnormal images (ductal carcinoma)

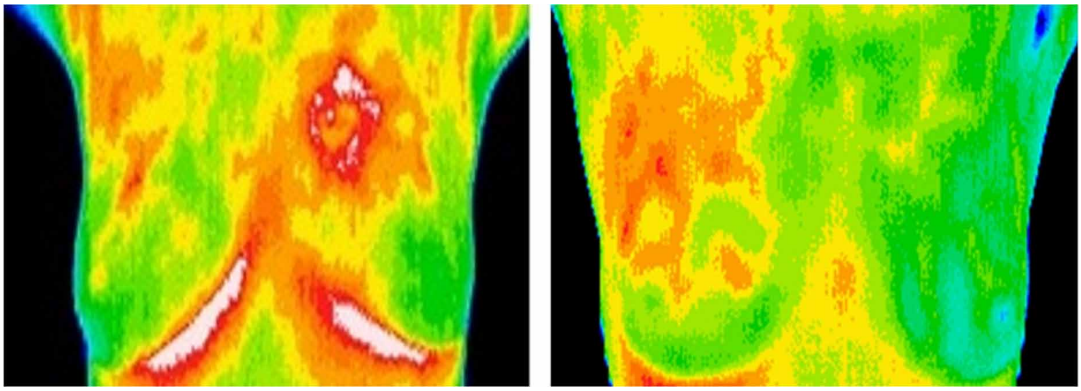

2015; Erturk, 2013). While considering the infrared images, there are certain cases where uniform re-distribution suffers due to nondiscrimination of background and foreground and allows noise to some extent (Yousefi et al., 2013). This study compares the influence of both distributions. Each histogram in the CLAHE refers to distinct section of the image referred to as tiles (Pizer et al., 1990). The tiles contrast enhanced the results in the specific distribution. Figure 5 (parts a-e) shows the entire process.

SEGMENTATION OF ROI

Segmentation of ROI is an important step in image processing, it is from this image that the accuracy of the system is determined. Segmentation follows pre-processing which includes background removal and resizing for removing the undesired body portions in the breast thermogram images. The resultant image is then subjected to canny edge detection to extract the breast boundaries, suitable threshold value is chosen to eliminate detection of extra curves (Scales et al., 2004). The next step includes the extraction of left and right boundary curves using gradient operator. The lower breast boundaries are extracted and the unwanted portions below it are removed and separation line is created to separate the right and left regions. Figure 6 depicts the resultant ROI with left and right breast regions.

Figure 5. (a) Sample image; (b) Gray scale image; (c) Histogram; (d) Contrast enhanced image; (e) Histogram

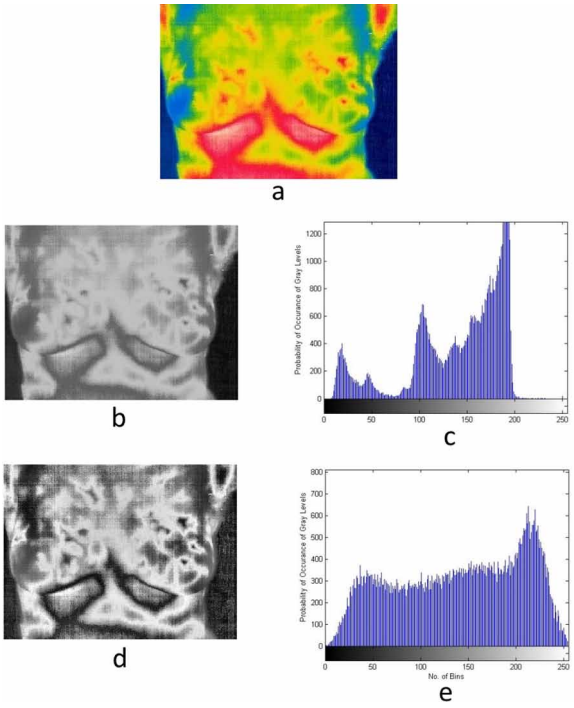

Figure 6. ROI with left and right segmented portions

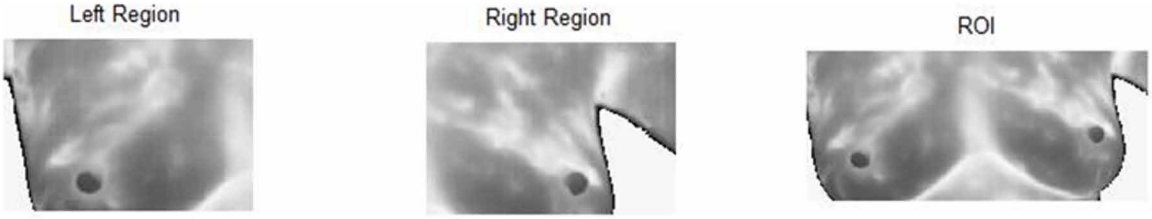

FEATURE EXTRACTION

After the thermal images were preprocessed, the resultant image was dimensionally segmented into two regions namely right and left. The following statistical moments were applied for the proposed work (Qi & Kuruganti, 2002; Ng et al., 2001):

1. **Mean:** It is average value of pixels in the region of interest. Slight variation of mean is seen in noncancerous patients and vice versa in cancerous patients. It is calculated by:

$$\mu = 1 / MN \sum_{i=1}^{M} \sum_{j=1}^{N} \left(P(i,j) - \mu \right)^2$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Standard deviation:** It is a measure of quantifiable amount of variance. It also measures pixels distribution. Once the preprocessed image is dimensionally segmented into right and left halves, above mentioned statistical features are extracted from both the regions. Standard deviation is calculated by taking the square root of variance which is given by:

$$\sigma = \sqrt{\mu = 1 / MN \sum_{i=1}^{M} \sum_{j=1}^{N} \left(P(i,j) - \mu \right)^2}$$

3. **Kurtosis:** It identifies the abnormality and classifies as normal or abnormal class. The image with high kurtosis have shaper peak near mean and the image with low kurtosis have flat peak near the mean. Kurtosis is calculated by:

$$K = \left\{ 1 / MN \sum_{i=1}^{M} \sum_{j=1}^{N} \left(\frac{P(i,j) - \mu}{\sigma} \right)^4 - 3 \right\}$$

4. **Skewness:** Measures asymmetry of the pixel value around the sample mean. Negative skewness indicates that the pixels are spread out more towards left side of the mean. Positive skewness indicates that the pixels are spread out more towards right side of the mean. Ideally skewness of normal distribution is zero. Skewness is calculated by:

$$S = 1 / MN \sum_{i=1}^{M} \sum_{j=1}^{N} \left(\frac{P(i,j) - \mu}{\sigma} \right)^3$$

Two entropies, Shannon's Entropy (SE) and Wavelet Packets Entropy (WE)were applied as features apart from the statistic features. The Wavelet Packet Entropy (WE) was calculated based on the work reported by Wong and Cheng (2013).

Figure 7 shows the plot of four statistical moments based on CLAHE with Uniform Distribution (UD) and Rayleigh Distribution (RD) respectively for right and left breast regions.

ASYMMETRY IDENTIFICATION

In order to recognize whether the test breast thermal image has cancerous tissue or not, asymmetry test was performed using the parameter, Bilateral Ratio (Kuruganti & Qi, 2004). It can be estimated based on the feature values calculated for right and left breast regions. It is understood that closer the value to one, more existence of correlation among the left and right regions that confirms the symmetry behavior. This aspect indicates that the given test image can be categorized as "normal." The Bilateral Ratio (BR) (closeness to 1) is defined as:

$$\mathbf{BR} = \left| \frac{\textbf{Feature value from left}}{\textbf{Feature value from right}} - \mathbf{1} \right|$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Feature plot distribution based on CLAHE-RD and CLAHE-UD

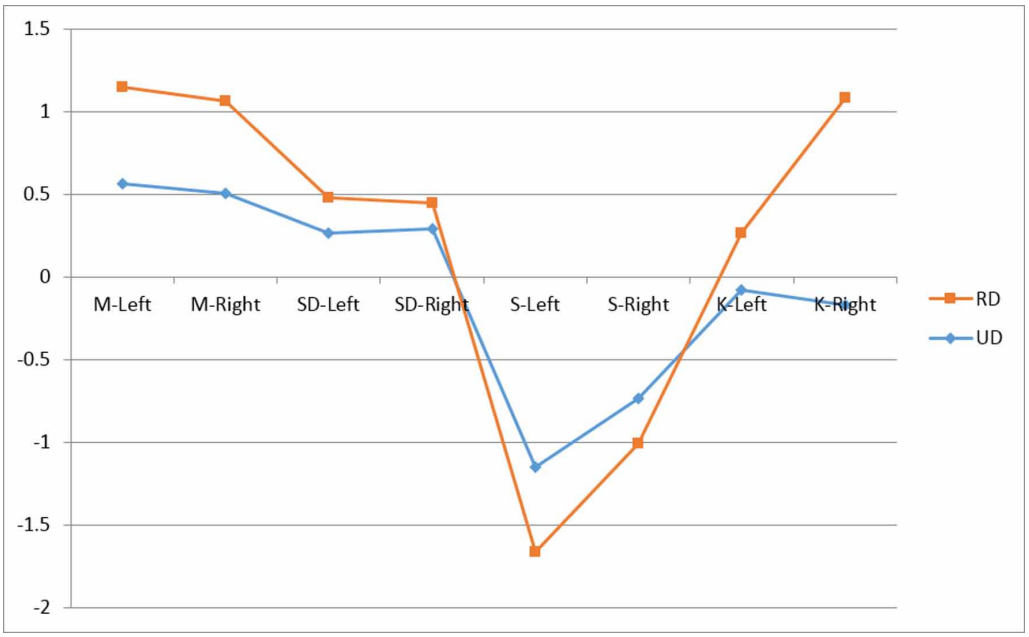

Figure 8 shows the BR results for statistical and entropy features. The influence of CLAHE with histogram distribution was also studied.

One can infer from Figure 8 that the Rayleigh's Distribution outperforms with Uniform Distribution. Among the four moments, entropy features, Wavelet Packet Entropy confirms its suitability with Rayleigh's Distribution for Asymmetry identification between left and right breast regions.

PERFORMANCE EVALUATION

The performance of the proposed scheme was evaluated by applying probabilistic neural network (PNN) model as classifier. PNN is a basically a radial/basis neural network which works on the principle of probabilistic theory typically a Bayesian model. It comprises of input layer, pattern layer, summation layer and an output layer. For the proposed scheme, 6 input nodes were used. One can refer Morey et al., 2016 for further functioning of PNN model. The spread factor was fixed as 0.08. The PNN classifier was evaluated in terms of sensitivity, specificity and classification accuracy. A three-fold cross validation procedure was adopted using all the given features. The classification accuracy was estimated based on (6):

$$\mathbf{CA} = \frac{\mathbf{No.\ of\ Correctly\ Detected\ Breast\ Images}}{\mathbf{Total\ no.\ of\ applied\ Breast\ Images}}$$

Figures 9 and 10 show the training and testing results obtained using PNN classifier.

Figure 8. Plot of estimating bilateral ratio

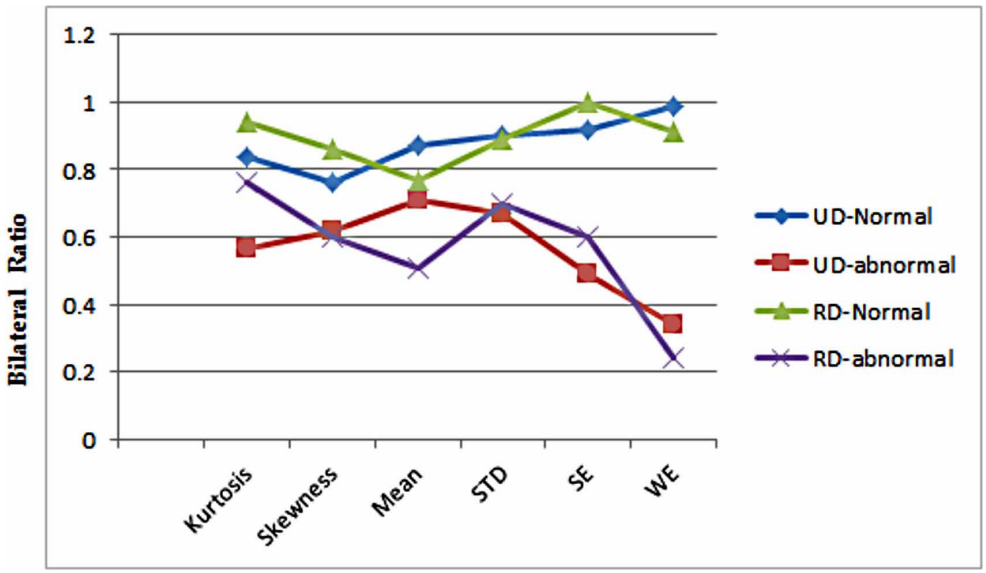

Figure 9. Three vectors – Training (PNN)

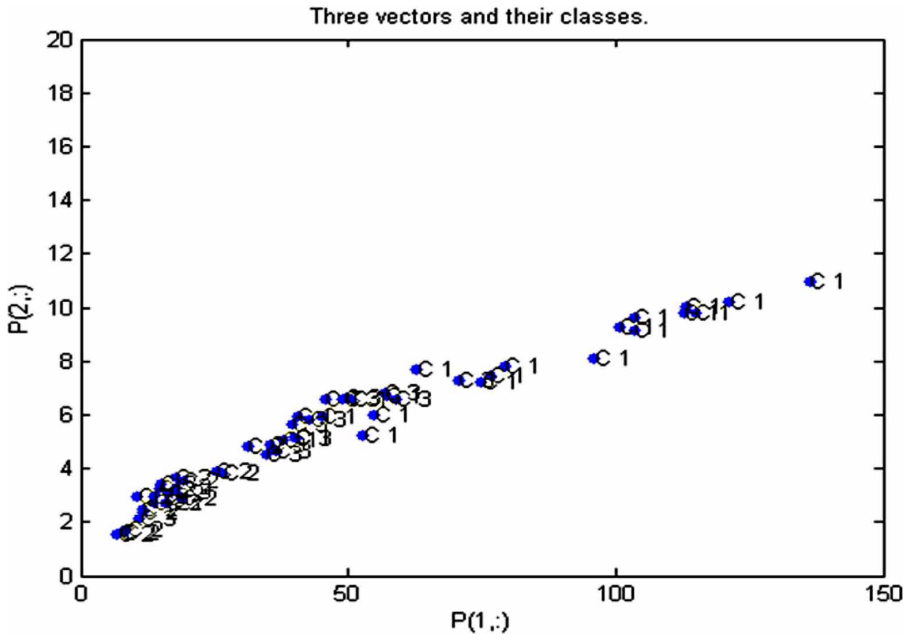

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11 shows the classification results using UD and RD distribution. It can be seen that the PNN classifier with multi features extracted based CLAHE-RD outperforms then CLAHE-UD. An overall CA of 92.5% was achieved.

The classifier performance was further analyzed using the receiver operating characteristics (ROC) and result is shown in Figure 12.

The area under curve was found to 93.5% and it can be seen the ROC study confirms the suitability of the proposed pattern classifier with the selected multifeatures.

CONCLUDING REMARKS

Automated screening of breast thermograms using statistical and entropy features with probabilistic neural network as classifier was discussed in the proposed study. A set of normal (n=53) and abnormal with indication of cancerous tissue (n = 42) was considered from a specific ethnic group. The contract enhancement procedure was done using CLAHE with uniform and Rayleigh's distribution. The ROI was selected based on canny edge detection followed by thresholding and the given image was segmented into left and right regions. The asymmetry behavior was tested using the Bilateral ratio. The entropy features with CLAHE-RD was found to be efficient in recognizing the level of asymmetry between the right and the left breast regions. All the six features extracted from the selected ROI were applied to the PNN classifier. The three-fold cross validation showed a classification accuracy of 92.5%. The current procedure can be introduced for screening of breast cancer on the woman population. The effect of CLAHE-RD and PNN classifier with the applied features can be validated with a large dataset for its clinical suitability.

ABSTRACT

Healthcare business is responsible of keeping patient data safe and secure by following the rules of the federal Health Insurance Portability and Accountability Act of 1996, (HIPAA). Agile software organizations that deal with healthcare software system face a number of challenges to demonstrate that their process activities conform to the rules of HIPAA. Such organizations must establish a software process life cycle and develop procedures, tools, and methodologies that can manage the HIPAA requirements during the different stages of system development, and also must provide evidences of HIPAA conformity. This paper proposes an auditing model for HIPAA security and privacy rules in XP environments. The design of the proposed model is based on an evaluation theory which takes as its input the work of Lopez ATAM, and the standards of common criteria (CC) concepts. The proposed auditing model has been assessed based on four case studies. The auditing result shows that the proposed model is capable of capturing the auditing evidences in most of the selected case studies.

1. INTRODUCTION

In a world of increasingly global competition, the competitive demands on companies and organizations in the healthcare industry become more intense (Wall, 2009). This has induced healthcare organisations to exploit new opportunities to gain competitive advantage (Reina, Lacroce, Cetani, & Ventura, 2012).

Regulatory compliance has become visible in healthcare industries. The federal Health Insurance Probability and Accountability Act of 1996 (HIPAA), passed by the United States Congress and signed by President Bill Clinton, is the first comprehensive federal guideline for the privacy of patients and health information (Brian & Daniel, 1997). HIPAA is a set of rules aimed at strengthening patients' rights, whilst decreasing administrative costs in the healthcare industry. Failure to comply with HIPAA could lead to large penalties and in extreme cases could lead to loss of medical licenses. Organizations that deal with protected health information (PHI) and wishing to be HIPAA certificated must follow the rules of HIPAA (i.e. physical requirements, network requirements, and security and privacy requirements).

HIPAA is designed to: 1) improve the quality of health insurance; 2) improve the portability, and continuity of health insurance coverage in the group and individual market; 3) simplify the administration of health insurance; 4) prevent fraud and corruption in health insurance and health care companies; 5) protect a subset of sensitive information known as protected health information (PHI); and 6) protect health data created, received, maintained or transmitted electronically, also known as electronic protected health information (ePHI) (Brian & Daniel, 1997).

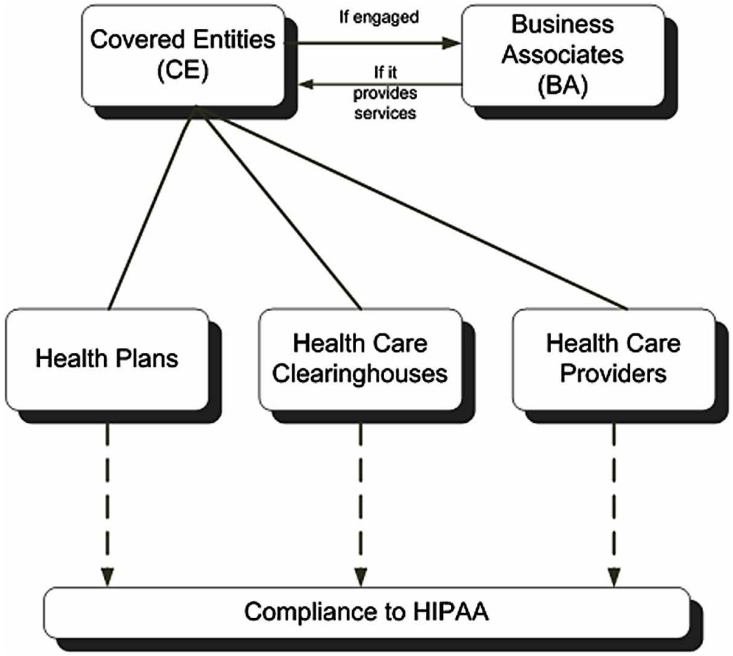
Organizations that deal with health information must comply with the HIPAA rules. In general, compliance means conforming to the authoritative rules in order to get certification for specific use (Ahmed, 2014). HIPAA rules apply to both covered entities and business associates. For that, industries or organizations that handle protected health information (PHI) or electronic protected health information (ePHI) are related to any of the covered entities or business associates. Next is a description of entities involved in the HIPAA compliance process, see Figure 1.

- **Covered Entities (CE):** According to HIPAA, the term "covered entity" refers to three specific businesses including: health plans, health care clearinghouses, and health care providers that transmit health information electronically (U.S. Department of Health & Human Services, 2014). Examples include software organizations (third parties), hospitals, pharmacies, academic medical centers, and other health care providers. Covered entities can be institutions, organizations, or persons.
- **Business Associates (BA):** The Department of Health and Human Services (U.S. Department of Health & Human Services, 2014) defined the term business associate as "a person or entity that performs certain functions or activities that involve the use or disclosure of protected health information (PHI) on behalf of, or provides services to, a covered entity". Examples of business associates include individuals who perform services as part of the workforce of a covered entity, financial and banking institutions when performing payment processing activities, medical transcription companies, and others such as: auditors, consulting firms, or software vendors and consultants.

Extreme programming (XP) is an agile software development process that is designed to simplify and expedite the process of developing software products by favouring close collaboration between software development and business teams via face-to-face communication, as opposed to putting an emphasis on written documentation.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Entities of HIPAA Compliance Process



Several studies can be found in literature indicating the high adoption of XP practices when developing medical device software (AAMI, 2012; McHugh, McCaffery, & Casey, 2014; Fitzgerald, Stol, O'Sullivan, & O'Brien, 2013). These studies are evidence of medical software based organizations shifting away from the use of traditional development processes towards agile development processes. Moreover, these studies show how such software originations are recently paying more attention to the compliance process with regulatory requirements.

A review of the research literature on the practices of XP has revealed weaknesses in its capabilities to satisfy the requirements of HIPAA rules. These weaknesses can be attributed to the gaps that exist between the HIPAA rules and the XP software processes such as:

- **Documentation:** HIPAA has strict documentation requirements that industries must comply with. On the other hand, XP aims to keep documentation as simple as possible.
- **Traceability:** HIPAA regulation requires documented evidence on how risk analysis has been done, and how the requirements (security and privacy rules) have been implemented, designed, and tested. While, XP uses simple documentation for traceability.

The aim of this paper is to enhance the auditability of XP in response to HIPAA, as well as to help software organizations that use XP when developing medical software to become HIPAA certified. This paper proposes an auditing model that 1) enables the HIPAA auditors to obtain evidence in conformity to HIPAA security and privacy rules, 2) provides HIPAA auditors with methodological approach of auditing process, and 3) helps the software developers in the medical environment to develop their software system with HIPAA rules in mind.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The design methodology for the proposed auditing model is based on evaluation theory (ATAM) and Common Criteria standards (CC) as well as an evaluation procedure proposed by CC concepts. The proposed auditing model has been assessed based on four case studies to investigate the compliably of the selected case studies with the HIPAA security and privacy rules.

The paper is organized as follows. In addition to the first section which provided an introduction to the research area of HIPAA compliance in medical software based systems, section 2 provides an overview of related works. Section 3 provides an analysis of HIPAA auditing requirements. Section 4 provides a description of XP process. Sections 5 and 6 provide a description of the proposed audit model. Section 7 provides an assessment of the proposed auditing model through a detailed auditing of selected case studies. Section 8 discusses the impact of the proposed auditing model on the XP process. Finally, section 9 concludes the research and discusses avenues for future work.

2. RELATED WORK

McHugh et al. (2013) present a study of agile software techniques adoption in software organizations that develop medical device in Ireland. In their paper, the researchers conducted a comparison between plan-driven software development life cycle and agile software development and then prepared some recommendations on how medical device software development organizations can modify their existing structure to become more suitable for adopting agile development techniques. Moreover, the researchers highlighted that when a medical device software development organization wants to use agile processes, it must fix its current organizational structure based on the use of home-ground analysis which examines five critical success factors for adopting agile methods within software organizations.

McHugh, McCaffery, Casey, and Pikkarainen (2012) discuss the challenges faced by developers when developing medical device software and how the shortcomings of both agile and plan driven approaches can be resolved by following a mixed method approach towards the success of medical device software development. The researchers point out that a single agile methodology is not appropriate to use when developing medical device software. For this reason, the researchers propose a mixed method approach which combines agile practices with plan driven software development lifecycle. Furthermore, the researchers suggest developing a tailored V-Model which integrates the agile practices to facilitate the achievement of regulatory compliance. The researchers do not explain how agile software development can meet the authoritative rules such as HIPAA.

Mehrfard, Pirzadeh, & Hamou-Lhadj (2010) focus on the Food and Drug Administration (FDA) regulations. The researchers discuss FDA requirements in details and show how XP lacks the necessary practices to support FDA. The researchers propose a mapping process between FDA and XP by focusing on human factor engineering requirements that must be met by any software process that claims to be FDA compliant. Moreover, the researchers show how XP does not support FDA. Additionally, the researchers propose an extension to the XP exploration phase which involves several sub-phases such as, contextual investigation, requirements scenario, vision/use scenario and stories. In their work, the researchers did not focus on security requirements and their generic framework is limited to a specific life-science regulation (i.e. FDA).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Qasaimeh and Abran (2011) propose an extension to the user story of XP as to enhance the ability of user stories to collect the information required for achieving ISO 9001 certification. The extension is based on sub processes related to the Capability Maturity Model- Integration (CMMI) model: 1) identification of the source of the user story; 2) categorization of the nonfunctional requirements; 3) identification of the user story relationships; and 4) prioritization of the user stories.

Qasaimeh and Abran (2013) proposed an audit model for ISO 9001 traceability requirements in XP environments. The objective was to help the IS-auditors in the process of extracting the auditing evidences that demonstrate the conformance of XP to ISO 9001 requirements. What distinguishes this paper from Qasaimeh and Abran's (2013) research is that their proposed audit model works only with ISO 9001 which is a general regulation for any software developing organization, but not focuses on specific development requirements. The contribution of this research is specific to HIPAA security and privacy requirements.

3. ANALYSIS OF HIPAA AUDITING REQUIREMENTS

According to HIPAA privacy and security rules, an organization that deals with patient health information must protect the confidentiality of health data for the individuals' by developing certain security controls and monitoring activities that comply with HIPAA security and privacy rule. For example, a security audit must be maintained at different levels of abstraction during the software development life cycle. The HIPAA security and privacy rule includes two provisions that impact the healthcare organizations security audits (HIPAA, 1996). The two extracted provisions are:

Section 64.308(a)(1)(ii)(c), Information system review, which states that organizations must "implement procedures to regularly review records of information system activity, such as audit logs, access reports, and security incident tracking reports". According to the HIPAA auditing rules, the information system review refers to monitoring the use of sensitive information that act as evidence in the process information security incidents investigation. In software engineering, information system review is the process of software product examined by project personnel, managers, users, customers, user representatives, or other interested parties for comment or approval (Wiegers, 2002). Moreover, the information system review is one of the HIPAA auditing procedures to ensure that the software products that deal with healthcare software systems or access the ePHI have been reviewed, audited, verified, to meet the required requirements of HIPAA rules.

Section 164.312(1) (b), Audit controls, which states that organizations must "implement hardware, software, and procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information". According to the HIPAA rules, audit controls are required in order to enforce the software organization into implementing auditing techniques to record and monitor each activity in any product or information system that implements ePHI. In software engineering, auditing can be divided into two categories (Westfall, 2007):

- **Functional Audit:** This type of audit is used to verify that all requirements specified in the software requirements specification have been met.
- **Physical Audit:** This type of audit is used to verify that the software product and its related documentation are internally consistent.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Audit controls are essential and required by the HIPAA rules to ensure that the requirements specified in the software specification have been met, and that the system operates correctly. While, HIPAA focuses on security and privacy, audit controls can be considered as the process of reviewing, monitoring, capturing, storing, analyzing, and reporting information related to security and privacy threats.

4. XP PROCESS

The core phases of the XP lifecycle as described by Beck (Beck, 1999) are discussed below- See Figure 2:

- **Exploration Phase:** In this phase, the requirements are collected. Customers write down the requirements that they intend to implement in the first release. The requirements are written on a card called a user story. Each user story card describes a set of features. In this phase, the project team identifies the tools, technologies and practices that will be used in the project. The duration of the exploration phase ranges from a few weeks to a few months, depending largely on how familiar the programmers are with the technology.
- **Planning Phase:** In this phase, the developers arrange the user stories cards by their priority level (i.e. which story is to be implemented first). Moreover, an agreement of the contents of the first small release is made. During this phase, an estimation is performed by programmers to estimate how much effort each user story requires and a schedule is then agreed upon. The duration of this phase is approximately two days.
- **Iterations to Release:** In this phase, several iterations of the system are conducted before the first small release. During iteration planning, the programmers break down the requirements or the features provided by the customers into a number of iterations that will each take one to four weeks to implement. At the end of the first iteration the architecture of the whole system is ready. This is achieved by selecting the stories that will enforce building the structure for the whole system. However, after the customer decides which stories are selected for each iteration, the programmers start, prior to coding the iteration, writing the test for the iteration. The programmers then create simple a design structure for the iteration. Acceptance tests are run by the customer at the end of every iteration. At the end of the last iteration, the system is ready for release.
- **Production / Release Phase:** In this phase, it is required from the development team to frequently make small releases of working software that customers can evaluate (Abrahamsson, Salo, & Ronkainen, 2002). This phase requires a lot of testing and checking of the performance of the system before the system can be released to the customer. During this phase, a small release of the system is given to the customer in order to test and check the functionality of the system and determine whether to accept the system or to provide feedback. The duration of this phase ranges from one week to three weeks.

The production/release phase is followed with the maintenance phase, which involves implementing the remaining requirements and updating the releases (including the new requirements of customer's feedback). After maintenance the final release is ready. This phase is known as the death phase.

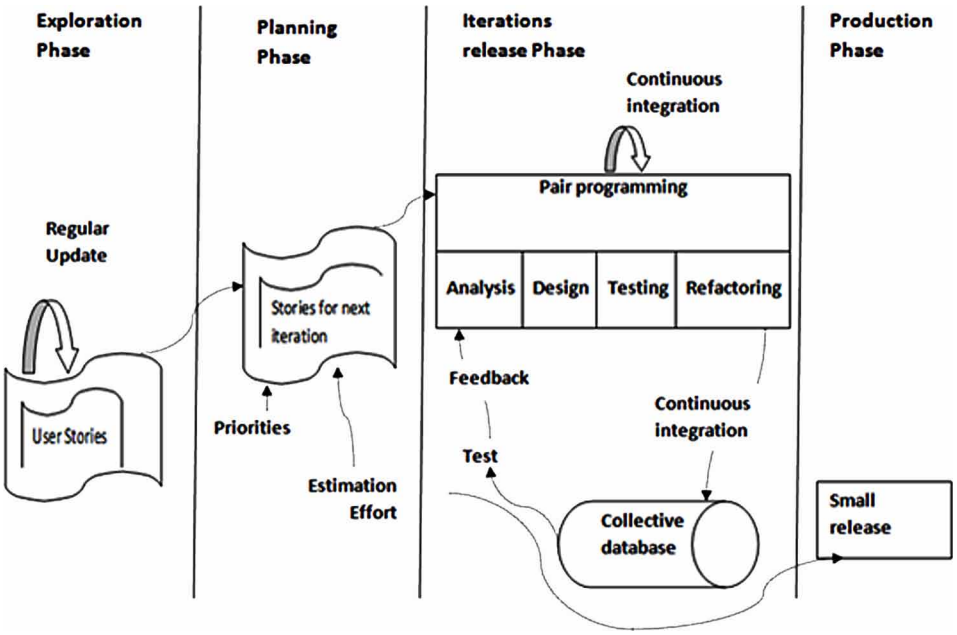
Figure 2. Life cycle of the XP process



5. DESIGN METHODOLOGY

This section presents the design of an audit model that covers HIPAA security and privacy rules. The proposed auditing model is aligned with XP process. The design methodology in this section is based on an evaluation theory (Lopez, 2000): An Evaluation Theory Perspective of the Architecture Tradeoff Analysis Method (ATAM), and Common Criteria (Common criteria portal, 2012).

5.1. Preliminary Design Constraint

The Common Criteria for Information Technology Security Evaluation abbreviated as (Common Criteria or CC) have been selected to support the design of the proposed auditing model. CC is an international standard (ISO/IEC15408) that can be used to ensure and validate that a particular product or system meets a defined set of security requirements. The proposed auditing model, deploy specific standards from the CC that support HIPAA auditing rules which are illustrated below:

- Target of Evaluation (TOE) which can be done through the following standards:
  a. Protection Profile (PP)
  b. Security Target (ST)
- Security Function Requirements (SFRs)
- Security Assurance Requirements (SARs)
- Evaluation Assurance Level (EAL)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The requirements that were extracted from HIPAA privacy and security rules are: information system review, and audit controls. The information system reviews are related to the technical aspect of secure system development and the audit controls are related to the management aspect of secure system development. Therefore, mapping processes have been developed to select the CC standard that supports HIPAA information system reviews and audit controls. For instance, TOE could support the management and technical aspect of HIPAA auditing rules as shown in Figure 3.

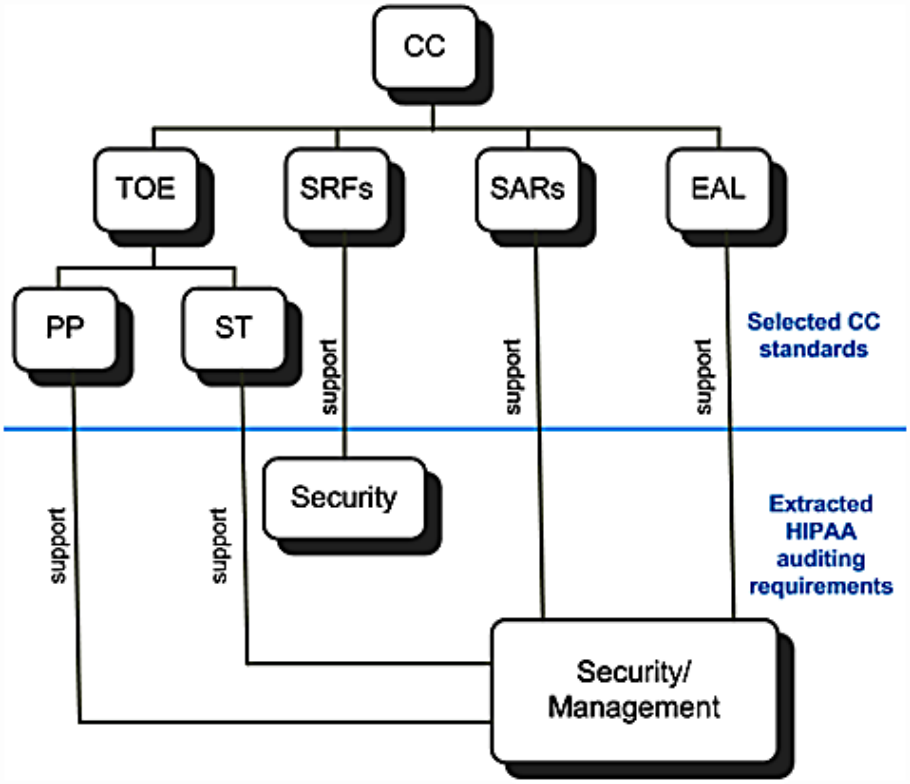
5.2. Evaluation Fundamental

The design of the proposed auditing model is based on the evaluation components proposed in (Lopez, 2000) and the evaluation components of CC as shown in Figure 4.

The main components of ATAM that will be used to support the design of HIPAA and the assessment of the auditing model are described as follows (Lopez, 2000):

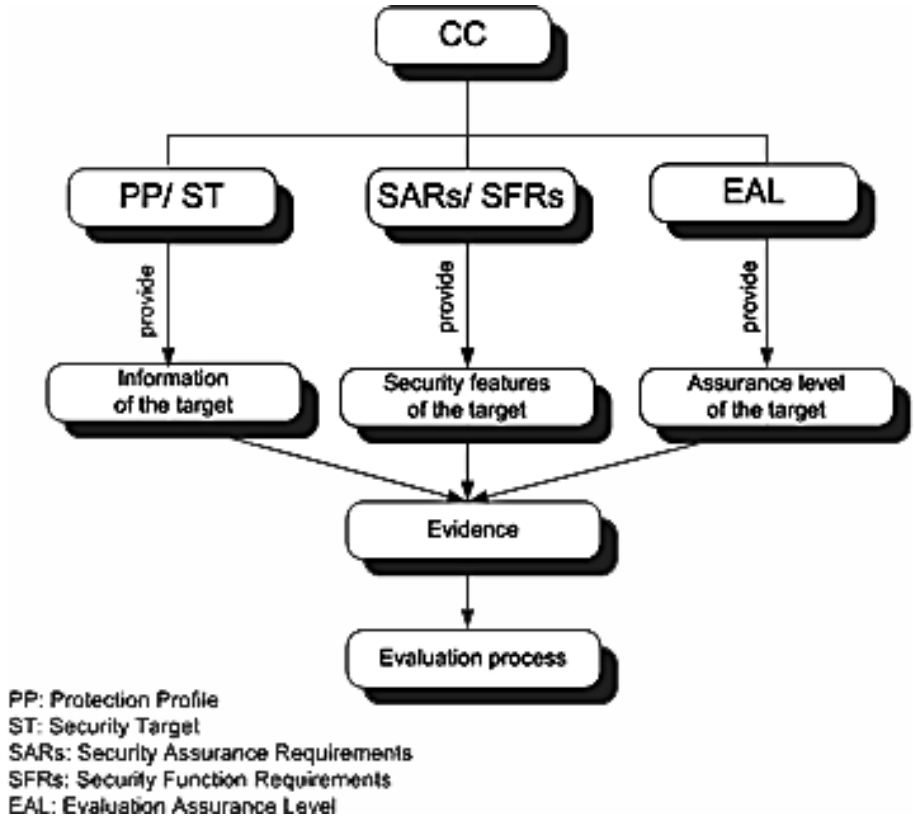
- **Target:** A system or product that is to be evaluated or audited.
- **Criteria:** The features of the target that is under evaluation or auditing.
- **Yardstick:** A comparison between ideal targets versus the actual targets based on specific criteria.
- **Data Gathering Techniques:** The process of gathering and measuring information for each criterion by using certain analysis techniques.

Figure 3. Mapping between CC and extracted HIPAA auditing requirements



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Evaluation components of CC



- **Synthesis Techniques:** The techniques used to prepare and synthesis information collected from analysis techniques, and then the results of synthesis compared to specific set of yardsticks.

The main components of CC that will be used to support the design of HIPAA and the assessment of the auditing model are described as follows:

- Selected standards of CC: PP, ST, SFRs, SARs, and EAL.
- **PP/ST:** Provide general information about the target to be audited. This information can be used as audit evidence.
- **SARs/SFRs:** Provide detailed information about the security features or security requirements such as security assurance requirements, and security functional requirements. This information can be used as audit evidence.
- **EAL:** Provide information about the assurance level of the evaluated target. This information can be used as audit evidence.

The design of the proposed auditing model follows a hybrid approach that combines the principles of Lopez- ATAM approach and the principles found in the CC, the first step of the design process is to identify the target of auditing and then identify the target's general information through PP/ST, and the target's security features through SFRs/SARs.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

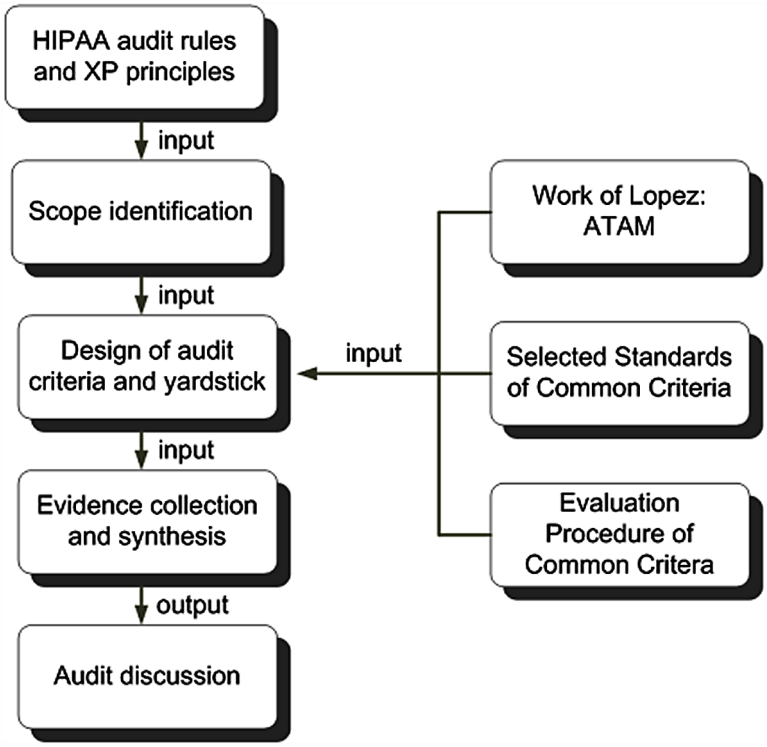
Lopez (2000) stated that when the target is already known and defined, its features must be identified for evaluation purposes. Once the data and security features are collected, the collected information is formulated in an applicable structure for the purpose of comparing it with the yardstick by using combination techniques, known as synthesis techniques. Figure 5 presents the main process of designing an audit model for HIPAA rules based on the work of Lopez and on the concepts of CC.

6. MODEL DESIGN

6.1. Scope Identification

The objective of the proposed auditing model for HIPAA security and privacy is to help HIPAA software auditors to extract the auditing evidences from the XP software processes. Additionally, the proposed audit model can also be useful for XP developers. It can help developers to follow the rules that are required by HIPAA and assure the auditors that certain steps and activities have been performed in compliance with HIPAA.

Figure 5. Design process for the audit model



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

6.2. Design of the Audit Criteria and Yardsticks

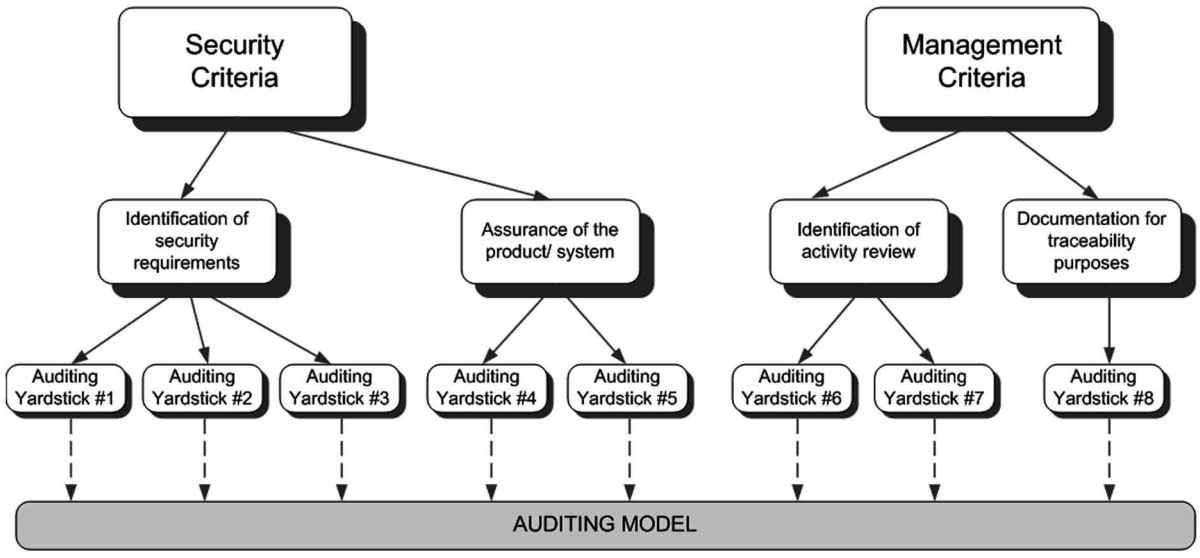
Auditing criteria is developed using a mandatory standard that indirectly contains the criteria to be applied in the auditing process. The auditing criteria should refer to any relevant study of targets, relevant standards, or ideals that might be relevant to the target in question (Qasaimeh, 2012; Lopez, 2000). Once the appropriate standards are selected, criteria should be driven from the selected standards. In this paper the mandatory standard is HIPAA. The proposed auditing model could not be achieved without the support from other relevant security standards such as ATAM and Common Criteria (CC) standard which identify appropriate processes for information technology security evaluation.

The objective of the auditing criteria is to translate the HIPAA security and privacy rules form legal based terminologies into a context based that can be understood for software project stakeholders. The proposed auditing model mainly consists of two categories of criteria: security criteria and management criteria and four main sub criteria (i.e. Auditing criterion) with multiple yardsticks for each criterion. The structure of the proposed auditing model is presented in Figure 6.

6.3. Security Criteria

The audit criteria presented in this section is based on the extracted HIPAA auditing rules and on the concepts of selected standards from CC such as PP, ST, SFRs, SARs, and EAL. The security criteria consist of two main auditing sub criteria which are identification of security requirements/features and assurance of the product/system

Figure 6. Structure of the proposed auditing model



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

6.3.1. Identification of Security Requirements and Features

Identifying the security requirements is necessary and required by the HIPAA auditing rules. This can be achieved by using the concepts of selected standards of CC. The security requirements identified by the TOE represent the target to be evaluated which can be part of the system, a specific function of the system, or the whole system. Security features of the product or system are the core of HIPAA auditing rules. HIPAA focus on three security features: confidentiality, integrity, and availability (CIA). As stated in HIPAA rule: section 164.306 (a) (1) "Covered entities and business associates must ensure the confidentiality, integrity, and availability of all electronic protected health information the covered entity or business associate creates, receives, maintains, or transmits." The following are the audit yardsticks identified for this auditing criterion:

- **Yardstick #1:** This yardstick focuses on demonstrating that security objectives are documented by the project description. The focus on this yardstick is to extract the evidences typically created by consumer/user to represent the set of security objectives and features. The evidences for this yardstick can be obtained in several ways, one of which is the answer to the question of 'what I want or need' from intended secure system. This yardstick can be used also by the developer as a starting point for developing product from HIPAA viewpoints.
- **Yardstick #2:** This yardstick focuses on extracting evidences to identify that certain technique or methods have been used in the efforts of modeling the security requirements including detailed product specific information, security properties, and system specification.
- **Yardstick#3:** The objective of this yardstick is to extract security measures evidences from the software project. This yardstick focuses on the measures taken during development and evaluation of the product to ensure the compliance with the claimed security functionality. These assurance evidences involve design documentation, design analysis, functional testing, and vulnerability analysis.

6.3.2. Assurance of the Product /System

Assurance means the level of confidence for product that can be gained, to ensure that an entity will meet its security objectives, and to ensure that the security controls being obtained will operate correctly in the operational environment. The evaluation level of the product security is required by HIPAA. Therefore, the auditor should give an evaluation value to the system by assigning a number to the product or system. This number indicates the level of confidence of the system. This can be achieved by using the concept of Evaluation Assurance Level (EAL) found in CC standards. The following are the audit yardsticks identified for this auditing criterion:

- **Yardstick#4:** The objective of this yardstick is to extract the evidences related to the security function requirements from the project artifacts. This yardstick focuses on the software textual and design artifact such as investigating certain security functionality for an actual product or system, and the design decisions that specifies the services integration during the software development process. This yardstick mainly expresses 'what' a product shall do, and what shall not happen while executing the software.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Yardstick#5:** This yardstick focuses on extracting evidences that are belonging to the evaluation assurance level. Typically, a numerical grade is assigned to the product after the completion of the evaluation process. CC lists seven levels, from EAL1 to EAL7. The highest level provides the highest guarantee that the security features of the system or product are correctly applied. The EAL number assigned to the evaluated system indicate that the system implements all requirements successfully for that level.

6.4. Management Criteria

The management criteria that are required by HIPAA auditing rules are the reviewing activities and the documentation for project traceability, this requirement is mentioned in in section 164.308(a)(1)(ii)(c) "*implement procedures to regularly review records of information system activity*." The management criteria consist of two main auditing sub criteria which are identification of activity review method and documentation for traceability purpose.

6.4.1. Identification of Activity Review Method

Organizations that met or are aiming to meet the HIPAA standards, must have documented review process for the software development activities to provide evidence to the HIPAA's auditors that certain steps have been done correctly and comply with regulation requirements. The following are the audit yardsticks identified for this criterion:

- **Yardstick#6:** The objective of this yardstick is to extract the evidences to prove that the organization follows the customer requirements. This yardstick can be extracted by ensuring that the required services are implemented in the project.
- **Yardstick#7:** This yardstick focuses on evidences about the evaluation of potential security threats and describes the assets to those threats. This yardstick then investigates the existence of security controls and demonstrates that these controls are sufficient to counter the potential security threats.

6.4.2. Documentation for Traceability Purpose

Documentation and traceability is an important aspect for HIPAA auditing process that enables the software developers to find the origin of each requirement and track every change that was made to this requirement. For this purpose, it may be necessary to document every change made to the requirement.

An auditing story card is proposed to improve the agile stand-up meeting in order to capture the auditing evidences in a formal manner. The improvement to the stand-up meeting can be achieved by creating a WHAT, HOW, NEXT card as shown in Table 1, where the programmer writes down a short description of what he/she has done, how he/she has done it, and what is he/she going to develop next. The following are the audit yardsticks identified for this criterion:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. WHAT, HOW, NEXT card

Card elements	Description
WHAT	What has done first and which part of the software has been completed
HOW	The techniques to develop particular software part
NEXT	Which part of software will be integrated next

- **Yardstick#8:** The objective of this yardstick is to extract evidences that are related to the techniques improved by the developers to support the requirements traceability. This yardstick enables the auditor to find the origin of each requirement and track every change that was made to this requirement. The proposed user story card describes the type of user, which feature is needed to implement and why.

7. ASSESSMENT OF PROPOSED AUDITING MODEL

7.1. Context and Scope

According to ISO/IEC 14102 (2008), assessment in software engineering is an action of applying specific documented criteria to a specific software module, package or product for the purpose of software evaluation and enhancement. The purpose of assessment is to improve the quality of future software performances (Idomir, Idomir, & Repanovici, 2011). To assess the applicability of the proposed auditing model, four case studies have been selected as shown in Table 2. The selection of these case studies is based on the following steps and criteria:

Table 2. Selected case studies

Cases	Authors	Case title	Case objective	Case date
Case A	Kalra	Clinical Foundations and Information Architecture for the Implementation of a Federated Health Record Service	To propose a Federated Health Record (FHR) to be deployed in a live clinical environment in the Department of Cardiovascular Medicine at the Whittington Hospital in North London. However, implantation of Federated Health Record (FHR). The implementation of the proposed system is based on agile software development	2003
Case B	Sun, Zhu, Zhang, & Fang	HCPP: Cryptography Based Secure EHR System for Patient Privacy and Emergency Healthcare.	To propose secure EHR system and HCPP (Healthcare system for Patient Privacy), based on cryptographic methods and wireless network infrastructures	2011
Case C	Yepes, Cobaleda,Villa D., & Aedo	Design a Medical Application for Android Platform using Model-Driven Development Approach	This case proposed a method to design medical device interoperability system, called SIMMIT (System Integration Medical Monitoring and Interoperability for Tele-care) based on a Model-Driven Development approach	2012
Case D	Kalra, et al.	Security and Confidentiality Approach for the Clinical E-Science Framework (CLEF)	This case summarizes the overall approach adopted by CLEF to meet data protection requirements, that's required by HIPAA.	2003

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- A search was conducted on IEEE Xplore and ScienceDirect-Elsevier for any paper proposing a methodology, model, technique, or framework that improves a HIPAA compliant system or building medical based software system for specific use with agile software processes. The following terms were used in the search process:
  a. Agile and healthcare regulations
  b. Agile and HIPAA
  c. Agile-XP and critical projects and/or security projects
  d. XP and development of software medical device
  e. XP and implementation of electronic health record (HER)
- A title and abstract analysis was performed to select the papers that discuss XP and the implantation of healthcare projects such as software medical device and electronic health record servers.
- All the papers that discuss the implementation of critical projects or security projects that are not related to healthcare system were discarded.
- Some authors discuss the XP implementation or the design process of critical projects and security projects that use ePHI such as HER, these kinds of paper were selected.
- Some authors discuss the use of XP principals in developing software systems for medical devices and refer to these principles as agile processes without specifying which agile processes they are using.

7.2. Discussion of the Evidence Gathered

The international standard of auditing (2009) defines the audit evidence as "all the information used by the auditor in arriving at conclusions on which the audit opinion is based." In this research, the auditing evidences were classified based on the evidences found in (Qasaimeh, 2012) and which are summarized below:

- **Textual Evidence:** Can be described as supporting proof in certain text format.
- **Modeling Evidence:** Can be described as supporting proof in certain modeling format such as Unified Modeling Language (UML).
- **Graphical Evidence:** Can be described as supporting proof in certain graphical format such as bar graphs, line graphs, pie charts, scatter plots, photographs, and figures.

This section discusses the evidences that were gathered from the four selected case studies. Table 3 shows the summary of evidences found in the selected case studies. Below is the discussion of auditing evidences found on each case study.

Most of the evidences found in Case A demonstrate the security criteria of the proposed auditing model such as yardstick#2 which focuses on extracting detailed security requirements from the project. The auditing evidences for this yardstick are found in a modeling format (i.e. Use Case Diagrams). Case A also supports the management criteria of the proposed auditing model for example; yardstick#6 focuses on extracting the evidences to prove that the organization follows the customer requirements. The evidences for this yardstick are found in a graphical format, (e.g. screen shots of the system). Case A supports both the security criteria and the management criteria of the proposed auditing model.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Summary of evidences in the selected case studies

	Case A (Kalra, 2003)	Case B (Sun, et al, 2011)	Case C (Yepes, et al, 2012)	Case D (Kalra, et al, 2003)
Security criteria				
Yardstick#1 (Identification of security objectives)	Evidence Exists	Evidence Exists	Evidence does not exist	Evidence exists
Yardstick#2 (Detailed security requirements)	Evidence Exists	Evidence Exists	Evidence Exists	Evidence exists
Yardstick#3 (Security measures)	Evidence Exists	Evidence Exists	Evidence Exist	Evidence exists
Yardstick#4 (Services integration	Evidence Exists	Evidence Exists	Evidence does not Exists	Evidence exists
Yardstick#5 (Evaluation assurance procedures)	Evidence Exists	Evidence Exists	Evidence does not exist	Evidence exists
Management criteria				
Yardstick#6 (Organization reviewing activities)	Evidence Exists	Evidence Exists	Evidence does not exist	Evidence does not exist
Yardstick#7 (Identification of security threats)	Evidence Exists	Evidence does not exist	Evidence does not exist	Evidence exists
Yardstick#8 (Security requirements traceability)	Evidence Exists	Evidence exists	Evidence Exists	Evidence does not exists

Case B supports the security criteria of the proposed auditing model. As an example, it's written in Case B that "no one should be able to obtain the secrets for retrieving and decrypting the PHI" this statement could be considered as security/privacy rules that can be used as textual evidence to support yardstick#1. Case B partially support the management criteria of the proposed auditing model such as yardstick#8 which is focuses to extract evidences that are related to traceability of the project, this yardstick represented in case B as modeling evidence in UML format (i.e. Flowchart) that describe the construction of the secure system proposed by case B. However, no evidence can be found to support yardstick#6 and yardstick#7 of the management criteria for case B. As a result, case B supports the security criteria and partially supports the management criteria of the proposed auditing model.

The auditing evidences found in case C partially support both the security criteria and management criteria. Case C lacks the evidences of security criteria that required by proposed auditing model. For example, yardstick#1 does not exist which focuses on extracting evidence from the project to demonstrate that security objectives are in the project. Case C also lacks the evidences of management criteria that are required by the proposed auditing model such as yardstick#6, yardstick #7. Therefore, Case C does not comply with most of the proposed auditing yardsticks.

Evidences in Case D fully support the security criteria of the proposed auditing model. For example, all the yardsticks of the security criteria exist in Case D. But, the yardsticks of the management criteria of the proposed auditing model do not exist in case D. For that, Case D is rich in security aspects that are required by the proposed auditing mode and poor in management aspects.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

7.3. Detailed Auditing

The results shown in Table 4 indicate that the approach proposed by Case A could comply with HIPAA privacy and security requirements. The eight proposed yardsticks exist and are supported by Case A. For example, in regards to yardstick#1 which focuses on extracting evidence from the project to demonstrate that security objectives are in the project; this yardstick exists as textual evidence in section 6.2. (Structured set of requirements), and as graphical evidence in Table 7 page 208 of Case A. Another example is yardstick#3, which focuses on extracting evidences that are related to the security function requirements from the project, and also exists as textual evidence in Section 6.3. (FHR functional requirements) page 171 and Section 6.6. (FHR technical requirements) page 193 and as modeling evidence in Figures: 70, 71, 72, 73, 74, and 75 in the pages numbered 251 through to 253.

Table 4. Auditing results of Case A

Case A (Kalra, 2003)				
	Evidence Status	**Evidence Type**	**Evidence Location**	**Page number**
Yardstick#1 (Identification of security requirements)	Evidence exists	1-Textual evidence 2- Graphical evidence	1-Section 6.2. (structured set of requirements) 2- Table 7 (Examples of end users and their potential interactions with an FHR service)	1-P. 170 2- P.208

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As shown in Table 5, the EHR system and HCPP system proposed by Case B could comply with HIPAA security and privacy requirements. Seven out of eight yardsticks exist and are supported by Case B. For example, yardstick#2, which focuses on extracting detailed security requirements from project, exists as textual evidence in Section III and as graphical evidence in Figure 1 page 4. Another example is yardstick #3, which focuses on extracting security function requirements from the project to demonstrate that security objectives are described in the project's documentation also exists as textual evidences in Section I.B.1, page number 2, and Section III.C in page number 4.

Case C is a proposed method to design a system for medical device interoperability, called SIMMIT (System Integration Medical Monitoring and Interoperability for Tele-care) as shown in Table 6, Case C does not comply with HIPAA, because it lacks the security aspects required by HIPAA. For example, yardstick#3, which focuses on extracting evidence related to the security function requirements form the project, does not exist. Moreover, Case C lacks the management aspects required by HIPAA and which are represented by yardstick#6, yardstick #7.

Case D is rich in security aspects as required by HIPAA and poor in the managerial aspects. As shown in Table 7, most of the yardsticks that are related to the security aspects required by HIPAA exist, such as yardstick#2 that focuses on extracting evidence that contains detailed security requirements from the project and that can be considered as evidence of compliance. Yardstick#2 exists as graphical evidence in Figure 1. Management requirements that are required by HIPAA do not exist in case D. For example, yardstick#9 does not exist, which is provides evidences of traceability of the project.

Table 8. Impacts of the proposed auditing model on agile XP phases

Agile XP phase	Impacted By
Exploration phase	Yardstick#1 (security objectives) Yardstick#2 (detailed security requirements) Yardstick#3 (security function requirements)
Planning phase	Yardstick#4 (security assurance requirements) Yardstick#5 (evaluation assurance level) Yardstick#7 (risk analysis)
Iterations to release phase	Yardstick#6 (meets customer requirements) Yardstick#8 (traceability)
Production / Release Phase	Yardstick#5 (evaluation assurance level) Yardstick#6 (meets customer requirements)

8. IMPACTS OF PROPOSED AUDITING MODEL ON AGILE XP

The core phases of XP life cycle are: exploration, planning, iterations to release, and production/ release phase. As shown in Table 8 and discussed below, the proposed auditing model will have an impact, either direct or indirect, on each phase of agile XP process.

- **Exploration Phase:** This phase focuses on collecting requirements from the customer. If the XP developer follows *Yardstick #1 (security objectives)* which focuses on extracting the evidences typically created by the consumer/user to represent the set of security objectives and requirements needed, the developer will identify the requirements needed for HIPAA. Moreover, by following *Yardstick #2 (detailed security requirements)* and*Yardstick#3 (security function requirements),* the developer will be able to recognise the details of the security requirements that need to be submitted as HIPAA compliance evidence. The detailed security requirements include specific product details such as security properties, and product or system specification.
- **Planning Phase:** During this phase, time, cost and risk estimation is performed by the programmers. Specific criteria, such as *Yardstick#4* which focuses on the measures taken during development and evaluation of the product to ensure compliance with the claimed security functionality, *Yardstick#5* which aims *to evaluate the assurance level* and *Yardstick#7* which provides criteria for *risk analysis,* all have an impact during this phase.
- **Iterations to Release Phase:** In this phase, several iterations of the system are conducted before the first small release. Acceptance tests are run by the customer at the end of each iteration. At the end of the last iteration, the system is ready for release. Similarly, several criteria have an impact on this phase including *Yardstick#6 (meets customer requirements)* which focuses on extracting evidences to prove that the organization follows the customer requirements and *Yardstick#8 (traceability)* which focuses on extracting evidences that are related to traceability of the project.
- **Production / Release Phase:** During this phase, more testing and evaluation are conducted before the system is released to the customer. During this phase, a small release of the system is given to the customer to test and check the functionality of the system in order to determine whether to accept the system or to provide feedback. Both *Yardstick#6 (meets customer requirements)* and *Yardstick#5 (evaluation assurance level)* which tests how secure the product is, have an impact on this phase.

9. CONCLUSION AND FUTURE WORK

The aim of this paper is to enhance the auditability of XP in response to HIPAA rules, as well as to help XP based software organizations that develop healthcare software in their effort to become HIPAA certified. This paper proposes an auditing model for HIPAA security and privacy rules in XP environments. The design of the model is based on an evaluation theory which takes as its input the work of Lopez (ATAM), and standards of Common Criteria (CC) concepts, as well as an evaluation procedure proposed by CC concepts. Finally, the proposed auditing model has been assessed based on four case studies to investigate the compliably of the selected case studies with the HIPAA security and privacy rules.

The main limitation of this research is the assessment approach which has been carried out by the same researchers who designed the model. This might introduce biases in the assessment process of the proposed model. For future work, the validation of the model is planned to be performed by external experts to assess the usability of the proposed model in the environment of XP. In this way, the same case studies can be audited by bodies external from the research team. This research as can also be improved by conducting the proposed audit model on medical projects that already implemented by agile software organization and wishing to become HIPAA compliant

Chapter 68
The Cloud Gets Personal:
Perspectives on Cloud Computing for Personalized Medicine

Rhoda Joseph
Penn State University, USA

Patrick Brown
Thermo Scientific NanoDrop Products, USA

ABSTRACT

Cloud computing, at its most fundamental level, is a technology that allows computing to occur as an on-demand utility. Personalized medicine is revolutionizing the field of medicine, and aims to provide individualized treatment for patients, based on their genetic material and medical history, through comparisons to genetic material from thousands of other patients. Better patient outcomes are expected in a personalized medicine domain as compared to more generic generalized options. In this paper the authors explore the use of cloud computing in the area of personalized medicine examining unique benefits and opportunities. They also recognize and discuss the presence of some inherent risks. Using the cloud for personalized medicine can expedite collaborations and data collection across different clinicians, researchers and other stakeholders involved in the fight against diseases. This paper examines key elements associated with using cloud computing in the specialized area of personalized medicine.

1. INTRODUCTION

The top three causes of death in the United States are heart disease, cancer, and chronic lower respiratory diseases (CDC, 2013). Each year thousands of people suffer through and die from chronic diseases. Information and communications technologies (ICTs) have long been a stalwart in the healthcare industry for diagnosing, treating and preventing chronic diseases. Wearable devices, sensors, mobile technologies, electronic health records (EHRs) are a few of the technologies impacting healthcare today (Jayanthi, 2014). In this paper, we demonstrate the use of cloud computing for personalized medicine as another tool in the arsenal of technologies to fight disease and improve human health.

Two main research questions are examined in this paper: 1. what are the risks associated with the use of cloud computing in the area of personalized medicine; and 2. how does/can cloud computing impact the field of personalized medicine? Personalized medicine first requires a genetic profile of the patient. This profile provides very specific information about the patient and also the disease(s) that they are diagnosed with. This profile is then analyzed, and compared to thousands of profiles of other patients to find an optimal tailored solution for the current patient.

One recent study by Horowitz (2014) identified the value of cloud computing in the area of personalized drug treatments for patients. More specifically this study collected genetic data and examined the treatment of elderly patients that take a large combination of prescription drugs. The program in the study - PACE (Program of All-inclusive Care for the Elderly) is a Medicare and Medicaid program that partnered with two firms: Coriell Life Sciences and CareKinesis; used cloud computing along with personalized medicine to better serve elderly patients taking as many as 16 different prescription drugs per day (Horowitz, 2014). Anticipated outcomes of this program include better understanding of drug side-effects and faster responses to patients that may develop complications associated with drug cocktails.

The use of cloud computing for personalized medicine requires effective management of sensitive and vast datasets. Vast datasets are characteristic of the big data landscape that exists today. As data sets continue to grow, it is increasingly challenging to maintain privacy for genomic data that is shared across computer networks (Chow-White, MacAulay, Charters, & Chow, 2015). In addition to managing the challenges associated with large data sets other issues exist such as: managing the versatility across different environments; scaling to accommodate large data centers; automating to create self-managed environments; and integration of non-cloud products into the cloud architecture (Martin-Flatin, 2014). Personalized medicine involves collaboration across different entities, so overcoming some of the managerial challenges is paramount for continued growth and success.

Personalized treatments for patient conditions are already established in the personalized device industry. Currently, personalized medical devices using both iOS and Android technologies comprise a financially lucrative industry of approximately $27 billion (Bendor-Samuel, 2014). Examples of personalized medical devices include the “Tinnitus Masker” a product that is designed for an individual’s auditory needs; and the “Zenith Fenestrated AAA Endovascular Graft” a product that is customized to fit the patient’s aortic anatomy (U.S. Food and Drug Administration FDA, 2013). Undoubtedly there is a strong financial incentive for some related businesses to pursue personalized medicine. Hopefully, these financial business gains will also translate to improving the quality of patient lives and reducing premature mortality.

To develop the presented research questions, this paper proceeds in the following sections. First we present an overview of cloud computing. Then an overview of personalized medicine is presented followed by a discussion on the overlap of personalized medicine and cloud computing. The theoretical model is presented showing the key factors involved in examining their intersection. Lastly, discussion, implications and conclusions are presented.

2. CLOUD COMPUTING OVERVIEW

Cloud technology has become an important change agent in the field of information technology. Cloud computing has revolutionized the way that many businesses operate today, by freeing up internal resources, and shifting some technology related tasks and data management to external cloud computing

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

vendors. The existing market for cloud computing in the healthcare field is segmented into two main categories: clinical information systems (CIS) with examples such as electronic health records and bioinformatics; and non-clinical information systems (NCIS) that includes items such as billing and payroll (Newswire, 2015).

The term "cloud" has become part of the daily vernacular in the field of information systems. In its simplest form the cloud utilizes the power of the Internet to shift computing architecture including hardware and software from on-site machines to off-site computers. At a consumer level, an individual may store personal data such as documents, images and music on Google Drive or Apple iCloud. Many companies, both large and small, are contemplating the use of or are currently using cloud services; however, as with any advancement in technology, there are careful cost-benefit considerations that must be examined before implementation.

A business or organization must also consider which category of cloud computing is most appropriate for their needs. One method used to classify cloud computing is based on the specific type of service that is provided. The three main service level categories are: IaaS (Infrastructure as a Service) which occurs when a cloud vendor provides virtual/remote machines for clients to use; PaaS (Platform as a Service) which occurs when the cloud vendor provides a developmental space for the client to use; SaaS (Software as a Service) which occurs when the client remotely leases software from the vendor (Chang, Walters, & Wills, 2013; D. Wang, 2015). . Other terms in the cloud computing vernacular include: HaaS (hardware as a service) and DaaS (data as a service) both subcategories of IaaS (H. Yang & Tate, 2012).

Cloud computing environments are supported by a variety of different technologies ranging across multiple types of hardware, software, algorithms and models. Data storage in the cloud has increased the size and scope of the amount of data that individuals and organizations can collect. As part of the changing landscape of cloud computing hardware, Amazon has introduced two new products the Snowball Edge and Snowmobile (Forrest, 2016). Both products function as mobile "semi-trucks" that allows Amazon to physically migrate data to their AWS cloud solution. These products also have embedded relevant software that includes capabilities for large scale applications such as Internet of Things (IoT) and big data applications. Changes in cloud technological solutions will impact application areas such as personalized medicine.

At a minimum a cloud architecture consists of a cloud service provider and a cloud consumer, but can be extended to include a cloud broker, cloud developer or cloud auditor (Samba, 2012). The cloud broker functions as an intermediary between the provider and consumer; the cloud developer designs and implements services based on customer requirements; and the auditor independently assesses performance and operations of the cloud provider in the interest of the clients. Each of the above configurations can occur with a private cloud (an internal organization solution), public cloud (independent vendor(s) with cloud solutions available to the general public including organizations and individuals), community cloud (shared solution for a community) and hybrid cloud (combination of two or more from private, public or community cloud). In the medical field cloud computing has an existing established presence (Badger, Grance, Patt-Corner, & Voas, 2012; Newswire, 2015; Puustjärvi & Puustjärvi, 2013). In this paper we specifically examine the area of cloud computing as it pertains to personalized medicine.

3. PERSONALIZED MEDICINE

Personalized medicine, also called precision medicine, genomic medicine, information-based medicine, and individualized medicine; encompasses individualized, customized treatments based on patient genetic material and environmental variables. Researchers have identified hundreds of specific genes and mutations associated with different illnesses, such as specific genetic abnormalities associated with breast cancer or colorectal cancer (Hamburg & Collins, 2010). One of the earliest genetic testing for disease was for a genetic mutation causing Huntington's disease (a neurodegenerative disease) in the early 1990's; since then steady interest in personalized medicine has grown, and it is expected to continue to grow with increasing healthcare costs and an aging population (Bolouri, 2010).

Personalized medicine requires access to detailed patient information including patient medical history and DNA information. With the genome sequencing of thousands of individuals, sub groups can be used to compare a specific individual's data and screen for different illnesses; following this, clinicians can provide better predictions and outcomes regarding individual patient care (Bolouri, 2010). Some third party private companies market services directly to consumers who desire individual genetic testing (e.g. 23andMe, Navigenics and i-gene). Private companies provide information to their clients such as genetic ancestry and genetic traits.

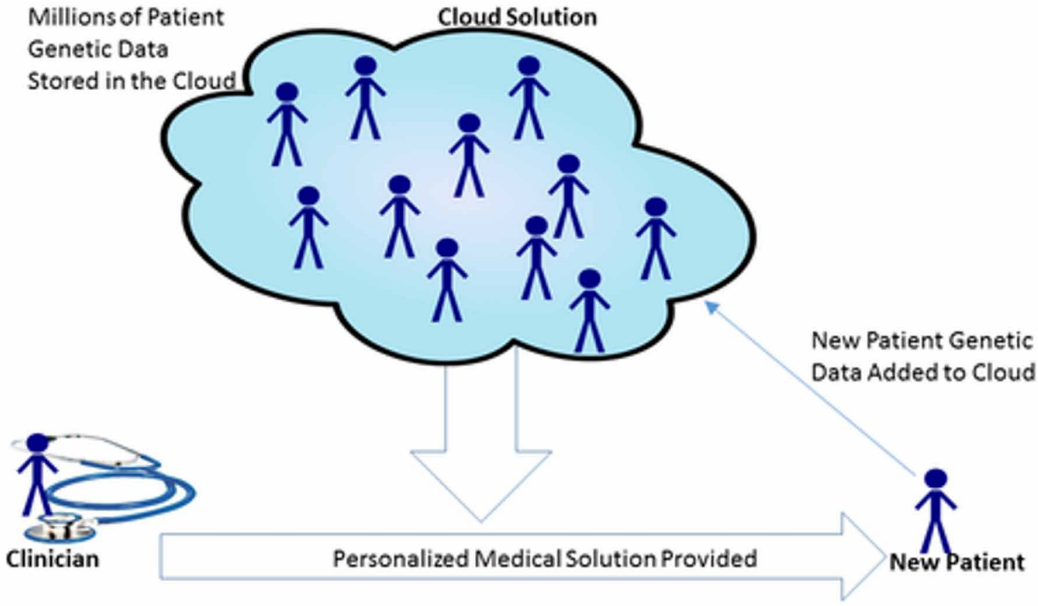
In this paper instead of looking at individual companies that are either marginally or directly involved in personalized medicine, we take a macro-level approach and look at the multiple partners involved in personalized medicine. The macro level includes both private and public entities such as patients, labs, hospitals, universities, government agencies and other agencies involved in personalized medicine projects. Even though there is tremendous potential for improved healthcare delivery through personalized medicine, its value has not been successfully communicated to relevant entities (Johnson, 2016). Effective collaborations, facilitated through relevant ICTs, can advance the case for personalized medicine.

Current medical treatments are prescribed based on how the average person responds to the dosage of medicine. Because of the variations between individuals, the same treatment dosage may work better or worse on different patients and yield different side effects. One of the key aspects of personalized medicine is the idea that treatment for a condition can be individualized or grouped with other similar patients, based on the patient's genetic traits compared to existing genomic datasets. As shown in Figure 1, the genetic material of each new patient is added to millions of records of other patients. Based on complex data computations combining the new patient data with the existing data, a personal medical profile for the new patient is created. The clinician can then use the personalized profile to find a more optimal solution to treat the new patient. Since the human genome was mapped in the early 2000s, interest in personalized medicine has grown tremendously and it is considered as a new cutting edge approach for medical treatment (Deakin, 2011; Podshivalov, Fischer, & Bar-Yoseph, 2014). However, large amounts of data are required for effecting personalized treatments.

The first step in personalized medicine is to gather and store patient data. When a new patient enters a hospital or medical facility, the patient must first consent to having his/her DNA purified from blood or saliva samples and having his/her genome mapped. A matrix of data is constructed including diagnosis, drug regiment, and genetic traits. The results of these analyses are stored in bio-repositories where researchers and clinicians can access them. Patient identifiers are removed in order to maintain patient confidentiality. The goal is that over time the drug treatment and genetic records of millions of patients

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Simplified clinician-patient personalized medicine cloud view



will be accessible to clinicians who can then compare their current patient to the database and determine the best course of treatment for the patient. Obstacles that need to be overcome include collection and storage of the data, accessibility of the data and querying of the data, and cost of testing.

As clinicians and other medical professionals add more individual patient information to relevant databases, more precise outcomes can be derived to treat individual patients. An individual's genetic information can range from family traits such as eye color, to more medically relevant information such as future risks for many diseases including different types of cancers. Personalized medicine is characterized as covering the 4Ps of medicine: personalized, predictive, proactive and participatory (Deakin, 2011).

Expansion of the 4Ps begins with personalization, which is the individualized care goal for each patient. Secondly, the computational power over thousands or even millions of collected patients' genetic profiles increases the predictive validity of future results. A proactive, solution oriented approach increases the accuracy of predicting the best course of action to treat individual patients Lastly, a key driver for success in the arena of personalized medicine is participation. If tools are available for easy upload of more data points, more gains can occur. Due to the network effect, in a clinical environment, as more patient information is entered, the value of the entire network increases.

The push towards personalized medicine requires that a clinician has access to a database that contains patient information either at a regional server or on a national server level. From there the clinician needs to query the database to determine the best treatment dosage for his or her patient given the prior patients' outcomes stored in the database. As the amount of information held in bio-repositories increases, the processing capabilities required to store and access the data will also increase beyond the capabilities of many existing stand-alone database systems. To solve this problem, partnerships between personalized medicine practitioners and cloud computing providers presents a viable solution.

4. THE CLOUD FOR PERSONALIZED MEDICINE – THEORETICAL JUSTIFICATION

Successfully implementation of personalized medicine using cloud computing requires a committed collaborative approach from different participants including clinicians, labs, medical facilities, hospitals, research facilities and of course patients. Resource pooling, on-demand services and elasticity are core characteristics of cloud computing (Badger et al., 2012) that bode well for collaborations and flexibility involved in personalized medicine. Collaboration theory provides the theoretical lens to support the use of cloud computing for personalized medicine.

Collaboration theory (Gray, 1989) identifies three phases in a collaborative endeavor: 1. problem setting – define the problem and get the different stakeholders involved; 2. direction setting – create an agenda and agreement; 3. implementation – utilization of solution, building support and ensuring compliance by participants. For cloud computing and personalized medicine there are multiple actors involved including cloud provider(s), clinicians, hospitals, and other relevant entities. The second phase of collaboration theory requires the creation of an agenda and agreement amongst relevant parties. In the personalized medicine cloud domain there can be multiple agendas and agreements. Lastly, the implementation of the solution is an on-going endeavor.

To demonstrate collaboration theory in action consider the area of pharmacogenetics - the study of understanding the genetic profile of an individual's specific disease. First the problem setting: understanding the genetic profile of a patient's specific illness. Second, is the direction setting – creating an agenda for the use of personalized medicine in the area of pharmacogenetics. Pharmacogenetics is already poised to be one of the primary beneficiaries of personalized medicine (Deakin, 2011; Sheng, Li, & Wong, 2015; U.S. Food and Drug Administration FDA, 2013). Lastly, the third piece of collaboration theory deals with implementation of a solution. This third piece would require buy-in and participation from different entities such as patients, clinicians, medical facilities etc.

With personalized medicine the one size fits all for medical treatment approach is no longer the only option for patient care. Ideally, each patient will receive a customized and personalized analysis of their disease and a unique treatment for his/her illness. However, only through the inputting of data points from thousands of patients, and effectively processing that data will these outcomes be possible. Cloud computing provides an opportunity for disparate and geographically dispersed participants to share and integrate such data.

The presence of disparate silos of human genetic data in the medical field, presents a compelling argument in support of integrated cloud-based solutions for personalized medicine. A recent study identified and highlighted the varied sources of data that is collected for personalized healthcare including data from labs, clinicians, simulations, wearable sensors, and medical imaging (Viceconti, Hunter, & Hose, 2015). Table 1 provides a sample of large scale genomic data repositories. The existence of data silos limits sharing of critical genetic variants that can lead to better outcomes for patients, providers, and other relevant parties involved (Rehm et al., 2015). Using cloud computing for personalized medicine facilitates more data integration however there are implications (developed further in sections 5 & 6) for many stakeholders including clinicians, researchers, patients, medical facilities, insurance companies, pharmaceutical companies and others.

From a solution oriented perspective, both private and public entities can participate in the cloud strategy for personalized medicine. Further, private, public, community and hybrid cloud options make up the solution. A medical facility can use their internal data and integrate patient information through

Table 1. Selected sample of large scale genomic datasets

Name	Data	Overview	Website	Reference
The Cancer Cell Line Encyclopedia (CCLE)	Data for approximately 100 cell lines.	Data used for human cancer models	http://www.broadinstitute.org/ccle/home	(Barretina et al., 2012)
The National Institute on Aging Genetics of Alzheimer's Disease Data Storage Site (NIAGADS)	Contains genomic Alzheimer's datasets.	Portal with software, resources and genomic data about Alzheimer's.	https://www.niagads.org/	(U.S. National Library of Medicine, 2015)
National Database for Autism Research (NDAR)	Genomic data collected from over 100,000 subjects.	Data repository for Autism research such as behavioral, genetic, environmental, neural tissue data.	https://ndar.nih.gov/	(U.S. National Library of Medicine, 2015)
Genomics of Drug Sensitivity in Cancer	Data for over 1000 human cancer cell lines.	Data used for human cancer models	http://www.cancerrxgene.org/about/	(Yang et al., 2013)
Global Alzheimer's Association Interactive Network (GAAIN)	Data from global partners including genetic information.	Shared network studying the causes of Alzheimer's disease.	http://gaain.org/	(Neu, Crawford, & Toga, 2016)

partnerships with other institutions. For example the laboratory for personalized medicine (LPM) established in 2009 at Harvard Medical School, uses Amazon's (AWS) cloud computing architecture to develop individual solutions for patients through computer simulations of millions of avatars (Center for Biomedical Informatics (CBMI) at Harvard Medical School, 2014). Both public and private sector entities are key participants in the continued upward trajectory for the growth of personalized medicine.

5. CHALLENGES OF CLOUD COMPUTING FOR PERSONALIZED MEDICINE

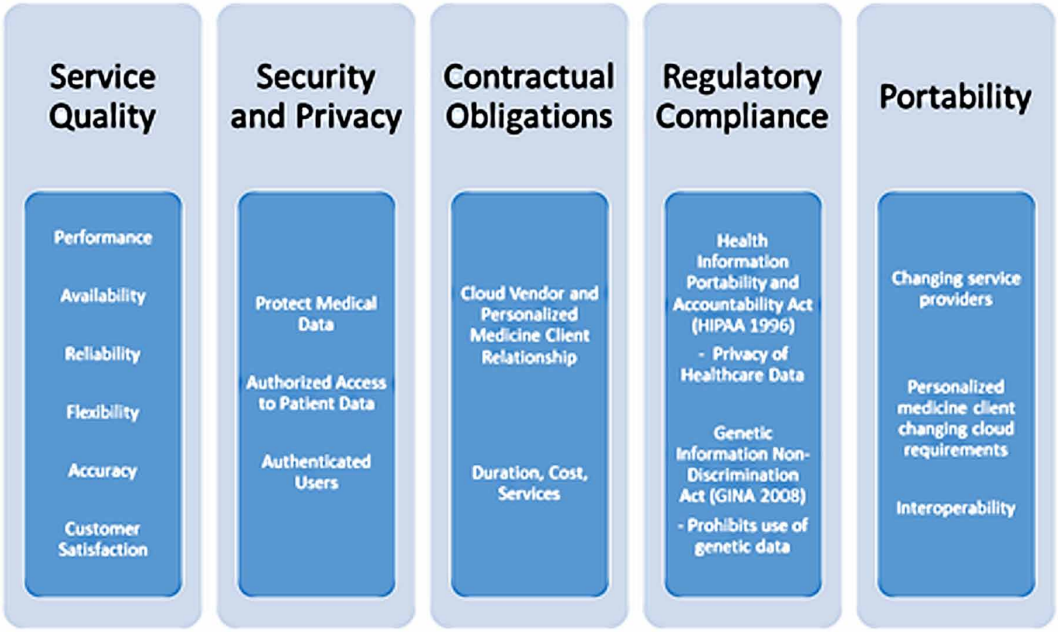
Although cloud computing has many benefits, there are also risks to using off-site technologies. Additionally, even though personalized medicine is an exciting area for innovation, there are some concerns as this field grows. The main challenges we identified associated with the use of cloud computing for personalized medicine are: service quality; security and privacy concerns; contractual obligations; government regulations; and portability. Each of these factors is described in more detail in Figure 2.

5.1. Service Quality

Unlike in-house software and hardware products where the business controls all its IT, with cloud-computing the vendors are in control of some or all of the IT infrastructure. As a result of this relationship dynamic, the quality of service provided by the vendor is an important issue. Three key dimensions of cloud service quality are performance, availability and reliability (Ardagna, Casale, Ciavotta, Pérez, & Wang, 2014). Particularly in the personalized medicine domain the system must perform in a manner consistent with the defined expectations. The systems must also be available whenever needed.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Risks of cloud computing for personalized medicine



In addition to the above three components of quality, we added three more variables: flexibility, accuracy and customer service. Flexibility reiterates the on-demand nature of cloud computing. Accuracy whether in SaaS, PaaS, or IaaS is paramount. Lastly, customer feedback and interaction can he used to improve the quality of service. Effective mechanisms to capture and resolve user complaints will also add to the perceived value of the cloud services provided.

5.2. Security and Privacy

The second risk with the cloud for personalized medicine is that of security and privacy. The cloud vendor must meet security and privacy standards for all sensitive data, even in the presence of anonymized patient data. Security and privacy ought to be of utmost concern to a client contemplating using cloud-computing technology in the area of personalized medicine. Cybercriminals attack all types of data repositories on a daily basis in an attempt to steal valuable information. Recent estimates indicate that a large company may have to fend off upwards of 1,400 cyber-attacks per week (telecomasia.net, 2013). Medical data breaches and medical identity theft are growing target areas for cyber criminals. Besides mitigating network attacks, a cloud vendor can also help maintain the privacy of a customer's patient data. This can be accomplished through advanced firewall techniques and high-level network encryption. These techniques help ensure that the data on their servers is only viewed by those with the proper clearance. However, these need to be implemented along with proper access control protocols. Appropriate authentication and authorization of users must occur. Authentication verifies that the user is who they say they are; and authorization verifies that the user has the correct permissions for the tasks they wish to complete.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

When personalized medicine clients are using cloud computing, they are likely to be storing sensitive patient information, even though this data would have been stripped of any personal identifiers. The social and legal ramifications of unauthorized disclosure of healthcare data outsourced to the cloud is of concern to both individuals and governments (Wang, Chen, & Zhang, 2015). A recent failed implementation of a cloud solution for a hospital cited data security risks as one of the primary concerns of healthcare providers (Sultan, 2014). The vendor must ensure that the data is neither lost nor stolen. Both private and public cloud solutions are vulnerable to cyber security breaches. A recent breach into personal iCloud accounts highlights the multiple vulnerable points that can exist with web-based cloud computing (Crosman, 2014). Information security and privacy is paramount for success of cloud computing for personalized medicine.

5.3. Contractual Obligations

Thirdly, contractual obligations for services can be complex, difficult and even misleading. On an individual level, problems seem to arise frequently between customers and Internet service providers, mobile phone companies, and cable companies. Grievances usually are made because customers aren't receiving services promised or are being charged more than anticipated. These same problems, and more, can arise with cloud computing. A cloud-computing client will likely have different levels of user privileges and needs, all of which need to be properly handled by the cloud vendor in the personalized medicine agreement.

For the personalized medicine cloud computing client, clear delineation of the relationships among all parties must occur. This includes clarification on items such as costs, duration of services, and types of services provided. Companies need to maintain comprehensive records pertaining to cloud contracts as well. Recently the Department of Defense (DOD) was unable to successfully complete a cost benefit analysis of their cloud solutions, because there was insufficient documentation about cloud contracts (Fabey, 2016). Given the many options for cloud computing including IaaS, PaaS, SaaS and others, clarity of contractual obligations cannot be over-emphasized.

5.4. Regulatory Compliance

The fourth risk to using cloud computing for personalized medicine is government regulation. In the United States, the main federal acts relevant to cloud computing and personalized medicine are HIPAA (1996), GINA (2008), and HITECH (2009). The Health Information Portability and Accountability Act (HIPAA) of 1996 governs the privacy and security of healthcare data. HIPAA mainly addresses how confidential information is protected by healthcare providers, and how that information is shared. Even with a 2013 Omnibus Final Rule update to HIPAA, it still does not directly address cloud storage of patient health information (PHI) (Chang 2013-2014). However, the term "business associates" is used in the omnibus rule which can be interpreted to include cloud vendors (Shwayri, 2014).

Further, neither does HIPAA specifically deal with the nuances of data breaches related to genetic material. The fear is that genetic discrimination, the mal-use of an individual's genetic material in an illegal or unethical manner, can occur and cause harm to individuals. To address this concern, the Genetic Information Non-discrimination Act (GINA), which prohibits insurance companies and employers from discriminating against individuals based on their genetic profile, was passed into law in 2008. The passage of GINA was aimed at reducing patient fears about genetic testing. However, there are limitations

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in its scope since it does not cover long term care, life insurance, disability insurance; and members of the military and persons under Federal Employees Health Benefits Plans or Indian Health Services (Lea, 2009).

The Health Information Technology for Economic and Clinical Health (HITECH) Act of 2009 was signed into law to promote the use of health information technology through incentive programs and strengthen civil and criminal penalties as defined by HIPAA (hhs.gov, n. d.). Healthcare professionals and institutions receive incentive payments from Medicare and Medicaid if they are compliant with the two phases of the HITECH Act: 1. meaningful use of electronic health records (EHRs) by 2015 and 2. provide end-users access to a patient portal (Carlson, 2013). Stage three of the HITECH Act is due to begin in 2017 and focuses on improved outcomes (Hitech Answers, 2016). Health status measures, healthcare population patterns and provider collaborations are paramount to phase three of the HITECH Act for improved outcomes (2010). Herein lies an opportunity for personalized medicine with cloud computing by integrating data and using technology to improve healthcare outcomes. However, timely compliance with regulatory requirements present both financial and managerial hurdles for some healthcare providers and other related entities.

5.5. Portability

A fifth risk for personalized medicine clients is the portability of services and data between cloud providers (LeManna, 2012). Portability issues of using cloud computing for personalized medicine can be even more severe if vendors are using specialized medical applications that would restrict clients from moving to other vendors where those software products are not available. Portability refers to both the movement of services from one cloud to another, as well as the movement of data from desktops to a cloud environment (Chang et al., 2013).

When a client adopts a vendor's software or a vendor develops software to meet a client's needs, the software systems will likely be proprietary. Over time the personalized medicine client(s) may decide to transfer data and or services to other cloud providers. Cloud portability is relevant regardless of the cloud services provided i.e. PaaS, IaaS, or SaaS (Chang et al., 2013). Difficulty may arise during this process because of the incompatibility between systems. Additionally, a client may have difficulty integrating the cloud vendor's software into their existing medical software suite. The term interoperability defines the ability of one system to communicate/integrate seamlessly with another system. Interoperability issues should be minimized if changes in cloud services occur.

6. OPPORTUNITIES AND RECOMMENDATIONS

The first research question addressed in this paper focused on the challenges associated with using cloud computing in the area of personalized medicine. This has been extensively examined in the preceding sections of the paper. In this section the second question, how cloud computing can be of value to personalized medicine is addressed in more specific detail. In spite of the many challenges that exist, technology poses many opportunities for the field of healthcare (Chow-White et al., 2015). Personalized medicine is one node under the vast universe of the topic of healthcare.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Our recommendation is that based on the challenges discussed in the preceding section, the client must evaluate many different factors to find the appropriate cloud computing solution based on their medical goals. These two solutions will address many of the security and privacy challenges that dominate the cloud in healthcare conversation. The Translational Genomics Research Institute (TGEN), a non-profit consortium, uses a private cloud supported by Dell to process human genomic data (Borzykowski, 2015).

According to Wang and colleagues (W. Wang et al., 2015) high dimensional medical data can include over 100 variables with data points such as blood pressure, heart rate and others. This type of profile is consistent with the high dimensional data that is part of the personalized medicine profile. Wang et al. (2015) further addressed security concerns of healthcare data on the cloud by using a hybrid cloud with a privacy-preserving protocol that moves sensitive data to the private cloud and less sensitive data to the public cloud.

Companies are looking at creative cloud solutions for personalized medicine initiatives. Through computational mining of multiple large data sets, it is possible to re-identify individuals that were previously part of anonymized genome data (Chow-White et al., 2015). One option is to create a virtual private cloud hosted on a public domain (Sultan, 2014). Ultimately the final decisions are based on evaluating the five main variables: service quality; security and privacy; contractual obligations; government regulations; and portability.

Public sector participation through National Institutes of Health (NIH) and the Food and Drug Administration (FDA) has made funding available to pursue some personalized medicine projects (Hamburg & Collins, 2010). Many other collaborative opportunities in personalized medicine exists both through public sector and private entities. Growth in the area of personalized medicine can also lead to more drug clinical trials based on the genetic understanding of disease (Hamburg & Collins, 2010). Ultimately, using the cloud for personalized medicine is an ongoing journey with many opportunities for growth.

7. CONCLUSION

The fields of medicine and ICTs are not strangers to each other. In fact, there is a healthy symbiotic relationship between these two giants as they equally strive to improve the quality of human life. The area of cloud computing for personalized medicine lends itself as stellar example for the intersection of medicine and technology. Personalized medicine is an important area in the field of medicine, and there are many opportunities to innovate through technology. Cloud computing presents many powerful advantages to bring disparate entities together to advance the field of personalized medicine. In spite of the apparent risks associated with both cloud computing and personalized medicine, the value and future potential of this marriage is too significant to ignore. In this paper we bring this issue to the foreground and discuss both the value and challenges of using cloud computing for personalized medicine.

Chapter 69
Analysis of Healthcare Workflows in Accordance with Access Control Policies

Sandeep Lakaraju
Dakota State University, USA

Dianxiang Xu
Boise State University, USA

Yong Wang
Dakota State University, USA

ABSTRACT

Healthcare information systems deal with sensitive data across complex workflows. They often allow various stakeholders from different environments to access data across organizational boundaries. This elevates the risk of exposing sensitive healthcare information to unauthorized personnel, leading 'controlling access to resources' a major concern. To prevent unwanted access to sensitive information, healthcare organizations need to adopt effective workflows and access control mechanisms. Many healthcare organizations are not yet considering or do not know how to accommodate the 'context' element as a crucial element in their workflows and access control policies. The authors envision the future of healthcare where 'context' will be considered as a crucial element. They can accommodate context through a new element 'environment' in workflows, and can accommodate context in policies through well-known attribute based access control mechanism (ABAC). This research mainly addresses these problems by proposing a model to integrate workflows and access control policies and thereby identifying workflow activities that are not being protected by access control policies and improving the workflow activities and/or existing access control policies using SARE (Subject, Action, Resource, and environment) elements.

INTRODUCTION

The wide adoption of information technology across healthcare organizations has increased the need for developing efficient workflows. Literature has shown that healthcare organizations with efficient workflows have more success rate in adopting healthcare information technology (HIT) into their organizations (Sittig, Krall, Kaalaas-Sittig, & Ash, 2005). Effective care delivery is possible through workflows with competent activities (Campbell, Sittig, Ash, Guappone, & Dykstra, 2006). Nevertheless, security and privacy of healthcare information have become major challenges for healthcare organizations (Akinyele et al., 2011; Alhaqbani & Fidge, 2007). In particular, effective access control mechanisms are needed to protect sensitive information from being exposed to unauthorized personnel.

Workflows

Workflows are used to describe the pattern of tasks to be executed by users to achieve business objectives. According to Welch (2014), "Efficient clinical workflow saves time, saves money, and saves lives. And in today's industry, workflow can have a significant effect on reimbursement". Workflows can be very complicated, especially in a complex environment like healthcare which may involve various subjects trying to perform actions on certain resources in multiple environments, thus requires controlling the access of resources by subjects. For a subject to perform an action on a resource in an environment, that subject should be authorized to perform the intended action. In this research, Business Process Modeling Notation (BPMN) has been used to develop workflows. BPMN (Business Process Modeling Notation) is visualization for business process workflows (Giaglis, 2001). The various elements of BPMN are given in Figure 1. We use four types of elements, defined as follows: Events that can be start or finish, distinguishable by size of circles; Activities (Tasks) have an "id" (A1; A2 etc.) and possibly user icons on the upper right corner of the rectangle, and groups indicate a group of activities; Gateways are diamond shaped, with multiple input channels; Conditional gateways are plain diamonds with only one output channel that is based on the evaluation of a condition; Parallel gateways have diamonds with a '+' sign inside. They have multiple input/output channels indicating that control flows on those channels in parallel; Sequences (flows) link tasks together, and associations are used to associate activities with flow objects; some of the extra events used are also shown in the Figure 1 representing Binding of Duties (BOD) policy and Separation of Duty (SOD) policy, and a release event.

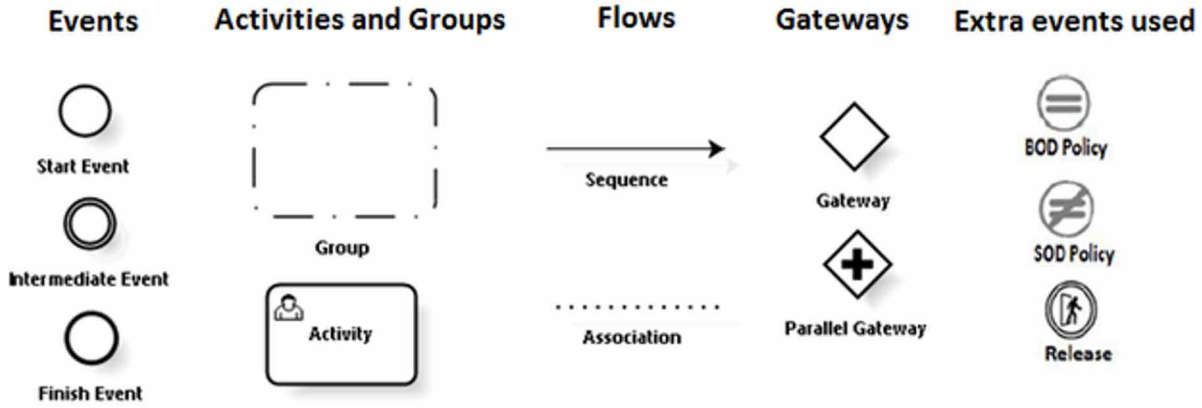
A workflow involves execution of a series of certain activities which help in achieving a goal (Chaari, Biennier, Amar, & Favrel, 2004). These workflows have to be executed in a secure way, which is made possible through access control.

Access Control

Inter-organizational systems allow users to access and share data beyond organizational boundaries and therefore needs proper authorization mechanisms to protect sensitive information from being exposed to unauthorized personnel. An access control policy defines the conditions to which access to resources can be granted and to whom (Ferreira, Cruz-Correia, Antunes, & Chadwick, 2007). With the increasing complexity of information systems, access control methods have evolved from Mandatory Access

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Workflow elements



Control (MAC), Discretionary Access Control (DAC), Task Based Access Control (TBAC), Context Based Access Control (CBAC), Role-Based Access Control (RBAC), to Attribute-Based Access Control (ABAC) (Xu & Zhang, 2014).

Attribute Based Access Control (ABAC)

ABAC provides dynamic access control capability. ABAC does not depend on subject-resource relation, but on various attributes (of subject, resource, environment, etc.). National Institute of Standards and Technology (NIST) indicates ABAC as a recommended access control language which can improve 'information sharing within organizations and between diverse and disparate organizations while maintaining control of that information' (Hu, Scarfone, & Kuhn, 2013).

Coming to attribute base access control (ABAC), it is "an access control method where subject requests to perform operations on objects are granted or denied based on assigned attributes of the subject, assigned attributes of the object, environmental conditions, and a set of policies that are specified in terms of those attributes and conditions" (Hu et al., 2013). The preferability of ABAC over other access control mechanisms is demonstrated in detail in (Yuan & Tong, 2005). In ABAC, the authorization elements are defined in terms of attributes, rather than identities, of subjects, actions, resources, and environments (SARE). Attributes are characteristics of these entities that are predefined and pre-assigned by an authority. Subject attributes help in identifying a user (or an operation or a process) with its characteristics rather than its role; for example: job title, user name, age, etc. A resource attribute is a characteristic of a resource (record, data, etc.); for example: medical elements of patient record, non-medical elements of patient record, etc. Action attributes help in identifying the type of action the subject will perform on a resource; for example: read, write, etc. Environment attributes are operational or situational characteristics, such as current time and IP address. Consider the following access control rule: Any doctor can read and write into patient health record (PHR) only for his/her designated patients from internal network. The subject attributes include 'doctor', the action attribute is 'read' and 'write', and the resource attribute is 'patient health record', and the environment variable is 'internal network' and the condition is that the doctor can only access the health records of the patients designated to him/her.

HIPAA Compliance of Workflows and Access Control

Implementing HIPAA compliance involves the steps below: (i) establishing a process to develop/improve policies (ii) administering security functions (iii) actively tracking personnel changes, and (iv) examining and recording the policy application (K. Cole, 2002).

The privacy rule involves: (i) Minimum necessary use: where an organization should delineate people who may request to have their hands on PHI. Organizations should also delineate the health information into various categories and should define the level of access an employee should have to access that particular information, and any other specific regulations that may apply; (ii) notice of privacy practice: Organizations should make understand the employees and any other stakeholders about their privacy practices, (iii) it also provides the patients with advanced rights of access about their health information. Upon patient's request, a healthcare entity should provide information sharing policies, and patients can request with whom their information may be shared or not shared.

The security rule involves confidentiality, integrity, and availability of information. Confidentiality involves restriction of access to information. Integrity imposes strict restrictions on type of modifications that can be performed on the protected health information. Availability ensures that recognized users have access to PHI whenever they require. This can be implemented in three ways as shown in this research: developing policies in plain English, implementing through computer models (such as workflows and ABAC), and using technical mechanisms. In this research, the access control policies and workflow activities are HIPAA compliant because:

1. This methodology requires to develop and use uniform SARE standards
2. Workflow activities and access control policies use same SARE attributes
3. Access control policies consider environment variables to allow or deny access
4. Policies can be modified based on patient's interests
5. The privacy will be enhanced by considering the environment attributes, which would further allow the administrator to know what information has been accessed from which location and by whom.

Integrating Access Control and Workflow

Many organizations treat access control and workflow as two separate issues. As both workflow specifications and access control polices can be complex, it is likely that there exists discrepancy between workflow activities and access control policies. For example, some workflow activities may not be adequately regulated by the access control policies. To address this issue, we propose a methodology for integrated modeling and analysis of workflows and ABAC policies.

The proposed methodology views workflow activities in terms of subject, resource, action, and environment. Specifying environment attributes in a workflow will provide more contextual information for analysis. It is also consistent with the ABAC concepts. Through cross-examination of inter-organizational workflow activities and access control policies, the proposed methodology can identify: (a) Whether there are workflow activities that are not covered by the access control policies, (b) whether there are unused access control policies, (c) how many policies are covering an activity, and (d) whether the workflow activities and the access control policies need to be modified or refined.

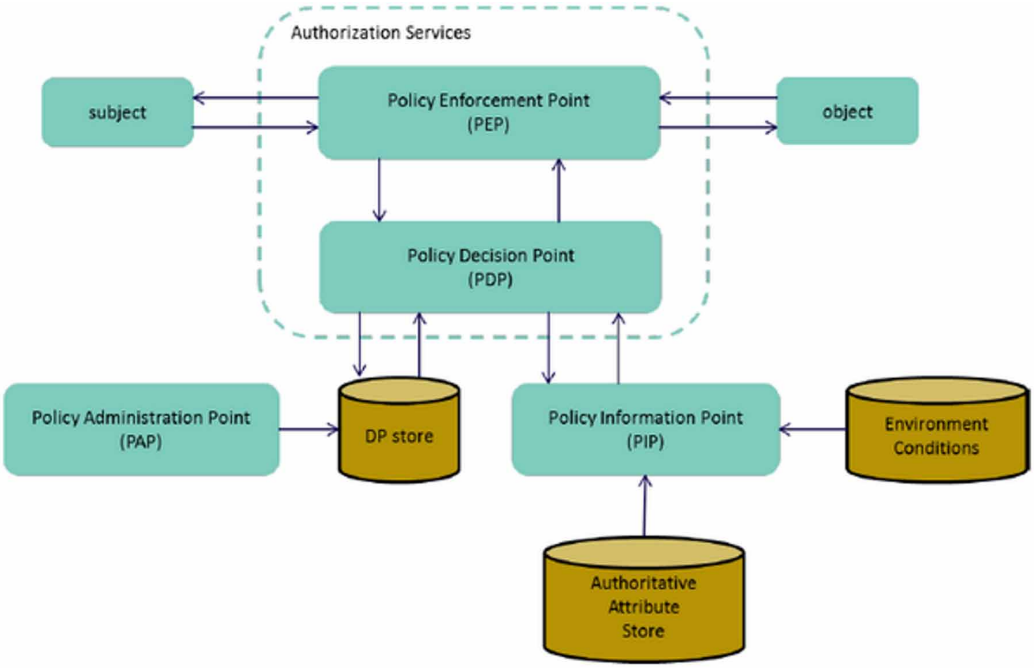
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Organizational Implementation of ABAC

An access control policy defines the conditions to which access to resources can be granted and to whom (Ferreira et al., 2007). With the increasing complexity of information systems, access control methods have evolved from Mandatory Access Control (MAC), Discretionary Access Control MAC (DAC), Access Control List (ACL), Role-Based Access Control (RBAC), to Attribute-Based Access Control (ABAC) (Xu & Zhang, 2014). The preferability of ABAC over other access control mechanisms is demonstrated in detail in (Yuan & Tong, 2005). In ABAC, the authorization elements are defined in terms of attributes, rather than identities, of subjects, actions, resources, and environments (SARE). Attributes are characteristics of these entities that are predefined and pre-assigned by an authority. A sample organizational ABAC implementation has been shown in Figure 2. It mainly involves certain functional 'points': Policy Enforcement Point (PEP), Policy Decision Point (PDP), Policy Administration Point (PDP), and Policy Information Point (PIP). Considering a particular scenario where a subject requests access to a resource under certain environment, this is sent as a request into a policy enforcement point (PEP) where a decision is taken whether to 'allow' that access or 'deny' the access based on certain attributes (user, action, resource, and environment). PEP sends that request to PDP where the request is broken into subject attributes, resource attributes, action attributes and environmental attributes.

Initially, each of those attributes is stored in their respective attribute stores managed at the policy information point (PIP). And the Policy Administration Point (PAP) is the point where policies are managed by the administrators. PDP will validate the request based on the available policies from PAP and the attributes available from PIP. Once the PDP is able to validate the request, it will send a notification

Figure 2. Access control mechanism distribution in a sample organizational ABAC implementation (Hu et al., 2013)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to PEP suggesting to 'allow' the access, otherwise 'denies' the request. To support ABAC, OASIS has developed the eXtensible Access Control Markup Language (XACML) standard (Identifier, 2005). Consider the following access control rule: *Any doctor can read and write into patient health record (PHR) only for his/her designated patients from internal network*. The subject attributes include 'doctor', the action attribute is 'read' and 'write', and the resource attribute is 'patient health record', and the environment variable is 'internal network' and the condition is that the doctor can only access the health records of the patients designated to him/her.

Literature Review

A workflow involves execution of a series of certain activities which help in achieving a goal (Chaari et al., 2004). These workflows must be executed in a secure way, which is possible through access control. To achieve these secured workflows, various access control techniques have been studied in accordance with the workflows, but none of the works have shown an integrated analysis and have only dealt with workflows and access controls separately. In (Chaari et al., 2004), authors have extended role based access control and proposed an authorization and access control model for workflows. Research by Chaari et al. (2004) mainly focuses on the user's role and the task the user has to execute; but it does not consider any other contextual information or user attributes except the role. Russello et al. (2008) have proposed a workflow based access control framework for e-health applications, where permission is granted to a user based on the necessity of the task that the users have to execute. Russello et al. (2008)'s research mainly focuses on the 'need' of the user to execute the task, but does not consider any of the environment or resource or subject attributes except the role. Russello et al. (2008) indicates that 'access rights must be granted only to entities that require access to a given resource and just for the amount of time that access is necessary', but healthcare is rather dynamic environment where access is required in varying contexts which requires precise contextual information to allow a user to access certain resource. This research will address this issue by focusing on importance of 'environment' attributes and our methodology will demonstrate the integrated analysis of workflow and access control which can grant access rights only to the entities that require access to a given resource under certain context where access is necessary. Le, Doll, Barbosu, Luque, & Wang (2012) have improved the traditional role based access control model to enhance the information access management in the environment of workflow and team collaboration in healthcare programs. Le et al. (2012)'s research has mainly concentrated on traditional RBAC and is an extension of RBAC. This research deals with ABAC, which not only deals with user attributes such as 'role' but also with various resource, environment and action attributes. Lu, Zhang, & Sun (2009) have developed a framework to specify security constraints in workflow by improving business process management notation model. Authors have improved the workflow model to aid role based access, separation of duty, history based task assignment, etc. Compared to this work, our model deals with the attributes of the subjects, action, resource, and environments rather than role based or SOD or history based or task based. Zhang & Liu (2011) have developed a workflow oriented attribute based access control model that provides 'Service-Oriented Computing', where any device's functionality can be offered as a standard service. Although Zhang & Liu (2011) talk about attribute based access control, they have not considered the need to identify unused policies or the need to identify unprotected workflow activities. XiangPeng, Cerone, & Krishnan (2006) have developed a framework integrating workflows (BPEL) and access control (RBAC) to execute security constraints through 'temporal logic'. Though the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

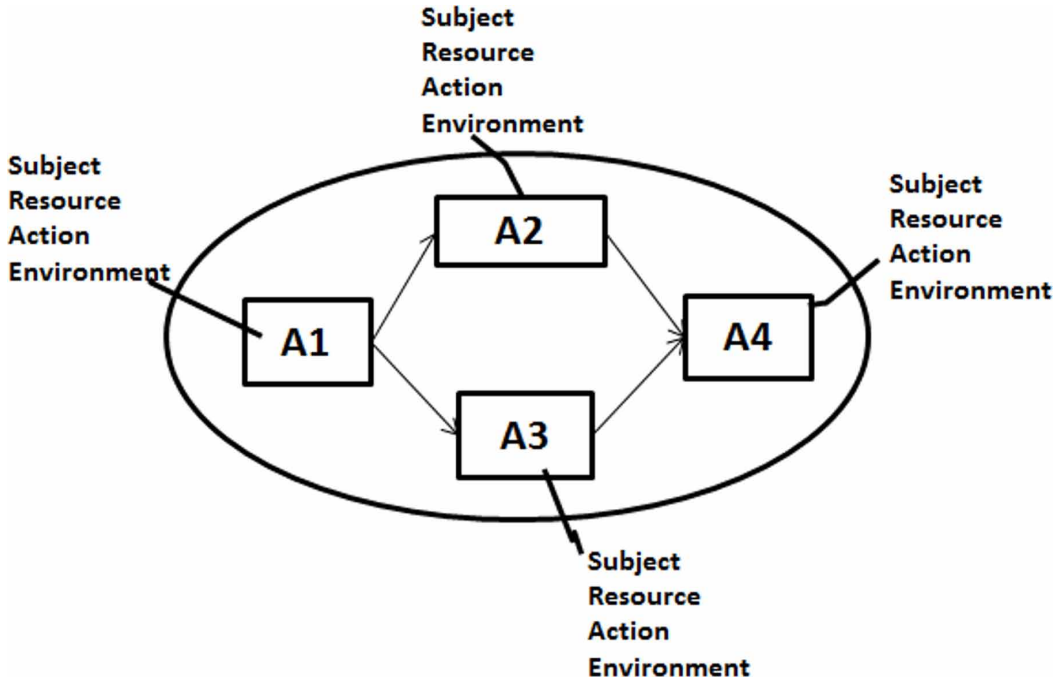
framework deals with integrating workflows and RBAC through temporal logic; regular people may not exercise the logic to execute security restraints. Compared to their work, our model deals with enforcing ABAC policies on the workflow activities which is not covered in (XiangPeng et al., 2006).

None of the above mentioned literature talks about integrated analysis of workflow and ABAC policies. One of the main takeaways from our research is that it is possible to identify any unused policies and also it is possible to identify any workflow activities that are not being protected by access control policies.

Assumptions

Some of the assumptions in developing the current model are discussed below. We are not developing a new modeling language. We are adding a new element 'environment' to the activity of the workflow. We are suggesting breaking down an activity in the workflow in terms of 'Subject, Action, Resource, and Environment' (SARE) elements as shown in Figure 3. Not every activity may have all of the four (SARE) elements, i.e. each activity may have any of the SARE elements. We identify common themes between the workflow and ABAC policies in terms of SARE elements. In any given situation to integrate a workflow and policies, we assume that workflow and policies will have any or all of the SARE elements. We assume workflow is a valid one without any deadlocks. Organization will define the SARE elements to be used commonly by both workflow and the ABAC policies.

Figure 3. Workflow activity breakdown



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Methodology

The general idea of integrated modeling and analysis is as follows: (a) specify workflow activities in terms of SARE elements, (b) specify ABAC policies, (c) cross-examine the workflow activities and ABAC policies to identify discrepancy, (d) if there is no discrepancy, then terminate, otherwise go back to (a) if the discrepancy is about the workflow activities, or go back to (b) if the discrepancy is about the ABAC policies. In the following, we focus on the cross-examination of workflow activities and ABAC policies, as illustrated in Figure 4.

Step 1: The given workflow may include many activities (A1, A2, A3…). Each activity has to be individually identified from the given workflow as (A1), (A2), and (A3) ….

Step 2: From the individual activity that has been identified from the workflow (say A1), subject resource action and environment (SARE) attributes have to be identified, i.e. each activity (A1) has to be broken down into SARE (subject action resource and environment) elements (Figure 4's break the activity in terms of SARE).

Step 3: ABAC policies will be written targeting the Subject and/or Resource elements of the SARE attributes. An ABAC policy is represented by the target which the policy is intended to cover. It is seen in Figure 4 where P1 is represented by R1, where R1 is the resource1 targeting any workflow activity which involves the resource1. All the workflow activities that involves resource1 (R1) will be covered by this policy. Therefore, in this step, the target element from the policy is extracted and used to represent the policy to match with the respective attribute in the workflow activity.

Step 4: Once the workflow activities are broken into SARE elements, and the targets are extracted from the Policies, each of the 'subject and resource' attributes of the workflow activity are cross examined across the available ABAC policies that are targeting the respective subject and/or resource attributes.

Step 5: It is important to identify all the policies that can be applied on an activity. Once the policies are applied on the activity of the workflow, record each of those policies per workflow activity into a table (Table 1). Identify all of the policies that are being applied on each of the activity of the workflow and develop a table (Policies applicable on each activity of the workflow: Table 1).

Step 6: Once the policies are applied on the activity of the workflow, identify all of the policies that are not being used on the workflow (Policies that are not being used on the workflow: Table 2).

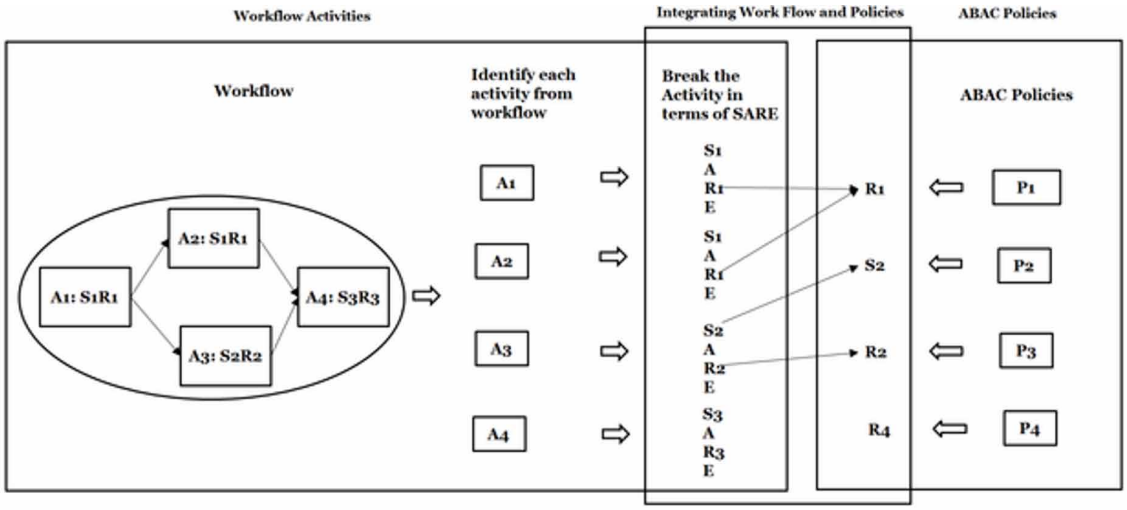
Implementing the Approach

Figure 4 represents the integrated model of the workflow and ABAC policies. It is evident from the Figure 4 that the 'workflow' denotes a workflow with four activities: A1, A2, A3, and A4. Each of these activities has 'subject, resource, action, and environment attributes'. Once there is the workflow, each of the activities of the workflow is extracted from the workflow as shown under the 'Identify each activity from workflow' task in Figure 4 ({A1}, {A2}, {A3}, and {A4}). Following this, break each of these activities into the subject, action, resource, and environment elements (SARE).

{A1} => {S1, A, R1, E}; {A2} => {S1, A, R1, E}; {A3} => {S2, A, R2, E}; and {A4} => {S3, A, R3, E}

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Model to integrate workflow and ABAC policies



Similarly, from the given ABAC policies {P1, P2, P3, and P4}, identify individual policies. Each of these policies will further include multiple rules which are written targeting either a subject or a Resource. Based on the target, each of these policies may be targeted to either subject or resource. Therefore, each of these policies can be shown as under 'ABAC Policies' in Figure 4, P1=>R1, P2=>S2, P3=>R2, P4=>R4. Once the subject and resource elements are found from the workflow activities, the policies with respective subject or resource targets must be imposed on that particular activity as shown below.

As {A1} has subject S1 and Resource R1, any of the policies that target Subject S1 or Resource R1 can be imposed. From the given policies, only P1 is applicable. This case is a special example where there is no policy specified on subject S1, and therefore this activity of the workflow is **incompletely covered (partial)** by the access control policy. It is the same case with A2.

Whereas {A3} has a subject S2 and Resource R2, and therefore, policies P2 and P3 can be applied on the activity A2 showing that A2 is completely covered.

Coming to the activity {A4}, it has subject S3 and Resource R3, but there is no policy targeting either subject S3 or Resource R3. Therefore, this activity is not at all covered. Similarly, Policy P4 is targeting resource R4, which has no occurrence in the workflow, resulting in no use of this policy. The outputs from the current model are shown in the below Tables 1 and 2. Based on these outputs, the workflow developers and access control policy administrators can make the necessary changes to the respective workflows and policies.

Expected Results of the Integration Model

Based on these outputs from Tables 1 and 2, it is evident that (i) Activities A1 and A2 are each covered by one Policy P1, whereas Activity A3 is covered by two policies P2 and P3, (ii) The workflow administrators that the 'IOS workflow activity A4 is not being covered by any ABAC policy and therefore it is recommended to re-evaluate the activity A4, (iii) the Policy P4 is not covering any workflow activity and therefore it needs re-evaluation, (iv) in re-evaluation, policy administrators may re-evaluate the un-

covered workflow activity and the policies that are not in use, and based on the need, they may suggest the organizations to add new SARE elements using which the administrators may develop new policies or workflow activities.

Demonstrating the Methodology in a Healthcare Scenario

Manipal hospital is located in Bangalore, India with 54 bed count and can accommodate up to 91 beds when fully equipped. It is located in the center of the city. The hospital has six departments: administration department, inpatient/outpatient department, pharmacy department, laboratory department, emergency department, and surgical ward. The hospital accommodates both inpatients and outpatients. The pharmacy department provides medications for both the inpatients and outpatients. The scientific staff of the hospital include: front desk specialists, doctors, nurse specialists, lab specialists, pharmacists, and surgical specialists. This hospital has recently implemented and mandated to use electronic health records across the hospital. The main parts of the electronic health records may include: administrative record, clinical record, pharmacist record, patient record, and surgical record. Administrative record of the EHR mainly includes patient demographic information (such as age, sex, first and last names, email addresses, physical addresses, etc.), date of admission and discharge, patient registration information, etc. This administrative record is restricted to be accessed only by the front desk personnel, nurse specialists and doctors. The clinical record stores the health related information of the patient. The clinical record may include detailed information of pathology reports, blood reports, ENT reports, doctor notes, nurse notes, prescriptions, etc. The pharmacist record includes prescription ids, patient ids, physician ids, and pharmacist notes. The surgical record of the EHR includes the surgical information, images (like Xrays, etc.), surgery specialist, and patient information. The subject, action, resource, and environment (SARE) attributes are provided by the hospital and are discussed below.

Subject attributes may include: department id (which includes an administration department, pharmacy department, emergency department, etc.); specialty id (which includes doctors, nurses, pharmacists, etc.); user id (which includes patient ids, doctor ids, nurse ids, etc.). Action attributes may include: read, write, update, delete, fill, validate, approve, reject, etc.; resource attributes include: electronic health record, patient health record, pharmacist record, clinical record, administrative record, surgical record, etc.; environment attributes include: ip addresses (92.92.1.1, 93.93.1.1, etc.), inpatient ward, outpatient ward, laboratory, surgery ward, doctor office, etc. Each of the departments of the hospital is assigned with different IP address as mentioned below: for hospital administration department: 92.92.1.1; for inpatient

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and outpatient wards, doctors' offices, and nurse quarters, the IP range is from 91.91.1.1 to 91.91.1.5; the internet protocol address for pharmacy department is 93.93.1.1, and for laboratory department is 94.94.1.1, for emergency department is 95.95.1.1, and for surgical ward is 91.91.1.6.

This case study contains multiple workflows which are developed for various causes. A basic scenario in a hospital starts when a patient walks in for an appointment with the doctor (Figure 5). This workflow mainly involves five workflow activities. Subjects involved in this workflow are patient and front desk person (FDP). FDP uses a system which has been configured for the IP address 92.92.1.1 and the FDP is allowed only to use this system from this IP address. The FDP cannot access any other systems configured with other IP addresses. Also the FDP can only access administrative record but not any other clinical information of the patient's electronic health record. When a patient walks in, the front desk person (FDP) asks the patient for his/her demographic information and tries to retrieve the patient information, if the patient is coming in for the first time, the FDP will request the patient to fill in the registration form and FDP validates the form, and thereby registers the patient into the hospital system followed by scheduling an appointment with a doctor.

This particular scenario can be considered as an example for separation of duties (SOD) and also binding of duties (BOD). There are mainly two roles: patient and FDP. A patient will check for an appointment with the FDP. FDP will check if the patient is valid, and then checks for doctor's schedule, and schedules an appointment. For this example, separation of duties applies between patient and receptionist. Main assumptions for a given scenario of patient's appointment with doctor to be static SOD are: (i) receptionist cannot be the patient; (ii) patient himself/herself cannot act as receptionist. If a receptionist is a patient, the receptionist cannot perform tasks checking the validity of the patient, checking for doctor's schedule and scheduling an appointment. Only another receptionist can perform those tasks.

As shown in the Figure 6, subject attributes to activity allocation can be seen, where multiple users with usernames (such as Tresa, Mary, etc) are allocated to subject attributes (role) and are thereby connected to their respective workflow activities.

As shown in the Figure 6, it is evident that activities 'FDP requests for patient demographic information...' and 'Patient fills the patient registration form...' cannot be completed by the same subject, accommodating separation of duty constraint. Similarly, activity 'FDP validates patient info in the admin record…' and activity 'FDP schedules appointment time with doctor…' should be done by the same subject, accommodating binding of duties constraint.

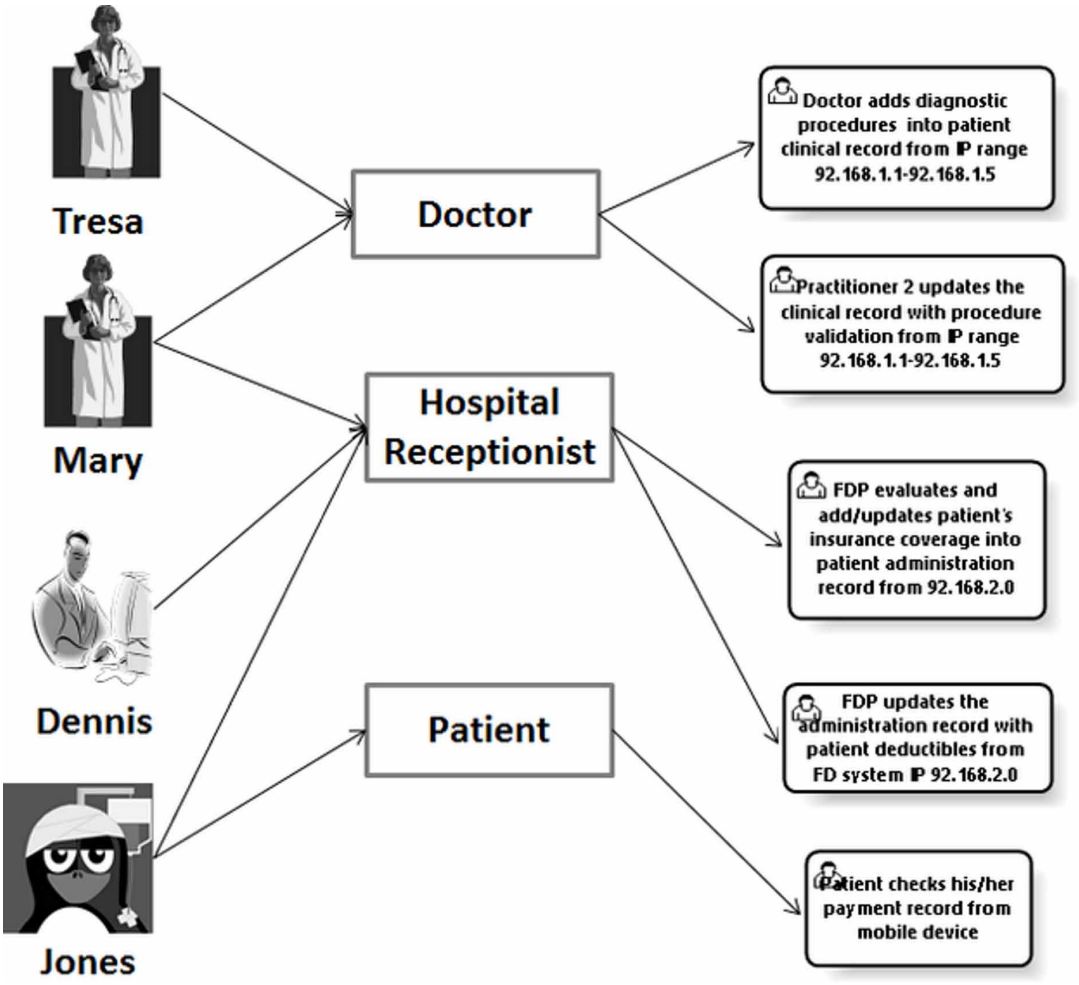
Once the patient has an appointment with the doctor, the workflow in Figure 5will begin. Activities of the workflow given in Figure 5 are discussed in detail. This particular scenario begins when a patient has an appointment with a practitioner and the practitioner recommends a diagnostic procedure.

This workflow starts with (activity A1) identifying the requirements for the diagnostic procedures to be performed (e.g. tests to evaluate a patient's health). Here the doctor will identify the tests and treatments for the patient from ip address 91.91.1.1-91.91.1.5;

Once the diagnostic procedures are identified, the recommended diagnostic procedures will be validated and performed in accordance with the Medicaid/Medicare regulations. This activity (A2) involves conducting the procedure validation to check for appropriate diagnosis in comparison with the Medicaid/Medicare regulations by another practitioner2 from 91.91.1.1-91.91.1.5. After that, if the procedure validation is correct and performed, the workflow will be carried on to Activity 4, otherwise diagnostic procedures will be reviewed and will be recommended to re-assess by the practitioner1 based on the Medicaid/Medicare regulations;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Patient walks in for an appointment



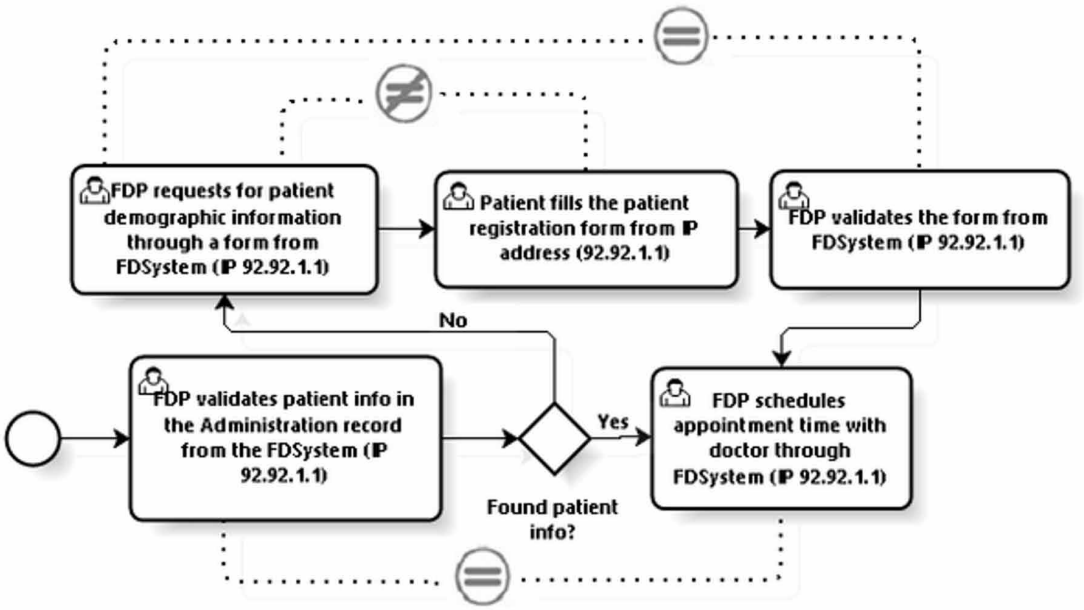
Then the patient's insurance will be evaluated by the front desk person of the hospital staff (e.g. by a receptionist) (A3) from ip address 92.92.1.1. Based on the patient's information, his/her insurance will be evaluated to verify whether his/her current insurance policy would cover that particular test (for example, an eye or a dental exam). If the insurance covers that particular test, workflow will move on to the next activity (A4). If the insurance will not cover the test, the patient may go back and check for a secondary insurance policy which will cover that test;

Activity 4 (A4) is where the financial administrator will calculate the patient's deductibles, once the patient's insurance is validated. This includes the percentage of the total bill that the insurance company would bear (e.g. 85%-15% deductible) vs the amount the patient is liable to pay.

Activity 5 (A5) is where the patient will access his/her payment record. The computed quote is available in the payment record and the patient will access it through a mobile device.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Subject attributes to resource allocation



Attribute based Access Control Policies

The following is a subset of the access control rules in the case study: Some of the ABAC policies for the proposed case study may include:

PPrac: Any user with the position Practitioner/SupervisorPractitioner and an employee of the Organization, and are assigned to the patient, can read/write a Patient record from 91.91.1.1-91.91.1.5

SARE: Target is Subject: Practitioner, Resource: Patient Record, Action: read/write, Environment: 91.91.1.1-91.91.1.5

PN: A Nurse who is working under a practitioner can access patient record from internet network (e.g., IP range: 91.91.1.1-91.91.1.5)

SARE: Target is Subject: Nurse, Resource: patient record, Action: access, Environment: 91.91.1.1-91.91.1.5.

PFDP: Any user with Position: FrontDeskPerson from Department Front Desk with UserID Receptionist can 'access' the 'insurance information' of a patient and thereby 'validate' the Insurance of a patient and add/update it to the payment record, from 92.92.1.1.

SARE: Target is Subject: FrontDeskPerson, Resource: Payment Record, Action: Add/Update, Environment: 92.92.1.1

PPR: Patient Record cannot be accessed by any user with Position: FrontDeskPerson from the IP 92.92.1.1.

If tried to access, email to the Supervisor 'FrontdeskPerson with name X has tried to access Clinical Record X from ip address 92.92.1.1.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

SARE: Target is Resource: 'Patient Record', Subject: FrontdeskPerson, action: access, Environment: 92.92.1.1.

PPayR1: Any user with Designation: Patient whose age is greater than 16 can read his/her own Payment Record from internal network or from his/her mobile device at any time.

SARE: Target is Resource: Payment Record, Subject: Patient, Action: read, Environment: Hospital's internal network or from his/her mobile device

PPayR2: Any user with Designation: guardian or parent can read Payment Record of a Patient whose age is less than 16 from hospital's internal network or from his/her mobile device.

SARE: Target is Resource: Payment Record, Subject: Gaurdian/Parent, Action: read, Environment: hospital's internal network or from his/her mobile device.

PIN1: Practitioner/Nurse/SupervisorPractitioner can only read/write patient record from 91.91.1.1-91.91.1.5.

SARE: Target is Subject: Practitioner or Nurse or SupervisorPractitioner, Resource: Patient Record, Action: read/write, Environment: 91.91.1.1-91.91.1.5

PFDD1: Only FDPerson can be logged into 'FDDesktop', and read PatientInsuranceInformation.

SARE: Target is Subject: FDPerson; Resource: Patient Insurance Information, Action: login, Environment: 92.92.1.1;

WSO2

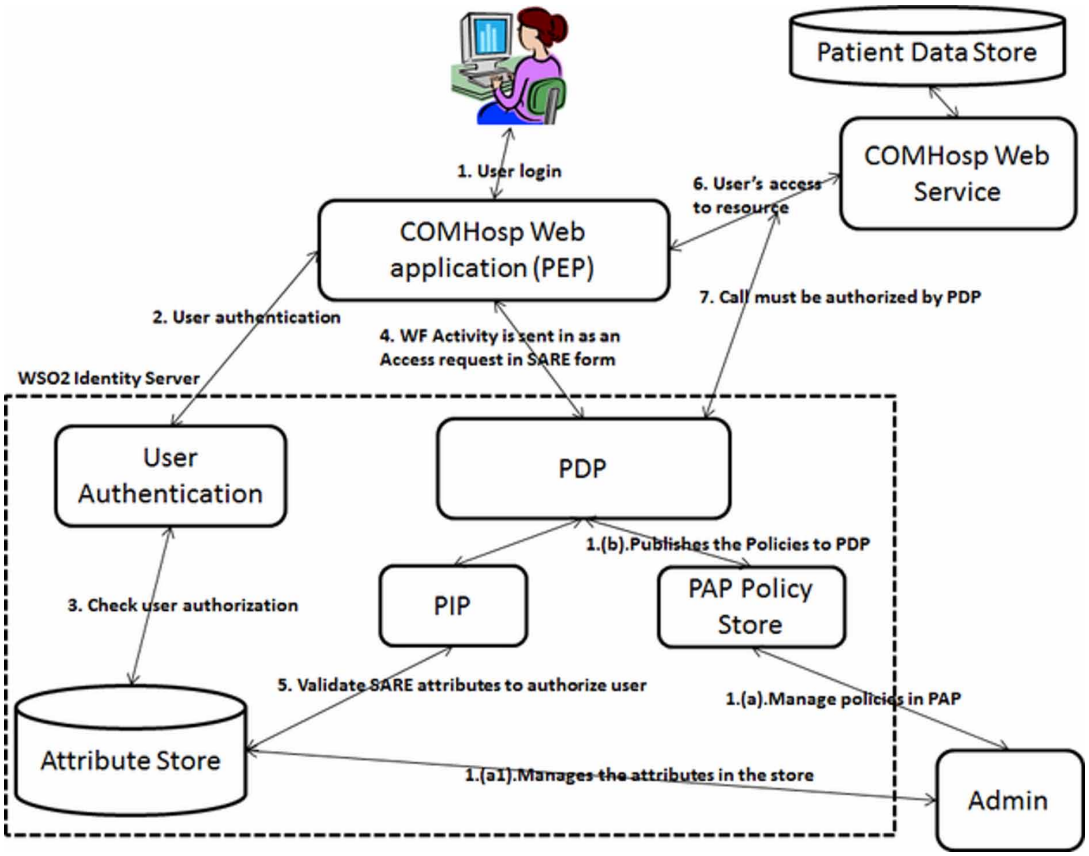
WSO2 identity server is an open source application, which hosts a web service and a web application. It offers a user interface with multiple features where a user can log into the system and create, edit, read, or delete an access control policy. A user can login as an administrator to create and manage access control policies which can be tested in another user interface in which the user can send a request in terms of SARE attributes. For example, if a practitioner tries to access a patient health record, the practitioner's credentials are validated against the access control policy file which is located on a XACML engine in the identity server, and after validation the engine will permit/deny the user's request. A detailed demonstration of the WSO2 identity server with an example is discussed below.

Demonstrating the Case Study using WSO2

The process of validation of policies on workflow activities is shown in the above Figure 7. To validate the model, we have used case study analysis in which we've used Business Process Management Notation (BPMN) to develop the workflow and WSO2 Identity Server to administer the ABAC policies. The steps involved in applying these two for our integrated model are discussed below: ABAC policies written in plain English are entered into the WSO2 Identity server's Policy Administration Point (PAP) through their admin interface, and workflow is developed using BPMN. Once we have policies in WSO2 Identity Server and the workflow, each of the workflow activities is individually identified. Each of the identified workflow activities are extracted from the workflow and the SARE elements are derived from each activity. A request is formulated from the workflow activity's SARE elements, and that request is sent to the WSO2 Identity server's Policy Decision Point. Once the request is sent, WSO2 Identity server will evaluate the request. Based on the policies specification, the server will generate a response containing either 'permit' or 'denied' or 'indeterminate'.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Demonstrating the approach using WSO2



- A 'permit' response will denote that the intended actions by the subject under certain environmental conditions are allowed.
- A 'deny' response will denote that the intended actions by the subject under certain environmental conditions are not allowed.
- An 'indeterminate' response will denote that the activity is not fully covered by the policies defined.

To accommodate complex ABAC policies, more coding is required to modify and accommodate more complex WSO2 features. With some coding into WSO2, it is possible to identify which policies are being enforced on the request (workflow activity).

WSO2 in Action

Here, we'll demonstrate the proposed research methodology using WSO2 Identity server. If we consider activity A1: A Practitioner adds diagnostic procedure into EHR from hospital's internal network, we send this as a request through WSO2 Identity server (in Figure 8). Once the request is evaluated, we can see the result 'permit' in the below Figure 9.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. PPrac Policy in WSO2

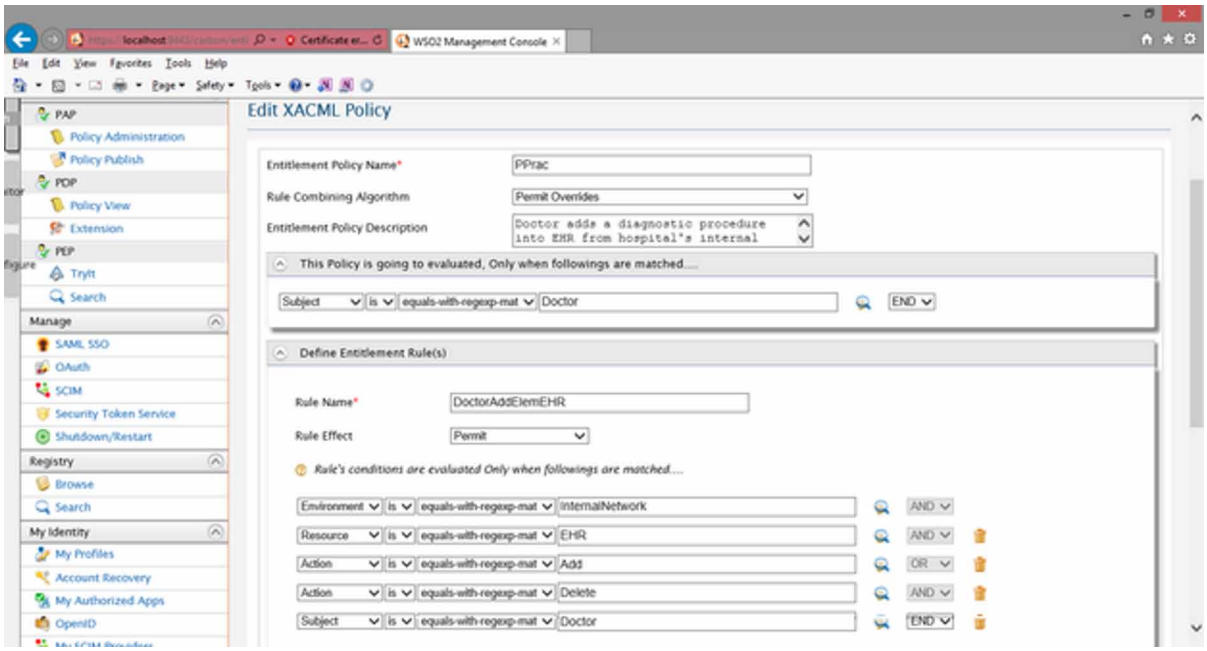


Figure 9. Policy PPrac in action

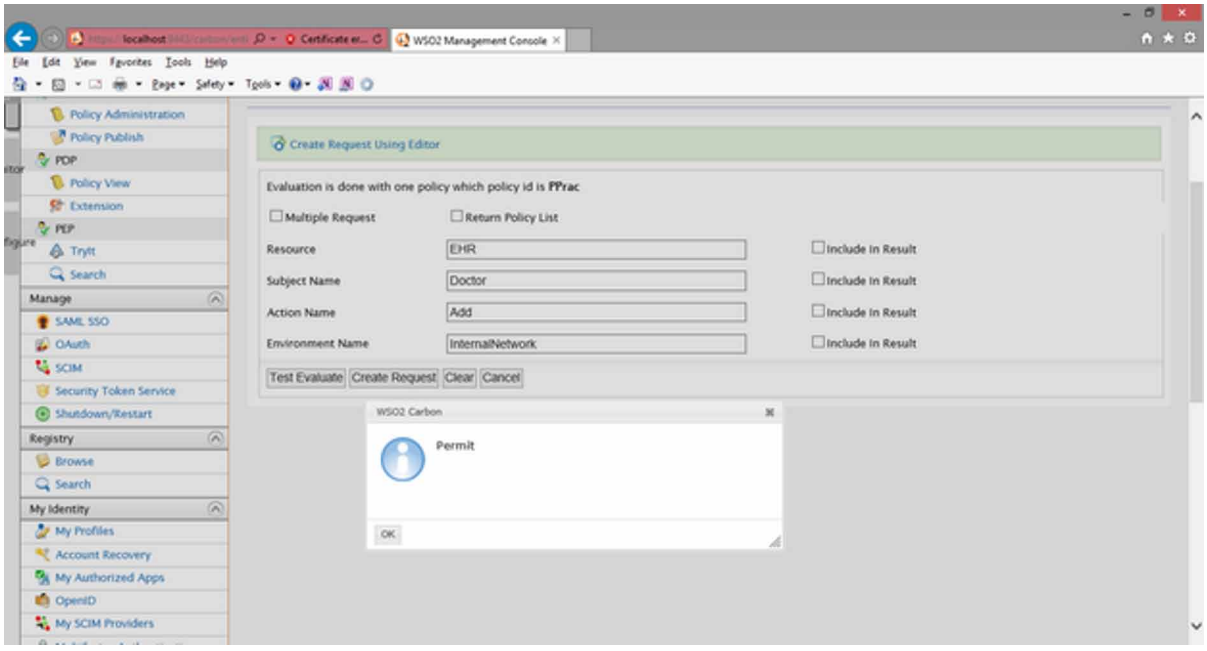

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Testing Results

All of the available ABAC policies are: PPrac, PPR, PFDP, PPayR1, PPayR2, and PN. The activity analysis helps in understanding that not all of the policies are being used across the activities of the workflow, and can be seen in Table 4. The policies (y) that are not being used at least once include: PN. The policies that are applicable on each activity of the workflow can be found in Table 3 and the policies that are being used (not used) on the workflow activities can be found in Table 4.

GUIDELINES FOR HOSPITALS TO IMPLEMENT THE APPROACH

Purpose

This guide contains the necessary specifications for the integration of workflows and access control policies in a healthcare setting. An integrated methodology will allow efficient and accurate specification and modification of access control policies and workflow activities while reducing the burden on dealing with access control and workflow activities separately. This guide defines how healthcare organizations can define attribute based access control policies; define the implementation of XACML through WSO2; defining and creating a policy administration point; defining the method to extract workflow activities from workflows.

Audience

The intended audiences for this guide are hospital personnel who intend to improve their current access control mechanisms by making environment element their organizational priority. This guide helps in integrating workflow activities and ABAC policies through WSO2 Identity server.

Table 3. Policies applicable on each activity of the workflow

Activity Name	Policy applicable (Yes/ N0/ Partial)?	If applicable, Policy Name
A1	Yes	PPrac, PPR, PIN1
A2	Yes	PPrac, PPR, PIN1

Steps to Implement the Proposed Approach

Assess Current Practice

Some of the elements to assess current practice at a healthcare facility may include: (a) performing an analysis on both workflows and access control policies in the organization; (b) performing an analysis on current type of access control mechanism (c) validating the clinical workflows to check if they are developed based on SARE elements; (d) are access control policies and workflow activities using same SARE elements; (e) does the organization considers environment element as a crucial element.

Setting the Goals

After assessing the current practice, healthcare organization should set clear goals. To implement the proposed methodology, organization is recommended to set and pursue 'specific' 'measurable' 'attainable' 'relevant' and 'time bound' (SMART) goals (Robert, 2005). The healthcare organization is recommended to make the 'environment' element an organizational priority. Some of the goals to be set by the healthcare organization include: (a) identifying and developing SARE elements across the organization, (b) developing workflow activities in terms of SARE elements, (c) developing ABAC policies in terms of SARE elements, (d) developing policy to use same SARE elements across the development teams, (e) making the environment element an organizational priority, (f) providing training and support to the workflow and policy developer team.

Planning the Process

Once the goals are identified, the organizational executive team should develop a plan to implement the methodology and should identify the necessary steps to analyze the process of implementation.

Forming an Expert Team to Identify SARE Elements Which Can Be Used Across the Workflow Development Team and Access Control Developing Team

Healthcare organization should identify an expert team to analyze current working process and identify the required SARE attributes so that the same SARE attributes can be used across the teams that develop workflows and access control policies. The purpose of this team is to define the SARE elements to be used commonly by both workflow and the ABAC policies. This team is recommended to have regular meetings to review and add/modify/delete the existing SARE attributes.

Creating a Policy Statement for SARE Elements Usage Across the Organization

To follow uniform standards of data usage across various electronic platforms, healthcare organization should make a policy statement about SARE elements across the organizational development teams. The organization should also make the policy statement available to the development teams and should work on making the teams to understand the statement.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Training on Developing Workflow Activities in Terms of SARE Elements

Proper training to the workflow developers on how to develop workflow activities in terms of SARE elements should be given. It is an important task to develop workflow activities in terms of SARE elements as these are the elements which would help in integrating the workflow activities with the ABAC policies.

Plan to Implement ABAC through WSO2 Identity Server

As WSO2 identity server is an open source application and accommodates healthcare requirements, WSO2 identity server has been used to implement the approach in this research. As the WSO2 identity server is an open source application and with proper coding knowledge, it can be easily modified based on the organization's requirement. It is recommended by the author to the organization to plan to implement ABAC policies through WSO2 identity server.

Employing an ABAC Policy and WSO2 Identity Server Expert

To implement and develop ABAC policies through WSO2, the developer team should have sufficient knowledge about the concept, which requires having an ABAC policy and WSO2 Identity server expert on team. ABAC policies should be developed from the SARE elements recognized by the expert team. The policy expert can provide required support and guidance to the policy developing team.

Training on ABAC and WSO2 Identity Server

In order to implement ABAC through WSO2 Identity server, the team should have proper training about ABAC concepts, how to implement WSO2, how WSO2 works, how to write ABAC policies in WSO2, how to validate requests through WSO2, and also how to edit the WSO2 identity server.

Summary

This research addresses crucial problem for future healthcare organizations which accommodate environment into workflow activities and access control policies; we have addressed a crucial objective: integrating the workflows and access control policies; and our integrated methodology can identify workflow activities that are not being protected by access control policies. They can further be improved by modifying the workflow activities and access control policies through integrating workflow activities and attribute based access control policies using SARE (Subject, Action, Resource, and environment) elements.

Our main contributions include: (i) proposing 'environment' as a crucial element in a workflow activity along with Subject, Action, and Resource, (ii) a methodology to integrate workflow activities and access control policies, using this methodology to address below questions: (a) Whether there are any workflow activities that are not covered by the access control policies, (b) Whether there are any unused access control policies, (c) How many policies are covering each activity, and (d) Whether the workflow activities and the access control policies need to be modified or refined, (e) Demonstrating the methodology with WSO2 Identity Server; (iv) guidelines for healthcare organizations to implement the approach.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

As a part of our future work we have plans to work on: (i) extend the case study to perform in-depth testing and analysis with multiple healthcare scenarios, (ii) modifications to WSO2 identity server are needed to accommodate extended policy sets, (iii) modifications to WSO2 are needed to view the policies that are effecting a workflow activity, (iv) identify any policy related conflict issues, (v) perform in-depth analysis of the integrated methodology.

Chapter 70
Big Data and IoT–Allied Challenges Associated With Healthcare Applications in Smart and Automated Systems

Mamata Rath
C.V. Raman College of Engineering, India

ABSTRACT

Most of the current smart applications are developed with basis on intelligent computing, most of which are implemented using big data analytics and much other advanced technology. With emerging technology, industrial and instructive improvements are causing greater changes in the lifestyle of people in smart cities and there is more chance of various health problems in urban areas. The way of life in metro urban areas with an expansive volume of people is similarly influenced by different applications and administration frameworks. In this way, the majority of the urban communities are transforming into smart urban areas by receiving mechanized frameworks in every conceivable segment. Therefore, there is more health-related issues and health hazard issues can be identified in urban areas. This article carries out a comprehensive survey of health care issues and improved solutions in automated systems using Big Data Analytics in smart cities integrated with IoT.

1. INTRODUCTION

Implementation of smart concepts like of smart homes, smart cities, and smart everything emerged the Internet of Things (IoT) as an area of inconceivable impact, prospective, and growth. The wide-scale dispersion of the Internet has been the main thrust for this developing pattern, to be specific the utilization of such worldwide communication foundation for empowering machines and brilliant articles to impart, coordinate, and take choices on genuine word circumstances. Nowadays, the evolution of the world of the Internet of Thing is promising the explosion of a number of devices connected to the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Internet. According to Cisco analysts (Scarfo et al., 2018) there were more than 25 billion devices in 2015 connected and with a projection of more than 50 billion devices connected by 2020. Also, the new business paradigms that the Internet of Things technologies enable are producing a super-fast increase of machine-to-machine communications. This is a real market breakthrough moment that opens up a lot opportunities for enterprises and, generally speaking, for the whole society. Inherently, it increases dramatically the security problems, which could frustrate a sizeable part of Internet of Things' potential benefits that McKinsey valuates are very high. Indeed, a recent survey by HP reports that the 70% of devices contain vulnerabilities. The aim of this section is to provide an overview of current trends about cyber security concerns and a glimpse of what the future of the Internet of Things will bring.

Big data is used in several research areas related to healthcare, area-based services, satellite data usage, online advertising, and retail marketing. In the coming years, the Internet of Things (IoT) will increase the measure of data on the planet, and an exponential rise in big data will be seen. There have been a few review papers on big data in general and in diverse specialized fields, e.g., science, healthcare, geography, and the Internet. Unlike previous reviews in the literature, this paper takes a gander at recent advances in big data from a different view and with different arrangements, i.e., data types, storage models, investigation models, protection, data security, and applications.

2. BIG DATA AND IOT INCORPORATED APPLICATIONS

Internet of Things (IoT) is a transformational technology for electronic security frameworks. In numerous regards, business and private security items were forerunners to IoT and keep on sharing numerous critical qualities of the class. All things considered, the fast drop in cost for IoT gadgets and the billions of new IoT gadgets that are relied upon to be introduced in the following 5– 10 years make it a power to be battled with as far as how we consider electronic security frameworks and the market all in all. IoT additionally enhances the industry tasks in light of the fact that the most every now and again referred to shopper profit of IoT in the house is for security applications. By and large, the ascent of IoT increment value for security purchasers on the grounds that the financial aspects of the IoT industry will apply descending cost weight (Qiu et al., 2015) on security segments, even as they turn out to be more competent and give more highlights.

Regardless of how hard directions and the intricacy of human science makes improving in medication, the pace of advancement in social insurance is incredibly quick. Declarations and news astonish us consistently, regardless of whether we grew up perusing and watching sci-fi. Organizations have effectively printed out liver and kidney tissues; tweaked prosthetics and even medications endorsed by the FDA. IBM Watson's computerized reasoning gathers gigantic measures of data and plans the best treatment alternative for patients by checking all important medicinal examinations, and profound learning calculations will do much more. Advanced tattoos can gauge the significant health care parameters and essential signs to tell us when there's brief comment care of through our cell phones. Increased reality gadgets, for example, Hololens from Microsoft can extend advanced scenes on what we see and get ready specialists for troublesome strategies. Medicinal services development simply doesn't quit shocking people. In 2013, there were bits of gossip about new businesses reforming adherence control by embeddings microchips into sedate containers to give doctors a chance to check whether and when patients take them. We have been sitting tight for gadgets that permit holographic information input yet just oversimplified, toy-like contraptions have turned out to be accessible. Without extensive organiza-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tions putting resources into them, they will have far to go before standard selection. An extraordinary case is L'Oréal, the beauty care products organization putting into a wearable sensor that fills the wearer in regarding whether their introduction to the Sun achieves risky levels.

As of late, the Smart City idea has turned out to be prevalent for its guarantee to enhance the personal satisfaction of urban residents. The idea includes different controls, for example, Smart social insurance, Smart transportation, and Smart people group. Most administrations in Smart Cities, particularly in the Smart medicinal services space, require the constant sharing, preparing and dissecting of Big Healthcare Data for astute basic leadership. In this manner, a solid remote and versatile correspondence foundation is important to associate and access Smart social insurance administrations, individuals and sensors consistently anyplace whenever. In this situation, versatile distributed computing (MCC) can assume a crucial part by offloading Big Healthcare Data related errands, for example, sharing, handling and examination, from portable applications to cloud assets, guaranteeing nature of administration (QoS) requests of end-clients. Such asset movement, which is likewise named Virtual Machine (VM) relocation, is exceptionally compelling in the Smart social insurance situation in Smart Cities.

The immense development of wireless communication has acquired an improved wireless communication network, for the present worldwide communication showcase. These sorts of network are equipped for working with no settled establishment not at all like cell framework. As a result of their self-sufficient, conveyed and multi bounce handing-off potential, mobile ad-hoc networks otherwise known as MANET (Rath et al., 2017) and other wireless networks, are on enormous interest for efficient recuperation, vehicle following and frontline administration. The network topology changes powerfully because of unusual hub developments. This makes a genuine level of challenges to keep up network availability with neighbouring substances. By the day's end, there is no assurance of solid information conveyance with satisfactory Quality of Services (Rath et al., 2018). Steering conventions assume an essential part in setting up end to end way, as hubs are not generally straightforwardly reachable to each other. The power-hungry elements over such data transfer capacity restricted network request hearty and productive directing methodologies for network life span. In this way, directing instrument should be outlined sensibly to streamline network operation. Routinely, there are two primary sorts of directing systems which are table driven and on request premise. Table based methodologies unnecessarily surges the network even without the nearness of real activity and in this way creates tremendous overhead. The wireless communication network having deficient data transmission can't generally manage the cost of the advantage of such extra payload. Despite what might be expected, any on request convention, for example, wireless ongoing begins involving the network resources (Rath et al., 2017) at whatever point there is a need from the clients to pass on any data to their associates. Wireless constant convention keeps quiet until the point when such interest originates from any network substance. Once the presence of previously mentioned undertaking is detected, wireless constant begins route disclosure methodology by communicating a route request parcel. This route request message goes through the network and reaches to real goal and structures a turnaround route table. The beneficiary at that point reacts back by producing a route reply parcel which is conveyed by the turn around route made before. This procedure makes the forward route for information parcels. Here, the route revelation plot prompts delay and furthermore some moderate hubs get over-burden because of doing the information dealing with much of the time. Along these lines, conventional directing strategies can't be used for versatile specially appointed networks straight away on account of their characteristic impediments. In this paper, we focused on tweaking the essential wireless steering convention to provide food the forceful QoS (Quality of Service) (Rath et al., 2017) request of ongoing network benefits in wireless communication. Constant information transmission

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in remote correspondence arrange is a testing issue because of the self-coordinated nature of cell phones which are associated with each other by remote connections. Hubs habitually changes their position and area by shaping a system with no base or any foundation. Cautious contemplations must be made amid planning the conventions for ongoing information transmission which are profoundly touchy. Regular difficulties looked by continuous information amid transmission are vitality use, versatility of the system, improved utilization of data transfer capacity, asset reservation, lessening possibility of connection disappointment, security, deal with QoS, powerfully changing topology and so on.

3. FOCUS ON QUALITY OF SERVICE IN HEALTH CARE SYSTEMS

These days, electronic Health mind services have been accepting increasingly consideration, because of the generously expanding number of superior processing gadgets interconnected with restorative sensors indicative frameworks through heterogeneous network advances. Portable Health mind is a sub-section of the eHealth field, expecting to utilize cell phones, wearable or implicit sensors with Body Area Networks and the vastest size of wireless correspondence advances to upgrade conventional restorative services. Propelled portable advancements assume an inexorably vital part in health care frameworks particularly in situations of tele-conference telediagnosis and versatile patient checking (Li et al., 2007). Normally, portable health care services require strict, therapeutic level QoS and QoE arrangement. The constant utilize instances of portable health care services, for example, remote versatile patient checking, telecare and remotely guided surgical mediation require significantly higher certifications (e.g., little deferral and jitter, quick reaction time, and low bundle misfortune). Numerous portable health care situations depend on wearable body key (e.g., ECG, heart rate screen, and ultrasound) or inherent sensors of advanced mobile phones (e.g., high-determination camera and whirligig). The very shifting qualities of various versatile health care applications in methods for the required network assets, QoS/QoE prerequisites conjure elaboration of cutting edge network administration structures. These actualities persuaded us to outline and actualize a network-helped wireless access network determination system for mHealth (mobile health care) services, which can choose the fitting accessible access network utilizing a multi-criteria choice motor. There is some exploration commitment in which the portable health care framework depends on the Distributed Decision Engine (DDE) and the Network Information Service (NIS) giving both static and dynamic parameters of the accessible human services correspondence networks. There are some methodologies in which the arrangement is executed for Wi-Fi networks. E-health mind frameworks additionally gives a proficient domain to therapeutic quality information transmission in different portable health care situations.

3.1. Big Data in Wireless Body Sensor Networks

Wireless sensor innovations, particularly wireless body area network and sensor networks have gone past the fine-grained constant checking stages and wound up plainly one of the empowering advancements that give numerous effective applications in therapeutic and non-medicinal fields (Zuhra et al., 2017). The physiological observing frameworks are produced to screen the human medical problems and are dependable to course the detected information (physical or imperative information for example, glucose, Electromyography (EMG), Electrocardiogram (ECG), Electro-encephalograph (EEG), temperature, and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

so on.) from biosensors hubs to the medicinal or non-restorative server for encourage examination. Many steering and information spread conventions have been particularly intended for WBSNs. Directing conventions in WBSNs may contrast contingent upon the application and network design.

With the taking off enthusiasm for the Internet of Things (IoT), some human services suppliers are encouraging remote care conveyance using wearable gadgets. These gadgets are utilized for constant spilling of individual therapeutic information (e.g., vitals, solutions, sensitivities, and so on.) into social insurance information frameworks for the reasons for health care checking and proficient conclusion. In any case, a test from the viewpoint of the doctors is the failure to dependably figure out which information has a place with who progressively. This test exudes from the way that medicinal services offices have various clients who claim different gadgets (Lomotey et al., 2017); consequently, making an information source heterogeneity and complexities for the gushing procedure. As a feature of many research, this issue has been streamlined by proposing some wearable IoT information gushing design that offers traceability of information courses from the beginning source to the health care information framework.

3.2. Design of Various Smart IoT Framework in Health Care

The upsides of Internet of Things (IoT) innovation in healthcare division and medical applications have colossally influenced the testing health care issues. Identity Management is a vital strategy in the Internet of Things (IoT), which has been utilized as a part of in an extremely encouraging zone of medical science. In this Identity Management strategy, everything, any client or any gadget, is basically doled out a novel identity, and all data with respect to the gadget can be assembled through its identity.

Numerous Real time system observing are finished utilizing IoT idea with a specific end goal to remain cautioned any sort of action at the gadget condition so vital move can be made instantly subsequent to getting warning about the occasion (Sun et al., 2012). An issue of IoT in mining region is likewise vital issue which is focused here, significant operations of which are completed in mining regions, winding up as tailings. To keep mine following dam disappointments and significant mishaps because of it in which there are ghastly harm and demise happening at a moderately higher rate.

Internet of Things (IoT) offers a consistent stage to interface people and articles to each other for enhancing and making our lives less demanding. This vision conveys us from process based concentrated plans to a more disseminated condition offering an immense measure of uses, for example, keen wearable, shrewd home, splendid movability, and wise urban areas (Farahani et al., 2018). A few articles examine pertinence of IoT in human services and medication by showing a widely inclusive engineering of IoT eHealth organic group. Human services are ending up progressively difficult to oversee because of lacking and less powerful social insurance services to meet the expanding requests of rising developing populace with endless infections. In a few presentations the examiners suggest that e-social insurance framework requires a change from the center driven treatment to persistent driven medicinal services where every operator, for example, facility, patient, and services are consistently associated with each other. This patient-driven IoT eHealth organic group needs a multi-layer engineering: (1) gadget, (2) haze processing and (3) cloud to engage treatment of complex data to the extent its assortment, speed, and lethargy. This fog driven IoT design is trailed by different case cases of services and applications that are actualized on those layers. Those representations keep running from versatile health care, helped living, e-medication, inserts, early forewarning frameworks, to populace checking in shrewd urban areas. The difficulties of IoT eHealth are data organization, versatility, directions, interoperability, gadget network human interfaces, security, and protection.

3.3. Confidentiality and Security in IoT Based Health Care Systems

Today, telemedicine has a great reputation because of its capacity to provide quality healthcare services to remote locations. To achieve its purposes, telemedicine utilizes a number of wireless technologies as well as the Internet of Things (IoT) (Hossain et al., 2017). The IoT is redefining the capacity of telemedicine in terms of improved and seamless healthcare services. In this regard, the set of features of telemedicine by proposing a model for an IoT-based health prescription assistant (HPA) have been discussed in, which helps each patient to follow the doctor's recommendations properly. This paper also designs a security system that ensures user authentication and protected access to resources and services. The security system authenticates a user based on the OpenID standard. An access control mechanism is implemented to prevent unauthorized access to medical devices. Once the authentication is successful, the user is issued an authorization ticket, which this paper calls a security access token (SAT). The SAT contains a set of privileges that grants the user access to medical IoT devices and their services and/or resources. The SAT is cryptographically protected to guard against forgery. A medical IoT device verifies the SAT prior to serving a request, and thus, ensures protected access. A prototype of the proposed system has been implemented to experimentally analyze and compare the resource efficiency of different SAT verification approaches in terms of a number of performance metrics, including computation and communication overhead.

4. HEALTH CARE IN IOT NETWORK AND SMART COMMUNITY

Wireless body sensor networks are remote systems that are intended to permit correspondence among sensor hubs that are joined to a human body to screen the body's key parameters and condition. The plan and advancement of such WBSN frameworks for health care checking have gotten a lot of consideration as of late (Harbouche, 2017), in inquire about examinations and in industry. This consideration is for the most part propelled by expensive medicinal services and by late advances in the improvement of smaller than normal health care observing gadgets and in addition developing advances, for example, the Internet of Things (IoT), which add to the primary difficulties of 5G. The presence of an unequivocal way to deal with address the required programming outline and check ought to be exceptionally valuable for the development and upkeep of such frameworks. This paper introduces a preventive human services framework that has an adaptable plan. The proposed framework depends on an engineering that has heterogeneous hubs and gives both day by day persistent checking and additionally particular controls. We characterized a model to depict the WBSN's worldwide conduct. A critical part of this work is that propose a model-driven building (MDE) way to deal with address the determination of every hub's conduct in the WBSN from the WBSN worldwide conduct. This approach enables engineers to acquire a framework plan from the worldwide detail of its necessity. To guarantee the conformance of this outline to its determination, the inferred practices ought to be approved and checked before their arrangement. Truth be told, formal strategies are effective apparatuses for programming specialists to check the consistent accuracy of simultaneous programming at various levels of its life cycle. Display checking is a standout amongst the most capable formal techniques for confirming the consistent accuracy of such simultaneous frameworks. In this work, we make utilization of a model checking approach that depends on a model change to approve the consequently determined conduct of a WBSN for health

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

care observing. This model-driven approach will check whether the determined framework carries on accurately as indicated by its worldwide detail, while the goal is to build the framework's execution and QoS. This approach enables the designer to reason about a model of the worldwide framework instead of about the framework itself.

4.1. Integration of Wireless Network and IoT

The steady progression and change of low-control remote correspondence advancements is engaging the ascent of various new applications (Patel et al., 2017) in the field of the Internet of Things (IoT). One of the essential areas of research inside the Smart City setting is keen prosperity, which attracts novel IoT exercises to improve both quality and access to social protection and astute organizations all around. In CUIDATS, an IoT mutt checking system for restorative administrations circumstances has been presented which facilitates RFID and WSN advancements in a single stage giving territory, status, and following of patients and assets. After its execution endorsement in a suitable testbed, CUIDATS has been passed on and surveyed with an abnormal state of accomplishment in a veritable recuperating focus.

The continuous development and improvement of low-power wireless communication technologies is enabling the emergence of many new applications in the field of the Internet of Things (IoT). One of the main areas of research within the Smart City context is smart health, which engages novel IoT initiatives to improve both quality and access to health care and smart services in general. In CUIDATS, (Adame et al., 2018) an IoT hybrid monitoring system for health care environments has been presented which integrates RFID and WSN technologies in a single platform providing location, status, and tracking of patients and assets. After its performance validation in a suitable testbed, CUIDATS has been deployed and evaluated with a high degree of success in a real hospital.

Ceaseless checking of unending patients enhances their personal satisfaction and decreases the financial expenses of the sterile framework. Be that as it may, with a specific end goal to guarantee a decent observing, high data transmission and low deferral are required (Patel et al., 2017). The 5G innovation offers higher transmission capacity, bring down deferrals and bundles misfortune than past advancements. This paper exhibits an engineering for savvy eHealth observing of unending patients. The engineering components incorporate wearable gadgets, to gather measures from the body, and a cell phone at the patient side so as to process the information got from the wearable devices (Lloret et al., 2017). Additionally. a database is required with a canny framework ready to send an alert when it distinguishes that it is going on something atypical. The astute framework utilizes machine taking in Big Data taken from various clinics and the information got from the patient to analyze and create alerts. Investigation tests have been done to reproduce the movement from numerous clients to the database keeping in mind the end goal to assess the appropriateness of 5G in engineering (Lloret et al., 2017). At the point when there are couple of clients (under 200 clients), we don't discover enormous contrasts of round excursion time in the vicinity of 4G and 5G, however when there are more clients, similar to 1000 clients, it increments significantly achieving 4 times more in 4G The Packet Loss is practically invalid in 4G until 300 clients, while in 5G it is conceivable to keep it invalid until 700 clients . The Outcomes call attention to that keeping in mind the end goal to have high number of patients ceaselessly checked, it is important to utilize the 5G organize in light of the fact that it offers low postponements and ensures the accessibility of data transmission for all clients.

4.2. Ethical Issues in Big Data Management in Healthcare

Prosperity of growth patients and survivors is a test around the world, thinking about the regularly incessant nature of the malady. Today, countless, items and administrations are accessible that mean to give systems to confront the test of prosperity in disease patients; by the by the proposed arrangements are frequently non-economical, exorbitant, inaccessible to those in require, and less generally welcomed by patients. These difficulties were considered in planning FORECAST (Kyriazakos et al., 2017), a cloud-based customized shrewd virtual training stage for enhancing the prosperity of malignancy patients. Customized training for disease patients concentrates on physical, mental, and enthusiastic concerns, which FORECAST can distinguish. Growth patients can benefit from training that tends to their passionate issues, encourages them concentrate on their objectives, and backings them in adapting to their illness related stressors. Customized training in FORECAST offers bolster, consolation, inspiration, certainty, and seek and is an important instrument after the prosperity of a patient (Kyriazakos et al., 2017).

The ability to incorporate and examine gigantic measures of data is critical to the achievement of associations, including those that include worldwide health care. As nations turn out to be exceedingly interconnected, expanding the hazard for pandemics and flare-ups, the interest for big data is probably going to increment. This requires a worldwide health care workforce that is prepared in the compelling utilization of big data. To evaluate usage of big data preparing in worldwide health care, we led a pilot review of individuals from the Consortium of Universities of Global Health. The greater part the respondents did not have a big data preparing program at their institution. Additionally, the majority concurred that big data preparing projects will enhance worldwide health care expectations, among other positive results. Given the watched hole and benefits, worldwide health care teachers may consider putting resources into big data preparing for understudies looking for a profession in worldwide health (Olayinka et al., 2017).

With the EU wide-ranging Data security instruction going into oblige in 2018, the stage is set for worldwide verbal come across on Big Data sharing in prosperity. Taking into consideration the way that prosperity information (and especially innate information) are seen as "touchy", is there a way to deal with structure the verbal encounter on the obstructions, and danger advantage extent that moves a long way from the conventional points of interest and burdens of potential insurance and isolation risks (Knoppers et al., 2017). Potential partition has been tended to in sanctioning and the altering of security rights against the potential advantages of information sharing in concentrated science is provoking a more proportionate approach. We suggest that a basic stimulus that will also move this practical talk from its customary structures is start the "right to science" as appreciated in general law. Of note, the Global Alliance for Genomics and Health has developed a Framework for Responsible Sharing of Genomics and Health-Related Data in perspective of that human right. So likewise, late standards from the Council for International Organizations of Medical Sciences and the Organization for Economic Co-operation and Development, and what's more from the American College of Medical Genetics and Genomics contain courses of action that propel information sharing showing that information concentrated science may a little bit at a time come to be set up on a more aggregate ethos.

In the period of "big data", late improvements in the territory of data and correspondence advances (ICT) are facilitating associations to enhance and develop. These innovative improvements and wide adjustment of ubiquitous figuring empower various opportunities for government and organizations to reexamine medicinal services prospects. Along these lines, big data and brilliant medicinal services frameworks are autonomously pulling in broad consideration from both scholarly community and in-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

dustry (Pramanik et al., 2017). The blend of both big data and brilliant frameworks can expedite the possibilities of the medicinal services industry. Notwithstanding, an intensive investigation of big data and shrewd frameworks together in the social insurance setting is as yet missing from the current literature. The key commitments of this article incorporate a sorted assessment of different big data and shrewd framework advances and a critical examination of the best in class propelled medicinal services frameworks. We depict the three-dimensional structure of a change in outlook. We additionally remove three wide specialized branches (3T) adding to the advancement of human services frameworks. All the more particularly, we propose a big data empowered savvy medicinal services framework structure (BSHSF) that offers hypothetical portrayals of an intra and bury authoritative plan of action in the social insurance setting. Pramanik et al. (2017) likewise specify a few illustrations announced in the literature, and afterward we add to pinpointing the potential opportunities and difficulties of applying BSHSF to human services business situations. We likewise make five proposals for viably applying `BSHSF to the social insurance industry. To the best of our insight, this is the first inside and out examination about cutting edge big data and shrewd social insurance frameworks in parallel. The administrative ramifications of this article is that associations can utilize the discoveries of our critical examination to fortify their vital plan of shrewd frameworks and big data in the human services setting, and thus better use them for feasible hierarchical creation.

A major information examination engaged change show in light of preparing based view is made, which reveals the causal associations among huge information investigation capacities, IT-enabled change sharpens, advantage estimations, and business values (Wang et al., 2017) . This model was then attempted in human administrations setting. By analyzing huge information use cases, we attempted to perceive how huge information examination capacities change legitimate practices, along these lines making potential advantages. Notwithstanding sensibly describing four major information examination capacities, the model offers a fundamental point of view of enormous information investigation. Three basic approach to-regard chains were recognized for social protection relationship by applying the model, which gives helpful encounters to boss.

4.3. Features of Smart and Connected Communities (SCC) in Health Care

Information experts are tested to plan health care data innovation (IT) answers for complex issues, for example, health care disparities, yet are accomplishing blended outcomes in exhibiting an immediate effect on health care results. This introduction of aggregate insight and the relating terms of shrewd health care, learning biological community, improved health care disparities informatics capacities, learning trade, big-data, and situational mindfulness are methods for showing the perplexing difficulties informatics experts look in attempting to model, measure, and deal with a canny and savvy frameworks reaction to health care disparities (Carney et al., 2017). A critical piece in our comprehension of aggregate insight for open and populace health care rests in our comprehension of open and populace health care as a living and developing system of people, associations, and assets. This exchange speaks to a stage in propelling the discussion of what a shrewd reaction to health care disparities should speak to and how informatics can drive the plan of wise frameworks to help with killing health care disparities and accomplishing health care equity.

Development of setting mindful advancements and IoT gadgets mirror that the quality of a human life has turned out to be a standout amongst the most basic angles in Smart Cities. With this objective health care monitoring of elderly and incapacitated individuals have a lot of consideration and center in

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the examination. The social insurance frameworks depend on the parts in charge of setting detecting, handling, stockpiling and derivation, and reaction. Keeping in mind the end goal to make the interoperability among the different human services frameworks, a regular standard is required so as to consistently get to the setting mindful social insurance data (Hussain et al., 2015) getting through a key foundation. An individual-driven detecting system for the human services of elderly and impaired individuals has been proposed, where such stage is planned to monitor strength of the elderly and debilitated individual and furnish them with an administration situated crisis reaction in the event of irregular health care condition. We concentrate on three viewpoints: (a) setting control from the cell phone in individuals driven condition; (b) crisis reaction utilizing setting base data; and (c) displaying portable setting sources as administrations. The most particular element of current work is that medicinal assets are productively used to give them ongoing restorative administrations if there should arise an occurrence of crisis at the same time expanding interpersonal organization of the elderly individuals. The framework usage demonstrates that the proposed individuals driven detecting framework is proficient and financially savvy in health care and crisis mind.

The immediate combination of sensors within the wrap to frame a brilliant dressing has been proposed as conceivable methods for handling a portion of the present difficulties in the treatment of incessant injuries. The improvement of an "associated health care" demonstrate (Finlay et al., 2016) through which the injury is remotely monitored within the community and surveyed by a clinician or independently by a proper brilliant application algorithm has many points of interest, however it is especially a "perfect." Although there are numerous indicative measures and detecting systems that can be interpreted from the lab seat to the center, the resulting adjustment for persistent/intermittent monitoring that would be required for outpatient monitoring faces various obstacles. The transition of the detecting innovation from the lab seat to the facility or to a patient's home requires the joining of the organic, compound, and materials components with present day correspondence. The coming of the advanced cell and tablet guarantees to upset human services offering customized pharmaceutical and more prominent patient mindfulness and administration of their condition. This part investigates the mechanical prerequisites important to process the flag from the sensor that is in contact with the injury, the mechanisms through which the flag can be transmitted and the more extensive ramifications of developing eHealth and mHealth models.

4.4. Big Data Analytic Method in Health Care Using IoT

The term biosensors includes gadgets that can possibly evaluate physiological, immunological and behavioral reactions of domesticated animals and various creature species. Novel biosensing approachs offer exceedingly particular monitoring gadgets for the particular estimation of individual and numerous parameters covering a creature's physiology and additionally monitoring of a creature's situation (Neethirajan et al., 2017). These gadgets are not just very particular and sensitive for the parameters being dissected, yet they are additionally solid and simple to utilize, and can quicken the monitoring procedure. Novel biosensors in domesticated animal administration give noteworthy benefits and applications in ailment location and confinement, health care monitoring and recognition of conceptive cycles, and in addition monitoring physiological prosperity of the creature by means of examination of the creature's condition. With the improvement of incorporated frameworks and the Internet of Things, the consistently monitoring gadgets are required to end up noticeably reasonable. The data created from coordinated domesticated animals monitoring is foreseen to help ranchers and the farming business to enhance creature productivity later on. The data is required to lessen the effect of the domesticated

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

animal industry on the earth, while in the meantime driving the new wave towards the changes of suitable cultivating procedures. This audit focuses on the developing mechanical headways in monitoring of animal health care for definite, exact data on productivity, and in addition physiology and prosperity. Biosensors will add to the fourth transformation in horticulture by fusing creative innovations into savvy analytic techniques that can mitigate the possibly disastrous impacts of irresistible flare-ups in cultivated creatures. There is and a comprehension of how we can uncover extra motivating force from the information delivered by human administrations and government. Far reaching measure of heterogeneous information is made by these workplaces. Nevertheless, without fitting information examination procedures these information advanced toward getting to be useless (Archenaa et al, 2015). Huge Data Analytics using Hadoop accept a convincing part in performing critical ceaseless examination on the tremendous volume of information and prepared to foresee the emergency circumstances before it happens. It portrays about the enormous information use cases in human administrations and government.
