economies have been increasingly investing abroad sparking the question of how FDI outflows or OFDI impacts the home country and why are companies in emerging economies engaging in more OFDI today? Outward FDI refers to companies investing abroad through various tools such as Green field investments, Brown field investments, and expansion of existing foreign facilities. Since the year 2000, there has been a surge in the OFDI from developing economies around the globe. The OFDI figures for all developing economies combined have increased exponentially. According to United Nations Conference on Trade and Development (UNCTAD, 2016; UNCTAD), FDI Outflows from developing economies increased from an estimated $88.63 billion to an estimated $377.94 billion from the year 2000 to 2015 respectively. The proportion of FDI outflows from developing economies to all FDI outflows from the world has also increased immensely, changing from 7.62% in 2000 to 25.64% in 2015. Whereas, the OFDI stock from developing economies increased from $734.81 billion (9.88% of global OFDI stock) in 2000 to $5, 296.35 billion (21.15% of global OFDI stock) in 2015.

Turkey holds a geographical advantage due to its location forming a connection between Asia and Europe. Turkey is also one of the fastest growing economies around the globe, growing almost three fold since the year 2000; the GDP of Turkey grew from $266 billion in 2000 to $798 billion in 2014. The increasing foreign direct investment has helped the Turkish economy grow over time, while there has been growth in FDI inflows there has also been an increase in FDI outflows. Turkish organizations are looking to take their business abroad and invest in different regions. But the question arises as to why Turkish companies are going abroad? Why invest in the international market rather than the domestic market? This study is undertaken in order to find the OFDI determinants among Turkish organizations.

The rest of the paper is divided into the following sections: Section 2, Turkey's Current Outward Foreign Direct Investment Overview; Section 3, Literature Review; Section 4, Methodology; Section 5, Results; Section 6, Conclusion.

## TURKEY'S CURRENT OUTWARD FOREIGN DIRECT INVESTMENT OVERVIEW

Turkey's OFDI flows have been increasing over the years improving the OFDI stock to over $40 billion. Turkish firms are looking to go abroad and have recently had major mergers and acquisitions. OFDI not only helps these Turkish firms reach new markets, resources, and technology but also provides employment to thousands of people in host countries. Several surveys completed over the years show the number of foreign workers which are employed by Turkish MNEs; in 2007 the top 12 Turkish MNEs employed over 72, 000 workers abroad (KHU-DEIK-VCC, 2009), in 2009 the top 19 Turkish MNEs employed over 90, 000 workers abroad (KHU-DEIK-KPMG-T-VCC, 2012), and in 2012 the top 29 Turkish MNEs employed over 115, 000 workers aboard (KHU-DEIK-VCC, 2014). Turkish MNEs continue to invest abroad and increase their foreign affiliates and assets. Turkish OFDI Stock had crossed the $40 billion mark in the year 2014 over double its size in 2008 (estimated $17.85 billion). UNCTAD (2015) data on Turkish OFDI shows that Turkish investors have substantially increased their investments abroad after the 2008 global financial crisis.

## Geographical Breakdown

A breakdown of the geographical OFDI is important because it helps us analyze the regions in which Turkey's investors hold interest. Europe has always been a close trading partner of Turkey especially after the Customs Union agreement between European Union and Turkey in 1996. Customs Union strengthened the trade relationship between EU and Turkey paving the way for higher volumes of trade and FDI. This is evident from the amount of money Turkish investors have been investing in Europe. A majority of the Turkish OFDI have been directed towards Europe. Since 2002, 63% of all OFDI flows have been to Europe whereas only 25% have been to Asia, 10% to America, and a mere 2% to Africa.

Surveys of top Turkish MNEs completed by KHU-DEIK-VCC (2009, 2011, and 2014) also show that the majority of their affiliates are located in Europe. Furthermore, these surveys also found drivers for foreign investments by Turkish MNEs. A survey of top 19 Turkish MNEs (KHU-DEIK-KPMG-T-VCC, 2012) revealed that Turkish MNEs target Europe to acquire technology and skills, Africa and Asia for low cost labor, and Central Asian Turkic Countries for natural resources. Through a survey of top 29 Turkish MNEs (KHU-DEIK-VCC, 2014), respondents were asked to identify drivers of investments abroad; these drivers

include new markets and market diversification (75%), sustainable growth (60%), managing risk (50%), and access to natural resources and low costs (almost 40%). The same study also identified that the Turkish Government has been assisting investors through the opening of new embassies in Africa. Furthermore, the Government of Turkey has adopted an expansion policy by opening trade and investment offices in new regions, increasing flight destinations of Turkish Airlines, and increasing development assistance by Turkish Co-operation and Co-ordination Agency (TIKA). OFDI flows trends towards Europe determine that Turkish MNEs are looking to move towards developed markets which can provide them with high technology and highly skilled labor. Africa is still an untapped market for Turkish investors however, the government of Turkey is trying to push Turkish investors to invest in the African region.

## Industry Breakdown

Through the industrial breakdown, a recent surge in OFDI in the Mining and Quarrying sector can be observed. This could be associated with recent large pipeline projects which Turkey has undertaken in neighboring countries. OFDI in Manufacturing has always been attractive since Turkish firms are going abroad in search for better technology which they have done by mostly acquiring firms in other nations. The financial sector of Turkey has also been very successful, various Turkish banks have opened offices in neighboring countries expanding their markets.

## LITERATURE REVIEW

Research on outward foreign direct investment from emerging economies picked up pace after the turn of the 21st Century. Various studies have been conducted on OFDI from emerging economies ranging from the determinants of OFDI to the benefits of OFDI for home and host countries. Evidence from various emerging economies suggest that motives for OFDI from these economies have changed over time and vary among regions and industries. Dunning (1993) explained that firms invest abroad for three reasons: foreign-market seeking FDI, efficiency-seeking FDI, and resource-seeking FDI. Emerging economies also look for asset acquisition when investing abroad (Hill & Jongwanich, 2014), especially acquiring of assets in western economies. It is possible that these emerging economies are trying to acquire assets in countries with sounder institutional environment. However, in general emerging economies look to invest in countries which have relatively close or weaker institutions, moreover, institutional distance is diminished given that the host country has natural resources which are required by the home country (Athukorala & Hill, 2010; Aleksynska & Havrylchyk, 2012). Investment in natural resource rich areas can also explained by the fact that emerging East Asian countries are generally investing abroad through Sovereign Wealth Funds (SWFs) hence their aim for acquiring natural resources (Hill & Jongwanich, 2014). According to Andreff (2015), Russian Multinational Corporations (MNCs) are targeting industries in U.S., Canada, Italy, Switzerland, and South Africa for natural resources.

Emerging economies are also investing abroad in order to acquire technological assets which are not available in their domestic market (Dunning et al., 2008). Further motivations for OFDI include large surpluses, to gain competitive advantage (strengthen R&D and increase knowledge of regionally close markets), to seek markets (in case there are high trade barriers), and due to unfavorable domestic investment climate (Hill & Jongwanich, 2014). Stoian and Mohr (2016) find various motives for firms investing abroad due to avoidance of home country regulative voids. They find that OFDI from firms in emerging economies is a result of high protectionism, high corruption, high bureaucracy, and missing or inadequacy of rules and regulations which aren't enforced. They suggest that firms in emerging economies engage in escapist OFDI in order to avoid competitive disadvantages which may result from regulative voids. However, escapist OFDI does not have positive effects on the home country since firms are leaving due to shortcomings in the domestic market. Hill (2012) In Stoian and Mohr (2016) explains that bureaucracy, corruption, and protectionism all lead to negative consequences for the home country which hamper the economic growth. Similarly, Luo and Tung (2007) state that MNCs in emerging economies expand internationally in order to escape institutional and market constraints within domestic markets because these constraints lead to competitive disadvantages for emerging economy MNCs. A large number of studies on emerging economies and their determinants for OFDI have been done on China and India hence the OFDI patterns from these two economies are studied in-depth in this literature review. Furthermore, past studies on OFDI behavior from Turkey are examined.

In the case of India, one of the fastest growing economies in the world today, OFDI was motivated through learning and knowledge acquired from multinational corporations (Matthews, 2002). According Pradhan (2008), Indian multinational corporations (MNCs) go abroad in order to avoid a stagnant domestic market as well as policies which restrict firm growth such as the Foreign Exchange Regulations Act, licensing, regulations, and the Monopoly & Trade Restrictive Practices Act. Likewise, Andreff (2015) states that Indian MNCs go abroad in order to reduce dependency on the local market and business cycle. Indian MNCs have also been targeting Western Europe and U.S. in an attempt to improve their research and development, strategic assets, and skill structure (Andreff, 2015).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Other motivations of Indian MNCs include attaining global size and status as well as combining international economy with the low cost labor market at home (Andreff & Balcet, 2013). Furthermore, Nayyar (2008) conducted a survey of Indian MNCs and their motives for investing abroad; the survey found that market access (51% respondents) was the top motive for Indian MNCs going abroad, other motives were efficiency seeking (22%), resource seeking (13%), and created asset seeking (14%). In the case of India, liberalization of investments policies according to the changing preferences of the Indian companies have helped these companies increase their investments abroad (Anupam, Rani, & Kumar, 2014). Government policies are very important when it comes to FDI and OFDI, the government of India has been able to facilitate investors looking to go abroad. Pradhan (2011) found several drivers for Indian multinationals investing abroad, these include attraction towards countries with larger population and GDP per capita and countries which hold bilateral investment agreements (BIT) with India. These factors show that Indian MNCs like to target bigger markets and are willing to invest in countries where they have favorable investment policies in place through a BIT.

China is the largest emerging economy in the world. The rapid economic growth of China has also led to a rapid growth in OFDI from China. According to Ye Gang (1992), the first foreign investments of China were made in 1979 when Chinese companies began creating subsidiaries in an attempt to open up to new export markets. The early growth in OFDI from China has been due to FDI spillovers which resulted in technology transfers from MNCs towards local firms (Andreff, 2015). The rapid growth of OFDI after 2001 is due to the "go global" strategy adopted in 2001 as well as China's accession into the World Trade Organizations (Chen, n.d.). Chinese OFDI is directed towards natural resources in countries with poor institutions which explains higher investment by the Chinese in African nations (Kolstad & Wiig, 2012).

Additionally, Zhang and Daly (2011) conducted a panel data analysis of China's top importing countries from 2003 to 2009 in order to find the determinants for OFDI from China. They found that China's OFDI is attracted towards regions in which China has large exports, high GDP growth, high GDP per capita, large natural resources, and open economic nations. Similarly, Chang (2014) studied the characteristics and determinants of China's OFDI using the spatial gravity model for the same time period of 2003-2009. Chang found that OFDI characteristics for China include a focus on extraction of natural resources from developing and developed nations such as Kazakhstan, Australia, and African nations and investment in technology-intensive firms in developed nations. Chang identified determinants for China's OFDI as host country's GDP, vertical OFDI opportunities, a common language, fuel exports of host nations, and an export platform in the case of petroleum exporting nations. These results reveal the preferences of the Chinese OFDI towards natural resources and specifically towards petroleum rich nations.

It is important to note that OFDI from China is dominated by state owned firms which are controlled by the central government (Chen, n.d.) therefore the determinants of these firms would be aligned with the government policies unlike other emerging nations where MNCs are the major players in OFDI. This is evident due to the Chinese government providing subsidies to state owned firms which have invested in energy such as zero percent loan to China National Oil Corporation when bidding for a U.S. oil company (Xiao & Sun, 2005) and preferential interest rates to Chinalco bidding on an Australian mining company (Yao, Sutherland, & Chen, 2010). This also provides evidence that Chinese OFDI is directed towards strategic assets which align with China's strategic needs (Deng, 2007). Some motivations for OFDI from China's state owned firms include bypassing host country trade barriers, securing natural resources, gaining managerial expertise, acquiring technology, and gaining strategic assets (Wei & Alon, 2010). Whereas, provincial firms (which are mostly non-state owned) in addition to the determinants

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

mentioned earlier, look for gaining knowhow, management skills, expansion of marketing networks, and increased competition at home leads to these firms seeking OFDI opportunities (Chen, n.d.).

Turkey is also a fast growing emerging economy which along with its economic growth has also increased in its OFDI although not as fast as other emerging economies such as China, Brazil, India, and Russia. To our knowledge there are only a handful of studies which have been conducted on the OFDI behavior of Turkey. These studies include a study of OFDI drivers for Turkish MNEs (Erdilek, 2008), determinants of OFDI from Turkey (Kayam & Hisarcikcilar, 2009; Onder & Karal, 2013), the impact of unfavorable home environment on Turkish Manufacturing firms' FDI (Kaya, 2009), and determinants of OFDI from Turkey towards Europe (Uray, Vardar, & Nacar, 2012; Gubbi & Sular, 2015). Erdilek (2008) conducted a case based study of MNEs in Turkey consisting of six SMEs and two large corporations. Several motives were found for OFDI from Turkey including ease of regulations, home environment (push factors such as high competition and exit costs), access to new markets, and host country environment (pull factors such as international brands, and access to natural resources). Similarly, considering Turkish manufacturing firms Kaya (2009) found utility costs, political instability, instability of exchange rate, and high inflation to be push factors for OFDI.

Kayam and Hisarcikcilar (2009) conducted an empirical study in order to find the determinants for Turkish OFDI using data of 11 countries from 1999 to 2005. They found the major determinants for Turkey's OFDI to be market seeking, substituting foreign markets for domestic markets, higher corruption index of host country, an increase in Turkish GDP decreases OFDI, and Turkish firms tend to produce low quality alternatives for higher quality products in host countries. Increase of Turkey's GDP has a negative impact on OFDI because Turkish firms are substituting domestic markets for foreign ones hence an increase in GDP per capita means that the buying power of domestic consumers are increasing leading to higher purchasing power motivating firms to focus on domestic markets. Uray, Vardar, and Nacar (2012) find that Turkish firms have invested in developed nations in order to attain technology and innovation. Furthermore, Turkish firms investing in Eastern European countries aim to change the country of origin in order to be more appealing toward the European customers (Uray, Vardar, & Nacar, 2012; Gubbi & Sular, 2015). Another important factor for investing in European countries is favorable tax policies for foreign investors (Gubbi & Sular, 2015). Literature shows that Turkish firms are investing abroad in order to expand their market, gain access to technology, present themselves are European firms (in the case of investment in Europe), gain product innovation, and avoid instability in the home environment.

## METHODOLOGY

The researchers applied a preliminary data analysis approach in order to narrow down the determinants for investing in a specific region and the determinants for leaving the domestic market. The Global Competitiveness Report was used to analyze a list of determinants which were deemed fit in the case of OFDI. The Global Competitiveness Report is published yearly by the World Economic Forum, the purpose of the report is to assess the competitiveness of economies around the globe. Currently the Global Competitiveness Index (GCI) comprises of 12 pillars divided into three sub-indices including basic requirements subindex (institutions, infrastructure, macroeconomic environment, health and primary education), efficiency enhancers subindex (higher education and training, goods market efficiency,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

financial market development, technological readiness, market size), innovation and sophistication factors subindex (business sophistication, innovation).

Global Competitiveness Report for 2015-2016 consisted of 140 countries within which 14, 000 business executives were surveyed about the dimensions mentioned above. The executives chosen for this survey are investment decision makers hence their ability to provide accurate information on the business environment of an economy. Furthermore, the data for analyzing a business environment is difficult to gather hence surveying business executives seems to be a good alternative. The researchers chose a few questions from within this survey to analyze the top 10 countries in which Turkish investors have invested over the past 10 years. A few questions from the survey were also chosen to analyze the business environment of Turkey. These factors would help assess the host and home country factors which motivate Turkish investment abroad. A period of 10 year is analyzed through GCI from 2006-2007 to 2015-2016. A preliminary analysis is conducted on these questions by analyzing the correlation between indicators and Turkish OFDI patterns over the years. This analysis facilitates understanding of whether if the GCI is a good fit for analyzing business environment factors which impact the decision making for Turkish investors.

## RESULTS

The analysis only showed meaningful results for several home and host country factors for a few countries (Appendix A and B). Through preliminary analysis it was found that only Germany, Netherlands, Russia, and UK showed significant results in some of their business environment factors. Similarly, correlation analysis for Turkey also showed that some home factors were significantly correlated to its OFDI patterns. Turkey's OFDI patterns show correlation with domestic competition and infrastructure. The Pearson correlation coefficient for OFDI and domestic competition is 0.882, which is statistically significant ($p < 0.01$ for a 2-tailed test). The Pearson correlation coefficient for OFDI and infrastructure is 0.690, which is also statistically significant ($p < 0.05$ for a 2-tailed test). The rest of the factors did not show any significant correlation. The relationships between domestic competition and OFDI from Turkey is interesting because the domestic competition has been increasing over the years which means that firms may be investing abroad in order to counter the competition at home. In the case of host countries, Turkish investors have invested the most in Netherlands with an OFDI stock of over $9 billion. Turkey's OFDI patterns towards Netherlands showed correlation with three market factors. Following are the results of Turkey's FDI in Netherlands. The Pearson correlation coefficient for Turkey's FDI and Labor Market Efficiency is 0.784, which is significant ($p < 0.01$ for a 2-tailed test). The Pearson correlation coefficient for Turkey's FDI and Infrastructure is 0.668, which is significant ($p < 0.05$ for a 2-tailed test). The Pearson correlation coefficient for Turkey FDI and Innovation is 0.738, which is significant ($p < 0.05$ for a 2-tailed test).

Germany receives the fourth highest FDI from Turkey having an OFDI stock of almost $2 billion since 2002. In the case of Germany we found only one factor to have significant results. The Pearson correlation coefficient for Turkey's FDI and Domestic Market Size is 0.856, which is significant ($p < 0.01$ for a 2-tailed test). The Pearson r shows a high correlation between Turkey's FDI to Germany and the German Market Size which could possibly mean that Turkish firms are investing there to capture a larger market. In the case of United Kingdom, which receives the fifth highest FDI from Turkey with an OFDI stock of over $1.5 billion since 2002, there are two factors which have been found significant when

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

correlated with FDI from Turkey. The Pearson correlation coefficient for Turkey's FDI and Technological Readiness is 0.741, which is significant ($p < 0.01$ for a 2-tailed test). The Pearson correlation coefficient for Turkey's FDI and Exports to UK is 0.778, which is significant ($p < 0.01$ for a 2-tailed test). This shows the Turkish firms willingness to go to the UK market for technology. Finally, two factors were found to be significantly correlated with the Russian market. Russia receives the 8th highest FDI from Turkey with an OFDI stock of about $835 million since 2002. The Pearson correlation coefficient for Turkey's FDI and Technological Readiness is 0.643, which is significant ($p < 0.05$ for a 2-tailed test). The Pearson correlation coefficient for Turkey's FDI and Innovation is -0.716, which is significant ($p < 0.05$ for a 2-tailed test). This is interesting because there is a negative correlation between Turkey's FDI to Russia and their innovation level. We would have to look into this further to understand this relationship. The rest of the top 10 FDI locations for Turkish investors did not show any significant relations in terms of their business environment and Turkey's FDI into that region. Although the results of the current study only showed significant relations with only a few dimensions and Turkey's OFDI, we believe that the Global Competitive Index can be helpful in predicting the OFDI host and home country indicators.

## CONCLUSION

Outward Foreign Direct Investment from emerging economies has been increasing since the 1990s and began to multiply greatly after the turn of the 21st Century. Studies on this topic have also been limited greatly due to a lack of data from within these emerging economies. We have found this to be true especially in the case of Turkey where data from primary sources was difficult to attain. Therefore, we tried a different approach by using several dimensions within the Global Competitive Index in order to determine the host and home country factors for OFDI. Although our results were not significant for many of the dimensions, we found there to be some significantly correlated factors for Turkish FDI towards various countries. The host country factors which were found to be significantly correlated with Turkish FDI were innovation (Netherlands and Russia), technological readiness (Russia and UK), labor market efficiency (Netherlands), infrastructure (Netherlands), domestic market size (Germany), and exports (UK). The home factors found to be significantly correlated with Turkish FDI were infrastructure and domestic competition. Data was a major limitation for this research since it was difficult to attain primary data which would have provided us with better results. However, for future research the researchers propose working with the Global Competitiveness Index to test the investment factors for other emerging economies such as China, India, Russia, Brazil, Indonesia, etc. because the researchers believe that the GCI can help provide much needed data for this topic which is difficult to attain otherwise.

## APPENDIX

Pearson's Correlation analysis was conducted between Turkey's OFDI and Business Environmental Factors of the top 10 countries towards which Turkish investors invest. The OFDI to each country was correlated with various business environmental factors to find the significance of these factors with the OFDI from Turkey. The results are given in Table 4.

*Table 4. Correlation between Turkey's OFDI and business environmental factors in partner countries*

## ABSTRACT

*Recent two decades witnessed unprecedented changes in the economies of Central and Eastern Europe. Accelerated economic growth following systemic transformations, globalisation and liberalisation and EU integration visibly intensified international capital flows, including foreign direct investment (FDI). Intense internationalisation of an economy is usually perceived as a positive process, which – in general – gives an opportunity to accelerate growth and strengthen competitiveness. Therefore the authorities of an economy try to support FDI flows by implementing different incentives. The main goal of the chapter is to show the scale and scope of outward foreign direct investments (OFDI) of Polish companies in the light of economic transformation experience and authorities support. The chapter is organized as follows: first it presents Poland's path from centrally planned state to developed, competitive economy. Secondly, the focus is laid on support offered to companies undertaking OFDI ventures and finally on the scale and scope of Poland's outward investments.*

## INTRODUCTION

Foreign direct investment, its definitions, forms, motives and consequences have already been broadly discussed in scientific literature. However the problem itself is still very urgent and hot-debated issue because dynamic changes in global economy triggers few directions and forms of flows. Central and Eastern European countries (CEECs), which have successfully overcame transition period, play growing role in this process. For many years they have been mostly recipients of foreign capital (in the form of FDI) while recently also companies originating form CEE economies start to internationalize actively.

It should also be stressed that the net benefits for the economy which come from inclusion into international capital flows are unquestionable. Therefore, legal authorities often implement numerous incentives and support solutions not only for inward FDI but for outward FDI as well. Poland seems to be a perfect example of that process, that is why the main goal of the chapter is to present and discuss the scale and scope of outward foreign direct investments (OFDI) of Polish companies in the light of economic transformation experience and authorities support.

The chapter is organized as follows: first it presents Poland's path from centrally planned state to developed, competitive economy. Secondly, the focus is laid on support offered to companies undertaking OFDI ventures and finally on the scale and scope of Poland's outward investments.

## BACKGROUND

Nowadays, transition economies, with Central and Eastern European countries and Poland in particular, are becoming increasingly important players at international FDI markets. So far these countries were mainly FDI recipients but since their EU accession their OFDI significantly increased. It was made possible as a result of intense economic and systemic transformations launched after 1989. The main objective was to do away with centrally planned economy model and adopt a strategy to build up liberal, free market economy. Reconstruction of the market system in CEECs after several decades of central planning was difficult, exhausting, and time consuming. These countries, including Poland, underwent macroeconomic reforms, which at the beginning consisted in implementing a tight monetary policy and market-economy rules, necessary in view of the total macroeconomic imbalance at the outset of the transformation.

Comparing the experience of Poland and other countries in the region, e.g., the remaining Visegrad Group Countries (the Czech Republic, Slovakia, and Hungary), we may conclude that Poland was confronted with the most difficult conditions at the start of economic transformations. According to the EBRD study the initial conditions index[1] for Poland was 1.9 while for the Czech Republic it amounted to 3.5, for Slovakia 2.9, and for Hungary 3.3 (the higher the index the better initial conditions to implement market reforms) (Transition Report 2000, 2000, p. 21). In spite of this, economic transformation in Poland produced a more general model for other CEECs. Major assumptions were based on five pillars of economic transformation: (1) rapid transformation into a functioning private market economy; (2) liberalization of economic functions, especially in relation to foreign trade and foreign direct investment; (3) privatization of state-owned-enterprises; (4) construction of an effective social safety net by reforming the pension, education, health care, and social security systems; and (5) mobilization of international financial assistance to support the process (Hunter and Ryan 2005). These pillars of transformation were

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

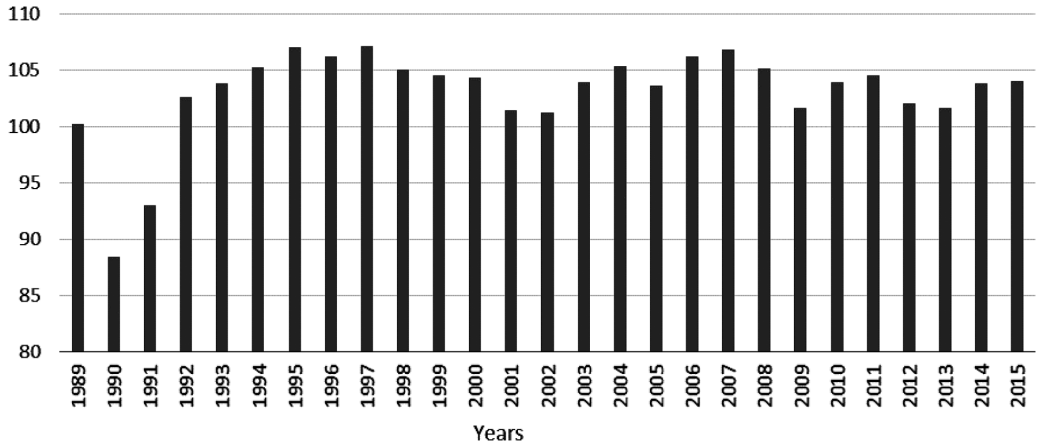
closely interrelated (Mickiewicz 2005, p. 26 and further). The program identified all steps necessary to ensure macroeconomic stabilization. These included, inter alia, the limiting of budget deficits, reducing inflation and establishing fully convertible currency with real exchange rate.

In order to accomplish the above assumptions, numerous concrete actions had to be undertaken, and the so called "shock therapy" started. It meant quick implementation of a radical and comprehensive economic program, which included macroeconomic stabilization, market liberalization, and fundamental institutional restructuring. To entrepreneurs systemic changes were of fundamental importance as entrepreneurship model changed. After 1989 everyone could start a business and many Poles took advantage of this opportunity. In the first decade of transformation, ownership changes that increased the share of the private sector in the economy and helped develop micro, small and medium-sized enterprises were very dynamic. A lot of new provisions entered into force that regulated economic activity, e.g. the commercial law, tax code and the banking law.

Micro and small enterprises, practically right from the outset of the transformation until to date, have accounted for the majority of firms in Poland. They are the core of the Polish economic transformation and nowadays play a critical role in the Polish economy. SMEs create employment and are the source of large part of value added. Besides, they shape foreign trade in Poland, its structure and dynamics. Their share in total exports was ca. 1/3$^{rd}$ and has not changed much since the beginning of the century (Central Statistical Office of Poland 2016). Developed markets, mainly of the EU Member States, were and still are the main partners of Polish foreign trade. They represent ca. 3/4$^{th}$ of all the SME exports.

Entrepreneurship development was facilitated by political decisions on the accession to the European Union structures. On February 1, 1994, Poland and the EU, signed the Europe Agreement giving Poland the status of an associated country. Accession negotiations were completed in 2003 and six months later Poland and nine other countries formally joined the EU. Within 10 years following the accession, they exported to the EU goods worth almost PLN 3.5 billion. This is twice the value of Poland's GDP (Poland's 10 years in the European Union 2014).

The membership in the European Union and the opening up of the Polish economy consequently pursued throughout more than two decades have given powerful development impulse to the Polish economy and contributed to its improved competitiveness. First of all, it opened up new opportunities of development to enterprises. We mean here better access to the EU funds and external sources of funding, higher demand for Polish products in the EU single market, better access to loans, and improved financial performance. Besides, we witnessed positive changes in the economy, e.g., increased share of services in the GDP with simultaneous drop in the share of agriculture, increased efficiency of the economy as a result of technological progress and intensified competitiveness in the internal market, higher production levels of medium- and highly processed goods, and an increased share in global trade (Poland's 10 years in the European Union 2014).



Transformation in Poland paved the way for systematic economic growth at a relatively high rate. Recession instigated by systemic transformations did not last long and was followed by dynamic growth, which substantially improved Poland's position in the group of transition economies (Jarmołowicz and Piątek 2013, p. 81). Economic recovery, which could be observed already in mid-1992, got stabilised and acquired solid foundations in 1994 (Leszczyński 2015). The foregoing was evidenced by lasting high GDP growth rate. (Figure 1).

Over the years 1992-2013 GDP per capita in Poland was growing at a rate that was twice high as the rate in the most developed EU member states (Gomułka 2014). World Bank data show that per capita GDP presented in terms of purchasing power parity increased from almost USD 6,000 in 1990 to USD

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

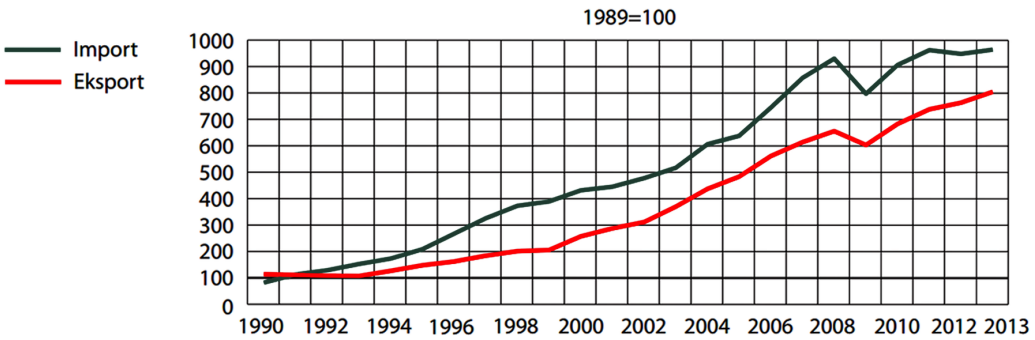


*Figure 1. GDP dynamics (in constant prices) over the period 1989-2015 (preceding year =100) (in %)*
*Source: authors' own compilation based on GUS data (GUS, 2016).*

26,135 in 2015, i.e. slightly more than fourfold (www.data.worldbank.org 2016). In 2013 GDP per capita reached 62% of income of developed Western European countries (Eurozone), a natural point of reference for Poland and a benchmark for social aspirations, while back in 1992 it represented less than 30% (Piątkowski 2013). In 2011, for the first time ever, OECD and the World Bank changed the classification of Poland from an "upper middle income country" to a "high income country", which means that economic transformation has produced expected results.[2]

A range of changes was also reported in Poland's exports and imports after 1989. First of all, the volume of international trade increased and its geographic structure changed. Until the EU accession, exports (in USD) increased fivefold while Polish imports increased more than ninefold. Also per capita trade with other countries rapidly increased (per capita exports increased almost four times, imports almost seven times). All the above only confirms substantial opening of Polish economy in the 1990s (Chilimoniuk and Czarny 2005, p. 157). In the period of 2004–2012, the value of trade in Poland grew over two times – exports (in current prices, expressed in EUR), increased by 140%, and imports by 116% (Poland in the European Union … 2014, p. 55). Exports and imports dynamics over the years 1989-2015 is presented in Figure 2.

*Figure 2. Exports and imports dynamics over the years 1989-2015*
*Source: authors' own compilation based on (GUS, 2016).*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The structure of Polish foreign trade by SITC sections is similar to the overall structure of trade in the EU where both imports and exports are dominated by products from the section: "Machinery and transport equipment". Unfortunately, the share of high-tech products in Polish exports is low, which is not good for the economy. That is due to marginal importance of the manufacturing of high-tech goods in domestic enterprises and a very small share of foreign companies from high-tech sector in incoming FDI (Potencjał innowacyjny gospodarki… 2016).

As we have already mentioned, systemic transformation and liberalisation of trade policy did not remain neutral for geographic transformations in the structure of Polish foreign trade. These changes clearly reinforced the role of developed countries, in particular European ones. Additionally, changes in the structure of trade were encouraged by intensive inflow of foreign capital (including IFDI). Businesses with foreign capital account for almost 60% of Polish exports (Kłysik-Uryszek 2012). Thus, we may conclude that liberalisation of economic ties between Poland and the EU member states was one of the major factors that changed the structure of exports and imports of goods (Czubek and Molendowski 2005, p. 31).

The above effects have become visible in annual competitiveness rankings where Poland, slowly but systematically, improves its position. For example, between 2004 and 2016 Poland markedly improved its Global Competitiveness Index ranking from 60 to 41 (The Global Competitiveness Report 2015–2016, 2016). It is also considered as a country with development potential in the manufacturing sector, BPO/SSC services, and R&D. This potential is enhanced by the highest rate of absorption of EU resources (85%) among the new EU Member States (Economist Intelligence Unit 2015, p. 10).

In the case of Poland it is also stressed that recent improvements have been made in terms of institutions, infrastructure, and education, and that the flexibility of the labour market increased. These key achievements "are steps in the right direction to boost the country's competitiveness" (The Global Competitiveness Report 2014-2015, 2015, p. 24).[3] When analyzing the results of other leading international rankings, we may conclude that over the last several years, including the times of crisis and economic downturn, Poland (from among the CEECs) was one of the most preferred destinations for foreign investors. They were attracted mostly by cheap labour and a big, quickly developing market (the biggest in the CEECs, which as a result of integration and liberalisation has become a good place to further develop exports to the neighbouring countries). Investment promoting policy of the State (including establishing Special Economic Zones) was another factor favouring the location. All in all, Poland's attractiveness was created by legal and institutional conditions, such as (Kłysik-Uryszek 2010, pp. 20-21):

1. Economic, political and social stability, security, and predictability of legal and administrative regulations;
2. Tax policy, State aid, including investment incentives and allowances;
3. Regulations concerning market entry (i.e. equal treatment), operations, and protection of competition;
4. Efficiency of state administration and institutions involved in creating the business climate.

In the opinion of Ernst & Young experts (EY's attractiveness survey, Europe 2014) other countries are battling to replicate the Polish model of attracting investors. Poland ranks high also in the World Bank Group flagship report "*Doing Business*". It suffices to say, that in 2016 the country occupies 25th place in the ranking (Doing Business 2016, 2015), while in 2006 it ranked 54 (Doing Business 2006, 2006).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Poland is also appreciated in the UNCTAD ranking. Poland's competitive advantages are: a large and rapidly developing internal market, an educated and flexible workforce, stable banking system, access to international local markets, and the availability of suppliers and partners. Report for 2014 also stresses that Poland adopted the "Programme to support investments of high importance to the Polish economy for 2011-2020", with the aim of increasing innovation and the competitiveness of the economy by promoting FDI in high-tech sectors (World Investment Report 2014, p.113). Most probably the above mentioned factors gave Poland a place in the group of the top 15 attractive FDI locations in recent years (World Investment Report 2010-2015).

The above-presented considerations show that the assessment of Poland's investment attractiveness has always been high. We can read it not only in reports of international institutions but, primarily, in the value of FDI incoming to Poland. Surely, attracting foreign investment into the exporting sector (manufacturing) and services (banks, large format retail trade, telecommunication and hotels) was a success, although invested amounts were relatively modest (in 1995-2008 they represented ca. 10% of all investment) but they focused on neglected sectors of economy. With the benefit of hindsight, we can say that they were crucial for the growth of exports and services (Gomułka 2014).

Systemic transformation and the EU accession not only improved Poland's investment attractiveness but also very much intensified the involvement of Polish enterprises in investment projects abroad. Polish enterprises have invested their capital in almost 100 countries, however, a detailed analysis of the geographical breakdown of their investments clearly indicates that European markets, in particular those in neighbouring countries, were especially attractive to Polish enterprises. Almost 85% of all foreign affiliates are based in Europe (and ca. 88–90% of affiliates owned by manufacturing companies) while over a half of foreign affiliates of Polish non-financial companies (and slightly more than 60% of manufacturing companies) were located in our immediate neighbourhood (Germany, the Czech Republic, Slovakia, Ukraine, Belarus, Lithuania, and Russia) (Buczkowski et al. 2015, pp. 98-99).

## INSTRUMENTS TO SUPPORT INVESTORS IN ACTIVE INTERNATIONALISATION

### Economic Rationale behind Support to OFDI

Generally, FDI may prove to be either advantageous or disadvantageous to the receiving economy (e.g. Moran, Graham and Blomström 2005; Tytel and Yudaeva 2006; Herzer 2012; Temiz and Gökman, 2014). In the developing or (post) transition countries they are usually seen as a reliable and cheap source of capital, technology, and management skills and an easy way to access international markets.

Many researchers have also relatively thoroughly discussed and studied effects of outward FDI at the macro- and micro-economic level in developed and developing countries (e.g. Globerman 2012; Wiliński 2013; Globerman and Shapiro 2008; Gorynia, Nowak and Wolniak 2009). Numerous studies confirm that FDI impact upon economic performance of multinational enterprises (MNEs) depends on various factors, among which we should list their size, motivation behind FDI and expansion strategy, industry, experience in operating in international markets, the quality of institutions in the home and host countries, time horizon, etc. Obviously, the multiplicity of potential determinants, which may be interpreted in various ways, makes conclusions drawn by individual researchers, as well as research methods and assumptions strongly context-dependant (Gorynia and Trąpczyński 2014).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The assessment of effects of outward FDI to the home country is often ambiguous. Controversies intensify when OFDI effects are assessed not just from the viewpoint of the investing entity, but in a wider context considering the home economy of FDI, which includes also other enterprises, central budget or economic environment. However, in general positive opinions prevail. Active policy pursued by public authorities in support of foreign investment, inward as well as outward, seems to be economically justified. It also explains why various types of investment incentives are applied (Buczkowski et al. 2015).

Principal objective of investment incentives addressed to foreign investors is to attract capital that will help modernise production assets and technology. Such support can be offered at all three levels of government: central, regional, and local. The role of incentives designed to attract inward FDI and economic rationale behind them have been usually analysed at the two first levels. To the best of our knowledge, outward foreign direct investment incentives have not generated much interest among researchers, which could well be explained by the difficulties in access to reliable data on OFDI support tools and by poor portfolio of instruments available to local authorities.

There is a broad consensus that resources inflowing to host countries as inward FDI produce positive outcomes and hence efforts made to attract them are seen as positive. However, such consensus has not been so strong over OFDI, which is why until quite recently supporting outward FDI has often been avoided. But approaches to OFDI are changing fast and many countries have come to believe that incentives to OFDI are appropriate and efficient. This new attitude encourages governments, as well as regional and sub-regional authorities to be much more active in this field also because countries have realized that domestic companies need to be competitive in the global economy (Investment Incentives 2013).

## OFDI Support Instruments

James (2009) defines investment incentives as measurable economic advantages that public institutions provide to specific companies or groups of firms, to steer investment into favoured sectors or regions or to influence the character of such investments projects.

Thomas (2007) describes investment incentives in a more unambiguous way and interprets them as a financial support given to affect the location of investment. The aim may be to enhance new investment projects or to retain an existing facility. As a general rule, wherever the system of investment incentives is in place, it exerts significant impact upon the investment climate in a given economy. This support also enhances investment attractiveness of the host country.

We may list various forms of investment incentives (Tavares-Lehmann et al. 2016, Investment Incentives 2013, OECD 2003):

1. **Regulatory:** E.g. exemptions from specific regulations binding in the host country (connected with the environment, labour market, social insurance);
2. **Financial:** E.g. providing physical infrastructure (e.g. roads, railways, harbours) or communication tailored to meet the needs of the investors; assistance in training workers where skilled labour is not available; relocation and expatriation support; administrative assistance; temporary wage subsidies; credits to investors; government preferential insurance; assistance in acquiring real estate (land or property sold below market prices);
3. **Fiscal:** E.g. reduced taxes (tax holidays, reduced rates of corporate income tax, special tax-privileged zones); incentives for capital formation (special investment allowances, investment tax credits, reduced impediments to cross-border operation, withholding tax);

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. **Technical:** They usually focus on technical matters relating to dissemination of information on investment opportunities and procedures and providing special services, and "aftercare" once an investor has already invested.

In the case of incentives offered as home country measures (HCMs) designed to intensify internationalisation of domestic entities through OFDI, classification of instruments (OFDII) slightly differs from the above presented catalogue. Hence OECD (2003) divided OFDII into three main categories:

1. Fiscal,
2. Financial,
3. Regulatory.

Economou and Sauvant (2013) proposed modified and extended OFDII classification, which encompasses:

1. Institutional framework,
2. Information services,
3. Financial measures,
4. Fiscal measures.

The Authors of Investment Incentives (2013) proposed 5 categories of OFDII, pointing at the same time to principal differences with regard to incentives intended for inward FDI (Table 1.).

The above summary demonstrates that public administration has got rather substantial possibilities to support active internationalisation of enterprises. The scope of support is close to that of incentives addressed to foreign investors, although the objectives are completely different.

## OFDI Support Instruments in Poland

Poland is one among the countries, which actively support various forms of internationalisation of domestic enterprises, also through foreign direct investment. Such support must be granted lawfully, based on detailed the EU and domestic regulations.

From the point of view of the EU law, which regulates some aspects of support to foreign investment, there are two key areas, i.e., regulations concerning bi- and multilateral investment agreements and regulations on State aid and competition.

In the first case, negotiating and concluding international agreements belongs to the so called the EU exclusive competences and pursuant to the Treaty on the Functioning of the European Union (TFEU) is subject to the rules of common trade policy. These common regulations are designed, first and foremost, to secure investors' interest in two points of time: when they enter a third country market and when investment project has already been launched. Moreover, they ensure equal treatment of the EU investors in third countries, irrespective of the country of origin of capital and potential differentiation of the scope of bilateral agreements (between an the EU Member State and a third country) (Art. 206-207 TFEU).

In the second case, incentives (financial and non-financial) granted by entities from the public finance sector at various levels must comply with competition and State aid rules. The same applies to Poland, who – as a EU member, must also observe State aid rules stipulated in Art. 107 and 108 of the Treaty

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 1. OFDII classification*

| No. | Type of OFDII | Typical Forms | (Potential) Differences Compared to Inward FDII |
|---|---|---|---|
| 1. | Financial | Money transfers, subsidies, grants, soft loans, capital holdings in investment projects | Obvious differences in the objective. Preferential financial support may be helpful, e.g., in acquisitions. |
| 2. | Fiscal | Tax allowances, exemptions, deferrals, reduction of rates, losses brought forward to the next accounting periods, accelerated depreciation | Tax allowances and exemptions are much more popular for inward FDI, although tax instruments may also be used as incentives that support active internationalisation of domestic enterprises. |
| 3. | Information and technical services | Scope of information and advisory support is wide and diverse. In general, these services are addressed to selected foreign markets, where enterprises are established and developed, including, e.g., the analysis of economic indicators, institutional and legal environment, competitors, suppliers, subcontractors, clients, R&D capacity, human resources and advisory services in investment procedures | Such incentives are relevant for both inward and outward investments. Apparently, from the viewpoint of domestic authorities the need to support domestic entities who invest abroad prevails over the need to support foreign investors. |
| 4. | Risk-minimizing measures | These incentives include primarily guarantees and insurances connected with risks involved in operating abroad. They may be linked with both political (conflicts, unfavourable changes in legislation, etc.) and economic (delayed payments, unreliable suppliers, clients, etc.) risks. | These incentives target OFDI only. International treaties and agreements (bilateral and multilateral) are important. A country, who is a signatory to such agreements usually offers more security to foreign investors. |
| 5. | Regulatory | All regulations and agreements connected, e.g., with taxation or restricting procedures that facilitate or encourage investing abroad. | Completely different than for inward FDI when the authorities of the host country may create favourable investment climate through adequate regulations. In supporting OFDI it is much more difficult as it depends mainly on foreign partners. |

Source: Investment Incentives (2013).

on the Functioning of the European Union [4] when granting aid to domestic and foreign investors. Pursuant to Art. 107.1, State aid is banned in general when it is granted selectively and favours only certain enterprises or the production of certain goods by which it distorts or threatens to distort competition and when it impacts trade among the EU Member States.

Art. 107.2 enumerates some automatic exemptions from general ban on granting State aid; besides, there are also conditional exemptions, which make aid acceptable in accordance with Art. 107.3. These conditional exemptions enable public administration bodies to assist enterprises directly, as well as indirectly by creating favourable climate for business development.

In domestic law harmonised with *acquis communautaire*, provisions on foreign direct investment made by Polish enterprises are included in the Act on Foreign Exchange Law (Journal of Laws of 2002, No. 141, item 1178). In accordance with the wording of Art. 7. of the Act on Foreign Exchange Law, minister responsible for public finances issues general foreign exchange permits by way of a regulation. Permits may be granted to all entities or to a certain category of entities, as well as to all kinds of activities or to a certain type of activities. Moreover, by issuing an administrative decision the Governor of the National Bank of Poland grants individual foreign exchange permits outside of the scope of general foreign exchange permit (Art. 8.1.of the Act).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Considering all legal limitations, Poland exploits a variety of possibilities related to investment incentives. Obviously, these efforts are dominated by measures applied by governments at different levels to attract and retain operators with foreign capital in Poland. By joining the EU Poland gained access to Structural Funds distributed under Operational Programmes. These funds have become the main source of State aid available to all companies operating in Poland. In some aspects, incentives designed to attract new foreign investors may put additional burden on the central budget, as well as on the budgets of local governments. Special economic zones (SEZs), Programme for the support of investments of considerable importance for Polish economy (Support programme), and property tax allowances are examples of such incentive arrangements. Besides, the Polish Information and Foreign Investment Agency (Polish abr. PAIiIZ) promotes Poland as a good location for FDI. The Agency runs Regional Investor Assistance Centres in provinces and Regional Investor Assistance Offices in various cities. PAIiIZ offers services free of charge. It helps select investment sites in Poland, organises tailor-made investor visits to Poland, provides information on legal and economic environment and on available investment incentives, facilitates contacts with central and local authorities, identifies suppliers and contractors, and takes care of existing investors (to support reinvestments in Poland) (Dorożyński et al. 2014).

Although much less popular, incentives that target Polish enterprises who export FDI are offered by public administration responsible for support to entrepreneurship and internationalisation of Polish economy (Table 2).

The system of OFDI support instruments in Poland is not fully comprehensive and coherent yet. Most of the above mentioned incentives have been implemented relatively recently and are still largely limited by the EU and international legal restrictions, ie. competition policy or common trade policy. Therefore, as for now within the whole system of support tools those of information and promotion in nature (thus – less quantitative) prevail. Moreover, support is offered in many forms by different organizations which makes the whole system blurred and not holistic or complementary enough – it may thus be hard and laborious for investors to get familiar with all solutions and available to choose the best option.

That all makes any attempts to assess the effectiveness of Poland's OFDI support system difficult and limited. However, it should be expected that in the coming years the list of support instruments will be not only topped up and complemented but also tailored to the needs and expectations of entrepreneurs, so that their effects and effectiveness will be more visible (and measurable).

## Poland's OFDI: Statistical Approach

Over the years of systemic transformation Poland became an interesting location for foreign direct investment. Its dynamics had been steadily growing since the 1990s while stable economic growth, gradual liberalisation of regulations, and preparations to the EU membership accelerated the process. Parallel, economic growth and the fostering of the position of Poland in international environment resulted in an increasing number of Polish enterprises who successfully entered foreign markets. Although Poland remains a net receiver of FDI, especially after 2004, the stream of OFDI has been continuously increasing.

Changes in the value of Polish OFDI over 1995-2014 can be observed in Figure 3. As we can see, dynamic increase in the involvement of Polish enterprises into OFDI started after Poland has joined the EU.

However, it is worth stressing that in the period covered by the study FDI classification changed twice. First, since 2010 FDI flows started to cover intercompany loans (i.e. flows of capital between sister companies within capital group). It considerably increased OFDI to almost USD 57.4 bn at the end of 2012 – mainly in "other capital" category (intercompany capital flows accounted for ca. USD

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 2. Examples of OFDII in Poland*

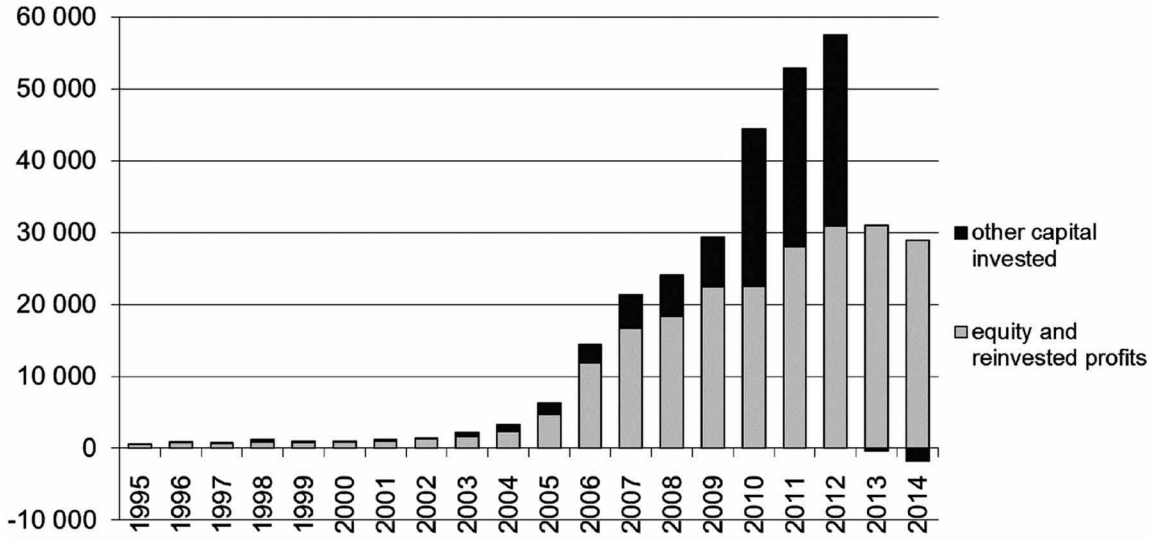
| No. | Type of Incentives | Source and Scope of Support | Responsible Institutions |
|---|---|---|---|
| 1. | Financial | Foreign Expansion Fund FIZAN (Firms may benefit from financing that takes the form of capital, mezzanine and borrowings secured by foreign project assets without redress to the Polish company. The share of Foreign Expansion Fund in project funding will typically reach between several to several dozen million PLN but it will not exceed 50% of the total investment). | Investment Fund Company BGK S.A |
| 2. | Financial | EU Structural Funds, in particular Operational Programme Smart Growth and regional operational programmes financed with the European Regional Development Fund (e.g., co-funding of innovative projects, internationalisation of enterprises and clusters) | Minister responsible for regional development and local authorities at provinces, which manage regional operational programmes |
| 3. | Fiscal | No special incentives but provisions of the Act on Corporate Income Tax (CIT) prefer certain countries as investment host countries, i.e., EU, EEA, and Switzerland. Operators, who invest in these countries may expect more favourable tax regulations, including tax allowances in the host country. | Minister responsible for public finances, tax chambers and offices |
| 4. | Risk-minimising instruments | Insurance of foreign direct investment, such as:<br>• Acquisition of a foreign enterprise or an organised part thereof,<br>• Establishing and running an enterprise abroad (also an affiliate or representative office),<br>• Outlays intended to expand an already existing enterprise,<br>• Capital injections and borrowings made by partners,<br>• Acquisition of real estate and other fixed assets.<br>• Insurance protection covers losses suffered in relation with a foreign direct investment that result from actions undertaken by the host country, such as:<br>• Changes in legal regulations (the so called regulatory risk),<br>• Expropriation,<br>• Inability to transfer receivables (e.g. dividend),<br>• Total depravation of rights related to the investment.<br>Compensation is also paid if the investment gets damaged as a result of force majeure, e.g., earthquake, flood, fire or war. | Export Credit Insurance Corporation Joint Stock Company (Polish company whose shareholders are State Treasury represented by the Minister of Development and Bank Gospodarstwa Krajowego. The only one insurance company in Poland to offer export insurance guaranteed by the State Treasury) |
| 5. | Information and advisory services | Provision of information about foreign markets, conditions of economic operations abroad; facilitates business relations; advisory services; assistance in taking part in fairs and economic missions abroad. | Ministry of Development, Polish Agency for Enterprise Development, Polish Information and Foreign Investment Agency, Departments of Trade Promotion and Investment, Regional Investor and Exporter Assistance Centres |

Source: Buczkowski et al. 2015, Świerkocki 2015, https://tfibgk.com.pl/fundusz-ekspansji-zagranicznej-fizan (accessed on 11.10.2016), www.poir.gov.pl (accessed on 11.10.2016), http://www.kuke.com.pl/dla-firm/ubezpieczenie-inwestycji-za-granica (accessed on 11.10.2016).

26.7 bn at the end of 2012). It also demonstrates relatively strong position of Polish enterprises in the times of crisis meaning, paradoxically, that Polish economy became the source of capital loans for all affiliates (subsidies, but also parent companies and associates).

The second – more substantial change – took place in 2013 and was consistent with OECD guidelines included in the Benchmark Definition of Foreign Direct Investment 4th ed. (BD4). As mentioned above, earlier classification (in line with International Investment Position statistics) of OFDI included also

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



flows between Polish investor and other entities in capital group irrespectively of where the dominant entity in the group is based. Since 2013 this kind of loans has no longer been included into OFDI flows in cases where Polish investor is controlled by a foreign MNE (this kind of flows is now considered a part of IFDI). Substantial reduction in "other capital" value confirms high proportion of intercompany loans granted to related entities within international holdings.

All in all, when analysing the international expansion of Polish enterprises attention should be paid predominantly to the value of primary investment ("equity and reinvested profits") rather than "other capital". Firstly, primary investment tells us how much have the enterprises got involved into manufacturing and service operations abroad; secondly, its definition and classification into FDI flows remains relatively unchanged.

The flow of primary investment is largely dominated by investments in new foreign equity acquisition. Until 2009 reinvested profits represented not more than 10% of all equity investment. In subsequent years proportions slightly changed, mainly as a result of reduced involvement of Polish enterprises in new foreign undertakings, which was due to the crisis. In general, the primacy of new investment projects was an expected tendency, typical of the initial stage of internationalisation of enterprises, when they have just started developing a network of related foreign affiliates by investing in production assets.

The entire period was dominated by investments made by companies from the service sector; at the end of 2014 their share reached almost 80%. Major role was played by enterprises active in financial intermediary services or managerial consultancy. Their total investment ranged from 56% up to even 94% of FDI from the service industry. Only in 2008 the share was lower, ca. 35%. At the end of 2014 the proportion of investments generated by financial companies represented 50% of cumulated value of Polish OFDI, while head offices operations, managerial consulting, as well as (increasingly important in FDI flows) administration and business support activities – ca. 14% each. (see also Table 3.). The later can be associated mainly with business optimisation at international scale: tax optimisation, raising financial capital in international markets through special purpose vehicle companies, etc.

*Figure 3. Polish foreign direct investment (cumulated value) in the years 1995-2014 in USD mio*

Source: Authors' compilation based on (NBP, 2016).

Investments made by manufacturing companies generated on average ca. 20% - 30% of total FDI of Polish companies after 2004. However, their share in the structure of Poland's OFDI was systematically decreasing. At the end of 2014 it amounted to only ca. 14%, which was not positive as it testified to the weakening manufacturing position of Polish companies, their decreasing competitiveness, even vis-à-vis service companies. On top of that, we may also suppose that Polish companies have started to approach international market as a place where they can optimise business rather than production processes. Little international involvement of manufacturing companies is an evidence of underused potential of international location-related assets, including cost reduction capabilities.

Throughout the entire period covered by the study manufacturers of coke and refined petroleum products enjoyed the biggest share in investments made by industrial companies (20% in 2014). Moreover, these projects were, first and foremost, primary investment, which means they included the development of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

new assets abroad. We may thus consider that these companies have the biggest competitive advantages (ownership advantages) among all Polish manufacturing companies and best tap into opportunities offered by the international market. That is not surprising as – against hopes vested in intensive economic growth – Polish economy still rests on traditional industries.

Next in a row were investments made by companies manufacturing motor vehicles, trailers and semi-trailers (which exceeded investments made by manufacturers of coke and refined petroleum products only in 2014) and chemicals and pharmaceuticals. Opposite to the previous – these were made largely as intercompany loans. Similar situation was observed for manufacturers of metal and metal products, which may be attributed to the facts that in those branches many Polish investors in belong to foreign MNEs. In general terms, a large chunk of investments made by these entities may be attributed to their mother-companies intention to inject capital into all foreign affiliates within the group rather than "classical" manufacturing expansion resulting from decisions and advantages of Polish companies.

Polish investments targeted mainly European countries. Their share in outflows of Polish capital over the period covered by the study amounted to more than 95% (see Table 4.). In principle, there are three groups of countries, to which capital was directed: 1) countries, which hosted financial investments and investments connected with optimisation of business processes: Luxembourg, Cyprus and Switzerland; 2) Poland's neighbouring countries similar in their Slavonic culture: Ukraine, Russia, the Czech Republic, Lithuania; 3) countries that have invested the most (in IFDI form) in Poland: Germany and the Netherlands.

*Table 4. Poland's OFDI at the end of 2014 broken down by host country in USD mio*

| | **Total** | **Equity and Reinvested Profits** | **Other Capital** |

Luxembourg, Cyprus and Switzerland were the biggest recipients of Polish capital in the period covered by the study. Their share was systematically increasing. At the end of 2011 these countries received in total ca. 35% of the total value of Polish investment, including over 24% addressed to Luxembourg alone. At the end of 2014, total share of these countries reached ca. 60%, out of which more than 30% of capital targeted Cyprus. Luxembourg, similarly to Switzerland, hosts many international funds, as well as investment and financial organisations. All shares (i.a. shares of stock or certificates) acquired by Polish residents (including minimum of 10% of shares in a given entity) are classified as FDI. Additionally, investors willingly establish special purpose vehicles (SPV) to get access to loan capital in local capital markets.

High value of investment into Cypriot economy is mainly due to some unique, favourable tax arrangements. Many companies, especially after the financial crisis started in 2008, decided to move their principal places of business or established their affiliates (also SPV) in Cyprus because it helped considerably reduce the average tax burden of all the company.

Manufacturing and trade-related investment projects headed mainly in the neighbouring countries - similar to Poland when it comes to their economic development, social and cultural environment. That is typical of the first stages of internationalisation of the economy. Such location facilitates "acclimatization" of a company in a new location, better understanding of market mechanisms, business environment institutions, and – the most important in business – interpersonal relations. The mechanism is explained by, e.g., the Uppsala model positively validated for Polish circumstances (Witek-Hajduk 2010, Kłysik-Uryszek and Kuna-Marszałek 2015).

Finally, we should pay attention to the period 2010-2012 when statistics showed the scale of loan support granted by Polish companies to related entities within capital groups. Significant share of loans granted within a group could be observed not only in Europe, but also in America or Asia. In Europe most countries used capital borrowed from Polish entities (usually ca. 65-75% of all Polish FDI cumulated in given economies). The highest values were reported for: Portugal (98%), Greece (97%), Finland (96%), Italy (95%), United Kingdom (90%), Germany (82%) or Hungary (81%). It proves again that Poland, who relatively little suffered from the crisis, has become the source of financial support to enterprises from countries that struggle with post-crisis difficulties. Average values of the discussed indicator both for Europe and for EU-27 amounted to ca. 45%, which was predominantly due to low share of capital flows in Luxembourg (ca. 20%) and in Cyprus (ca. 3,5%).

## FUTURE RESEARCH DIRECTIONS

Further studies could develop along two major lines. Firstly, it would be worthwhile to examine the efficiency with which support instruments available to entrepreneurs who expand abroad within the OFDI framework are used. While in literature we can come across a variety of studies that discuss this very issue in the context of developed countries (te Velde 2007; Bannò, Piscitello and Varum 2014), very few such studies can be found in relation to the emerging markets or transition economies (Buczkowski et al. 2015). The problem, however, seems relevant as it refers to the efficiency of spending public funds and the outcomes of studies in field are ambiguous. On the one hand, some authors question the rationale behind offering assistance schemes to investors, while on the other hand we can hear voices that point to positive aspects of such schemes and their favourable impact upon the involvement of entrepreneurs into OFDI. Such studies could be particularly useful for the central government and for lower levels of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

administration, which increasingly often play a vital role in developing economic policy. This knowledge is important for managers and politicians responsible for commercial policy especially in the light of a rather common global practice of offering government support to domestic FDI (Sauvant et al. 2014).

The assessment of if and how the enterprises involved in foreign direct investment influence the economy of their home country and brought changes in, e.g., in local employment and jobs quality, or in collaboration level with R&D centres also seems interesting. The same can be said about studying the spillover effects for other domestic firms or business partners. By the same token we could demonstrate how OFDI from Poland or from other emerging markets impact economic development, at local, regional or national levels. So far literature on the subject is rather scarce and most researchers focus on developed economies (Globerman and Shapiro 2008; Sunesen, Jespersen and Thelle 2010). Effects of FDI exports to emerging economies are far less known (Gorynia i in. 2014).

## CONCLUSION

Intensive international capital expansion of Polish enterprises which can be observed recently is the evidence of successful economic development and efficient market transformations that have taken place in Polish economy since the early 1990s. Gradual liberalisation of capital flows, opening up of the economy to the inflow of foreign direct investment and integration processes have made Polish enterprises capable of effectively competing not only in the domestic but also in international markets. With the support of own experience gained on national, but highly opened market they are becoming active players also at the international level.

Growing support (in the form of different OFDI incentives) is provided also by national and regional public institutions. Unfortunately, due to the short period of their presence on the market, as well as the substantial restrictions put by EU legal regulations, the fully effective and comprehensive system of OFDI support have not been settled down yet, and therefore investors do not use these incentives broadly. However, the dynamics of OFDI flows as well as its cumulated value show the increasing interest in internationalization process of firms. It will probably trigger the expansion of support instruments more and more custom-fitted to the companies' needs.

Sectoral structure of Poland's OFDI suggests the domination of the service sector, in which financial and advisory services play the major role. It is not surprising because financial markets and capital flows are among the most mobile ones. Besides, it is much easier to relocate financial and advisory activities or head offices in a group than to relocate manufacturing. It also shows that enterprises are not seeking only traditional resources or increased sales in foreign markets but also sources of higher effectiveness.

Investments in industry focus mainly on traditional, technologically little advanced sectors. It demonstrates comparative advantages of the economy, which – although experiences structural transformations – is still not particularly competitive in modern and technologically advanced production.

## KEY TERMS AND DEFINITIONS

**Central and Eastern Europe:** For the needs of this publication we adopted the most commonly used scope of Central and Eastern Europe including: Poland, the Czech Republic, Slovakia, and Hungary (Visegrad Group), Baltic States (Lithuania, Latvia, and Estonia), countries of the former Yugoslavia, Romania, Bulgaria, and Albania.

**Economic Transformation:** Change of economic system, in particular shifting from centrally planned to market economy, based on a functioning free market, competition and private business. Centrally planned economy was the system in most of the Central and East European countries until the end of the 1980s. It made the economy fully dependent on the decisions of central authorities. Private business was limited to the minimum, production assets were fully owned by the state, there was not any financial or capital market, market mechanism did not work, prices were decided by officials, and competition was replaced with a monopoly. Trade with third countries was regulated.

**FDI:** Foreign direct investment (outward – OFDI; inward – IFDI), the most advanced form of internationalisation of companies; FDI are undertaken to exercise a long-term capital supervision over an entity located abroad (branches or subsidiaries).

**Intercompany Loans:** Are perceived as part of FDI flow, as long as the debt concerns entities belonging to one international group or MNE.

**Internationalization of a Company:** A process, through which a firm moves from operating in a domestic marketplace to international markets.

**Primary Investment:** Part of FDI flows that consist of equity investments. They precede the other parts of FDI flows – reinvested earnings and intercompany loans.

**State Aid:** Any action undertaken by state authorities consisting in granting aid, in any form whatsoever, to an individual entrepreneur or to a group of entities, which distorts competition on the market. In the EU State aid is regulated in Art. 107 and 108 TFEU. The following premises must be met (jointly) to

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

decide, that we are dealing with incompatible State aid: 1. A measure is an aid to an undertaking; 2. Aid is granted by the State or from the State resources; 3. Aid favors certain undertakings or the production of certain goods; 4. Aid distorts competition or threatens to distorts it; 5. Aid distorts trade among member states; 6. Aid is not covered by any of the Treaty exemptions. An example of aid covered by the Treaty exemption and, as such, compatible with the EU market, is aid to promote economic development of areas where the standard of living is abnormally low or where there is serious underemployment. State aid consists in granting direct financial or in-kind advantages to the beneficiary, e.g. subsidies, grants for equipment. State aid may also consist in the reduction of public and legal liabilities of the beneficiary, e.g., liabilities write-off.

## ENDNOTES

1. To calculate the index account was taken of: weighted average of measures for the level of development, trade dependence on the Council for Mutual Economic Assistance, macroeconomic disequilibria, distance to the EU, natural resource endowments, market memory and state capacity (Transition Report 2000, 2000, p. 21).
2. Investment bank Goldman Sachs foresees that until 2030 Poland (and other CEECs) should grow by at least 2 percentage points annually faster than the EU-15.It means that until 2050 GDP per capita in Poland would be by only 15% lower than in the most developed EU member states but higher than, e.g., in Spain (Zsoldos and Zadornova 2008).
3. Besides strengths, the report also highlights barriers faced and observed by foreign investors in Poland. The following dimensions have been assessed as poor in the ranking: transport infrastructure, some institutional aspects, such as the regulatory burden, rather inefficient legal framework for settling business disputes, and difficulties in obtaining information on government decisions for business. To bolster its innovative capacity, more attention should be paid to reinforcing its innovation ecosystem in close collaboration with the private sector.
4. Consolidated version of the Treaty on the Functioning of the European Union, 30 March 2010.

## ABSTRACT

*The objective of this paper is to measure the degree of Home Bias within the holdings of portfolio and to identify their determining factors. By following an intuitive reasoning, the authors have chosen a number of susceptible factors that have an impact on Home Bias. In fact, they have developed an international CAPM (Capital Asset Pricing Model). This model is estimated for 20 countries, with the use of cross-section econometrics. The authors' results show that all countries have recorded a high level of Home bias in their holdings of portfolio. In order to study whether the Home Bias of the newly emerging markets and that of the developed markets react differently to the determining factors or not the authors have evaluated the model so much jointly for all markets as separately for the developed and the newly emerging ones. In the case of classification of the sample, the results have permitted us to draw an important conclusion and to have cognizance that the volatility of the exchange rate is statistically significant concerning the newly emerging economies at a threshold of 1%, while it is hardly remarkable for the developed countries. This means that this variable prevents the American investors from investing in the former countries. Samely, for both variables of joint- variance and size.*

## 1. INTRODUCTION

Financial markets are characterized by quite an important volatility and an environment that is laden with risks, wherefore the investor finds himself confronted with the problem of [dynamically] managing his portfolio. Within this context, ever since the model theory of portfolio selection has emerges by the founding works of Markowitz (1952, 1959). His research has concentrated on the problem of portfolio selection based mainly upon the gadgets of returns-risk. This theory stipulates that the inclusion of less correlated securities within a portfolio drastically reduces its risk. However, this risk may also be reduced by the geographical diversification of the portfolio across many markets over the world. This very phenomenon is called "international diversification". It is important to allude to the fact that international diversification goes in line with the renowned adage: "Don't put all your eggs in one basket".

Numerous writers, notably Solnink (1974), Harvey (1991), De-Santis & Gérard (1997), Lewis (2000) and Arouri (2005, 2006 b) show that international diversification allows to considerably downsize the risk of portfolio and /or to improve its anticipated investment yields. Nevertheless, despite the recommendations of the financial theory prompting the importance of international diversification, institutional investors show strong preference for national assets. This issue is called "Home Bias". Meanwhile, many researchers have been interested in the study of this phenomenon. We can mention as an example the study of Tesar & Werner (1995); who observed the phenomenon in a dynamic fashion from 1970 to 1990: the weak share of foreign securities in the portfolios of German, American, British, Canadian and Japanese investments. It is to be noted that many studies have focused the attention on the question of factors that are significantly contributing to the existence and justification of Home Bias.

Yet, it is quite clear that this present work contributes to the literature by widening the scope of analysis of Home Bias in the field of shares. Our objective, within the framework of this research, consists in resolving the following question:

What are the benefits of international diversification?
What are the explanatory factors of Home Bias?

The upshot of this article is to study the determinants of Home Bias in connection with the newly emerging and developed markets both jointly and separately. After having presented the objective of our work, we shall bring forward, in the second section, a brief review of the major works and latest developments concerning the topic of international diversification, together with the issue of Home Bias. This is all in accentuating the related explanations presented in the literature of international financial markets. The data being used and the methodology being followed shall be the object matter of the third section. The fourth section exposes the results of our empirical part. At last, we shall finish by discussing our results. In the fifth section, we shall conclude.

## 2. A SUMMARY OF THEORETICAL LITERATURE

The international diversification is considered as a central area of management that seeks to improve the performance of portfolio. In fact, as we have previously seen with many already done, studies such as those of Grubel (1968), Levy & Sarnat (1970) and Solnik (1974), the international allotment of portfolio's investments constitutes the best way to ameliorate the performance of portfolios.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The pioneering researches about this strategy had been conducted principally by Grubel (1968) and then by Levy &Sarnat (1970). The idea initiated by these researchers was to derive the efficient portfolio out of the international stock-markets.

The study of Grubel (1962) supposes that the international diversification of the portfolio represents a source of benefit through the making out of international relations that differ from those coming out from the traditional exchange. Grubel has made an empirical test about the stock-market indexes of 11 countries over the period spanning from January 1959 to December 1966 in order to examine the advantages of international diversification for American investors. He has proven that the international diversification between the assets of 11 surveyed countries allowed investors, either to reach the highest rates of return on investment, or the lowest variance of their portfolios.

Extending from this contribution, Levy & Sarnat (1970) have documented low coefficients of correlation between the returns on assets and concluded that the gain from international diversification was substantial.

Liljeblom, Loflund & Krokofrs (1997) have made an investigation about the benefits of international diversification concerning Nordic countries. These researchers have applied their analyses over the period between 1974 and 1993, based upon the monthly returns of assets of 18 national capital markets. These returns were based on the value of MSCI index (Morgan, Stanley Capital International) within the national capital markets and included notably the capital gains on assets and the payment of dividends. These writers have divided the period of study into two sub-periods: the first one spanned from 1974 to 1986, whereas the second stretched from 1987 to 1993. In the light of this study, they concluded that the substantial gains of the geographical investors were there for all Nordic countries with the exception of Denmark.

Likewise, Lapp (2001) has tried to analyze the benefits of international diversification for the German investor. This examination was applied on a sample of 18 countries throughout a period of 10 years, from 1988 to 1997 and showed that a diversified portfolio was much more profitable than a purely domestic portfolio without taking into account the degree of aversion to risk. However, Schroder (2002) shows that the strategy of international diversification permits to supply additional and significant returns for all investors belonging to the examined sample (British, French, & German investors) with the exception of the American investor.

In brief, international diversification is often regarded as the most efficient way to ameliorate the performance of the portfolio.

K.Li, Sarker and Wang (2003) have also studied within the frame of average-variance the dynamics of gains of international diversification put under certain constraints of short sale. The study was realized on the period spanning from January 1976 to December 1999, and the sample of this research included the monthly returns on the stock market indexes of the G7 [countries] together with 8 newly emerging markets of Latin America and Asia. From their empirical results, these writers have concluded that the anticipated gains from international diversification remain substantial for investors in the American stock market wherein there are no constraints of short sale on the newly emerging markets. They have remarked a reduction at the level of financial integration of international markets, but this does not allow to delete the anticipated gains from the international diversification put under the constraints of short sale.

Arouri (2005) has elaborated an extension of the multi-varied model of GARCH initially proposed by De Sentis & Gérard (1997) in order to derive a measurement of the predicted gains from the international diversification of the portfolio. This study dealt with the stock markets of the G7 countries and the international markets, while it covered the period from February 1970 to May 2003. The results

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

of this study show that the benefits of international diversification are statistically and economically significant for all financial markets except those of France and UK, wherein the gains of international diversification record a slight tendency of decrease. Generally, for all the surveyed markets, the gains of international diversification have once again become—over the last decades—greater than their average that is calculated during the entire period. Most of the time, the gains stemming from international diversification depend upon the low correlation of return of the different securities invested in the markets. That's why, any increase of such correlation may be responsible for the decreases of the predicted benefits of international diversification. This increase results from the rise of the level of integration of financial markets. Consequently, the gains of diversification are linked with the level of integration or segmentation of financial market.

In order to better profit from the strategy of international diversification many researches have shown that the worries of investors are directed towards the developed markets. Nevertheless, with the turning of the 1980s and 1990s, many writers made their studies within the frame of international management of portfolio [of stocks] to assess the significance offered by the emergent stock markets. Beforehand, these markets had to be able to manage important potentials of diversification in comparison with the markets of developed countries which have a tendency to be more and more integrated with each other. These changes can be explained by the low correlation of the newly emerging markets with one another and with the rest of the world.

Odier et al. (1995) have tried to examine the characteristics of returns for the newly emerging markets in comparison with the developed markets. These writers recorded an important increase of returns in the newly emerging markets, but these returns were associated with high levels of risk. They have deduced that the correlation between returns within the newly emerging markets and the international index of the developed markets was 0.31, which means that the gains anticipated from the international diversification on the newly emerging markets are much more beneficial than investing uniquely on the developed markets.

In tune with the preceding studies, Bellalah Makram and Fadhlaoui Kais (2006) have given evidence of the importance of the newly emerging markets for the international diversification by measuring the relations of interdependence between the developed markets and the newly emerging ones. In this respect, the benefits of international diversification resides firstly in the reduction of the risk, and secondly, in the improvement of performance. However, in spite of the theoretical and empirical evidences about the additional gains of international diversification, investors have tendency to allot part of their wealth in foreign securities smaller than that which they invest in domestic securities. In other words, investors hardly diversify their portfolios and prefer to hold local securities. This fact is called Home Bias, or else national preference which can be defined as the gap between the shares of wealth being effectively invested in foreign assets and the optimal shares determined by the financial theory.

Home Bias is a well-established phenomenon in international finance. French & Poterba (1991) demonstrate the strong proclivity of American, British and Japanese investors to hold national securities. According to French & Poterba (1991), in 1989 investments in domestic securities exceeded 90/100 in the US and Japan, and 80/100 in Europe (GB, Germany and France). Moreover, the preference of domestic assets is considered to be a normal behavior as Gorman & Jorgen (2002) show. These two latter writers conducted a research that included the investors from 5 greatest countries in the world using the performance measurement of Sharpe (1966). In fact, they show that the ratio of sharp for the optimal portfolio is typically below the ratio of Sharpe for the 100/100 domestic portfolio. Therefore, the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

100/100 allocation is much more profitable than the portfolio with optimal tangency. To sum up, they conclude that domestically-oriented investors are not "irrational" and that the benefits of international investments are difficult to attain.

In line with the same principle, Cambell (2006) in developing a finance study of "household" suggests that investors have tendency to prefer national securities. In fact, he conducts his study basing upon the body of information accumulated by precedent researchers such as French & Porterba (1991), Cooper & Kaplanis (1994) in order to show that domestic investors have a very important level of "Household" comparatively with foreign investors. Besides, investors exhibit a preference for regional companies against non-regional enterprises. However, this Home Bias paradigm can be explained mainly by the existence of barriers against the flux of capitals manifested basically in the costs of transaction due to the holding of foreign assets, the withholdings at source, the political risk, the failure in parity of the purchasing power, informational asymmetries and the constraints on short sales. Hence, it clearly appears that there are numerous factors which encourage international under -diversification since the investor might be hindered to settle himself in a given market other than that of his own country, or he might be hampered by the weakening of his gain under the effect of the excessive costs of transaction or heavy taxation.

Within this framework, Mishra (2008) fixes a given set of factors pertaining to explain national preference relying upon the economic theory. Among these factors, he uses the exchange risk, distance, language, the joint-variance, the legal origin, the cost of transaction and other informational variables. According to certain studies, the volatility of the exchange rate constitutes a brake on the growth of international investment. Within this purview, the exchange risk constitutes an important variable that has to be taken into consideration in every strategy of international investment and more particularly within the newly emerging markets. At this level, we equally have to emphasize the fact that the occurrence of financial crises in some markets is translated by important devaluations of the currency in which the securities are made out. Hence, a positive link is made up between the volatility of the exchange rate and Home Bias.

Within this context, Bin, Morris & Chen (2003) have shown that the foreign exchange rate and the interest rate make up the principal determinants of ADR's assessment. These writers conclude that the ADRs of the developed countries (Australia, Japan, Europe) and those of the newly-emerging countries (China, Chile, Korea, Mexico and South Africa) are affected by–and sensitive to – variations in comparison with their corresponding currency. However, monetary fluctuations affect significantly the aggregate return of a diversified internationally portfolio. This comes from the fact that the description of a given monetary unit is not often made by the estimation of another. This deduction can be considered as a major advantage that encourages investors to hold possession of domestic securities. In tune with the preceding studies, Giurda & Tzaralis (2004) equally ask whether the exchange risk is assessed within the international stock markets. They remarked that a dynamic strategy of a portfolio, which is covered against the variations of the exchange rate, supplies much more important returns than another strategy which may happen to ignore them. So, the exchange risk constitutes an obstacle that thwarts the investors to hold possession of foreign assets. Within this context, a great deal of theoretical and empirical corpus has been conducted to explain the Home Bias taking into account diverse frictions in the financial markets. These frictions manifest basically in a fiscal advantage following the investment on the domestic level together with the tax on repatriation of foreign dividends.

Within this framework, taxes appear to have an enormous effect on the demand of foreign assets. In fact, the inversive relation between tax and the demand of foreign assets indicates that investment in foreign asset diminishes as tax increases.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

From this point of view, Stulz (1981) concludes that the valuation of tax may be at the origin of segmentation of financial markets, which discourages the international investment and, consequently, increases the interest of the investor to direct towards the local market. He proves that certain assets can only be possessed by domestic investors because their interest in terms of diversification does not compensate the cost in terms of foreign investment taxes on creditor and debtor positions. In fact, this result shows that the tax-factor contributes significantly to the explanation of Home Bias.

The inversive relation between tax and demand of foreign assets indicates that investment in foreign asset diminishes as the tax increases. Thence, drawing upon Black (1974), we should say that the heterogeneity of taxes explains the elucidation of financial assets and particularly the preference of investors for national assets.

On the empirical plane, the other major contribution has been brought about by Amadi (2004) who supports the idea that common language, distance, as well as immigrants equally influence the strategy of foreign investment. This implies the existence of such costs that may hinder the entrance to a foreign market. In this perspective, investors move typically over markets that have the same language, culture or other notions of familiarity. (Amadi; 2004 & Grimblat & Kelaharju; 2001). In tune with this recent study, Berkel (2004) examined the institutional determinants of international portfolios of assets. In particular, the results of estimation indicate that the asymmetries of information, approximated by geographical proximity, together with the existence of a common language, or a common colonial background, have an enormous effect upon the composition of international portfolios of assets. Therefore, it is convenient to recall that the impact of geographical distance upon the holdings of assets is quantitatively of first rank since the increase of 1/100 within the distance between 2 countries diminished the average of foreign asset's ownership share to approximately 0.15 in 1997 and 0.27 in 2001. This result is namely evident even if the two countries had the same legal origin. In fact, the share of ownership of foreign asset diminished with roughly 0.25 in 1997 and 0.39 in 2001, which leaves room to note that distance is expected to be positively linked with the cost of information. In other words, a farther distance implies a weaker cultural link. Thus, we are going to use the distance between the country of origin and the country of destination as a proxy variable to replace the cost of information needed to the acquisition of foreign assets. In this context, investors prefer to make their investments within the country that has the same language in use as their native countries, which helps facilitate the financial analysis of organizations.

Moreover, the size of a market improves its liquidity and its capacity to mobilize its funds and diversify risks. This means that American investors are going to orient themselves towards the markets that have an important share within the global market. As a consequence, the increase of size of the country favors the strategy of international diversification with this country. In fact, if the share of this country is important within the global market, the American investor decreases his foreign investments.

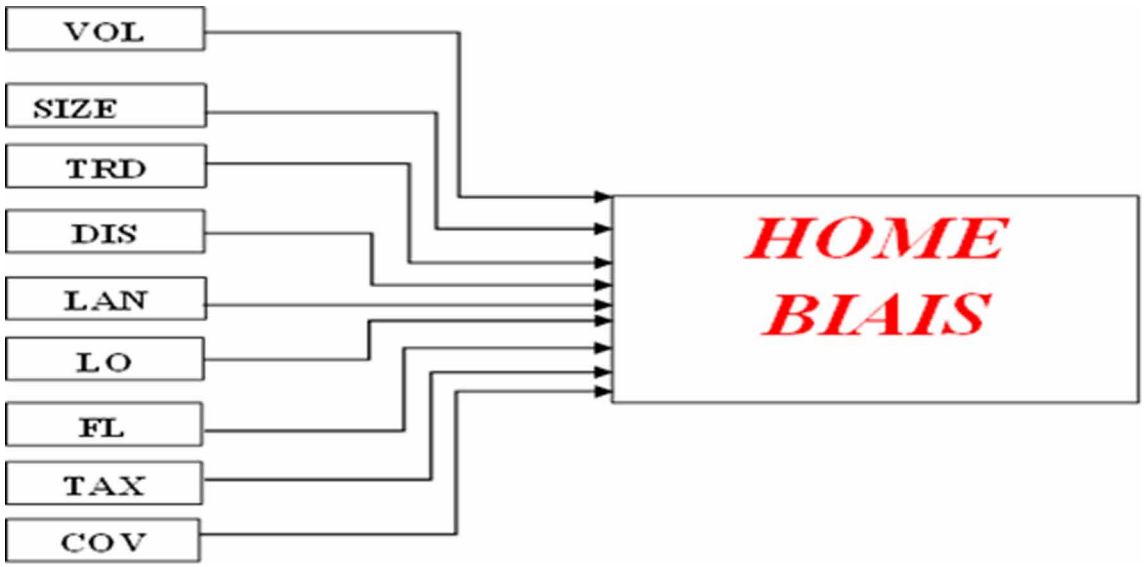
A good openness to the external trade gains the trust of international investors and attracts more the foreign funds. Once the country of destination invests some assets within the American market, the barriers between both countries would be reduced. In other words, the more the number of foreign organizations increases within the American market, the more the American investors would have better information and vision about the markets of those countries. This would facilitate the holding of foreign assets while those countries would gain from the strategy of international diversification. In the light of the precedent discussion, our objective is to test the influence of the volatility of exchange rate, size, transaction, distance, language, legal origin, foreign organizations' share, the joint-variance-diversification, as well as tax, upon the phenomenon of Home Bias for the American investor. The hypothesis which we are going to test in this respect is the following:

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**Hypothesis:** Volatility of the exchange rate, size, transaction, distance, language, legal origin, foreign organizations' share, the joint-variance diversification and tax all encourage the issue of Home Bias.

## 2.1. Conceptual Framework

Based on the arguments presented above, the conceptual model proposed in this study is presented in Figure 1.



On the basis of the above cited arguments, the conceptual model of this research is presented in Figure 1:

## 3. RESEARCH METHODOLOGY

In order to cover this stage and achieve it, we have chosen a sample of 20 countries. The regional classification of countries is displayed in the table of appendix. This classification is based on the division of the geographical area. Besides, in relation to the selection of these countries, the choice has excluded many countries due to the availability of data. Our research spans over a period of 6 successive years, from 2008 to 2013.

The starting point of our empirical approach consists essentially in measuring the issue of Home Bias. This stage will be a descriptive analysis which verifies the under-weightings of foreign assets within the portfolio of investors for the majority of sample-countries in the course of the studied period. To meet that end, we are going to use as data, on one side, the total cross-border holdings of assets while on the other side, the portion of invested assets at national level. In fact, the data that have to do with holdings are excerpted from WEF (World Exchange Federation) which submits a respectable body of information about the holdings of the portfolios of securities for the end of year of individual economies assessed in market price. Besides, it is essential to note that the investors of the sample-countries effectively make the exchange of financial assets with the American market and vice-versa.

*Figure 1. Conceptual model of study*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Within this context, we shall try to know if the Home Bias in assets is observed for the majority of countries within our sample during the indicated period of research. This means that the countries significantly hold portfolios of assets which are largely biased towards domestic securities. Likewise, we are going to verify if the investors invest a much more important proportion in the domestic market than that being suggested by the theory of share-portfolio. In fact, after regulating the measurement of the global Home Bias of countries, it has been quite interesting to mark out the distribution of Home Bias by subdividing the holdings of assets by pairs of countries. This stage consists in analyzing the Home Bias in a bilateral way. This research is focusing solely on the study of conspicuous and salient American foreign share-holdings, which means that we are going to make holdings of American investors. Then, we are going to move in a third stage to test the determinants of Home Biases based upon an econometric model. In this respect, it is essential to recollect and recall the factors which are at the origin of Home Bias.

## 4. APPLICATION AND RESULTS

In this research, we are going to call back the explanatory variables that are largely used by Mishra (2008). We shall start with the overall measurement of Home bias of a given country as being the relationship between the real relative share of assets invested in the domestic market and the aggregate assets of the country

Formally:

HB = Real Share of domestic holding / Aggregate Asset, with:
Aggregate Asset = Domestic Asset + Foreign Asset + Investment Fund

After having conveniently analyzed the aggregate holdings of foreign assets of the countries, and for the purpose of better locating the distribution of Home bias, we intend to implement a bilateral analysis of the bias. This is why; we are going to adopt the measurement applied by Mishra (2008) who has studied the holding of Australian shares by a certain number of countries. However, our point of focus in this research shall be the study of holdings relative to American investors, which means that we are going to be concerned mainly with American market. Here, we are going similarly to quantify the volume of home bias of a given country *i* towards country *j* as the relative difference between the weight of real or actual foreign portfolios and optimal ones. In other words, we shall prove the existence of home bias, in regard to American portfolios, through the comparison of the actual proportion of foreign assets in American investors' portfolios coming from the selected countries of the sample with that predicted by the global market.

$$HB_{ij} = 1 - \frac{I_i^j}{I_i^*}$$

The holding of foreign assets within the total share portfolio of American investors is attained via the relationship between their holdings of foreign shares and their aggregate holdings of shares (foreign and domestic).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Within the track of our objective to identify the factors affecting investors to choose domestic assets, we are going to develop an econometric model of international CAPM type which has made these factors obvious and discernible. In fact, the main point within this model is to present and discuss the pertinence of the susceptible variables for being the same self-factors determining the issue of Home bias. We are, similarly, going to verify in measurement the potential causes of this bias between the stipulations of financial theory and the economic reality. This model in question is relying upon that developed by Mishra (2008), except that we shall replace the exchange of financial assets with the Australian market with that of the American one. In fact, this model encompasses integratively the variable of exchange risk with other variables that measure the frictions in the financial market, and it is tested through the MCO econometric method using cross-country data. So, in mathematical terms, the estimated basic statistical model can be formulated as follows:

$$HB_{ij} = \alpha_1\left(VOL\right) + \alpha_2\left(COV\right) + \alpha_3\left(SIZE\right) + \alpha_4\left(LAN\right) + \alpha_5\left(LO\right) + \alpha_6\left(FL\right) + \alpha_7\left(TRD\right) + \alpha_8\left(DIS\right) + \alpha_9\left(TAX\right) + \varepsilon_{ij}$$

with:

- **$HB_{ij}$:** This is the dependent variable which indicates the bilateral measurement of home Bias
- **The Volatility of Exchange Rate (VOL):** This variable is measured by the standard deviation of monthly change of bilateral exchange rate over the specific period of study.
- **Diversification-Covariance: (COV):** Indicates the covariance between the American market's returns and the country of destination.
- **Language (LAN):** This is a mute variable that can take two values: 1, if both countries either have a common language or a common colonial background, and 0, if it is not the case. This variable indicates the legal system in use within the country.
- **The Share of Foreign Organizations (FL):** This is the share of foreign organizations out of the total sum of all organizations located in the domestic market. This measure is credited to Mishra (2008) and Amadi (2004).
- **Transaction (TRD):** Measures the degree of tentative offers of the country. This variable is given under the following formula:
  0.5* (Exports + Imports) / GDP
- **Distance (DIS):** Indicates the physical distance in kilometers between the country of origin (the USA) and the country of destination. This variable is estimated using the logarithm
- **The Tax (TAX):** Indicates the set of taxations imposed by the country
- **$\varepsilon i_{j:}$** indicates the margin of error

The real holdings of portfolio are identified by using the date of international investment locations. In fact, Table 1 displays the different elements to be considered in the measurement of home bias for the year 2012.

The contemplation of the figures in the table permits drawing strong conclusions. Besides, it is highly interesting to remark, according to this table, that all countries record a high level of home bias. This implies that investors of these countries significantly hold share portfolios that are biased towards

Source: Author calculations

national securities. In other words, investors prefer to invest [their stocks] within the national market, while they ignore the potential gains of international diversification strategy.

In 2012, the least elevated value of home bias concerning portfolios was registered in the UK where only 56.10 percent of the total volume of share portfolios was invested in domestic stock. while the most elevated value was registered in Columbia, India and Turkey; where we find that all investments in portfolio were domestic. It seems that home bias in the holding of shares has been diminished within developed countries' markets (US, France, Germany..), whereas the markets of the newly-emerging economies (Brazil, UK, Egypt..) record a much higher level of home bias. In this respect, it is self-proven that the markets of developed countries offer the best opportunities to diversify the share portfolios at international scale. This means that the correlations between the financial markets of these countries are weak.

After having conveniently analyzed the holdings of aggregate foreign assets of countries and for the purpose of better locating the distribution of home bias, we are going to make a bilateral analysis of the bias. So, we shall calculate this bias between the American market and the other countries of the sample. In fact, Table 2 presents the components of bilateral bias in 2012.

However, this table shows, as we have already mentioned, American investors' strong preference for domestic shares. This means that investors tend to invest less internationally than what is theoretically predicted, and thence, the real foreign participation is smaller than the optimal portion of international

Source: Author calculations

assets within investors' portfolios. In this respect, we notice that the American share portfolio is roughly composed of 85% of American stock.

The main point of this work is to analyze the factors that are affecting the choice of financial assets of economic agents. To do that, we have developed a multifactorial econometric model in which we have analyzed the degree of explanation supplied by the explanatory variables that are already mentioned. Then, this brings forth a clearer vision about the causes behind this economic model. We estimate this model relying upon the econometric model MCO and in use of cross-section data for the period that spans from 2008 till 2013.

The results of the econometric regression of this basic model for the year 2013 are presented in Table 3.

Although the obtained results at continental level could not supply us with enough information to determine whether the considered factors- seemingly the root of home bias- had specifically been at a certain sub-sample [level] or not. That's why, we have classified our sample-countries into developed (Australia, Canada, Germany, Japan, France, Spain, UK) and newly-emerging ones (Brazil, Egypt, Poland, Thailand, Turkey, China.). In the light of this classification, we have estimated the determining factors of home bias for every category aside. Therefore, Table 4 and Table 5 display the results of this estimation:

## 5. DISCUSSION AND CONCLUSION

According to the estimation of this model, it is evident to notice that the explanatory factors are indispensable for the existence of home bias. This implies that these factors contribute largely in the formation of home bias.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The analysis of Table 3 allows us to deduce that the variable of volatility of the exchange rate is positively correlated with home bias phenomenon at (0.18) for the year 2013. The positive figure obtained for the exchange risk is conformed to economic intuition. This means that the volatility of the exchange rate generally reflects the uncertainties [of investors] towards the economic situation of the country in question and towards the efficiency of the predicted shares. From this perspective, a strong volatility of the exchange rate encourages the American investors to invest in the domestic market. Consequently, this variable represents a barrier against the international movements of capitals, which sustains the results attained by Mishra (2008) concerning the Australian market. He concluded that the exchange risk constitutes a potential conductor towards the issue of Home bias. This is to say that the exchange risk plays a primordial role in the explanation of national preference in using the method of generalized moments in order to test the predetermined model.

More precisely, when we separately examine the developed countries and the newly-emerging economies, we find that the volatility of the exchange rate is generally of low importance for the developed countries' markets during the limited period for study, while it is quite important at a threshold of 1% for the years 2008, 2009 and 2011, and at a threshold of 10% for the years 2010, 2012 and 2013 concerning the emergent markets. Hence, the volatility of the exchange rate encumbers American investors from embarking on the markets of the newly-emerging economies.

Let's consider, now, the covariance factor. The obtained figure of this variable is positive at (0.00843) for the year 2013, and it is strongly important at a threshold of 10% for almost the whole period of study. As for the newly-emerging countries, the coefficient of this variable is positive and interesting over the whole period of study at a threshold of 10%. This indicates that there is a strong correlation between the return of the American market, which consequently means that domestic assets are strongly weighed within the portfolios of American investors.

Yet, for all the developed countries, the joint-variance variable is positive, but it is not that important except for the years 2012 and 2013. From this perspective, we can conclude that the American market is weakly correlated with the markets of developed countries, something which facilitates the acquisition of foreign assets by these countries. Consequently, the American investors benefit from the strategy of international diversification. From this, we can deduce that this variable is not in the advantage of the issue of home bias concerning the developed countries. As a result, we find that American investors prefer to invest in the markets of these countries.

Moreover, we have used the distance between the country of origin and the country of destination as a proxy-variable to replace the costs of information. Within this frame, we find a very interesting result that the coefficient of this variable (distance) is quite significant, which means that the distance between the financial centers is important in determining the choice of investors of their assets. Nevertheless, this coefficient is positive, which gives credence to the previously mentioned hypothesis. This indicates that the holding of foreign assets diminishes when the distance between the two countries increases. This can be explained by the fact that the width of distance between countries creates much higher costs to get to information.

Within this same purview, the size of the country influences home bias. The coefficient of this variable is negative at (-4.89) and (-3.51), and quite significant at a threshold of 1 percent for the years 2008 and 2010, and a threshold of a 5 percent for the years 2009 and 2013. We should recall that this variable indicates the market share of every country within the global market. As the share of the country increases

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

within the global market, the holding of domestic assets decreases. In this respect, investors prefer to direct themselves towards the developed markets more than the emergent ones in case they profit from the strategy of international diversification.

We shall move now to focus on the significance of mute variables selected in this research which manifest essentially in language and legal origin. These variables indicate the cultural, linguistic and historical links between the American market and those markets making the sample of our study.

Estimations show that the coefficients of these variables are negative at the values of (-0.384) and (-1.15) for the years 208 and 2012; and at the values of (-0.44) and (-1.04) for the years 2011 and 2013. These coefficients are equally important at a threshold of 5% for the first range of values, and at a threshold of 1% for the others. Besides, the same result has been remarked concerning the estimation of these variables for both categories of countries (developed and newly-emerging). These results show us that, in the case where the country of destination and the United States have the same language in use, American investors additionally increase their investments towards that country. This goes hand in hand with the logic of our hypothesis concerning the impact of information. Likewise, the legal origin appears very important and it is true in absolute terms. It has an influence yet more powerful at continental level as it is proven by the extent of its estimated coefficient. It is very likely that the same legal origin permits the economies to reinforce diversification and, hence, to diminish the impact of home bias.

The results which we have attained emphasize the importance of informational functions as being the fundamental determinants of holdings of international share portfolios. In other words, both variables (language and legal origin) play a prominent role in the reduction of home bias phenomenon, and they also have some important effects on the extent of diversification.

We still have another important domain for investigation which has to do with the role that transactions play in the process of home bias. The resulting figures for transaction are negative at the values of (-0.00609) and (-1.27) for the years 2008 and 2012, which goes in tune with the economic intuition. This variable is important at a threshold of 10% equally for all the markets of our sample of study as for the emergent and developed markets when treated separately. The classical trade theory emphasizes the positive relation between the trade openings and the international diversification strategy. This indicates that American investors would head towards the countries that have a respectable level of development concerning their financial markets. Here, the effect seems much more important for the country of destination. Therefore, the more developed the financial market of the country of destination is, the more advantageous the opportunities of investment are that's why American investors would be inclined, in advance, to hold the portions of portfolio in such economy. Concerning tax, it means that this variable is positively correlated with national preference (0.044) and (0.076) for the years 2010 and 2013. This means that the increase of tax rates in the country of destination leads American investors to invest less at international scale. However, the obtained coefficients are most often statistically important at a threshold of 5% equally for all the sample countries together as for all the emergent and developed markets when taken independently. From this perspective, we need to note that the increase of tax rate prevents American investors from holding foreign assets and, hence, they prefer domestic assets.

Furthermore, we still have another element that is very interesting in determining the choice of investor in relation to his or her portfolio of financial assets at an international level. This variable manifests in the share of foreign organizations located in the domestic market (American market); that is to say: the more the number of these organizations increases in the American market, the more the American

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

investors would have the opportunity to gather information about the markets of these organizations' native countries. This facilitates the holding of foreign assets, and thence, they would benefit from the strategy of international diversification. This result contributes in reducing the extent of home bias.

The estimated results of our sample demonstrate that this variable constitutes an unfavorable determinant of home bias, in such way that it shows negative coefficients (-0.4) for the year 2008. Besides, this variable is significant in the choice of investments concerning economic interplayers at a threshold of 1% for the same year. Similarly, for the remaining period of study, we deduce that this variable seems to be highly significant at a threshold of 1%.

Generally, the results of estimation for the year 2008 show a median coefficient of determination ($R^2$) at the value of 58%, which means that the model has a moderate explanatory power. Putting this otherwise, the exogenous variables explain the endogenous variables at 58%. Similarly, for the remaining period of study, the coefficient of determination ($R^2$) seems to be the medium of the values 34%, 57.5%, 30%, 34% and 27% respectively for the years 2009,2010,2011,2012 and 2013. In general, the model is significant during the period of study. As a matter of fact, concerning the newly-emerging markets and those developed ones, the result that has to do with the significance of the model is very similar to the basic model.

Our analysis means that the issue of home bias is there all the time and at very similar levels in spite of the process of financial integration followed by the countries.

The consequences of the estimation reveal that our econometric model has succeeded to demonstrate its applicability on financial reality. In this respect, we have deduced that numerous factors can explain the allocation and allotment of financial assets.

In the case of classification of the sample, the results have allowed us to draw an important conclusion to have cognizance that the volatility of the exchange rate is statistically significant for the newly-emerging economies at a threshold of 1 percent, while it is not quite mentionable for the developed countries. This means that this variable prevents American investors from investing in those countries, which is the case for both variables of Joint-variance and size. Another conclusion drawn from this estimation is that American investors prefer to overweight their share portfolios by the assets of foreign countries comparatively with the newly-emerging ones.

In addition, there will be an interesting effect of investors' behavior in the matter of choice of assets. It seems quite important, then, to identify the impact of the behavioral approach upon the issue of home bias. In this respect, an interesting track for such kind of study would be to include the behavioral factors in the explanation of home bias, which will be the object of contemplation for future researches.

# Chapter 57
# Dilemmas on OFDI Measuring and Interpreting: The Case of Poland

**Agnieszka Kłysik-Uryszek**
*University of Łódź, Poland*

**Anetta Kuna-Marszałek**
*University of Łódź, Poland*

## ABSTRACT

*Foreign direct investments (FDI) seem to have been thoroughly studied in specialised literature. However the scope of available statistical data often significantly hampers or even prevents any in-depth analysis of the phenomenon. The dynamic economic processes lead to the formation of new linkages, new organisational solutions in international enterprises that co-exist with well described and recognised forms of FDI but escape proper monitoring of statistical institutions. The chapter discusses the different concepts of measuring and interpreting FDI to provide researchers helpful guidelines how to deal with the problems of different methodological dilemmas. A main conclusion is that data provided by official statistics are insufficient and incoherent, and analysis of the scale of OFDI engagement of enterprises (especially from emerging countries) carries some risk and its results should be approached with caution. The case study of Poland's statistics has been used to portray the most significant discrepancies and problems.*

## INTRODUCTION

Foreign direct investment plays crucial role in contemporary economy; however, despite abundant theoretical and empirical writings on the subject many issues have still remained unclear or unclassified. Additionally, rapidly changing economic reality generates new business relationships in connection with international capital flows. These new flows not always fit already existing FDI classification framework

and thus cannot be reflected in theoretical considerations. Yet, they take place at significant scale and should be explored when it comes to their motives and economic effects. Hence, attention needs to be paid to indicators that measure and evaluate contemporary FDI.

Methodological difficulties connected with FDI analysis can be divided into two groups: statistical and formal. The first ones refer to inconsistencies between available statistical data (at national and international levels) and classifications described in official documents of international organisations (OECD, World Bank, UNCTAD, IMF) and in specialised literature, which provide the basis for analysing motives and assessing effects of investment. Despite many publications that offer detailed description and categories of international flows of capital (OECD 1999, OECD 2005, IMF 2004), national and international statistics often prevent any precise analysis of the phenomena due to over-aggregation of indicators or interpretation discrepancies.

Second group of difficulties results from the absence of theoretical considerations and in-depth cognitive surveys of different types of FDI (especially non-manufacturing ones). Numerous theoretical concepts that discuss FDI at micro scale focus predominantly on relocation of industrial operations and leave services, support to export or financial sector out. The main research problem concerns the interpretation of financial flows, which account for a growing share of FDI flows. And it is not just about establishing special purpose entities abroad to achieve tax optimisation but also about large scale investments made by investment funds (i.e. M&A). On top of that, balance of payments-based macroeconomic statistics classify as FDIs not only primary investment (in foreign affiliate equity and reinvested profit) but also intra-corporate loans used to support related companies. These FDIs are also out of the mainstream of theoretical considerations but they significantly impact overall FDI amount (in particular OFDI from countries such as Poland) and investment position of countries.

The goal of the chapter is to put in order all FDI-related lack of clarity at micro and macro levels; it also draws attention to serious inconsistencies between theoretical considerations that explain FDI specificity and the reality revealed by available statistical data.

The chapter is composed of the following parts: the Background gives a general outlook at selected methodological problems connected with FDI analysis. It identifies difficulties and discrepancies in definitions, collection and presentation of statistical data, as well as main problems of how theoretical concepts of FDI (motives, investment modes and effects) translate into real position of investors and countries.

Main focus of the chapter has been laid on the exemplification of the above mentioned problems and inconsistencies using the case of OFDI from Poland. The authors provide a general outlook at the available sources of data and discuss individual challenges faced by researchers who wish to explore reasons and effects of Poland's OFDI. Then, propose solutions and recommendations, as well as future research directions. Main findings are summarized in Conclusions.

## BACKGROUND

FDI is an important category in international accounts, and one of the five functional categories used as the primary basis for classifying data on financial transactions, positions, and income (Kozlow 2011, p. 27). Unfortunately, the quality of FDI data remains unsatisfactory and apparently the collection of high quality data on inward and outward FDI is a challenge to statisticians and researchers, which has been raised as an issue since the 1990s (Cantwell 1992). The problem becomes particularly clear when we

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

compare FDI in international and national economic accounts. The lack of reliable statistical information and inconsistency in data collection and reporting methods of many countries complicate studies and make impact assessment difficult. Besides, it limits the ability of policymakers to formulate appropriate FDI policies and strategies (Fujita 2008, p. 108). Timely and reliable statistics are the key if they are to be used as tools by decision makers and potential investors.

For example, in principle inward FDI and outward FDI across the world should balance. However, due to differences in the interpretation of FDI definition, various ways of calculating and the compilation and reporting of statistics, they rarely do (Table 1). Lack of balance between global inward FDI (IFDI) and outward FDI (OFDI) flows is also due to the so called "capital in transit", treated as a separate category by very few countries, which does not improve the transparency of generally available statistics.

Many studies highlight the "problem of limited generalizability due to the idiosyncratic and country-specific nature of the subject" (Bellak 1998, p. 253).

At microeconomic level FDI analysis relates to the theory of international manufacturing and it focuses on the investing enterprise. FDIs are undertaken in order to conduct a long-term control over an enterprise located abroad. This "lasting interest" is usually defined as direct or indirect ownership of equity that entitles it to the minimum of 10% voting rights (i.e. of ordinary or voting shares) in the direct investment enterprise.

Investors may create independent economic entities from scratch (*greenfield* investments) or by taking over the control of an already existing enterprise (*cross-border acquisitions and mergers)*[1]. Sometimes *joint-ventures*, where the new entity is created together with a national partner may be isolated out of a *greenfield* investments. Among the acquisitions there are *brownfield* investments. Their aim is to modernize and restructure an acquired enterprise into a competitive entity through its development, replacement of equipment and technology and often also human resources and assortment. In transformation economies, including Poland, *brownfield* investments are most often connected with the privatization of state enterprises.

Referring to main definitions, FDI capital flows are made up of three basic components: (Navaretii, Venables 2004, p. 285):

1. Equity capital, which comprises equity in branches, all shares in subsidiaries and associates (except non-participating, preferred shares that are treated as debt securities and are included under other direct investment capital) and other capital contributions such as provisions of machinery, etc.;

*Table 1. Imbalance between global (world) FDI inflows and outflows, 2010-2015 (millions of USD)*

| Year | FDI Inflows | FDI Outflows | FDI Inflows - FDI Outflows |
|---|---|---|---|
| 2010 | 1 388 821 | 1 391 918 | -3 097 |
| 2011 | 1 566 839 | 1 557 640 | 9 199 |
| 2012 | 1 510 918 | 1 308 820 | 202 098 |
| 2013 | 1 427 181 | 1 310 618 | 116 563 |
| 2014 | 1 276 999 | 1 318 470 | -41 471 |
| 2015 | 1 762 155 | 1 474 242 | 287 913 |

UNCTAD, WIR 2016, p. 196.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. Reinvested earnings consisting of the direct investor's share (in proportion to direct equity participation) of earnings, no distributed, as dividends by subsidiaries or associates and earnings of branches not remitted to the direct investor;
3. Other direct investment capital or intercompany debt transactions, meaning capital involved in debt-generating transactions within a multinational corporation; these are debt securities and trade loans between parent company and its foreign affiliate. It should be stressed that need to stress that these long-term loans may be provided at lower than current market rates.

However, in many cases non-financial involvement (such as participation in management process, membership in advisory board, technical, know-how or organizational support) is decisive for the effects and success of an investment. Unfortunately, while financial engagement of an investor in a foreign entity is quantifiable and, to a certain extent, reflected in national and international statistics, there are no statistics or measures that would describe other (non-financial) engagement of an investor (although theoretically, e.g., the value of available technology or know-how could be calculated).

At macroeconomic scale FDIs are one among types of international capital flows and belong to the balance of payments. Earnings on FDI are often a major component of property income from abroad in the distribution of income accounts. FDI stocks are reflected in current and financial accounts. In the first case they include income of foreign direct investors that can be divided into income from shares in corporate equity and income from other debts. FDI on financial account comprises: capital inflows from cash purchases of shares and stock, in-kind capital, injections of capital, reinvested profits and the balance of other receivables and liabilities (Golejowska 2008, p. 13). There are various ways in which countries collect and process statistical data pertaining to FDI flow and stock. The most important of them include: 1) international transactions reporting system (ITRS) that uses records of bank transactions of foreign economic operators – most often used by central financial institutions (e.g. central banks) to produce the statistics of the balance of payments, 2) enterprise surveys, most often deployed by central statistical offices, and 3) administrative sources such as investment promotion agencies, tax revenue offices, security exchange offices.

Incompatibility of presented data is, unfortunately, the main obstacle. With respect to FDI value, the fullest picture can be obtained from balance of payments statistics as they include all transactions within a given economy. However, the level of aggregation (adequate for data in the balance of payment) totally ignores data relating to decisions and outcomes of investments made by individual enterprises, the element highlighted in data from enterprise surveys. Other sources of data cannot be unambiguously classified and they usually limit themselves to, e.g., data on the biggest investments made in cooperation with a particular entity (promotion agencies). Additional research problem may also consist in lack of access to specific data (e.g. originating from tax agencies) – some institutions that do not manage statistical data but have access to them within the scope of their operations, do not present data in collective reports and do not make them available to external entities even upon special request.

To sum up, a number of difficulties associated with measuring FDI could be indicated. The most relevant of them include (Bürgi-Schmelz et al. 2010, p. 7; Kozlow 2011, p. 31)

1. Identifying the units that meet the definition of a direct investor, direct investment enterprise, and fellow enterprise;

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. Differences in the level of consolidation between business registers, particularly where different registers are used in international and national accounts. It often happens when separate agencies are responsible for compiling data. For example, for national accounts, countries often include each individual enterprise into national registers, while for international economic accounts countries often consolidate domestic units that are under common control for statistical purposes. That may produce inconsistencies in how direct investors, direct investment enterprises and fellow enterprises are classified by industry sector in national and international economic accounts;
3. Conducting a survey, in which respondents provide data according to the concepts used in direct investment;
4. Ensuring that direct investment equity position data reported by the direct investor are based on information from the books of the direct investment enterprise abroad. In other words, information on equity holdings is often not recorded on the same basis by the direct investor and its direct investment enterprise;
5. Estimating reinvested earnings of direct investment enterprises, especially on a timely quarterly basis. On many occasions, information on reinvested earnings is available only after a very long delay, and then sometimes only for annual data.

Despite attempts to master statistical systems on FDI they are still full of gaps and their quality is questioned by many researchers. According to Bellak (1998), international standards are often either neglected by those who collect data on FDI or they are too complex to fulfil. Harmonisation of various FDI-related definitions and statistical systems for collection and presentation of FDI data is going on. The same can be said about what international corporations are doing but important discrepancies remain, even among developed countries (Fujita 2008, p. 108). Measuring FDI is a difficult task especially in transition economies. These difficulties are also reinforced by the transformation of statistical systems (von Westernhagen 2002, p. 208).

According to UNCTAD (2006), in some developing and transitional economies additional difficulties emerge. Much FDI are transactions referred to as "round tripping". They consist in capital exports by domestic agents and their return as FDI, which results from, e.g., bureaucratic and tax difficulties faced by enterprises in their home countries. Investment abroad gives them some freedom to continue investing domestically or abroad. The practice is the result of financial incentives intended exclusively to foreign investors, lack of effectively operating institutions that could intermediate the funds domestically and better protect ownership rights abroad. "Round-tripping" is quite a widespread phenomenon (Borga 2016), it can be witnessed, e.g., in China (Geng 2004; Garcia-Herrero, Xia, Casanova 2015) or Russia (Ledyaeva, Karhunen, Whalley 2013).

## SELECTED "ORGANIZATIONAL" ISSUES

Although FDI account for a large portion of international investment, not all investments are really "direct". Hence, to analyse it, we first of all need to study types of transactions and entities that conclude them. Against this background, identification of investor's motivation is also important as that is the initial criterion that distinguishes direct investment from other types of international investment (e.g. portfolio investment). As it has been already mentioned, FDI include both initial transactions between two operators and any later capital transactions between them and related companies, whether they are legal persons or not.

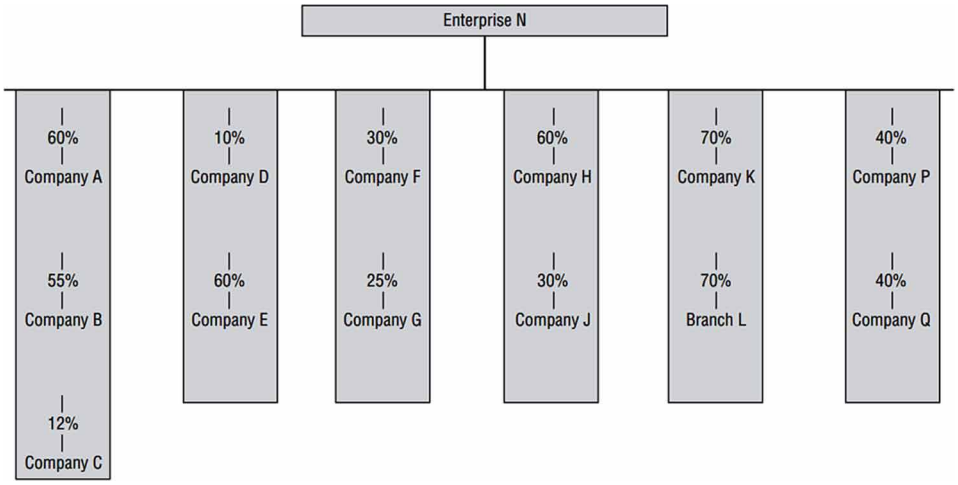
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sometimes enterprises from different countries establish relations that carry some FDI characteristics, even when formally they are not related (two enterprises in two different countries that have the same Management Board, units responsible for the strategy and joint funds but none has got the minimum 10% share in the other). Under such circumstances enterprises are tied not with any direct investment but rather with broadly understood capital links. In some countries FDI statistics cover just loan-based relationships between a parent and a daughter company while in other all links among entities within a capital group. On the international scale this problem had been discussed and solved in Benchmark Definition of Foreign Direct Investment 4th ed. (OECD 2008), but the guidelines have not been implemented into all the national statistics yet.

Nonetheless, at this point attention should be paid to general FDI breakdown on organisational side. An enterprise Embarking on FDI may hold shares abroad in:

- Independent economic operators (legal entities) as
  - Subsidiary companies with more than 50% of investor's share in equity capital,
  - Associate companies with up to 50% (but more than 10%) of investor's share in equity capital,
- Operators who formally belong to the investor (i.e. without legal personality) as
  - **Branches:** Units authorised to conduct the same activities as the parent company,
  - **Representations:** Unit whose responsibilities are limited to representation, promotion, marketing and trade activities performed for the parent company.

Sometimes FDI may be a simple and straightforward structure but it may also be a maze of very complex relationships. In accordance with international standards, statistics on outgoing and incoming direct investment should cover all enterprises owned directly and indirectly, with and without legal person that meet certain criteria (i.e. all dependent and related companies, as well as their affiliates). Full scope of direct investment relations allows to use the so called „*Fully Consolidated System*" (FCS) recommended by international organisations (e.g. OECD, IMF, and UNCTAD). This subject has been extensively discussed in literature (OECD 2005, IMF BOPCOM-04/32). Examples of its practical applications are presented in Fig. 1.



According to the FCS the example presented in Figure 1 could be analysed as follows (OECD 2005, pp. 51-52):

- Company A is a subsidiary of N. Company B is a subsidiary of A and thus a subsidiary of N even though only 33% of B is indirectly attributable to N.
- Company C is an associate of B and, through the chain of subsidiaries A and B, of N as well, even though only 4%of C is indirectly attributable to N.
- Company D is an associate of N, Company E is a subsidiary of D and thus an associate of N even though only 6% of E is indirectly attributable to N.
- Company F is an associate of N and G is an associate of F, but G is not an associate of N.
- Company H is a subsidiary of N and Company J is an associate of H and thus an associate of N.
- Company K is a subsidiary of N and L is a branch of K and thus of N.
- Company P is an associate of N and Q is an associate of P, but Q is not an associate of N.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 1. Application of the Fully Consolidated System*
*OECD 2005, p. 52.*

The above analysis shows that FCS-based FDI statistics would cover enterprises A, B, C, D, E, F, H, J, K, L and P but would exclude G and Q. The method is neither easy for researchers (Gregorová 2005) nor is it free of disadvantages (IMF 2004), however, it is often recommended in practice to identify an indirectly owned direct investment relationship. As an alternative, the "*US Method*" (USM) could be used. The USM excludes (the FCS may include) foreign enterprises in which the direct investor has less than a 10% equity interest but it includes (and the FCS excludes) associates of associates in which the direct investor has 10% or more equity interest. In the example in Figure 1 the USM would exclude companies C and E but include Q.

In this context, the problem of overlapping investment is also very important. If that is enough to have more than 10% of equity capital of an affiliate to establish a FDI relationship, therefore one FDI venture can become a FDI of several direct investors. Thus, firstly we may not unambiguously identify investor's home country, which prevents precise analyses that would consider geographical distribution of FDI (directions of capital flows, motives and effects of investments undertaken by investors from one country in another, etc.); and, secondly, at international scale we will have statistical inconsistencies. Investors declare their affiliated entities while statistics in the host country will show only one entity with the involvement of foreign capital.

The above described problems are largely true of transition economies (including the Central and Eastern Europe countries) although most direct investors from these countries are at first stages of active internationalisation and they develop little extensive structures where capital relations are easily detectable. However, these countries also host MNE-dependent entities with complex capital structures, which (as residents) make further direct investment (chain ones). Thus, they directly impact the scale and structure of OFDI. Moreover, corporations originating from emerging economies are becoming increasingly stronger.

## THEORETICAL APPROACH VS. FDI REALITY

Relocation of economic activities (i.e. FDI) is economically justified as the market experiences numerous distortions, such as (Witkowska 1996, p. 37): market imbalances, distortions generated by government and international institutions, imperfect market structure and market inefficiencies that perpetuate differences in availability (and prices) of production factors at international level. That is why rationally operating enterprises decide to engage in foreign direct investment in order to discount potential benefits of having a network of enterprises or affiliates in various market and business environments and to optimise the performance. Improved efficiency, the fundamental goal of foreign investment, may be achieved, inter alia, by reducing the costs of manufacturing and distribution, expansion of the scope of operation (increased sales), risk reduction through geographic and sectoral diversification of activities. Literature identifies two main types of foreign direct investment, depending on global strategy of a given enterprise:

- Vertical investment,
- Horizontal investment.

They have been distinguished based on empirical observations and theoretical studies. The starting point comes from theories of multinational enterprise and foreign direct investment[2] initially based on neoclassical assumptions and then on the assumptions of new trade theory[3]. Unfortunately, despite extensive theoretical writings on potential consequences of specific types of investment, we have no indications as to how allocate investments to specific types. Ability to precisely examine vertical and horizontal FDI relations could importantly help to identify relationships between FDI and trade, crucial for wider studies of economic growth. It is even more important because vertical and horizontal investments produce different effects not only in host countries but also in home economies. Vertical investment generates international trade flows between the parent company (or at least related companies) and a foreign entity. Under favourable circumstances, it may not just prevent the reduction of capacity output and employment in the home country (caused by capital exports) but stimulate increased production of goods that are further used as components in the production of a foreign affiliate. Similar scenario may develop when an investor establishes a representative office abroad to assist export.

Totally new effects can be produced by horizontal investment intended to substitute export. The situation is much less favourable for investor's economy as it limits production in the home country and may reduce employment and income. M&A in new sectors of economy undertaken to diversify risk have relatively the least impact upon the home economy. Such foreign investments can be treated as lost investment opportunities at home.

Obviously, it should be stressed that the problem consists not only in developing appropriate measures to identify production relations between an investor and a foreign entity (where the scale of vertical trade relations between the parent company and related companies within capital group can be used as an approximant) but also in the difficulty to identify dominant nature of a concrete investment. In practice, extensive production structures of MNEs unable simple classification of performed on operations they actually pursue.

Investments made by investment funds pose another interpretation problem in particular in the context of FDI analysis as a type of international production pattern. These funds often acquire enterprises operating at international level and as such they count as FDI flows. However, their motives and, first of all,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

investment directions go beyond FDI concepts that can be found in literature. Their actions more often coincide with conclusions of portfolio investment theory. Similar things can be said about big financial holdings – their investments, although often classified as FDI (since they exceed the 10% threshold), result from macroeconomic mechanisms of the financial market rather than from production location abroad.

A relatively new phenomenon in MNEs growth is the expansion of organisational structure with geographically dispersed special purpose entities. Usually they are established to optimise financial effect of assets management (e.g. when a given economy offers favourable tax arrangements connected with a particular business profile), tax optimisation or, e.g., seeking financial resources in international markets (e.g. stock issued in international stock exchanges). Such operations are especially easy within integration groupings where there are no legal limitations in establishing a new entity abroad or where difficulties are reduced to minimum. At theoretical level, such operations can be attributed to "efficiency seeking" motivation, however, they are hard to explain with international production concepts or models of stage or network internationalisation.

Deepened analyses of investment operations are seriously impeded by chain investment made by MNEs' affiliates, which are formally residents of a given economy. Their investment operations result from decisions, resources and competitive advantages of the corporation, not just the affiliate based in a given economy, which can be analysed in the light of internationalisation of enterprises. Yet, these operations hinder the life of researchers who explore investment operations of companies from transition economies. Their investments are often much bigger and more "advanced" than it would be expected from economic development of the home economy. Thus, by trying to anchor the analysis in macroeconomic FDI concepts (models of Ozawa, Investment Development Path by J.H. Dunning or even R. Vernon's international product life cycle) we may draw erroneous conclusions as to the general level (stage) of economic development and advantages of an economy.

## METHODOLOGICAL PROBLEMS OF OFDI STUDIES IN POLAND

Despite increasing interest in Poland's OFDI, access to complete and reliable statistical data about companies engaged in internationalisation is very limited. Analysis of the methodology used to collect and process published data calls for a cautious assessment of reality. It is not possible to directly compare data in available statistical sources.

Data on foreign direct investments undertaken by Polish enterprises under the Polish reporting system come, in principle, from two sources: the National Bank of Poland (NBP) and the Central Statistical Office of Poland (GUS). General comparison of the data provided by the two is presented in Table 2. All international sources, such as Eurostat, IMF, UNCTAD, OECD use data supplied by the Polish reporting system, i.e., effectively by NBP and GUS.

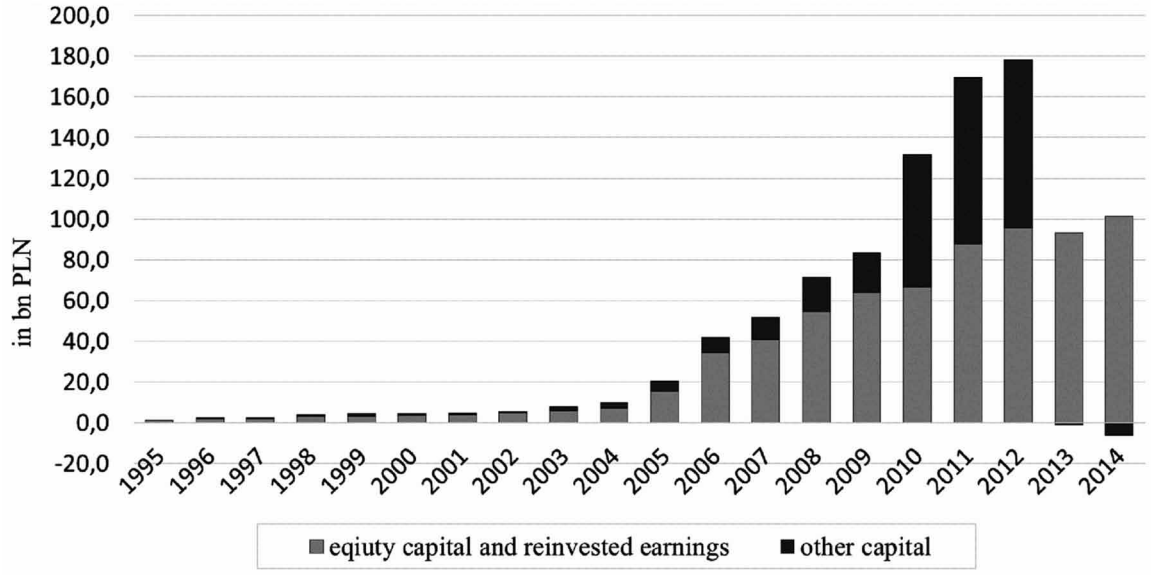
NBP data – due to the specificity of how data are collected from the balance of payments statistics – give information about the values of all financial flows (i.e. initial equity investment, intra-group loans, reinvested profits and other income of direct investors) broken down by geographic regions, industries and sectors. Moreover, they provide both stock values and yearly flows. Nevertheless, we should be careful when combining these values as the sum of flows in subsequent years does not add up to the overall stock value. It connects, inter alia, with the present market evaluation of assets held by Polish investors and the changing exchange rate.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The second source of information, not necessarily about FDI but about investors with holdings in foreign entities, is periodical publications of the Central Statistical Office of Poland. These data are collected and made available since 2009. They come from annual statements of economic operators that must be submitted by all operators active in Poland. This method of data collection helps to analyse the effects of foreign subsidiaries' operations (employment, revenue from sales, foreign trade, including trade with related operators within capital group). However, they do not provide any information about the value of investments (neither about the initial investment nor later capital flows between the parent company and its related entities). We also need to bear in mind that GUS is not able to require statistical data from companies who do not comply with the reporting requirement and it cannot verify the accuracy of provided data. As a result, it has got data concerning companies that voluntarily provided them. Hence, data published in individual years and reports differ and generally may somehow be underestimated. That is due to the unwillingness of economic operators, in particular small ones (to whom the need to fill in long questionnaires means a considerable time burden) to provide data.

Another serious inconsistency in NBP and GUS data, which makes direct comparison of the two sources impossible results from the scope of entities obliged to submit statements. The NBP data include all operators within the national economy while the GUS area of competence excludes the financial sector. Therefore, in order to realise the scale of Poland's OFDI one should rather use NBP data. Figure 2 presents cumulated value of Poland's OFDI. It can be clearly seen that significant intensification of international involvement of enterprises took place after 2004. In the record-breaking 2012 cumulated investment amounted to ca. 12% GDP.

*Table 2. Comparison of the scope of statistical data on OFDI: GUS and NBP*



| Measure | | GUS | NBP |
|---|---|---|---|
| Value of OFDI (Position) | Of which:<br>• Equity capital investment<br>• Reinvested earnings<br>• Other capital (intracompany loans) | - | + |
| OFDI yearly outflows | | - | + |
| Data in PLN | | + | + |

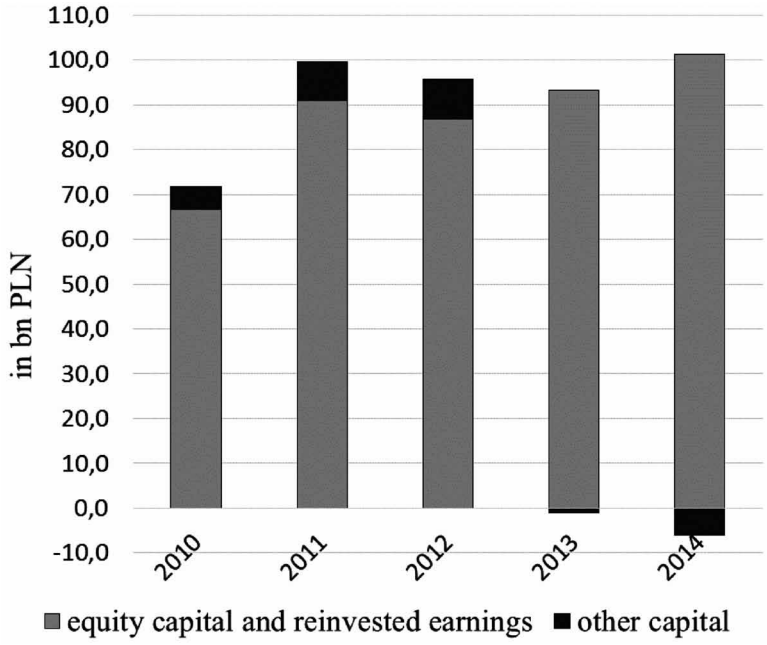
*Figure 2. Poland's OFDI according to NBP (in bln PLN)*
*Authors' own compilation based on NBP data.*

Still, closer analysis of Poland's OFDI shows the need of sceptical/cautious assessment of these significant values. Firstly, subsidiaries and associates of multinational enterprises located in Poland also enjoy resident status in Polish economy. Thus, their investments, which are in fact chain investments, are reflected in NBP and GUS statistics as Poland's OFDI. It may slightly complicate the examination of regulations governing Polish foreign direct investments since not all of these investments result from the competitive merits of affiliates operating in Poland but from ownership advantages and the strategy of the corporation. Hence, they may be independent of the economic development and current economic performance of the country. Unfortunately, neither NBP nor GUS give information about the direct scale of engagement of Polish affiliates of multinational corporations in FDI.



Secondly, a large part of OFDI represents „other capital", meaning intra-corporate loans. Studies demonstrate that to a large extent the loans were granted by affiliates of multinational enterprises to parent companies based in Western Europe. In the times of crisis Polish subsidies were the source of capital to the "Western economy".

More attention should be paid to methodological problem with the continuity of data (in data for the years 2010-2012). In 2010 the approach to "other capital" changed and started to include not only net loans granted directly to parent companies but all other forms of support made available to related entities within capital group, i.e. also those where non-resident was a dominant entity. This change produced significant increase in "other capital". Three years later this interpretation was given up and loan-based relationships with non-resident as a dominant party and entities operating within a capital group were transferred to IFDI account. Considerable drop in „other capital" may also be attributed to partial repayment of debt incurred earlier or to big liabilities of Polish companies vis-a-vis their „daughter" companies based abroad through which investors raise capital from bonds issued in the European market (NBP 2016). In connection with this change, NBP made available a new time series reviewed since 2010 in accordance with new guidelines – see Figure 3.

*Figure 3. Reviewed Poland's OFDI according to NBP*
*Authors' own compilation based on NBP data.*

Summing up, while amounts in statistics are significant, most of them are dedicated to support exports, investment in financial sector or chain investment of multinational enterprises (including intra-corporate loans). Therefore, there are many OFDIs but in reality they do not stem from advantages referred to in theoretical FDI concepts.

Comparison of GUS and NBP data in sectoral (Table 3) and geographical (Table 4) breakdown provide interesting information about the structure of Poland's OFDI. Of course, different scopes of data are very important: GUS provides information about investors' economic activity while NBP gives the value of investment.

The comparison of sectoral OFDI structure applied by GUS and NBP reveals two principal issues. Half of Polish foreign investments are made by operators from the financial sector and thus are completely ignored by GUS. As it has been already mentioned, the mechanism of such investments is totally different than for investments of non-financial sector. Considering general development level of Polish economy and the structure of entities from the financial sector (largely based on foreign capital) one may assume that to a large extent these investments result from decisions of international financial operators (banks, capital or insurance funds). Hence, we should not attach to much importance to this component of Polish foreign investment in the context of macroeconomic assessment of Poland's development (e.g. to calculate NOI indicator in accordance with the concept of IDP J. H. Dunning).

By excluding investments of the financial sector from comparative analysis one should, in principle, bring sectoral investment structure (according to NBP) to the structure of investors and their foreign entities (according to GUS). Relative shares of investments of individual non-financial sectors according to NBP would then be twice as high as those presented in Table 2. Assuming, with some caution, that populations of entities based on which GUS and NBP organised their statistics are similar, one may try

*Table 3. Sectoral structure of Poland's OFDI in 2014 according to GUS and NBP*

| | GUS | NBP |
|---|---|---|
| Total | 1645 Investors | 95 237.9 bn PLN |
| **Mining and extraction** | 0.7% | 5.1% |
| **Industrial manufacturing** | 35.1% | 14.1% |
| Manufacture of food products, beverage and tobacco products | 3.3% | 1.0% |
| Manufacture of coke and refined petroleum products | 1.8% | 2.9% |
| Manufacture of pharmaceuticals | 4.0% | 0.9% |
| Manufacture of metals and fabricated metal products | 7.5% | 2.4% |
| Manufacture of electric devices | 3.0% | - |
| Manufacture of cars, trailers and semi-trailers | 0.5% | 3.4% |
| **Manufacture and distribution of electricity, gas, steam and air** | 1.0% | -5.4% |
| **Construction** | 10.8% | -1.0% |
| **Wholesale and retail trade; repair of cars and motorcycles** | 20.7% | 6.5% |
| **Transport and warehousing** | 3.9% | 1.2% |
| **Information and communication** | 5.5% | -11.0% |
| Activities connected with production of films, video recording and TV shows, other entertainment activities | - | -4.8% |
| Telecommunications | - | -7.9% |
| **Finance and insurance** | 4.5% | 50.4% |
| Operations of financial holdings | - | 39.0% |
| **Services to real estate market** | 3.6% | 1.2% |
| **Professional, scientific and technical activities** | 8.1% | 14.4% |
| Head offices operations | - | 9.8% |
| Management consultancy | - | 4.2% |
| **Administration and support services** | 3.6% | 14.1% |

Authors' own compilation based on GUS and NBP data.

to identify how much capital-intensive are investments in individual sectors. For example, manufacturing companies account for 1/3rd of all investors from non-financial sector and they invested ca.30% of total Poland's non-financial OFDI. Entities from mining and extraction sector represented only 0.7% of all investor but value of their investment is almost 10% of all OFDI. That is indicative of high capital-intensity of their ventures. The same can be said about the section "Professional, scientific and technical activities". Operators in this section account for ca. 8% investors but their investments exceed 28% of all Polish non-financial investment. Of course, these conclusions are very general and carry high risk of error. Significant differences in the methodology of data collection do not allow formulating universal conclusions even if the structures are compared.

Analysis of investment directions according to standards applied by GUS and NBP also reveal serious differences. In this case, any comparison is even more difficult as we may not remove the financial sector from the analysis of NBP data because the NBP does not inform where these investments are

Authors' own compilation based on GUS and NBP data.

directed. Based on general knowledge and external data we may expect that large portion of these flow to financial centres in Europe: Luxembourg, Switzerland, and United Kingdom (London). These locations dominate in NBP reports but they are not indicated in GUS statistics.

If we omit investments in countries perceived as financial centres or offering preferential financial terms (e.g., in taxation such as Cyprus), we can clearly see Polish investors' interest focusing mainly on neighbouring countries. They are interested in German, Czech, and Lithuanian markets. Many affiliates have been established also in Ukraine and Russia, however, the value of these investments is small.

To complete the picture, it should be mentioned two more issues that hinder studying investment-related activities of Polish investors based on data originating from GUS and NBP. The first is the problem with access to panel data. Confidentiality of statistical data introduced by virtue of binding legislation in Poland forbids publishing data when aggregated in a way that would enable the identification of data concerning a particular company. In practical terms, it means that the statistical office (GUS) may not make sectoral or sectional data available when there are fewer than 4 entities or when an operator's dominant position is strong enough to determine indicators for all of the group. NBP does not publish

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

any data disaggregated to the level of groups of enterprises. It seriously impedes studying FDI in Poland using econometric methods since to do that, in most cases, we need panel data, and in Poland building such a time series is impossible.

The second problem consists in the absence of possibilities to trace investors' activities in foreign entities. Generally available GUS statistics organise company-related data by investor or foreign entity's PKD (Polish classification of economic activities), however, it is not possible to directly trace whether an investor in his foreign affiliate replicates his principal activities or whether he focuses on other business activities (industries). Thus, one does not know if, e.g., manufacturing companies manufacture the same products in their dependent entities or if they deal with manufacturing at all (or perhaps just trade or act as special purpose vehicles established to acquire additional funds or for tax optimisation purposes).

## SOLUTIONS AND RECOMMENDATIONS

Identified inconsistencies and gaps in available statistical data make us approach all results of studies with caution and require good knowledge about the basis on which conclusions have been drawn. The scope of data and potential exclusions may considerably impact the picture. Hence, the attention is to be paid to the methodology of data collecting used in particular studies and avoid direct comparisons.

Dynamically changing international business relations, expanded activities of international corporations, and globalisation favour new organisational and financial solutions between economic operators. Many of them are close to internationalisation, which forces out changes in the approach to definition and classification of FDI, as well as notions used to describe firms involved in direct investment. Theoretical achievements connected with the analysis of the phenomenon should be the closest possible to what actually happens in economy.

Besides, it seems justified to collect data for the same time, i.e. data on business activities in different countries should reflect the situation as at the end of calendar year. Data collected either for the beginning or for the end of fiscal year (which may be different for each country) may impact their comparability at international level. Besides, for many enterprises, information on reinvested earnings is available only after a very long delay and thus early estimates are subject to considerable change when more complete data become available. Uniform time, for which data are collected facilitates comparisons not only at international but also at national level.

It is also important to collect data for the same degree of consolidation of accounts in multinational enterprises (e.g., if in a given country data on the number of dependent entities are collected based on consolidated accounts while other data are taken from non-consolidated accounts we are not able to compare the variable which is subject to analysis) and to distinguish between direct and indirect control. Some countries do not treat all investments on an equal footing that is why we need to harmonise the rules.

It is also worth mentioning that statistical data must be allocated to places where investor's business actually takes place, not to his headquarters (Domański 2002) – but this postulate seems the most difficult to comply with. In most cases it is impossible to unequivocally identify the location where business takes place, especially when we deal with investment in the financial sector.

## FUTURE RESEARCH DIRECTIONS

Insufficiencies with respect to the scale and structure of published data on foreign investors' activities seriously hinder (or even prevent) any reliable assessment of investors, as well as the impact of OFDI on both home and host economy. OFDI is important enough for the economy to justify its in-depth studies aimed at developing the best rules of FDI policy. All parties are interested in achieving maximum benefits.

Two main directions of action can be suggested: firstly, we should try to conduct as much research as possible based on available data and try to work out new indicators that would help learn more about the specificity of Poland's OFDI. On top of that, studies could be supported with other research methods, e.g., questionnaire-based studies in enterprises or, to a certain extent only, econometric analysis. (Świerkocki et al. 2015; Kłysik-Uryszek, Kuna- Marszałek 2015, 2016). On the other hand, we should identify gaps in available data to mobilise reporting organisations (GUS and NBP) to go more in-depth in their OFDI related research and to provide increasingly more detailed data. It seems necessary to improve interpretation and classification of terms and to unify the collection and presentation of statistical data by different institutions.

Since most issues discussed in this chapter are universal, it would be advisable to reporting institutions from other countries to expand their statistics to achieve the most complete and coherent internationally available data (from international institutions) and to enable the widest possible international comparative studies.

## CONCLUSION

Over twenty five years of economic transformation in Poland, including radical stabilisation, liberalisation and institutional reconstruction, have widened the scope of economic freedom, promulgated private ownership and rationalised economic operations. Foreign direct investments, both IFDI (Kłysik-Uryszek 2010; Świerkocki ed. 2011; Michałek, Brzozowski, Cieślik 2012; Wydmus, Bombińska, Pera 2012), as well as OFDI, especially after EU accession, (Karaszewski ed. 2013, Gorynia, Nowak, Wolniak 2010, Kłysik-Uryszek 2013a, 2013b; Gorynia et al. 2014; Buczkowski et al. 2015) played fundamental role in the process.

However, despite many discussions, interest of international organisations and broad literature concerning FDI, the data provided by official statistics are still insufficient and incoherent. Two sources of data about Poland's OFDI – GUS and NBP provide divergent data about investments and, unfortunately, cannot be freely combined or used in joint studies. Analyses conducted based on NBP data show the value and scale of investments, sectors from which capital has been exported and countries, to which it has flown. GUS, in turn, provides data on investors' activities rather than on the value of investment. However, it should be stressed that GUS data come from statements submitted by companies and data included in them are not verified. Moreover, not all enterprises comply with the reporting requirement thus we may expect that statistics published by GUS are largely underestimated. Analysis of the scale of OFDI engagement of Polish enterprises carries some risk and its results should be approached with caution. On top of that, many aspects relevant from the viewpoint of the specificity of Poland's OFDI are missing from these reports. We mean here types and forms of foreign investments and their importance to parent companies, as well as the scope of ties between investors and MNEs, which may impact the scale of chain investments.

## KEY TERMS AND DEFINITIONS

**Balance of Payments (BoP):** A statement that summarizes all economic transactions between the residents of the country and the rest of the world in a particular period (over a quarter of a year or more commonly over a year). It encompasses all transactions involving: goods, services and income; financial claims on and liabilities to the rest of the world; and transfers such as gifts.

**Economic Transformation:** Change of an economic system, in particular shifting from a centrally-planned to a market economy, based on a functioning free market, competition, and private business.

**FDI:** Foreign direct investment (outward – OFDI; inward – IFDI), the most advanced form of internationalisation of companies; FDI are undertaken to exercise a long-term capital supervision over an entity located abroad (branches or subsidiaries). Investors may create independent economic enterprises from scratch (*greenfield* investments) or take control over an already existing company (acquisitions and mergers).

**Foreign Entity:** An entity (affiliate company or a branch/representation) located in host economy in which a foreign investor has a long term capital supervision.

**Foreign Investor:** An enterprise (legal person) located in home economy that sets up an OFDI abroad in the form of independent entity, i.e. affiliate company (subsidiary or associate company) or branch/representation.

**GUS:** Main Statistic Office in Poland.

**Internationalisation of a Company:** Process, through which a firm moves from operating in a domestic marketplace to international markets.

**NBP:** National Bank of Poland.

## ENDNOTES

1. It is not the only division present in literature. An extensive discussion of other classifications of FDI is included in: *Strategie firm polskich wobec ekspansji inwestorów zagranicznych*, Gorynia (2005).
2. Overview of studies on the subject can be found in: Cieślik (2005).
3. The theory includes elements of market organisation, imperfect competition, product diversification and increasing revenues from scale. For new trade theory see: Cieślik (2000).

*This research was previously published in Outward Foreign Direct Investment (FDI) in Emerging Market Economies edited by Tomasz Dorożyński and Anetta Kuna-Marszałek; pages 40-58, copyright year 2017 by Business Science Reference (an imprint of IGI Global).*

# Chapter 58
# Facilitating Hospitality and Tourism Management in Global Business

**Kijpokin Kasemsap**
*Suan Sunandha Rajabhat University, Thailand*

## ABSTRACT

*This chapter explains the overview of hospitality management; the overview of tourism management; product quality, service quality, price, customer satisfaction, and consumer trust in hospitality and tourism management; the significance of hospitality management in global business; the significance of tourism management in global business; and the managerial implications of hospitality and tourism management. Tourism and hospitality industry is one of the most important industries in the modern business world. It is essential to acquire a driving enthusiasm for customer service and a strong sense of professionalism to develop and maintain customer satisfaction in the hospitality and tourism industry. Effective hospitality and tourism management positively affects customer satisfaction, firm growth, and productivity in global business. The chapter argues that facilitating hospitality and tourism management in global business has the potential to enhance organizational performance and reach strategic goals in the digital age.*

## INTRODUCTION

From a practical business perspective, hospitality and tourism management sector is one of the most important sectors in the global economy (Israeli, 2014). From an academic perspective, the perspectives of hospitality and tourism management are the interdisciplinary fields that focus on many areas, such as management, strategic management, human behavior, organizational behavior, finance, yield management, planning, and marketing (Israeli, 2014). Tourism contributes to the growth of regional economies, thus providing a source of income for both resident households and local firms (Incera &

Fernandez, 2015). Tourism is related to globalization and modernity (Wang, Niu, Lu, & Qian, 2015). Tourism is viewed as the development priority concerning government and international organizations (Tolkach & King, 2015).

Tourism has become one of the most growing service sectors in global business (Tang & Tan, 2015). Modeling tourism demand is important in countries where the income from tourism constitutes a considerable percentage of their gross domestic product (Akın, 2015). Tourism marketing can help facilitate the dynamic evolutions and the demands of tourism industry concerning the diversity of tourism marketing topics (Kasemsap, 2015a). The hospitality industry in many parts of the world is expected to realize the significant rates of growth in the next few years (Pirani & Arafat, 2014). Recognizing the importance of product and service quality, satisfaction, and trust every firm in the hospitality and tourism industry is becoming more concerned about managing and improving quality, satisfaction, and trust (Han & Hyun, 2015).

This chapter aims to bridge the gap in the literature on the thorough literature consolidation of hospitality and tourism management. The extensive literature of hospitality and tourism management provides a contribution to practitioners and researchers by describing the theory and applications of hospitality and tourism management in order to maximize the business impact of hospitality and tourism management in global business.

## BACKGROUND

Research with the tourism and hospitality management realms has reached a certain degree of maturity, demonstrated by researchers via both qualitative and quantitative methods (Köseoglu, Sehitoglu, & Craft, 2015). An emergent contemporary hospitality literature is dedicated to the methodological appraisal and development (Robinson, Solnet, & Breakey, 2014). There are a number of scholarly works published by researchers that investigate the domains of tourism and hospitality management (Tsang & Hsu, 2011).

Many studies map the intellectual structure of tourism and hospitality management-related disciplines, such as organization studies (Ferreira, Pinto, & Serra, 2014), general management (Tahai & Meyer, 1999), strategic management (Nerur, Rasheed, & Natarajan, 2008), international management (Acedo & Casillas, 2005), knowledge management (Ponzi, 2002), human resource management (Fernandez-Alles & Ramos-Rodríguez, 2009), business ethics (Tseng, Duan, Tung, & Kung, 2010), information systems management (Culnan, 1987), and operations management (Pilkington & Liston-Heyes, 1999).

Contributions of economics to hospitality literature are largely empirical and microeconomics-related (Mohammed, Guillet, & Law, 2015). Many researchers recognize hospitality management as a field of study with a mission of preparing students for successful careers in this industry and helping the industry solve its problems (Lugosi, Lynch, & Morrison, 2009). The focus of hospitality management research should be on instrumental research that addresses the main challenges of hospitality industry, rather than topics that have little practical implications (Pizam, 2003). Tourism affects economic growth (Jalil, Mahmood, & Idrees, 2013). The tourism sector has become the main source of income for many countries contributing to their economies, generating markets for a wide variety of goods and services both directly and indirectly related to tourism (Eugenio-Martin & Campos-Soria, 2011).

## PERSPECTIVES OF HOSPITALITY AND TOURISM MANAGEMENT

This section emphasizes the overview of hospitality management; the overview of tourism management; product quality, service quality, price, customer satisfaction, and consumer trust in hospitality and tourism management; the significance of hospitality management in global business; the significance of tourism management in global business; and the managerial implications of hospitality and tourism management.

### Overview of Hospitality Management

The hospitality industry is a major industry that combines the components of product and service (Israeli, 2014). Given that performance in the hospitality sector is a multi-dimensional construct, there are various recognized measure approaches (e.g., the balanced scorecard) that combine quantitative and qualitative performance measures (Kaplan & Norton, 1996). However, hospitality leaders often adhere to one paradigm (e.g., production or service) which title their management and decision-making style as production-oriented or service-oriented perspective (Harris, 1999). Israeli et al. (2006) stated that hotel managers may lack a clear vision about managing hospitality performance under production and service paradigms.

Competency models have become a meaningful method for determining requisite skills in both hospitality and tourism education (Chung-Herrera, Enz, & Lankau, 2003) and operations (Tas, 1988). Competency models can serve a wide variety of organizational functions and can help develop managerial skills (Testa & Sipe, 2012). Many studies have described significant competencies in the hospitality field (Johanson, Ghiselli, Shea, & Roberts, 2011). Hospitality researchers have continued to indicate the fundamental competencies and curricular needs perceived to be important by practitioners in the hospitality areas (Fjelstul, 2007). Researchers have compared how students, educators, and practitioners effectively perceive such competencies in order to determine whether there is the broad stakeholder agreement on the skills needed for various roles in the hospitality industry (Raybould & Wilkins, 2005).

Managers should learn through work activities (Marsick, 2003). Pre-designed educational programs and training courses limit learning that reflects constantly changing work practices. In the hospitality industry, the pre-planned approach utilizing information and communication technology (ICT) (e.g., learning management system) drives management development provision (Li, Buhalis, Lockwood, & Benzine, 2007). Hospitality leaders should utilize the learning management system and ICT applications in their daily practices toward gaining potential to facilitate their learning in the hospitality industry (Li, Lee, & Law, 2012). Modern organizations that emphasize employees' learning requirements can achieve business objectives through building knowledge, transferring knowledge, and applying knowledge in the learning organizations (Kasemsap, 2016a).

Service quality and customer satisfaction is the fundamental goal of tourism organizations that takes a strategic approach (McCole, 2004). Customer value is positively correlated with customer satisfaction (Kasemsap, 2014a). The balance of business and people-related competencies is required for effective service leadership (Sandwith, 1993). The managerial success is related to the constant development in the hospitality industry (Testa & Sipe, 2012). Self-development is the most influential issue for the hospitality leaders (Kay & Russette, 2000). Hospitality leaders should professionally act, effectively organize the service standard, and provide organizational value (Yoon, Beatty, & Suh, 2001).

## Overview of Tourism Management

Tourism is one of the most significant service industries in global business (Pérez & del Bosque, 2014). Tourism can be an impetus for the positive growth and economic success (Dodds & Kuehnel, 2010). However, if irresponsibly utilized, tourism can be a source for leakage, low fares and seasonal employment, instability and low job status, environmental degradation, displacement of local people, inflation, and the dilution of culture (Agarwal, 2002).

Sustainability has gained momentum in the tourism industry, where tourism organizations must play a role in the exercise of good governance practices (Martínez, Pérez, & del Bosque, 2013). Sustainability is considered as a multi-dimensional construct that equally emphasizes the economic, social, and environmental duties of companies (Panwar, Rinne, Hansen, & Juslin, 2006). Regarding sustainability, triple bottom line (TBL) include three dimensions (i.e., economic, social, and environmental perspectives) (Pérez & del Bosque, 2014).

The economic dimension is based on ensuring the feasible economic activities so that all stakeholders suitably receive the distributed socioeconomic benefits (Dyllick & Hockerts, 2002). The social dimension refers to the consideration for the cultural authenticity of host communities, the preservation of their architectural and living cultural assets and traditional values, and a contribution to intercultural understanding and tolerance (Dyllick & Hockerts, 2002). The environmental dimension refers to the optimal utilization of environmental resources, which is a crucial component of tourism development, protecting ecological processes, and conserving natural resources (Dyllick & Hockerts, 2002).

The academic literature contains the investigation of case studies of countries and tourist destinations that have sought to rebrand themselves by promoting cultural events, exhibitions, sports competitions and tourism (Lahav, Mansfeld, & Avraham, 2013). Kulendran and Dwyer (2009) indicated that investment in destination promotion and marketing has a positive effect on inbound tourism. The adoption of various public diplomacy means has limited effect when a destination is associated with risk due to war, violence, and instability (Taylor, 2006). The negative characteristics dominate the perception of the destination and harm its attempts to attract tourists (Avraham, 2015).

Tourism firms are required to adapt their strategies to fit the rapidly changing environment (Pechlaner & Sauerwein, 2002). A great deal of innovation is vital for tourism firms to increase their competitiveness through the establishment of new products, such as customization and ICT interaction (Sundbo, Orfila-Sintes, & Sorensen, 2007). Executive's human capital and social capital are important to provide a better quality of supervision of the strategic position of tourism firms to ensure that the firms are able to adapt to the changing environment (Ooi, Hooy, & Som, 2015). Regarding the increasing advances in technology, information technology (IT) and knowledge management applications effectively improve the strategic tools for providing the direct link between customers and tourism organizations, thus encouraging the communication channels in global tourism (Kasemsap, 2016b).

Although tourism development brings about a great deal of positive benefits, the residents of host communities can experience the negative socio-cultural changes in their daily lives (Jordan, Vogt, & DeShon, 2015). Theoretical frameworks (e.g., social exchange theory, power theory, and identity theory) are utilized to investigate the resident perceptions of, support for, and responses to tourism development (Nunkoo & Ramkissoon, 2012). Emotional and psychological well-being is an influential part of individuals' overall quality of life (Schalock, 1997). There is an increasing body of literature toward understanding how individuals' lives are affected beyond attitudes for tourism development (Kim, Uysal, & Sirgy, 2013).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Corporate social responsibility (CSR) is an innovative way to create value for society and tourism organizations (Starr, 2013). The aims of CSR in tourism management are to reinforce ties with community (Kasim, 2006), to engage with the social and environmental issues (Henderson, 2007), and to sustainably utilize tourism resources (Chhabra, 2009). Environmental protection and well-structured CSR strategies are the foundation of the environmental and socially responsible cultural tourism (Black, 2012), can help target the financial pressures experienced by heritage attractions which is expected to become more challenging (Garrod & Fyall, 2000).

Rural tourism, also called ecotourism, has been adopted by many countries in the world as one of the major rural policies to generate the rural vitality (Brandth & Haugen, 2011). Although there exists a fundamental debate about the driving agency of rural tourism, common understandings are converging to emphasize the importance of the public sector (Logar, 2010). Rural tourism is one of the major components representing the transition from an economy of production to an economy based on consumption in rural area (Woods, 2005).

Rural tourism is a composite of agricultural products, eco-products, cultural resources, and spatial amenities, involving diverse functions (e.g., economic, social, educational, environmental, recreational, and therapeutic activities) (Lee & Kim, 2010). Bel et al. (2015) stated that tourism has the potential to make a major contribution to the development of rural areas. Rural tourism facilitates rediscovering the values of rural resources that have been neglected in the modernization process of the world economy (Hwang & Lee, 2015). Rural tourism offers diverse implications for farm-based rural businesses and sustainable rural development plans (Lane, 1994).

## Product Quality, Service Quality, Price, Customer Satisfaction, and Consumer Trust in Hospitality and Tourism Management

Product quality, service quality, satisfaction, and trust are recognized as the important concepts in explaining customer post-purchase behavior (Han & Hyun, 2015). Researchers explain that these variables contribute to creating positive intentions toward affecting customer retention and loyalty (Han, 2013). Conceptualizations of the perceived quality of products and services differ little in the extensive literature, but an essential aspect of this concept is the process of evaluating the products and services offered by a specific company for excellence against alternatives provided by competitors (Han & Ryu, 2006).

Product quality and service quality involve the two major facets (i.e., core-product and service-product performances) (Bitner, Booms, & Tetreault, 1990). Quality of core product indicates the performance of the basic product relative to its value (Clemmer, 1990) while service-product quality suggests the performances derived from interactions with service personnel (Price, Arnould, & Deibler, 1995). Product quality and service quality contribute to building customers' behavioral intentions (Cronin & Taylor, 1992). Keeping existing customers is about five times more profitable than attracting new customers (Chiu, Hsu, Lai, & Chang, 2012) as the increased customer retention is likely to improve business's profitability (Jiang & Rosenbloom, 2005).

Price is an increasingly vital topic in the hospitality and tourism industry (Han & Hyun, 2015). Customers tend to utilize price reasonableness when evaluating their experiences with a product and service (Ryu & Han, 2010). Customers utilize the reasonableness of price as a cue when estimating their product and service experiences and organizing their attitudes toward the provider (Varki & Colgate, 2001). Individuals' judgments about whether a firm's price is reasonable or unreasonable result in negative decisions concerning the firm (e.g., deciding to spread the negative word-of-mouth) and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

increase price sensitivity (Oliver & Swan, 1989). Customers tend to remember the perceived price rather than the actual price after evaluating price reasonableness compared to the reference prices offered by competitors (Oh, 2000).

A considerable body of literature has indicated the significance of price reasonableness in explaining consumer behavior (Crozier & Baylis, 2010). In a hospitality context, Han and Kim (2009) stated that reasonableness of price importantly affects individuals' intention formation. Price perception (e.g., expensive or cheap and reasonable or unreasonable perspectives) plays an important role in customers' decision-making processes (Ryu & Han, 2010). Customers' perceptions of a firm's price reasonableness in comparison to its competitors' prices is central in building the enthusiastic intentions and loyalty toward a firm (Han & Kim, 2009). Price reasonableness is a critical product and service cue affecting consumer decision making (Watchravesringkan, Yan, & Yurchisin, 2008).

While various conceptualizations of customer satisfaction have evolved over the past few decades, the general agreement among practitioners and researchers is that individual satisfaction is an evaluation of the overall experience of consumption (Oliver, 1997). If customers positively evaluate their overall consumption experiences, their satisfaction levels and readiness to repurchase will increase (Jani & Han, 2013). Many studies have offered the support for the essential role of quality and satisfaction in the intention formation (Lee, Lee, & Yoo, 2000; Ting, 2004). While the complicated character of the relationship between quality and customer satisfaction exists, quality acts as a significant predictor of customer satisfaction toward generating behavioral intentions (Han & Ryu, 2006). Quality is an important origin of customer satisfaction (Han & Ryu, 2006). The quality-satisfaction relationship is vital in establishing individual's intention (Ting, 2004).

Wang et al. (2014) indicated that consumer trust has attracted the increasing attentions from hospitality and tourism researchers since the 1990s. Consumer trust is largely investigated in hospitality sectors, especially in hotels (Lovell, 2009) and restaurants (Oh, 2002). Consumer trust is studied in the hospitality settings, such as tourism suppliers and travel (Macintosh, 2002), nature-based tourism provider (Zillifro & Morais, 2004), conference (Lee & Back, 2008), and airlines (Forgas, Moliner, Sánchez, & Palau, 2010).

For service businesses (e.g., tourism and hospitality industry), the unique natures (e.g., intangibility and inseparability of production and consumption) emphasize the consequential roles played by building and maintaining strong relationships with customers (McCole, 2002). Zillifro and Morais (2004) indicated that the inherent natures of tourism services (e.g., intangibility of service performance and lack of services transparency) lead to information asymmetry and opportunistic behavior. The existence of intense competition in the marketplace on the supply side makes business operations more challenging as switching costs for consumers are greatly lowered (Álvarez, Casielles, & Martín, 2009).

Consumer trust is viewed as a crucial aspect to sustain continuity in the consumer-provider relationship (Han & Hyun, 2013). Sirdeshmukh et al. (2002) defined consumer trust as the expectations held by the consumer that the service provider is reliable. Consumer trust serves as a powerful method for minimizing uncertainty and diminishing the sources of uncertainty (Pavlou, Liang, & Xue, 2007). Trust in a firm's practices refers to the organizational performance, policies, and practices (Santos & Basso, 2012). Consumer trust leads to the loyalty, irrespective of the magnitude of the level of the relationship between the company and its customers (Agustin & Singh, 2005). Consumer trust based on such satisfactory experiences acts as an influential determinant of the repeat purchase intention (Lankton, Wilson, & Mao, 2010).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## Significance of Hospitality Management in Global Business

Ruetzler et al. (2014) stated that in hospitality management, strategic planning is critical in a competitive environment. Christou (2002) determined that managing guest problems and maintaining positive customer relations are the crucial skills indicated by hotel managers. Other dimensions of strategic planning include quality management, systems design, process improvement, teamwork, business policy, strategy analysis, and sustainability (Okumus, Wong, & Altinay, 2008). Although strategic planning remains a popular activity within organizations (Whittington & Cailluet, 2008), it is surprising that the subject has received relatively little attention in the tourism literature (Soteriou & Roberts, 1998).

Strategic planning is an important management tool for profit and non-profit making organizations in competitive and turbulent environments (Liu, Siguaw, & Enz, 2008). Slattery (2002) recognized the structure of hospitality as freestanding (e.g., hotels and cruise ships), operations within leisure venues (e.g., casinos and sports stadia), operations in travel venues (e.g., airports and train stations), and subsidized hospitality (e.g., workplaces and education). Earlier strategic planning research emphasized tourism enterprises (Phillips & Moutinho, 2000) with interest in not-for-profit tourism enterprises growing in more recent work (Soteriou & Coccossis, 2010). Contemporary developments in tourism highlight, the mixed nature of the industry involving private firms, public agencies, and not-for-profit associations (Andersson & Gertz, 2009).

Social networking sites involve blogs, photo sharing sites, message boards, and other online communities (Hanna, 2008). Social networking sites are the modern technological trends to reach the hospitality industry and hospitality managers should obtain the social media skills (Sieburgh & Berkus, 2007). Social media technology can enhance the organizational productivity by fostering the communication and collaboration of employees which aids knowledge transfer and makes organizations more profitable (Kasemsap, 2014b). Social media enables the development of knowledge value chain to customize information and delivery for a technological business growth (Kasemsap, 2014c). The capability of social media in building brand is essential in modern advertising (Kasemsap, 2015b). Social networking sites can be utilized to increase productivity and reduce employee turnover through developing team loyalty among employees (Ketter & Ellis, 2010).

## Significance of Tourism Management in Global Business

Tourism remains a critical economic activity, which continues to grow (Phillips & Moutinho, 2014). Tourism incorporates both public and private sector organizations (Cooper, 2006). The current economic upturn suggests that tourism industry will not only experience another business cycle, but also a restructuring of the economic order (Phillips & Moutinho, 2014). Regarding cultural perspectives, the internationalization of tourism has brought attention not only to the cross-cultural peculiarities that arise from traveling internationally, but also to the inter-religious locus of modern tourism (Kirillova, Gilmetdinova, & Lehto, 2014). Modern business organizations must recognize the differences in cross-cultural values and develop strategies for reconciling these cross-cultural differences in the digital age (Kasemsap, 2015c). New hybrid cultures are emerging and blending elements of different culture origins (Kasemsap, 2015d).

Hospitality on the part of hosts leads to the feeling of welcome on the guest side and acts as a fundamental prerequisite for an enjoyable vacation (Mill & Morrison, 2009). Hosts who rely on tourism for economic benefits tend to perceive the presence of tourists in the area more favorably than other

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

residents (Látková & Vogt, 2012). The success of tourism development should not be measured by the increased number of tourists or tourism revenues, instead it should be evaluated according to how it is integrated within the local economy, and to what extent the industry contributes to the well-being of local people (Buzinde, Kalavar, & Melubo, 2014). Both the positive and negative impacts of tourism influence residents' support (Sinclair-Maragh & Gursoy, 2015).

Ritchie (1999) drew the attention to the growing level of international competition in the tourism marketplace that makes strategic planning increasingly imperative. Competitiveness is defined as the capability a geographical area has to compete in international markets (Kogut, 1993). This vision is based on the theory of comparative advantage (Leamer, 1993). With this approach, the explanation of competitiveness in international tourism markets is limited to considering the cost advantages derived from the productive resources controlled by the tourism sector in each location and the endowments of factors in the space in which it is located (Camison & Fores, 2015). Pham et al. (2015) stated that the impacts on tourism are complicated due to the offsetting income and exchange rate effects.

Tourism development generates social harmony (Airey & Chong, 2010) and helps in the preservation of local cultures (Stronza & Gordillo, 2008) and the environment (Dwyer, Edwards, Mistilis, Roman, & Scott, 2009). Regardless of these economic, social, cultural, and environmental benefits, tourism activities are recognized as having negative effects (Gursoy, Jurowski, & Uysal, 2002). Tourism activities can likewise damage the natural and physical environment (Brida, Osti, & Barquet, 2010) on which tourism depends (Moeller, Dolnicar, & Leish, 2011). Sociological analysis of districts (Grandori, 1999) is relevant in the tourism sector which emphasizes the competition around human capital and knowledge-related resources (Galbreath & Galvin, 2008). The importance of the collective learning processes that occur around the firms located in a tourist district or destination (Camison & Fores, 2015).

The culture of host communities can be negatively influenced due to the erosion of traditional values (Besculides, Lee, & McCormic, 2002). Organizational culture is positively correlated with organizational climate (Kasemsap, 2014d). The strategic perspective of industrial districts emphasizes shared competence in the pattern of knowledge and information assets deposited in a territorial setting near the firm (Breukel & Go, 2009), such as the flows of knowledge, information, and experience circulation within the district with a certain degree of freedom (Hjalager, 2002); the existence of a common positioning and branding; and the culture, values, and vision established in the territory (Saxena, 2005).

Empirical studies show that income positively affects the decision to travel (Fleischer & Rivlin, 2009), and its effect is higher for individuals with the high levels of income (Nicolau & Mas, 2005). The income elasticity is below the unit value (Alegre & Pou, 2004), and has a value greater than one for the decision to travel abroad (Eugenio-Martin & Campos-Soria, 2011). Rapoport and Rapoport (1975) defined age as a major determinant of tourism expenditure behavior. Age conditions the different stages of the tourist participation pattern (Bernini & Cracolici, 2015).

## Managerial Implications of Hospitality and Tourism Management

Executives and managers in the hospitality and tourism industry need to know what hospitality and tourism management is, the economic, environmental, social, and cultural impacts of hospital and tourism management in global business. In addition, executives and managers need to know the relationship between hospitality and tourism industry with other industries, the roles, and the responsibility of individual staff to plan and organize the hospitality and tourism businesses toward gaining sustainable competitive advantage in hospitality and tourism industry. In order to gain an advantageous edge in the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

competitive environment, hospitality and tourism practitioners should organize the relationship marketing and should recognize it as a strategic tool in the hospitality and tourism industry (Wang et al., 2014).

Hospitality industry encompass an extensive variety of service industries that include food service, tourism, and hotels. Hospitality industry can be empirically divided into two parts, namely entertainment areas (e.g., clubs and bars) and accommodation. Accommodation takes the form of public houses, resorts, inn, campgrounds, hotels, hostels, serviced apartments, and motels. The clubs and bars category include restaurants, fast foods, and nightclubs. The hospitality industry also includes tourism support commercial activities (e.g., airline cabin staff and travel agents). To encourage a tourist's preference for a specific destination, an effective tourism marketing strategy needs to gain a large share of first mentions among consumers who are choosing between competing travel destinations (Ruhanen, Whitford, & McLennan, 2015).

Hospitality and tourism consist of several nuances ranging from being both capital and labor intensive (Olsen, West, & Tse, 2008). The structure of the hospitality field includes the dispersed units, franchised, managed operations, and independent operators (Phillips & Moutinho, 2014). The intangible nature of the tourism experience renders complications. The generation of a valuable tourism experience depends on the provision of intangible services, which are derived from intangible resources, such as knowledge and innovative capability (Voelpel, Leibold, & Eckhoff, 2006). The adoption of tourism strategy ranges from destinations, trade associations to special events, and strategies for specific defined needs (Tribe, 2010).

While the attrition curve is a model that can be utilized to evaluate tourist awareness, preference, and intention to adopt a tourism experience, it is not a continuous phenomenon that can be employed to predict behavior (Ruhanen et al., 2015). Correlations between preference and arrival are a function of tourism product (Macfarlane & Jago, 2009). The development of accessible tourism product has to replicate tourist product offered to all tourists by concentrating on its competitive advantages in the perspectives of heritage resources (e.g., wealth, parks, and landscape) and creative resources (e.g., artistic, sports, nature, and adventure activities).

## FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of hospitality and tourism management will provide the potential opportunities for future research. Sustainable tourism is tourism committed to generating a low impact on the surrounding environment and community by acting responsibly while generating income and employment for the local economy and aiding social cohesion. Customer relationship management (CRM) becomes one of the most important business strategies in the digital age, thus involving organizational capability of managing business interactions with customers in an effective manner (Kasemsap, 2015e). The relationship between sustainable tourism and CRM in the tourism and hospitality industry will be the beneficial issue for future research direction.

Social media platforms (e.g., Facebook and Twitter) and the Web 2.0 technologies are the technological tools to facilitate various marketing activities (e.g., advertising, personal selling, sales promotion, public relations, direct marketing, and brand building). Practitioners and researchers should explore the applications of social media platforms and the Web 2.0 technologies in promoting the tourism and hospitality services. Customer service is an array of significant activities designed to enhance the level of customer satisfaction. Understanding the importance of good customer service is essential for a healthy business in creating new customers, keeping loyal customers, and developing referrals for future

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

customers. Good customer service is strongly related to how service quality is effectively managed and which holds a meaningful importance to customer satisfaction and customer loyalty. In the hospitality and tourism industry, customer service, customer satisfaction, and customer loyalty are certain to remain important topics for future research directions.

## CONCLUSION

This chapter highlighted the overview of hospitality management; the overview of tourism management; product quality, service quality, price, customer satisfaction, and consumer trust in hospitality and tourism management; the significance of hospitality management in global business; the significance of tourism management in global business; and the managerial implications of hospitality and tourism management. Tourism and hospitality industry is one of the most important industries in the modern business world. Tourism occurs as a result of the different types of business that provide a range of products and services to tourists. It is essential to acquire a driving enthusiasm for customer service and a strong sense of professionalism to develop and maintain customer satisfaction in the hospitality and tourism industry.

Hospitality and tourism sector involves a wide variety of related sectors providing a range of services and facilities and a range of jobs in various departments. Career and job opportunities can be created due to the expansion of tourism and hospitality businesses toward business success and economic growth. Individual staff in the hospitality and tourism sector can work as chef, housekeeper, receptionist, concierge, marketing executive, travel agent, and tour operator. In the hospitality and tourism sector, the skills and abilities (e.g., automated ticketing and reservation systems, sales and marketing, information seeking, customer service, administration, accounting, and strategic planning) are required. Executives and managers in the hospitality and tourism industry must have the particular knowledge and skills (e.g., leadership skills, human resource management, facility management, and service management) to organize and control individual staff to effectively perform in the industry.

Effective hospitality and tourism management positively affects customer satisfaction, firm growth, and productivity in global business. The facilitation of hospitality and tourism management is vital for modern organizations that seek to serve suppliers and customers, increase business performance, strengthen competitiveness, and achieve continuous success in global business. Sustainable tourism, rural tourism, and responsible tourism are the emerging trends in the hospitality and tourism industry and should be studied for future research. Facilitating hospitality and tourism management has the potential to enhance organizational performance and reach strategic goals in global business.

## KEY TERMS AND DEFINITIONS

**Corporate Social Responsibility:** A company's sense of responsibility toward the community and environment in which it operates.

**Customer Satisfaction:** The degree of satisfaction provided by the products or services of a company as measured by the number of repeat customers.

**Hospitality Industry:** The industry related to hotel, motels, inns, or such businesses providing transitional lodging, with or without food.

**Product Quality:** The group of features and characteristics of a saleable good which determine its desirability and which can be controlled by a manufacturer to meet certain basic requirements.

**Service:** A valuable action or effort performed to satisfy a need or to fulfill a demand.

**Service Quality:** An evaluation of how well a delivered service conforms to the client's expectations.

**Strategic Planning:** A systematic process of envisioning a desired future, and translating this vision into broadly defined goals and a sequence of steps to achieve them.

**Tourism:** The marketing of the enjoyable features of a travel destination, and the provision of facilities and services for the pleasurable tourists.

# Chapter 59
# The Effects of Economic Structural Transformation on Employment:
## An Evaluation in the Context of Economic Complexity and Product Space Theory

**Muhlis Can**
*Hakkari University, Turkey*

**Buhari Doğan**
*Süleyman Demirel University, Turkey*

## ABSTRACT

*Structural transformation concept emphasized by countless numbers of policy makers and scholars. Structural transformation affects not only countries' income levels but also a number of their economic parameters. Employment is one of the most significant of these parameters because the success of structural transformation is measured by the contributions of agriculture, manufacturing, and the service sector to growth and employment. In this chapter, the changing effects of economic complexity (as a major indicator of structural transformation) on employment, and the visual representation of this complexity, which is called product space, are studied using samples from South Korea and Japan. As a result of research, it is found out that increased complexity of a country's economy (increased intensity of the product space center) will lead to a decrease in the employment in agriculture and manufacturing, an increase in the employment in the services sector.*

## INTRODUCTION

In today's world, countries are competing with one another economically in ways that they have not before. While some compete through their cheap workforce, others keep up with the competition through their sophisticated product manufacturing capabilities. This competition is also reflected in the incomes of countries. The question is whether countries can outmatch the competition by more products in general or manufacturing more sophisticated products. According to Rodrik (2006), the number of products a country sells is not significant anymore. What is more important is what type of product the country sells. For example, both Singapore and Pakistan sell 133 different sorts of products to the world market. However, when compared in terms of per capita income, the case of each country is quite different. Singapore is 38 times richer than Pakistan (Hausmann et al., 2011, p. 22). If this is the case, what contributes to this striking difference? The answer to this question takes us to the "structural transformation" concept emphasized by countless numbers of policy makers and scholars.

The first studies on structural transformation were carried out by Prebisch (1950), Singer (1950), Lewis (1954), and Hirschman (1958). The mutual point underlined by all these studies is that countries which specialize in primary products and have a limited export basket might experience problems in terms of trade in the long run. Moreover, these studies suggest that countries should move from selling traditional products to more complex ones (Petralia, Balland, & Morrison, 2015). Additionally, in their studies, Rostow (1959) and Kaldor (1967) emphasized that knowledge and skills, structural transformation, forward and backward linkage among sectors, and productivity growth are significant for countries that aim to grow over the long term. These studies also strongly underlined that structural transformation can significantly contribute to output and employment growth. Furthermore, structurally transformed countries have the capability to overcome macro-economic shocks more easily (De Bandt & Vigna, 2008). In general terms, structural transformation can be defined as changing the manufacturing structure of a country from one of agriculture to industry and then from industry to service.

Structural transformation affects not only countries' income levels but also a number of their economic parameters. Employment is one of the most significant of these parameters because the success of structural transformation is measured by the contributions of agriculture, manufacturing, and the service sector to growth and employment (Srinivasan, 2013, p. 54). Transformation generally formed out of the growth of a country results initially in the workforce moving from agriculture to the manufacturing industry and then to the service sector. Increased economic growth also leads to urban migration from rural areas (De Brauw, Muller, & Lee, 2014, p. 33). The most significant reason for migration is the higher life standards provided by larger cities (The United Nations Human Settlements Programme [UN-HABITAT], 2011, p. 13). Also, when compared with the agriculture sector, wages in the manufacturing and service sectors are higher.

In this chapter, the changing effects of economic complexity (as a major indicator of structural transformation) on employment, and the visual representation of this complexity, which is called product space, are studied using samples from South Korea and Japan. The underlying reason for selecting these two countries as samples is their achievement of structural transformation through conscious policies. The chapter begins with a discussion of economic complexity and product space theory. The effects of structural transformation on employment in agriculture, manufacturing, and the service sector in South Korea and Japan are then examined separately.

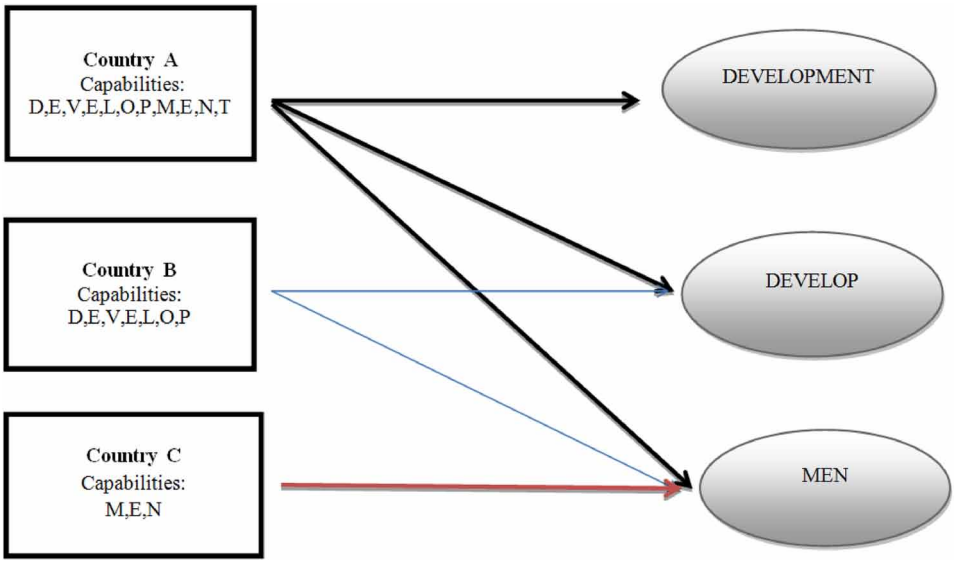
## ECONOMIC COMPLEXITY

Economic structural transformation, which has been referred to quite often in economic literature in recent years, influences countries in many ways. Countries' features underlie this transformation. The variety (or scarcity) of these features (capabilities) has a determining role in the increase (or decrease) of countries' incomes. Moreover, turning toward sectors other than agriculture is of high significance in increasing income because agriculture is a low-productivity sector (McMillan, Rodrik, & Verduzco-Gallo, 2014, p. 11). In these terms, structural transformation is regarded as redistribution of input used for manufacturing in the economy from the low-productive agriculture sector to non-agricultural sectors (Lee & Malin, 2013). Structural transformation first requires transformation from agriculture to manufacturing and then from manufacturing to service (Gilmann, 2011). To realize structural transformation, a shift of focus to high-productivity areas is needed. This provides more rapid growth of the economy (Hausmann, Hwang, & Rodrik, 2007). This also means that the productive economic structures determine the countries' welfare (Hidalgo, 2009, p. 2).



Products are composed of the aggregation of inputs that are different in terms of content. Some of these inputs are non-tradable (Hausmann & Hidalgo, 2011, p. 310). These include a country's human and physical capital, the legal system, institutions and infrastructure. Each one of these can be defined as a "capability" of the country (Hidalgo, 2009; Hidalgo & Hausmann, 2009). "Knowledge" itself is a type of capability. In this context, the factors of production, technology level, and a country's other capabilities play a significant role in producing a product. Increasing these capabilities means increasing the variety of the production basket (Hausmann & Hidalgo, 2011, p. 310). In other words, increasing the qualifications of the country's human capital, improving the legal system, protecting intellectual property rights, increasing the quality of infrastructure, and increasing physical capital can provide the country with the ability to manufacture more sophisticated products. For example, let's assume that each capability can be represented by one letter and that each word composed of these letters represents one product. The words with more letters symbolize complex products, while the ones with fewer letters represent products that do not require complex knowledge and skills to produce. We shall choose the following letters for this example: D, E, V, E, L, O, and P. In this assortment of letters, the most sophisticated product will be DEVELOP. If the country can increase its capabilities and provide M, E, N, and T inputs as capabilities, it can manufacture a DEVELOPMENT product, which will be more sophisticated than the DEVELOP product. However, if the country has the letters (capabilities) M, E, and N letters, it can only manufacture MEN (or the other combinations of these letters). More precisely, the more the capability level (letters) of a country is increased, the more sophisticated and complex the products (words) that can be manufactured.[1]

Figure 1 represents manufacturing capabilities in the way described above. As can be inferred from the figure, the A, B, and C countries have different capabilities. The country with the highest number of capabilities is A. The fact that this country has the most diverse set of capabilities means that it can manufacture three different products using its different capabilities. Country B has a more limited set of capabilities in comparison with country A. Country B can manufacture two different types of products with its existing capabilities. Country C has the most limited set of capabilities, which means that it can manufacture only one type of product. It cannot manufacture the most sophisticated product manufactured by country A. In order for country C to manufacture the products produced by country A,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 1. Capabilities and products*

it needs to increase its capabilities. In other words, it is necessary for country C to increase its human capital, improve its legal system, resolve infrastructure problems, protect intellectual property rights, and increase physical capital.

Limited capabilities forcibly lead the country to focus on simple products that do not require complex knowledge and skills to produce. If the country has limited knowledge and skills, it is quite challenging for it to manufacture nuclear reactors or technologically advanced machines of even low quality (Schetter, 2015). Nations that hold complex knowledge are able to make complex or sophisticated products that cannot be made in countries with only basic knowledge. Therefore, there is a causal relationship between knowledge and development (Yameogo, Nabassaga, & Ncube, 2014, p. 402). Diversity of productive knowledge, however, is not enough. In order to put knowledge into productive use, societies need to reassemble these distributed bits of knowledge through teams, organizations, and markets (Hausmann et al., 2011, p. 7). What's more, capabilities require individual and social quality, information efficiency, and experience. These features lead to the improvement of a firm's technological and organizational skills (Andreoni, 2011, p. 1). Economically, this can be defined as productivity growth. For productivity growth, companies must spend money on research and development (R&D), prioritize mechanization, and train their workforce (Chang, Andreoni, & Kuan, 2013, p. 14). It is clear that this process cannot be accomplished in a short time. In other words, a long and continuous process is necessary for ensuring productivity growth in the economy as a whole. Hidalgo and Hausmann (2009) stated that the most prominent factor affecting a country's productivity level is non-tradable capabilities. According to Hidalgo and Hausmann, the basis of the difference in income among countries is a difference in capabilities.

If this is the case, how can one identify the capabilities (including knowledge) of a country? In other words, how can one determine how complex a country's economy is? Hidalgo and Haussmann (2009) claimed that the most suitable way to find out about the capabilities of a country is to look at its export basket. According to these scholars, the export basket is, in fact, the best indicator of to what extent a country is capable of manufacturing knowledge-skills-involved products. According to Lall (2000), the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

strength of a country's production capabilities is reflected in the manufactured products. If the country is able to manufacture sophisticated products, this shows the extent of its human capital, physical capital, institutions, and other capabilities. The capabilities of countries can be divided into general and private. While some capabilities (general ones such as institutions, infrastructure, etc.) are necessary for the manufacturing of all products, other capabilities are needed for specific products. From this point of view, what is more significant for countries is that they have general capabilities because such capabilities make it more possible for countries to manufacture new products. However, countries that are deprived of general capabilities will find it less possible to produce new products (Boschma & Capone, 2015, p. 4).

Today, countries are exporting many products of various content. Scholars create different indexes to measure export baskets. The most commonly used are the Herfindahl-Hirchman and entropy indexes. However, these indexes do not contain data on the quantity and types of product a country exports. In these indexes, there is no difference between an export basket consisting of 10% banana and 90% mango and one consisting of 10% motorcycle and 90% aircraft engine (Hausmann & Hidalgo, 2011, p. 316). What is more significant for the above-mentioned indexes is the diversity of exported products. The economic complexity index is different from the other two in this regard. This index emphasizes the diversity of product content. Product diversity is the most prominent indicator of the income level of a country.

So, what does economic complexity mean? Arthur (2013) stated that it is more than a theory involving efforts to understand how the elements of a system work. Economic complexity can instead be defined as the efforts of individuals who come together to create a new model (Arthur, 2013). According to Hidalgo (2009), on the other hand, complexity is the effect of a country's capabilities and qualifications on the economy. If the products manufactured by a country are produced by many others—*if the products are common everywhere*—the knowledge and skill level of a country is regarded to be present in many other countries as well. Minondo and Requena-Silvente (2013) defined complexity as the whole of knowledge and skills that are used in manufacturing. Ferrarini and Scaramozzino (2016) underlined that product variety and the ubiquity of the manufactured products are indicators of a country's economic complexity. According to Lall (2000), turning toward complex sectors is important for structural transformation, technological advancement, modernization, and development. For instance, in Malaysia and Chile in 2012, per capita income and gross enrollment were almost similar. In the same period, Chile was ranked 72$^{nd}$ in economic complexity in the world, while Malaysia was in 24$^{th}$ place. The most important reason for this is that Malaysia focuses on the manufacturing of electronic and mechanical products that require complex knowledge and skills to produce. Conversely, Chile predominantly specializes in copper, fish, and fruit production, which do not require complex knowledge and skills (Hartmann, Guevara, Jara-Figueroa, Aristaran, & Hidalgo, 2015). Commodity exporter countries intensify the production of less sophisticated products because of the Dutch disease. As these sectors are mainly physical capital intensive, they lead to less employment and fewer spillover effects (Daude, Nagengast, & Perea, 2015, p. 3).

Lall (2000) expressed that knowledge- and skills-intensive (technology-intensive) product manufacturing plays an important role in the growth of countries. The most significant reason for this is that these types of products have high income elasticity. Knowledge-intense manufacturing also affects other sectors via a spillover effect. For example, let's assume that engineers in the chemistry industry develop a product that functionally decreases energy loss in vehicles by 20%. So, will this product be used only in the automotive industry? The answer is no. We can predict that this product will swiftly expand into other sectors. It will be used in each product in which energy loss through friction occurs (e.g., aircrafts, trains, washing machines, refrigerators, etc.). Another example can be given from the medicine industry. Cancer is one of today's most challenging health problems. We know that different types of cancer ex-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

ist. Let's assume that a country has developed a medicine for 10 types of cancer and that this drug has a 100% success ratio. In your opinion, would it be easy to develop an imitation of this product? The answer is absolutely not because long studies were carried out on this drug, a number of experiments were done, and scientists from different disciplines (biology, chemistry, pharmaceuticals, etc.) were employed. The country that discovered this medicine will export it to a number of other countries and earn a serious amount of revenue. This will increase the income differences of manufacturer country and other countries. The above scenario is an example of what Hidalgo and Haussmann mean when they speak of economic complexity. If a product requires a variety of knowledge and skills in its manufacturing procedure and can be exported by very few countries, this is an indication of how sophisticated and unique the product is (Özgüzer &Binatlı, 2015).

Various knowledge and skills are needed for the manufacturing of complex products. If a country has limited knowledge and skills, it will experience difficulty in finding the resources to manufacture such products. However, if a country has a vast scale of knowledge and skills, it will not experience such hardship (Daude et al., 2015, p. 3). Having advanced and efficient knowledge-skills enables countries to manufacture high-value-added and sophisticated products. Furthermore, a country's knowledge-skills provide significant advantages for manufacturing new products (Hartmann & Pyka, 2013). Today, it is clear that developed countries are the ones with extensive knowledge and skills. It is because of these knowledge and skills that this group of countries is ranked at the top of the economic complexity index. Additionally, the biggest advantage these countries have is their ability to combine the small differences in qualifications among the workforce in their manufacturing process (Minondo & Requena-Silvente, 2013, pp. 929-930).

Table 1 shows the world's economic complexity index (ECI) rankings. As can be inferred from the table, Japan has the most complex economy in the world. Switzerland, Germany, and Sweden follow, in second, third, and fourth place, respectively. When the 2011, 2012, and 2013 tables are compared, the top 10 countries are more or less the same. These countries are also in the World Bank's high-income countries group which can be regarded as a reflection of capability differences on income level.

*Table 1. Economic complexity index rankings*

| Rank (2011) | Countries | ECI | Rank (2012) | Countries | ECI | Rank (2013) | Countries | ECI |
|---|---|---|---|---|---|---|---|---|
| 1 | Japan | 2.31 | 1 | Japan | 2.23 | 1 | Japan | 2.29 |
| 2 | Switzerland | 2.04 | 2 | Switzerland | 1.97 | 2 | Switzerland | 2.16 |
| 3 | Germany | 1.96 | 3 | Germany | 1.84 | 3 | Germany | 1.95 |
| 4 | Sweden | 1.86 | 4 | Sweden | 1.71 | 4 | Sweden | 1.83 |
| 5 | South Korea | 1.80 | 5 | South Korea | 1.70 | 5 | England | 1.72 |
| 6 | Austria | 1.80 | 6 | Czech Republic | 1.62 | 6 | Czech Republic | 1.71 |
| 7 | Czech Republic | 1.80 | 7 | England | 1.61 | 7 | South Korea | 1.70 |
| 8 | Finland | 1.73 | 8 | Finland | 1.59 | 8 | Finland | 1.64 |
| 9 | England | 1.57 | 9 | Singapore | 1.59 | 9 | Austria | 1.64 |

## PRODUCT SPACE THEORY

It was once quite difficult to assess the economic complexity and knowledge and skill levels of countries. By means of product space theory, however, these phenomena have become observable (Ferrarini & Scaramozzino, 2016). Product space theory was introduced by Hausmann and Klinger (2006) and developed by Hidalgo, Klinger, Barabasi, and Hausmann (2007). Later, Hidalgo and Hausmann (2009) and Hidalgo (2009) contributed more significant studies to product space theory. Product space theory provides the opportunity to observe economic complexity in a visual way.[2] Hidalgo et al. (2007) tried to visually represent products whose manufacture and knowledge and skill level were similar. Hidalgo et al. (2007) and Hausmann et al. (2007) defined the product space as the relatedness of products that are subject to world trade. This means that product space is the network between products. In this network, products requiring similar knowledge, skills, and capabilities are grouped together. A new product that is similar to those in the existing product group is more likely to be added to the production basket. Therefore, countries tend to expand and diversify in sectors that are strongly related to their current activities (Boschma & Capone, 2015, p. 2). For instance, let's suppose that country A does not manufacture anything related to machinery equipment products, while country B manufactures machinery tools for different fields. Accordingly, in which country is it more possible to produce a new jet engine? (Hidalgo, 2011, p. 1). In such a context, it is essential for the country to consider the previously manufactured products in their efforts to produce the new one. If this new product requires similar infrastructures, physical factors, and organizations to products produced in the past, it will be more likely to be produced (Hidalgo et al., 2007). This fact is supported by empirical studies as well. For example, in their industry-based studies, Klepper (2002) and Klepper and Simons (2000) discovered that the success of companies who start to manufacture in new sectors/industries is built on their previous experience in a similar industry and their use of this experience in their new industry by means of knowledge, skills, and capabilities.

Using classifications by STIC of 1006 products (4-digit level of desegregation), Hausmann and Klinger (2007) first assessed the comparative advantages of a country from a given product. They then checked the relationship of this product to the remaining 1005 products. The more the product was connected to the other products, the more central its position in the product space.

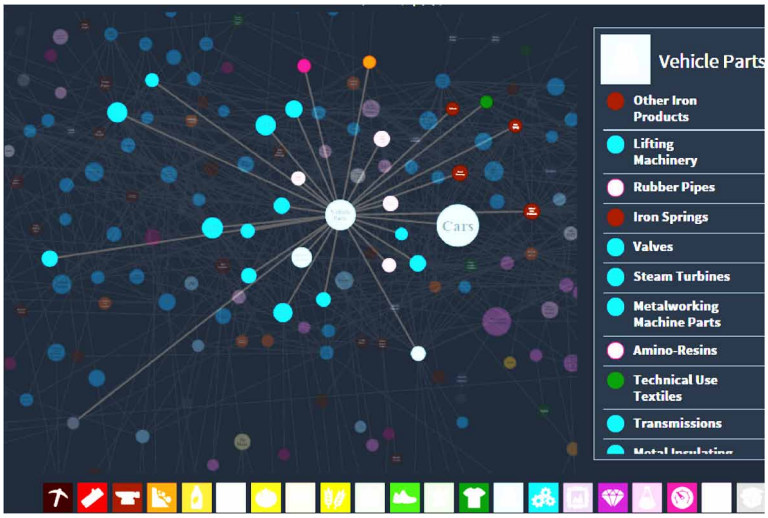

Figure 2 demonstrates this phenomenon. "Vehicle parts" is located in the center of the product space. It is connected to 27 products. Some of these products are as follows: other iron products, lifting machinery, rubber pipes, cars, valves, steam turbines, and metalworking machine parts. If a country can manufacture vehicle parts, it is highly likely that it can produce the 27 other products. This was explained in detail in the economic complexity section. What is more significant for countries are whether they can manufacture the products that are in the center of the product space and that have extensive network connections.

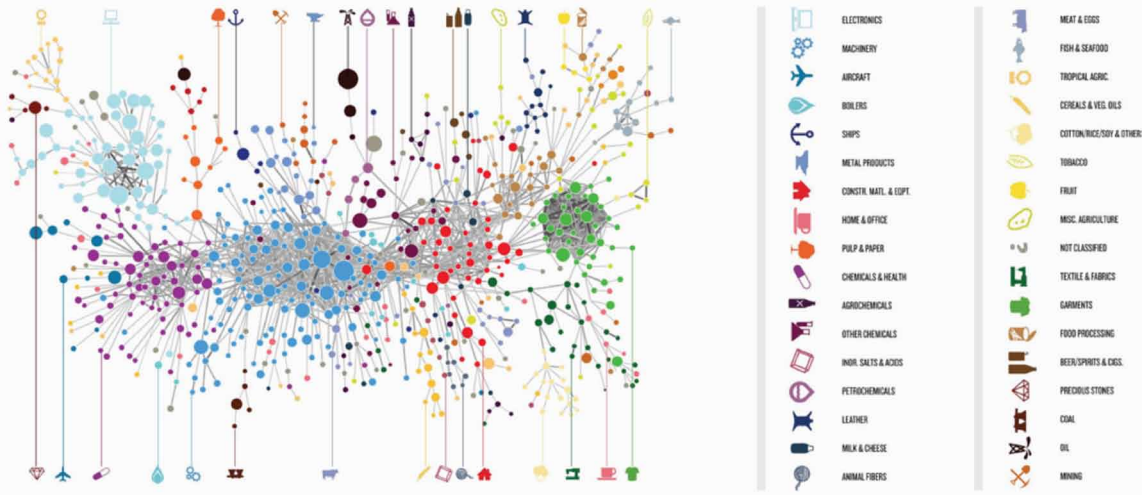
In product space theory, each circle represents one product. The size of this circle shows the product's weight in terms of world trade. In accordance with Leamer's (1984) classification scheme, each color represents a product group. Leamer's classification scheme consists of 10 different product groups. The lines connecting the circles reveal the relatedness of the products. This relatedness does not indicate physical similarity between products but rather a country's likelihood of exporting a product on the basis of its export of a similar one (Felipe, Kumar, & Abdon, 2010, p. 3). In the product space, the outermost products are the non-sophisticated ones that do not require much knowledge and skills to produce (Hidalgo, 2011, pp. 3-4). The center of the product space is mostly occupied by machinery, chemical, and metal products, whereas petroleum, raw materials, vegetable and animal products, and labor- and



EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 2. Backward-forward connections in product space*
*Source: Atlas Media Database.*

capital-intensive goods (except metal products) are located on the outer border. The closer the products a country manufactures to the center (core), the easier it is to manufacture new goods because the existing capabilities can be redeployed to realize this production (Felipe et al., 2010, p. 4). Hausmann and Klinger (2006) symbolized each product in the product space as a tree, the product basket of a country as a forest, and the country's knowledge and skills as monkeys. The closer the trees are to one another, the higher the likelihood of the monkeys jumping from one tree to another. Moreover, the more individual connections the products in the product space have, the higher the possibility of the country facing frequent and longer recessions (Hausmann & Klinger, 2006).

*Figure 3. A sample of product space*
*Source: The Atlas of Economic Complexity and Hausmann et al. (2011, p. 45).*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Product space is reviewed from left to right. As can be inferred from Figure 3, the products located on the right-hand side of the space consist of agriculture and clothing products, which mostly require less knowledge and skills. On the other hand, products on the left-hand side of the space are sophisticated products that require advanced knowledge and skills (Stafforte & Tamberi, 2012, p. 101). Complex products with a high spillover effect are located in the center of the space. Human capital also has a crucial role in the product space. Quality human capital makes the manufacturing of products that are close to one another easier. In other words, the more qualified the human capital of the country, the easier it is for the country to head toward the other areas in the product space. It has been observed that products sometimes become intensified in specific areas. Such intensification is the most significant indicator of the comparative advantages of a country (Hausmann & Klinger, 2007).

## THE EFFECTS OF ECONOMIC COMPLEXITY AND PRODUCT SPACE THEORY ON EMPLOYMENT

In today's modern economies, the most basic productivity growth source is the manufacturing industry. In essence, the manufacturing industry contributes greatly to the productivity of other sectors by producing intermediate inputs such as machinery and chemicals. Furthermore, the industry is regarded as the first area in which new organizational abilities appear. Productivity growth, especially in the last two centuries, cannot be explained solely by technological advancement. It is a well-known fact that the new organizational abilities that have appeared in the manufacturing industry have had a considerable role in productivity growth (Chang et al., 2013, p. 11). However, it is almost impossible to claim that this productivity growth has had a positive impact on employment in the manufacturing industry. Quite the contrary, productivity growth is one of the factors contributing to decreased employment in this industry (Harrison, Jaumandreu, Mairesse, & Peters, 2014, p. 30). As they grow, companies add new technologies (automation, computerization, etc.) to their production lines in order to decrease their costs. These types of applications negatively affect the low-skilled workforce. In countries that have completed their structural transformation, it has been observed that low-skilled occupations have started to disappear. On the other hand, the same structural transformation period leads to the emergence of high-skilled occupations. This has been specifically observed in the information technology industry (Gesthuizen & Wolbers, 2010).

It is essential to discuss this phenomenon in the context of economic complexity and product space theory. One can comfortably assert that new employment opportunities emerge as economic complexity increases because transformation from the lower productivity of agriculture to sectors with higher productivity also results in the creation of new jobs. Intensity in the center of the product space means increased employment (number of persons) in the manufacturing industry. However, industries such as textiles, which are significant in the initial stages of development and create new employment opportunities, are also part of the manufacturing industry. From this point of view, the intensity in the center of the product space of a country (showing an increase in economic complexity) might affect areas such as textiles negatively. For example, it is expected that employment will decrease in related industries. When evaluated in general, even though intensity in the product space means an increase in the number of people employed in the manufacturing industry, it can be claimed that the manufacturing industry's share in the total employment of the country could decrease. This may vary depending on the industri-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

alization stage of the country that is being studied. If a country cannot complete the industrialization process in the relevant period, the total share of employment in the manufacturing sector is expected to increase initially and then to decrease.

Established companies in high-income countries tend to move their production lines to countries with lower production costs, and this leads to changes in the existing production structure of the world. In this context, countries' previous expertise differentiates them from one another (Corcoles, Diaz-Mora, & Gandoy, 2014, p. 33). For instance, a century ago, textile products were manufactured in today's developed countries, including England, Germany, Japan, and Korea. However, today it is not possible to claim the same thing. Nowadays, it is a well-known fact that textile manufacturing has moved to countries with lean production in East Asia and other parts of the world. The most prominent underlying reasons for this are increased production costs and high wages in the developed countries.

In order to manufacture sophisticated products of increased economic complexity, a serious amount of R&D spending is needed. What companies are trying to create here is "innovation." One example of this is smartphones. Let's assume that a company invested a great deal of money in a new application that is to be used on smartphones. The company needs to form a team to develop this application, which means increasing employment in the service sector. Moreover, to launch this application, the company might need to receive service support from other firms with no prior connections to the company. This new application will, therefore, contribute to employment both in the company itself and in other firms in the same sector. The company might also invest more money to develop the specifications of this smartphone application in order to compete with its competitors in the market. It can be suggested that when this company researches new software that makes playing games on smartphones easier, both the company and other companies in the sector will increase the number of their employees. Acquired innovation can be said to have a positive impact on employment because new products manufactured as a result of this innovation lead to the emergence of new employment opportunities. Additionally, the increasing market demand for new products has an active role in increasing employment (Harrison et al., 2014, pp. 29–30). Another industry that has caused increases in the service sector is the pharmaceutical industry. This industry intensively requires knowledge and skills. Scientists perform various tests on the manufacturing of a drug for years, and therefore manufacturers work with a number of different teams. For example, let's assume that a medicine manufacturer invests in R&D for a drug that has not been produced previously. In this case, it will not be possible for this manufacturer to develop a new drug with its existing team. The company has to form a new team for this new drug, and this will lead to increased employment in the service sector.

The financial and education sectors both have a huge impact on the formation of complex economic structures (Cristelli, Tacchella, & Pietronero, 2015). The reason for this is that companies are unable to produce new complex products with their own capital. Therefore, companies might need support from bank loans. As the economic complexity in the country increases, the number of people who are employed in finance is expected to increase too. It is possible to claim the same thing about the education field. Human capital is one of the key factors in the increase of economic complexity. Educational investments made in qualified human capital play an important role in the increase of employment in the service industry. In the agricultural industry, farmers whose education levels increase begin to use advanced farming equipment in agricultural production (Cochrane, 1993). This leads to a decrease in the use of old methods of production in the agricultural industry, leading to a decrease in employment in the industry as a whole.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

It would not be right to claim that increased employment in the service sector can be maintained only through innovation and knowledge-skills-based production. Structural changes also lead to the introduction of low-skilled service jobs, mainly in the catering and cleaning industries (Gesthuizen & Wolbers, 2010). Call center jobs, which require fewer qualifications, are also an example of such a job. Call center employees have the ability to speak properly, which is an important skill for people employed in the service sector. These employees may have good knowledge and skills in physics, chemistry, and mathematics, but such knowledge is not important in the context of their sector.

Moreover, the increase in retail stores, especially in the last 20 years, also lies behind the employment increase in the service sector. These stores are operated by national and international companies. They offer a wide range of products at cheap prices to consumers, which have led to the emergence of new employment opportunities. This phenomenon has affected not only developed countries but also the other country groups (Cho, Chun, & Lee, 2015, pp. 559–560). Increasing a country's economic complexity (increasing the intensity in the center of the product space) leads to an increase in per capita income in the country, which is a factor that has paved the way for the opening of many different retail stores. In other words, an increase in economic complexity in the country will result in the opening of more retail stores, and the number of people employed in the service sector will grow. In addition, increased economic complexity makes a significant contribution to the expansion of the country's export markets and the increase of its exports, which in turn cause an increase of employment in the transport sector.

According to Hallak (2006), complex and more sophisticated goods are generally purchased by high-income countries and, within countries, by those segments of consumers that have been less exposed to external shocks and may guarantee a more stable demand. Moreover, as the substitution of complex products is also quite difficult, it would not be wrong to claim that countries that specialize in complex product groups could have some advantages. Countries specialized in more complex goods are less exposed to external shocks and have higher stability in their overall sales (Maggioni, Turco, & Gallegati, 2014). When this is considered in terms of employment, big fluctuations are not expected to result from the impact of external shocks. However, the impact of external shocks to the agricultural sector is different because the income elasticity of agricultural products is very solid. Even if their prices decline, there will not be a big change in the demand for agricultural products. What is significant here is that if prices rise in countries that manufacture agricultural products, purchasing countries are then directed to where they can get cheaper products, which might also negatively affect the employment structure in the country specializing in agricultural products. Also, being exposed to the seasonal impacts of the agricultural sector is a major disadvantage in terms of employment.

## Structural Transformation of South Korea Economy: A Brief Overview

Korea is a well-known case of successful economic catch-up achieved through state-sponsored manufacturing and export-oriented strategy. Korea is one of the few recent examples of a country that has managed to rapidly transform its agriculture-based economy to the extent of becoming a leading industrial power (Organisation for Economic Co-operation and Development [OECD], 2014, p. 32; Chung, 2010; Chen & Suh, 2007, p. 4). The main focus of South Korean industrial development shifted from light to heavy and high-tech industry in the 2000s. The Korean form of catch-up was shaped by strong state leadership, a state-controlled banking system, and the dominance of the chaebol—large, highly diversified family-owned companies[3] (Organisation for Economic Co-operation and Development [OECD], 2009, p. 13, 60).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The origins of many of the larger chaebol can be traced to the period after Japanese colonialism. Most of these companies started small; however, the South Korean government from 1961 to 1987 actively supported chaebol operations through successive strategies and policies as a means of pursuing the government's industrialization objectives. The chaebol has therefore played a central role in Korea's economic development (OECD, 2009, p. 62).

It is necessary to focus primarily on the processes of South Korea's economic transformation in the 1960s and 1970s. In the literature, there is a widespread belief that many institutional and economic changes occurred that led to fast growth during this period. The three main periods of South Korea's economic transformation are as follows: first, the imitation era of import substitution/ protectionist policies that encouraged exports (the 1960s and 1970s); secondly, the transformation era, during which structural arrangements were made, liberalization policies were promoted, and the private sector established its own R&D structure (1980s); and third, the innovation era, during which policies in favor of technological development were encouraged, and rather than large R&D-based companies, dynamic and innovative SMEs gained importance (the 1990s onwards) (OECD, 2009, pp. 173–176).

Park Chung Hee, who rose to power after a military coup d'état in 1961, spearheaded two developments. First, he encouraged companies' exports by transferring foreign aid to the entrepreneurial firms. Second, he initiated a shift from light industry to heavy manufacturing and high-tech industry (Kim, 2000). In the 1960s, South Korea began developing its agriculture (e.g., rice) and labor-intensive light manufacturing industries (e.g., textiles and bicycles) (Chen & Suh, 2007, 7; OECD, 2009, p. 58). In this process, the realization of the country's export-oriented production efforts occurred. Export-oriented policies have contributed to the fall in the unemployment rate and the opening of new manufacturing companies throughout the country. Initially, the development of basic industry for the promotion of exports (cement, fertilizer, etc.), light industry based on manpower (textiles, footwear, etc.), and basic infrastructure (communications, electricity, etc.) was encouraged (Chung, 2007). South Korea's biggest problems in this process were inadequate technological capabilities and inadequate domestic capital. Therefore, capital accumulation was encouraged, and the government made significant investments in education. These investments allowed a gradual transition toward more sophisticated products. The key to this transition was the acquisition of new technologies through foreign licensing and the adaptation of them to domestic manufacturing (Chen & Suh, 2007, p. 7; OECD, 2009, p. 58).

Selection and assimilation of appropriate technology required a reasonable level of local R&D capacity and S&T (science and technology) infrastructure. To address these needs, in the 1960s research institutes[4] such as the Korea Institute of Science and Technology (KIST) were established. These institutes aimed to carry out R&D in key technological fields, with a view to supporting the industrial upgrading strategy, facilitating the adoption of new technologies in industry, and developing projects for private companies (OECD, 2014, p. 32; OECD, 2009, p. 58). Furthermore, in order to investigate export opportunities in foreign markets, Korea Trade Promotion Corporation (KOTRA) was founded (Lee, 2000, p. 145). Subsequently, the Ministry of Science and Technology (MOST) was established, and the Science and Technology Promotion Law was enacted. In this process, foreign direct investment (FDI) played an important role in the transfer of technology (Ernst, 2000). Strong commitment to economic independence led to economic policies based on long-term loans to finance industrial development instead of FDI. These loans were then allocated to the South Korean government to make direct investments in selected sectors. This process led to the import of a significant proportion of foreign capital goods. Later, reverse engineering methods were used to obtain the necessary technologies (Chung, 2010).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the 1970s, Park Chung Hee made efforts toward the establishment of high technology and heavy industry. At the same time, the state continued to encourage research to meet the needs of industry. In this process, foreign- owned companies were given limited access to the South Korean market. In other words, mostly protectionist policies were implemented in the country during this period (OECD, 2009, p. 58; Park, 1997). In the mid-1970s, the government's use of a well-targeted industrial policy resulted in a major shift toward the development of heavy industries (e.g., chemicals, shipbuilding). Along with industrial targeting, policies were enacted to further improve technological capabilities, together with improving access to and quality of technical and vocational training (Chen & Suh, 2007, p. 7). The government also played a key role in developing domestic R&D capability by establishing industry-oriented government research institutes (GRIs) in areas such as machinery, electronics, chemistry, and shipbuilding (OECD, 2009, p. 58). For this reason, it is possible to claim that the role of government as a major planner of strategic industrial policy was very important in South Korea's industrialization process (Park, 1997).

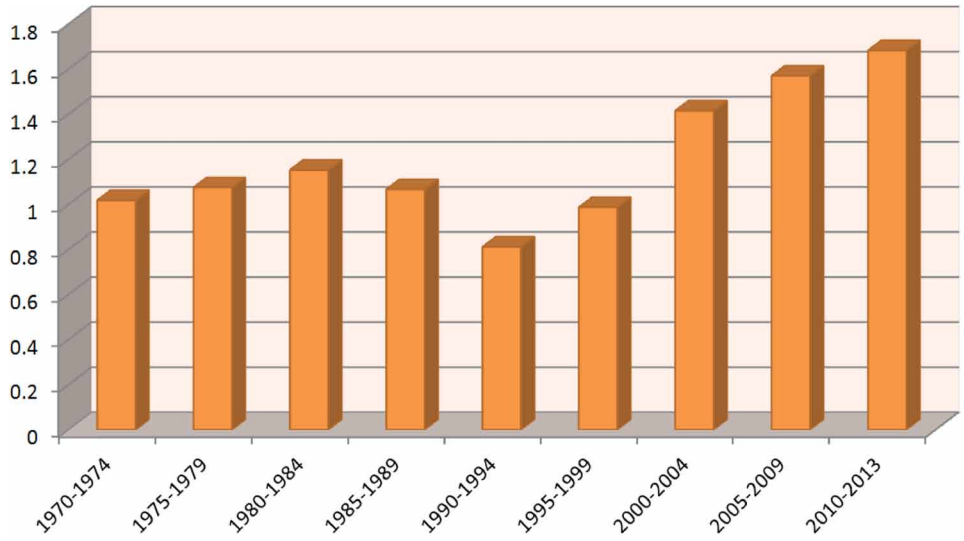
In the 1980s, South Korean industry dependence on imports of technology and increasingly expensive domestic labor made it difficult to compete in international markets. To overcome this situation, South Korea created a new domestic center for research and innovation (Bartzokas, 2007). Additionally, the first national R&D program initiated by MOST was introduced in 1982. Shortly afterward, similar R&D programs were set up in various institutions. In particular, a separate directorate to support industrial R&D was set up inside the Ministry of Industry. In addition to public funding of R&D, the private sector was encouraged to actively engage in absorbing and improving technologies from countries operating at the technological frontier (OECD, 2014, p. 33).

South Korea continued to pursue high-value-added manufacturing in the 1990s by promoting domestic high-technology innovation (Chen & Suh, 2007, p. 7; OECD, 2009, p. 59). Since the second half of the 1990s, the Korean government has been pressured to change its catch-up-oriented industrial development policy, which is based on extensive labor and capital input, and to seek new growth engines. Economic growth, which averaged more than 8% a year from 1960 to 1997, has slowed from the mid-1990s to a yearly average of 5%. The Asian financial crisis in 1998 caused negative Gross Domestic Product (GDP) growth and led to a high increase in mass unemployment (Chen & Suh, 2007, p. 13; OECD, 2014, pp. 33-34).

In the post-2000 period, South Korea underwent a comprehensive and innovation-oriented transformation in all areas. Its Vision 2025 program proposed the following fundamental shifts in technology policy (OECD, 2014, p. 35):

1. Moving from a government-led and development-oriented innovation system to a private-industry-led and diffusion-oriented innovation system,
2. Moving from a closed R&D system to a globally networked R&D system,
3. Moving from a supply-dominated investment enhancement strategy to an efficient utilization and investment-distribution strategy,
4. Moving from a short-term technology-development strategy to a long-term market-creating innovation strategy,
5. Moving toward a science-and-technology-led national innovation system.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



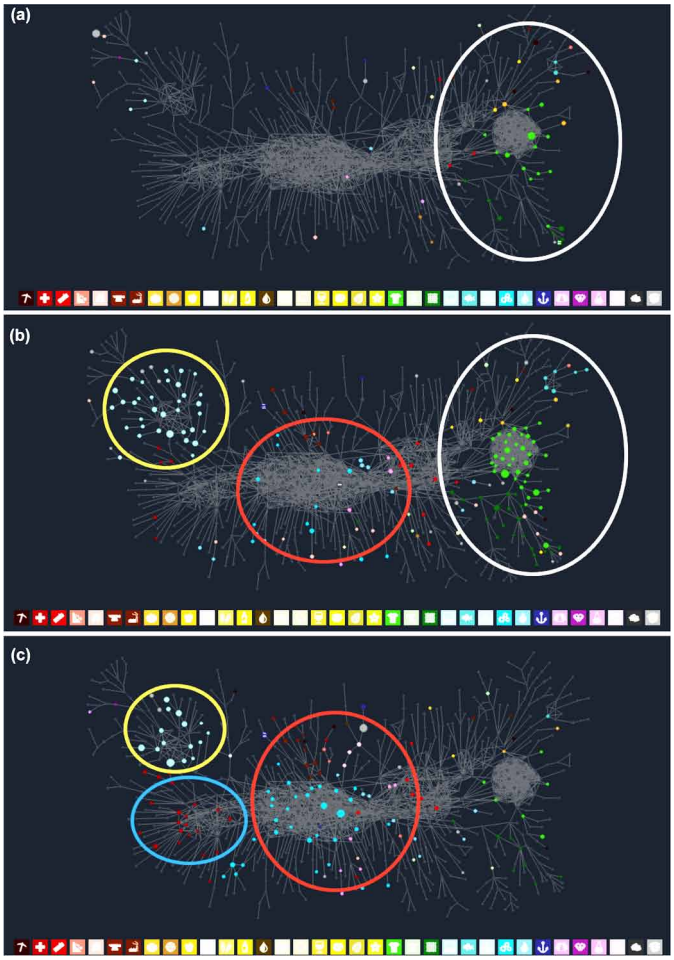
In brief, several factors appear to be behind South Korea's achievements. In particular, state-oriented plans for the realization of economic development efforts can be regarded as the roots of the South Korean miracle. In addition, these plans have been revised according to the circumstances and needs of a given period. Strict adherence to these strategies could be the underlying reason for the high likelihood of coming across a South Korean product in most of today's houses.

## South Korea's Economic Complexity and Product Space: An Evaluation in the Context of Employment

This section examines South Korea's economic complexity and product space. In addition, the effects of the transformations encountered in economic complexity and product space on employment are discussed. Figure 4 shows the development of South Korea's economic complexity. Economic complexity index values, except for those in the 2010–2013 period, have been calculated as five-year averages.[5] When South Korea's economic complexity is analyzed, we observe that its index value during the period 1970–1974 is below one. The index values of 1975–1979, 1980–1984, and 1985–1989 are above one. The 1990–1994 period, however, shows a significant decline in South Korea's economic complexity. This is because products produced by South Korea in previous periods began to be manufactured by many other countries in this period. But as can be seen from the chart, the manufacturing structure during the period between 1995 and 1999 recovered and complex production increased. This rise accelerated in the 2000–2004, 2005–2009, and 2010–2013 periods. In the most recent period, South Korea's economic complexity index value was over 1.6.

South Korea's economic complexity world rankings in the above-mentioned periods can be seen in the table. According to Atlas Media Database, South Korea ranked 23rd in economic complexity in 1970, 18th in 1980, 24th in 1990, 22nd in 2000, and 7th in 2013.

*Figure 4. South Korea's economic complexity index*
*Note: Economic complexity is calculated as five-year averages.*



EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition to its evolving economic complexity, South Korea's product space changes should be examined. In 1970, as seen in Figure 5 (part "a"), the product space is mostly concentrated on the right-hand side (in the large white circle). Additionally, the left-hand side and the center of the product space are almost empty. The most conspicuous product group on the left side is miscellaneous manufactured goods (in the upper left corner). The right-hand side of the product space consists of knit clothing accessories, footwear, embroidery, pharmaceutical flora, silk-woven fabrics, dried vegetables, crustaceans, and mollusks, etc. On the basis of this data, we can claim that South Korea had a mainly textile manufacturing structure in the 1970s and specialized in agricultural products.

In the 1990s, South Korea's product space was divided into three main sections, as seen in Figure 5 (part "b"). What is significant is that less sophisticated products, which mainly comprise textile and agriculture products, are centered on the right-hand side of the product space (see white circle). Especially when compared with the 1970s, there is a visible increase in this section. In addition to the products from the 1970s on this side, there is a concentration of the products of leather accessories, miscellaneous men's outerwear, knitted outerwear, synthetic woven fabrics, frozen fish, and temporarily preserved fruit.

*Figure 5. South Korea's product space in 1970 / 1990 / 2013*
*Source: Atlas Media Database. Please note that (a), (b) and (c) represent 1970, 1990 and 2013 respectively.*

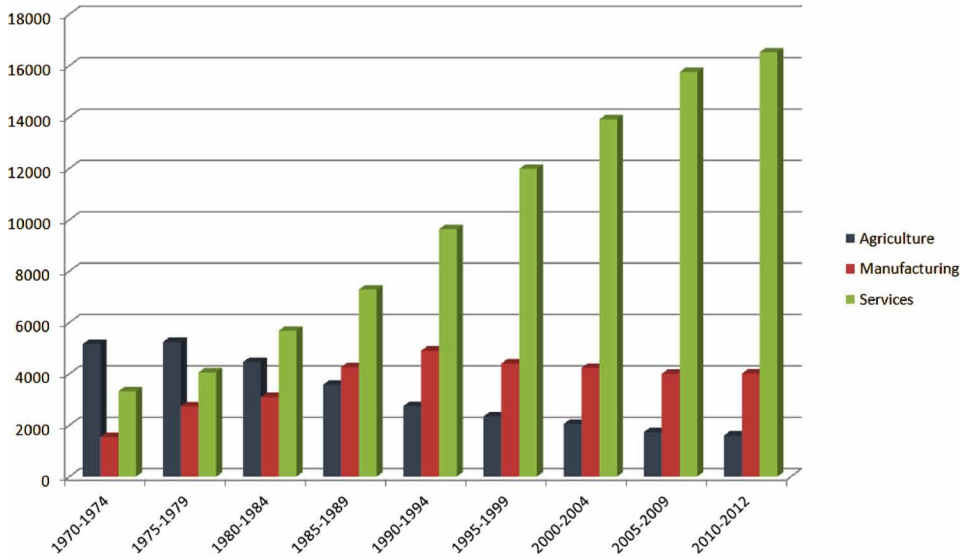
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

We can see that more new products started to appear in South Korea's product space in 1990 in comparison with the 1970s. This section is indicated by the red circle. Among these products are cars, fasteners, electric heating devices, car tires, and metal cables. Almost nonexistent in 1970, the products on the left-hand side of the product space in 1990 are indicated by a yellow circle. This area represents the production of complex products whose spillover effect is limited to spread to other sectors. Some of these products are electronic microcircuits, color TVs, computer peripherals, telecom parts and accessories, toys and games, and vehicle stereos.

There are significant differences in South Korea's product space in 2013 compared to 1990. As seen in Figure 5 (part "c"), in 2013, the products that were located on the right-hand side of the product space have disappeared. Additionally, there are relatively fewer products compared to 1990 in the upper-left side of the product space, which is composed of electronic products and indicated by a yellow circle. Two condensation areas are seen at the center of the product space. These areas are those in which backward and forward connections among the sectors are strong. There are also important changes in the area marked by the red circle when compared with the 1990s. In addition to the products manufactured in the 1990s, the country started to specialize in construction machinery, circuit breakers and panels, air pumps and compressors, vehicle parts and accessories, piston engine parts, miscellaneous heating and cooling equipment, and miscellaneous machinery products. Another major development occurred in the area marked by the blue circle involving chemicals and health-related products. This section is not included in the previous periods. However, it is believed that South Korea's space expanded into this area because of past R&D investments. Remarkable products in this section are polymerization products, synthetic rubber, acrylic polymers, cyclic hydrocarbons, silicones, and polycarboxylic acids.

All in all, it can be said that the South Korean economy was based on agriculture in the early development phase. In the 1970s and 1990s, it can be understood from the product space that the South Korean economy attached importance to industrialization. We have observed that South Korea focused on the textile industry, especially in the 1970s and 1990s. However, the textile industry was subsequently abandoned in the manufacturing area. This can be ascertained from the concentration of products in the center and left-hand side of the product space. When this process is evaluated in terms of employment, initially increasing and then decreasing percentages of people employed can be expected in the manufacturing sector. Moreover, while the tendency toward complex manufacturing in the product space negatively affects the number of people employed in the agriculture sector, it brings a remarkable increase in the service sector.

## The Effects of Structural Transformation on South Korea's Employment



The structural transformation of the South Korean economy has been discussed in the previous sections. It is obvious that this structural transformation would have economic effects as well. In this chapter, the effects of structural transformation on employment in South Korea's economy will be evaluated in the context of economic complexity and product space.

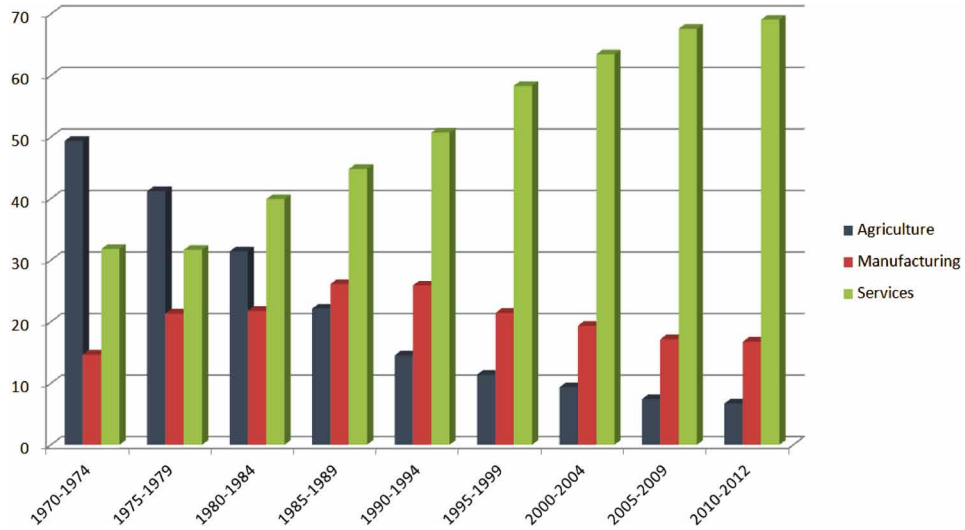
As can be seen from Figure 6, the agricultural sector was significantly superior in the 1970s in terms of the number of people employed. During this period, the number of people employed is understood from the graph to be around five million. However, in the 1980s, we can see that a downward trend in the number of people employed in agriculture started. This process continued regularly until the 2010–2012 period. The development of this process is easily understood from the graph. Whereas there was around a 50% share of the agricultural sector in total employment in the 1970s, Figure 7 shows that this share was

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 6. Number of employed people by sector in South Korea (Thousands)*
*Note: Numbers are considered as averages. Data sets were obtained from the Bureau of Labor Statistics.*

around 5% in the period 2010–2012. This is supported by the South Korean product space as well. As you recall, the right-hand side of the product space in the 1970s was dominated by agriculture-oriented textile manufacturing and consisted of mostly agriculture-based products. However, in the following years, this trend changed, and this section on the right side of the product space disappeared.

The number of people employed in the manufacturing area seems to have steadily increased until the period 1990–1994. This is clear from Figure 7 with regard to the share of the manufacturing sector in total employment. The most important factor in the emergence of this trend is the production structure based on the textile industry. As you recall, there was a serious increase in the concentration on the right-hand side of the product space in the 1990s. This situation had an effect on employment as well. With the increased concentration in the center of product space in the following period, we can deduce that the number of people employed in the manufacturing industry decreased. These industries require mostly complex knowledge and skills and are areas in which automation and computerization are necessary instead of manpower.



Considering Figure 6 and Figure 7 in terms of the service sector, we are faced with a very different picture from the other two sectors. It can be inferred from both Figure 6 and Figure 7 that the number of people employed in the service sector consistently increased between the years 1970 and 2012. This trend is seen in South Korea's product space too, if you recall the parts marked with yellow and red circles in 1990. The industries in this sector require knowledge and skills, and intensive research and development. In addition to the concentration in these two areas, in the 2013 product space, we have a blue marked area comprising health-related products. This area is among the main reasons for the increase of employment in the service sector, as serious research and development activities must be carried out for production to be made in this field.

When evaluated in general terms, the structural transformation of the South Korean economy was also reflected in employment. This transformation process has been observed primarily in the steady decline of the agricultural sector. The manufacturing sector initially experienced an increase and then

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 7. South Korea's sector shares in total employment (%)*
*Note: Numbers are considered as averages. Data sets were obtained from the Bureau of Labor Statistics.*

a decrease. The biggest reason for this was the use of automation instead of labor in the manufacturing sector, along with technological progress. On the other hand, the service sector experienced steady growth in the number of people employed because of the greater need for knowledge and skills with the increase in economic complexity (represented by intensity in the center of the product space).

## Structural Transformation of the Japanese Economy: A Brief Overview

Contrary to common belief, the Japanese miracle did not start after World War II. The main foundations of the process were laid in the 18th and 19th centuries. Japan realized its most striking transformation in the 1540–1856 (Edo) and 1868—1914 (Meiji) periods. During the Edo period, Japan adopted a practice of isolation from the world. The country banned entrances and exits, and all commercial relations were operated only from Nagasaki. Also in this period, developments in European countries were closely followed, and new discoveries were transferred to Japan. In particular, a strong industrial infrastructure was formed during this closed economic period by absorbing and assimilating many technical innovations from China, which were imported through South Korea (Derya, 2015).

In the 1850s, Western states made great efforts toward Japan's adoption of liberal economic policies. With the development of international trade, Japan was forced to restart trade relations with the West as a result of the need for its ports to meet demands for water and steam for steamships. Using their military power, the U.S. and other Western countries signed a number of trade agreements[6] with Japan, indicating that these countries had achieved a number of privileges (Fletcher, 1996). Once the country was free of the unequal treaties in 1913, there was a major switch in Japan's trade policy. Japan gained full autonomy because of this change in policy (Hunter, 1998, p. 86).

Japan's economic development process started at the beginning of the Meiji Restoration. During this time, the government embarked on a plan to create a modern infrastructure. Investments were carried out by the state or state-aided private sectors. The origins of "sector selection," which can be regarded as the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

basis for Japan's industrial policy, can also be traced back to the Meiji period (Derya, 2015). The textile industry, which is the pioneer of the industrialization process, is an example of sector selection because the state invested in this industry and played a direct role in its development. Public policies contributed to the formation of the necessary human resources for the development of this industry. Within nearly 40 years of the Meiji period of recovery/development policies, Japan had achieved economic and social transformation. The country also achieved trade surpluses in this process (Ito, 1996).

After the First World War, despite Japan's greater industrialization compared to other Asian countries, Western countries still viewed Japan as an agricultural country. During this period, Japan dominated a large part of the Asian market by filling the industrial gap that had emerged in the world with its modern and effective institutions (Derya, 2015). In the 1900s, Japan's productivity, technology, and industrial infrastructure were clearly inferior to that of the West. However, receiving a strong impetus and pressure from abroad, Japan made earnest efforts to mobilize its civil service and people to catch up (Ohno, 2003, p. 38).

The Japanese economy expanded at an average annual rate of about 3 percent for more than a half century before the Second World War. This long period of sustained growth was accompanied by rapid structural change from an agrarian to an industrialized economy (Ito, 1996). The agricultural sector played an important role at the beginning of this period of high growth in Japan. The increase in productivity in the agricultural sector and the mobility of the workforce contributed significantly to this process. Labor productivity in Japan doubled[7] during the Meiji Restoration (1881–1920) (Asian Development Bank, 2013, p. 9). However, after the Second World War, the Japanese economy entered a very troublesome phase. As productive resources had been either diverted to military use or destroyed in the war, real output fell by half from 1944 to 1946. Recovery was quick, however. By the mid-1950s, GDP had regained its 1943 level, and by 1960, it was at the level predicted by its prewar trend. In the post-war period, the economy shifted from labor-intensive sectors to capital-intensive heavy industry (Ito, 1996).

Japan experienced a period of rapid export-led growth from 1953 to 1973 (Yülek, 1997). Until the oil crisis of 1973–1974, the main purpose of industrialization in Japan was to increase wealth. In the process of industrialization, the Japanese government acted by connecting trade, finance, and industry policies (Yülek, 2013, p. 4). In 20 years' time, the country had become a highly industrialized country with more complex (sophisticated) technology. Japan's annual growth rate in the postwar years was around 10%. The determining factor in the rapid growth of Japan was its concrete support of promising industries (Ito 1996; Ifo Institute for Economic Research, 1997, p. 46; Beason & Weinstein, 1996). In this process, the country focused on heavy industry products. But by the 1970s, Japan's priority was no longer capital-intensive heavy industry. During this period, the country focused on research-intensive high-tech products. Automobile manufacturing and electrical machinery production, in which technology plays a decisive role, gained importance. On the other hand, the intermediate products (e.g., iron and steel) provided by the labor-intensive textile industry and heavy industry lost their significance (Kohama, 1990).

The growth trend of the 1960s slowed suddenly after the first oil crisis, in 1973–74. Possible reasons for this abrupt decline are the Japanese economy's transition to different industries leading to a reduction in high-yield investments; high oil prices; pollution prevention arrangements.[8] Additionally, the annual growth rate from 1975 to 1990 was roughly half of that achieved in the previous two decades. Another interesting feature of this period was the sharp nominal increase in the value of the Japanese yen: its value tripled from 1970 to 1995. However, the growth rate did not rise above 1 percent between 1992 and 1995 (Ito, 1996).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

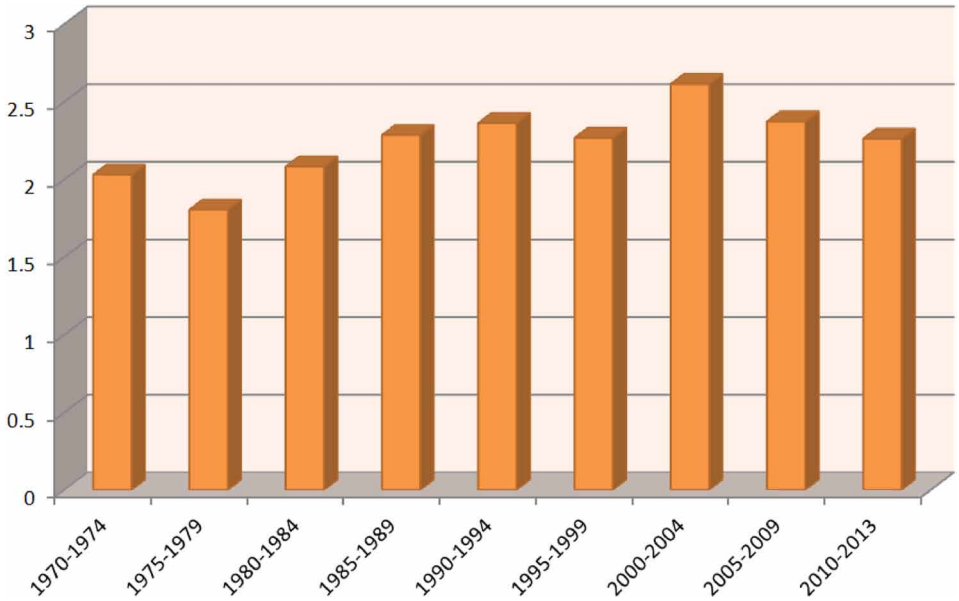
In Japan's Meiji and other rapid growth periods, strengthening the industries' implementation of traditional industrial policy and the state's direct intervention in the market played an important role in economic transformation. In later periods, rather than managing coordination and dissemination of information through government intervention, Japan found a better way. After the 1980s, a transition to policies based on technology and innovation occurred. Thereafter, liberal policies in Japan gained weight, and traditional policies were dropped from the agenda. Transformation taking place alongside the liberalization experienced in recent years has been shaped around "new generation" policies. These policies and the government's role in shaping them are different from the traditional industrial policies. Innovation in sophisticated production structures and R&D stand out in the new generation policies (Yülek, 2013, p. 22). Hence, structural transformation is expected to play a significant role in leading the Japanese economy to be among the modern industrial and service economies in the 21st century as well (Asian Development Bank, 2013, p. 59).

## Japan's Economic Complexity and Product Space: An Evaluation in the Context of Employment

In this section, Japan's economic complexity and the changes in its product space will be discussed. In addition, the possible effects of changes in economic complexity and product space on employment will be evaluated. Innovation is an important stage in the creation of a complex production structure. The unit of analysis is the national economy, and the major players involved in innovation are the government, universities, government-sponsored laboratories, and private companies. While companies and laboratories endeavor to develop new products, universities contribute to this process by educating scientists and engineers. The government is among the actors in the process that leads to technological development. Japan is considered to be one of the most successful countries in terms of innovation, and this success is thought to be closely linked to the country's innovation system. Thanks to harmony in innovation, the country has achieved a considerable growth rate (Lee & Han, 2002).

Looking at Japan's economic complexity index, we observe that the index value is under two in the 1970s. Figure 8 shows that this index value exceeded two in the 1980s and maintained stability until the end of this period. The period 2000–2004 was when Japan had the most complex economy. The index value was over 2.5 during this period.

Japan's economic complexity rankings for the period between 1970 and 2013 can be found in the Atlas Media Database. In 1970, Japan was ranked third for economic complexity. It ranked first between the years 1972 and 1990. Between the years 1990 and 2000, the country's ranking varied between 1st and 3rd. From 2000 to 2013, Japan was ranked 1st.



We shall now have a look at the country's product space. As can be seen from Figure 9 (part "a"), in 1970, manufactured products were concentrated in three main areas. The white circle represents weak complexity areas, including agriculture and agro-based industries. Some of these products are footwear, linens, blouses, embroidery, finished cotton fabrics, rice, pasta, silk-woven fabrics, prepared fruit, and temporarily preserved fruit.

In the same period, there were also many products in the center of the product space. This situation is an indicator of Japan's ability to produce many complex products in the 1970s. Some of the manufactured products marked by the red circle include cars, trucks and vans, seamless iron tubes, motorcycles, railway track fixtures and fittings, roller bearings, fasteners, metal cables, thin iron sheets, and iron coils. In the same year, there is a concentration marked by a yellow circle in the top left corner of the

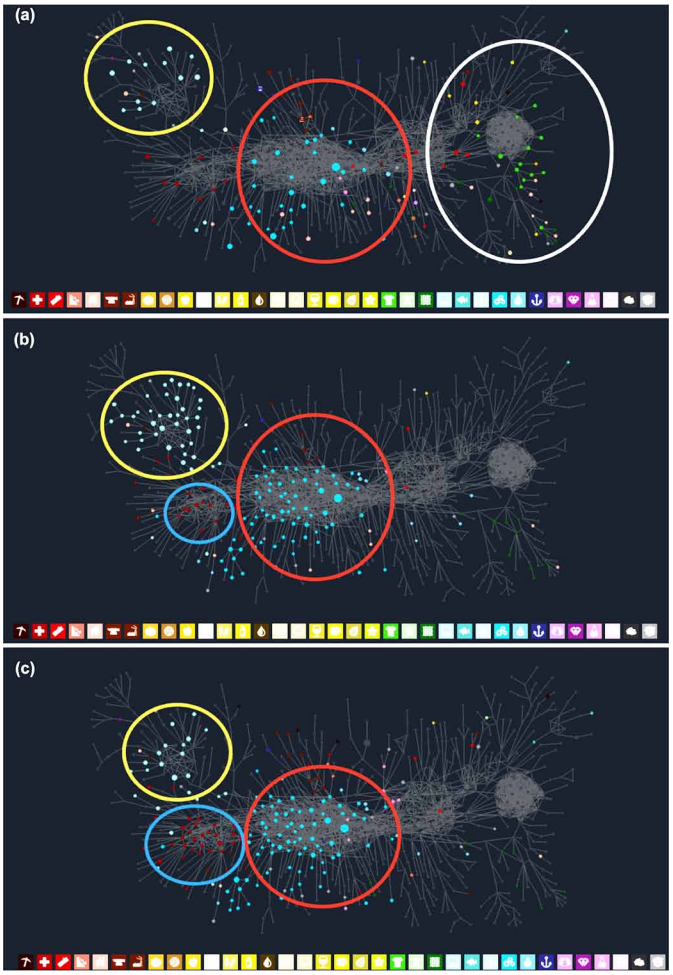
*Figure 8. Japan's economic complexity index*
*Note: Economic complexity is calculated as five-year averages.*



product space. This area includes cameras, calculating machines, clocks, sporting goods, and toys and games. When evaluated in general, Japan's economy in 1970 was mainly based on both agriculture and manufacturing (including agro-textiles).

There were dramatic changes to Japan's product space in 1990 (Figure 9, part "b"). For instance, the area marked by the white circle in 1970, which represented agricultural manufacturing, disappeared. This can be interpreted as arising from the decline of the share of manufacturing and agriculture in total employment. In comparison with 1970, there is an increase in density in the red and yellow areas. The causes of increased density in the red zone are vehicles parts and accessories, valves, pulley system parts, motor vehicles piston engines, construction machinery, DC motors, car tires, and miscellaneous parts of stream power units. The reasons for the increased density in the yellow zone are color TVs, TV tubes and cathode rays, computer parts and accessories, computer peripherals, video and sound recorders, miscellaneous electrical machinery, telecom parts and accessories, and printed circuits. Additionally, there is a newly added blue circle, which was non-existent in 1970. This area consists of health-related products. Some of the manufactured products included in this area are synthetic rubber, monocarboxylic acids, photographic film, x-ray equipment, cyclic alcohols, heterocyclic compounds, medical instruments, and regenerated fiber. We can infer that Japan began to manufacture new products. This meant the emergence of new business opportunities in the service sector and the manufacturing industry in terms of employment. In this context, the manufacturing industry in the 1990s could be expected to increase the number of people employed. However, it seems that there might have been a decline in the share of the manufacturing sector in total employment, because instead of labor automation, computerization became more important in the center of product space. It is also possible that there was an increase in the number of people employed in the service sector and an increase in the share of total employment in the service sector.

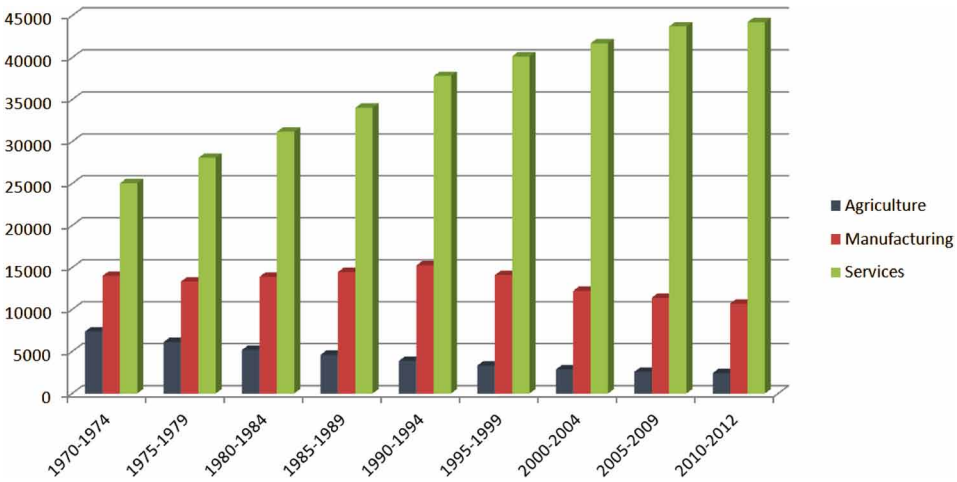
*Figure 9. Japan's product space in 1970/1990/2013*
*Source: Atlas Media Database. Please note that (a), (b) and (c) represent 1970, 1990 and 2013 respectively.*

When Japan's product space in 2013 is assessed (Figure 9, part "c"), greater density in the red-marked area is observed in comparison with the 1990s. The underlying reason for this is that more new products were being manufactured compared to the 1990s. Some of these products are transmission belts, miscellaneous centrifuge and filtering machinery, miscellaneous pump parts, electrical insulators, control instruments of gas or liquid, and valves. Moreover, there is also a significant reduction in the yellow area when compared with the 1990s. The reason for this may be the shifting of manufacturing in this area to different regions across the world. For example, today, even though the originating country of cameras and digital cameras is Japan, most of them are manufactured in China. This could be the underlying reason for the decline in the yellow area. Furthermore, the blue area in the product space is denser in comparison with the 1990s. Some of the new products appearing in this area are regenerated fiber, photographic chemicals, photographic film, chemical products, ethers and acetyls, inorganic esters, printing ink, analog instruments for physical analysis, and glycosides and vaccines.

We can conclude that overall, the Japanese economy was well structured in terms of the agriculture, manufacturing, and service sectors in the 1970s. However, in the 1990s, agriculture and agro-based

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

manufacturing sector production disappeared. This led to a decline of the manufacturing sector's percentage share in total employment. There was also a higher concentration in the product space in the areas involving complex manufacturing. This situation is an indication of the emergence of new business opportunities in the manufacturing and service sectors. In 2013, we can deduce from the figure that there was a decrease in the production of electronic devices while there was an expansion in the production of health-related products. This signifies an employment increase in the service sector but a decline (both in terms of percentage share of employment and number of people employed) in the manufacturing industry.



## The Effects of Structural Transformation on Japan's Employment

The structural transformation of the Japan economy has been discussed in the previous sections. It is obvious that this structural transformation would have economic effects as well. In this chapter, the effects of structural transformation on employment in Japan's economy will be evaluated in the context of economic complexity and product space.

As can be understood from Figure 10, agricultural employment in Japan in the period 1970–1974 was over five million. A steady decrease is observed in the number of people employed in agriculture in subsequent periods. This was also observed in Japan's product space in the 1970s and 1990s. As you recall, agro-production, which was on the right-hand side of the product space (marked by the white circle) in 1970, disappeared 20 years later, in 1990. The effects of this are also reflected in the number of employed people, which can be seen in Figure 11. For instance, the percentage share of agriculture in total employment was around 15% between the years 1970 and 1974 but decreased to 4% in the 2010–2012 period.

In terms of the manufacturing sector, both the agro-based textile industry (white circle) and the other manufacturing sectors (red and yellow circles) were present in the product space in the 1970s. It can be inferred from Figure 10 that the number of people employed in manufacturing in 1970 was around 14 million. Moreover, Figure 11 shows that the manufacturing sector's share in total employment was around 28% in the 1970–1974 period. However, in the 1990s, there was a concentration mainly in the

*Figure 10. Number of employed people by sector in Japan (thousands)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

red and yellow areas of the product space. This is also reflected in the number of people employed in these areas. Approximately 15 million people were employed in the manufacturing industry from 1990 to 1994. The share of the manufacturing sector in total employment is close to that of the previous period. In the 2010–2012 period, on the other hand, there was a significant decline in the number of people employed in the manufacturing industry compared to the previous period. During this period, the total number of people employed was around 10 million. The manufacturing sector's share of total employment was around 17% in this period. This can be explained by comparing the product spaces of 1990 and 2013. As you remember, we saw that there was a concentration in the yellow area in 1990. This area primarily consisted of electrical and electronic equipment. However, in 2013, the country abandoned the manufacturing of the products in this area, which was an important factor in the decline in employment in the manufacturing sector. Besides, when compared with 1990, more products were manufactured in the blue circle area in 2013. We previously mentioned that this area was knowledge-skills intensive.

Figure 10 shows that the total number of people employed in the service sector in the 1970–1974 period was around 25 million. Furthermore, Figure 11 indicates that the share of the service sector in total employment was approximately 49% during this period. The same table also shows that this share in employment continually increased over time. In 2010–2013, the total number of people employed in the service sector was 45 million. Also during this period, the share of the service sector in total employment climbed to 70%. These developments can be observed in the product space too. For example, we observed that the Japanese product space in 1970 and 1990 was mainly composed of the red and yellow circled areas, which mean R&D had a significant role in the manufacturing of these products. Besides, there was a significant increase in the manufacturing of health-related products (marked by the blue circle) in 1990 and 2013. In line with this development, it is possible to claim that the concentration in red, yellow, and blue areas, where knowledge- and skills-intensive manufacturing is performed, had an impact on the employment increase in the service sector.

*Figure 11. Japan's sector shares in total employment (%)*
*Note: Numbers are considered as averages. Data sets were obtained from the Bureau of Labor Statistics.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

When Japanese structural transformation is evaluated with regard to employment, it is obvious that there has been a steady decline in the agricultural sector. The underlying reason for this is that the increase in economic complexity has led to increased productivity in the agricultural sector. Additionally, the manufacturing industry has experienced a steady decrease in employment (of a percentage basis). This situation can be interpreted as a negative effect of automation on the manufacturing industry. In the service sector, on the other hand, there has been an increase both with regard to people employed and in percentage terms. This can be interpreted as a positive contribution of knowledge- and skills-intensive manufacturing to the service sector.

## CONCLUSION

Structural transformation is a concept often discussed in today's economic literature. To realize sustainable growth and development objectives, countries have to succeed in structural transformation. Success in structural transformation has the power to influence many economic parameters, one of which is the employment structure of the country. In this chapter, changes in the employment structure of South Korea and Japan, both of whom have successfully completed the structural transformation, were studied in terms of economic complexity and product space theory. Economic complexity refers to a country's knowledge and skills production structure. The product space, on the other hand, is a visual representation of economic complexity. As a result of our research, we found out that increased complexity of a country's economy (increased intensity of the product space center) first affects agriculture. The basic dynamic of structural transformation is to shift from agriculture to other industries. However, the process of employment in the manufacturing industry differs depending on the development level of the country. If industrialization of the country is not fully completed, then initially there may be an increase in employment in the manufacturing industry, followed by a decrease through the effects of automation and computerization. On the other hand, if industrialization of the country is fully completed, then a decline in employment in the manufacturing sector on a regular basis may be expected. By contrast, growth in economic complexity may lead to an increase in the service sector. In other words, concentration in the center of the product space may lead to an increase in employment in the service sector both in terms of percentage share in total employment and the number of people employed.

## KEY TERMS AND DEFINITIONS

**Capabilities:** Abilities of a country including human and physical capital, legal system, institutions and infrastructure.

**Economic Complexity:** A country's whole knowledge and skills used in manufacturing.

**Employment:** An agreement between an employer and an employee that the employee will provide certain services on the job.

**Japan:** An island country in East Asia.

**Product Space:** Relatedness of products which are subject to world trade.

**Production:** A process to transform tangible and intangible inputs into goods or services.

**Sophisticated Product:** A product which needs more knowledge, experience or education for being manufactured.

**South Korea:** A country in the southern part of the Korean peninsula.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**Structural Transformation:** The reallocation of resources across the agriculture, manufacturing, and services.

# Chapter 60
# Investigating the Relationship between Foreign Direct Investment and Corporate Social Responsibility:
## Central Bank Independence and Inflation

**Marianne Ojo**
*North-West University, South Africa*

**Olusegun Felix Ayadi**
*Texas Southern University, USA*

## ABSTRACT

*Should regulatory incentives which incorporate the lowering of environmental and labor standards, generate life threatening and environmental repercussions, as well as those resulting in moral hazard and excessive risk taking levels, be encouraged? This chapter not only investigates whether central bank independence is positively correlated with inflation, but also highlights other variables which could impact the relationship between Corporate Social Responsibility and Foreign Direct Investment. It will highlight why a continuous need for updating of data is necessary given the inability to capture data specific variables and why the introduction of complementary standards would serve to bolster measures aimed at promoting financial stability and encouraging investors – rather than incentives aimed at diluting such standards. In so doing contributes to previous and current literature on the topic – by way of reference to investigations and studies which have revealed concerns in the ability to adequately capture data – particularly in light of the recent 2008/2009 Financial Crisis.*

## INTRODUCTION

The recent introduction of Enhanced Supplementary Leverage Ratios in several jurisdictions, despite arguments related to the burdensome nature of requirements and conditions attached to their implementation, as well as competitive advantages or disadvantages, not only underlies the importance of these regulations in aiming to avert disastrous consequences which could arise where systemically relevant institutions are threatened, but also highlights the importance of sending appropriate signals to foreign investors that the jurisdiction is relatively stable in terms of financial stability and regulatory measures.

The OECD Guidelines highlight the fact that:

- The ability of multinational enterprises to promote sustainable development, is greatly enhanced when trade and investment are conducted within the context of open, competitive and appropriately regulated markets (OECD, 2008).

Why should standards which have the potential to facilitate the realization of CSR goals and objectives be relaxed as a means of accommodating and attracting foreign investment?

Should cost benefit considerations apply where such standards are so crucial to the realization of CSR goals? Should economic and profit considerations supersede those relating to ethical, and legal obligations?

Does this necessarily mean that jurisdictions with less stringent standards – such as those pertaining to Basel III Leverage and Supplementary Leverage Ratios, have greater potential to attract foreign investment than those jurisdictions which have imposed more stringent requirements? (Ojo, 2014, 2015)

A financial environment which operates with the optimal level of regulatory requirements, which are crucial in facilitating a business environment built on trust, confidence – such that investors are able to rely on information being generated by the management and directors of an enterprise or business, as well as an environment which facilitates transparency, disclosure, should generally constitute incentives for investors to be attracted to such an environment. Further, as rightly, indicated in OECD Guidelines, a competitive market environment, should also serve as an engine which fosters growth and development.

Why is it then the case that foreign direct investment in certain jurisdictions does not necessarily translate to propellers of growth and development in such jurisdictions – whether these are developed, emerging or developing economies?

Whilst UNCTAD statistics reveal dramatic growth in certain jurisdictions, this cannot be said of others. [1]

One plausible reason can only be that certain jurisdictions have failed to consider the benefits of fully implementing or complying with regulatory, environmental or ethical standards, or are encouraging investment incentives which whilst aimed at encouraging growth and development, are not necessarily facilitating the generation of benefits which full implementation of certain regulatory and ethical standards would have facilitated.

It is definitely a trade game where you either implement the standards at a level such that costs of such implementation are minimal – whilst compromising certain Corporate Social Responsibility goals. Further, the environment within which such standards are supposed to be implemented may be negatively influenced by political, institutional and legal impediments, such that it warrants little effort to fully implement or even introduce such standards. In other words, profits dominate the firm or MNEs' corporate goals and objectives given such negative external influences.

According to UNCTAD (2014),

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Investment incentives mostly focus on economic performance objectives, less on sustainable development. Incentives are widely used by governments as a policy instrument for attracting investment, despite persistent criticism that they are economically inefficient and lead to misallocations of public funds. To address these concerns, investment incentives schemes could be more closely aligned with the SDGs (Sustainable Development Goals).

The following incentives have been highlighted by UNCTAD as constituting means of attracting foreign investment (UNCTAD, 2014):

- Financial Incentives
- Fiscal Incentives
- Regulatory Incentives

Regulatory incentives, namely those which include the "lowering of environmental, health, safety or labor standards, as well as temporary or permanent exemption from compliance with applicable standards", will constitute greater focus of this chapter.

As well as responding to issues and concerns related to whether standards which have the potential to facilitate the realization of CSR goals and objectives should be relaxed as a means of accommodating and attracting foreign investment, whether cost benefit considerations should apply where such standards are so crucial to the realization of CSR goals, and whether economic and profit considerations should supersede those relating to ethical, and legal obligations, this chapter also aims to highlight why foreign direct investment in certain jurisdictions does not necessarily translate to propellers of growth and development, with the expected results in such jurisdictions – as is the case with other jurisdictions. It will attempt to address many of these questions by way of reference to other variables which may impact financial growth and development - variables such as inflation, external factors such as political influences on economic decisions and the importance of corporate governance and institutional frameworks aimed at ensuring that vital regulations and standards are complied with and effectively enforced.

## BACKGROUND AND LITERATURE REVIEW (CONCEPTUAL, THEORETICAL AND EMPIRICAL FRAMEWORKS)

In order to illustrate the impact of political interference on monetary and economic policies, as well as financial development in certain economies, reference will be made to the literature and empirical analyses relating to central bank independence and financial development. This will serve to consolidate the argument that other variables, namely inflation, can impact corporate social responsibility and goals, where political factors impact economic and monetary policies and decisions.

### Central Bank Independence

Central Bank Independence (CBI) is often cited as prescription to assure price stability in an economy. Cross-country empirical studies especially in industrial economies suggest a negative relationship between CBI and inflation. According to Hayo and Hefeker (2002), Central Bank Independence is neither necessary nor sufficient for reaching monetary stability.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In relation to the debate on whether Central Bank Independence is evidential of low inflation, several theories have been propounded:

## High CBI and Low Inflation?

The following three theories have been put forward by Eijffinger & Haan (1996):

- The public-choice theory[2] whereby Buchanam and Wagner (1977) examine concepts of Keynesian economics.
- Sargent-Wallace (1981) theory
- Time-inconsistency theory problem of monetary policy as explained by Kydland and Prescott (1977), Calvo (1978) and Barro and Gordon (1983).

Based on the summary of empirical studies carried out by Cukierman et al. (1992) and Berger et al. (2001), they conclude that among industrial countries, legal CBI index is negatively correlated with inflation but TOR (turnover of central bank governors) has no correlation with inflation. They also conclude that among developing countries, legal CBI index is not correlated with inflation but TOR is significantly related to inflation.

The following five measures and indicators of financial development and financial systems are highlighted by Beck et al. (2000):

- DMCD: Ratio of deposit money banks assets to central bank assets
- LLGDP: Ratio of liquid liabilities to GDP[3]
- CBGDP: Ratio of central bank assets to GDP
- DMGDP: Ratio of deposit money banks assets to GDP
- INF: Inflation index $[\pi/(1 + \pi)]$

The following data, figures and tables reflect annual data collected between the period 1970 and 2003 and are based on the five above mentioned indicators.

## SUMMARY OF RESULTS (1)

Based on ADF unit-root test, in which all the time series data are integrated of order 1,

The Johansen cointegration results show:

- INF and DMCD are cointegrated
- INF and LLGDP are cointegrated
- INF and CBGDP are cointegrated
- INF and DMGDP are not cointegrated

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## SUMMARY OF RESULTS (2)

Inflation is negatively correlated with DMCD and DMGDP
Inflation is positively correlated with LLGDP and CBGDP

## Interpretation of Results

There is a long-run relationship between the level of financial development and inflation. The level of financial development is more appropriate than the existing indices of central bank independence. It is not logical to assume that all developing countries are homogenous in terms of the role and influence of central banks on price stability.

## Issues, Controversies, Problems

### Adequately Accounting for Data and Capturing of Data Following the 2008/2009 Financial Crisis

According to Beck, Demirguc-Kunt, and Levi (2010):

- While the previous indicators measure the liability side of financial intermediaries' balance sheets, indicators of the asset side capture credit allocation, one of the most important functions of financial intermediaries. Private credit by deposit money banks and other financial institutions to GDP is the ratio of claims on the private sector by deposit money banks and other financial institutions to GDP. It is a standard indicator in the finance and growth literature; countries with higher levels of private credit to GDP have been shown to grow faster and experience faster rates of poverty reduction. A somewhat narrower indicator—limited to deposit money banks—is private credit by deposit money banks to GDP.

Beck et al also add that whilst the data figures for the period ending 2007 do not fully capture the recent crisis, indicators of banking efficiency, profitability, and stability match the trends in the boom period leading up to the recent global financial crisis (Beck, Demirguc-Kunt, & Levi, 2010). Further, they make the following observations (Beck, Demirguc-Kunt, & Levi, 2010):

- That the lower margins for traditional lines of business and the search for higher returns were possible only through high-risk taking, especially in high-income countries.
- Integration into global financial markets has also increased, though the driving forces have differed for different income groups.
- While the increase in international lending and bond issues has been concentrated in high-income countries, low- and lower middle-income countries have benefited from higher remittance flows.

The following section hence makes reference to present and previous literature on variables impacting financial development, foreign direct investment and corporate social responsibility, as a means of highlighting and addressing gaps which may arise from inadequately accounting for data – as well as highlighting the importance of effective corporate governance mechanisms in realizing corporate social goals.

## SOLUTIONS AND RECOMMENDATIONS

### Relationship between Foreign Direct Investment (FDI) and Corporate Social Responsibility (CSR)

Drawing on investigations carried out by Fortanier and Van Wijk (2010) - based on the analysis of three sub Saharan countries and in which it is ascertained by them that that MNEs crowd out local firms from the labour market by hiring their best-trained employees and where it is implied that human capital development in the hotel sector will not be driven by FDI, Kolk and Tulder (2010) conclude on this basis and are of the opinion that "well-developed institutions - in this case via training and education systems, are a prerequisite for positive effects from FDI" and that further, country-of-origin aspects were considered by Auger, Devinney, Louviere and Burke (2010), in terms of the products included in their study as well as consumers from six different countries.

Based on studies undertaken by Goyal (2006) and Kolk and van Tulder, (2010) they conclude that there has been a correlation between increases in CSR and increases in FDI since the 1990s.

However, as reflected by recent UNCTAD reports (2014), whilst positive effects of FDI are evidenced in certain countries, this cannot be said of others. Based on conclusions derived from Kolk and Tulder, as regards their opinions on training and education systems being pre requisites for positive effects from FDI, an argument can be made for the need to distinguish between those jurisdictions which are well equipped with the adequately balanced institutional, legal, and governance frameworks and those without such frameworks as constituting a basis for evaluating and analyzing the effects of FDI. In this respect, and drawing on Carroll's pyramid of Corporate Social Responsibility (DiGabriele & Ojo, 2016), training and education cannot constitute the sole pre requisites, particularly in jurisdictions with underperforming institutional structures, for determining the positive effects of FDI. As highlighted in the Chapter "Corporate Social Responsibility and Foreign Direct Investment: Engaging Innovation, Auditors and Stakeholders in Corporate Social Responsibility" (2016), compliance with laws, business principles and codes of conduct, without doubt, constitutes the most fundamental and strategic level of the pyramid since goals and objectives attributed to other levels of the pyramid, namely longer term goals of sustainability, and goals relating to nutritional, water and rural development, will not be realised to their maximum potential where compliance with regulations and other related laws and principles are not effectively implemented and enforced.

### Further Empirical Studies on the Relationship between Corporate Social Responsibility and Foreign Direct Investment

Based on results derived by Gonzalez Perez, Riegler and Riegler (2011), as regards the relationship between Corporate Social Responsibility and Foreign Direct Investment, investigations of which incorporated "two different approaches for the empirical examination of the relationship between FDI and CSR", such approaches in their opinion denoting and implying a significantly correlated relationship between the variables of interest (Perez, Riegler, & Riegler, 2011):

- It was concluded that the first approach implied a correlation between a CSR index and FDI, while the second approach suggests that FDI in Colombia is environmentally responsible because it reduces its negative externalities on CO2 emissions.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Further, they add that the first approach, whilst having the advantage of being more general, was also disadvantageous in the sense of ignoring any specific effects of the relationship and that even though the second approach provided deeper insight into the specific relationship between the variables, was limited in the sense that it only takes into account the actual results.

## FUTURE RESEARCH DIRECTIONS

Challenges involving private sector investment in the public sector, as well as efforts aimed at consolidating regional and international standards – particularly in matters of environmental matters, reducing pollution and dangerous chemical emissions continue to constitute focal points and whilst progress is being made in certain jurisdictions, evidence exists to support the fact that many developing economies still suffer from environmental consequences resulting from failures of their governments to implement and enforce required environmental standards and effective corporate governance mechanisms.

## CONCLUSION

Should regulatory incentives, namely those which include the "lowering of environmental, health, safety or labor standards, as well as temporary or permanent exemption from compliance with applicable standards" be encouraged where such incentives generate behavior which not only has life threatening and environmental repercussions, but also results in moral hazard and excessive risk taking levels? Given efforts being undertaken to address systemic risks, with particular reference to: recently introduced Enhanced Supplementary Leverage Ratios; as well as their applicability to systemically relevant institutions; the need to adequately balance interests of wider stakeholders;

The consideration of more damaging consequences of a major disruption to financial stability, as well as the need to implement reliable complements to present financial indicators, should take precedence over a dilution of standards which would only encourage reckless behavior emanating from the desire to place profit maximizing priorities at the fore.

The literature review concludes that legal CBI index is negatively correlated with inflation but TOR (turnover of central bank governors) has no correlation with inflation. It is also concluded that among developing countries, legal CBI index is not correlated with inflation but TOR is significantly related to inflation.

As reflected from the investigation and results from the data incorporated into this chapter, it is not logical to assume that all developing countries are homogenous in terms of the role and influence of central banks on price stability. Further, certain data may not adequately capture specific effects which exist between variables and such data need to be continuously adjusted to reflect actual results. In order to ensure that corporate social responsibility goals and objectives are maximally realized, more effective corporate governance mechanisms, standards and effective compliance and enforcement mechanisms should be in place. Training and education cannot constitute the sole pre requisites for determining the positive effects of FDI – particularly in those jurisdictions where political influences are of such impact that economic policies, legal and institutional frameworks are affected and environmental repercussions emanate as a result of such external social and political factors.

## ENDNOTES

1 "Europe, traditionally the largest FDI recipient region, is at less than one third of its 2007 inflows and one fourth of its outflows. The United States and the European Union (EU) saw their combined share of global FDI inflows decline from well over 50 per cent pre-crisis to 30 per cent in 2013." See UNCTAD, "World Investment Report 2014: Investing in the SDGs: An Action Plan" see page x

2 "*Democracy in Deficit* paved the way in economics in endogenizing the role of government in discussions of macroeconomic theory and policy. The basic discovery was that Keynesian economics had a bias toward deficits in terms of political self-interest. That is, at the margin politicians preferred easy choices to hard ones, and this meant lower taxes and higher spending. Thus, whatever the merits of Keynesian economics in using government fiscal policy to "balance" the forces of inflation and deflation and employment and unemployment in an economy, its application in a democratic setting had severe problems of incentive compatibility; that is, there was a bias toward deficit finance. And, of course, there is no need to reiterate here the evidence in the United States and elsewhere for the correctness of the Buchanan insight on Keynesian economics." See J M. Buchanan and R E. Wagner, *Democracy in Deficit: The Political Legacy of Lord Keynes* (New York: Academic Press, 1977), volume 8 in the series.

3 "Liquid liabilities to GDP is a traditional indicator of financial depth. It is the ratio of currency plus demand and interest-bearing liabilities of banks and other financial intermediaries to GDP." ## ABSTRACT

*This article describes how foreign direct investments (FDI) is one of the most important forces that influences the global economy. Along the last two and a half decades, the motivations and the field of interest of multinational enterprises (MNEs) mutated to new forms under the influence of globalization and the international financial crisis. Those two events had a dramatic impact on the evolution of inward and outward flow of FDI. The main scope of this article is to analyze the advance of the EU28 member states through the stages of the Investment Development Path (IDP) in the period from 1990 to 2014 and to explore the viability of the original model in nowadays global economy realities. The results show that FDI is useful to gauge the economics of lesser developed countries.*

## 1. INTRODUCTION

Foreign direct investment is no longer attributed to the exclusive use of the multinational enterprises (MNEs). There are new entities implicated in cross border mergers and acquisitions or green field projects like sovereign wealth funds, private equity firms, venture capital, state-owned MNEs or international financial organizations like International Financial Corporation (IFC) or European Bank for Reconstruction and Development.

In the last decades, a new trend can be observed. The FDI flows are initiated by companies from developing countries. New multinational enterprises from emerging economies, such as China, India or Brazil generate important FDI to developed economies such USA and European countries (Dohse et al.,2012). In fact, this trend has several waves:

- from the 1960s until the early 1980s, MNEs from developing countries (the main part from Latin America) made FDI in other developing countries, exactly neighboring economies;
- beginning in the 1980s, the MNEs (especially from Asia) have been oriented to growing foreign markets or invested in less developed economies than their home countries;
- in the last decade, MNEs from Asia have invested in developed countries and they are now net FDI exporters, a position specific to developed economies.

The developing countries removed barriers and they have engaged in a struggle to attract foreign capital, taking in considerations the positive effects of FDI on host countries (Zubovic et al. 2009; Subic et al. 2010; Zaman et al. 2011; Zaman et al., 2012, Iacovoiu 2013; Ivan & Iacovoiu 2008; Zaman & Vasile, 2012, Anghelache et al., 2014; Popescu, 2014; Munteanu, 2015; Anghel et al., 2016; Anghelache et al. 2016; Panait & Dusmanescu 2017; Podasca, 2017; Panait & Voica, 2017).

The developing countries have changed their optics on the FDI and MNEs that were consider tools of imperialism, one of the causes of persistent underdevelopment (Narula, Pineli 2016) and a threat to political and economic sovereignty of these countries (Narula and Driffield, 2012).

With the economic development of these countries, private state-owned companies invested abroad. Thus, from the receivers of FDI, these countries turned in FDI issuers. Specialists like Dunning and Narula (Narula & Dunning, 2010; Narula, & Guimon, 2010, Fonseca et al. 2016) observed that evolution of inward and outward FDI flows of a country varies in accordance with its relative level of economic development. So, a new model was designed: investment development path (IDP) model divided in five main stages that explain the nature and extent of FDI relating to the development level of the country.

With the development of a country, there is also a change to the conditions offered to local and foreign companies, with direct implications on FDI inflows. In turn, FDI influences economic structure and development of a country. Therefore, there is an interaction between the two elements. Governments can affect the conditions of a country through the creation of public goods, acting on competition and the advantages of ownership of local and foreign companies (Matei, 2004; Dracea, & Cristea, 2010; Cristea, & Drăgulin, 2016). According to this theory, countries go through five stages of development (Buckley & Castro, 1998, Narula & Dunning, 2010, Narula & Guimon, 2010).

- The first stage is specific to least developed countries (being in the pre-industrialization period): FDI flows (inward and outward) are almost nonexistent because the local market is small, the infrastructure is not adequate, and the workforce and the legal framework are poorly prepared.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The stage 2 is characterized by the development of specific location advantages (improving infrastructure, resources, increasing the size of the domestic market). This stage is characterized by increasing inward FDI concentrated in the traditional branches of manufacturing and labor-intensive industries (such as construction, distribution and trade). At this stage, we are witnessing faster growth of FDI stock received than GDP. The outward FDI stock is very low because the ownership advantages of local companies are still weak.
- The stage 3 is characterized by a less spectacular growth of FDI received. These are exceeded by outward FDI; for the first time, the countries recorded an increase in net FDI stock, even if sometimes recorded negative values. This change is given the benefits of ownership of local companies that become more specific to companies and less country-specific. The companies will become stronger and even more competitive, they will engage in investment to exploit the resources in less developed countries and the seeking of assets or markets in more developed countries. This stage is specific to countries that have managed to create a legal system and satisfactory infrastructure.
- The stage 4 is characterized by the predominance of FDI output compared with those received.
- The stage 5, the final stage is the characteristic of the most developed countries, the inward and outward FDI flows are very high, and the net position is nearly zero, alternating negative values with positive ones, depending on the evolution of exchange rates and business cycle.

The development investment path varies from country to country, depending on economic structure (market size, the availability of natural resources), such as type of FDI and government policy (Iacovoiu & Panait, 2014, Voica et al., 2015). The financial international crises affected the activity of companies (Zefinescu et al., 2015) and the flows of FDI that cut dramatically (Haralambie, 2010; Podasca 2010; Zaman&Geamanu, 2010, Voica &Panait, 2014).

In fact, in scientific literature, researchers discuss about the broad version and narrow version of the IDP (Narula & Dunning, 2010, Narula & Guimon, 2010), because the globalization has a dramatical impact on the MNEs` activities (Masca & Vaidean, 2010). So, the MNEs "have responded proactively to globalization modifying their strategies, their spatial organization and the modalities by which they interact with host economic actors"(Narula&Guimon, 2010). Taking in consideration aspects like the "idiosyncratic economic structures of countries, the heterogeneity of FDI and to the effect of government policies", a new version of IDP was developed. For example, some countries have a similar level of development measured by macroeconomic indicators, but the important determinants for FDI such "economic structure, industrial and technological specialization patterns" (Narula and Dunning, 2010) are different and has implication on FDI types and method of entry in the host countries. So, globalization and the activity of public authorities are shaping the flows of FDI at international level. (Serafim, 2011)

Taking in account these considerations, in this paper, the authors analyzed the connection between the development`s stage of a country and the inward and outward FDI flows and stocks for EU members for 1990-2014 period.

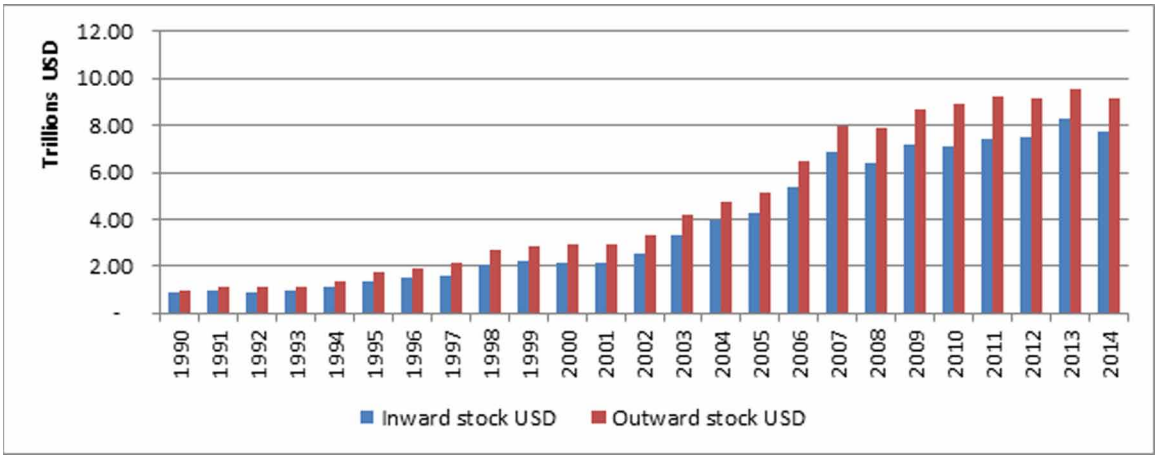
## 2. THE EVOLUTION OF IDP INDICATORS IN THE EUROPEAN UNION

In this paper, we will study the evolution of the IDP indicators for the 28 EU member states. We used as data source the statistics from United Nations Conference on Trade and Development regarding inward and outward stock of FDI, GDP and population for a time span from 1990 to 2014 and we calculate the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

NOI/capita (net outward investment/capita) and GDP/capita indicators. The monetary unit was the US Dollars at current prices and current exchange rates.

Analyzing the raw data, we observed that the inward and outward FDI stock had an ascending trend for the EU in the analyzed period. The inward FDI grew around 8.7 fold from 0.8 trillion USD in 1990 to 7.6 trillion USD in 2014. At the same time, the outward FDI stock grew around 9.3 fold from 0.9 trillion USD in 1990 to 9.2 trillion USD in 2014.



In Figure 1, we observe the evolution of inward and outward FDI stock from 1990 to 2014. The trend for both indicators was ascending through the analyzed period. The inward FDI stock registered an average rate of growth of 10.8% annually. The highest rates of growth have been registered in 1998 with a growth of 32%, 2002, 2003 with growth rates of 22% and 29% and 2006, 2007 with growth rates of 27%. Among these annual growth rates, we find some years with a negative growth and the most important are the year 2008 and 2014 with decreases of around 7%. The outward FDI stock registered an average rate of growth of 10.2% annually. The highest rates of growth have been registered in 1995 with a growth of 28%, 1998 with a growth of 25%, 2003 with a growth rate of 24% and 2006, 2007 with growth rates of 24% and 23%. Among these annual growth rates, we find some years with a negative growth and the most important is the year 2014 with a decrease of around 5%.

Next, we will make a comparative analysis between the EU member state as they evolve through the IDP stages between 1990 and 2014. In order to achieve a better understanding of the phenomenon, we group the states according to their medium value of GDP/capita and evolution through the IDP stages in sets of 5 countries.

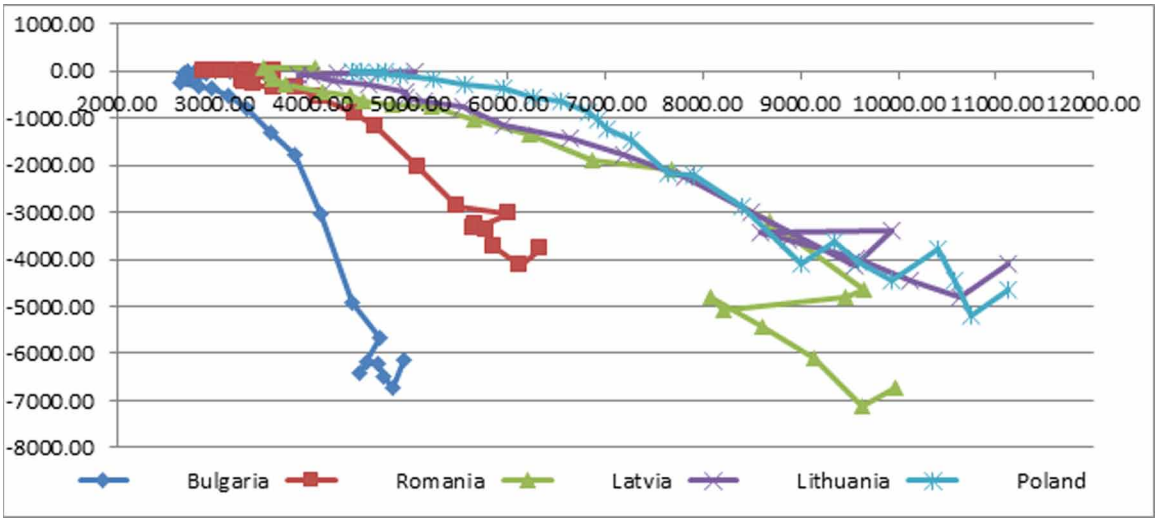
The methodology used to group the states on the IDP stages is initiated around the GDP/capita indicator as it follows: stage 1 for GDP/capita lower than 2.500 USD, stage 2 for GDP/capita between 2.500 USD and 10.000 USD, stage 3 for GDP/capita between 10.000 and 25.000 USD, stage 4 for GDP/capita between 25.000 USD and 36.000 USD and stage 5 for GDP/capita higher than 36.000 USD.

In Figure 2, we study the first group of five states, Bulgaria, Romania, Latvia, Lithuania and Poland. All five countries have a similar evolution in concordance with the IDP theory which states that the NOI/capita will be negative. Romania, Bulgaria and Latvia are in stage 2 throughout the entire period;

*Figure 1. FDI inward and outward stocks in European Union 1990-2014 (Source: Authors calculation based on data from UNCTAD)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Lithuania and Poland started in stage 2 and advanced to stage 3 in 2012 respectively 2011. According to Figure 2, we can view the financial crisis influence on the stock of FDI, influencing the flow of FDI. Another important aspect is represented by influence of the communist breakdown since 1989 that can be observed at the start of the period in the GDP/capita indicator which had a decreasing trend in the first years generated by the transition from communist economy to capitalist economy with the change of the property from state owned to private owned.



All five countries evolution of NOI/capita indicator was influenced mainly by the inward FDI evolution. Outward FDI had almost no influence on NOI/capita because of the low level registered in the analyzed period. As we can see from Figure 2, the evolution of the two indicators was smooth until 2008 when the financial crisis determined a chaotic evolution for all countries influenced by the disruption of FDI flows and lack of confidence between countries. The GDP/capita registered an important fall in 2008 and then recovered the ascending trend while the NOI/capita registered high variations from the main trend registered until then.

Forward, we analyze the next group formed of Estonia, Slovakia, Croatia, Hungary and Czech Republic. All these countries were in stage 2 of IDP in 1990 and they went to the next stage like this: Estonia in 2005, Slovakia in 2006, Croatia in 2005, Hungary in 2003 and Czech Republic in 1996. Since 2007, all these countries are in stage 3 of the IDP and the values of NOI/capita were negative in concordance with the IDP model. In this group, we also have former communist countries which registered a decreasing trend of GDP/capita at the beginning of the analyzed period, as we can observe from Figure 3.

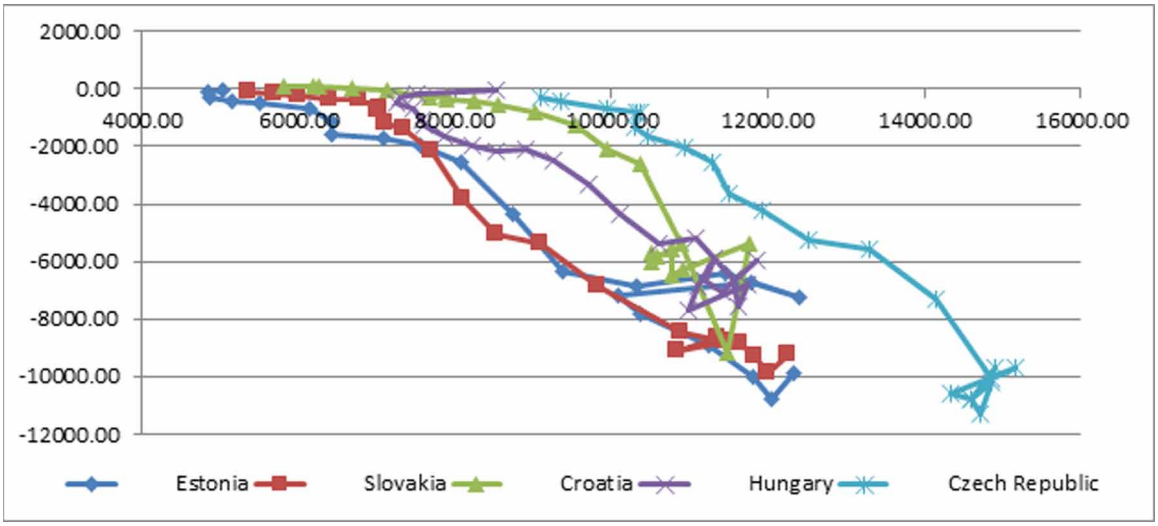
In Figure 3, we see that the five countries have a similar evolution of the two indicators, in concordance with the IDP model.

Slovakia and Czech Republic had a similar evolution through the analyzed period with a high level of inward FDI and a low level of outward FDI, similar to the countries of stage 1 and 2 of the IDP model. The financial crisis of 2008 did not have a big influence on the evolution of the NOI/capita and GDP/capita indicators.

*Figure 2. The correlation of GDP/capita – NOI/capita for Bulgaria, Romania, Latvia, Lithuania and Poland (Source: Authors calculation based on data from UNCTAD)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Estonia, Croatia and Hungary received the shock of 2008 harder and with very high influence on both GDP/capita and NOI/capita. Estonia registered the highest decrease of GDP/capita, but recovered quickly and retook the trend registered before the crisis. Croatia on the other hand took the blow easier but didn't recover from it, the IDP graphic showing that the country is blocked in the same spot for the last three years.



Slovenia, Portugal, Greece, Spain and Italy are the countries that compose the next group. Among them are some of the most competitive economies of the EU and also some of the most affected by the financial crisis.

In Figure 4, we observe that Slovenia Portugal and Greece remained in stage 3 of the IDP throughout the entire period, Spain started in stage 3 and advanced to stage 4 in 2002 while Italy was in stage 4 throughout the analyzed period. Slovenia, Portugal, Spain and Italy evolve in concordance with the IDP model while Greece. Slovenia and Portugal registered a negative NOI/capita according to stage 3 of the IDP. Greece and Spain went from negative to positive values of NOI/capita while Italy registered only positive values for NOI/capita in concordance with its stage 4 of the IDP.

Slovenia and Portugal had a similar evolution with a trend near the X axis which meant that the value of inward and outward FDI were almost similar and with a very high rise of GDP/capita for Slovenia, almost surpassing Portugal, but in 2008 the financial crisis stopped the evolution and the reduction of FDI flows pushed the NOI/capita towards more negative values.

Greece is a special case that went from negative to positive NOI/capita when the financial crisis stroke. This can be explained by the reduction of inward FDI stock while the outward FDI stock stayed almost the same. At the same time the public debt problem exposed by the financial crisis caused a lack of confidence from investors and pushed Greece into recession whit the need to take unpopular measures in order to ensure the future economic viability of the country. These actions had a negative influence on GDP/capita indicator which decreased almost to the levels of the first quarter of the analyzed period.

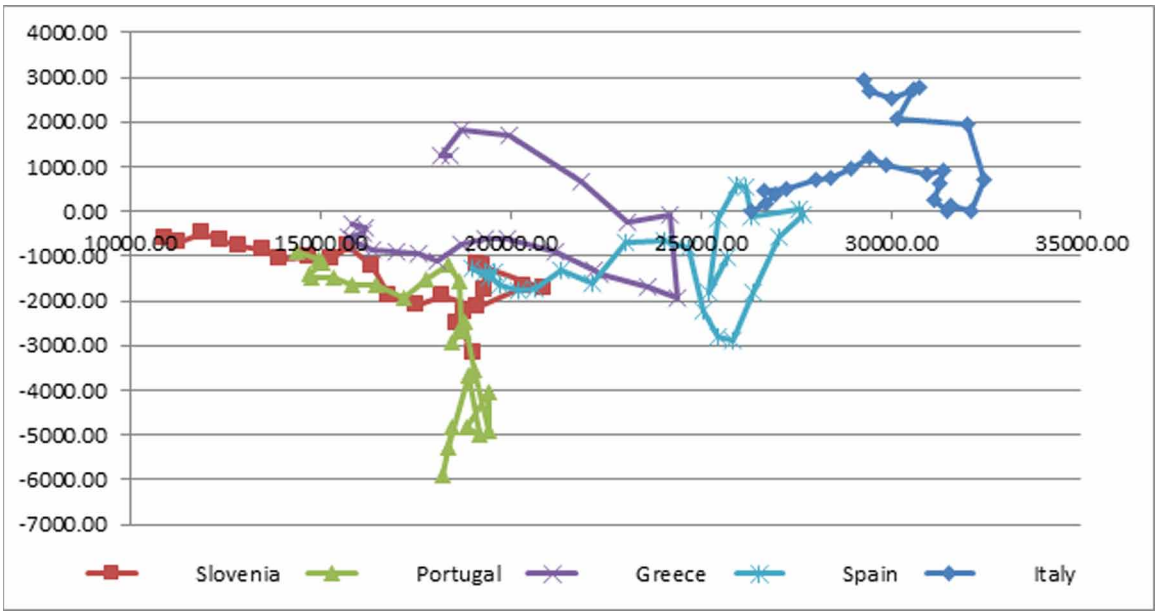
*Figure 3. The correlation of GDP/capita – NOI/capita for Estonia, Slovakia, Croatia, Hungary and Czech Republic (Source: Authors calculation based on data from UNCTAD)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Spain had a similar evolution like Greece, but in its case, the financial crisis had a lower influence on GDP/capita because Spain didn't have the public debt problem of Greece. Spain on the other hand had a structural problem with the real estate sector and the unemployment level. On this background the GDP/capita registered a decrease after 2008. The NOI/capita went back to negative values after the positive values of 3008, 2010 and 2011.

Italy is one of the most developed economies of EU and the only country situated in stage 4 of the IDP model for this group. Throughout the analyzed period the NOI/capita values have been positive in concordance with the IDP model.

The next group is formed from France, Germany, Finland, United Kingdom and Austria. All these countries started in stage 4 of the IDP model and advanced to stage 5.



France is the only country that went from stage 4 to stage 5 in 2007, but in the next year it came back to stage 4 because of the effects of the international financial crisis. The other four countries went to stage 5 and stayed there as it follows: Germany in 2006, Finland in 2002, United Kingdom and Austria in 2001 (Figure 5).

The values of NOI/capita are positive for all of these countries with the exception of Austria which had negative values between 1990 and 2007 and positive value from 2008 onward. United Kingdom went from positive values of NOI/capita to negative values in 2013 and 2014.

In this group is formed from Netherlands, Sweden, Ireland and Denmark. These are the countries with the highest level of GDP/capita from the EU member states.

Netherlands started in stage 4 and advanced to stage 5 in 1998, but throughout the observed period the NOI/capita registered positive values, which is not in concordance with the IDP theory. The level of outward and inward FDI registered and ascending trend until 2007. In 2008, both indicators decreased

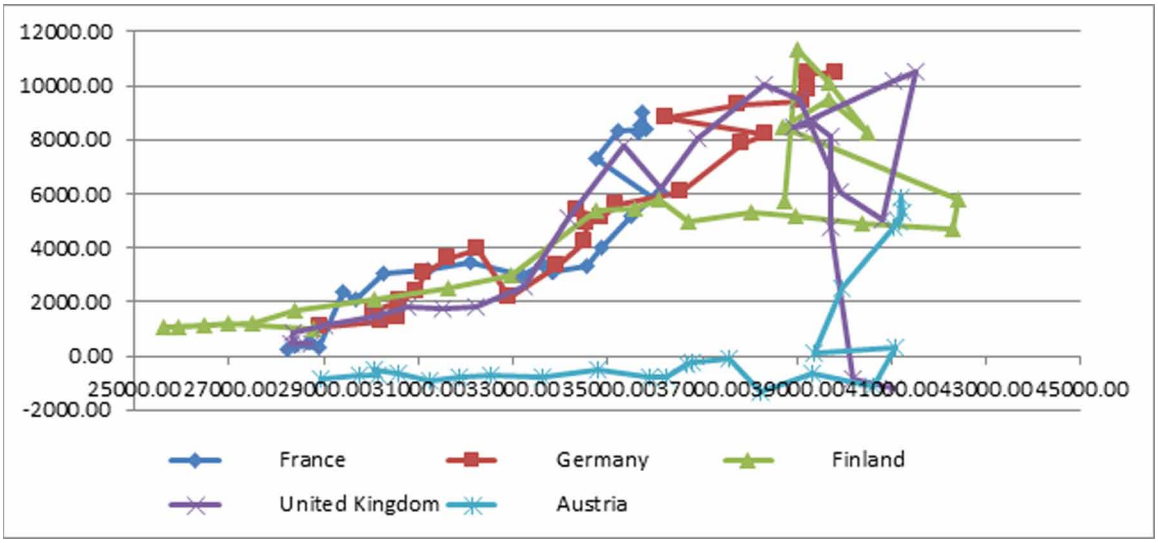


*Figure 4. The correlation of GDP/capita – NOI/capita for Slovenia, Portugal, Greece, Spain and Italy (Source: Authors calculation based on data from UNCTAD)*

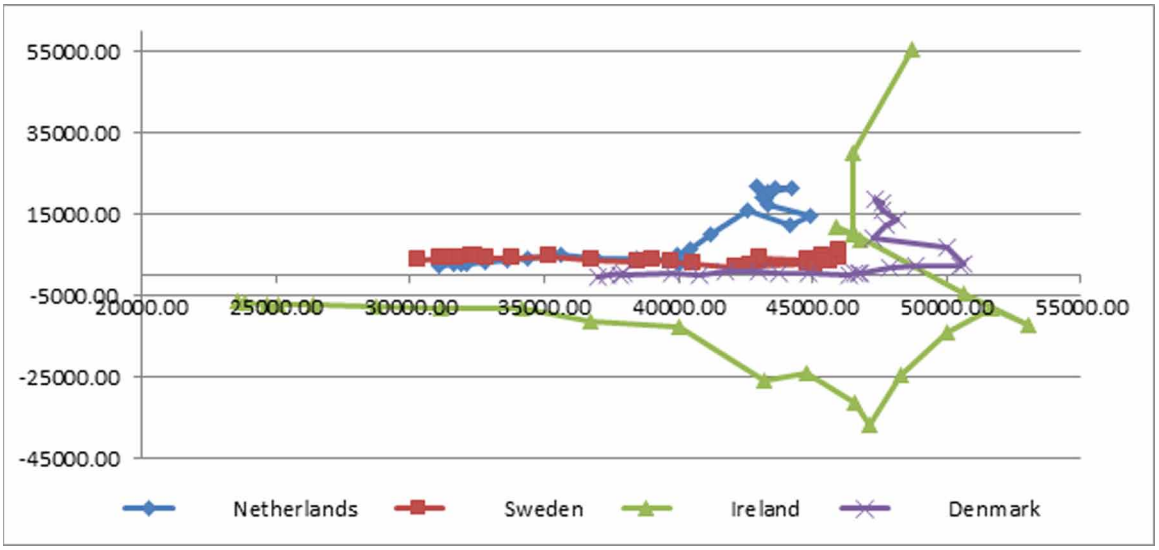
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 5. The correlation of GDP/capita – NOI/capita for France, Germany, Finland, United Kingdom and Austria (Source: Authors calculation based on data from UNCTAD)*

and in the following years the inward FDI had an oscillating trend while the outward FDI had an ascending trend until 2014 when a sharp decrease has been experienced.

Sweden started in stage 4 and advanced to stage 5 in 1997 and registered similar evolution of NOI/capita, like Netherlands, with positive values throughout the analyzed period which is not in concordance with the IDP theory. Thought the analyzed period the inward FDI has been lower than the outward FDI, but the difference between the two indicators has been on a descending trend. In the analyzed period the inward and outward FDI registered an ascending trend. This trend wasn't registered in the first years between 1990 and 1993, in 2008 because of the financial crisis and 2014.

Ireland started in stage 3 of IDP, advanced to stage 4 in 1992 and then advanced to stage 5 in 1997. The NOI/capita evolution has been negative in the period 1990 – 2008 and positive since then. IDP theory says that, in stage 4 NOI/capita should be positive and in stage 5 should be alternant which did happened in the case of Ireland, but the change from negative to positive values for NOI/capita was highly influenced by the financial crisis. In the analysis of the inward and outward FDI evolution, we observe that the international financial crisis marked the point when outward FDI surpassed the level of inward FDI.



Denmark is the country that started in stage 5 and maintained it throughout the entire analyzed period. Its NOI/capita has been positive for the entire analyzed period except for two years, 1990 and 2000. Stage 5 countries should have alternant value for NOI/capita and in the case of Denmark this was true until 2003 when the values for NOI/capita were very close to zero, but after 2003 the positive values of NOI/capita went on an ascending trend until 2013 when we record the first decrease for the NOI/capita value (Figure 6). As a result, we conclude that this country doesn't respect the IDP theory for the entire period.

The last group is composed of countries that have very high variations of NOI/capita like Malta and Luxembourg and countries that have gaps in the data regarding the inward and outward FDI reported like Cyprus that has no data for the years 1990-1995 and 2001, Belgium for the years 2001-2004 and Luxembourg for 1990-2001.

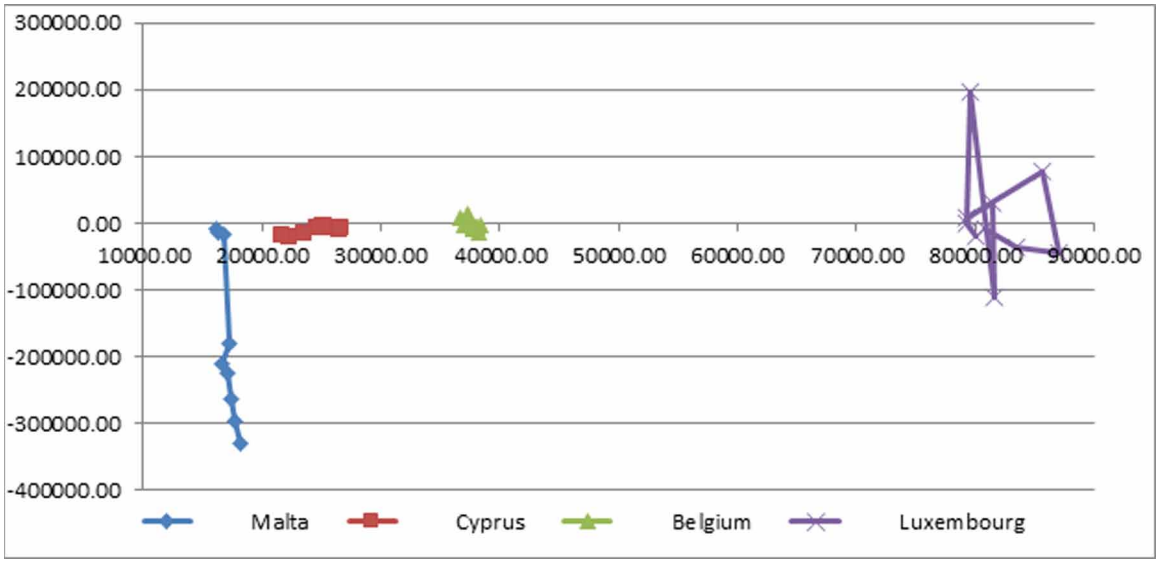
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 6. The correlation of GDP/capita – NOI/capita for Netherlands, Sweden Ireland and Denmark (Source: Authors calculation based on data from UNCTAD and World Bank)*

Malta started in stage 2 and advanced to stage 3 in 1991 and for all the analyzed period his NOI/capita has been negative in accordance with IDP theory (Figure 7). The outward level of FDI indicator is very low compared to the inward FDI. This is a characteristic of countries that are in stage 1 or 2.

Luxembourg is the second of the two countries that was in stage 5 throughout the analyzed period. The recorded NOI/capita is available from 2002 onward and it has negative values before the financial crisis and after it has alternant values in concordance with countries from stage 5 countries. Luxembourg is different from the other countries because it has a small population and a high level of inward and outward FDI, so a small change in the inward-outward FDI equilibrium has an important impact on NOI/capita indicator. The outward FDI of Luxembourg wasn't influenced by the financial crisis while the inward FDI was heavily influenced, registering great falls in 2008 and 2012.

Cyprus started in stage 3 and advanced to stage4 in 2005 only to return to stage 3 in 2011. Cyprus has negative values for the NOI/capita in the years that the data is available. Cyprus felt a higher impact on the inward FDI which had an up and down evolution after the crisis. The outward FDI wasn't that affected at first, but in 2012 the stock of outward FDI decreased by 71%, because of the banking system collapse.



## 3. FUTURE RESEARCH DIRECTIONS

Taking in considerations the idea presented by representative specialists in this field, in many articles (Narula, Dunning, 2010), the IDP model could be applied in the case of regions within countries. These specialists observed major differences between the three macro-regions of China regarding the inward and outward FDI flows. The same situation is presented in Romania, where the FDI inward flows are concentrated in the south region. As future research direction, we intend to use the IDP model for the macro-regions of Romania and to analyze the activities of MNEs that have their headquarters in Romania.

## 4. CONCLUSION

The IDP theory is very useful to forecast the evolution of a country in its first three to four stages of development. However, it has its drawbacks when it comes to developed countries from stage four and five where there are more aspects that influence the development of a country. In fact, Narula and Dunning stress that "The IDP as a framework has been useful in making the point that an increase in FDI (or MNE activity) does not result in a concomitant increase in development".

IDP is a good benchmark for comparisons between countries and their path on development but it is no exhaustive, mainly because it uses only two indicators NOI/capita and GDP/capita, which cannot include all the aspects of the economic life.

We also find frequent exceptions which have different paths according to specific factors like, small country, valued target for foreign investors, factor endowments and so on. For the countries from Central and Eastern Europe, there are a few scientific results regarding the correlation between net outward investment and level of development. These countries are in stage two or three of IDP model. To explain this situation, we must consider certain particularities generated in large part by their political situation before 1990. The communist regimes have not allowed the access of foreign investors in their national economies, but encourage or tolerate investments abroad. In former communist countries, domestic capital formed with difficulties and in a first phase, the public authorities have not encouraged the export of capital. The accession of these countries to the EU has not boosted local firms to make foreign investment in EU countries, as access to the vast European market is secured by holding implicit EU membership. Companies in these countries are oriented mainly towards other less developed countries or in the neighborhood (Romanian investments in Republic of Moldova).

After foreign trade and inward FDI liberalization, the outward FDI could be a tool used by the former communist countries from Central and Eastern Europe in the process of reintegration at European and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

international level. The financial international crisis and globalization are the main determinants that reshaped the flows of FDI in these countries. But the public authorities could have the major impact of the country`s stage of IDP model by promoting the national economy as host for inward FDI and by supporting domestic companies to invest abroad.

# Chapter 62
# Chinese Investment in the European Football Industry

**Sue Claire Berning**
*University of Erlangen-Nuernberg, Germany*

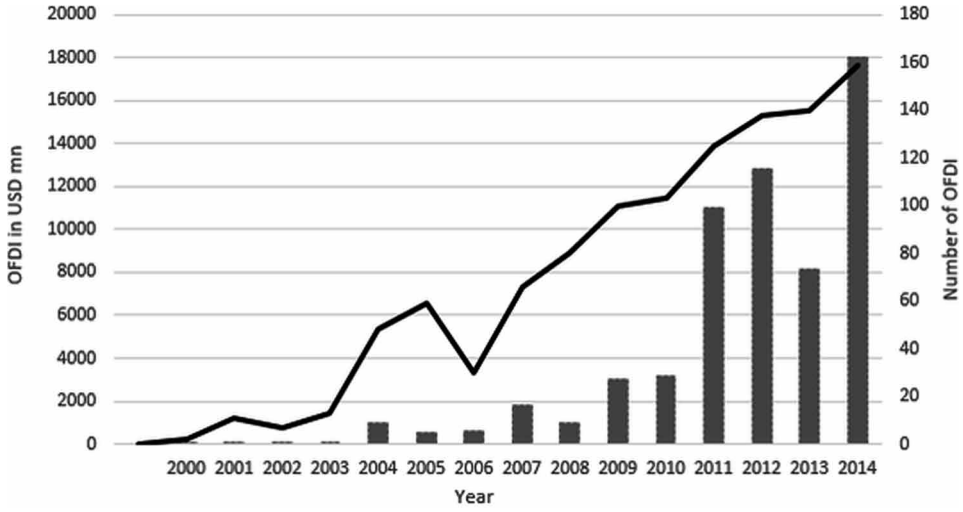
**Daniel Maderer**
*University of Erlangen-Nuernberg, Germany*

## ABSTRACT

*Outward foreign direct investment of Chinese firms in developed markets is a relatively new phenomenon. Since December, 2014 when the Chinese government announced a major investment program in sports, Chinese firms have particularly focused on foreign direct investments in the European football industry. We analyze the investment patterns, the determinants, and the motives of six investment cases of Chinese Outward Foreign Direct Investment (OFDI) undertaken in European football clubs. Based on Dunning's OLI paradigm and the determinants-framework from Holtbrügge and Kreppel, a within-case and cross-case analysis was conducted. We reveal that the main motives of Chinese investments differ between asset-seeking and market-seeking to a combination of both. The most important determinants of OFDI were the size of the host market and the level of know-how in it, while firm-specific resources and the strategic importance of the industry for the home government was a joint determinant for all Chinese companies.*

## INTRODUCTION

### Problem and Objective



The rise of China's economy has brought a constantly growing number of Chinese firms which, being pushed by the Chinese government's GO GLOBAL POLICY implemented in 2001, entered into the international markets. These global activities of Chinese firms captured the attention of international managers, politicians, and scholars alike. Besides the remarkable pace and scope of Chinese outward foreign direct investment (OFDI) development, three further specifics account for this unprecedented

*Figure 1. Chinese OFDI development in Europe*

phenomenon: First, mergers and acquisitions (M&A) gradually became the preferred form of Chinese OFDI. Second, since 2012 the majority of Chinese M&A has been targeting developed countries. Third, since 2011 Europe attracted twice as much annual Chinese OFDI as the United States, while in 2014 Chinese OFDI to Europe reached new record levels with US$18 billion (Baker & McKenzie, 2015; MOFCOM, 2013). Figure 1 illustrates the tremendous growth of Chinese OFDI in Europe.

Numerous studies exist that examine Chinese firms regarding either their market entry strategies, i.e., location choice (Kang & Jiang, 2012; Liu, Buck, & Shu, 2005), ownership mode (Globerman & Shapiro, 2009; Rui & Yip, 2008), entry mode (Cui & Jiang, 2009; Liu & Buck, 2009), or regarding their antecedents, such as determinants (Alon, 2010; Buckley et al., 2007), and motivations (Deng, 2004; Lu, Liu, & Wang, 2011). However, studies focusing solely on Chinese OFDI in Europe and on just one industry hardly exist (Di Minin, Zhang, & Gammeltoft, 2012; Milelli, Hay, & Shi, 2010). By considering both industry-specifics and host country-specifics, it can significantly contribute to a better understanding of the drivers and thus of the investment patterns of Chinese firms.

The common base line of most studies is that Chinese firms' internationalization shows some unique characteristics in their investment patterns. These include the active involvement of the home government (Luo, Xue, & Han, 2010; Nolan & Zhang, 2002), the search for strategic assets (Boateng, Qian, & Tianle, 2008; Duanmu, 2012), or the fast learning capabilities (Zhou & Li, 2007; Morck, Yeung, & Zhao, 2008). Because of these peculiarities, some scholars argue that Chinese OFDI cannot be explained by traditional internationalization theories and hence new theories must be generated (Barney & Zhang, 2009; Peng, 2012). On the opposite side, other scholars view existing theories as suitable for China's global operations (Rugman & Li, 2007), or just call for their extensions (Dunning & Lundan, 2008; Mathews, 2006).

Dunning's (1980) Ownership-Location-Internalization (OLI) paradigm has been widely used for investigating Chinese firms' investment motives and determinants (Berning & Holtbrügge, 2012; Wei, 2010). Asset- and market-seeking are found to be the two most important investment motives behind Chinese OFDI in developed countries (Marchand, 2015; Mathews, 2006). In particular, Chinese firms are driven by strategic asset-seeking motives (Luo & Tung, 2007) that results in both asset exploiting and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

asset augmenting (Cui & Jiang, 2010; Yiu, 2010), stronger emphasis on strategic intent than strategic fit (Rui & Yip, 2008), rapid setup of Chinese R&D laboratories (Deng, 2007), and the preference for M&A over greenfield investment in developed countries (Deng, 2009; Spigarelli, Alon, & Mucelli, 2015).

Regarding the investment determinants of Chinese firms, most existing research states that a single theoretical lens may be inadequate to explain them because of the complex and unstable external environments, as well as the heterogeneous internal resources and capabilities (Alon, Child, Li, & McIntyre, 2011; Lu et al.2011; Peng, Wang, & Jiang, 2008). A comprehensive and systematic framework to examine the determinants of Chinese and other emerging market firms' (EMF) OFDI was developed by Holtbrügge and Kreppel (2012) comprising country-, industry- and firm-level determinants. As this framework includes all idiosyncrasies of Chinese firms' internationalization, it enables a more fine-grained comprehension of how the investment motives are contingent on country, industry and firm factors.

The purpose of this chapter is to examine the investment patterns, motives and determinants of Chinese firms in developed European countries. In particular, the focus is on M&A undertaken in only one industry; namely, the football industry. The reasons for the choice of the football industry are threefold: First, this under-researched industry represents a good opportunity to examine if the overall Chinese trends and their unique specifics are also reflected here. Due to the high media attention the football industry receives, a lot of detailed information about these investments are available. Second, the European football industry became an economic heavy weight during the last two decades with revenues of more than €19 billion (Hamil & Chadwick, 2010). Third, China's government strongly focuses on football development and China's president Xi Jinping is a big football fan. Xi has already made football a compulsory part of the national curriculum for schoolchildren and has developed a series of football textbooks for students in primary and secondary school (MacFarlan, 2015).

The contributions of this chapter are as follows. By adding Dunning's typology of investment motives, this study extends the level-wise determinants-framework of Holtbrügge & Kreppel (2012). In order to test the explanatory power of this extended framework, a within-case and cross-case analysis is conducted. Moreover, by addressing the interplay between context-specifics and firm internationalization, this article considers the often-cited uniqueness of Chinese firms. In doing so, this chapter contributes to the above-mentioned academic debate about the applicability of traditional internationalization theories to China (Boisot & Meyer, 2008; Child & Rodrigues, 2005; Cuervo-Cazurra, 2012), i.e., regarding the key question of "why" outward foreign direct investment (OFDI) is undertaken, by suggesting a way of how to conceptualize a theoretical extension.

The remainder of this study is as follows. After a review on Dunning's OLI paradigm the country-, industry- and firm-level determinants-model with reference to distinct investment motives is outlined. Then the explanation of the methodology and the case studies' results are presented. A concluding section with theoretical and managerial implications, limitations and future research directions follow.

## Theoretical Background

### OLI Paradigm

Dunning's OLI paradigm is one of the most powerful tools to understand the extent and pattern of OFDI. It argues that firms internationalize because they have developed competitive advantages at home (O(wnership)-advantages), which can be transferred to specific countries to exploit location advantages (L-advantages) through foreign direct investment (I(nternalization)-advantages). O-advantages are de-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

fined as unique capabilities proprietary to the firm which are built upon managerial capabilities, product or process technology. These advantages are firm-specific resources and assets (Dunning, 1980, 2001).

Based on these O-advantages, the firm chooses the host country location following its specific motivation which is market-, efficiency- or asset-seeking. Market-seeking OFDI is undertaken to protect existing markets or to promote new markets (Dunning & Lundan, 2008). Apart from market size and expected market growth, firms engage in market-seeking OFDI because of the need to adapt products to local tastes, cultural norms or indigenous resources (Luo & Tung, 2007). Efficiency-seeking OFDI aims to rationalize established structures of resource-based investment in such a way that the investing firm can benefit from the common governance of geographically dispersed activities (Wei, 2010). These gains are essentially achieved through economies of scale and scope and risk diversification. Asset-seeking OFDI strives to acquire abroad particular resources of a higher quality at a lower real cost than could be obtained in the home country. These resources can be both tangible and intangible (Dunning, 2001). Strategic asset-seeking OFDI is a subgroup thereof, and is part of the firm's long-term strategic objectives, especially that of sustaining or advancing its global competitiveness (Rui & Yip, 2008).

In the case of Chinese OFDI, several studies highlight that additional factors of the current economic and political situation have an effect on Chinese firms' OFDI decisions which have to be integrated into existing theoretical perspectives (Alon et al., 2011; Nolan & Zhang, 2002; Wang, Hong, Kafouros, & Boateng 2012). The particular context of Chinese firms is key to an understanding of Chinese particularities, being the firms' background, ownership, administrative structure, and the landscape of political and institutional support and constraints they are bound to (Gugler & Boie, 2008). These are competitive advantages and disadvantages for Chinese firms which create considerably different starting points of analysis.

## Determinants-Framework

With reference to different levels of analysis, Holtbrügge & Kreppel (2012) developed a comprehensive framework to study the determinants of Chinese firms and other EMFs on the country-, industry- and firm-level (Table 1). Country-level determinants, such as the size of the host market, the potential of forward integration into the host market, and the level of technological and managerial know-how are relevant for all EMFs, whereas industry-level determinants differ between diverse industries. Firm-level determinants encompass the strength of firm-specific resources innate to particular firms.

When OFDI is motivated by market-seeking and growth opportunities outside the home market, the size of the host market is a crucial determinant. As several Chinese firms have invested in large and prosperous EU-28 countries (e.g., Lenovo, Haier), they do not only confirm this tendency, they also

*Table 1. Country-, industry-, and firm-level determinants of EMFs' OFDI*

| Level of Analysis | Determinant | | |
|---|---|---|---|
| Country-level | Size of the host market | Potential of forward integration into host market | Level of technological and managerial know-how |
| Firm-level | Strength of firm-specific resources | | |
| Industry-level | Strategic importance of the industry for home government | Competitive pressures in home market | |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

exhibit theoretical implications. They contradict traditional internationalization theories, like the Uppsala Model (Johanson & Vahlne, 1977) which suggests an incremental internationalization from psychically and culturally close to more distant countries. Thus, new theoretical perspectives, like the 'Springboard perspective' (Luo & Tung, 2007) and the 'Linkage-Leverage-Learning perspective' (Mathews, 2006) emerged reflecting the preference of OFDI into developed countries with attractive market size and market potential.

Another country-level determinant for EMFs' investment is the potential of forward integration into the host market. Chinese firms benefit from low labor and other cost advantages at home, but they lack marketing and sales know-how (Cuervo-Cazurra, 2007). In order to catch-up with the incumbent global giants as latecomers, Chinese firms hence engage in these asset-seeking OFDI aiming at moving up the value chain and thereby enhancing their global competitiveness (Deng, 2009).

Closely related hereto is the third country-level determinant, the level of technology and management know-how in the host market. Chinese firms are often driven to invest abroad because they want to learn and benefit from these strategic assets, like advanced technology, international known brands, management and marketing skills (Wei, 2010). The consequence is asset augmenting which was found to be another Chinese firms' unique characteristics (Demirbag, Tatoglu, & Glaister., 2009; Gammeltoft, 2008). The concept of O-advantages should therefore be extended to include combinative, dynamic, and innovative capabilities as well as absorptive capacity (Cui, Jiang, & Stening, 2011).

On the firm-level, the strength of firm-specific resources is the most important determinant of EMFs' OFDI activities. These resources are the origin of the firm's competitiveness and growth at home (Barney, 1991). The types of resource advantages of Chinese companies differ from the ones developed-country firms enjoy (Wright, Filatotchev, Hoskisson, & Peng 2005) as they are mainly home-country based (Rugman & Li, 2007), like exploitation of economies of large-scale, preferential access to raw material, institutional support, and recruiting the most qualified employees (Morck et al., 2008; Yiu, 2010) leading to a dominant position in their home market. The motive to invest abroad can be both asset- and market-seeking driven as asset exploiting as well as strategic intent of Chinese firms could be observed in the past (Narula, 2006; Yiu, Lau, & Bruton, 2007).

At the industry-level, the strategic importance of the industry for the home government is a key determinant of Chinese OFDI. The Chinese government does not allow unregulated investment in every industry, but explicitly names priority industries of national strategic importance (Buckley et al., 2007). These are listed in the Party's Five-Years-Plans or in the "Countries and Industries for Overseas Investment Guidance Catalogue". This means that all OFDI complying with this guidelines enjoy favorable treatment and institutional support (Luo et al., 2010). Additionally, the investment motive for Chinese firms is to acquire assets which can strengthen these strategically important industries.

Another industry-level determinant is the competitive pressure in the home market. After China's entry into the World Trade Organization (WTO), some domestic firms were confronted with declining market shares, growing competition from international rivals, lower demand and falling prices (Holtbrügge & Kreppel, 2012). Consequently, some Chinese firms started with market-seeking OFDI engagements.

Table 2 gives an overview of the distinct investment determinants with the associated investment motives. It is striking that efficiency-seeking OFDI cannot be related to one of the determinants. However, this fact can be backed by the current state of research which did not find any relevance of this investment motive either (Kang & Jiang, 2012; Liu, Lu, & Chizema, 2014; Peng, 2012).

*Table 2. Investment motives and determinants of EMFs' OFDI*

| Level of Analysis | Determinant | | |
|---|---|---|---|
| Country-level | Size of the host market | Potential of forward integration into host market | Level of technological and managerial know-how |
| | Market-seeking | Asset-seeking | Asset-seeking |
| Firm-level | Strength of firm-specific resources | | |
| | Asset- & Market-seeking | | |
| Industry-level | Strategic importance of the industry for home government | Competitive pressures in home market | |
| | Asset-seeking | Market-seeking | |

## Methodology

As stated in the introduction, for the purpose of this study we focus on only one industry; namely, the football industry. Since OFDI of Chinese firms in developed markets is a relatively new phenomenon, an exploratory and qualitative research design seems to be appropriate. Case studies are recognized as an appropriate method to obtain a deeper insight into a new phenomenon and to explore factors which have been neglected in previous research (Eisenhardt & Graebner, 2007; Yin, 2004). The methodology of using multiple case studies creates comparisons which can determine whether a finding is ascribed to a specific case or consistently replicated by several cases (Eisenhardt, 1991; Eisenhardt & Graebner, 2007).

With reference to Eisenhardt (1989), a within-case analysis was conducted primarily aimed at understanding specific aspects of a case, and a cross-case analysis that explores similarities and differences between the cases. Thus, our study is qualitative in nature and based on secondary data retrieved from various company homepages, business reports, and periodical articles in German, English, and Mandarin Chinese. Due to the high media attention the football industry receives, a plethora of information about the motives and determinants of Chinese companies' investments into the European football industry is available online. In total, six investments by Chinese companies in 2015 have been identified (Table 3).

Investments occurred in the Czech football club SK Slavia Prague, French 2nd division club FC Sochaux, Dutch club ADO Den Haag, English club Manchester City and in two Spanish clubs, Atletico Madrid and Espanyol Barcelona. We collected information such as company name, amount invested, acquired club share, date, and European target clubs as well as determinants and motives of these investments.

China Energy Company Limited (CEFC), which is China's sixth largest private company and counts energy and financial services as core businesses, ventured a 60% majority ownership stake in Czech football club SK Slavia Prague. CEFC refused to give any information about the price of this acquisition. Despite being one of the most historic names in Czech football, Slavia Prague has been struggling financially. This investment was part of a bigger investment move by the firm into the Czech Republic. In 2014, it decided to establish a major European base in Prague by buying two historic properties in the city and a number of businesses. Slavia Prague avoided relegation last season and is now placed fifth in the table. CEFC also plans to support Czech football by becoming a partner of both the national team and youth football setup, and to promote cooperation between China and the Czech Republic.

Ledus, a Hong Kong based electrical components manufacturer, acquired 100% of French second division football club FC Sochaux from Peugeot for €7 million in July, 2015. FC Sochaux is the first

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

soccer club in Europe under the full control of a Chinese investor. Founded in 1928, it is one of the oldest French professional clubs and until the sale to Ledus, Peugeot had always owned the club. It had spent 66 seasons in the top flight before being relegated in 2014. The aim of the investment is to return the club to Ligue 1 in the shortest possible time. With that intent, the new owners of the club promised to allocate a higher budget than the previous season.

China's United Vansen International Sports Corporation (UVISC) bought 98% of the Dutch soccer club ADO Den Haag for €8 million in January, 2015. ADO Den Haag is a 110-year-old club and was also struggling financially before the investment. It is the only major soccer club in The Hague, the seat of the Dutch government. UVISC focuses mainly on the sports industry, organizing the Italian Super Cup in Beijing for three seasons, helping to organize the closing ceremony of the 2008 Beijing Olympics, and bringing the French Super Cup to China in August, 2014. Wang Hui, the Chief Executive Officer of UVISC, wants to turn the team into a powerhouse capable of challenging the top Dutch clubs. The motivation of this investment was to take the club into European competition while sending the club's Dutch coaches to China to improve young players there. The investment should also provide opportunities for Chinese football players to play in Europa League and to establish an incubator for young Chinese talents in Europe. While a handful of ADO coaches went to Beijing to coach at the former school of Chinese president Xi Jinping, an avid soccer fan, the former Chinese national team coach Gao Hongbo was unveiled as an ADO assistant coach.

China Media Capital (CMC), China's leading media, entertainment, sports, and internet dedicated investment firm, and CITIC Capital, a state-owned investment company, invested €364 million to buy 13% of City Football Group (CFG). The City Football Group is a global football enterprise of linked clubs comprised of New York City FC (USA), Melbourne City FC (Australia), and Yokohama F. Marinos (Japan) under the leadership of Manchester City FC (UK). CMC will represent the consortium at the board level of City Football Group with its chairman, Li Ruigang. The investment will be used to fund City Football Group's growth in China, further international business expansion opportunities and to further develop CFG infrastructure assets.

Dalian Wanda property group purchased a 20% stake in Atletico de Madrid football club for €45 million. The Spanish club has also been struggling financially, but achieved remarkable success by winning La Liga and reaching the final of the UEFA Champions League in 2014. Wanda acquired its stake through capital increase. Miguel Angel Gil, the chief executive and leading shareholder, and Enrique Cerezo, the chairman, will continue to control the club. Dalian Wanda's chairman Wang Jianlin stated, "Wanda Group is delighted with the possibility of contributing to the growth of Atletico Madrid and the development of its brand in Asia, as well as being able to rely on their extraordinary experience in the training area, which no doubt will be very useful in the growth of base football in China" (Atletico, 2015).

Rastar Group, a leading Chinese manufacturer of model cars and related raw materials business, acquired 56% of Espanyol Barcelona for €17.8 million. The company hopes to expand its interactive entertainment business in the sports sector with this investment. Moreover, there are several rumors about Chinese companies making further investments which were not considered in this study as they have not yet been finalized. For instance, Spanish club Malaga CF are in talks to sell up to 95% of the club to a consortium of Chinese investors. Furthermore, Chinese corporate money has also been linked with takeovers of Aston Villa in the English Premier League and AC Milan in Italy's Serie A. We had to eliminate Hong Kong businessmen Carson Yeung's October 2009 investment into the English second division club Birmingham City FC because the deal was conducted via his company Birmingham International Holdings (previously Grandtop International Holdings) which is located in the Cayman Islands.

*Table 3. Investment details of Chinese companies in European football clubs*

| Company Name | Investment Amount | Acquired Club Share | Date | European Target Club/ Country |
|---|---|---|---|---|
| United Vansen International Sports Corporation (UVISC) | € 8m | 98% | January 2015 | ADO Den Haag/ Netherlands |
| Dalian Wanda | € 45m | 20% | January 2015 | Atletico Madrid/ Spain |
| Ledus | € 7m | 100% | July 2015 | FC Sochaux/France |
| China Energy Limited (CEFC) | Refuse to give any information about the amount | 60% | September 2015 | SK Slavia Prague/ Czech Republic |
| Rastar Group | € 18m | 56% | November 2015 | Espanyol Barcelona/ Spain |
| China Media Capital (CMC) & CITIC Capital | € 364m | 13% | December 2015 | Manchester City/ United Kingdom |

## Findings

In the following section, the findings of our case analysis explores similarities and differences of internationalization determinants and motives are presented. An overview of these cases is presented in Table 4.

### Country-Level Determinants

- *Size of host market.* Our cases reveal that market-seeking motives are one of the main drivers for Chinese OFDI. These companies are obliged to search for growth opportunities outside their home markets. The size of the host market is a crucial determinant when OFDI is motivated by foreign market-seeking opportunities. Interestingly, most Chinese companies do not see these opportunities in neighboring countries, but rather in Europe. Chinese investments targeted professional football clubs in England, Spain, France, the Netherlands and the Czech Republic. This is in line with the Chinese OFDI stock since 2000, according to which Chinese investments in Europe mainly went to United Kingdom (€14.7 billion), Germany (€7.7 billion), France (€7.4 billion), Portugal (€6.2 billion), Italy (€5.1 billion) and the Netherlands (€3.7 billion) (Baker & McKenzie, 2015).

Furthermore, Chinese investments in the football industry targeted Spain (€1.4 billion) and the Czech Republic. No Portuguese or Italian club has yet been acquired, but China National Chemical Corporation has acquired Pirelli, part-owners of Serie A club Inter Milan, in a €7 billion deal (Chadwick, 2015a). This behavior contradicts classical models such as the Uppsala model of Johanson and Vahlne (1977). The reason is that European markets are more attractive in terms of market size and market potential (Luo & Tung, 2007). By investing in European football clubs, Chinese investors seek to promote their business in Europe, to raise corporate awareness, and subsequently to boost sales.

For instance, it is unlikely that Ledus will be able to build a fan base in China around the club. The new owners rather use Sochaux as a vehicle to develop the Ledus brand in France and Europe and to improve the company image (Wilson, 2015). Dalian Wanda wants to position Atletico Madrid as a hub in an entertainment axis that stretches from Beijing to Hollywood, while the Rastar Group hopes that

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the deal will help to expand its interactive entertainment business in the sports sector. This finding goes along with the fact that other investments are performed in targeted countries. For example, Dalian Wanda bought the landmark Edificio España tower in downtown Madrid for €265 million and the acquisition could also open the way for further investments in Spain.

Furthermore, CEFC's investment in Czech football club Slavia Prague was part of a bigger investment move as two historic properties in the city and a number of businesses were also purchased, thus establishing a major European base in Prague. CEFC with €680 million is the biggest Chinese investor in the Czech Republic. According to the chairman of CEFC, the investment is also the starting point of a "silkroad strategy" from the central government, in order to promote the friendship and cooperation between China and the Czech Republic (Ren, 2015). These investments can also be a powerful marketing tool for the Chinese market. Soccer in China has the highest marketing revenue and most TV viewers of any sport and European football matches accounted for half of all sports broadcasts on China Central Television in 2013 (Gu, 2014).

- *Potential of forward integration into host market.* China benefits from cost advantages at home, but they lack marketing and sales know-how (Cuervo-Cazurra, 2007). In order to catch-up with global giants, Chinese firms engage in asset-seeking OFDI aiming at moving up the value chain and thereby enhancing their global competitiveness (Deng, 2009). This determinant could only be confirmed for two of our six cases. Two Chinese investors, Dalian Wanda and UVISC, had established parts of their business in the sports industry and "want to move to the upper part of the value chain" to acquire marketing and sales know-how (NetEase, 2015). For the other companies, the potential of forward integration into the host market was not a relevant determinant for OFDI as their previous business activities were not related to the sports industry.
- *Level of technological and management know-how in the host market.* Resource-seeking motives are also vital for Chinese companies. While China's competitive advantage is mainly based on low labor costs, Chinese companies often lack recognizable management / marketing know-how or technological equipment (Holtbrügge & Kreppel, 2012). One way to overcome these limitations is to invest in firms in developed countries that possess these resources. Chinese business investors often have enough money, but they often do not have the knowledge or experience in football, an industry that is notoriously difficult for corporate owners to understand and in which to excel (Chadwick, 2015a).

In particular, because China currently lacks a proper football infrastructure and the national team performs poorly (FIFA-ranking: 82), many Chinese companies invest in European football clubs to acquire necessary football competencies which can then be transferred back to China. They seek know-how on youth development and professional coaching programs (CEFC), know-how on the building of facilities (Dalian Wanda), or simply want to provide opportunities for Chinese football players to play in a European league (CMC & CITIC). Sports business professor Simon Chadwick confirms, "But they need to learn more about football – that is crucial. With these club purchases, they have been going about acquiring competence" (Wilson, 2015).

While conventional theory views FDI as a firm's attempt to pursue the exploitation of firm-specific assets, firms from emerging markets tend to invest in developed countries to gain access to technological and management know-how. Thus, OFDI is aimed at acquiring new resources rather than exploiting existing ones (Holtbrügge & Kreppel, 2012). This asset augmenting is part of Dalian Wanda's investment in

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Spain. The company will invest €20 million annually over the next six years to support the development of 180 young Chinese soccer players in Spain. Moreover, Atletico plans to build a new youth training center for Chinese players studying in Spain to nurture future Chinese talent (Burkitt & Davies, 2015).

## Firm-Level Determinants

- *Firm-specific resources.* At the firm level, the strength of firm-specific resources is the most important determinant of OFDI. These firm-specific resources include different assets, organizational processes, information, and knowledge (Barney, 1991). Firm-specific resources lead to sustained competitive advantages in the domestic market and allow firms to grow there before entering the global marketplace (Holtbrügge & Kreppel, 2012). Several Chinese firms in our sample were already leaders in the Chinese market prior to expanding abroad. For example, Dalian Wanda is owned by China's 2nd richest CEO, Wang Jianlin, CEFC is China's 6th largest private company, and Rastar Group is a leading manufacturer of model cars and related raw material businesses. Furthermore, two companies are backed by the government, CMC is a public equity and venture capital firm and the CITIC Group Corporation is a state-owned investment company. The dominant position in their home market allowed them to develop strong firm-specific resources for their international activities, such as recruiting the most qualified employees and exploiting economies of large-scale.

## Industry-Level Determinants

- *Strategic importance of the industry for the home government.* The Chinese government does not allow unregulated investment in every industry, but explicitly names priority industries that are of national strategic importance (Buckley et al., 2007). These industries are listed in the Party's Five-Years-Plans or in the "Countries and Industries for Overseas Investment Guidance Catalogue". Chinese firms receive particularly strong government support to invest abroad in these strategic industries. In December 2014, the Chinese government announced a major investment program in sports that aims to create a domestic sports industry worth €780 billion by 2025. The entire global sports economy is currently estimated at only €370 billion (Wilson, 2015). China's government is therefore strongly focusing on the development of the football industry, in part because China's president Xi Jinping is a big football fan and has realized the potential in this industry. Xi has already made football a compulsory part of the national curriculum for schoolchildren and has developed a series of football textbooks for students in primary and secondary school (MacFarlan, 2015). The importance of this investigation is underlined by the fact that all Chinese OFDI in European football clubs occurred in 2015. One aim of these investments is to impress the government (Chadwick, 2015b). All OFDI complying with these strategic industries enjoys favorable treatment and institutional support (Luo et al., 2010). Chinese businesses that follow the wishes of their home government by supporting football development may be looked upon favorably by state authorities (Wilson, 2015). According to Rupert Hoogewerf, publisher of the Hurun China Rich List, "it is no coincidence that three of China's 10 richest people are all investing in football. There is an element of ego, and there is an element of business sense. Xi Jinping likes football and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

it is very good for developing local government relationships, and gives people access to networks they won't normally have access to" (Guo, 2014). Thus, Chinese firms may benefit politically from acquiring know-how from developed football clubs abroad and transferring it back to China.

- *Competitive pressures in the home market.* After China's admission to the WTO, several Chinese firms were faced with a declining market share, increasing competition from international brands, low demand and falling prices (Holtbrügge & Kreppel, 2012). As a consequence of the growing competition in its home market, Chinese companies are seeking market opportunities abroad. China's domestic football market is not very well developed because its growth has long been hindered by organizational problems and corruption (Hamil & Chadwick, 2010). Thus, we argue that competitive pressures in the home market was not a relevant determinant of Chinese investments. This is confirmed by our case analysis where no statement regarding competitive pressures in the home market was found.

Table 4 summarizes the case analysis and shows mixed results. Based on the analyzed statements, the main motive of two investments was primarily market-seeking, the motive of two investments was mainly asset-seeking and the other two investment combined both of these motives. Furthermore, we confirm several universal motives of OFDI with the help of our cases. One important motive was profit-making. The commercialism of and the subsequent organizational changes in the football industry have made clubs attractive to international investors (Nauright & Ramfjord, 2010).

Foreign investment in Europe is not limited to Chinese investors. In particular, foreign ownership is prevalent in the English Premier League. Since 2003, there has been a rapid expansion of foreign ownership and half of the 44 clubs in the Premier and Championship League now have foreign owners. For example, Chelsea is owned by Russian billionaire Roman Abramovich, Cardiff City was purchased by Malaysian Vincent Tan and US American Malcolm Glazer owns Manchester United. The main motive of these investments is profit-making (Duke, 2002) as in traditional companies (Carlin, Dorobantu, & Viswanathan, 2009). However, foreign investors must be careful as football is a very emotional product and local fans often see foreign investments as predatory (Duke, 2002).

*Table 4. Determinants and motives of Chinese investments in European football clubs*

| Company Name | UVISC | Dalian Wanda | Ledus | CEFC | Rastar Group | CMC & CITIC |
|---|---|---|---|---|---|---|
| Ownership | Private | Private | Private | Private | Private | State-owned |
| Size of host market | - | + | + | + | + | - |
| Forward integration | + | + | - | - | - | - |
| Level of know-how | + | + | - | + | - | + |
| Firm-specific resources | + | + | + | + | + | + |
| Strategic industry importance | + | + | + | + | + | + |
| Competitive pressures | - | - | - | - | - | - |
| Main motives of OFDI | Mainly asset-seeking | Asset-seeking/ Market- seeking | Mainly market-seeking | Asset-seeking/ Market- seeking | Mainly market-seeking | Mainly asset-seeking |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is often a lack of financial transparency and fans fear unsustainable management due to the short-term orientation of foreign investors. That is why only CMC and CITIC's investment in Manchester City and that of Rastar Group in Espanyol Barcelona confirmed profit-making as a motive. Rastar Group believes that the Spanish economy is now at the lowest point, thus they have bought the club at a very low price. On the one hand, when foreign investors buy stakes in a club, the club consequently receives greater media exposure in the native countries of the investors. Foreign owners also extend financial resources. It is also a great chance for Chinese companies, to use the emotional attachment of fans to their clubs in a positive way by respecting their culture and tradition.

On the other hand, particularly local fans argue that foreign owners do not understand the ethos of the team and are not sensitive to the needs of their fans. Foreign owners are often seen as interested in buying a club purely to turn a profit (Duke, 2002). They are not comfortable with the notion that foreign investors could suddenly halt investment or leave the club. Furthermore, foreign owners often ignore the history and the tradition of the club, as the example of Vincent Tan and Cardiff City shows. The Malaysian owner changed the main color of the logo and the team jersey from blue to red, and added a dragon instead of a bluebird to attract Asian fans, however he faced a major protest from local fans and was forced to change it back.

Another universal motive for OFDI is personal relationship, in particular in China, where the basic dynamic in personalized networks is important and referred to as "guanxi" or relationship (Chadwick, 2015b). For example, Wang Jialin and the CEO of Atletico Madrid have had a long personal friendship before the investment was done. The cases also do not reveal preferences for specific types of investment forms. Ledus completely acquired Sochaux (100%), ADO Den Haag was almost taken over completely (98%), CEFC and Rastar Group bought majority stakes in Slavia Prague (60%) and Espanyol Barcelona (56%), and two companies bought minority stakes in Atletico Madrid (20%) and Manchester City (13%). The reason for the differences in the investment form is related to the size of the club. Based on the UEFA club ranking, Atletico Madrid (5$^{th}$) and Manchester City (14$^{th}$) are very big and successful football clubs, hence the acquired club share is rather low. On the other hand the share percentage is higher (56%-100%) for smaller and less successful clubs such as FC Sochaux (139$^{th}$), Slavia Prague (179$^{th}$), ADO Den Haag (191$^{st}$) and Espanyol Barcelona (n.a.).

When companies mainly focus on asset-seeking motives, Chinese investors should target the Big Five. The Big Five are the five highest earning football leagues worldwide and represent half of the overall size of the European football market (Deloitte, 2012). The financial strength of these leagues is also evident in the Union of European Football Associations (UEFA) rankings, in which these countries occupy the first five positions (Walters & Rossi, 2009). In these countries, professional football is characterized by commercialization and a very good infrastructure. It is also interesting to see that the Netherlands and the Czech Republic are target countries. The fierce competition they face in European markets may help them to learn from competitors and to overcome disadvantages resulting from negative country-of-origin effects (Holtbrügge & Kreppel, 2012).

Chinese firms use international expansion as a springboard to acquire strategic resources and reduce their institutional and market constraints at home. Thus, they overcome their latecomer disadvantage in the global stage via a series of aggressive, risk-taking measures by aggressively acquiring or buying critical assets from mature multinational enterprises (MNEs) to compensate for their competitive weaknesses (Luo & Tung, 2007). Combined with the fast learning capabilities (Morck et al., 2008; Zhou & Li, 2007) of Chinese firms, this will help to support Xi Jinping's plan to qualify for the Football World Cup, to host the event and to win it as soon as possible.

## CONTRIBUTIONS, LIMITATIONS, AND SUGGESTIONS FOR FUTURE RESEARCH

The purpose of this study was to analyze the investment patterns, motives, and determinants of Chinese OFDI in developed European countries. In particular, we focused on Chinese OFDI undertaken in the European football industry. This focus followed the call of Chadwick (2015b) and allowed us to take both industry-specifics and host country-specifics into account, and hence to significantly contribute to a better understanding of the drivers of investment patterns of Chinese firms. Based on Dunning's OLI paradigm (1980) and the determinants-framework from Holtbrügge & Kreppel (2012) a within-case and cross-case analysis was conducted. Using secondary data, our analysis revealed that Chinese firms have many similar motives for acquiring shares of European football clubs, but some differences were also observed. The main motives of the investments differ between asset-seeking and market-seeking to a combination of both. The most important determinants were the size of the host market and the level of know-how in it. Firm-specific resources and the strategic importance of the industry for the home government was a joint determinant for all Chinese companies.

A major theoretical contribution of our paper is the linking of Dunning's typology of investment motives (1980) with the level-wise determinants-framework for EMFs from Holtbrügge & Kreppel (2012). This extended framework enables the association of market-seeking and asset-seeking investment motives with distinct investment determinants on the country-, industry- and firm-level. Thereby it addresses one of the key questions of internationalization "why", and more specifically "what is the goals" and "what influences the OFDI decision".

Moreover, this chapter contributes to the analysis of OFDI from Chinese firms from a country-specific advantages (CSAs) perspective. Based on Rugman and Li's (2007) findings that China CSAs stem from cheap labor and natural resources, and that Chinese firms are knowledge-seekers, our work shows another CSA. The growing global importance of Chinese firms is closely linked with policies decreed by the Chinese government for which several studies provided evidence (e.g., Luo, et al., 2010; Nolan & Zhang, 2002; Yang & Stoltenberg, 2014). In addition, our study shows the strong impacts of and interplay between Chinese policies and investment motives (strategic asset-seeking) and determinants (strategically important industry). The substituting and supporting role of the Chinese government enables Chinese firms to invest in geographically and culturally distant countries, and hence constitutes another CSA for Chinese OFDI.

In doing so, this paper also contributes to the scholarly debate about the applicability of traditional internationalization theories to Chinese firms by supporting the view that existing theories need some extensions and modifications (Dunning & Lundan, 2008; Morck et al., 2008; Peng, 2012) in order to be able to provide explanatory power for Chines firms' internationalization behavior.

Another theoretical contribution lies in showing that traditional definitions and concepts must be broadened beyond their conventional scope in order to capture Chinese firms' internationalization (Moon & Roehl, 2001). In particular, the concept of firm-specific advantages (FSA) needs to be reconsidered as Chinese firms generally lack traditional FSA, such as globally recognized brands or internalized knowledge. But they apparently possess "non-traditional" FSA, like differentiated capabilities in catching-up by learning, dealing with weak and fast-changing institutions, or tolerating ambiguity. These absorptive capacities and dynamic capabilities also constitute sources of competitive advantages, and hence help Chinese firms to prosper overseas (Contractor, 2013).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, Chinese firms appear to define the role of internationalization differently (i.e., as a means to access new advantages and assets rather than to exploit existing ownership advantages). This has important implications for their host countries' location choice (Williamson, 2015). Because their main motivation is to learn and gain access to strategic resources, Chinese firms increasingly choose to invest in markets with rich opportunities for learning, such as Germany or UK. Therefore, traditional theories assuming that asset exploitation is the primary goal need some extensions to be suitable for Chinese firms.

From a practitioner's point of view, this study enhances our knowledge of the determinants and motives of Chinese OFDI. For example, firms from China which have not yet invested abroad may better understand the factors that influence the internationalization process of their competitors and may evaluate the relevance of these factors (Holtbrügge & Kreppel, 2012). Since OFDI often occurs in the form of acquisitions, this might be particularly important for European football clubs that either seek a Chinese partner or fear the risk of being acquired by one. Similarly, the employees of acquired firms may better understand the motives of acquirers from China.

Our analysis reveals that access to specific football know-how is one of the main determinants. One example is Li Wing Sang, chairman of Ledus' holding company who said, "We do not want to change anything in the club. The goal is to keep its culture and to make its history continue. We are not traders, we are there for the long term" (Xinhua, 2015). But there are also counterexamples. For instance, Jialin Wang seems to have lost his passion for ADO Den Haag after only one year because the club did not perform as expected. He even missed the deadlines to make another critical € 3.7m investment in the club. "After I pay the takeover, the club is mine. It is my business in terms of how much I will invest in the club" (Montague, 2016). Additionally, the fans from FC Sochaux felt betrayed and felt like a financial tool of Ledus. In particular in France, there have been disastrous examples of foreign businessmen taking over clubs and pushing them into bankruptcy, or nearly, such as Grenoble, Lens, Strasbourg. Sochaux fans feel they are next (Porteus, 2016).

Some limitations must be considered when interpreting and generalizing the study's results. One limitation is the sole use of secondary data from company homepages, business reports, and periodical articles. While secondary data is more objective and helps to improve the understanding of the problem, future research could use interview or survey data to complement the information on the investment motives and determinants. Furthermore, the relatively small number of cases (6) is another limitation. This fact is related to the quite recent appearance of the phenomenon of Chinese investment in European football overall as all existing cases were included. An investigation at a later point in time could lead to an increased sample size as well as shed some light on the development over time as we expect the importance of the topic to increase over time.

As Chinese OFDI is evolving quickly and the fast learning of Chinese firms is expected to continue (Lyles, Li, & Yan, 2014) their internationalization behavior might change as well. After the Chinese government announced the investment plans for the sports industry, six investments took place in 2015. Additionally, there have been many rumors about further acquisitions. For example, the Beijing Successful Investment Management company is considering putting up to €35 million into the Dutch premier division football club SC Heerenveen (Dutchnews, 2015). Chinese investors also agreed on a €210 million deal with English club West Bromwich Albion, but a Far East stock market dip with a loss of more than 30 percent in three weeks has caused the negotiations to be suspended.

Another prominent example is Italian club AC Milan which was supposed to be taken over from a Chinese Consortium, but Milan's owner Silvio Berlusconi did not want to sell the majority of his shares. Thus, Berlusconi sold 48% of the club to an investor from Thailand (Gladwell, 2015). While previous

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

studies (Buckley et al., 2007; Kumar, 2007) mainly analyzed single countries, comparative studies could further analyze the similarities and differences between investors from different countries. For example, half of the 44 clubs in the Premier and Championship League now have foreign investors from many different countries.

Many Asian tycoons have been attracted to the European football industry for various reasons, from promoting their businesses to vanity projects and a declared love of the game. Last year Singaporean investor Peter Lim took a controlling stake in Valencia. Furthermore, AirAsia boss Tony Fernandes, together with the family of Indian steel tycoon Lakshmi Mittal, co-owns Queens Park Rangers of the U.K.'s Premier League. Finally, Vichai Srivaddhanaprabha from Thailand owns Leicester City. Similarly, a comparison of Chinese investments in other European sport industries could analyze if the football industry is unique in that regard.

Another avenue for further research is the European perspective of these investments. Future studies could investigate the aims of European companies. For example, Atletico Madrid was strategically looking for a Chinese investor to attract new fans and sponsors in China, while CMC and CITIC representatives and City Football Group executives have already been working together to identify China-based initiatives for the football clubs. Additionally, future research should consider the impact of these investments on the domestic Chinese football market. The recent developments in fact also have an impact on the domestic Chinese football market.

Only recently, China has unveiled a strategy to become a world football superpower by 2050, with plans to convince 50 million children and adults to play the game by 2020, including having at least 20,000 football training centres and 70,000 pitches in place by the same year. It establishes short, medium and long-term targets, including ensuring there is one football pitch for every 10,000 people by 2030. By 2050, China should be a first-class football superpower that contributes to the international football world (BBC, 2016). The growing financial impact is also shown by the latest transfer signings of Chinese football clubs. During the last winter transfer period, Chinese soccer clubs were buying players from the world's best leagues for big money. Chinese clubs were responsible for three of the four biggest deals in the winter transfer window. In January Chelsea's Brazilian midfielder Ramires went to Jiangsu Suning €28 million, Hebei China Fortune bought Ivorian striker Gervinho from AS Roma for €18 million and Shanghai Shenhua Inter Milan's Colombian international Fredy Guarin for €13 million (Fangjing, 2016).

Furthermore, the analysis of the growing number of Chinese sponsorships in European football clubs could yield interesting results. Although sponsorships are no classic FDIs with decision-making power, and thus are mainly having market-seeking motives, there have been recent examples which had also asset-seeking motives. For example, the Chinese LED manufacturer Ledman bought the sponsorship rights of the Portuguese second division with the aim to have 10 Chinese players included in the starting line-ups of the top teams. One of their motives was to train young Chinese players better in Portugal. After huge protests of Portuguese fans, the company had to row back on its demands.

Moreover, there are interesting developments in contiguous technological industries. For example, Alibaba Sports has decided to collaborate with _wige in bringing European sports to China, equipping Chinese sports venues with technical infrastructures and in the production and marketing of sporting events. Zhang Dazhong, CEO of the Alibaba Sports Group, confirms "We are very pleased to be a partner with _wige, as they are experts in sports broadcasting and operating with innovative digital technology and consistently making breakthrough in this area. Technology and science bring society progress, we'd like to have deep collaborations with _wige, dedicating ourselves to developing stadium intelligence and media presentation, bringing brand-new sports experience and making everyone a sports person." (Wige, 2016).

# Chapter 63
# Trade Liberalization, Infrastructure Development, and FDI in India and China

**Rajib Bhattacharyya**
*Hooghly Mohsin College, India*

## ABSTRACT

*The two largest economies in Emerging Asia, China and India, are considered to be the 'power houses' of global economy. China and India adopted the policy of 'opening up to the outside world' respectively in 1978 and 1991. Trade openness and infrastructure development has been acknowledged as crucial pre-conditions for attracting foreign direct investment (FDI). China's path of development was guided by the so called fast growing nations, which laid substantial emphasis on building strong infrastructural base at great speed. But India, on the other hand did not adopt the strategy of building infrastructure base prior to the growth of demand, like the one which has been followed by most successful Asian countries achieving rapid infrastructure development. So early opening up and improved infrastructure has attracted more FDI in China than in India. So the present study seeks to examine the relationship between trade liberalization, infrastructure development and FDI inflows in India and China using secondary time series data in a comparative analytical framework.*

## INTRODUCTION

The relationship free trade and economic growth is a highly debatable issue and there is no general consensus regarding the impact of external liberalization on growth. In these context the experiences of newly industrializing countries (NICs), Hong Kong, South Korea, Singapore and Taiwan, have been analyzed with mixed conclusions. Of late, the two giants of Asia, India and China, with their domestic markets providing vast scope for diversified industrialization and trade, are classified by international agencies as emerging markets with potential for rapid economic growth. Both economies possess the capacity to become the 'power houses' of global economy. There are many similarities between the two

economies such as vast pool of employable labour and abundance of natural resource endowments. Also both countries suffer from paucity of capital and a large part of population is still dependent on farm activities. Poverty and relatively poor standard of living continue to affect a large number of people in both the countries. Eradication of poverty and improvement in living standard, therefore, are seen as the basic objectives of development and acceleration in the rate of economic growth as the means to achieve them. Both India and China are home to the world's largest pools of skilled work force and are expected to be the engines of global economic growth in the present century (Bhat, Guha & Pal, 2006).

Foreign trade liberalization received little attention in early stages of the development policy of both India and China. To start with, both the countries adopted inward-looking import substitution policies with an emphasis on self-sufficiency. Later in 1978, China adopted the policy of 'opening up to the outside world' and in 1991, India initiated an import liberalization policy. Comparative advantage replaced self-sufficiency as the basic tenant of trade policy and both the countries are now pursuing market-oriented and outward-looking policies (Sahoo, 2010). India has been a member of the WTO since its inception and China joined the WTO in the year 2001. Both the countries are adhering to the WTO rules in conducting their international trade. Over the last twenty years many developing countries, including India and China have abruptly and substantially lowered tariffs and scaled back other trade barriers.

India's growth has been through information technology (IT), while China's economic growth has been led by manufacturing. To sustain growth, India strives to be a stronger player in manufacturing while China is striving to increase its presence in IT. For India to improve its manufacturing sector, it must increase its FDI inflows for manufacturing and improve basic infrastructure. Conversely, for China to increase its IT sector, necessary policy steps include: focus current IT industry on global exports; spur entrepreneurship and reduce dependence on central government; create a strong trade association to improve regulatory environment; and improve quality and approach of educational system.

The two largest economies in Emerging Asia, China and India, are expected to show different growth trends in 2015 and 2016. GDP growth is expected to accelerate in India (7.7% and 8% in 2015 and 2016, respectively) with expectations of reform under the new government. However, the apparent improvement in forecast growth rates for the Indian economy is also partly a result of significant revisions made by the country's to its GDP data, which raised the base growth rate through 2014 and of the lower oil prices. However, investment and export growth are slow and significant risks remain in theform of obstacles to further reform. China, on the other hand, should continue to see slowing growth momentum (to 7% in 2015 and 6.9% in 2016) despite the benefits of lower oil prices and small stimulus and structural reform measures implemented in 2014.

There is no denial of the fact that infrastructure plays a pivotal role in both the social and economic development of a nation. Direct investment on infrastructure (a) creates production facilities and stimulates economic activities, (b) improves competitiveness by reducing transaction and trade costs and (c) provides employment opportunity to the poor. Global investment (both domestic and foreign) in infrastructure has increased continuously since 2000, reaching a peak in 2008, and then decreasing slightly but maintaining levels reached in 2006. Throughout the 2000s, Asia received the largest amount of global project investment in infrastructure, followed by Latin America. In terms of sector, the number of projects conducted was largest within the power / energy sector during the 2000s in all developed, developing and transition areas, followed by transportation. In case of China, the massive development of physical infrastructure has been the major influencing factor behind its sustained high economic growth and increased competitiveness. But India, on the other hand did not adopt the strategy of building infrastructure base prior to the growth of demand, like the one which has been followed by most successful

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Asian countries achieving rapid infrastructure development (Kim & Nangia, 2008). So early opening up and improved infrastructure has attracted more FDI in China than in India. As per the Eleventh Five Year Plan, more than US$500 billion worth of investment is planned to flow into India's infrastructure by 2012. Construction projects account for a substantial portion of the proposed investments, making the Engineering &Construction sector one of the biggest beneficiaries of the infrastructure boom in India. The regulatory environment is relaxing to encourage further foreign direct investment (FDI).

## LITERATURE SURVEY

There has been an enormous body of literature, both theoretical and empirical, in the area exploring the interlinkages between external trade liberalization, infrastructure development and FDI flows. The following are the instances of some notable works in this area. Using time series data for the period 1960-2005, Ang (2008) studied the determinant of FDI in Malaysia. The author concludes that financial development, infrastructure development and trade openness promotes FDI inflow. Babatunde (2011) explores the relationship between trade openness, infrastructure, foreign direct investment (FDI) and economic growth using a panel of forty two sub Saharan Africa (SSA) countries over the period 1980-2003.Bhagwati and Srinivasan (1975) describes elaborately the nexus between foreign trade regime and economic development in India. The study by Bhat, Guha and Pal (2006) provides detailed analysis of the trade development policies adopted in China and India. It deals with the structure and potential of Indo-China bilateral trade and measures the degree of complementarities in trade between the two countries along with the impact of FDI. Bosworth and Collins (2007) examined the sources of economic growth in the two countries compared and contrasted their experiences over the past 25 years. The work of Kim and Nangia (2008) provides detailed comparative analyses of the infrastructure development of India and China. Kirkpatrick, Parker and Zhang (2006) provides an empirical examination of the relationship between the quality of the regulatory framework and foreign direct investment (FDI) in infrastructure in middle and lower income developing countries during the period 1990 to 2002. The results confirm that FDI in infrastructure responded positively to an effective domestic regulatory framework. Sahoo, Dash and Nataraj (2010) had argued that infrastructure development in China has significant positive contributions to growth. But they emphasized the need for appropriate policy design to improve physical infrastructure as well as human capital formation for sustained economic growth. In another paper by Sahoo, Dash and Nataraj (2012) an attempt has been made to understand growth accounting equations to investigate the impact of infrastructure development on output in China. Sahoo (2014) paper outlines India's foreign direct investment (FDI) policies and highlights challenges for foreign investors, recent policy developments, and the potential for foreign firms.A study by Shah (2014) assesses the importance of infrastructure availability in the host developing country in increasing its attractiveness for overseas investors. Srinivasan (2006) shows the influence import demand and export supply on the growth of China and India. He concludes that China is integrated to a greater extent than India with the world economy, but in the next two decades both countries will be economic powerhouses and their growth will have significant impacts on the world economy. Tan and Yu (2012) analyzes and compares the trade openness pattern of China and India since 2000 and reviews the results in the context of the respective national development strategies. Asiedu (2002) studied the determinant of FDI in 70 developing countries between 1988 and 1997 using OLS estimation technique. Mottaleb (2007) examined the link between trade openness, infrastructure and FDI and its impact on economic growth in developing

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

countries empirically. The empirical research results of Liu (2014) demonstrated that there's a short-run equilibrium relationship rather than a long-run one between trade openness and economic growth and the import trade is related with the export trade. Report of the Committee GOI (2015), Department of Economic Affairs, Ministry of Finance highlights the importance of revisiting and revitalizing Public private partnership model of infrastructure in India.

## OBJECTIVE OF THE STUDY AND METHODOLOGY

The primary objective of the present study is to explore the relationship between trade openness, infrastructure, foreign direct investment (FDI) and economic growth using a time-series data two countries of Asia viz. India and China over the period 1996-2014. FDI flows in a country is taken as the dependent variable and the independent variables are (i) Trade- GDP ratio [(export + import) / GDP], denoted by TRADE_GDP, the most widely used measure of trade openness of a nation; (ii) real GDP growth, denoted by RGDP_GR (iii) Current account balance as a percentage of GDP, denoted by CAB_GDP (iv) Infrastructure Development, represented Electric Power consumption (kWh per capita) (ELEC_POWER) and Internet Users (per 100 people) (INT_USERS) (v) Consumer Price Index, denoted by CPI. Also, attempt has been made to examine the effect of all these variables on RGDP_GR. The data for the current empirical analysis pertaining to the period 1996 to 2014 compiled basically from HBSIE ('Handbook of Statistics on the Indian Economy 2014-15), World Economic Situation and Prospects (2006, 2015), World Development Indicator (WDI) (1996-2014), China Statistical Yearbook (2014),UNCTAD, FDI/ TNC database (2014)and DIPP (Newsletter), FDI Factsheet (2015). The empirical analysis has been done using statistical package e-views-7 to arrive at comparative results.

## RELATION BETWEEN TRADE OPENNESS AND ECONOMIC GROWTH

The major channels through which greater openness is supposed to stimulate the economy are the analyzed below:

- **Expansion of Demand and Cost Reduction Effect:** The basic macroeconomics demonstrates that an increase in net exports (NX) increases aggregate demand in an open economy. A sustained rise in this component has boosted the GDP growth in countries like Japan, NICs and more recently in China. In addition to demand enhancement, producers can take advantage of trade liberalization to import cheaper and better quality inputs and capital equipment from abroad. Demand expansion and cost reduction can increase profits which may lead to greater capital formation and faster growth.
- **Increase in Competitive Efficiency:** Openness induces domestic firms to improve its efficiency to survive in competition with the foreign firms. A protected domestic market paralyses competition and gives shelter to both efficient and inefficient firms. Greater competition raises average efficiency by forcing the less efficient firms to contract or shut down.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Improvement in Learning and Developing Technology:** International linkages enhance the "learning effect" through better technical knowhow, managerial skill, marketing networks which again increases efficiency and competitiveness overtime. This is normally reflected in the improvement in total factor productivity (TFP) in an open economy. Growth in TFP as an index of efficiency remains a widely used measure despite of its various limitations.
- **Increase in Capital Mobility:** Openness in trade in goods and services also involves free movement of capital, both long term (FDI) and short term (FPI). Among the two FDI is permanent and less volatile in nature and acts as a vehicle of technical transfer and managerial skill. This has a positive impact on the supply side and is reflected in the growth of TFP, while FPI stimulates the stock market.

## Foreign Trade Regime in China and India Prior to 2000

Foreign trade was considered as a residual part of the economic planning in China in the early 1960s and 70s. A handful of state owned foreign trade corporations were responsible for carrying out the trade plan prior to 1978. Exchange rate and relative prices played little role in determining the magnitude and commodity composition of China's foreign trade since the planning process was carried out in physical terms, the. Since 1978, the Chinese economy went through a process of gradual transformation from a "centrally planned" to a "market-based" economy and this was implemented through a phased-manner liberalization of foreign trade and investment regimes. The system of physical planning of foreign trade was gradually dismantled in1980s and by the end of 1990s was largely abandoned. Direct trade controls were phased out and the system began to rely more on indirect instruments such as tariffs and non-tariff barriers to regulate the flow of imports and exports. On the import side, in the early years of the reform era, China maintained a complex and highly restrictive system of controls such as tariffs, quotas, and licensing requirements and an array of other tools. By the time China entered the WTO in 2001 the import regime had been entirely transformed. The average statutory tariff, which stood at the relatively high level of 56 per cent in 1982, was reduced to 15 per cent by 2001 (Sahoo, 2010).

Though India followed an inward looking import substitution policy, the foreign exchange crisis in 1956 - 57 put an end to the phase of liberalization and comprehensive import controls were introduced and maintained until 1966.In June 1966, under the pressure from the World Bank, India devalued the rupee from 4.7 to 7.5 rupees per dollar. But by 1968, intense domestic reaction to devaluation led India to turn inward and almost all liberalizing initiatives were reversed and import controls tightened. There was a general problem of poor quality and technological backwardness, which beset even low cost sectors with comparative advantage such as textiles, garment, leather goods, and primary industries such as cotton. To overcome the problems faced, a steady liberalization of imports of capital equipment and technology began thereafter. Against this backdrop, reforms were undertaken in late 1970s and 1980s.The pace of import liberalization picked up significantly in 1985. In response, the external sector registered a dramatic improvement in performance.

There was significant relaxation of industrial controls and related reforms beginning in 1985 In 1991, the government devalued the rupee by 22 per cent against the dollar. In February 1992, a dual exchange rate system was introduced, which allowed exporters to sell 60 per cent of their foreign exchange in the free market and 40 per cent to the government at the lower official price. The general direction has been towards liberalization with top rates coming down to 25 per cent in 2003-04 and further to 20 per

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

cent in 2007-08. From February 1994, many current account transactions including all current business transactions, education, medical expenses, and foreign travel were also permitted at the market exchange rate. These measures culminated in India accepting the IMF Article VIII obligations, which made the rupee officially convertible on current account.

Openness and growth have proceeded in tandem in these two countries. The trade- GDP ratio [(export + import) / GDP], the most widely used measure of openness increased from a low value of 8 per cent in 1970s to 26 per cent in 2000-01 to 53 per cent in 2013-14 in the case of India. In this respect, China has had extraordinary achievements in raising the ratio of total trade to GDP to 65 percent in 2004 compared to 14 percent in 1978. But it fell sharply since the global financial crisis, from 57 percent in 2008 to 44 percent in 2013. India was at the same 14 percent of GDP in 1978 and for many years lagged far behind. Recently, however, India's trade has also expanded rapidly. The link between free trade and growth is a highly debatable issue and in the context of the experiences of NICs like Hong Kong, South Korea, Singapore and Taiwan no consensus has emerged from this debate.

There was a great divergence between trade-GDP ratios of China and India in the pre-crisis period, It started to narrow down from 2008 and this continued until 2010. After that India surpassed the ratio of China. So the adverse impact of crisis on trade-GDP ratio is more pronounced for China than India.

If one compares the export growth (as a percentage of GDP) in India and China (Figure 2) it will be seen that the difference between the two widened from 2002 till 2008 (with China showing a higher percentage than India). But thereafter it dipped down sharply and went below that of India in 2013. Almost picture emerges when we compare the import growth in the two countries (as a percentage of GDP). From 2009 onwards following the global financial crisis the imports share fell below that of India and since 2010 the gap between them has started to rise but in a reverse direction (Figure 3).

The difference in the trade balance ratio [i.e. (Export – Import)/ GDP, %] between the two countries for the period 1996- 2014 shows that throughout this entire period China maintained a positive trade balance or trade surplus compared to India which continued to have trade deficit except for the period 2001 to 2004. China's trade surplus recorded the highest in 2007 (10.02 percent). Though it dipped down sharply due to impact of the crisis in 2008 but it never became negative.

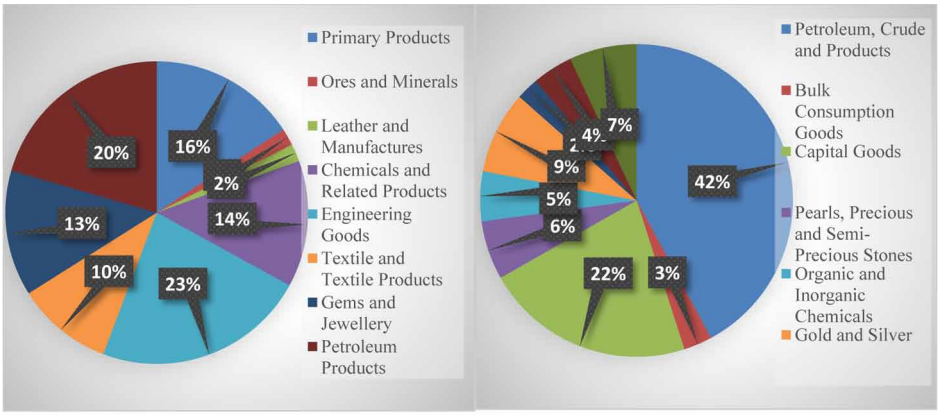
## Comparison of Composition of Trade Between India and China

Economic reforms and trade and investment liberalization have helped transform China into a major trading power. China's abundance of low-cost labor has made it internationally competitive in many low-cost, labor-intensive manufactures. As a result, manufactured products constitute a significant share of China's trade.



A substantial amount of China's imports is comprised of parts and components that are assembled into finished products, such as consumer electronic products and computers, and then exported. Electrical machinery, Machinery, Furniture and bedding, Knit apparel and Woven apparel occupies the major components of merchandise exports in China in 2014. Electrical machinery, Mineral fuel, oil etc, Machinery, Ores, slag, and ash are the major components of imports in China in 2014 (Figure 5a, 5b).

*Figure 5. (a) China's Exports (2014) (b) China's Imports (2014)*

In the 1990s, the export growth was subject to wide ranging fluctuations and the base of the imports and exports enhanced considerably during the decade of 1990s along with considerable diversification in both exports and imports commodity baskets. The major components of export 2013-14 from India comprises of engineering goods, petroleum products, primary products (e.g. tea), gems and jewellery, textile products, chemical and related products. The major components of imports are petroleum crude and products, capital goods, Pearls, Precious and Semi-Precious Stones, Gold and Silver, Organic and Inorganic Chemicals etc.

## INFRASTRUCTURE DEVELOPMENT AND ECONOMIC GROWTH

The development of a country's infrastructure is vital to the growth of its sectors and the overall economy. The infrastructure sector primarily comprises of electricity, roads, telecommunications, railways, irrigation, water supply and sanitation, ports and airports, storing facilities, and oil and gas pipelines.

Over the last few years, researchers have devoted considerable attention to the role of not only to the trade and FDI but also to development of infrastructure in promoting growth. Many important contributions on the role of infrastructure in enhancing economic development has been well documented (e.g. Sahoo, Dash, & Nataraj 2010; 2012). More recently, increasing attention has also been paid to the impact of infrastructure on poverty and inequality (Murty & Soumya, 2006). Further, it has been found that social infrastructure such as education, health, and housing are essential to promote better utilization of physical infrastructure and human resources, thereby leading to higher economic growth and improving quality of life.

### China's Infrastructure Development

China's growth over the past two decades was primarily export-led driven by investment in infrastructure (China's spending on infrastructure increased from 5.7 percent of GDP in 1998 to about 14.4 percent of GDP in 2006) supported by domestic savings and foreign direct investment. The liberalization policy made it possible for the inflow of foreign direct investment (FDI) mainly to the manufacturing sector. The abundance of cheap labour and better than adequate infrastructure were important pre-requisites that led to a successful the export-led growth strategy in China. However, due to the global economic crisis since 2008, China's export-led growth suffered a set-backowing to in fall external demand. But unlike other WTO members, China responded to the crisis with a large economic stimulus package designed to boost domestic demand by investing in infrastructure and public services to help sustain economic growth. One of the remarkable feature of the Chinese infrastructure development was that China has followed the path of the "Asian Infrastructure Model" and fast growing economies, building impressive infrastructure ahead of demand at lightning speed. China's unparalleled growth and poverty reduction in the last two decades has gone hand in hand with development of infrastructure stemming from its export-led strategy. The bulk of infrastructure financing in China flowed from three major channels- (a) direct budget expenditure, (b) direct public financing and (c) borrowing and market based financing. But in recent years the Chinese economy started showing signs of overheating because of basic infrastructure constraints. The gap between the potential demand and the available supply of infrastructure to sustain high growth has been increasing given the importance of infrastructure development for sustainable economic growth and poverty reduction in China (Sahoo, 2010).

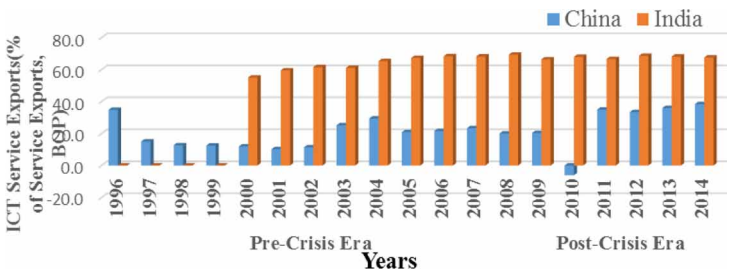
## India's Infrastructure Development



The Indian policy makers did not follow the successful Asian infrastructure model in building infrastructure ahead of demand. Its development strategy from time to time focused on redistribution of wealth rather than growth. Following the 1991 fiscal crisis in India, the Government of India adopted several reform measures to make the economy globally competitive. It recognized that the success of these policies would crucially depend on the expansion and improvement of physical infrastructure. In 1994, the Government set up an Expert's Group to recommend policy and reform program to guide the future course of infrastructure development. The Expert Group found that for India to maintain its target growth of 7-9% per annum, its infrastructure investments would need to increase from the 4-5% of GDP experienced in the 1980s and 1990s, to 8% in 2005 requiring a threefold increase in absolute levels. The Group recommended several strategies to encourage this investment, including privatization. With the exception of pricing reforms, most infrastructure reforms in India did not begin until the late 1980s and early 1990s. In the early 1990s, the telecom sector was the first one to allow entry of private sector firms in both basic and cellular telephone systems. Even though the telecom reforms had many ups and downs, the government was committed to allow growth of access of service and connectivity through entry of the private sector and the creation of markets. Inadequate infrastructure was recognized in the Eleventh Plan as a major constraint for rapid inclusive growth. The Plan had, therefore, emphasized on the need for massive expansion on investment in infrastructure based on a combination of public and private investment, the latter through various forms of Public Private Partnerships (PPPs).

## Comparative Overview of Infrastructure Development in China and India

Given the different level of importance given to infrastructure development in China and India, overall outcomes are very different today. Using various index related to various components of infrastructural development we can compare the path of the level of improvement in infrastructural facilities in the two nations. We begin with the ICT service exports (% of service exports, BOP). In ICT service exports India is far ahead of China during the period 1996 – 2014 (Figure 7). But recently, China policy emphasis on ICT has made the gap narrowed from 2011 to 2014.

In electric power consumption (kWh per capita) china maintained a constant gap with India. But from 2001 onwards and particularly after the global crisis the gap between them increased significantly (Figure 8). Generation and consumption of electricity is considered to be an important component of infrastructure, where India is lagging far behind of China.

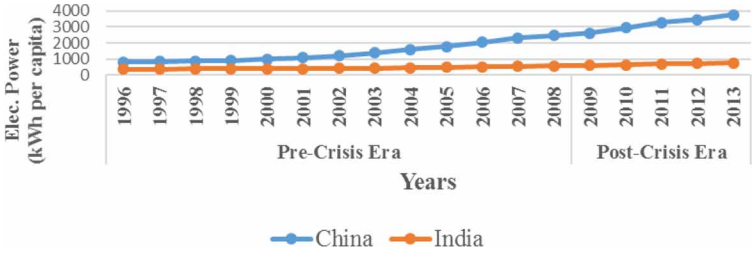


*Figure 7. Comparison of ICT Service Exports*

*Figure 8. Comparison of Electric Power Consumption*
*[Source: World Development Indicator, World Bank]*

Road transport is useful for everyday movement of people to their workplaces or to meet every day needs. For efficient road transportation we need good quality roads. For lack of comparable data we have used length of High-ways (10,000kms.) as a proxy for road transport. Till 2004 India was ahead of China in the construction of highways, but there was a steep jump in the construction of Highways in 2005 and it surpassed that in 2005. After that China continued to maintain that same increment till 2011 (Figure 9).

In case of rail lines (total route-km) India was ahead of China till 2008. But after the crisis China surpassed that of India. But in case of air transport during the entire period of analysis China was well ahead of India and the gap widened after the crisis (Figure 10).

One of the most significant indicators of infrastructure development in the improvement in telecommunication and connectivity is the mobile phone and internet uses. Though in terms of mobile subscription and fixed broadband services there have not much significant difference between the two countries, but in terms of internet users India has been lagging way back of China (Figure 11).

## Comparison of Infrastructure on the Basis of Global Competitiveness Index (GCI)

According to the Global Competitiveness Report, 2015-16 the position of the two countries may be compared on the basis of Global Competitiveness Index, of which one of the major pillars is the infrastructure. India's present GCI rank is 55th compared to China's 28th (Table 1).

According to Global Competitiveness Infrastructure Index ranking China is in 39th position, well ahead of India (81st position).Though the differences are small with regard to quality of roads, quality of railroad infrastructure, but with respect to quality of air transport, quality of electric supply, mobile subscription, fixed telephone lines the divergences are quite large (Table 2).

## FDI AND ECONOMIC GROWTH

## Comparison of FDI Flows Between India and China

Prior to 1990s India followed a fairly restrictive foreign private investment policy as compared to most industrializing economies- relying more on bilateral and multilateral loans with long maturities. Besides reforms of capital markets and exchange controls, a much more liberal FDI and trade policy was pursued. The New Industrial Policy, announced on July 24, 1991 marked a major departure in respect of FDI policy with the abolition of industrial licensing system except for a few industries, creation of a system of automatic clearance of FDI proposals fulfilling the conditions laid down such as the ownership levels of 50/51/74/100 percent foreign equity and opening up of new sectors to foreign owned companies subject to sectoral caps. There was a marked increase in FDI inflows in India until 1997 (Figure 12).

*Table 1. Comparison of Global Competitiveness Index, 2015-16*

| | GCI Rank | Infrastructure | |
|---|---|---|---|
| | | Rank | Score |
| China | 28 | 39 | 4.73 |
| India | 55 | 81 | 3.72 |

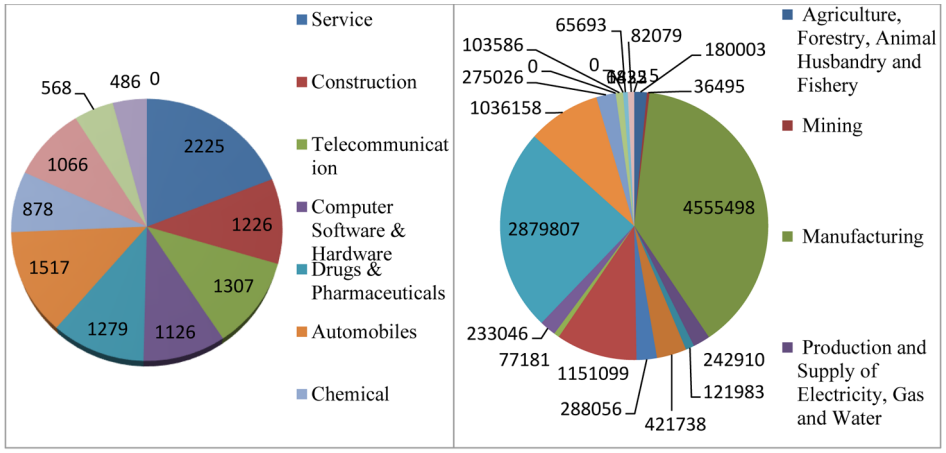
| Available airline seat km/week, millions | 15491.1 | 2 | 3726.6 | 11 |
| Quality of electricity supply | 5.3 | 53 | 3.7 | 98 |
| Mobile telephone subscriptions/100 pop. | 92.3 | 107 | 74.5 | 121 |
| Fixed-telephone lines/100 pop. | 17.9 | 63 | 2.1 | 116 |

[Source: Global Competitiveness Report, 2015-16]

*Figure 12. Comparison of FDI Flows between India and China (1996-2014)*
*[Source:UNCTAD, FDI/TNC database (www.unctad.org/fdistatistics), 2014]*



In the year 2000, a paradigm shift occurred, wherein, except for a negative list, all the remaining activities were placed under the automatic route. Caps were gradually raised in a number of sectors/ activities. Some of the initiatives that were taken during this period were that the insurance and defense sectors were opened up to a cap of 26 per cent, the cap for telecom services was increased from 49 per cent to 74 per cent, FDI was allowed up to 100 per cent in single brand retail and 51 per cent in multi-brand retail. Until 2005 there was a huge gap between FDI flows of china and India. But there was a steady increase in FDI in India between 2006 and 2008. After that the global financial crisis affected the FDI flows adversely in both the nations. But again from 2011 onwards there was a revival to the rising trend till 2014. In 2014, China recorded an FDI inflow of US$119.6 billion, up 1.7 percent from 2013. The stable FDI level shows that the country is still an attractive destination for foreign investments (Figure 13a and b).

A comparison of sector-wise composition of FDI between India and China reveals that in India service sector attracts the largest share of FDI, while in China the manufacturing sector grabs the lions share.

## Position of Current Account Balance

Again if we compare the current account balance position as a percentage of GDP we find that from 2005 to 2014 it is negative in case of India, while it positive in case of China (though the magnitude has declined since 2009 following the global financial crisis) (Table 3).

## EMPIRICAL ANALYSIS

A number of studies have been carried out on empirically testing the link between trade openness, infrastructure and FDI and its impact on economic growth in developing countries (Asiedu, 2002 & Mottaleb, 2007). The literature demonstrates that the benefits of FDI are strongly dependent on how open a country is to globalization. In addition, the positive effect of trade on FDI has been found to be quite robust to the type of econometric method used and countries considered. Using time series data for the period 1960-2005, Ang (2008) studied the determinant of FDI in Malaysia. The author concludes that financial development, infrastructure development and trade openness promotes FDI inflow. The implication of this result is that trade liberalization leads to more FDI inflow in a host country. Asiedu (2002) studied the determinant of FDI in 70 developing countries between 1988 and 1997 using OLS estimation technique.

Our basic objective here is to establish the fact that economic growth of a nation is greatly influenced by the three factors – (a) trade openness or extent of liberalization; (b) infrastructural development and (c) FDI flows. Also, FDI flows in a nation are typically dependent on the growth of real GDP, extent of trade openness, infrastructure development and macroeconomic stability (measured by inflation). So, to assess the relationship between trade openness, infrastructure, FDI and economic growth we have tried to estimate the following two equations by least square technique.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Trade relates to the openness of the economy to the rest of the world. However, due to lack of time series data for the measure of openness, the sum of import and export as a ratio of GDP is used to proxy trade. This is justified by arguing that the more open a country is to globalization, the more attractive it is to FDI. According to the literature, countries with better infrastructural development tend to attract more FDI when compared with others, which implies the positive effect. Infrastructural development is measured using Electric Power consumption (kWh per capita) and Internet Users (per 100 people) in a country. A positive relationship between FDI and infrastructure development is expected.

On the other hand, a higher GDP per capita growth is assumed to imply better market opportunity and increases the attractiveness for FDI, thus a positive relationship is expected.The interaction of trade and Electric Power consumption (kWh per capita) and Internet Users (per 100 people) in a country is the variable of interest and its relationship with FDI is uncertain. CPI, consumer price index denotes macroeconomic stability. According to Asiedu (2003), countries with high (low) inflation rate tend to be unattractive (attractive) to FDI, hence, a negative relationship with FDI is expected.

## Empirical Results

Initially, two regression equations (equations 1 and 2) were set to be examined following the standard literature in one, where FDI is the dependent variable and other, where real GDP growth (RGDP_GR) is the dependent variable. But after performing unit root test (following Augmented Dickey-Fuller Test), separately for the two countries, it was found that some variables have non-stationary problems and so they had to be dropped for the regression. So the modified regression equations in case of China are represented by equations 3 and 4 and in case of India by 5 and 6 respectively.

| | ELEC_POWER1 | 17.81124 | 36.66971 | 0.485721 | 0.6376 | |
| | FDI1 | -0.101373 | 0.086381 | -1.173550 | 0.2678 | |
| | TRADE_GDP1 | -0.290760 | 0.213915 | -1.359234 | 0.2039 | |
| | CAB | -0.348472 | 0.563030 | -0.618922 | 0.5498 | |
| | CPI1 | 0.027245 | 0.210159 | 0.129638 | 0.8994 | |

From the regression table it follows that in case of China change in the real GDP growth, change in electric power consumption (which has been used as a proxy for infrastructure development), current account balance and change in CPI overtime have positive influence on FDI, whereas the coefficient of RGDP_G2 (which denotes the change in slope) has a negative impact. Moreover, in China infrastructural development has a positive impact (the coefficient of ELEC_POWER is positive) on the change in growth of real GDP. But the impact of FDI on real GDP growth is negative. In case of India change in real GDP growth, trade openness (i.e. trade-GDP ratio) has a positive impact on FDI, but the impact of infrastructural development on FDI has turned out to be negative. Again, increase electric power consumption has a positive influence on real GDP growth in India. One aspect is common in both the nations and that is infrastructural development has a positive influence on the change in real GDP growth in both China and India, but it is just the opposite in case of impact on FDI in both the nations.

The R-squared value in all the regressions are high (expect one) which shows that the explanatory variables explain a greater percentage of variations in the dependent variables. R-squared is a statistical measure of how close the data are to the fitted regression line. It is also known as the coefficient of determination, or the coefficient of multiple determinations for multiple regressions. It is the percentage of the response variable variation that is explained by a linear model. Or: R-squared = Explained variation / Total variation. An interesting feature is observed if we look into the DW statistics of the variables in the two countries. The Durbin-Watson test statistic tests the null hypothesis that the residuals from an ordinary least-squares regression are not autocorrelated against the alternative that the residuals follow an AR1 process. The Durbin-Watson statistic ranges in value from 0to 4. A value near 2 indicates non-autocorrelation; a value toward 0 indicates positive autocorrelation; a value toward 4 indicates negative autocorrelation. In almost all the cases the values are nearer to 2 here.

## POLICY SUGGESTIONS FOR INDIA AND CHINA

This study may provide important policy suggestion for the policy makers in both China and India. As China's economic growth has been driven by substantial investment in infrastructure and FDI liberalization in a phased manner, so in future the policy makers may continue to give more emphasis on these two areas. But for the development of the service sector, particularly the IT sector, more emphasis should be laid on building up of human capital formation along with the rapid development of physical infrastructure. In India there is no denial of the fact that openness to current account trade has indeed played a significant role in India's growth surge. Removal of trade restrictions and development of information and communication technology has boosted the growth of knowledge-based IT sector, which is supposed to enjoy demographic dividend in future. But the manufacturing sector did not perform its desired role mainly due to poor quality infrastructure, persistence of inefficiency and declining public investment. FDI has failed to effect any major supply side changes mainly because of availability of complementary inputs and technological improvement. But strict vigilance on movement of foreign funds by the RBI has acted as an insulator to mitigate the terrible impact of the financial crisis to which a large number of fast developing nations, including China, got affected. Moreover, investment in health and education needs to be emphasized more for a sustainable development goal.

## CONCLUSION

The chapter clearly reveals that though China is integrated to a greater extent than India, Openness to current account trade has indeed played an important role in the growth surge of both the countries. China's economic growth has been led by manufacturing, while India's growth has been through information technology (IT). China's GDP is equivalently contributed by the secondary and tertiary sectors while India has a sectoral imbalance as the corresponding contribution to GDP is more for the tertiary sector than the secondary sector. During the period of analysis china's trade –GDP ratio was quite higher than that of India (except in recent times). China's share of world export rose steadily during the period 2000 to 2008 but India's share remained stagnant at 1 per cent in spite of a jump in the volume of exports. For the entire period China maintained a trade surplus while India was adversely affected by the trade deficit. But one of major limitations of the present study is that it didn't consider export trade openness and import trade openness separately due to lack of comparable data, which would have thrown a more detailed idea about the extent of trade openness in the two countries.

The present chapter analyzes the role of the interaction between trade openness and infrastructural development in the attraction of FDI and in fostering economic growth in the two fastest growing countries of Asia. The results indicate that trade openness and infrastructural development encourages the inflow of FDI in both the countries. In China and India trade openness and infrastructural development has a positive impact on growth in real GDP and FDI. So India and China should develop their macroeconomic policies and structural reform programs in such a manner so as to encourage economic openness, infrastructural development to attract foreign investments for sustainable growth.

## KEY TERMS AND DEFINITIONS

**Economic Growth:** Economic growth of a nation is generally measured by the growth of per capita income or real GDP. It provides the first hand measure of the level of standard of living of the population of a particular nation. Economic growth captures only the GDP or income growth and so it is a necessary but not a sufficient condition for development of a nation.

**FDI Flows:** Real investment in factories, capital goods, land and inventories where both capital and management are involved and the investor retains control over the use of the invested capital. Among the various forms of private foreign investment, foreign direct investment (FDI) flows are usually preferred over other forms of external finance because they are non-debt creating, non-volatile and their returns depends on the performance of projects financed by the investors. FDI can complement local development efforts in a number of ways, including boosting export competitiveness; generating employment and strengthening the skills base; enhancing technological capabilities (transfer, diffusion and generation of technology); and increasing financial resources for development.

**Foreign Trade Regime in India and China:** Liberalized foreign trade regime is the basic condition for fostering foreign trade and FDI. Opening up of foreign trade is a watershed in development policy of both India and China. To start with, both the countries adopted inward-looking import substitution policies with an emphasis on self-sufficiency. Later in 1978, China adopted the policy of 'opening up to the outside world' and in 1991, India initiated an import liberalization policy.

**Global Competitiveness Index (GCI) in Infrastructure:** Competitiveness is defined as the set of institutions, policies and factors that determine a country's level of productivity. The level of productivity, in turn, sets the level of prosperity that can be reached by an economy.The GCI combines 114 indicators that capture concepts that matter for productivity. These indicators are grouped into 12 pillars- institutions, infrastructure, macroeconomic environment, health and primary education, higher education and training, goods market efficiency, labor market efficiency, financial market development, technological readiness, market size, business sophistication, and innovation. Effective modes of transport—including high-quality roads, railroads, ports, and air transport, uninterrupted electricity supplies, solid and extensive telecommunications network ensures the effective functioning of the economy.

**Infrastructure Development:** Infrastructure has been used as an umbrella term for many activities. The development of a country's infrastructure is vital to the growth of its sectors and the overall economy. The infrastructure sector primarily comprises of electricity, roads, telecommunications, railways, irrigation, water supply and sanitation, ports and airports, storing facilities, and oil and gas pipelines.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**Time Series Data:** A set of statistics, usually collected at regular intervals. Secondary time series data for two countries of Asia viz. India and China over the period 1996-2014 has been used to provide an empirical support to the various comparative analysis. Correlation and regression analysis are used to arrive at the results.

**Trade Liberalization:** Opening up of foreign trade or external liberalization. Opening up of foreign trade is a watershed in development policy of both India and China. The trade- GDP ratio [(export + import) / GDP] is the most widely used measure of trade openness of a nation. Following the WTO rules it implies substantially lowered tariffs and scaled back other trade barriers and a gradual movement towards a free trade regime.

# Chapter 64
# Integration to the WTO and Economic Transition in the South Caucasus Economies

**Khatai Aliyev**
*Qafqaz University, Azerbaijan*

## ABSTRACT

*Economic transition story in the South Caucasus economies started after the collapse of the Soviet Union. Theoretically, integration to the World Trade Organization (WTO) system should improve the economic transition performance. This research uses the yearly transition indicators by the EBRD to discover the relationship between economic transition performance and integration to the WTO in the contexts of before-and-after WTO membership and before-and-after the end of concession period defined for a new member to implement all obligations. Author employs bivariate de-trended regression analysis estimated by using Ordinary Least Squares (OLS), individually for Armenia and Georgia, and within a panel analysis covering all three countries of the region. Research findings provide strong evidence of significant positive or acceleratory effect of integration to the WTO on economic transition in the South Caucasus. Surprise finding is insignificant impact over competition policy index, which is supposed to be affected by integration.*

## INTRODUCTION

When Georgia acceded to the World Trade Organization (WTO) in June 14, 2000, WTO Director-General Mike Moore expressed that "this accession is particularly noteworthy given Georgia's remarkable transition to a market economy" (International Centre for Trade and Sustainable Development, 2000). This research investigates the role of integration to the WTO over the economic transition performance of South Caucasus economies, namely Georgia, Armenia, and Azerbaijan.

The WTO encompasses most of the world countries as the largest trade organization in the world of today. Founding of the organization started in the second half of the 1940s or more precisely, by signing the General Agreement on Tariffs and Trade (GATT). From the end of the 1940s until now, the GATT

has been a subject to many trade negotiations and was transformed to the GATT 1994 when the WTO was established. As the aim of this organization is enhancing trade liberalization and opening trade to all countries to benefit, its role in economic transition of former centrally planned economies is a subject of this study. Thus, the WTO has several compulsory principles, which must be followed by all member countries. Moreover, a country that wants to join the WTO passes several stages and undertakes obligations for the WTO until its accession as a full member.

After the establishment of Bretton Woods system, the idea of the GATT was purposed due to the aim of increasing the living standards, continuous rising of real income and effective demand, achieving the full employment, the "full use" of world resources and enlargement of goods production / trade (Irwin, 1995). In order to achieve these aims, the GATT would decrease tariff and non-tariff barriers over trade and remove discriminatory trade policies in international trade in the context of "reciprocal and mutually advantageous arrangements" (Irwin, 1995, p. 324).

After 1947, the scope and the sphere of influence of the GATT were enlarged as a result of the rounds of negotiations in Geneva (1947), Annecy (1949), Torquay (1951), Geneva (1956), Dillon (1960-1961), Kennedy round (1964-1967), Tokyo round (1973-1979), and Uruguay round (1986-1993) (Oatley, 2008, p. 26). After Uruguay round, the WTO was established on the basis of the GATT-1994, General Agreement on Trade in Services (GATS), Trade-related Investment Measures (TRIMs), Trade-related Aspects of Intellectual Property Rights (TRIPS) within "Final Act Embodying the Results of the Uruguay Round of Multilateral Trade Negotiations Marrakesh Agreement Establishing the World Trade Organization" (World Trade Organization, 2011).

Despite the expectations from the WTO to make better of all countries through the tools mentioned above, it is still under question if the organization does this. As the direct impact is over international trade, many empirical studies investigated if the WTO really increased trade, some of them found insignificant effect (Rose, 2004a, 2004b, 2004c; Gowa & Kim, 2005; Park, 2009; Eicher & Henn, 2011; Roy, 2011; Swinnen, Olper, & Vandemoortele, 2012) while many others revealed significant impact of the WTO over trade (Subramanian & Wei, 2007; Tomz, Goldstein, & Rivers, 2007; Tomz, Rivers, & Goldstein, 2007; Balding, 2010; Liu, 2009; Dutt, Mihov, & van Zandt, 2013; Konya, Matyas, & Harris, 2011; Kim, 2008; Grant & Boys, 2012; Herzl & Warner, 2011; Chang & Lee, 2011; Anderson, 2010; Mansfield & Reinhardt, 2008; Jansen, 2010; Buthe & Milner, 2008; Shah, Hasnat, & Li, 2010). However, none of those has analysed the impact of the WTO membership over economies in transition.

This study attempts to fill this gap partially, for the South Caucasus economies. The South Caucasus region covers three independent countries – Armenia, Azerbaijan, and Georgia, which all had centrally planned economic system within the Soviet Union until its collapse in 1991. All three declared the desire of liberalization or from economic point of view, economic transformation towards market economy immediately after the declaration of their independence. Integration process of these economies into the WTO will be discussed in the following section. Before, it is noteworthy to mention what determines the economic transformation.

In a centrally planned economy, trade and all other aspects of international exchange of goods and services are controlled by the government institutions such as ministries and state owned trading enterprises (Michalopoulos, 2000, pp. 65-66). Here, the data for economic transition of these countries are the yearly transition indicators, output of European Bank of Reconstruction and Development (EBRD). Instead of calculation an overall transition indicator, the EBRD divides the transition into 6 categories: 1) large-scale privatization, 2) small-scale privatization, 3) governance and enterprise restructuring, 4)

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

price liberalization, 5) trade and forex system, and 6) competition policy. Despite the official declaration of the government that economic transition is ended, real empirical data analysis is employed, not political considerations.

The issue is that all three countries launched accession process to the WTO in 1995-1997. Georgia and Armenia completed the accession negotiation in 2000 and 2003, respectively, while Azerbaijan still continues its negotiations. For each year, before-and-after the accession, transition indicators are available for Georgia and Armenia. Therefore, empirical analysis is applicable for these two countries individually, and for the all three within one model.

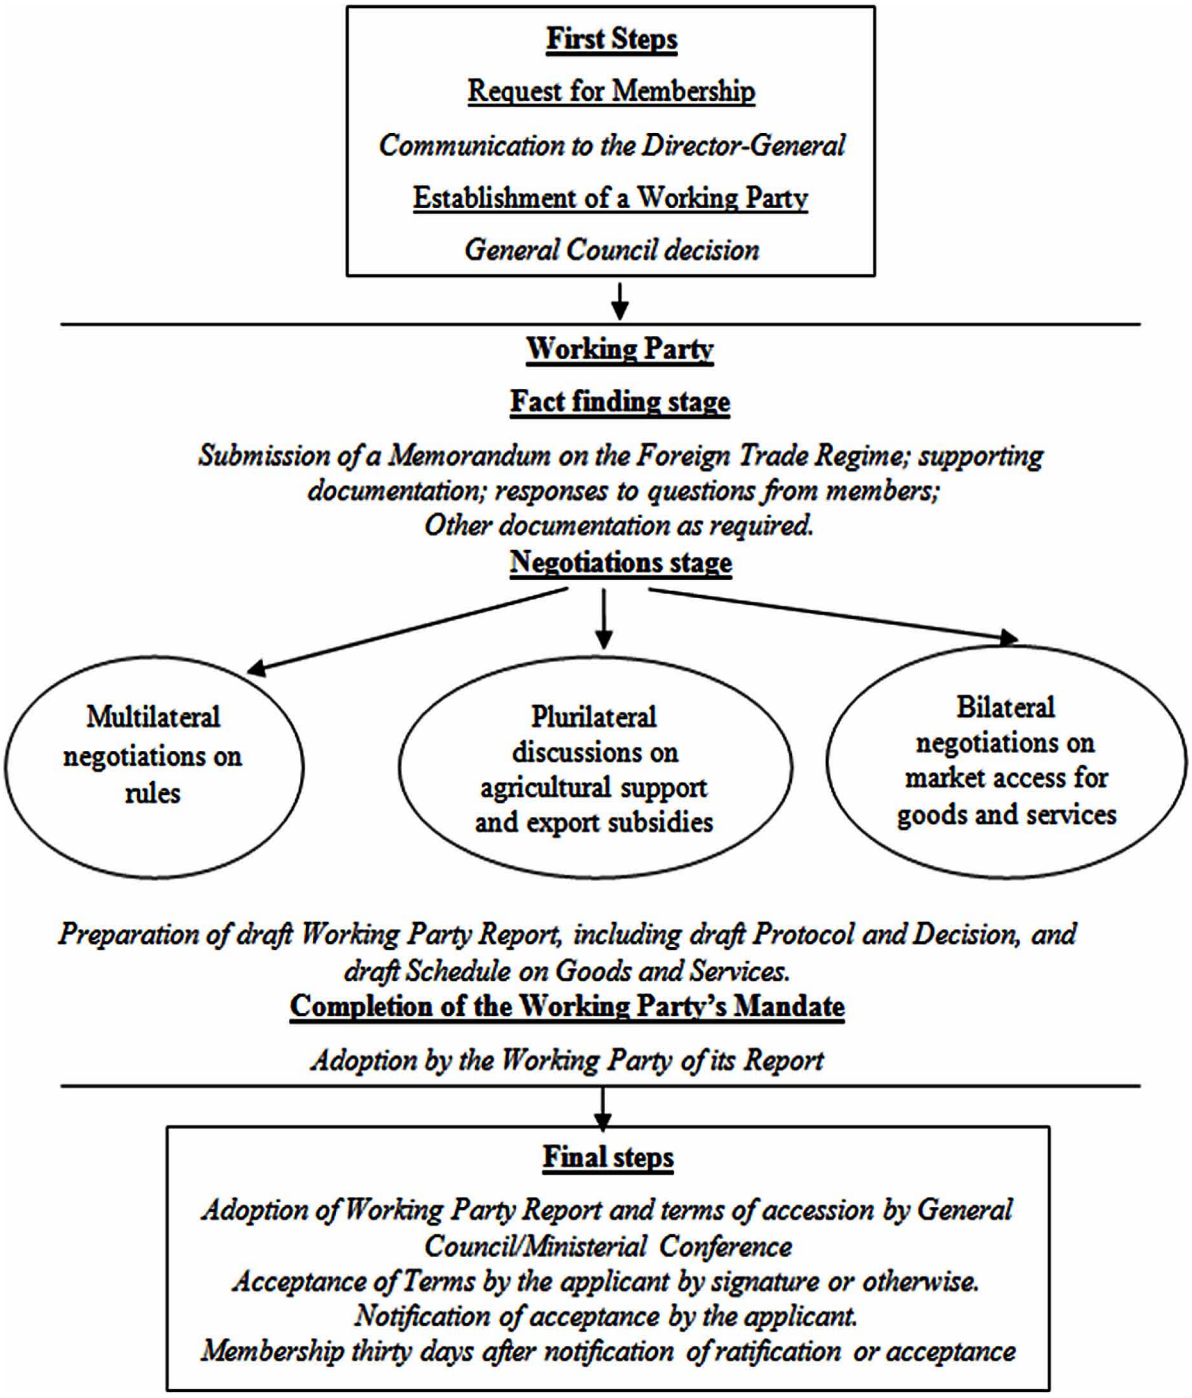
This research investigates the differences in economic transition performances of those three economies before and after accession to the WTO. The regression analysis is conducted for Georgia and Armenia before and after the relative concession periods. While pooling all three within one model, the analysis shows if the WTO membership matters for the economic transition performance of a member country in comparison with a non-member one. For this purpose, the following section reviews accession experience of these economies to the WTO. Later, the author looks for relationship between economic transition and the WTO membership by discussing theoretical considerations and available literature. The remaining parts include graphical analysis of transition indicators, empirical methodology representation, results and their interpretation.

## BACKGROUND

For a non-member country, achieving full membership status in the WTO is a long lasting process, which usually takes several years. "Accession to the WTO – Procedures for Negotiations under Article XII" defines the accession procedure or the framework of an accession process to the WTO for a nonmember country (Williams, 2008) (Figure 1).

Nevertheless, the organization provides an observer status to a non-member for five years to ensure the country is well informed about the WTO and its activities before the accession (Markovic, 2009, pp. 118-119). This status does not impose any commitment on that country.

Shortly describing the accession process, it is a six-staged process towards full membership (Markovic, 2009, p. 119). More precisely, the process starts with submission of an official request by the government of the candidate country. This request must indicate the willingness of the candidate to adopt the Marrakesh Agreement and to become a full member of the WTO, which should be submitted to the WTO's General Director. Afterwards a request is introduced to all members of the organization and added to the agenda of General Council's next meeting. Upon acceptance of the request, a Working Party is formed for accession negotiations in which all members can participate.



Accession process continues with stages of submission of "Memorandum on the Foreign Trade Regime" which clarifies policies and institutions of a candidate country. Further information can be found in Eromenko (2010) and Markovic (2009) among others. This memorandum is very crucial for the accession as all the following stages refer to, discuss and decide based on it. The following and the most time-taking stage is successfully ending bilateral negotiations with all Working Party members.

At the end, the WTO Secretariat prepares the "Accession Package" for a candidate country, which covers "Working Party Report", "Protocol of Accession", "Schedule of Specific Commitments on Services", and "Schedule of Concessions and Commitments on Goods" (Eromenko, 2010, p. 44). After

all, if the Working Party accepts the Package in its last meeting, the Package is confirmed by General Council of the Ministerial Conference, and the candidate country approves the Protocol of Accession, gains membership status, and becomes full member of the WTO.

The WTO history of the South Caucasus economies started after the first half of the 1990s. Before 1991, all economies were part of centrally planned Soviet Union economy. However, after gaining independence, these countries declared the desire of market economy and initiated reforms, which are all covered by the notion of economic transition. Integration process to the international organizations is also essential in this context. As the largest trade organization, the WTO became at the interest of these countries and in 1995-1997, all three requested to launch the accession process.

Georgia's accession process lasted four years, and the country became the 137th member of the WTO in 2000. Following Georgia, Armenia completed its accession process in 2003 and gained full membership status. Despite a launch of accession process in 1997, Azerbaijan has not completed the process, and bilateral and multilateral negotiations continue at the moment.

There are several reasons behind delaying Azerbaijan's accession process to the WTO. The biggest issue is the structure of Azerbaijan economy even in time of application. Thus, Azerbaijan's main imports and exports were based on oil industry under the framework of "Contract of the Century" special agreements (Kavass, 2008). Another reason was the unawareness of Azerbaijan government about the procedure and preparation of documents, which is called as "weak follow-up" by Michalopoulos (2000). As stated by Kavass (2008), despite of organizing the first meeting of the Working Party on Azerbaijan's application five years after launch of the process, in 2002, no significant improvements related to preparing of required documents were done by the applicant country, as well as the questions asked by the Working Party members were not answered.

This issue was resolved soon after by the support of the European Union (EU), the USA, and World Bank trainers. Consequently, eleven more meetings of the Working Party were held until March 2015. However, final agreement still has not been achieved on Azerbaijan's application. Vital reasons behind the current delaying are several major disputable economic issues, for example, status of the membership, bound level of tariffs, government support of agriculture, participation in sectoral initiatives, etc. (Aliyev, 2014). Azerbaijan insists on joining to the WTO with developing country status to be able to acquire longer concession period to implement all the WTO commitments and several other concessions while joining, such as 10% de minimus opportunity to subsidize its agricultural sector.

Despite many disputable economic and non-economic reasons (harmonization of Azerbaijan's legislation with the WTO standards), observed in the Working Party meetings, most probably, the issue behind the delaying is different. As stated by Azerbaijani economist, V. Bayramov, "As long as the oil price remains high there is no incentive" for the country's WTO membership from the government's point of view (Center for Economic and Social Development, 2012). While discussing "to join or not to join" to the WTO in case of Azerbaijan, Aliyev (2014) also stresses the similar issue and argues that in the situation, when Azerbaijan's domestic production, especially exports, is strongly dependant on oil and gas, while competition experience of entrepreneurs is fairly weak, accession to the WTO is not beneficial for Azerbaijan at the moment. However, this situation cannot be maintained in the long-run, and the country must implement reforms to develop competitiveness of the domestic economy. In this context, the incentive for Azerbaijan government to join the WTO should increase.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Overall evaluation of the current situation in the South Caucasus in terms of integration to the WTO shows that Georgia and Armenia had completed the transition by 2005, which was the last year of concessions. However, the biggest economy of the region in terms of its natural deposits, Azerbaijan, has been undergoing negotiations since 2002 (first Working Party meeting). Now the question is how integration to the WTO affected economic transition of these economies.

## MAIN FOCUS OF THE CHAPTER

### Theoretical Framework

The measurement method of economic transition used in this research refers to the methodology of EBRD. Thus, EBRD measures economic transition performance of an economy under six different categories: large-scale privatization, small-scale privatization, governance and enterprise restructuring, price liberalization, trade and foreign exchange system, and competition policy. Detailed description of the categorization and evaluation scores are provided in Appendix.

It is noteworthy to look for the solution of the question asked above in existing theoretical framework related to the WTO effects. In fact, transition from planned to market economy is a complex process which requires significant structural, institutional, and behavioral changes (Melo, Denizer, & Gelb, 1996). Despite the fact that the WTO does not exclude explicitly a socialist country or a country with centrally planned economic system from membership, some obligations can be carried out only through having market economy (Laird, 1998).

Note that first two categories measuring economic transition performance (large-scale privatization, small-scale privatization) represent the performance of structural changes in economy. Governance and enterprise restructuring, and trade and foreign exchange system categories mostly embody institutional changes in economy. Remaining ones – price liberalization, and competition policy demonstrate both institutional and behavioral changes.

As discussed above, accession process towards becoming a full member of the WTO is a long and multiple-stage process. More precisely, the WTO is built on several founding principles, and all WTO negotiations are aimed at integration of those principles to the economic environment of the accessing country.

There are strong reasons, which affect economic transition throughout the accession process. The candidate country should harmonize its legislation basis with those of the WTO standards. This is expected to bring better performance at the first sight. However, much more affecting factor is bilateral negotiations in which all the Working Party members intend to get the best for their own interests, especially in the domestic market of the candidate country under the WTO principles (principle of nondiscrimination, reciprocity, enforceable commitments, transparency, and safety valves).

The principle of nondiscrimination means that the same level of tariffs must be imposed on imported goods from all the WTO members in case of accession (Bagwell & Staiger, 1999, p. 217) and follow nondiscriminatory behavior in all cases. Nondiscriminatory behavior in the GATT/WTO agreement includes two main principles emphasized in the articles of the Agreement: Article I "General Most Favored Nation" (MFN) and Article III "National Treatment on Internal Taxation and Regulation" (Srinivasan, 2005, p. 72). Nondiscrimination principle is expected to affect economic transition mostly through competition policy channel, which brings fair competition.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reciprocity is another basic principle of the GATT/WTO system. According to this principle, a country admits to decrease the degree of its protection over trade as a response to the "reciprocal concession" from another country as its commercial partner (Bagwell & Staiger, 1999, pp. 216-217). This implies the "ideal" level of reciprocal shifts in trade policy of different countries that lead to approximately same shifts in amount of imports between trade partners (Bagwell & Staiger, 1999). Bagwell and Staiger (1999) consider that as the key principle of tariff negotiations where participants try to acquire a "balance of concessions". Joining the negotiations is optional and requires willingness to set "reciprocal and mutually advantageous" decreased level of tariffs (Bagwell & Staiger, 1999, p. 225). In this context, reciprocity principles may accelerate economic transition mainly through governance and enterprise restructuring, and trade and foreign exchange system channels.

The third principle – bindings and enforceable commitments – encompasses implementation of the commitments by member countries in accordance of Articles II, VII, and XI of the GATT/WTO Agreement. Thus, countries are not allowed to apply tariffs higher than bound level or the highest level of allowed level of tariffs without renegotiating this issue with other members as well as non-tariff measures over imports and other commitments of agreed documents (Hoekman, 2002, p. 43). Obviously, this principle is also related with economic transition performance through governance and enterprise restructuring, and trade and foreign exchange system channels.

Another principle, which plays crucial role in the WTO activities and is expected to affect economic transition performance of a country, is the principle of transparency. Thus, following this principle means ensuring stable and predictable trade law arrangements of the WTO members (Matsushita, 2004, p. 368). Matsushita (2004) emphasizes that the "rule-oriented" foreign trade policy is based on this principle including both publishing of all appropriate regulations due to make any changes achievable for all parties before application, and notifying the WTO and all member countries about the actions of the member country's government. Transparency principle is represented in Article X of GATT 1994, Article III of GATS, and Article LXIII of TRIPS, as well as in some other WTO agreements.

The last principle of the WTO is the principle of safety valves. Unlike the other ones, this principle is for a government to restrict trade in some conditions such as maintaining fair competition or avoiding dumping, and in case the government's intervention to the market due to some economic causes and non-economic objectives is needed (Reis, 2009, p. 49). Correlation between the principle of safety valves and economic transition performance is controversial. However, the channels of influence certainly are governance and enterprise restructuring, trade and foreign exchange system, and competition policy.

For more information about background of each principle see Hoekman (2002), Bagwell and Staiger (1999), Srinivasan (2005), Matsushita (2004), Reis (2009) among others. Considering possible correlation between the WTO principles and economic transition performance, it is expected that the WTO membership might lead to better economic transition indicators. Theoretically, the WTO membership might accelerate economic transition performance in the South Caucasus economies.

## Literature Review

According to the theoretical framework of this relationship, integration to the WTO and economic transition are expected to be highly correlated with each other. If a country does not perform well in liberalizing its economy in accordance with market economy requirements, it should be out of the WTO system. However, this is only a theoretical statement. Further empirical investigations are required to prove it. Unfortunately, the literature in this sphere is too limited, and most of the sources are rather theoretical.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

While discussing the effects of accession to the WTO on policy making in sovereign states, Drabek and Bacchetta (2004) review the experience of the WTO members among transition economies on market access, governance, government budget, structural reforms, trade and investment with regional partners, and macroeconomic management.

Related to market access, authors reveal that opening markets in transition countries is not due to the WTO membership or its "unreasonable pressures", even WTO commitments of those countries are relatively less liberal while the real tariff levels are taken into consideration (Drabek & Bacchetta, 2004, p. 1093-1094). In other words, actual applied tariff rates are generally lower in comparison with the bound tariff rates of the countries committed to the WTO. Governance is another main issue affected by the WTO membership although hardly measurable. Employing institutional quality index provided by the International Monetary Fund (IMF) as a proxy variable for governance provides evidence in favor of the WTO increasing quality of governance (Drabek & Bacchetta, 2004, pp. 1096-1100). Drabek and Bacchetta (2004) conclude that "accession to the WTO has played an important albeit not exclusive role in this process of liberalization".

Several researchers attempted to analyze competition policy impact of the WTO membership (Hoekman & Mavroids, 2002; Bilal & Olarreaga, 1998) without empirical applications. Within the WTO framework, the impact seems to exist as also mentioned above in the Theoretical Framework section. However, existence of the relationship could not be approved without empirical analysis in a single country or in a group of economies in transition.

American economist, Andrew Rose has made significant empirical contributions to the literature about the effectiveness of the GATT/WTO system (Rose, 2004a, 2004b, 2004c). First two works of Rose provide the research on how the WTO affects trade, and the latter one studies the question if the WTO members' trade policy is more liberal in comparison with non-members. Therefore, the results are useful for this research. In his research, Rose (2004b) implements 68 different measures of trade policy and trade liberalization used by various authors to found out if "membership in the WTO and its predecessor the GATT is associated with more liberal trade policy". The conclusion is that there is no significant correlation.

The role of the WTO membership in accelerating transition process in former centrally planned economies has not been studied sufficiently yet. The evidence is a few studies in the existing literature not directly related to the issue. Theoretically, the relationship between the WTO membership and performance of the economies in transition seems to be correlated, but empirically it is not. This chapter partially fills this gap on a case of the South Caucasus economies.

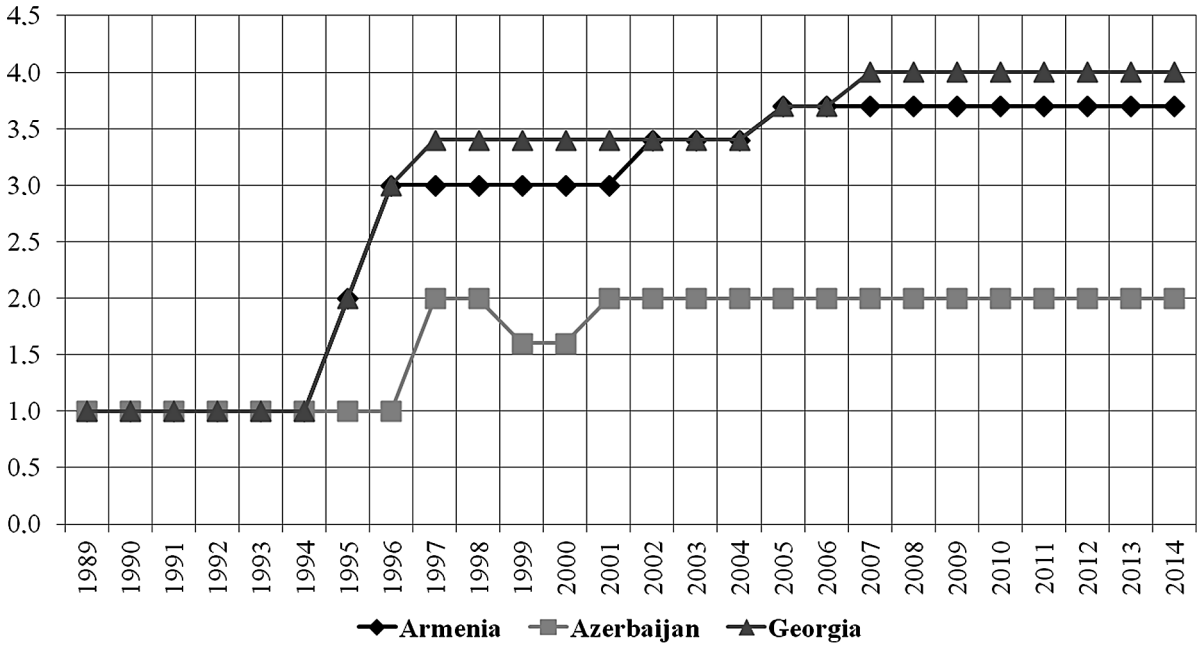
## Data

Used data is taken from the EBRD yearly transition indicators database and publications, and covers the period 1989-2014. Detailed description of the data and meaning of transition scores for each transition category are provided in Appendix. Transition indicators are categorized under six measures: large-scale privatization, small-scale privatization, governance and enterprise restructuring, price liberalization, trade and forex system, and competition policy.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## Graphical Analysis

Figure 2 and Figure 3 embody time-trend lines for each of the transition indicator categories in 1989-2014. Because all countries of the region regained their independence in 1991, real analysis of economic transition performance starts after 1991 for all indicators.



EBRD transition indicators show that large-scale privatization in Armenia and Georgia was initiated after 1994, and in Azerbaijan after 1996. Clearly, the biggest large-scale privatization index belongs to Georgia followed by Armenia. Azerbaijan's score remains on the same level (2) throughout the years of new millennium.

Figure 2 presents the large-scale privatization trends for Armenia and Georgia before-and-after the WTO accession.

When Georgia and Armenia acceded to the organization, in 2000 and 2003 respectively, their large-scale privatization indices did not change immediately. The indices were changed only in 2005, increased from (3+) to (4–) for both countries. In the following years, Armenia's score remained the same, while the index again changed towards positive from (4–) to (4). The year of 2005 was the last year of concessions to implement the WTO commitments for each country. As a non-member country, Azerbaijan's large-scale privatization index is significantly lower than that of Armenia and Georgia.

When small-scale privatization index is considered as an indicator of economic transition, it seems that Georgia realized fast privatization of small entrepreneurship and reached high score even before the launch of the accession process to the WTO. However, Armenia's index increased from (4–) to (4) after the country's accession to the WTO in 2003. For Azerbaijan, it increased to (4–) in 2002 and remained

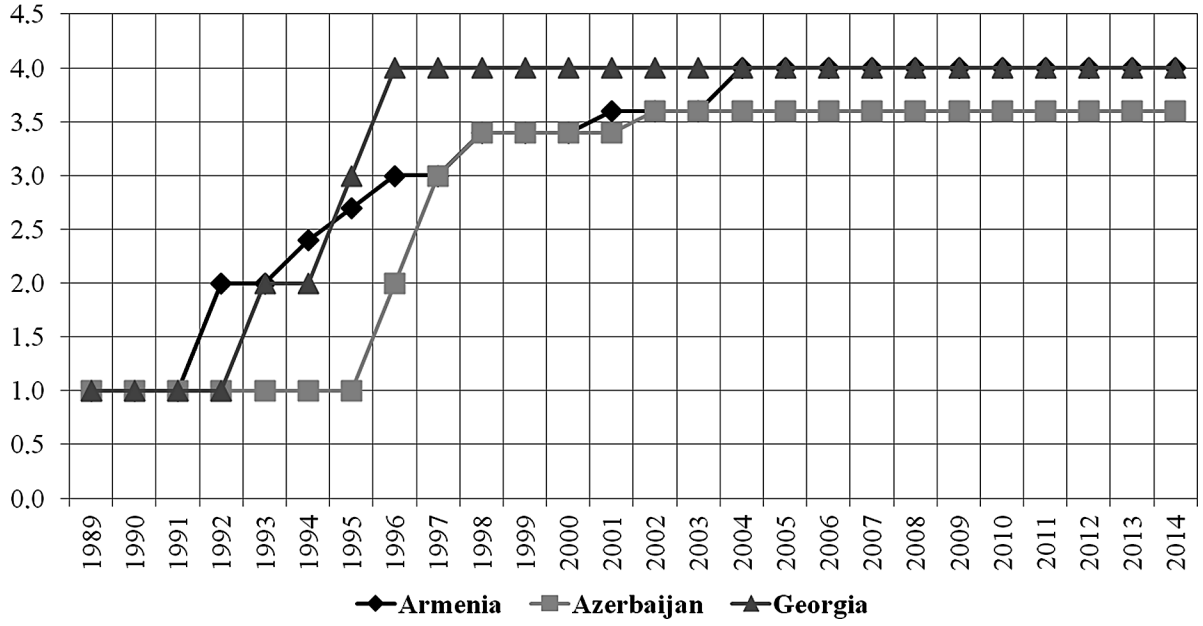


*Figure 2. Large-scale privatization index by country*
*Source: Author's own development based on the European Bank for Reconstruction and Development (2015)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 3. Small-scale privatization index by country*
*Source: Author's own development based on the European Bank for Reconstruction and Development (2015)*

on that level during all the following years. Therefore, the conclusion from the Figure 3 is that the WTO membership has not affected small-scale privatization in Georgia, but has had a positive effect in case of Armenia. Azerbaijan's small-scale privatization index is lower than the one of both countries.

Another indicator of economic transition process is governance and enterprise restructuring (Figure 4). The scores for the three countries are not very high. Until 2001, the scores for Armenia and Georgia were equal (2), while Azerbaijan's score was (2–). In 2002, Armenia's score increased up to (2+), and the same happened for Georgia in 2005. Another low index is observed for Azerbaijan. It increased up to (2) and has remained on that level until now.

In before-and-after WTO membership context, the score did not change for Armenia after the country's accession in 2003. For Georgia, the score increased from (2) to (2+) after the end of the concession period in 2005.

Regarding price liberalization, the countries have gained nothing from the accession. Thus, Figure 5 shows that all countries liberalized price regulations already during their first years of independence, before the launch of the accession processes. The scores did not change after Armenia and Georgia joined the WTO.

Theoretically, the WTO membership is expected to make the trade system more liberal. However, there is a doubt on this expectation (Rose, 2004b). Figure 6 embodies transition performance of the economies in trade and forex system context.

Georgia's and Armenia's trade and forex were scored with (4) or evaluated as highly liberal already in 1996 and 1997, respectively. After accession of those two countries to the WTO, the scores increased up to (4+) level for both of them. In other words, trade and forex systems in Georgia and Armenia are considered as highly liberalized as a result of the WTO accession negotiations, ended with the full

*Source: Author's own development based on the European Bank for Reconstruction and Development (2015)*

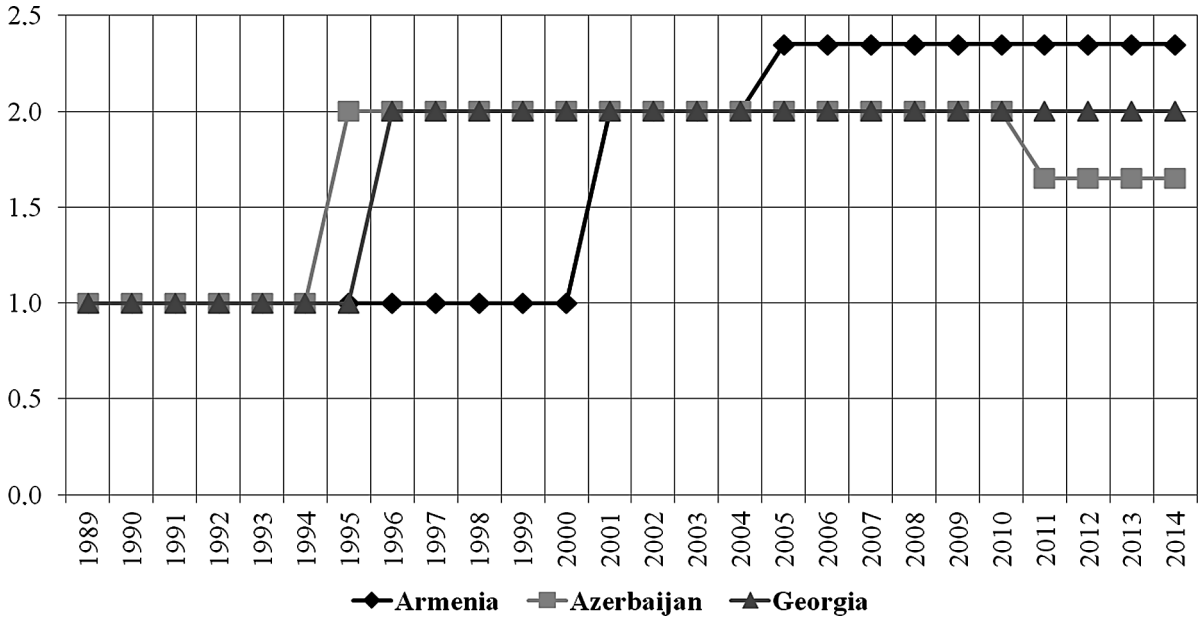
membership. The score of Azerbaijan, which is a non-member country, is less than other two countries in the region, but is fairly high still (4). Considering all these trade and forex system indices, positive impact of the WTO membership over economic transition is revealed.

Unlike index values of previous categories, competition policy is not sufficiently high for all three countries. The upper bound of the index is (4+) also for competition policy category. Nevertheless, the highest competition policy score (which is (2+) only) belongs to Armenia. The second most competitive country in South Caucasus is Georgia with index value equal (2). Azerbaijan's score was similar with that of Georgia until 2011, but later decreased down to (2–) (Figure 7).

Although most of the WTO foundation principles imply better competition situation in the economies after their accession to the organization, data for these countries does not provide any evidence of significant positive impact. For Armenia, the score increased up to (2+) only after the end of the concession period in 2005, not immediately after the accession. In case of Georgia, there was no change in competition policy score after the accession year (2000) as well as after the end of the concession period (2005). It has remained at (2) which means rather insufficient transition performance in this category.



## SOLUTIONS AND RECOMMENDATIONS

By using bivariate regression analysis, empirical results would light the relationship of interest more successfully. For each category used for measuring transition performance, the model regressed against the dummy variable, named "WTO membership" equals 1 throughout the years after joining to the WTO, otherwise 0. Three models are run in total, two are time-series analysis for Armenia and Georgia, individually, and one is a panel data analysis covering also Azerbaijan.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 7. Competition policy index by country*
*Source: Author's own development based on the European Bank for Reconstruction and Development (2015)*

The general model equation is as follows:

$$\log(Y_{t,i,n}) = \beta_{0,i,n} + \beta_{1,i}D1_{t,i} + \beta_{2,i}t + u_{t,i,n} \quad (1)$$

$$\log(Y_{t,i,n}) = \beta_{0,i,n} + \beta_{1,i}D2_{t,i} + \beta_{2,i}t + u_{t,i,n} \quad (2)$$

Where:

Y – transition performance index for each category, separated by *n* equals 1, 2, …, 6.
*D1* – dummy variable "WTO membership", which provides comparison of transition performance before-and-after the WTO membership, respectively 2000 and 2003 for Georgia and Armenia.
*D2* – dummy variable with the same meaning, but showing the transition performance difference before-and-after the end of the WTO concession period, 2005 for both Georgia and Armenia. The end of the concession period means the end of the period given to the new member countries to implement admitted obligations while joining. Because Azerbaijan is still out of the WTO system, dummy variable gets always 0 value in panel data analysis. Hence, the same equation will be used for the panel of all three countries of the region, as well in addition to individual time-series analysis for Georgia and Armenia.
u – error term.
t – time.
i – target country, more precisely, Georgia, Armenia, and the panel data set of all three.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Estimation is done by using E-Views 8 econometric software. Standard errors in all regressions are robusted against heteroscedasticity and autocorrelation.

## Empirical Results

All empirical findings are included in the Table 1 below. Remember that the independent variables *D1* and *D2* are dummy variables. Former one is to show the economic transition performance of the countries under research before-and-after the WTO membership, while the latter one does the same in the context of before-and-after the end of the concession period.

## Georgia

Because Georgia's small scale privatization index, price liberalization index and competition index have never changed after the country's accession to the WTO; models (1) and (2) are not applicable. In other words, the WTO did nothing for price, small-scale privatization or competition policy aspects of economic transition in the country.

However, the model reveals significant impact of integration to the WTO for the remaining aspects, i.e. large-scale privatization, governance and enterprise restructuring, and trade and foreign exchange system.

The role of the WTO membership in expanding large-scale privatization and developing governance and enterprise restructuring is statistically insignificant and negative in before-and-after WTO membership context, while the same is statistically significant and the signs of coefficients are positive in before-and-after the end of the concession period. Moreover, joining the WTO means immediate significant positive impact over transition of trade and foreign exchange system. This provides evidence for the theoretical view that implementation of the WTO commitments leads to better economic transition performance in these three categories of economic transition in case of Georgia.

## Armenia

Armenia's experience is somewhat different. All categories have been affected by the integration to the WTO. It is noteworthy to emphasize that all coefficients are positive, which confirms that the accession to the WTO is a driving force of economic transition in Armenia. Statistical significance of coefficients also supports this point of view.

The impact over large-/small-scale privatization, governance and enterprise restructuring, and price liberalization are statistically significant in before-and-after WTO membership context. Nevertheless, the size and significance of the impact over large-scale privatization is greater in the context of before-and-after the end of the concession period.

Unexpectedly, the WTO membership does not significantly increase economic transition performance in terms of trade and foreign exchange and competition policy, as the coefficients are positive but statistically insignificant.

## Three Countries Put Together

This model includes all three countries of the region and shows the difference in economic transition performances throughout the years due to the WTO membership status. For Azerbaijan as a non-member

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

country, the model demonstrates what effect is expected in case of the accession or gaining the WTO membership status (Table 1).

Model findings from the panel data analysis presented in the third panel of the Table 1 also support the general expectations of positive effect. Thus, in all categories of transition indicators, the impact of the WTO membership is positive and statistically significant. Especially, effect over large-scale privatization is considerably large.

Considering the situation of Azerbaijan economy, it is obvious that the WTO membership will make the domestic economy much more transited to the market economy with comparatively higher transition indicators calculated by the EBRD. Throughout bilateral and multilateral negotiations, members of the Working Party established specially for the applicant country (in this case Azerbaijan since 1997) push the government to implement some reforms in consistent with the WTO principles (Aliyev, 2014). Clearly, those countries participating in the Working Party negotiations pursue their own interests, what leads to a much more advanced economic transition. Summarizing, the findings are consistent with theory and practice.

## FUTURE RESEARCH DIRECTIONS

This chapter addressed the issue on how integration to the WTO affects economic transition in the countries of the South Caucasus. However, several crucial shortcoming points should be taken into consideration in the future researches.

First shortcoming is related to the econometric methodology and the data. The data is obtained from the European Bank for Reconstruction and Development (2015) on an annual basis. Apart from proxy variable for economic transition at each category, some other variables would describe the relationship in a clearer manner. Second shortcoming is that the research shows only the relationship, numerically. Within this framework, it is difficult to reveal the reasons and measure the weight of impact channels. Use of various proxy variables, control of some variables, and measurement of weight of different impact channels are promising directions for future researchers.

Beyond shortcomings, this chapter is concluded with "magical relationship" between the WTO membership and competition policy during economic transition. The magic behind the found evidence of the WTO's ineffectiveness for liberalizing competition policy is a good point to start new research for the countries of the South Caucasus region, with cross-sectional data for this specific category.

## CONCLUSION

Integration of the South Caucasus economies to the market economy has always been at the center of interests. In this context, all three economies are expected to integrate to the international organizations. As international trade is one of the most important aspects of market economy, the interest of each country to the WTO membership is understandable.

The theory also supports the views on driving role of the WTO in accelerating economic transition of planned economies to market ones, what is in line with the fundamental principles of the WTO. However, existing literature does not provide clear and common approach to the discussed issue. From this point of view, the current study contributes to the literature with graphical and empirical analysis of the relationship between the WTO membership and economic transition performance on the case of three South Caucasus economies, which all left centrally planned system after the collapse of the Soviet Union in 1991.

Empirical findings are generally consistent with the expectations but show differences across countries, i.e. Georgia and Armenia. Common results are that implementation of the WTO membership commitments leads to higher large-scale privatization, and governance and enterprise restructuring performance.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The impact over trade and foreign exchange system, which is a strongly expected one, is insignificant in Armenia, but significant in Georgia.

Surprisingly, as individual case analysis shows, the WTO membership does not lead to any change in competition policy index in Georgia and insignificantly affects that in case of Armenia, while the indices for both countries are low. Hence, this finding is in converse with maintaining "the principle of nondiscrimination". Despite gaining the WTO membership status and completing concession period, the study discovered almost no improvements related to the competitiveness of the economies of the region, as well as restrictions to enter domestic markets, and reductions of abuse of market power in both countries. This is a novel interesting evidence, which requires further research related to background reasons.

While considering the region as a whole by including Azerbaijan as a non-member country to the model, coefficients strongly change. In this case, the WTO membership is found as a strongly affecting factor for the economic transition performance. Graphical analysis also presented Azerbaijan as the evidence of less transited economy in comparison with Georgia and Armenia. Therefore, it is expected that Azerbaijan's economic transition will accelerate in case of successful completion of accession negotiations, gaining membership status, and carrying out of the WTO commitments until the end of the concession period.

Summarizing, the conclusion is about supporting the hypothesis that accession negotiations and obligations over an applicant country lead to accelerating economic transition process, in short positive relationship. It is statistically significant in most categories except competition policy index and partially governance and enterprise restructuring index. Thus, these two category indices are not high in all three countries of the region.

## KEY TERMS AND DEFINITIONS

**Accession Negotiations:** The WTO is open to any state or customs territory to become a member. However, there is a condition that all members of the WTO must agree on the terms. The process of achieving these agreements with the Working Party members from the WTO side is called accession negotiations.

**Bivariate Regression:** A regression analysis, which includes a single independent variable.

**Dummy Variable:** The variables, which indicate an absence or presence of some categorical effect, equal 0 or 1.

**EBRD Transition Indicators:** The indicators presented by the European Bank for Reconstruction and Development (EBRD), reflect country-specific progress of a country in transition. Classification system for the scores is provided in Appendix.

**Economic Transition:** A process of changing the economic system from centrally planned to a market economy, which requires a set of structural transformations intended to develop market-based institutions.

**Ordinary Least Squares (OLS):** The method of estimation in regression analysis producing unknown parameters in a linear regression model.

**WTO:** The World Trade Organization, which currently has 161 member countries as of April, 2015.

*This research was previously published in Global Perspectives on Trade Integration and Economies in Transition edited by Vasily Erokhin; pages 58-79, copyright year 2016 by Business Science Reference (an imprint of IGI Global).*

## APPENDIX

*Table 2. Measuring economic transition: methodology*

| Variable | Definition | Score |
|---|---|---|
| **Large-Scale Privatization** | Little private ownership | 1 |
| | Comprehensive scheme almost ready for implementation; some sales completed. | 2 |
| | More than 25 per cent of large-scale enterprise assets in private hands or in the process of being privatized (with the process having reached a stage at which the state has effectively ceded its ownership rights), but possibly with major unresolved issues regarding corporate governance. | 3 |
| | More than 50 per cent of state-owned enterprise and farm assets in private ownership and significant progress with corporate governance of these enterprises. | 4 |
| | Standards and performance typical of advanced industrial economies: more than 75 per cent of enterprise assets in private ownership with effective corporate governance. | 4+ |
| **Small-Scale Privatization** | Little progress. | 1 |
| | Substantial share privatized | 2 |
| | Comprehensive programme almost ready for implementation. | 3 |
| | Complete privatization of small companies with tradable ownership rights. | 4 |
| | Standards and performance typical of advanced industrial economies: no state ownership of small enterprises; effective tradability of land. | 4+ |
| **Governance and Enterprise Restructuring** | Soft budget constraints (lax credit and subsidy policies weakening financial discipline at the enterprise level); few other reforms to promote corporate governance. | 1 |
| | Moderately tight credit and subsidy policy, but weak enforcement of bankruptcy legislation and little action taken to strengthen competition and corporate governance. | 2 |
| | Significant and sustained actions to harden budget constraints and to promote corporate governance effectively (for example, privatization combined with tight credit and subsidy policies and/or enforcement of bankruptcy legislation). | 3 |
| | Substantial improvement in corporate governance and significant new investment at the enterprise level, including minority holdings by financial investors. | 4 |
| | Standards and performance typical of advanced industrial economies: effective corporate control exercised through domestic financial institutions and markets, fostering market-driven restructuring. | 4+ |
| **Price Liberalization** | Most prices formally controlled by the government. | 1 |
| | Some lifting of price administration; state procurement at non-market prices for the majority of product categories. | 2 |
| | Significant progress on price liberalization, but state procurement at non-market prices remains substantial. | 3 |
| | Comprehensive price liberalization; state procurement at non-market prices largely phased out; only a small number of administered prices remain. | 4 |
| | Standards and performance typical of advanced industrial economies: complete price liberalization with no price control outside housing, transport and natural monopolies. | 4+ |

# Chapter 65
# Recent Status of Capital Market Regulations in Bangladesh: Capital Market Regulations in Bangladesh

**Md Azizul Baten**
*Shahjalal University of Science and Technology, Sylhet-3114, Bangladesh & Universiti Utara Malaysia, Kedah, Malaysia*

## ABSTRACT

*The capital market of Bangladesh perceived a self-important growth which is not in line with developed economy. The Securities and Exchange Commission (SEC) tried to correct the irregular behaviour observed in the market, lack of proper decisions from the regulator's side which has contributed to the creation of market instability. This study tried to identify the factors on market crash and regulatory failure. Government had reform SEC to soothe the market but unsuccessful as investors' confidence is in the bottom level. The reasons behind the stock market crash are found irrational market behavior, inconsistency in regulations, excess liquidity in the market, stock split by companies, faulty listing system, issuance of right shares and preference shares by companies at high price, stock manipulations by insider trading, serial trading and excessive greed of investors. Government and regulators should work together to detect the main speculators and should bring investors back to the market.*

## INTRODUCTION

Stock market is one of the most important financial institutions and it releases door for companies to nurture huge amount of capital from individual investors in and out of a country. Sound capital market is an indispensible part of an economy and without the efficient capital market; economic development could be hampered as capital market delivers long term funds to entrepreneurs. The capital market of Bangladesh is the third largest in South Asia and one of the smallest in Asia. There are two full-fledged automated stock exchanges namely Dhaka Stock Exchange (DSE) and Chittagong Stock Exchange

(CSE). Bangladesh Securities and Exchange Commission (BSEC) was established in 1993 to regulate the businesses of the exchanges, confirm proper issuance of securities and agreement with laws and protect the interests of securities investors.

The global economic crisis in 2008 and 2009 was known as a volatile year but during this year Bangladesh economy benefited from low prices of imported goods and was able to avoid negative pressure on its export of goods and services (CPD, 2011). Regulators had taken some measures to stabilize the market with the introduction of central depository, circuit breaker, online trading, etc. to attract investors. As a result, the market started to grow and investors started to invest again. Unfortunately, investors had lost their money when the bubble started to burst in December 2010. The Benchmark index came down to 3616 points in early February 2012 from its highest point of 8918. After the crush of the capital market in 2011, a continuous fall in turnover is observed. In FY 2011-12, the turnover in DSE dropped to Tk. 117145.07 crore from Tk. 325879.77 crore of the previous FY in 2010-11, which was a decrease rate of 65.05 percent. The regulators had failed to take proactive measures to avoid the market from crashing and caused losses for millions of investors.

The volatility of the capital market of Bangladesh is an abnormal phenomenon and such volatility tends to create economic instability. In the state of market growth, role of regulators has been questioned in two accounts. Firstly, whether regulators act promptly to address the volatility of the capital market and secondly, whether frequent changes in regulators' decisions contribute negative impact on the sustainable development of the market. Again, as volatility raises many questions on the regulatory capability of the Securities Exchange Commission (SEC), it is unknown whether the stock market fluctuation is due to regulatory failure or due to irrational behaviors of investors. It is necessary to determine the main reasons of the stock market crash in Bangladesh and the roles of the regulators. Eventually, some guidelines will be recommended for better regulations to strengthen the capital market of Bangladesh.

## Background

The history of Bangladesh Capital Market started on the 28$^{th}$ of April, 1954 when Bangladesh was known as East Pakistan and the market was known as East Pakistan Stock Exchange. In April 28, 1954 where Bangladesh was still known as East Pakistan as East Pakistan Stock Exchange Association Ltd, the journey of stock market started while Bangladesh used to be ruled by Pakistan. But trading on this market started in 1956 with a total paid up capital of Taka 4 billion and 196 securities were listed on this market. The exchange was renamed on in June 23, 1962 as DSE Limited. Trading on DSE was suspended from 1971 to 1976 because of liberation war and its post-independence weak economy. Then the trading was resumed in 1976 with 9 listed securities having a total paid up capital of Taka 137.52 million (Hassan et al., 2000). By 1987, the number of listed companies in DSE increased up to 92 and the development of the market is noticeable in the 1990s since its establishment (Economy watch, 2010).

### Dhaka Stock Exchange (DSE)

Dhaka Stock Exchange is the first stock exchange regulated by its Articles of Association rules & regulations along with the Securities and Exchange Ordinance 1969, Companies Act 1994 & Securities & Exchange Commission Act 1993. DSE was used to trade in the open outcry system, installed on 10th of August, 1998. The latest upgrading was done on 21st of December, 2008. There are 238 members and total of 507 listed securities in DSE. The working days of DSE are 5 days in a week excluding Saturday,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sunday, public holidays & other government holidays. The trading time is from 11:00 am to 15:00 pm (local time). Investment options for an investor are ordinary share, Debenture and Bond & Mutual funds. There are three different indices of DSE which are DSI (All share), DGEN (A, B, G & N) and DSE 20 (www.dsebd.org).

Functions of DSE:

A. Listing of Companies (As per Listing Regulations).
B. Providing the screen based automated trading of listed Securities.
C. Settlement of trading (As per Settlement of Transaction Regulations).
D. Gifting of share / granting approval to the transaction/transfer of share outside the trading system of the exchange (As per Listing Regulations 42).
E. Market Administration & Control.
F. Market Surveillance.
G. Publication of Monthly Review.
H. Monitoring the activities of listed companies (As per Listing Regulations).
I. Investor's grievance Cell (Disposal of complaint by laws 1997).
J. Investors Protection Fund (As per investor protection fund Regulations 1999).
K. Announcement of Price sensitive or other information about listed companies through online. (Source: www.dsebd.org)

## Chittagong Stock Exchange (CSE)

Chittagong Stock Exchange is the 2nd stock exchange introducing modern technology & sophisticated logistic support. It was incorporated as a self-regulated non-profit organization on 1995 and started its automated trading on 2nd June, 1998 and internet trading service on 30th May, 2004. CSE has 147 members and 238 of listed securities. There are four different markets in CSE which are public, Spot, Block & Odd and Lot market. Five categories of company namely A, B, N, G and Z listed in CSE of which none company is in G category. The trading time of CSE is between 11:00 am to 15:00 pm. The working days & holidays of CSE are similar with DSE. CSE consists of 25 members of whom 12 are elected through election of its members, 12 members are elected from different major economic & social arena of Bangladesh. CSE has 3 indices in the stock exchange namely All Share Price Index (CASPI), CSE Selective Index (CSE30) and CSE Selective Categories' Index (CSCX) (www.cse.com.bd).

## Security and Exchange Commissions (SEC)

The Government of Bangladesh is founded SEC on 8th of June, 1993 under the Securities and Exchange Commission Act, 1993. The commission is consists of a chairman and four members. The Chairman & members of security exchange commission are appointed by the government of Bangladesh. According to Securities and Exchange Ordinance, 1969 SEC has been empowered to control the self-regulatory institutions for instance Stock Exchanges.

Responsibilities of SEC:

A. Conducting transparent trading, stop fraudulent practices like market manipulation, insider trading, short selling.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

B. Ensuring submission of transparent accounts as per rule, statements, reports and returns.
C. Carrying out inquiry to alleged irregularities and taking legal action for all kinds of violation of securities law and regulations.
D. Ensuring submission of annual financial statement in time containing balance sheet, profit and loss account, cash flow statement and notes to the accounts.
E. Examining audited financial statements, ensure that audit conducted in accordance with prescribed rules and take necessary action for deficiencies.

Functions of SEC:

A. Registering and regulating the business operation of DSE, CSE, stock brokers, merchant banks, underwriters, share transfer agents, portfolio managers and other intermediaries.
B. Developing investor`s education, providing training for intermediaries, executing market research and publishing.
C. Controlling every authorized self-regulatory organization.
D. Inspecting and controlling fraudulent and unfair trading in security markets.
E. Auditing and investigating of any intermediaries or stock exchanges.
F. Collective investment scheme registering & controlling.
(www.secbd.org)

### Central Depository Bangladesh Limited (CDBL)

CDBL was incorporated as a public limited company on 20th August, 2000. The owners of CDBL are DSE, CSE, banks, Investment Corporation of Bangladesh and some other financial institutions.

Functions of CDBL:

A. Operate and maintain the Central Depository System (CDS) of Electronic Book.
B. Recording and maintaining securities accounts and registering transfer of securities.
C. Changing the ownership without any physical movement or endorsement of certificates.
D. Supervision of Depository participant activities.
E. Providing different investor services including providing a platform for the secondary market trading of Treasury Bills and Government Bonds issued by the Bangladesh Bank (www.cdbl.com).

## MAIN FOCUS OF THE CHAPTER

### Regulatory Renovations and Market Developments

From return perspective, the year 2012 seemed to be an unfortunate; it included some regulatory changes and progresses as follows:

A. Implementing Mandatory shareholding requirement from BSEC by corporate directors.
B. Development of draft guidelines on Research and Investment Advisor services.
C. Amending Margin Loan Rules.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

D. Progress in Omnibus account closeout.
E. Developing BSEC Roadmap for capital market.
F. Initiation of demutualization process for the Exchange.
G. Implementing New MSA-Plus Software for Trading.
H. Amendment in the Mutual Fund Rules.
I. Inaugurating Surveillance system by BSEC.
J. Progress in introducing new Indices for DSE.

The impact of these changes in market development was not found significant for most of these events.

(Capital Market Review 2012, IDLC Investments Ltd., January 2013.)

## Regulatory Problems

SEC could not identify and investigate many irregularities that happened in the process of the stock market bubble. To restructure SEC with skilled human capital is one of the major constraints. Both SEC and the stock exchanges failed to monitor the issue of IPO and rights shares. Overpricing through overstating EPS (earning per share) and NAV (net asset value) was found to be the problem. The SEC did not allow merchant banks to make forced-selling when share prices started to fall.

(Source: Bangladesh Economic Update, Volume 4, No. 3, 1-27, March 2013).

## Comparison of Stock Market volatility of DSE with Other Markets

Price fall in DSE was sudden and persistent which caused a significant loss of paper wealth and was abnormal in nature as compared to other stock markets.

From Table 1, it was observed that during December 2011 to January 2012, Bombay Stock Exchange index (BSE-30) was fallen by 14% while SET index of Thailand increased by 55.62% and Dhaka Stock Exchange general Index (DGEN) was fallen by more than 50% during this period, i.e., DGEN lose its value by 50% during the period which indicated that this was not a simple volatility and it can be defined as a collapse. On the other hand, Standard deviations of index return for BSE-30 and SET index were recorded to be 7.8% and 5.84% respectively. But for DSE, the standard deviation of index return was 11% which was much higher than the other two indices.

*Table 1. Comparison of DSE Volatility with Other Markets*

| Name of the Index | Index Return (Dec'10-Jan'12) | Std. Dev. of Index Return (Dec'10-Jan'12) |
|---|---|---|
| DSE | 50% | 11% |
| BSE-30 | 14% | 7.8% |
| SET | 55.62% | 5.84% |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## SOLUTIONS

### Rules and Stock Market Crash of Bangladesh in 2010-11

During the military-backed regime in 2007, investment in real sectors as well as in Foreign Direct Investment (FDI) decreased but the inflow of foreign remittance was increased. Banks & other financial institutions had a lot of excess liquidity due to less business opportunities in the recession period of 2009-10. These financial institutions & its officials as well as other people took loan and invested in the share market in order to minimize the cost of bearing excess liquidity. It was seen that the daily transaction in the share market was on an average from Taka 20,000 to Taka 30,000 million in 2010 and the figure was doubled comparing to 2009 (Raisa, 2011). Investors tried to find alternative investment sector to invest their savings and found stock market as an attractive alternative (Khaled, 2011).

The total number of BO Account holders on 20th December, 2010 reached to 3.21 million though the number was 1.25 million in December 2009. Internet-based trading operation, opening branches of brokerage houses across the country, easy access to the market information, arranging a countrywide 'share mela (fair)' are the factors for increasing investors. But supplies of new securities through IPOs were not enough to chase huge capital of too many investors in the market (CPD, 2011).

The directives of 6th & 7th December 2010 applied by SEC were cancelled on 8th December 2010. The reason of cancelling these directives was a significant fall of share prices on 8th December. SEC changed directive of margin loan ratio by increasing it from 1:0.5 to 1:1 on 13th December and later it was again hiked to 1:1.5 & 1:2 because of free fall of share prices (Bhuiyan, (2011). As the Institutions & banks started selling their shares from the beginning of December 2010, the turnover of DSE was the highest ever in its history on 5th December 2010. On 19th December 2010, DSE witnessed its biggest one day fall in 55 years history until the date with a loss of 551.76 points or 6.71 percent. The losing index was even higher than 284.78 points or 3.32 percent in 12th December 2010 (Raisa, 2011).

On 11th January 2011, market recovered 15.6 percent of General index by initiating with Institutional buyer for instance merchant banks, state owned banks & non-financial institutions and made a record in Bangladesh stock market history of gain (Chowdhury, 2011). Moreover, Ahmed (2011) mentioned that institutional buyers were asked not to sell shares rather to buy. Though steps were taken and applied by the government, BB and regulators to improve the market conditions and bring the investors' confidence, nevertheless market index declined heavily on 20th January 2011 DGEN by slipping 599.77 points or 8.68 percent. From 26th of January 2011 there was an increase trend of index. But finally Index stood at the lowest point which is 5579 from 7th to 14th February 2011. (Khalid, 2011)

Bangladesh Bank (BB) adopted accommodative monetary policy during the high inflation periods to support investment and pegged Taka against dollar to support exports. The policy that was adopted by BB to grow economy by increasing exports & investment eventually misguided and ended up blowing the mother of all bubbles. Government again fuelled the bubble after permitting whitening of black money through tax breaks and schemes (Rahman, 2011).

Due to the poor monitoring of SEC & market surveillance share prices of Z Category Companies and small companies increased dramatically. Some initiatives taken by SEC were not effective and changing directives frequently such as; it changed directives of margin loan ratio 19 times (Raisa, 2011).

## Recent Trends in Capital Market and Regulators

The current most important problems of the capital market are lack of confidence of investors and lack of liquidity of the capital market. After the crush of the capital market in 2011, a continuous fall in turnover has been observed, revealing the crisis of liquidity in the capital market. In FY 2011-12, the turnover sunk to Tk. 117145.07 crore from Tk. 325879.77 crore, meaning a fall of 64 percentages. In FY 2012-13, the volatility capital market followed a declining trend. DSE index movement was found not normal and the fall was so abrupt that it caused huge loss for investors. In FY 2011-12, the market capitalization ratio was 21.12 percent, which sharply declined from 29.55 percent of the previous FY 2010-11. In January 2013 total market capitalization of DSE was Tk. 184545.2 crore, a less of 4.5 percent than that of previous FY 2011-12.

In FY 2012-13, the market capitalization and investment ratio witnessed a downward trend, reaching at 83.01 percent. This indicates the descent in ratio between capitalization and investments, revealing a continuous fall in the capital market. In January 2013, a declined trend of market capitalization was witnessed for the banking sector, reaching at Tk. 49251.80 crore, a sharp drop Tk. 1986.9 crore than in FY 2011-12 in which year the banking sector contributed a total amount of Tk. 51238.60 crore. From FY 2010-11 to January 2013 falling rate of contribution in banking sector in market capitalization was 2 percent which came down from 29 percent in FY 2010-11 to 27 percent in January, 2013 (Bangladesh Economic Update).

## Factors Contributed to Capital Market Crash in Bangladesh

The contributed factors to the crash are commonly accused by different market analysts, economists and stakeholders. As Hossain (2011) evaluated "this time liable factors are -omnibus account, placement share, book building method, rumors and so on. Misuse of those factors causes the capital market debacle". Again Haque (n.d.) stated "Combination of wrong information to the investors, illegal participation of banks and institutions in the stock markets, weak accounting functions are at the core of the crisis that saw billions of Tk. wiped out".

The *"Ibrahim Khaled share market probe Committee"* identified the following factors that caused the capital market to crash:

A. Primary issue related problems
    i. Direct listing in Primary issue.
    ii. Abuse of Book Building Method of IPO.
    iii. High premium for stock listing.
    iv. Illegal Private placement market.
    v. Asset Revaluation of Companies before listing to charge higher premium.
B. Secondary market related problems
    i. Circular trading in Secondary market.
    ii. Block trading.
    iii. Stock Price Manipulation through Omnibus Accounts.
    iv. Most of the market players are identified in the report.
C. Irregularities in issuance of Right Share/Preference Share/Repeat IPO etc.
D. Recommendation of Stock Dividend by companies against unrealized Profits.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

E. Regulatory Failure
   i. Inconsistency in regulatory activities.
   ii. Supporting and legalization of unethical activities of Big Investors.
   iii. Irresponsible Behavior/Weakness in many areas.
   iv. Formulating policies to support market Players (Manipulators).
   v. Lack of Due Diligence.
   vi. Lack of Co-ordination between SEC and Stock exchanges.
   vii. Allowing Financial Institutions to invest in capital market aggressively.
   viii. SEC Failed to take measure against manipulation of financial statements.
F. Stock Exchange Demutualization
   i. Formulating policy for Capital Market financing by FI's.
   ii. Ensuring transparency in dealing with Omnibus Accounts.
   iii. Prohibit share trading by some Government Officials (e.g., SEC, DSE, CSE, Bangladesh bank, Commercial bank officials).
   iv. Asset Revaluation by companies should be reviewed by SEC.
   v. Review the Book-Building Method of IPO.
   vi. Restructuring of SEC.
   vii. Uniform face-value of all companies.
   viii. Legal actions against market players/manipulators.

## RECOMMENDATIONS

The following recommendations for stronger capital market in Bangladesh are in line of this study.

A. Demutualization of Stock Exchanges.
B. Strengthening the Market Surveillance Systems.
C. Ensuring Integrity and Efficiency of SEC Members and Staffs.
D. Co-ordination between SEC and Stock Exchanges.
E. Bank Finance in Capital Market.
F. Introduction of Asset Revaluations Policy.
G. Consistency in Regulation.
H. Supply of adequate securities.
I. Transparency in listing procedure.
J. Serial Trading and Manipulation.

The *Ibrahim Khaled share market probe* Committee recommended some suggestions to the Government to recover the capital market crash. There are:

A. Restructuring of SEC
   i. Termination of SEC chief and some other corrupt members.
   ii. Comprehensive inspection of their corruption and necessary legal actions.
   iii. Recruiting qualified accountants/financial analysts/experts/Talents for SEC.
   iv. Increase the remuneration of SEC staff to attract talents.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

v. Ensuring integrity of SEC personnel.

B. Stock Exchange Demutualization
   i. Form Committee within DSE to give report regarding demutualization process within 3 months.
   ii. If DSE fails to give report on time, Government should take steps after 3 months.
   iii. Government can take advisory supports from World Bank or any other international organization.
   iv. Government can employ an "Administrator" to DSE to implement the demutualization process.
C. Co-ordination between SEC and stock exchanges for better regulation.
D. Capital Market financing by Financial Institutions (FI's).
   i. Formulate policy for capital market investment by FI's in the line of such policies in India and Pakistan.
   ii. Take measures against FI's who are involved with the recent stock market manipulation.
   iii. Central Bank should monitor FI's aggressive stock investment very strictly.
E. Formulate clear policy for Pre-IPO placement.
F. Ensure transparency in dealing with Omnibus Accounts.
G. Prohibit share trading by some Government Officials (e.g., SEC, DSE, CSE, Bangladesh bank, Commercial bank officials).
H. Asset Revaluation by companies should be reviewed by SEC.
I. Review the Book-Building Method of IPO.
J. Make uniform face-value of all companies.
K. Take legal actions against market players/manipulators.
L. Government should be more aware about the capital market and they should be free from influence of top market players (Salman F. Rahman, Rakibur Rahman etc.).
M. SEC should Open Investors advisory support services to avoid rumor-based trading.

## FUTURE RESEARCH DIRECTIONS

The results of this study is of a great interest to academics, policy makers and local and foreign listed and unlisted companies and have an important practical implications to different capital market participants such as investors, managers and regulatory authorities. This study identified the factors on capital market crash and regulatory failure would be of a great benefit to investors at home and abroad. Researchers can further study in finding new tools, strategies, directives, rules and regulations for market development and to prevent the stock market from crash in future. Finally, it may also be useful for international organizations (such as the World Bank, IMF, WTO) and governments of development partners who are interested in the development of capital markets in the emerging countries.

## CONCLUSION

The study endeavored to find out the major reasons for the stock market to crash of in Bangladesh and the role of different regulatory organizations including DSE, CSE, and SEC of the country. It reviewed the background of the capital market crash with reasons. The continuous fall in the capital market exhibited lack of confidence by the investors. In January 2013, the continuous fall in the contribution of banking

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

sector was observable. The capital market could not revive after the crush and in certain circumstances the fall continued, despite the announcement of certain measures such as tax rebate, exemption of credit for marginal level investors. SEC did not come forward to stop while thousands of totally inexperienced investors open by the brokers from remote areas to the overpriced market. Most of promises by the government like Bangladesh fund, market stabilization fund, bank investments remained unfulfilled eroding investor confidence seriously and it was wondering why SEC did not come forward to take necessary action to stop these irresponsible comments and acts. Due to poor regulatory framework, capital market of Bangladesh was found to be highly speculative and lacks of market's transparency and the recommendations of Ibrahim Khaled committee have not been implemented. It was observed that developing faulty accounting practices and methods, recruiting honest officials, providing education on the stock market to the general investors and taking strict actions against manipulators are crucial.

In addition, it was observed that the stock market boom and fall was due to following reasons:

1. Direct Listing and Book Building in IPO, high indicative price for IPO, Misuse of Book Building method of IPO, and pre-IPO Private placement activity.
2. Circular trading, Block Trading and unusual trading of securities where few numbers of investors/ institutions are involved.
3. Issuance of Right Share, Preference share, Repeat IPO at excessive price.
4. Excessive Greed of Investors and Institutions.

SEC responsibility need to ensure in a market that where various kinds of manipulation, insider trading, circular trading, pump and dump practices may prevail and create market distortion. Again, they need to concentrate on transparent listing procedure, proper IPO pricing, adequate financial disclosure, market surveillance and monitoring and promote investor confidence. The regulators and government is required to introduce new tools, strategies, directives, rules and regulations for market development and to prevent the stock market crash in future. SEC should stop excess bank investment violating provision of law.

Actions should be taken against those who were involved in this stock market crash

1. Improving security laws and penalty for breaking those.
2. Balancing of demand and supply of shares.
3. Follow-up the market and protect against any kind of manipulation.

## KEY TERMS AND DEFINITIONS

**Capital Market:** A capital market is a market for both debt and equity securities, where business enterprises and governments can raise long-term funds. It is defined as a market in which money is provided for periods longer than a year (Sullivan et. al., 2003). Bangladesh capital market has two full-fledged automated stock exchanges namely Dhaka Stock Exchange (DSE) and Chittagong Stock Exchange (CSE). It consists of a regulator, the Securities and Exchange Commission (SEC), since, it implements rules and regulations, monitors their implications to operate and develop the capital market. It consists of Central Depository Bangladesh Limited (CDBL), the only Central Depository in Bangladesh that provides facilities for the settlement of transactions of dematerialized securities in CSE and DSE.

**Demutualization:** Demutualization of a stock exchange is the process of transforming a non-profit member-owned mutual organization into a profit seeking Shareholder Corporation. Exchanges all over the world have been demutualizing due to increasing international competition and technological challenges to traditional modes of securities trading.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**Generally speaking:** crashes usually occur under the following conditions, a prolonged period of rising stock prices and excessive economic optimism, a market where P/E ratios exceed long-term averages, and extensive use of margin debt and leverage by market participants (Galbraith, 1979/1988).

**Omnibus Account:** Omnibus account is a type of account between two futures merchants (brokers). Transaction of individual accounts is combined in this type of account that allows easier management of portfolio by the futures merchant. But this type of account could be used to manipulate stock as many individual transactions are kept hidden over there.

**Present Coverage:** Chittagong, Dhaka, Sylhet, Rajshahi, Khulna, Barisal, Tangail and Coxsbazar.

**Share Category: "A":** Category Companies: Companies which are regular in holding the Annual General Meetings (AGM) and declared dividend at the rate of 10 percent or more in a calendar year. **"B"** Category Companies: Companies which are regular in holding the AGM but failed to declare dividend at least at the rate of 10 percent in a calendar year. **"G'** Category Companies: Greenfield companies. **"N'** Category Companies: All newly listed companies except Greenfield companies are placed in this category. **"Z'** Category Companies: Companies which failed to hold the AGM or failed to declare any dividend or which are not in operation continuously for more than six months or whose accumulated loss after adjustment of revenue reserve, if any is negative and exceeded its paid up capital.

**Stock Market Bubble:** A stock market bubble is one kind of economic bubble that takes place in stock markets when market participants drive stock prices above their value in relation to some system of stock valuation (Smith et.al. 1988).

**Stock Market Crash:** "Stock market crash is a sharp and unexpected decline of stock market prices for a very short period of time, usually accompanied with the decline of many other assets' prices" mentioned by stockmarketcrashes.net. Amadeo (2012) defined stock market crash as more than 10% loss within few days in a stock market. But stock market crash has differentiated from stock market correction where the loss is 10% or less.

**Stock Market:** Fellowes (2008) described that stock market has same features like a normal market with buyers, sellers and agreed price. There will be a middleman who guides investor to deal offers of buying and selling shares in the stock market. Stock exchange, regulatory organizations, investors, listed companies with securities, broker houses, merchant banks, and other intermediary organizations are found in a stock market with co-operation of central bank and government of the country.

**Trading System:** Fully automated screen-based. Nation-wide online trading network.

# Chapter 66
# Export-Led Recovery in Portugal: Can It Also Sustain Growth?

## ABSTRACT

*The recent expansion of Portuguese exports can not only promote post crisis recovery but also accelerate economic growth if the theoretical predictions on the relationship between exports and growth are correct. The export-led growth hypothesis advocates that export expansion is key in promoting long run performance. However, controversies remain on the causal relationship between the variables. We investigate this nexus for Portugal over the period 1970-2012 by estimating a bivariate VAR model with output and exports and applying cointegration, Granger causality and impulse response analysis. The results show a long-run equilibrium relationship between exports and output supporting the export-led-growth hypothesis. We also investigated the growth impact of exports of manufactured and non-manufactured products. The findings point to the existence of a positive impact of manufactured exports on output and a "limiting" effect of non-manufactured exports supporting in this way the view that what a country exports matters for growth.*

## INTRODUCTION

After joining the European Economic Community (EEC) in 1986, the Portuguese economy enjoyed a phase of sustained economic growth until the early 2000s, recording an annual average growth rate of real GDP per capita of more than 3 per cent (Andrade, Duarte & Simões, 2014). However, since around the year 2000 up to 2010 growth receded to less than 1 per cent a year (accompanied by declining exports performance) and the recent evolution of the Portuguese economy has been strongly affected by the austerity policies recommended by the Troika (the IMF, the European Central Bank and the European Commission) following the sovereign debt crisis, which resulted in Portugal agreeing to a bailout programme in May 2011 and exiting the three year Economic Adjustment Programme in June 2014. The need to reduce the deficit and public debt are the main objectives that have underpinned austerity policies and resulted in a depleted domestic demand and the need to promote exports as a driver of recovery. According to the OECD (2014), p. 4 "The authorities have been implementing a wide-ranging structural reform agenda, which is helping to rebalance the economy towards the export sector." Portugal showed impressive export growth (as high as 10% a year), especially when compared with other Southern European countries like Spain and Italy, with Portuguese exports going from 27 per cent of GDP in 2009 to 39 per cent of GDP in 2013 (Arnold, 2015).

Besides their role as a driver of economic recovery, given the dismal growth prospects faced by the Portuguese economy an even more important question is whether exports have the potential to ignite and sustain economic growth in Portugal. The potential of exports to be the engine of growth is known in the economic literature as the Export-Led Growth (ELG) hypothesis and has given rise to substantial research (Giles & Williams, 2001a; 2001b; Palley, 2011). A fundamental issue that remains open to debate concerns the existence of a feedback relationship between exports and output that implies a Growth-Led-Export hypothesis (GLE) (Kónya, 2006). The ELG hypothesis is justified on the basis that competition in international markets fosters economies of scale and increases efficiency by concentrating resources in sectors in which the country has greater comparative advantage. These positive externalities promote economic growth (Balassa, 1978). On the contrary, the GLE hypothesis advocates that economic growth leads to productivity gains, creating a comparative advantage for the country that facilitates exports (Santos, 2012). Additionally, countries that record high growth rates but have relatively low absorption rates must necessarily export the surplus of goods and services (Mishra, 2011). In any case, the two hypotheses are not mutually exclusive and a reciprocal/feedback relationship between the two variables may exist (Kónya, 2006).

This chapter investigates the dynamics among exports and output over the period 1970-2012 for Portugal. The main aim is to examine whether the expansion of Portuguese exports may constitute an opportunity for its long run macroeconomic performance. For this purpose, we estimate a bivariate VAR model with output and exports and apply cointegration, Granger causality and impulse response analysis to take into account both the ELG and GLE hypotheses. Following the suggestion of several authors according to whom what a country exports matters for growth (Herzer, Nowak-Lehmann & Siliverstovs, 2005; Hausmann, Hwang & Rodrik, 2007), we will also take into account the composition of exports by investigating the separate effects of manufactured and non-manufactured exports on output.

The chapter is organized in three sections, besides the introduction. Section 2 gives an overview of the theoretical and empirical literature on the relationship between exports as a whole and economic growth, and the relationship between the composition of exports and growth. In section 3, we describe the estimation methodology and present and discuss the results obtained. Finally, section 4 contains the main conclusions.

## EXPORTS AND ECONOMIC GROWTH: AN OVERVIEW OF THE LITERATURE

There is by now an extensive and rich literature on the relationship between exports and economic growth that has been carefully and thoroughly surveyed by Gilles & Williams (2001a, b), Hausmann, Hwang & Rodrik (2007) and Palley (2011), among others. However, the relationship between the two variables is still controversial, given the lack of consensus in the results obtained. The aim of this chapter is to present an overview of the theoretical and empirical literature on the relationship between exports and economic growth. In the first part, we concentrate on the relationship between aggregate exports and economic growth and in the second part we address the issue of exports composition.

Although we do not explicitly address it in this chapter, we are aware that the nature of exporting activity, in particular which industries, what share of domestic produced value added and which regional destination, is also a potentially important determinant of the economic growth impact of exports. Gkagka and Zarotiadis (2011) constitutes an example of a recent study that tries to distinguish the growth impact of exports according to destination by considering the exports of 15 EU member states over the period 1995-2007 to three different markets: other EU countries, China and the rest of the world. The results obtained indicate that exports destination matters with a positive growth impact of intra-EU exports, a negative growth impact of exports to China and a non-significant impact of exports to the rest of the world. Santos, Ribeiro and Carvalho (2013) also conclude, for a sample of 23 EU members over the period 1995-2010 that higher growth is fostered by export diversification across member states while enlarging destination to less developed and more distant countries has a negative growth impact. The authors also find evidence that export specialization in high value-added products, such as manufactures and high technology, accelerates economic growth. Pistikos and Zarotiadis (2014) deals with the importance of destination for exports performance based on a sample of 19 EU member states over the period 2002-2012. The main concern of the authors is identifying how crises affect intra-EU net exports, concluding that export intensity declined in the crisis period in countries whose main exports destinations were other EU member states that recorded important GDP decelerations or declines after the crisis. On the other hand, EU member states outside the Euro Zone and that were thus able to devaluate their currency were able to increase the respective exports intensity. Finally, the fragmentation of production across different countries makes it increasingly difficult to measure a country's export performance and its contribution to domestic output growth since it is necessary to evaluate the value added that exports create in a given country. A high import content of exports will result in weak linkages between exports and the rest of the economy and thus economic growth.

A slightly different but related issue concerns the importance of competition in domestic markets for export performance. Based on a review of empirical literature, Goodwin and Pierola (2015) claim that intense domestic competition is a pre-requisite to export more. According to the authors, for more productive firms to enter the domestic markets there must be effective competition. In this way, the most productive competitors will gain additional market share, which in turn improves aggregate productivity levels and leads to higher exports levels. This claim is supported, for instance, by empirical studies that find that higher domestic concentration is associated with a smaller domestic share in world output and fewer net exports while other studies obtain a positive relationship between domestic rivalry and export performance. Moreover, Goodwin and Pierola (2015) provide evidence from previous studies that anti-trust policy for input product and services markets contributes to export competitiveness of downstream sectors.

## Aggregate Exports and Economic Growth

The idea that international trade is associated with faster economic growth goes as far back as the mercantilist theory that dominated Europe from the 16th to the 18th century and gained a renewed interest with the classical and neo-classical schools of economic thought through the 19th and 20th centuries until today. The Export-Led-Growth (ELG) hypothesis in particular argues that export expansion is a key factor in promoting long-run output growth. Several arguments support this view. From a demand-side perspective, increasing the degree of openness of an economy expands the market, overcoming the effects of a possible deceleration or exhaustion of domestic demand (Herzer, Nowak-Lehmann & Siliverstovs, 2005). On the supply-side, export expansion can promote economic growth through an increase in productivity, achieved through three different mechanisms. First, an increase in exports may promote specialization in sectors where a country has greater comparative advantage and lead to a reallocation of resources from (relatively) inefficient sectors to more productive export-oriented sectors (Santos, 2012). Second, exporting requires facing stronger competition, which encourages the exploration of economies of scale and stimulates not only an improvement in product quality, but also the reduction of inefficiency in domestic production (Akbar & Naqvi, 2000). Finally, export growth could positively affect productivity through spillovers effects to the rest of the economy. According to Chuang (1998), the possible sources of spillovers are increased competitiveness, access to more efficient forms of management and organization, labor training, the acceleration of technological progress and increased knowledge of international markets. The Growth-Led-Export (GLE) hypothesis, on the other hand, argues that it is the fact that economic growth enables the development of human and technological capacities by a country that improves efficiency, creating comparative advantages in certain areas, lowering the prices of domestic production and consequently promoting exports (Kónya, 2006).

The early empirical literature from the 1960s and 1970s that examined the exports-economic growth relationship applied the Spearman's rank correlation index to determine the degree of association between exports and growth (Emery, 1967; Kravis 1970; Michaely 1977). This first group of research was followed by a second one that applied cross-country regression analysis (usually ordinary least squares) to estimate an augmented production function that included exports as an independent variable, in addition to investment and human capital accumulation (Balassa 1978; Tyler 1981; Ram 1987). The results from both groups of studies reveal a positive correlation between exports and economic growth. However, as noted by Rodriguez & Rodrik (2001), these studies do not address the problem of endogeneity, questioning the robustness of the results. The methodologies applied do not investigate the cointegration properties of the variables involved, nor the potential bidirectional relationship between exports and growth. More recent studies try to overcome these drawbacks by applying methodologies that better take into account the potential bidirectional relationship such as cointegration techniques, estimating VAR models (or VECM, depending on the results), which treat all variables as endogenous, and applying Granger causality analysis. Overall, this group of empirical studies has obtained four different types of results corresponding to:

1. Support for the ELG hypothesis, that is those that confirm a unidirectional relationship from exports to economic growth;
2. Support for the GLE hypothesis, that is those that confirm a unidirectional relationship from economic growth to exports;
3. Results that indicate a bidirectional relationship between exports and economic growth; and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Results that find that the behavior of both variables is independent of one another.

Table 1 contains a summary of some empirical studies (according to the date of publication) that examined the relationship between aggregate exports and economic growth belonging to the last group of studies identified above.

As far as the Portuguese economy is concerned, Oxley (1993) applied stationarity, cointegration and Granger causality tests to Portuguese annual data (log of real GDP and log of real exports), over the period 1865-1985, and found support for the GLE hypothesis. Kónya (2004) considered a sample of twenty-five OECD countries over the period 1960-1998 to study the relationship between real GDP and real exports. The author found support for: the ELG hypothesis in Iceland, Australia, Austria and Ireland; a unidirectional relationship from growth to exports in Canada, Japan, South Korea, Finland, United States and Portugal. As for the case of Luxembourg, Netherlands, Denmark, France, Greece, Hungary and Norway the author found no evidence of causality between the two variables, while for Sweden and the UK he found evidence of a bidirectional relationship.

In light of such varied results, some researchers tried to improve the existing empirical models by taking into account the structure (composition) of exports and its impact on economic growth.

## Exports Composition and Economic Growth

The composition of exports is a relevant factor when analyzing the impact of exports on economic growth. Hausmann, Rodrik & Hwang (2006) suggest that the type of exports in which a country specializes has significant effects on subsequent economic performance. Their results show that countries

*Table 1. An overview of some empirical studies*

| Author | Period | Sample | Variables | Conclusions |
|---|---|---|---|---|
| Jung and Marshall (1985) | 1950-1981 | 37 Developing Countries | Real GDP, real GNP, real Exports | ELG hypothesis valid for 4 countries |
| Dutt and Ghosh (1994) | 1953-1991 | Israel and Turkey | Real GDP, real GNP, real Exports | ELG hypothesis valid for both countries |
| Khalafalla and Webb (2001) | 1965-1996 | Malaysia | Real GDP, real Exports, real Imports | Bidirectional relationship |
| Kónya (2006) | 1951-2004 | India | Real GDP, real Exports, real Imports | ELG hypothesis valid |
| Jordaan (2007) | 1970-2005 | Namibia | Real GDP, real GDP per capita, real Exports, real Imports | ELG hypothesis valid |
| Elbeydi, Hamuda and Gazda (2010) | 1980-2007 | Libya | Real GDP, real Exports, | Bidirectional relationship |
| Amiri and Gerdtham (2011) | 1961-2006 | France | Real GDP, real Exports, real Imports | ELG hypothesis valid |

Source: Authors' own elaboration

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

that export goods associated with higher productivity levels grow faster. According to Santos (2012), the probability of developing production and consumption goods associated with more advanced technologies is higher in more developed countries. From a demand-side perspective, this is explained by the higher demand for more innovative goods in wealthy countries. On the supply-side, Grossman & Helpman (1991) argue that the most advanced economies have technological advantages, particularly when it comes to Research and Development (R&D). Thus, the more developed a region is, the higher is its level of technology, production and exports of sophisticated goods and, consequently, the greater the impact on economic growth.

An interesting way forward consisted in analyzing exports taking into account the respective technological intensity. Cuaresma & Wörz (2005) tested the hypothesis of high-tech exports having a stronger impact on productivity for 44 industrialized and developing countries between 1981 and 1997. Applying a random effects model, the authors found that high tech-intensive exports have a significant impact on economic growth in industrialized countries, while low tech-intensive exports have a negative effect on economic growth.

Previous empirical studies have also pointed out the need to distinguish between the impact of primary and manufactured products exports on economic performance. Several authors suggest different arguments to explain why primary products exports may become an obstacle to productivity increases. According to these authors, primary products are not a sustainable source of knowledge spillovers and an increase in exports of such products can draw resources away from the externality-generating manufacturing sector (Herzer, Nowak-Lehmann & Siliverstovs, 2005). In addition, exports of primary products are more likely to suffer from price and volume fluctuations and therefore increasing such exports could lead to greater GDP volatile and macroeconomic uncertainty. In turn, the high volatility and economic uncertainty may affect negatively investments' efficiency.

Ghatak, Milner & Utkulu (1997) examined the ELG hypothesis for Malaysia and the effect of manufactured and primary exports on growth, over the period 1955-1990. Using cointegration and causality techniques, the authors found that aggregate exports Granger-cause economic growth, but not the other way around. This relationship is driven mainly by manufactured exports, given the negative effect of non-fuel primary exports on GDP.

Herzer, Nowak- Lehmann, & Siliverstovs (2005) investigate the impact of primary and manufactured exports on economic growth, in Chile. Using annual time series data from 1960 to 2001, the study applies cointegration techniques and the Granger methodology. The results show unidirectional causality from manufactured exports to economic growth, and the presence of a bidirectional relationship between primary exports and GDP. The main conclusion of this work is that although both types of exports contribute to the Chilean GDP, manufactured exports are especially important because of the increased productivity they provide and therefore induce sustained economic growth. In a similar study, Ngumi, Kimuyu & Gakure (2013) analyzed the influence of manufactured exports on economic growth in Kenya over the period 1970-2007. The authors found a long-run equilibrium relationship between GDP, manufactured and non-manufactured exports, imports and the terms of trade. The results from the causality analysis also point to an independent relationship between manufactured exports and growth. According to the authors, a possible justification for this result is the relative low weight of this type of exports relative to total output of the sector representing on average around 27% of total sectoral output. As to non-manufactured exports, the impact of these on GDP is negative because of the instability of the respective prices.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

From this literature overview, it is clear that exports can have a key role on a country's economic performance. Despite the large number of studies that have been conducted to test the ELG hypothesis, the results concerning the direction of causality between exports and economic growth are not consensual depending on the specific country under analysis. Accordingly, this chapter will investigate the direction of causality between exports and economic growth for Portugal, also taking into account the structure of exports, which allows for more specific and detailed results.

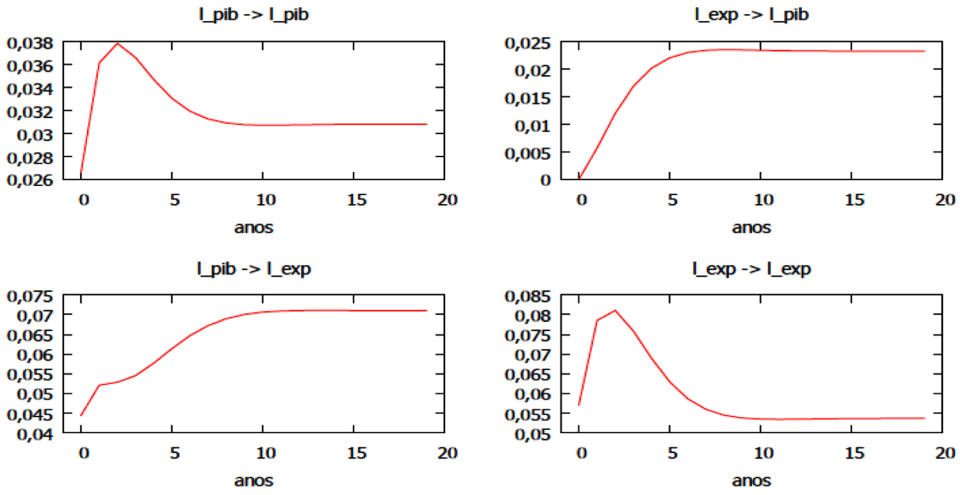
## DATA, METHODOLOGY, AND RESULTS

This section examines the causal relationship between exports and economic growth in Portugal over the period 1970-2012 within a VAR model with two variables, exports and output. We apply cointegration analysis, Granger causality tests and impulse-response functions to analyze the existence of a long-run relationship, the direction of causality and check how unexpected changes influence growth. VAR models allow us to take into account inter-dependencies and dynamic relationships between variables by explaining the behaviour of the endogenous variables by their own past values. Theoretical predictions point to increased export performance as being able to generate faster growth. However, richer countries also tend to export more. Thus, estimating a single regression with output growth as the dependent variable can lead to misleading results since it does not adequately capture the relationship under analysis if inverse causality applies. In a VAR model all variables are considered as potentially endogenous making this a suitable framework to model interdependent variables as is the case in this study. In summary, we estimate a country-specific model in a VAR-framework with all variables treated as endogenous, which avoids the often arbitrary classification, within a growth framework, of variables as endogenous or exogenous, and the imposition of restrictive specifications on the dynamic adjustment mechanisms inherent in the structural approaches, such as those associated with the estimation of cross-country growth regressions (Gobbin & Rayp, 2008; Frank, 2009). Cointegration, granger causality and an impulse response analysis are used to determine the sign of the association between variables.

Our basic VAR model can thus be generically represented as:

$$X_t = \alpha + \beta_1 X_{t-1} + \beta_2 X_{t-2} + ... + \beta_p X_{t-p} + \varepsilon_t, \quad (1)$$

with vector X including the variables under analysis:



$$X = \left[ l_GDP \quad l_\exp \right]' \quad (2)$$

where "l" stands for the logarithm; "GDP" is the real Gross Domestic Product at 2005 prices and "exp" refers to real exports of goods and services at 2005 prices, either total or of manufactured or non-manufactured products (the last two variables are considered as a ratio of total exports). All variables were taken from the World Development Indicators database, from the World Bank, with an annual frequency. The evolution of all the series is shown in Figure 4 in the Appendix..

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 1. Impulse-response functions - l_GDP and l_exp*

As a preliminary step to investigate the link between exports and growth in Portugal, we test for the order of integration of variables, a necessary condition to perform Granger causality analysis. We examine the unit root properties of the variables by applying the augmented-Dickey-Fuller (ADF) unit root test (see Dickey & Fuller (1979)). This test considers as the null hypothesis (H0) the presence of a unit root in the series against the alternative hypothesis (Ha) that the series is stationary. This can be expressed as, for any series *y*:

$$\Delta y_t = C + \beta T + \delta * y_{t-1} + \theta_1 \Delta y_{t-1} + \theta_2 \Delta y_{t-2} + \ldots + u_t \quad (3)$$

where C is a constant and T a time trend, included according to the characteristics of the series. The test for a unit root is conducted on the coefficient of $y_{t-1}$ in the regression. If the coefficient is significantly different from zero, then the hypothesis that *y* contains a unit root is rejected. Rejection of the null hypothesis implies stationarity. If H0 cannot be rejected for the series in levels, we next apply the test to the first differences of the series ($\Delta$) and so on until the series becomes stationary.

Given the low power of the ADF test in small samples such as ours, we also applied the Kwiatkoswaski, Phillips Schmidt and Shin (KPSS) stationarity test ((Kwiatkoswaski et al., 1992)). This test considers as the null hypothesis that the series is stationary against the alternative of non-stationarity and is used in the literature as a complement to the ADF test. The interpretation of the results of both tests combined is summarized in Table 2. If the series are non-stationarity in their levels, the tests are applied to their first differences to determine the respective order of integration.

If the series are integrated of order one, we next perform cointegration analysis that allows for the identification of long-run relationships between variables and to avoid the problem of spurious regressions. We say that the variables are cointegrated if they have the same order of integration (one, in our case), and if there is a linear combination of the variables that is integrated of order zero. To test the number of cointegration vectors in our model we follow the Johansen procedure (see Johansen & Juselius

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 2. Possible outcomes of the ADF and KPSS tests combined*

| KPSS Test | ADF Test | |
|---|---|---|
| | **Do Not Reject $H_0$** | **Reject $H_0$** |
| **Do Not Reject $H_0$** | Inconclusive outcome | Stationaraty |
| **Reject $H_0$** | Non-stationary | Inconclusive outcome |

Notes: the null hypothesis indicates non-stationarity in the ADF test and stationarity in the case of the KPSS test
Source: Nusair (2003)

(1990); Johansen (1995)). If there is no cointegration vector, we can continue to estimate a VAR in first differences in order to perform causality analysis. If there are one or more vectors, we must estimate a Vector Error Correcting Mechanism (VECM) system.

## Aggregate Exports and Economic Growth: Estimation of a VECM Model

We begin by analyzing the relationship between output and aggregate exports considering total real GDP and total real exports, respectively, as proxies.

Table 3 contains the results obtained with the ADF and KPSS tests, with constant and trend (CT) for the variables in levels and only with constant (C) for the first differences. The results obtained with the ADF test reveal the presence of a unit root in the variables in levels since the p-value is greater than 0.05; when applied to the variables in first differences the null hypothesis is rejected. For the KPSS test, it is possible to verify that the only variable that is not stationary at a 5% significance level is l_GDP. Comparing the results of both tests, we conclude that a single differentiation is sufficient to make the series stationary, so we can say that both series are integrated of order one, *I*(1).

Since the series are integrated of the same order, *I*(1), the next step is to determine the optimal number of lags to consider in the estimation of the VAR model in order to eliminate the autocorrelation of the residuals. The optimal number of lags corresponds to the minimum value of three information criteria: AIC (Akaike Information Criterion), BIC (Bayesian Information Criterion) and HQC (Hannan-Quinn Criterion). Note that the inclusion of too many lags implies the loss of degrees of freedom (low power

*Table 3. Results of the ADF and KPSS tests - l_GDP and l_exp*

tests) and increases the risk of collinearity. However, an estimation with insufficient lags may lead to biased estimates. From the inspection of Table 4 it can be seen that the optimal number of lags is two according to the three criteria used.

We next investigate the existence of a cointegration relationship between the variables, in other words, we determine if there is a long-run equilibrium relationship between the two series. To this end, we use the methodology proposed by Johansen (1995), which applies two statistical tests to determine the number of cointegration vectors: the trace test (λ trace) and the maximum eigenvalue test (λ max). In the trace test, the null hypothesis ($H_0$) is that the number of cointegration vectors is $r \leq p$, where r is the number of vectors and $p = n - 1$ (where n is the number of variables included). As for the maximum eigenvalue test, the null hypothesis ($H_0$) is whether there are at most r cointegrating vectors, against the alternative that there are exactly $r + 1$. The cointegration analysis results are shown in Table 5. It can be seen that there is one cointegrating vector since the null hypothesis of both the trace and the maximum eigenvalue tests for the presence of at least one cointegrating vector was not rejected at a 5% significance level (p-value greater than 0.05). Thus, the two variables of our VAR model show a long-run equilibrium relationship between them, although short-run deviations can occur relative to this equilibrium.

The cointegration equation between GDP and exports is reported in Table 6. Based on the estimated cointegration vector corresponding to the long-run equilibrium relationship between the variables, we can say that our results confirm the theoretical predictions on the relationship between exports and output for Portugal over the period under analysis with the estimated coefficients presenting the expected sign and also being statistically significant. An increase in exports as a positive long-run effect on output, probably because it enables access to larger markets by the Portuguese economy, with the associated increase in competition that leads to higher efficiency in order for the exporting firms to stay competitive, allowing for the exploration of scale economies. Higher exports seem also to have encouraged technology diffusion and knowledge spillovers that contribute to faster productivity growth

The presence of cointegration between the two variables implies a causality on at least one direction. To determine the direction of causality between the series we proceeded to the estimation of a VECM model, which is identical to a VAR model with variables in first differences. However, the first includes an error correction term, which aims to correct the deviations from the long-run equilibrium through a series of partial short-run adjustments. The VECM model to estimate is given by the following two equations:

$$\Delta l_{GDP} = \beta_0 + \beta_1 \Delta l_GDP_{t-1} + \beta_2 \Delta l_exp_{t-1} + \delta_1 EC_{t-1} + \varepsilon_{1t} \quad (4)$$

$$\Delta l_{exp} = \alpha_0 + \alpha_1 \Delta l_GDP_{t-1} + \alpha_2 \Delta l_exp_{t-1} + \delta_2 EC_{t-1} + \varepsilon_{2t} \quad (5)$$

where EC are the error correction terms corresponding to the cointegration vector identified before.

When the variables are *I* (1) and cointegrated, Granger causality should be analyzed based on the results of the estimation of the corresponding VECM model, and it can be said that there are two sources of causality: via the lagged differences and via the error correction term. For instance, if the estimated coefficient of the error correction term is negative and statistically significant in the equation for l_GDP, this variable is also influenced/caused by l_exp via adjustments / corrections of the deviations from the long-run equilibrium between the variables. Table 7 shows the estimation results for the Δl_GDP equation (equation (4)) and the Δl_exp equation (equation (5)) in our VECM model. According to the estimation results for equation (4), since the estimated coefficient of the error correction term is negative and statistically significant, we can conclude that in the long-run real exports Granger-cause GDP. The fact that the estimated coefficient of lagged exports is not statistically significant indicates the absence of causality in the short-term. In turn, the estimation results for equation (5) indicates that there is no causality from real GDP to exports since the estimated coefficients on lagged GDP and the variable of adjustment to the long-run equilibrium (EC) are not statistically significant in this equation.

From the results above, we can conclude that, in the long-run, there is a unidirectional causal relationship from exports to GDP, which means that the ELG hypothesis is valid. This result contradicts the conclusion of some of the works that analyzed the Portuguese economy, like Oxley (1993) and Kónya (2004), who found results supporting a unidirectional causal relationship from economic growth to exports. However, the period under analysis used in both of these studies are distinct (1865-1985 and 1960-1997, respectively), thus covering quite different institutional and commercial arrangements and so it is not surprising that we found different results.

Finally, we performed impulse response functions analysis that shows how a one standard deviation shock in one of the variables of the model affects the contemporaneous and future values of all endogenous variables in that same model. The impulse response analysis is thus an alternative way of obtaining

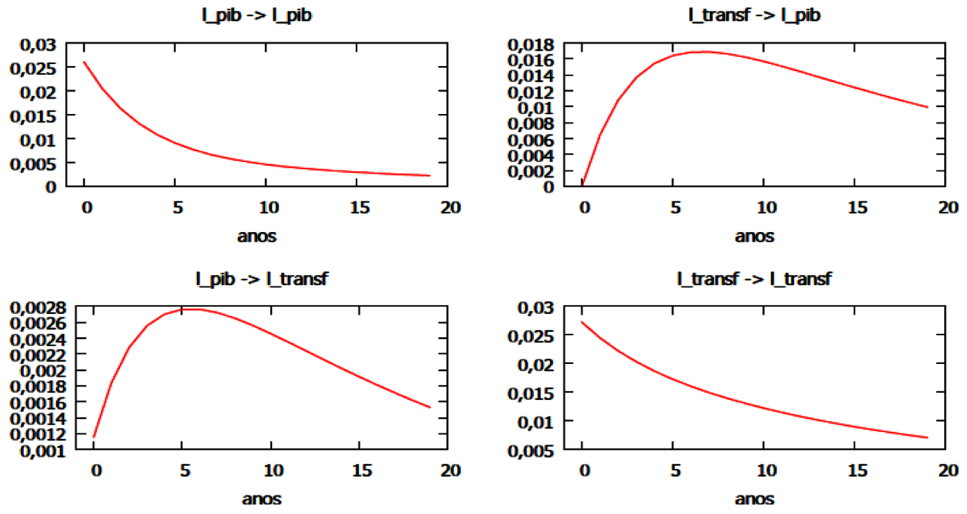
information regarding the relationships among the variables since these functions allow us to analyse the sign and duration of the reaction of the different variables in the model to an exogenous shock in one of the other variables. The responses of each variable over a 20 year timeframe are shown in Figure 1.

As can be seen, an unexpected shock to exports has a gradual positive effect on GDP over the first 5 periods, reaching a clear long-term equilibrium above the baseline, thus, an increase in exports causes an increase of GDP and the adjustment is quite fast. This effect again confirms the predictions of the theoretical literature since, for instance, exports growth originates productivity gains achieved by a more efficiently reallocation of resources, by creating economies of scale and through the acceleration of technological progress that promotes economic growth. On the other hand, a positive shock to GDP has an increasingly positive effect on exports, stabilizing after 10 years in a higher equilibrium. This adjustment period is consistent with the modest value of the coefficient associated with the error correction term of the exports equation in the VECM model, which is the speed of adjustment to the long-run equilibrium (see Table 7). According to the theoretical predictions, economic growth promotes exports through the development of human and technological capacities, which cause an increase in efficiency, creating comparative advantages in certain areas and lowering the price of production, in this way improving exports performance. However, this is a lengthy process, which may explain the longer time horizon to reach the long-run equilibrium. On the other hand, the faster adjustment of GDP to a shock to exports reinforces the ELG hypothesis for the Portuguese case.

## Exports Composition and Economic Growth: Estimation of two VAR models



This section takes into account the composition of exports, disaggregated into manufactured and non-manufactured products, to analyze its impact on the Portuguese economic growth, replicating the methodology used in the previous section.

To study the relationship between manufactured exports and economic growth, vector X consists of:

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 2. Impulse-response functions - l_GDP and l_Manuf*

$$X = \begin{bmatrix} l_GDP \\ l_Manuf \end{bmatrix} \tag{6}$$

where l_Manuf is the ratio of manufactured exports to total exports.

To analyze the causal relationship between non-manufactured exports and economic growth, vector X consists of:

$$X = \begin{bmatrix} l_GDP \\ l_NonManuf \end{bmatrix} \tag{7}$$

where l_NonManuf is the ratio of non-manufactured exports to total exports. The evolution of the percentage of manufactured and non-manufactured products in total exports of goods is shown in Figure 5 in the Appendix.

Table 8 presents the results of the stationarity tests - ADF and KPSS - for the new variables l_Manuf and l_NonManuf variables. According to the approach proposed by Nusair (2003), which analyses the combined results of both tests, we conclude that the variables in levels are not stationary for a 5% significance level. When applied to the first differences the tests indicate that these are stationary, since their p-values are lower than 0.05 and their statistical test are lower than the critical value for the% significance level 5. We thus conclude that the series are integrated of order one, $I(1)$.

We next determine the optimal number of lags for each VAR model. According to the results of three information criteria - AIC, BIC and HQC, presented in Tables 13 and 14 of the Appendix, the optimal number of lags is one for both models. We can thus proceed to test for the existence of cointegration relationships between, on the one hand manufactured exports and output and on the other hand non-manufactured exports and output, again using the Johansen (1995) procedure. We report the results in Tables 13 and 14, respectively. As can be seen, the assumption of at least one cointegration vector was

Source: Authors' own calculations

not rejected for the two models, at a 5% significance level (p-value greater than 0.05). It can therefore be concluded that there is a long-run equilibrium relationship between each of the exports variables and output.

The cointegration vector for the long-run equilibrium relationship between l_Manuf and l_GDP is presented in Table 15 in the Appendix. The results are consistent with the theoretical predictions. An increase in manufactured exports as a positive long-run impact effect on output, which indicates that an expansion of these type of exports is accompanied by an increase in GDP due to the high added value of such exports. As for the cointegration vector corresponding to the long-run equilibrium relationship between l_NonManuf and l_GDP, presented in Table 16 in the Appendix, the estimated coefficient of non-manufactured exports implies that decreasing the weight of such products in total exports will raise GDP. Several previous studies, Ghatak et al. (1997), Herzer et al. (2005) and Ngumi et al. (2013), found

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

similar results, supporting the argument that, due to the fact that these products are not a sustainable source of positive productivity spillovers and their prices are volatile, higher non-manufactured exports increase macroeconomic instability, which in turn impacts negatively on capital accumulation, and thus GDP.

Again, the existence of one cointegration vector means that there is at least causality in one direction between the variables, but does not allow us to identify the direction of that causality. Contrary to what we have done in the model with aggregate exports, in this case, we will note estimate a VECM model, since the optimal number of lags is one for both models. Thus, using this methodology would lead to an increased loss of information about the dynamics of the variables since the VECM model would just include the error correction term as an explanatory variable. We thus decided to use the strategy proposed by Doan, Litterman, & Sims (1984) which consists on the estimation of a VAR model with the variables in levels and the analysis of the respective impulse-response functions. This strategy is also suggested by Kónya (2004) as an alternative to the VECM methodology when the variables are $I(1)$ and the system is bivariate as is the case of our variables.

The results of the estimation of the first order VAR model with manufactured exports model is documented in Table 11. As shown in equation (6a), given the statistical significance of the estimated coefficient for l_Manuf, it is possible to conclude that an increase in the ratio of manufactured products to total exports Granger-causes real GDP. Using the information from equation (6b), on the other hand, it is possible to conclude that there is no causality from l_GDP to l_Manuf, since the respective lag is not statistically significant in this equation.

Still focusing on manufactured exports, we next estimated the impulse-response functions for a 20-year time horizon. The results are presented in Figure 2. According to these, an unexpected shock to the ratio of manufactured products to total exports of goods causes a progressive increase in l_GDP, which reaches its peak in the sixth year, gradually decreasing from that period onwards. A similar effect, but less intense, is caused by a shock in real GDP in the ratio of manufactured products to total exports of goods.

As for the relationship between output and non-manufactured exports, the estimation results for the respective first order VAR model composed of the equation for l_GDP (7a) and l_NonManuf (7b), can be found in Table 12. The statistical significance of the estimated coefficient for l_NonManuf in equation (7a) reveals that the ratio of non-manufactured exports to total exports of goods Granger-causes real GDP. In equation (7b), the absence of statistical significance in the respective lag invalidates the existence of causality from l_GDP to l_NonManuf.

Finally, we estimated the impulse-response functions for the VAR model with non-manufactured exports and output. The results can be found in Figure 3. As can be seen, an unexpected shock to non-manufactured exports a progressive decrease in real GDP that reaches its lowest value in the ninth year after the shock, growing slightly from that period onwards. A similar effect, but less intense, is caused by a shock to real GDP on non-manufactured exports.

## CONCLUSION

The increasing openness to international trade in the second half of the twentieth century is an undeniable feature of the Portuguese economy, especially after the accession of Portugal to the former EEC in 1986. Currently undergoing a recession following the financial and economic crisis that started in the USA in 2007-08 and resulted in the Portuguese sovereign debt crisis in 2011, export promotion appears as a crucial source to achieve sustained economic growth. To aid in the discussion on the role of exports as a driver of economic growth in Portugal, this study examined the causal relationship between exports and output in this country. For this purpose, we estimated a bivariate VAR model with real GDP and exports over the period 1970-2012. We first considered the relationship between aggregate exports and output and afterwards we disaggregated exports into manufactured and non-manufactured products to derive additional insights.

Taking into account the results of the stationarity and cointegration tests, they revealed the existence of a long-run equilibrium relationship between real GDP and overall exports and also between real GDP and exports disaggregated into manufactured and non-manufactured goods. Causality analysis showed a unidirectional relationship from exports of goods and services to GDP validating the Export-led-Growth hypothesis. This result goes in line with economic theory, since exports allow countries to overcome the limitations of its domestic market and contribute to productivity gains by creating economies of scale in sectors where the country has comparative advantage, allowing the countries to specialize in what they do best and thus lead to technological and overall productivity improvements.

Disaggregating exports of goods and services into manufactured and non-manufactured goods showed different effects on output from the two categories. The ratio of manufactured products to total exports of goods has a positive effect on GDP and the opposite applies to the ratio of non-manufactured products to total exports of goods. This result is justified by the fact that exports of non-manufactured products cannot be a sustainable source of spillovers and positive externalities and because this type of products are more likely to suffer from fluctuations in their prices, which may generate macroeconomic instability.

In conclusion, the results from this study indicate that Portugal should use exports, especially of manufactured products, as a strategy to accelerate economic growth and therefore decision makers should provide the institutional and macroeconomic conditions that promote exports (see Arnold, 2015).

In order to derive more precise and accurate policy implications, future research should focus on the identification of the sign of the relationship between more disaggregated types of exports (which industries) and output growth/productivity in Portugal, which can also involve the estimation of multivariate VAR models with a higher number of variables that can help clarify the nature of the relationship. This also applies to the study of the importance of the import content of exports and regional destination for economic growth. As Cardoso, Esteves and Rua (2013), p. 107 highlight: "the effect on domestic production resulting from an increase of the Portuguese exports is certainly lower if it is driven by a product such as fuels (which have a high import content) than tourism (since services related with hotels and restaurants present a low import content)." As for the second issue, the literature seems to agree that market diversification enhances the positive growth impact of exports but more recently research has focused on the importance of particular markets of destination such as more developed countries and regional trade agreements partners. Finally, domestic market competition has been identified as a pre-requisite for the growth enhancing role of exports that deserves further investigation as this can be a particularly important issue for Portugal. According to the OECD (2014), p.6, "… Portuguese exporters continue to be at a potential disadvantage vis-à-vis international competitors across a number of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

dimensions, notably with respect to access to inputs from non-tradable sectors…" Wider international comparisons applying panel data methodologies could also allow for important generalizations on the relationship under analysis.

# Chapter 67
# Investment Decision Making: Where Do We Stand?

**Aleksandar Šević**
*Trinity College Dublin, Ireland*

**Srđan Marinković**
*University of Nis, Serbia*

## ABSTRACT

*This chapter is a review of different approaches academics take to find right answers on the question how investors' community makes decisions on optimal portfolio of securities and how this process converges toward capital market equilibrium. Authors will try to reconcile the approaches that come from different intellectual traditions. The authors start with the Capital Assets Pricing Model (hereafter CAPM). For decades long the model has been a cornerstone of modern finance literature and a guide for investment decision making. The model assumes that the choice of investment portfolio is directed toward optimization between statistically defined risk and observable return of a universe of available investments, in the setting of rational and homogeneous agents where information is common knowledge. The rigidity of CAPM assumptions led to a plethora of studies where some of those assumptions are relaxed. An important breakthrough to the extant body of knowledge has been made by the introduction of the asymmetric information in the decision-making process.*

## INTRODUCTION

In the process or investment decision-making agents are imbued with beliefs about potential returns, but until mid-1960s it was rather difficult to find a comprehensive story that would link returns to the evaluation of risk. Markowitz (1952) examines the so-called second stage of portfolio construction in an attempt to link the beliefs to the final asset selection and refers to the relevance of both anticipated return and variance in the process, with a specific focus being paid to diversification. Depending on the level

of risk averseness investors would choose to invest in cash, or a combination of cash and risky assets (Tobin, 1958). Following these studies an additional step seemed inevitable in an attempt to provide a more stylized theory on the selection of assets in a two-dimensional risk-return space.

Sharpe (1964) uses the utility theory to create a market equilibrium theory for asset prices and risks involved in asset allocation, and creates the early version of the Capital Asset Pricing Model. Investors select the universe of potential investment choices and then choose the most efficient portfolios, i.e. those that secure the highest return for the given level of risk or the lowest risk for the assumed expected return. By paying special attention to varying levels of risk aversion and probability assessments, including the cases of limited short sales and unavailability of riskless assets, Lintner (1965) further improves the model. Black (1972) examines the assumption that an investor can take a long or short position in any asset, which may not be readily confirmed in the investment process. Therefore, a more restrictive environment without riskless assets, borrowing or lending has been analyzed, just to conclude that the CAPM model is still valid with statistically significant beta coefficients in explaining individual returns.[1] In the CAPM modelling efficient portfolios could comprise short sales, since the expected value of the individual asset return could be smaller than the risk-free interest rate or the asset could be shorted so as to achieve diversification goals even though its expected value could be higher than the risk-free rate of return. In certain cases, shorted assets could account for as much as 50 percent or more of the entire efficient portfolio (Levy, 1983; Sharpe, 1991; Levy, 2010).

Merton (1973) extends the model to multiple periods, while Breeden (1979) applies this approach to a multi-good Consumption CAPM. Following attempts to find a comprehensive model in the international settings Stulz (1981) manages to evaluate the expected return without reference to the exchange rate risk. In addition, int order to assuage differences between *ex-ante* assumptions and *ex-post* testability a Conditional CAPM has been suggested. Fama and French (1992, 1993, 1996, 2013) suggest the introduction of a range of variables to examine the validity of beta coefficient estimates.

In this chapter we first examine the studies leading to the creation of the basic CAPM model. Then we'll discuss issues faced by empiricists in testing CAPM caused by the rigidity of *ex-ante* assumptions that cannot be easily confirmed *ex-post* due to the lack of stable betas and market proxies that do not represent all tradeable risky assets in respective markets. Then we shall discuss variations in CAPM, which have evolved over more than half a century of persistent research to find the best fit for markets and investors. Afterwards, our attention will turn to challenges faced by advocates of CAPM.

## CAPM

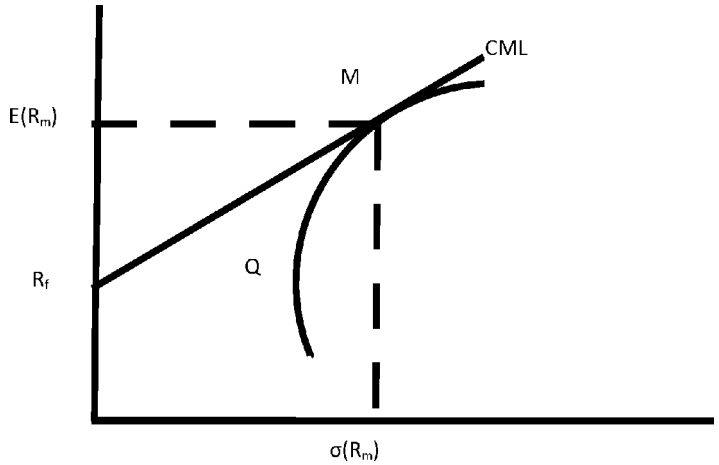
The CAPM is a market equilibrium theory with very strict requirements such as:

- Investors maximize the expected utility of their wealth at the end of the period
- Investors are risk averse and act as price takers. Normality of distribution has been assumed in addition to homogenous expectations across the investment universe
- Frictionless markets without imperfections are associated with costless information available to all investors.
- A risk-free rate is available and investors may borrow and lend without restrictions
- Assets are marketable, divisible and available in fixed quantities.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Following these requirements, it is possible to create an efficient set of investments in the two-dimensional risk-return space. Less risk-averse investors will opt for higher return and a commensurate increase in risk, while cautious agents will be more inclined to achieve lower returns with a proportionate decline in risk. However, their investment choices should be aligned across the convex efficiency frontier, in Figure 1 depicted from point Q upwards. All choices below point Q, the so-called minimum variance portfolio, would render investors with comparatively lower returns for the same level of risk. All portfolios below Q on the convex curve and on the right-hand side from the curve offer inferior returns when compared to dominant portfolios on the efficient frontier.

The straight line connecting the risk-free rate ($R_f$) on y-axis with the market portfolio M is called a capital market line (CML). When all above-mentioned conditions are met investors could invest money only in a risk-free rate when σ, i.e. total risk, is non-extant, aim at the combination of risk-free and risky assets by moving along the upward sloping CML, invest all funds in the market portfolio M or even borrow at $R_f$ and invest proceeds in risky assets, thereby moving further along the upward-sloping line and away from M (Figure 1). Higher returns will be *ex-ante* justified by higher risk and this relationship is captured by the following formula for the CML:



$$E(R_p) = R_f + [(E(R_m) - R_f)/\sigma(R_m)]\sigma(R_p)$$

The term within brackets denotes the slope of the firm and it is a market risk premium in excess of the riskless rate scaled by the unit of risk, the standard deviation of a market portfolio. Higher market risk premium will create a higher risk exposure and, consequently, higher portfolio *p* returns.

Assuming that an investor can invest in asset *i* a *c* amount of money and *(1-c)* in a market portfolio it is possible to partially differentiate the expected return and standard deviation of this portfolio with respect to *c*. Assuming that in equilibrium money will not be invested in any particular asset and all funds will flow to the diversified market portfolio, the final equation is rendered as:

$$E(R_i) = R_f + (\sigma_{im}/\sigma^2_m)[E(R_m) - R_f]$$

*Figure 1.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

where $\sigma_{im}/\sigma^2_m$ is the slope of the security market line (SML) and it is more routinely referred to as beta ($\beta_i$). Accordingly, expected returns are linear with market risk (β), but not total risk (σ) (Sharpe, 1991).

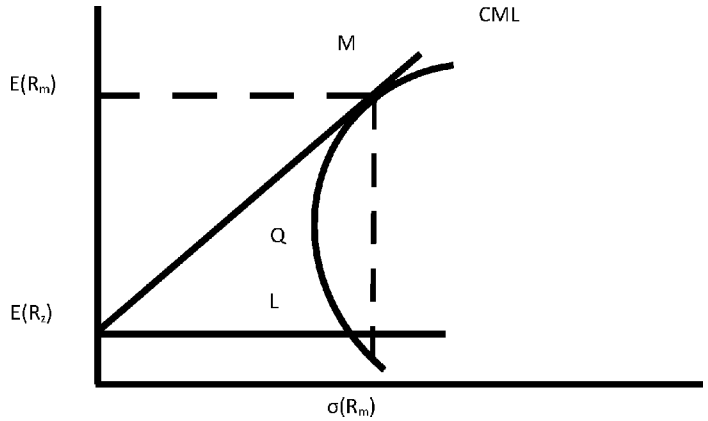
If investors are not able to borrow or lend at the riskless rate Black (1972) offers a solution via the provision of a minimum variance zero-beta portfolio. Unlike the case of Sharpe-Lintner's CAPM, the investors allocate *c* amount of money to a market portfolio and (*1-c*) to the minimum variance zero-beta portfolio. When all investor's wealth is invested in the market portfolio, i.e. when *c* amounts to 100%, the tangential efficient market portfolio M has been selected (Figure 2). Partial derivations of expected returns and standard deviation with respect to *c* and further manipulations provide:

$$[E(R_m)-E(R_{zb})]/\sigma_m = [E(R_j)-E(R_m)]\sigma_m/(\sigma_{jm}-\sigma^2_m)$$

leading to

$$E(R_j) = (1-\beta_j)E(R_{zb}) + \beta_j E(R_m), \text{ subject to } \beta_j = \sigma_{jm}/\sigma^2_m$$

and



$$E(R_j) = E(R_{zb}) + \beta_j[E(R_m) - E(R_{zb})]$$

This is a two-factor model confirming that the CAPM is a linear model and $\beta$ still explains much of the variation in asset returns. However, this model is valid if there are no constraints in short sales, and a zero-beta portfolio comprises long and short positions, thus reflecting general investment patterns.

## TESTABILITY OF CAPM

CAPM faces challenges in empirical tests due to its initial assumptions. It is *ex-ante* valid, but test can be conducted in the *ex-post* environment since the inputs for the former analysis are not observable. The commonly accepted testing procedure comprises two steps. In the initial phase empiricists run a simple

*Figure 2.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

regression with the market proxy return used as an independent and a return on any particular asset as a dependent variable:

$$R_{it} = \alpha + \beta i R_{mt} + \varepsilon_{it}$$

The values of these variables are not *ex-ante* assumed, but sourced from secondary data and thus analyzed *ex-post*. The coefficient estimates of market proxy returns are calculated over a period of 36 or more months and the calculation windows move by one period, i.e. one month so as to calculate a series of coefficient estimates. In the second step the expected value of asset *i* is calculated with the coefficient estimates of beta used as independent variables:

$$R_i = \lambda_0 + \beta_i \lambda_i + \nu_i$$

Where $\lambda_0$ should equal the risk free rate and $\lambda_i$ is expected to be close the market premium calculated as $E(R_m) - R_f$. Nevertheless, these claims are not generally purported in studies and regression $R^2$s are quite low. Therefore, a large amount of return variation is not explained by the inclusion of a single *ex-post* variable. Levy (1983) takes into account differences between *ex-ante* and *ex-post* betas and shows that after small modifications the second step could render an efficient portfolio as long as a range of *ex-ante* betas are used in the evaluations process. Levy and Roll (2010) apply reverse engineering to implement changes in parameters in order to make a market proxy mean-variance efficient. It has been shown that small modifications are necessary to achieve efficiency.

Early CAPM critiques are comprehensively analyzed in Roll (1977). Since the mean-variance efficiency of the market portfolio is the only hypothesis that could be independently tested it is impossible to examine the linear relationship between betas and returns without prior reference to efficiency. In addition, the market proxies[2] do not include all risky individual assets and the assumption about efficiency cannot be easily purported. The linear relationship between betas and returns can be achieved even for inefficient portfolios, while the market equilibrium theory does not make any claims about the expected value of parameters as opposed to simple linear relationships. Portfolios could comprise assets that demonstrate non-linear relationships, but these could be cancelled out cross-sectionally. Finally, it is not clear what is the meaning of non-zero Jensen's alpha, because in CAPM its value is expected to be zero across all aggregated assets. If a positive alpha has been reported it means that the market portfolio is inefficient. All further claims about superior (positive) or inferior (negative) performance could be questioned in the milieu of inefficient portfolios and the inappropriate selection of relevant benchmarks.

The mean-variance or stochastic dominance theory are not useful in making decisions even when a vast majority of economic agents would prefer a specific option vis-à-vis all others. Both theories relate to utility functions, but do not specifically determine the preferred option. Leshno and Levy (2002) modify the stochastic dominance approach so as to exclude the impact of extreme utility functions in the cumulative distribution. The so-called Almost Stochastic Dominance (ASD) theory allows for the ranking of available alternatives, excludes alternative options and creates a link between stock allocations in a portfolio and investments horizons tailored for specific groups of investors.

An important contention point in CAPM discussion is related to the type of distribution necessary to achieve equilibrium. In the mean-variance space initial reference is made to the Gaussian normal distribution, but *ex-post* model tests sample assets from the distribution that is non-normal. Early seminal

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

papers refer to restrictive assumptions and a single investment period, while subsequent studies attempt to include multiple periods, consumption, international assets, alternatives to the mean-variance space and other conditions.

## VARIATIONS OF CAPM

Merton (1973) questions strict one-period CAPM requirements and extends the model to multiple periods. Assets are traded continually and the stochastic changes are explained by the Markov process. In addition, investment opportunity sets change in time and investors revise expected returns accordingly. It is evident that the assumption about the exclusion of transactions costs and taxes allows for investors to trade at any point in time and as frequently as possible. However, in the real investment world trading frequencies would vary and aggregated transaction costs could range from being negligible to an important return reducing factor in a portfolio.

Breeden (1979) extends Merton's (1973) methodology in the multi-good and continuous-time framework to obtain a single beta asset pricing model. In this manner the constraints imposed by not being able to recognize multi state variables have been circumvented. The asset beta in this Consumption CAPM is calculated relative to aggregate consumption and is not related to the market portfolio as Sharpe-Lintner-(Black) CAPM. The author manages to find an equilibrium model even if the riskless rate is not available, by calculating expected returns on the zero-beta portfolio relative to the portfolio that does not include returns on assets correlated with aggregate consumption. Campbell (1993) evaluates the problem of extending the one-period CAPM to multiple periods. With an increase in time lengths the stability of parameters is affected, and researchers may be urged to shorten time periods. However, Campbell claims that the variation in the consumption-wealth ratio is small, which allows for the loglinearity in intertemporal evaluations. The market equilibrium reached in this intertemporal CAPM could be tested without consumption data that are measured with errors and inconsistencies in aggregations across time.

Solnik (1974) assumes that the market portfolio comprises value-weighted stocks and a set of risk-free assets collected from countries across the globe. Risk aversions and net foreign investments seem to be the determinants of relative weights in a portfolio. In this model, the final version of the International Asset Pricing Model (IAPM) is quite similar to the initial CAPM, with $\beta$ representing the international systematic risk exposure of a particular security. However, inconsistencies in setting up utility functions and other assumptions made it impossible to create a comprehensive model (Solnik, 1983). Stulz (1981) introduces varying consumption opportunity sets across countries, while prices of commodities and exchange rates follow an Ito process, and the PPP is applicable to traded goods, only. In this model the expected return is not related to the exchange rate risk.

Major criticism about CAPM claims that beta has weak or non-extant relationship with expected returns and that it may not be the only relevant factor in explaining returns. Pettengill *et al*. (1995) purport that a two-step approach to testing the CAPM includes the reference to realized returns and market proxies, which could lead to the *ex-post* rejection of betas. The suggested Conditional CAPM evaluation separates the beta into two components, i.e. $\rho*\beta i$ if $Rm - Rf > 0$ and $(1-\rho)*\beta i$ if $Rm - Rf<0$. In this manner, large beta portfolios could underperform low-beta portfolios if excess market returns turn negative. Authors also claim that this beta decomposition is historically supported by the fact that the 90-day Treasury bill rates were larger than market returns in more than 40 percent of all observations. Regression results indicate a consistent and positive relationship between beta and expected returns. Jagannathan and Wang

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

(1995) suggest another approach to conditionality by assuming that risk premia vary in time and occasional inaccuracies in *ex-post* CAPM tests indicate varying betas across multiple periods rather than the violation of theoretical assumptions per each period. The expected return on *j*th asset is:

$$E[R_{jt}|I_{t-1}] = \theta_{0t-1} + \theta_{1t-1}\beta_{jt-1}$$

with $\beta_{jt-1}$ calculated as $\beta_{jt-1} = Cov(R_{jt},R_{mt}|I_{t-1})/Var(R_{mt}|I_{t-1})$, $I_{t-1}$ representing the investment set available to investors at the end of the previous period, $\theta_{0t-1}$ being the conditional expected return on the zero beta portfolio and $\theta_{1t-1}$ representing the conditional market risk premium. The authors introduce two types of unconditional betas:

$\beta_j = Cov(R_{jt},R_{mt})/Var(R_{mt})$, i.e. market beta and

$\beta^{\theta}_j = Cov(R_{jt},\theta_{1t-1})/Var(\theta_{1t-1})$, a so-called premium beta

and claim that as long as betas are not linked via linear function unconditional returns could be calculated as:

$$E(R_{jt}) = \alpha_0 + \alpha_1\beta_j + \alpha_2\beta^{\theta}_j$$

Grauer (1978) questions the validity of the mean-variance space in providing the best support for CAPM and compares it against additional five utility-based models, such as square root, logarithmic, generalized logarithmic, negative one power and negative five power. All models are supportive for linearity and a positive relationship between risk and return. However, the last assumption about no restriction in riskless borrowing and lending is not supported. Kandel and Stambaugh (1995) question the assumption that as long as the market proxy lies on the efficient frontier that relation between expected returns and betas will be linear. OLS regressions can indicate that there is a linear relationship even though the market proxy may be inefficient, or linearity may not be confirmed even though there is a strong assumption about efficiency. In order to circumvent these constraints, the authors suggest the use of GLS regressions and confirm there is a linear relationship between expected return in betas when market proxies are efficient. Linearity weakens as the market portfolio moves away from the efficient frontier. The repackaging of assets within the portfolio allows for a removal of the market portfolio towards the efficient frontier while the linear relationship in the mean-beta space gradually strengthens until it finally reaches the highest point concurrently with the full efficiency of the market proxy.

## CHALLENGES FOR CAPM

The multitude of restrictive conditions associated with CAPM led to the provision of alternative models. Ross (1976) suggested a model that explains the random rate of return on *j*th asset:

$$\tilde{r}_j = E\left(\tilde{r}_j\right) + b_{j1}\tilde{\delta}_1 + \ldots + b_{jk}\tilde{\delta}_k + \tilde{\varepsilon}_j$$

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

where $E\left(\tilde{r}_j\right)$ is the expected return on asset *j*, various *b* are factor loadings, i.e. sensitivity of the *j*th asset's returns to one of the factors ranging from 1 to k, while $\tilde{\varepsilon}_j$ is a zero mean noise representing the unsystematic risk of the *j*th asset. The Arbitrage Pricing Theory (APT) distinguishes between expectations that could be identical for all agents *ex-ante*, and anticipations for each factor, which may be divergent. The model allows for the creation of an arbitrage portfolio as the number of assets in a portfolio becomes very large and no wealth is being used in the process. For instance, agents could dispose of some assets and use the derived income to purchase others. In the process of arbitrage portfolio creation, it is necessary to eliminate not only the unsystematic, but also the undiversifiable systematic risk. Keeping investment changes at a low level, a large number of assets and making sure that the weighted sum is zero for the systematic risk components, i.e. all b factor sensitivities, will achieve these goals. Ross (1976) indicates that an increase in the number of assets will reduce the importance of the unsystematic risk term $\tilde{\varepsilon}_j$, but an increase in the risk aversion as the wealth of an agent becomes larger provides a counter effect that will allow for noise to persist in this model.

If CAPM establishes a simple relationship between the expected return and a single market-based factor, it is meaningful to explore whether other factors could be identified. Fama and French (1992) analyze the cross-sectional variation in average returns in the US from 1963 until 1990 with respect to market beta, size, book-to-market (B/M) ratios, earnings-to-price (E/P) ratios and leverage. Betas have weak or non-extant relationship with returns when other factors are included in the model. The coefficient estimates of size and book-to-market ratios are significant, and assume most of the explanatory power away from E/P and leverage. When stock markets have been analyzed concurrently with bond markets, the significance of the market proxy is evident in justifying the discrepancy between returns on stocks and one-month bills. The persistency of size and book-to-market variables in explaining stock returns is reconfirmed, and jointly with the market proxy their impact on returns can be extended to bond markets. Nevertheless, the inclusion of a term premium and a default premium eliminates the importance of stock market factors in explaining bond returns (Fama and French, 1993).

The search for explanations shedding light on occasional anomalies documented in contravention of CAPM postulates prompted Fama and French (1996) to regress a set of variables on a portfolio *i*th risk premium:

$$R_i - R_f = \alpha_i + \varsigma_i(Rm - Rf) + \lambda_i SMB + \varphi_i HML + \varepsilon_i$$

where SMB implies the discrepancy between the return on a portfolio of small stocks and the return on a portfolio comprising large stocks, and HML indicates the difference between the return on a portfolio that includes high-book-to-market stocks and the return on a portfolio of low-book-to-market stocks. The selection of variables in this multifactor models was influenced by findings published in previous papers, since the omission of leverage and earnings ratios due to rather poor explanatory power documented earlier, is noticeable. The three-factor model appropriately explains the average return of 25 portfolios made by combining five quintiles of size and book-to—market (B/M) rankings. Only portfolios in smallest size and smallest B/M intersections had non-zero excess returns, in addition to the largest size and smallest B/M quintile cell. The authors then allocate assets to ten portfolios, in accordance with ten deciles calculated for B/M, earnings-to-price (E/P), cash-flow-to-price (C/P) and five-year-sales-rank, and conclude that the suggested multifactor model explains the average returns for most of these portfolios, including the sales-rank. The latter result is important, since it is the only variable not derived

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

from stock data. DeBondt and Thaler's (1985) claim that past winners will underperform in the future, and that past losers will become future winners is examined in conjunction with findings suggested by Jegadeesh and Titman (1993) and Asness (1995) that for short periods of up to one year, the momentum prevails. Rouwenhorst (1998) examines the short-term momentum in twelve European countries, and concludes that in the short-term periods of up to one year the one-month difference between winner and loser portfolios amounts to one percent. However, when companies are sourced from winning and losing industries, the momentum strategy is more successful than in the case of the selection of individual stocks. The best results are in the initial month and the difference dissipates until the end of the one-year period (Moskowitz and Grinblatt, 1999). Fama and French confirm that depending of the period selection (i.e. prior to or after 1963) the reversal story is valid for longer periods of time to varying extent. The reversal pattern is much stronger in the period prior to 1963. It has been found that in both long-term and short-term periods the loadings on HML and SML are quite strong for past losers. While in the long-term this relationship explains the reversal, it fails to capture the short-term momentum story.

By referring to the discounted dividend growth model Fama and French (2013) link profitability and investments to the market-to-book equity price. An increase in a firm's earnings, i.e. the proxy for profitability, would be related to an increase in the expected return. In addition, an investment in book equity would be converted to lower expected returns. The suggested five-factor model is an extension of the three-factor model:

$$R_i - R_f = \alpha_i + \varsigma_i(Rm - Rf) + \lambda_i SMB + \varphi_i HML + \nu_j RMW + \chi_j CMA + \varepsilon_i$$

with RMW as a difference between the returns on a portfolio with robust profitability and the returns on a portfolio with weak profitability, and CMA representing a difference between the returns on a portfolio of low (conservative) investment stocks and the returns on a portfolio with high (aggressive) investment stocks. The five-factor model is evaluated with the addition of the two decades of datasets as opposed to the previous three-factor study. Following various combinations of factors in the analysis, the authors conclude that the HML can be omitted, since its impact is fully accounted for by other four factors. The four-factor model without HML performs as satisfactorily as the initially outlined five-factor model.

The rigidity of CAPM assumptions led to a plethora of studies where some of these assumptions are relaxed. An important breakthrough to the extant body of knowledge has been made by the introduction of the asymmetric information in the decision-making process, not only by individual economic agents by also companies.

## INTRODUCING LIQUIDITY CONSIDERATION INTO FINANCIAL SCIENCE

So far we have explained a family of general asset pricing models that do not get into calculus the fact that actors may have available information set less than complete. In various fields of economic sciences, particularly in the field of finance, various forms of dilution of the omniscience assumption were frequently studied issue. We daresay that such discussions are as old as economic science itself. There is a clue:

When Walras sent his classic work devoted to general equilibrium theory to Henri Poincaré, Poincaré commented that Walras makes two critical assumptions:

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*…you regard men as infinitely selfish and infinitely farsighted. The first hypothesis may perhaps be admitted in a first approximation, the second may call for some reservations (quoted in Minsky, 1995).*

Thus, the assumption of perfect information was never considered as granted. But it was a sacrifice that academia was ready to accept in order to reach mathematically elegant solutions for complex economic problems. In contemporary times, as was the case in past times when economic science was given contours of an exact science, it is a dominant style of writing. However, occasionally, pendulum swung back to the other side and voices that claim that the perfect knowledge assumption reduces economic interactions to the level that real economic life in nothing more than a futile ground overpowers the voices that would rather stick to the old tradition. However, theories and models that explicitly incorporate dilution of omniscience assumption are rarely as elegant and complete as economic mainstream theories and models.

From the very beginning we would like to address reader attention on some concepts that at first glance may be seen as distinct phenomena: liquidity, uncertainty, and asymmetric information. The concepts appeared in different times, and have been cornerstones of flourishing intellectual debates for a long, and that continue up to contemporary times.

Let us start with liquidity. It is a concept that can be most easily understood. Put it simply, it is easy with which an asset can be traded. However, the concept has multiple dimensions. According to Kyle (1985, p. 1316) "market liquidity" is a slippery and elusive concept, in part because it encompasses a number of transactional properties of markets. These include "tightness" (the cost of turning around a position over a short period of time), "depth" (the size of an order flow innovation required to change prices a given amount), and "resiliency" (the speed with which prices recover from a random, uninformative shock). Although at first glance the first two dimensions show no direct link to informational features of asset, it is not the case with the third one.

In the very root liquidity is an informational phenomenon. In the informationally complete market (everyone knows everything) there is no need for money. Any asset may serve the roles of money, and there is no need for institutions that are inevitably important for modern economies (e.g. financial intermediaries, etc.). Gorton and Pennacchi (1990) have developed a notion of security liquidity based solely on asymmetric information. According to the authors, a liquid security has the characteristic that it can be traded by uninformed agents without loss to insiders. It means that a less informed trader aware of possibility to trade with better informed may react either asking for price concession in order to take trade offer, or give up from the trade. In the first case, transaction is accomplished but the price will absorb asymmetric information effect. If a trader operates with an incomplete set of information, and is aware of that, he or she might be reluctant to trade. If widespread, such situation will make trade less frequent or less likely to take place, and in its extreme a market may ultimately disappear. In theory this possible outcome is known as 'no trade equilibrium', or market autarchy (Glosten and Milgrom, 1985). We will return to this point latter in this chapter.

## INVESTMENT DECISION MAKING UNDER CONDITIONS OF RISK 'OR' UNCERTAINTY

Any discussion of informational impediments to market efficiency and investment process should start with prominent ancestors of what we have established today as asymmetric information paradigm. The

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

first contribution to the research of uncertainty phenomenon is Knight's distinction between insurable and non-insurable risk. In his thesis (1921, pp. 21-22) he wrote: "uncertainty must be taken in a sense radically distinct from the familiar notion of risk, from which it has never been properly separated. The term 'risk', as loosely used in everyday speech and in economic discussion, really covers two things which, functionally at least, in their causal relations to the phenomena of economic organization, are categorically different … The essential fact is that 'risk' means in some cases a quantity susceptible of measurement, while at other times it is something distinctly not of this character; and there are far-reaching and crucial differences in the bearings of the phenomenon depending on which of the two is really present and operating. It … appear that a measurable uncertainty, or 'risk' proper, … is so far different from an unmeasurable one that it is not in effect an uncertainty at all". As well known, Knight offered an explanation of all entrepreneurial profit (and consequently the same explanation for an existence of firm) as a kind of award for exposing to pure uncertainty. The risk situations can be insured so that they cannot be priced in competitive markets the way that increases entrepreneurial award.

For a long time since Knight's pioneering attempt, academia has been trying to draw the line between the notions of risk and uncertainty. What we know for sure, now as we knew before, is that the boundary is elusive one. If we quote Knight (1921, p. 46) "while a single situation involving a known risk may be regarded as 'uncertain', this uncertainty is easily converted into effective certainty; for in a considerable number of such cases the results become predictable in accordance with the laws of chance, and the error in such prediction approaches zero as the number of cases is increased". It is the essence of insurance business, or 'raison d'être' of insurance companies.

Nevertheless, it was equally agreed long time ago (Samuelson, 1963, p. 113) that no matter how large the number in the sample, in every actuarial situation of mathematical probability, we are left with a finite sample, so "…in the appropriate limit law of probability there will necessary be left an epsilon of uncertainty even in so-called risk situations". Therefore, despite of diversification or actuarial probabilities, we have always to deal with uncertainty. This remark has great importance for the attempt to create a difference of risk and uncertainty in the economics of investment and decision-making.

It is empirical fact that investors seldom know accurately what most securities are worth. They undertake analysis to form as precise as possible estimates. However, this process may differ in that the same information may imply different estimates for different investors. There may not be enough available information to assign a reliable probability measure on all security prices (opposite to CAPM assumptions). Uncertainty will exist about the identity of the major factors that will influence the future path of prices of a given security. Uncertainty reduces to return variance only in the case where the distribution is restricted to a particular form whose corresponding parameters are known to everybody (Kane, 1999). Moreover, casual empiricism suggests that investors seldom bother to make themselves maximally informed. Since information is costly, investors will undertake gathering and processing information as long as benefits of this activity exceed costs. Opposite to traditional asset-pricing models, which assume frictionless markets without imperfections associated with costly information, in real life investment process investors have to deal with frictions of that kind. An investor who is not indifferent to risk may value the complete resolution of uncertainty more than a risk-neutral investor. According to Mehrez et al. (1984) there must be a premium related to incomplete knowledge, that one should not confuse with the conventional risk premium, since the latter stems from subjective averseness to risk while the former reflects the objective cost imposed by imperfect knowledge.

Although Knight's work did not even mention liquidity, he actually laid ground for future research in that field, by pointing out crucial difference between risk and (subjective) uncertainty phenomena,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

and its implications on market functioning. Shortly afterwards the notion of liquidity has taken place of the notion of uncertainty, and researchers have started using liquidity as a superficial manifestation of hard-to-operate notion of uncertainty.

Liquidity premium was an argument used by Keynes in his seminar work in order to explain the very essence of risk free interest rate. He set up two assets investment universe with investors choosing between default risk-free interest-bearing asset and zero-return money. The implication of the model was that investors have liquidity preference, or readiness to stick to the money, since they are not certain about future path of prices of interest bearing asset, or they fear that positive return may turn into (capital) losses. In the equilibrium, the zero-return asset which holds its value through time will be demanded by investors since the required return for the asset with uncertain value includes a liquidity premium. A couple of sentences derived from the 'General theory', we are of opinion, are exclusively able to express Keynes' (1936, p. 240) view. "The liquidity-premium … is partly similar to the risk-premium, but partly different; – the difference corresponding to the difference between the best estimates we can make of probabilities and the confidence with which we make them". By contemplating about the role of expectations in the process of economic decision making, he wrote: "The state of long-term expectations, upon which our decisions are based, does not solely depend on the most probable forecast we can make. It also depends on the confidence with which we make this forecast – on how highly we rate the likelihood of our best forecast turning out quite wrong. If we expect large changes but are very uncertain as to what precise form these changes will take, then our confidence will be weak" (Keynes, 1936, p. 148). Investment activity is always forward looking one. Investment return is what should be realized in future. If investors are not completely certain, or confident in their forecasts, that must influence their decision making.

This element of Mr. Keynes analysis is frequently misidentified with some other elements, or simply neglected. For example, one of his followers, Tobin, offered explanation for liquidity preference on the basis of investors' risk aversion. According to Tobin's interpretation, within the two-asset class model, investor will demand zero-return riskless asset (money) since risk-averse investors must be compensated for investing in risky interest bearing alternative. He stated (Tobin, 1958, p. 70): "when he [Keynes, added] refers to uncertainty in the market, he appears to mean disagreement among investors concerning the future of the rate rather than subjective doubts in the mind of an individual investor". We have found some points referring to Keynes's liquidity preference and asset pricing modelling in Woodward contribution (1983, p. 356) that matched with our point of view. Author admits that at least part of what Hicks and Keynes had in mind as a source of the liquidity premium was that the far future was inherently more uncertain that the near future, a proposition few of us would dispute.

These influencing ideas published decades ago, again are actualized recently. For instance, Holmström and Tirole (1996, p. 187) agree that "given incomplete insurance, assets will command liquidity premia (even though all agents are risk-neutral). Such liquidity premia correspond to risk premia in standard asset-pricing models, but the empirical implications can be rather different", and in the same paper later, "… liquidity premium on the asset depend on what the asset delivers conditional on the productive sector experiencing a high liquidity shock … While a liquidity premium is a form of risk premium, its structure is different from that seen in standard asset-pricing models. In particular, how the asset behaves when liquidity is abundant is less relevant than how it behaves when liquidity is tight."

## MARKET MICROSTRUCTURE THEORY AND ASSET PRICING

Keynes's enlightening ideas, published nearly a century ago, inspired many authors. The idea that there is a spectrum of assets, which can be classified in the continuum from perfectly liquid to ultimately illiquid, further is developed in Davidson (2002). According to the author, an asset with perfect liquidity is the one able to convert (sell) into cash on the spot market where a market maker guarantees firm spot price expressed in money units. It follows an inspiring notion that such an asset will hold the full liquidity as long as the market maker has enough money at hands to support his given guarantee, or as long as investors believe that he will be able to do so. The author uses the word market maker in more general sense, so that any intermediary fits into his notion of market maker.

The institution of organized financial markets, opposite to what is believed out of academic circles, is not able to generate liquidity; per se. Davidson (2002) forceful analogy portrays liquidity generating financial markets as two-edged sword. In good times they make investment process easy, but in bad times they will bring additional instability to the system. Indisputably, financial markets are valuable invention. Markets are good since they make real investments that are fixed for the community to look liquid from the angle of an individual investor. However, the bad thing is that it only looks like that. Namely, as long as financial markets operate orderly, investors will believe that they have a fast-exit option that should be activated whenever they are not satisfied with the investment. In some extent, asset liquidity is possible to increase by organizational design of modern traded markets. It is called endogenous liquidity.

In the next section, we will review the basic results of the intellectual efforts of the market microstructure theory. This strand of economic literature appears in late 70's and focuses on organizational design of contemporary markets, but has equally forceful implications for the asset pricing.

Market microstructure theory brought back into the research focus the nexus between asset liquidity and its price. However, this time the issue was enlightened from the different angle. What was common for majority of researchers that tried to explain what influence asset liquidity might have on the price of financial assets from the market microstructure milieu is their focus on the transaction costs. Existence of transaction costs, which may appear as asymmetric information costs (e.g. adverse selection costs), costs of turning around position and other kinds of transaction costs, diminishes equilibrium value of assets. According to theory, this is why even a risk-neutral agent would demand return that has to compensate him for those extra costs (Amihud and Mendelson, 1986). The focus on the transaction costs as an observable liquidity dimension probably comes along with efforts to test empirically influence of asset liquidity on its price.

For instance, in his comprehensive empirical study, Lesmond (2005) found that in majority of emerging markets, rather high return on stock market investments (which corresponds to depressed stock prices), in some occasions even eighty percent annually, fully corresponds to low liquidity. Market liquidity assessed on the basis of bid ask spread varies from one percent in case of Taiwan to even nearly fifty percent in case of Russian stock market. Similarly, Amihud and Mendelson (1986, 2003) assigned large share of cross-sectional variation in securities return to the liquidity differences among the various kinds of financial and real assets, and markets. All the same, in a frequently cited paper, Amihud and Mendelson (1991) found the difference in bid-ask spread solely able to explain differences in rates of return of long term and short term governmental securities. On the same way, Shen and Starr (1998) found the conventional measure of risk (return volatility) unable to explain the return differences once the bid ask spread appears into the regression model. A rationale offered by authors is on the line with above

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

argumentation. Namely, assets with different liquidity will trade with different bid-ask spread. When we shift to the stock markets this regularity is not as clear as in the case of markets for governmental securities. For instance, Madhavan (2000) found bid-ask spread as a proxy for asset liquidity less informative, and called for more sophisticated measures of liquidity.

The crucial feature of any financial market is the way that the role of providing liquidity is distributed among actors. It is in the very design of financial markets. Trading itself is a process of providing and absorbing liquidity, or buying and selling it. In quote driven markets, dealers are actors solely responsible for providing liquidity, since they create opportunity for other traders to trade, by standing ready to accept a trade proposal that comes from investors' community. Order-driven markets operate without dealers. Trade will take place with no dealer intervention, among traders themselves which will either place or take an offer to trade, in any specific case. Traders that submit standing limit order offer liquidity to other traders while traders that submit marketable limit orders or market orders will take offered liquidity (Harris, 2003). At the end, so called hybrid market structure combines both liquidity providing mechanisms. Hybrid markets either impose dealer role in order driven structure, or allow some traders to compete directly with dealers, changing that way pure order or quote driven structure, respectively. The very choice between different market structures depends on 'availability' of actors that are ready to create liquidity or sell liquidity insurance to other actors. However, the availability of actors that are ready to provide liquidity on the market is determined by informational reasons (Grossman and Miller, 1988). A trader that is ready to postpone execution of its trade demands better price that the trader which wants to execute trade immediately. The price concession belongs to the trader that creates liquidity (dealer or speculator). It is compensation for holding position open till the trade order arrives from the other side of the market, and the trade circle is accomplished. By holding position open for some time the trader exposes himself to risk. The asset price (or value of the position) may change either because of non-informative trade (utilitarian trading interest) takes place and moves the price away from fundamentals, or because new information arrivals bring the price to the new fundamental value. If the dealer is forced to trade with better informed counterparty, which possesses new information that is not yet available to the dealer, the dealer will ex post learn that the executed trade was mistake; loss will be inevitable. In order to avoid trading with better informed a rational dealer will quote less aggressively, increasing the ask (offer) quote and decreasing the bid quote for the amount high enough to compensate him for the perspective losses. Thus, bid-ask spread will include an informational component, known as adverse selection component in addition to other costs like costs of processing and executing orders, cost of financing position, and even costs of oligopolistic dealer market structure.

If informational disturbances are too high, it may even prevent establishing regular market. Namely, if traders are aware of possibility to trade with better informed they will be reluctant to trade and consequently their hesitation will influence transaction properties of market, diminishing market/asset liquidity.

Because of transaction cost financial markets behave like a network. They are susceptible to special sort of network externality, known as 'order flow externality'. From the pure theoretical point of view, the existence of transaction costs prevents traders to trade continuously. From the empirical point, high transaction cost will make transactions less frequent, even sporadic, and probably less balanced. Less frequent trade or less active markets will in turn further increase the transaction cost. Traders will find balancing inventory/position less likely, the position will longer stay open, and consequently the cost of financing inventory and position risk will be higher. Some traders will be forced to leave the market and circle will be closed when because of fewer traders the market become less competitive.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

From market microstructure theory we know that risk-averse dealers when selling the asset will command premium above buying (bid) price (Stoll, 1978, O'Hara, 2004). They demand to be compensated for holding position open till accomplishing round trip trade. In this tradition, bid-ask spread is simply market given award for taking inventory risk. It is crucial argument in so-called inventory models (Garman, 1976, Stoll, 1978, Amihud and Mendelson, 1980, Ho and Stoll, 1981). In new generation of models, information models (Milgrom and Stokey, 1982, Copeland and Galai, 1983, Easley and O'Hara, 1992) a dealer must quote ask price above the bid price in order to protect himself against better informed counterparty, which will trade if the dealer quotes are posted so that new market price (determined on the basis of information that dealer is not aware of) stays away of quotes. In both cases, dealer will record losses if unable to simultaneously buy and sell, faced with imbalance in order arrival. In inventory models order arrival process is stochastic, opposite to the case of information models, which assume that a dealer, by making quoting mistakes trigger loss-making trade with better informed counterparty.

We see that bid ask spread as the best proxy for dealership market liquidity can be seen as both as risk premium and a premium related to asymmetric information. The same conclusion holds for order driven markets where similar determinants are identified (Cohen et al. 1981). Theory opts for one or another depending on how much it relies on perfect information assumption. Nevertheless, mainstream theory operates with the concepts of risk and asymmetric information, trying to combine both influences in explanations of investors' decision making, and consequently market equilibrium. It is quite unusual that theory operates with some other informational concepts that are more close to genuine subjective uncertainty. A rare exception is Muranaga and Shimizu (2000) paper. In that study, the authors found that the level of confidence with which investors made their decisions influences assets liquidity. If investors underestimate risk, then they will be more active traders, consequently market 'depth" will increase, and vice versa. Moreover, the level of risk-aversion of market participants has identified as negatively connected to market liquidity. In this paper, levels of confidence and uncertainty are defined as divergence in investors' opinions, rather than subjective uncertainty. However, the divergence in investors' opinions is a consequence of the divergent perceptions of riskiness.

In order to summarize, we would say that followers of traditional models experimented with many variables that could possibly make the core models (CAPM) able to more fully fit real markets data. As expected, richer, more sophisticated models that add some more variables are better performing ones. However, the list of variables merely complies with those that are considered to be core determinants of asymmetric information. For instance, small capitalization stock differs from large capitalization stocks not only in terms of available utilitarian trading interest (existence of large number of shareholders) but also in terms of coverage by stock analysts, or generally the level and accuracy of information provided. Thus the size puzzle may indicate importance of asymmetric information (or liquidity) in asset pricing.

It seems that real life reconciles two strands of literature that rely on the different intellectual tradition. Perfect market models regress financial assets return solely on risk feature of assets, leaving no space for liquidity differences. However, it must be place for both.

Clear distinction between risk and liquidity is an academic issue which is not given definite theoretical answer, yet. Firstly, it is because risk (price volatility) goes hand in hand with liquidity. With no variations in price, there is no element on which traders have to disagree. Whatever measure of informational disturbances we take it will exist if the asset price is changeable. Secondly, even such measures of liquidity like bid-ask spread, contain both influences, meaning that they are elastic on variation in both risk and liquidity. We have seen that even in the ambience of perfect information dealers will command bid-ask spread.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Traditionally, market microstructure microscope is placed over the attributes of individual assets. Just a few theoretical and almost no empirical papers are devoted to studying either common liquidity determinant, or their empirical manifestations (a rare example is Chordia et al. (2000)). Therefore, a promising field of research could be studies of correlated movements of individual assets' liquidity.

There are also valuable but isolated attempts to explore financial market equilibrium from the intellectual tradition of asymmetric information paradigm (Holmström and Tirole, 2001). In contrast to the logic of traditional asset pricing models based on perfect markets, corporation are not able to raise funds on the capital market up to the level of their expected income, and the corporate sector need a cushion against liquidity shock (Holmström and Tirole, 1996, 1998). Financial asset that serve as the cushion will command liquidity premium. Thus, the model belongs to market imperfections models, because it relies on influence of non-pledgeable part of future income, derived solely from asymmetric information nature of financial markets.

## CONCLUSION

Although there is a bulk of literature that is dealing with the models built on dilution of 'omniscience' assumption, little has been changed in traditional asset-pricing models. Since appearance of Sharpe (1964) path breaking paper, the traditional model (CAPM), thanks to many contemporary upgrades of them (CCAPM, ICAPM), still is a main reference point, or a cornerstone of modern finance literature. The choice of investment portfolio is directed toward optimization between statistically defined risk and observable return of a universe of available investments, while the equilibrium assets pricing is determined simply by copying the superior investment strategy, in the setting of rational and homogeneous agents (in all aspects but the degree of risk-affinity), where information is common knowledge (everyone knows everything).

An avalanche of empirical studies followed in order to test if the real life fits to the model-predicted outcomes. Despite of large and systematic CAPM pricing errors, the models based on separation of diversifiable and non-diversifiable risk continue to play an important role both in business community and amongst academics. For academics that stand up in defense of beta world-wide documented cross-section anomalies of securities return (e.g. the size effect, the earnings-yield effect, the market-to-book effect and many others), taken by opponents to be inconsistent with the traditional models, are stimuli to further rearranging the basic model, specifications and choice of data etc.

The recent advancement in market microstructure theory brought about a new momentum in exploring asset pricing modeling and risk-reward nexus on financial markets. Researchers assigned large share of cross-sectional variation in securities return to the liquidity differences among the various kinds of financial and real assets, and markets. For example, the size (stock market capitalization) is a good proxy for stock liquidity, meaning that the size effect, as some others can be plausibly linked to the differences in liquidity. It is now well accepted that both very market design and presence of asymmetric information amongst actors help in explaining liquidity differences, with both elements being largely mutually determined. This is why rather frequent re-designs of market clearing mechanism in emerging markets provided effects not even close to that of leading markets.

## KEY TERMS AND DEFINITIONS

**Asset Liquidity:** A feature of an asset or market on which the asset is traded that is represented by the easy with which the assets is traded. An asset is more liquid if it is more certainly realisable at short notice without loss. The liquidity is usually measurable by various concepts of transaction costs.

**Bid-Ask Spread:** The difference between the bid and ask price quoted by a dealer or autonomously formed difference between current best priced sell and buy limit orders in the order book of a continuous auction market. It is used as a good proxy for market liquidity.

**CAPM:** Also known as capital assets pricing model, it is a single factor general equilibrium model that explains return of any asset, financial or real, as determined by its sensitivity to the market return.

**Diversification:** An investment strategy that relies on pulling multiple types of asset (or conducting different business activities) in order to make investment outcome less sensitive to specific (idiosyncratic) risk.

**Market Portfolio:** A virtual or real portfolio that is consisted of all assets available to investors on specific market, or globally.

**Portfolio Investment:** A process of selection of different securities and other investments in order to achieve investment goals, usually to increase return for the given level of risk, or to decrease the risk for a given level of return.

**Size Puzzle:** An empirical regularity not explainable by the traditional asset pricing models, i.e. small capitalization stocks are traded with a premium over large capitalization stocks.

## ENDNOTES

[1] Accordingly, the CAPM model is routinely called Sharpe-Lintner or Sharpe-Lintner-Black models.

[2] Market proxies could be efficient portfolios, while market portfolios could be inefficient. Alternatively, market portfolios may be efficient, but sampled assets would not be allocated to an efficient portfolio (Roll, 1977)

# Chapter 68
# Demographic Transition, Oil, and Institutions:
## Lessons from the Global Experience for Iran

**Mohammad Reza Farzanegan**
*Philipps-Universität Marburg, CNMS, Germany*

## ABSTRACT

*We examine political and economic drivers of demographic transition and the moderating role of institutions, macroeconomic instability and oil rents dependency in the final effects of increasing working age population on economic development and internal conflict. Using panel data estimations for more than 100 countries from 1984 to 2012 we find that demographic transition may lead to demographic dividend only if the country enjoys good quality of economic and political institutions, a diversified economy and stable consumer prices. Otherwise demographic dividend is not guaranteed. By contrast, we may expect a demographic curse. These results have important policy implications for the case of Iran which is expecting a significant transition in its population age structure since 1990s. Future of Iran is highly dependent on the proper use of potential demographic rent which can turn against the political stability if the wrong policies and institutions are in place and country dependence on oil rents continues as before.*

## 1. INTRODUCTION

Iran like most other countries in the Middle East and North Africa (MENA) is experiencing a significant demographic transition. Demographic transition is defined as increasing share of working age population (15-64 years of age) in total population. Countries at their initial stages of development have high birth and death rates. Over time by improving health and increasing levels of education, especially for women, the mortality rate falls while birth rate remains constant or falls with delay. In this second stage of development, countries face a baby boom period; i.e., population growth. Increasing young age dependency (% of working-age population) is a main characteristic of this second stage in demographic

transition. Industrialization and modernization of the economy besides higher participation of women in labor market increases the opportunity cost of having more children. The third stage which accompanies with higher stability of political systems reduces the willingness of women to increase the size of family. Birth rates converge to death rates in the third stage. This is an important phase in demographic changes: babies of previous stage now enter into the working age population, increasing pressures on job market. Figure 1 shows the trend of birth and death rate (per 1000 people) in Iran from 1950 to 2100. The largest difference between birth and death rates is observed during 1985-1990 and 1990-1995. Both rates are approaching to each other over time. The projections show that death rate will exceed birth rate from 2060 onwards in Iran. The significant increases in population growth rate in 1980s and 1990s will enter into working age population in coming decades, creating an important source for either economic growth or political instability. Such an increase in working age population, *per se*, is positive news: decreasing age dependency ratio and increasing labor force means more saving and higher investment which consequently can lead to higher economic growth (Lee, Mason and Miller, 2001; Mason and Lee, 2004 and Lee and Mason, 2006). For example, in Iran from 1965-2007, the correlation between the share of working age population and domestic saving rates is 54%. Table 1 provides a summary of key demographic indicators in Iran from 1960 to 2012.

Total age dependency ratio is the ratio of dependents-people younger than 15 or older than 64-to the working-age population-those ages 15-64. Data are shown as the proportion of dependents per 100 working-age population. A high age dependency ratio indicates that the relative number of net consumers (children and elderly) is more than the number of net producers (working age population). This is a burden for the whole economy since more resources should be allocated for schooling and child care. As fertility rate declines, age dependency ratio initially reduces because there are fewer children and more working age population. This demographic window of opportunity closes when the population grows older and the relative share of elderly increases; i.e., higher old age dependency ratio. Age dependency was significantly high before revolution and continued to increase in early years after revolution and war

*Table 1. Demographic indicators of Iran (1960-2012)*

| Indicator Name | 1960-1969 | 1970-1979 | 1980-1989 | 1990-1999 | 2000-2012 |
|---|---|---|---|---|---|
| Age dependency ratio (% of working-age population) | 91.99 | 87.91 | 92.42 | 84.04 | 46.62 |
| Age dependency ratio, old (% of working-age population) | 6.90 | 5.95 | 5.76 | 6.81 | 7.12 |
| Age dependency ratio, young (% of working-age population) | 85.08 | 81.96 | 86.66 | 77.23 | 39.50 |
| Birth rate, crude (per 1,000 people) | 45.15 | 41.63 | 41.60 | 25.73 | 17.75 |
| Death rate, crude (per 1,000 people) | 19.00 | 13.68 | 13.73 | 6.07 | 5.36 |
| Population growth (annual %) | 2.64 | 2.97 | 3.83 | 1.66 | 1.26 |
| Population ages 0-14 (% of total) | 44.31 | 43.61 | 45.03 | 41.82 | 26.75 |
| Population ages 15-64 (% of total) | 52.09 | 53.22 | 51.98 | 54.47 | 68.38 |
| Population ages 65 and above (% of total) | 3.60 | 3.16 | 2.99 | 3.71 | 4.87 |
| Population, female (% of total) | 48.63 | 48.58 | 48.68 | 49.09 | 49.12 |
| Fertility rate, total (births per woman) | 7 | 6 | 6 | 3 | 2 |
| Mortality rate, infant (per 1,000 live births) | 163 | 106 | 60 | 41 | 27 |

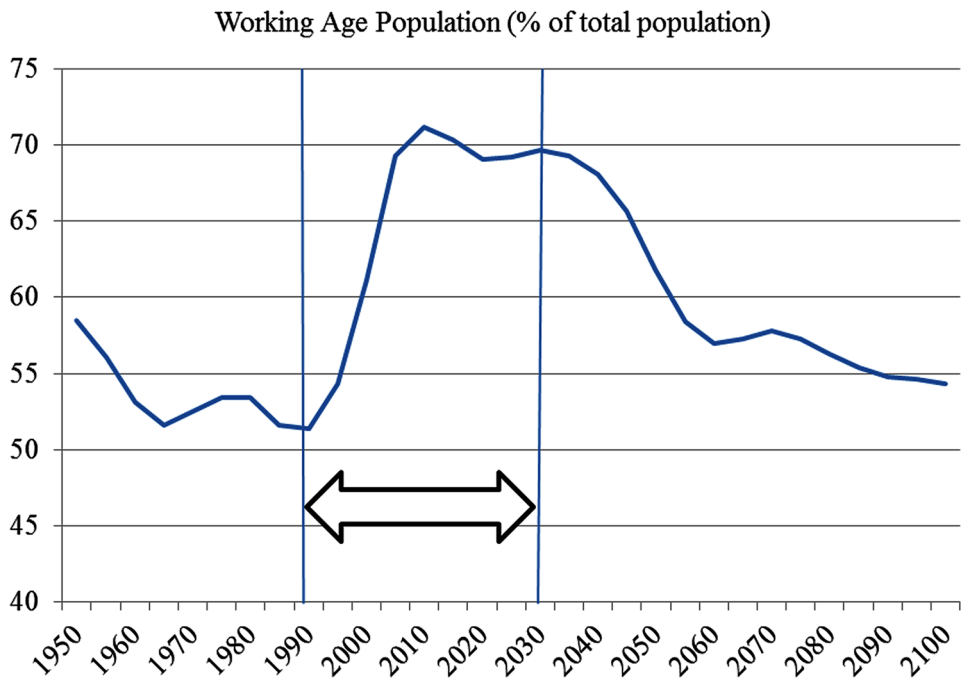
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

with Iraq. It began to decrease since 1990s and especially during 2000s, following implementation of population control policies in Iran. Old age dependency ratio is a minor issue at present but will increase in coming decades. Young age dependency ratio has also decreased significantly in the last decade, freeing economic resources for production and investment: The period in which this positive growth effect of age structure is expected to happen is called a *Window of Opportunity*. If such a positive connection is seen between demographic transition and economic growth then we call it a demographic dividend, bonus, or gift. The prominent example of demographic dividend is in the South East Asia region, where the Asian Tigers emerged. Bloom and Williamson (1998) and Bloom et al. (2000) explain that one-third of economic growth in this region was due to appropriate use of demographic window of opportunity by their state.

The highest population growth in Iran is observed during 1980s which was, on average, 3.83% per year. This decade accompanies with ideological, political and economic incentives for larger size of families. The effective population control policies since 1990s has resulted in a significant reduction of population growth rate to an annual average of 1.26% in the 2000s. This demographic transition is realized by reduction of fertility rate from 7 children per woman in 1960s to 2 in 2000s similar to figures for fertility rate in the US and UK in 2000s.

The window of opportunity does not remain open for an unlimited time (see Figure 2 in which we show the time span of window of opportunity in Iran). To reap the demographic dividend, governments need to have good quality of political and economic institutions. In the absence of right institutions which

*Figure 1. Demographic transition in Iran (crude birth and death rates are numbers per 1000 people). Source: http://esa.un.org/unpd/wpp/*



EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

define the rules of the game, we will not observe a demographic bonus. The key role of institutions in final income effects of demographic transition is emphasized by Bloom et al. (2007) for a sample of African countries. Bjorvatn and Farzanegan (2013) highlight the role of dependency on natural resource rents besides institutions in income effects of demographic transition. They show that higher dependency to resource rents lead to lower size of manufacturing in the economy, increasing unemployment rate and reducing the positive effects of increasing working age population on national income. In other words, increasing working age population as a proxy for demographic transition *per se* is positive for growth but such demographic dividend reduces significantly in resource rich countries, controlling for role of political and economic institutions. In extreme cases of dependency on resource rents, increasing working age population as a share of total population can even lead to negative income growth: a demographic curse.

The first question of our study is the reasons behind demographic transition: What are the political, economic and social factors behind demographic transition around the world? Upon having a better understanding of the drivers of demographic changes, the next question will be examined: Under which conditions increasing working age population can lead to the demographic dividend? Demographic dividend is examined in the context of income and political stability effects of population age changes. Global experience and derived empirical results from worldwide sample will help us to understand the future of Iran under its ongoing significant demographic revolution. Section 2 reviews the theoretical and empirical literature on drivers of fertility rates and transmission channels of demographic rent to economic growth. Section 3 presented data, methodology and results. Section 4 evaluates the situation of Iran and its opportunities and challenges in the context of demographic transition. Section 5 concludes the paper.

## 2. LITERATURE REVIEW

### 2.1. Determinants of Demographic Transition

There are two general approaches to explain the drivers of demographic transition in literature. The first approach emphasizes on the importance of modernization of economy in reduction of fertility rate, age dependency ratio and increasing working age population. Increasing income per capita accompanies with more production and investment opportunities which bring new job opportunities for all including women. According to modernization theory, more economic growth and improving health and education of citizens especially women has a critical effect in decision to have an addition child. In short, it will be enough to increase economic development to get rid of age dependency burden across societies. Easterlin (1983) uses urbanization, access to health and education facilities as indicators of modernization. Under reduction of mortality rates, the supply of children will increase and demand for having many children decreases. Low fertility rate is correlated with lower mortality rates (see Drèze and Murthi, 2001 for the case of India). Thus the economic value of children declines. As a result of the gap between supply and demand for children during modernization phase, the people seek methods to reduce the extra supply of children by reducing fertility rates, approaching to the equilibrium point. There is a review of modernization impacts on willingness to have children by Jensen (1995).

The second approach goes beyond economic modernity and refers to the role of political institutions in explaining the demographic transition. There are three main channels through which political institutions affect demographic structure: political freedom, political stability and policy certainty (Feng, 2003). Pro-democracy arguments highlight the reducing effect of political openness on fertility rate. This can happen by increasing property rights, investment and economic growth which can lead to more educational and job opportunities for women. Przeworski et al. (2000) show that population growth rate is faster under autocracies than in democracies. But we have also some examples of fertility reduction in "less democratic" or "autocratic" states (example of Iran or the Arab region since 1990s). Kricheli et al. (2010) show that dictatorships are significantly more effective than democracies at implementing population control policies such as male and female sterilization and reducing fertility rates. In other word, coordination of population control policies may be easier under a strong autocracy than in a multiparty political system. Political instability as a second aspect of political institutions can increase fertility rate. Internal conflicts push the loss probability of children upward, increasing incentive for larger families. Also such conflicts and instabilities reduce the opportunity cost of having children. Instability of political system reduces investment, production and economic growth which lead to lower job opportunities for the women. Having an additional child will not be anymore a costly decision under such condition. Policy uncertainty as a result of drastic and frequent changes in policies in a factionalized political system can also hamper population growth control efforts. The effect of policy uncertainty on fertility goes through instable investment environments which again shapes the participation of women in labor markets.

### 2.2. Income and Demographic Transition

What can we learn from literature on income effects of demographic transition? It is clear that there is no guarantee that increasing working age population following a reduction in fertility rate should lead to more economic growth. The positive effects of demographic transition on income depend on a set of institutional and economic factors. Without a well-functioning economic institutions and free flow

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

of information governments may not be able to benefits from the potential dividend in demographic transition. Lack of rule of law, weak property rights, internal and external conflicts, extensive corruption and rent-seeking and lack of political freedom and government accountability, the increased working age population may not lead to prosperity. In such a weak institutional framework, such structural age changes may even turn into a political risk for the ruling system.

If, due to structural problems, an economy is unable to provide necessary job opportunities for a large army of working age population, then we may not observe a demographic bonus but a demographic curse. The level of education in general and for women in particular shows a significant increase after revolution of 1979 in Iran. While the enrollment rate at secondary school before revolution was 40%, it reached to 74% in the post Iraq-Iran war. For women this indicator shows an increase from 28% to 70% for the same period. We can also see the same significant improvement in enrollment rate at tertiary schools from 4% before revolution to 26% in post-war period, while for the women the figure has increases from 2.4% to 27%. This means more educated labor force for the economy. Given significant increases in working age population and human capital, we may expect to observe significant improvements in level of real income per capita in post-war Iran. But this has not been realized: real GDP per capita before revolution, on average, was $2364, falling to $1949 during war with Iraq and returning to $2360 in post-war period. Successful examples of Latin America and East Asian countries show the relevance of demographic transition for growth under good policies. Although levels of education for all, especially for women, have increased in post-revolution but the job market was not able to absorb the young educated population. Unemployment rate especially for the youth is significantly high. On average, 44% of women with tertiary education are unemployed in post-war period, while the figure for male is 13%. The unemployment rate does not change much for women with secondary education: 38.8%. But it increases significantly for men: 30%. 52% of men with primary education are unemployed while the figure for women is lower (15.2%). In short, higher education levels have not matched with job market demands especially for the women (see Table 2).

Of course, fragile job market for young people is not only limited to Iran. The whole MENA region has a global record in youth unemployment rate. The women suffer most in this respect. The last available data for 2008 show that the unemployment rate for the youth female in the MENA region is 39.60% which is significantly higher than OECD countries (13%), and Latin America (17.79%). This indicator for youth male in the MENA region is 18.78%, while for the OECD and Latin America is 13 and 11%. (World Bank, 2013).

Literature has emphasized on the role of good governance in realizing demographic dividend. Indeed without good quality institutions we may not experience higher growth and as a result demographic transition cannot turn into a blessing for the economy. Acemoglu, Johnson and Robinson (2001) were the first to show that not all institutions matter to the same degree in their growth effects. They show that institutions effecting the protection of property rights and the enforcement of contract seem to be one of the determinants of long-run economic growth. The core theoretical mechanism is that if property rights are secured, individuals have higher incentives to invest and to trade. Eicher and Leukert (2009) differentiate between different institutions in developed and developing countries. They show that economic institutions such as labor market and trade policies have a direct effect on output. They show that for non-OECD countries, economic institutions matter more. However, economic institutions under good quality of political institutions can perform even better. Studies by Bloom and Williamson (1998) and Bloom and Finlay (2009) show that the increase in the working age population had a significant positive income impact, leading to East Asia's economic miracle. Bjorvatn and Farzanegan (2013) show that

quality of economic institutions does not differ much between East Asia region and MENA countries for a sample period of 1976-2006. They, however, acknowledge that quality of political institutions in the MENA region, on average, is lower than East Asia region. They discuss that there may be other reasons besides role of institutions which can shape the final income effects of demographic transition across countries. They aim to explain why the MENA countries have not benefited from their significant population rent. The authors model the moderating role of natural resource wealth dependency and show that resources hamper the positive growth effects of demographic transition even after controlling for the role of economic and political institutions. Resource rents dependency shape the structure of economy by de-industrialization of economy, reducing the size of productive jobs in manufacturing which is the engine of economic growth. Countries with large resource rents have also large size of government which may not necessarily provide productive job opportunities, reducing pool of knowledge. It is important to have right mechanism to reduce the asymmetric shocks of resource rents volatilities on the national economy.

Next section examines the drivers of demographic transition around the world, and in different geographical region. We also examine the conditional income and stability effects of demographic transition across countries. This analysis helps us to learn from global data pattern. We then use the empirical findings of global sample to understand the current situation of Iran and its possible future.

## 3. DATA, EMPIRICAL METHODOLOGY, AND RESULTS

Regarding determinants of demographic transition, we aim to test the following hypotheses (H1-H3) which are extracted from literature:

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**H1:** Higher income per capita reduces fertility and birth rates, *ceteris paribus* (modernization hypothesis).
**H2:** Higher political openness reduces fertility and birth rates, *ceteris paribus*.
**H3:** Higher political instability increases fertility and birth rates, *ceteris paribus*.

In order to examine the final income and stability effects of demographic transition, following hypotheses (H4-H6) are formulated:

**H4:** Increasing working age population can lead to demographic dividend if there is a good quality of economic and political institutions, *ceteris paribus*.
**H5:** Increasing working age population may lead to demographic curse if the economy is dependent on resource rents, *ceteris paribus*.
**H6:** Increasing working age population may lead to political instability if the economic situation is degrading (higher inflation rate and unemployment), *ceteris paribus*.

To examine the hypotheses related to determinants of demographic transition, we use the following model:

$$TFR_{it} = cons + \beta_1.DEMOC_{it} + \beta_2.CONF_{it} + \beta_3.GDPP_{it} + u_i + \theta_t + \varepsilon_{it} \quad (1)$$

$$CBR_{it} = cons + \beta_1.DEMOC_{it} + \beta_2.CONF_{it} + \beta_3.GDPPC_{it} + u_i + \theta_t + \varepsilon_{it} \quad (2)$$

$$WAP_{it} = cons + \beta_1.DEMOC_{it} + \beta_2.CONF_{it} + \beta_3.GDPPC_{it} + u_i + \theta_t + \varepsilon_{it} \quad (3)$$

where *i* indicates country and *t* for time period (1984-2012). Dependent variables are TFR (total fertility rate), CBR (crude birth rate) and WAP (share of working age population-15 to 64 years- in total population). TFR is the average *stock* of children per woman in their reproductive years. CBR is the number of birth per 1000 people which is *flow* variable adjusted for the size of population. Reducing TFR, CBR and increasing WAP are indicators of demographic transition. DEMOC is a democracy index. We use Polity2 index (Marshall et al., 2013) which is from -10 (full autocracy) to 10 (full democracy). This is subjective and widely used index of political institutions across countries.[1] We rescale this index from 0 to 1, the higher scores means higher political openness. CONF is an index for internal conflict from ICRG (2013). The internal conflict index of ICRG measures three major components of political (in) stability in a country: Civil War/Coup Threat, Terrorism/Political Violence, and Civil Disorder. The range of this index is from 0 to 12. The higher value of the internal conflict index means lower risk of internal conflict or higher levels of political stability. To stimulate the interpretation we reverse the index: the higher values show higher degree of internal conflict or political instability. GDPPC is the GDP per capita (in constant prices of 2000). According to modernization theory, higher levels of income should reduce fertility and birth rate, increasing working age population. We also control for the country and time fixed effects, reducing the risk of omitted variable bias which is common if we use cross country regressions. The country fixed effects for example control for time constant factors which may shape demographic structure such as geographical location, ethnical composition, religious and traditional norms, culture and history among others. All data except for DEMOC and CONF are from World Bank (2013).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3 shows the results of estimations. We start with pooled OLS regressions which show the general pattern in data. Pooled OLS regressions, however, suffer from omitted variable bias due to neglecting country unobservable characteristics. Also common time shocks such as oil price shocks which affect all countries in our sample can also shape the fertility pattern among population. Panel country and time fixed effects (models 3.4-3.6) control for these factors and thus the results of their estimations are more reliable than pooled OLS models (models 3.1-3.3). Following Feng (2003) we use log-log specification. The estimated coefficients show the percentage change in dependent variables in response to one percent increase in each of independent variables, *ceteris paribus*. The Pooled OLS results convey a robust message: countries which enjoy a more political openness (higher DEMOC), lower internal conflicts and higher income per capita (GDPPC) have lower fertility and birth rates and higher working age population.

As expected in theory, democracies encourage also liberalization of economy, increasing education and health conditions for all and especially for women, increasing employment opportunities for men and women and opportunity cost of increasing family size. Conflicts and instability lead to lower investment and production which causes lower job opportunities for all. It also increases the likelihood of human loss which encourages families to increase the number of children. Increasing GDP per capita as a main indicator of modernization provides facilities for women empowerment and increasing their preferences for the quality of family rather than the quantity. Models 3.4-3.6 control for both country and time unobservable effects which pooled OLS neglected. The latter estimations show that democracy is not anymore a significant driver of demographic transition. However, internal conflict and political instability still plays a major role in higher fertility rates and lower working age population. Modernization theory gets some empirical supports for its positive correlation with higher share of working age population.

A potential concern in previous estimations is the possible reverse feedback from dependent variables (demographic indicators) to independent variables. Higher fertility rates can also affect the national income per capita. Also it is also likely that the demographic effect of democracy, conflict and income on demographic variables realizes after some years and not immediately. In order to address these concerns, we use 5 and 10 years lag of independent variables in fixed effects estimations. Results are presented in Table 4. The only significant driver of fertility, birth rates and working age population relative share is

the internal conflict. Democracy and income do not show a statistically significant effect on demographic transition, using 5 and 10 years lag of them. Are these findings also valid for the MENA region? Table 5 shows the results restricting the sample to only MENA countries. There are some interesting similarities and differences between MENA and rest of the world.

Countries with better quality of democratic institutions in the last 5 years are experiencing a larger size of demographic rent (higher working age population) today. Democracies in the past 10 years do not show a statistically significant effect on demographic indicators today. The important result is long run effect of internal conflict and instability on fertility and birth rates in the MENA region. Here the MENA results are in line with global findings. Conflict has a more robust effect on decision of families to increase their size due to their survival concerns and lower opportunity costs for the women under internal conflict condition.

The significant difference between MENA and rest of the world is the effect of income per capita on fertility and birth rates. While modernization theory highlights the dampening effect of higher income levels on fertility indicators but the MENA region presents a different picture. Higher national wealth has a long term positive and statistically significant effect on fertility and birth rates (in 10 years). This is in contrast with modernization idea. One explanation can be the source of wealth in the MENA region.

The MENA is a natural resource (oil) rich region and oil rents form a major share of national wealth and growth in these countries. Thus it is important to differentiate between non-oil and oil based modernization. In oil rich economies the government transfers in a form of subsidies are higher. Family can receive higher subsidies depending on their family size. Also oil rents shape the structure of the economy which in long run lead to lower size of industry and manufacturing and higher unemployment in the

economy (the Dutch Disease). This means that there will be fewer jobs for women in long run in oil rich economies and consequently weaker representation of women in politics (Ross, 2012).

But can demographic transition automatically lead to higher economic growth? Hypotheses 4 to 6 indicate that it depends. If countries have already good quality institutions then an increase in the share of working age population can result in higher productive employment, production and growth. Also if countries are dependent on resource rents we may expect not to see demographic dividend. Also demographic transition may affect political stability if we have mismanagement of economy and fragile institutions. We examine these hypotheses using global sample. To examine the transmission channels of demographic rent to economic development, we use the following empirical models:

$$GDPPC_{it} = cons + \beta_1 WAP_{it} + \beta_2 INST_{it} + \beta_3 \left(WAP_{it} * INST_{it}\right) + \beta_4 Z_{it} + u_i + \theta_t + \varepsilon_{it} \quad (4)$$

where the *INST* is a simple average of control of corruption, government stability, rule of law, bureaucracy quality and investment profile from ICRG (2013). Higher scores mean better quality of economic institutions. Following Bloom et al. (2007), we expect that final income effect of increasing working age population depends on the quality of institutions ($\beta 3>0$).

$$GDPPC_{it} = cons + \beta_1 WAP_{it} + \beta_2 RES_{it} + \beta_3 \left(WAP_{it} * RES_{it}\right) + \beta_4 Z_{it} + u_i + \theta_t + \varepsilon_{it} \quad (5)$$

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

where *RES* is the total natural resource rents (as % of GDP) from World Bank (2013). Following Bjorvatn and Farzanegan (2013) we expect that the higher RES, the lower the final positive income effects of WAP ($\beta_3<0$).

$$CONF_{it} = cons + \beta_1 WAP_{it} + \beta_2 INF_{it} + \beta_3 \left(WAP_{it} * INF_{it}\right) + \beta_4 Z_{it} + u_i + \theta_t + \varepsilon_{it} \quad (6)$$

In Eq. 6 we test the moderating role of macroeconomic instability in conflict-demographic transition nexus. We use inflation rate as a proxy for macroeconomic instability. Higher share of working age population may lead political instability if the economy suffers.

Table 6 shows how quality of economic and political institutions shape the final income effects of demographic transition around the world. In line with previous findings of Bloom et al., both political and economic institutions matter. Higher quality of institutions has a positive effect on the final income effects of demographic transition which is also statistically significant (see Models 6.3 and 6.5).

Bjorvatn and Farzanegan (2013) while acknowledging the role of institutions highlight the independent intermediary effect of natural resource rents dependency and in particular oil rents in hindering the demographic bonus. Regardless of quality of institutions, increasing the role of oil rents in the economy through its structural effects on the economy (downgrading manufacturing and increase the size of public services) can lead to decreasing pool of knowledge, increasing unemployment rates, and undermining the sustainable economic development. We re-examine this hypothesis using updated data. Table 7 shows the how oil rent dependency besides institutions shape the final income effects of demographic transition around the world.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The interaction term between oil rents and working age population is negative and significant in all models: the higher dependence on oil rents, the lower is the positive income effects of demographic transition. This finding is robust even after controlling for institutions, their interactions with working age population and triple interaction term. In order to reap the dividend of demographic transition, countries should cut their dependence on oil rents.

## 3.1. What is the Stability Consequence of Demographic Transition?

Lower fertility rates and larger working age population happens when the country enjoys a political stable system and low risk of conflict. Equation 6 implies that final stability effect of working age population depends on macroeconomics conditions. Mismanagement of economy reflects itself in high inflation rates among other indicators. If wages do not adjust properly, higher inflation has a direct effect on real disposable income of people, reducing the economic cost of engaging in political movements to change the ruling system.

This is more evident in countries which lack good democratic institutions. Thus, we expect that larger working age population be correlated with lower internal conflict *per se*. However, higher inflation rates moderate this nexus. Increasing working age population in an economy with high inflation rates can lead to higher risks of internal conflict and instability. We expect also to see these effects from inflation and demographic transition on internal conflict with a time lag. In addition to the channel of inflation, following resource curse literature, demographic transition in *oil rich economies* may lead to political instability and conflict.

Bjorvatn and Farzanegan show that demographic can turn into a demographic curse in oil rich economies in respect with national income growth. Based on their theoretical explanations which support the Dutch disease hypothesis, we show that oil also matters for stability effects of demographic transition. Increasing demographic rent when an economy depends on oil rents is a curse for political stability.

Due to economic volatility in oil rich countries, the investment, production and inflation is also uncertain. Dutch Disease also can lead to higher unemployment in productive part of economy. Rent-seeking and corruption are other side effects of oil based economies. Under such condition, increasing working age population can foster the army of unemployed young people and challenging the stability of political system. Table 8 shows the estimation results.

As we expected potential demographic dividend turns into a curse for political stability under macroeconomic mismanagement. Also it is less likely to see a demographic bonus for stability in oil rich economies (see Table 9).

The results remain robust after controlling for the role of economic and political institutions, persistency of conflict (2 years lag of conflict)[2], income per capita and secondary education, country and time fixed effects.

Triple interaction term between working age population, oil and economic institutions is negative and statistically significant. It shows there is a solution for oil rich economies for their demographic puzzle. Still they might reap the demographic dividend as far as stability matter by investing in their economic institutions such as control of corruption, improving rule of law and investment profile.

## 4. WHAT ARE THE LESSONS FOR IRAN?

Our previous global findings imply that demographic transition can lead to demographic dividend for national income and political stability if

1. The quality of political and economic institutions are reasonably high,
2. Dependence on oil rents are reasonably low; i.e., the economy is adequately diversified

We examine the condition of institutions and degree of oil dependency in Iran in order to understand the future of Iran under significant demographic transition.

### 4.1. Quality of Political Institutions

The most common indicator for quality of political institutions is the Polity index which is from -10 (full autocracy) to 10 (full democracy). Figure 3 shows the trend of this index in Iran from 1960 to 2012.

The quality of democratic institutions was at its minimum under the Pahlavi monarchy. Islamic Revolution of 1970 increased the political openness and freedom of press and political participation of masses immediately. The index shows a significant increase from -10 to 0. This politically open situation was however temporarily and power struggles among different political factions began to capture the executive power. The war with Iraq which began in 1980 and lasted till 1988 was also another amplifying factor in consolidation of power and reduction of political openness. This repressed political atmosphere continued until the election of Mohammad Khatami in 1997 as the reformist president. For the first time in modern history of Iran the Polity index enter the positive zone, indicating Iran as a factionalized democracy. Again this positive development was not sustainable and mis-coordination in different layers of government especially in economic issues led to election of the neo-conservative Mahmoud Ahmadinejad as the president of Iran who replaced by a moderator candidate, Hassan Rouhani, in 2013. The Polity began to fall during presidency of Ahmadinejad.

Another indicator of political institutions in Iran is the Vanhanen index of democracy. Figure 4 shows development of Vanhanen index in Iran from 1960 to 2010. The van_index is the principal index of power distribution (Vanhanen, 2000). This index combines two basic dimensions of power balance – competition and participation – measured as the percentage of votes cast for parties other than the largest (competition) times the percentage of the population who actually voted in the election (participation). This product is divided by 100 to form an index that in principle could vary from 0 (full dominance of one political faction) to 100 (lack of any dominant political faction). Higher levels of this index reflect more competition of factions within political power and the participation of their supporters. Vanhanen argues that both dimensions of power balance (competition and participation) are critical to build a principal index of power distribution.

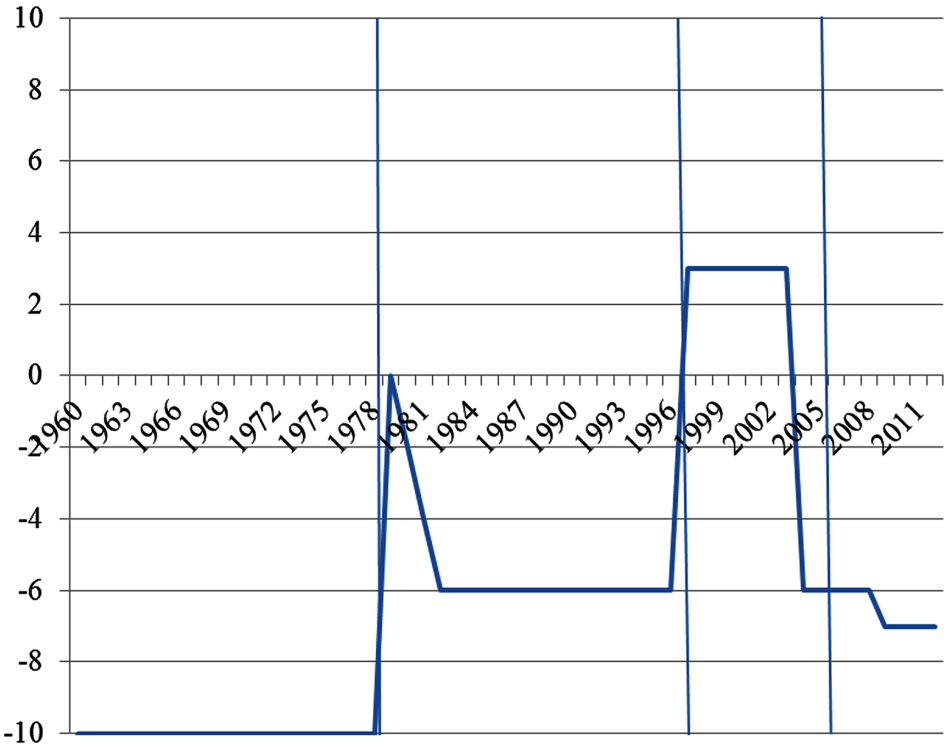

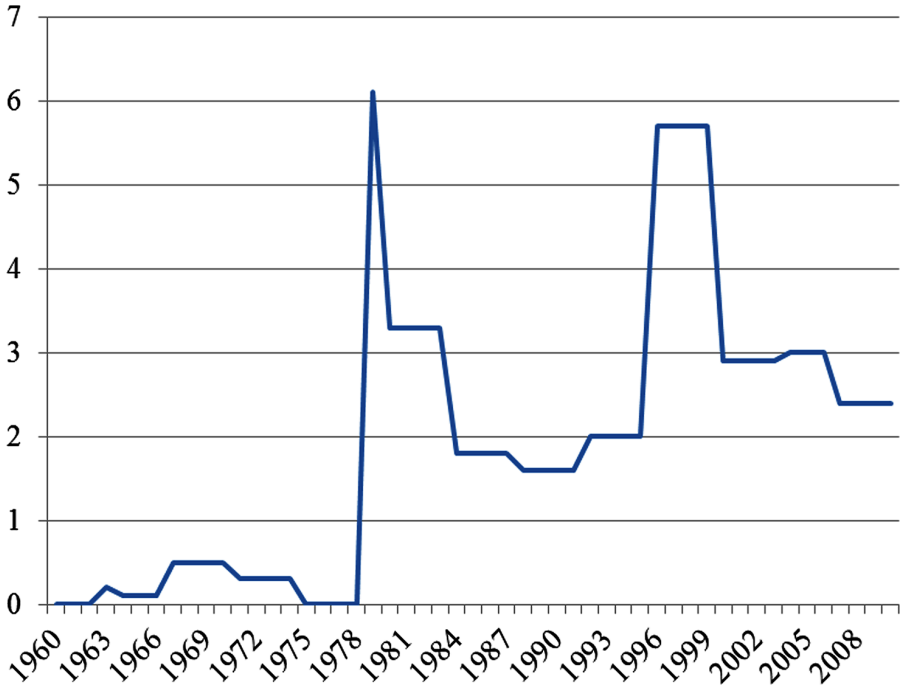

*Figure 4. The Vanhanen Index in Iran. Higher scores show higher political competition and participation of electorates in elections. Source: http://www.fsd.uta.fi/en/data/catalogue/FSD1289/meF1289e.html*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The lowest values of this index recorded during the full power of the Shah and dominance of his party (National Resurgence) from 1975-1978. The highest value of this index realized in the first year of Islamic Revolution (1979) which accompanied the largest balance of power among different revolutionary factions. During the years after revolution the balance of power diminished and the index reached to 2 in the end of Rafsanjani government (1995). Reformist movement during the 5th parliament and election of Khatami boosted the role of smaller factions in the politics of Iran. The power distribution index of Vanhanen increased during this period to 5.7, indicating reduction of dominance of ruling group. In summary, the post-revolution governments in Iran never experienced a full dominance in their political life. Both presidential and parliamentary elections have been competitive within the pre-defined limits of ruling clergy (Vanhanen, 1997, p. 121). Bayart (1994, pp. 295-298) agreed. He explains that "Iranian political society is now too diversified and complex for anyone to be able to impose as clear a hegemony as that of the Shah in the 1970s, although it is not yet 'democratic'.[3]

## 4.2. Democratic Accountability Index of ICRG

ICRG (2013) also publishes a group of indicators which we used in previous section to build economic institutions. One index which belongs to political institutions is Democratic Accountability index: it is from 0 to 6. The higher scores mean higher levels of democratic accountability of state. The ICRG defines this index as following:

*This is a measure of how responsive government is to its people, on the basis that the less responsive it is, the more likely it is that the government will fall, peacefully in a democratic society, but possibly violently in a non-democratic one.*[4]

The highest score (6) is given to a political system in which following conditions are present:

- A government/executive that has not served more than two successive terms,
- Free and fair elections for the legislature and executive as determined by constitution or statute,
- The active presence of more than one political party and a viable opposition,
- Evidence of checks and balances among the three elements of government: executive, legislative and judicial,
- Evidence of an independent judiciary,
- Evidence of the protection of personal liberties through constitutional or other legal guarantees.

The lowest number is given when a country is in the Autarchy category:

- Leadership of the state by a group or single person, without being subject to any franchise, either through military might or inherited right.

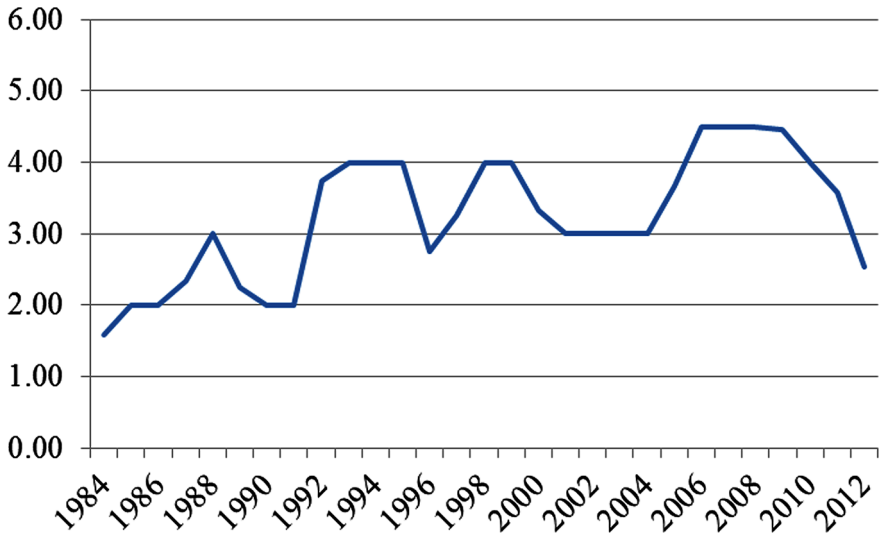
Figure 5 shows the trend of ICRG democratic accountability index in Iran from 1984 to 2012.

The political risk of lack of democratic accountability in Iran has increased since the second office of Ahmadinejad in 2009 until 2012. The drop of 2 scores from 4.5 to 2.5 from 2006 to 2012 is a significant degradation of political institutions.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally the Voice and Accountability index of the World Bank also shows a worrying situation for political institutions in Iran. Voice and Accountability captures perceptions of the extent to which a country's citizens are able to participate in selecting their government, as well as freedom of expression, freedom of association, and a free media. Estimate gives the country's score on the aggregate indicator, in units of a standard normal distribution, i.e. ranging from approximately -2.5 to 2.5.[5] The trend, as is shown in Figure 6, presents a continues decline in the quality of political institutions in Iran since 1996. It has reached to its minimum scores in 2011.

In short, the quality of political institutions on the basis of most indicators does not show a positive trend. Increasing working age population in such an environment may not lead to a bonus for Iranian economy.



## 4.3. Quality of Economic Institutions

There are countries which are not showing a sound democratic institution but have increased the quality of economic institutions stimulating the flow of local and foreign investment. Examples for GCC countries such as the UAE, Bahrain, Oman, Qatar and Kuwait show that to control corruption, protecting property rights are not necessarily correlated with democracy. For production and creating employment opportunities for increasing working age population governments need to install a rule of law, improving property rights, controlling corruption, and improving bureaucracy quality. How is the quality of economic institutions in Iran?

## 4.4. Socioeconomic Conditions

This is an evaluation of the socioeconomic burden in society that could undermine government action or fuel social dissatisfaction especially in countries which are dealing with demographic transition as in Iran. The index is the sum of three subcomponents: unemployment, consumer confidence and poverty.

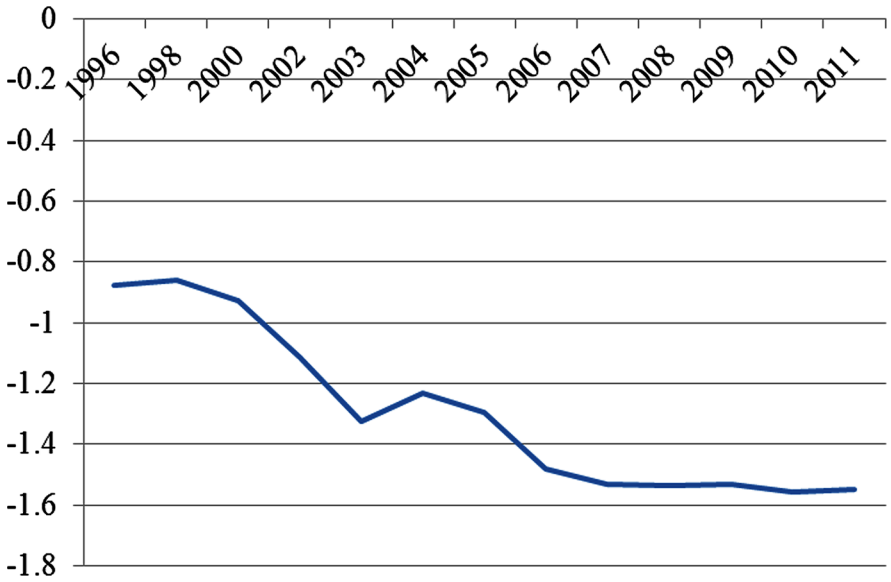


*Figure 5. Democratic accountability in Iran (higher scores mean higher democratic accountability of state), Source: ICRG (2013)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 6. Voice and accountability in Iran (higher scores mean higher democratic accountability of state), Source: WGI (2013)*

Higher scores (maximum 12) is given to countries with the lowest socioeconomic pressure and 0 to those with the highest pressure. Figure 7 shows the trend of socioeconomic condition in Iran from 1984-2012, with average score of 5.21 from 12 over this period. This average score for Iran is lower than the UAE (8.19), Kuwait (8.23), Oman (7.90), Qatar (7.43), Saudi Arabia (6.77) and Bahrain (6.51).

Socioeconomic conditions show a one-time significant improvement immediately after end of war with Iraq and presidency of Hashemi Rafsanjani. It was however began to deteriorate due to increasing inflation. It improved marginally under reformist government of Khatami by controlling inflation and increasing consumer confidence. It declined during Ahmadinejad government and remained constant till 2012. It is expected that due to ongoing sanctions the index declines further in coming years.

## 4.5. Investment Profile

This indicator evaluates the factors which influence the risk of investment in countries. It covers three subcomponents each of them has given a maximum score of 4. A total score of 12 for this index shows the lowest risk for investment in a country which is of high importance for realizing the demographic dividend in a country. The three elements in this index are: Contract Viability/Expropriation, Profits Repatriation, and Payment Delays. Figure 8 shows the trend of investment profile index. It is far from ideal score of 12 and it is decreasing continuously since 2008. Again due to financial and insurance sanctions the situation is critical in coming years, making the way to demographic bonus more challenging.

## 4.6. Corruption

A major hindering factor in realizing demographic dividend is the extensive corruption in the political system. Administrative and political corruption distorts markets and lead to misallocation of scarce

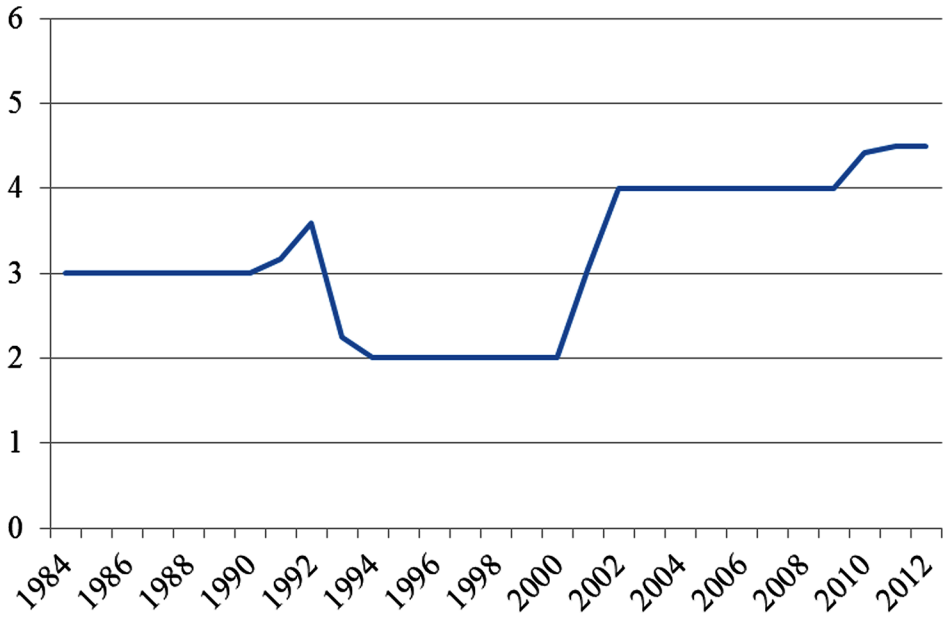
economic resources. Corruption has a significant negative effect on economic growth (see Mauro, 1995, Knack and Keefer, 1995; Tanzi and Davoodi, 2001; and Mo, 2001, among others). This means that there will be also reduction in employment opportunities, mitigating positive income effects of demographic transition.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, such corruption can hinder the economy in benefiting from its demographic rents by affecting investment: Corruption is a threat to foreign (and local) investment for several reasons:

- It distorts the economic and financial environment;
- It reduces the efficiency of government and business by enabling people to assume positions of power through patronage rather than ability; and,
- Introduces an inherent instability into the political process.



Corruption index of ICRG is more concerned with actual or potential corruption in the form of excessive patronage, nepotism, job reservations, 'favor-for-favors', secret party funding, and suspiciously close ties between politics and business.

The index is measured from 0 to 6; higher values show lower levels of corruption. To facilitate the interpretation, we rescale the index; higher scores now show more corruption. Figure 9 shows the trend of corruption in Iran. The risk of corruption for investors is increasing in Iran.

## 4.7. Law and Order

Rule of law is a key element in economic development. There is hardly any investment in an economy with fragile judiciary system and lack of transparency of rules and regulation and their effective enforcement. In order to attract international investors governments need to guarantee and protect property rights. High crime rates and widely illegal strikes can discourage investors for any significant and long term investment, adding to unemployment problems and hindering realizing demographic bonus. Figure 9 shows the development of this index in Iran. The index was in an alarming level in 1980s which was mostly due to revolutionary and ideological approaches to rules and regulation and special situation of

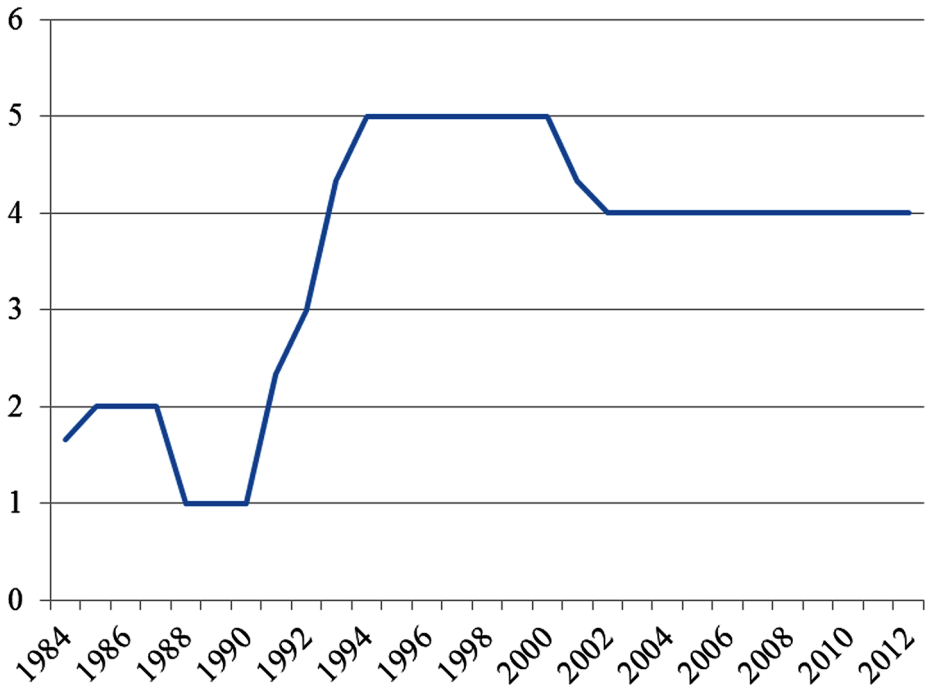


*Figure 9. Risk of corruption in Iran. Higher scores mean higher risk. Source: ICRG (2013)*

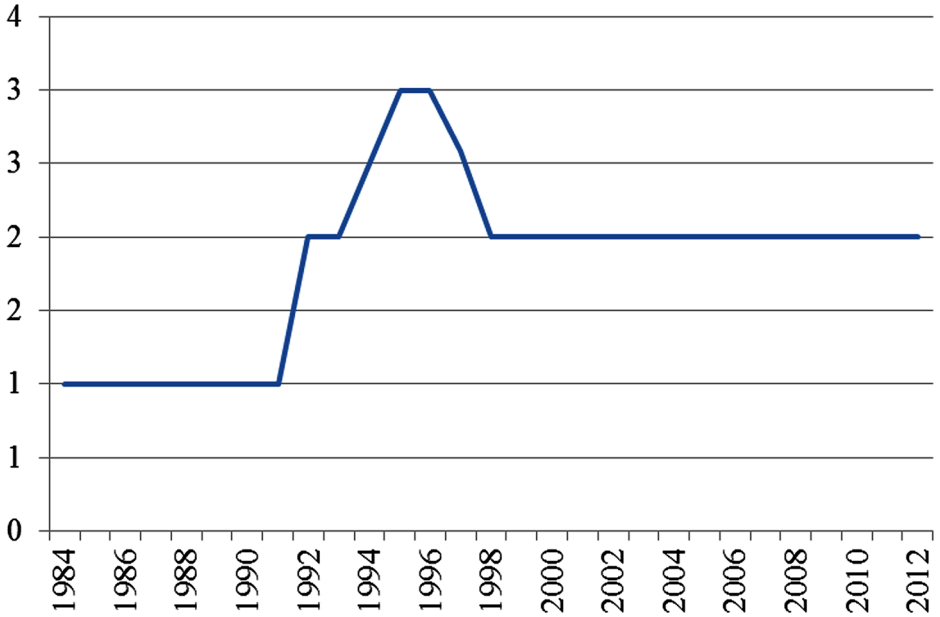
*Figure 10. Rule and order index in Iran. Source: ICRG (2013)*

country which was with war with Iraq. The index shows a significant improvement under Hashemi and Khatami governments which was necessarily to attract investors to rebuild the destroyed infrastructures and creating employment for the large size of ready to work population. Figure 10 illustrates the trend of law and order in Iran.



## 4.8. Bureaucracy Quality

Stability of regulations and general policies toward macroeconomic policies across different governments are important factors for investors who want to invest for long term in a country. The institutional strength and quality of the bureaucracy is a shock absorber that tends to minimize revisions of policy when governments change. ICRG gives higher scores to countries in which "*bureaucracy tends to be somewhat autonomous from political pressure and to have an established mechanism for recruitment and training. Countries that lack the cushioning effect of a strong bureaucracy receive low points because a change in government tends to be traumatic in terms of policy formulation and day-to-day administrative functions*". The maximum score is 4.Average of this index for Iran from 1984-2012 is 1.83 which is lower than UAE (2.53), Bahrain (2.41), Saudi Arabia (2.27), Oman (2.20), and Kuwait (1.94). Since 1998 the score of Bureaucracy Quality in Iran has remained constant at 2. Figure 11 shows the trend of this index in Iran.

## 4.9. Degree of Dependency to Resource Rents in Iran

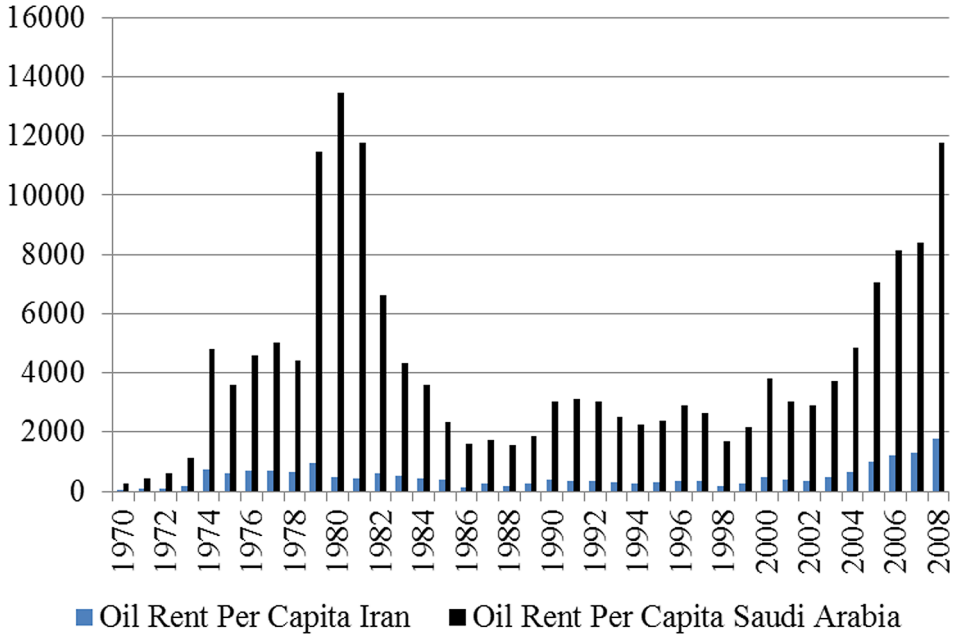
Another important moderating factor in final income effects of demographic transition is the degree of dependency on natural resource rents. Resource wealth has been found to affect the structure of the economy, a phenomenon known as the Dutch disease. It leads to the expansion of the non-traded sector at the expense of the traded sector. As argued by van Wijnbergen (1984), if the traded sector is more "dynamic" than the non-traded sector, this change in sectoral composition of the economy may have detrimental growth effects. Bjorvatn and Farzanegan (2013) provide theoretical and empirical evidence on the key role of resource rents in demographic and growth relationship. We also re-examined this hypothesis using a larger and updated dataset as well as considering it in conflict-demography nexus.

Due to its high dependence on oil rents, Iranian economy is at the danger zone. Demographic blessing can become a demographic curse in countries which are unable to provide adequate job opportunities in growth inducing sectors such as manufacturing and industry.

We can summarize indicators of resource wealth in two groups: resource dependency and resource abundance.

## 4.10. Resource Dependency Indicators

- **Share of Natural Resource Rents in GDP:** This measure shows the relative importance of resource sector value added (rent) for the whole economy. We use, for example, oil rents, coal rents, gas rents, mineral rents, and forest rents as share of GDP.
- **Share of Natural Resource Exports in Total Exports:** This ratio shows how much of export of a country depends on the raw material or natural resources.



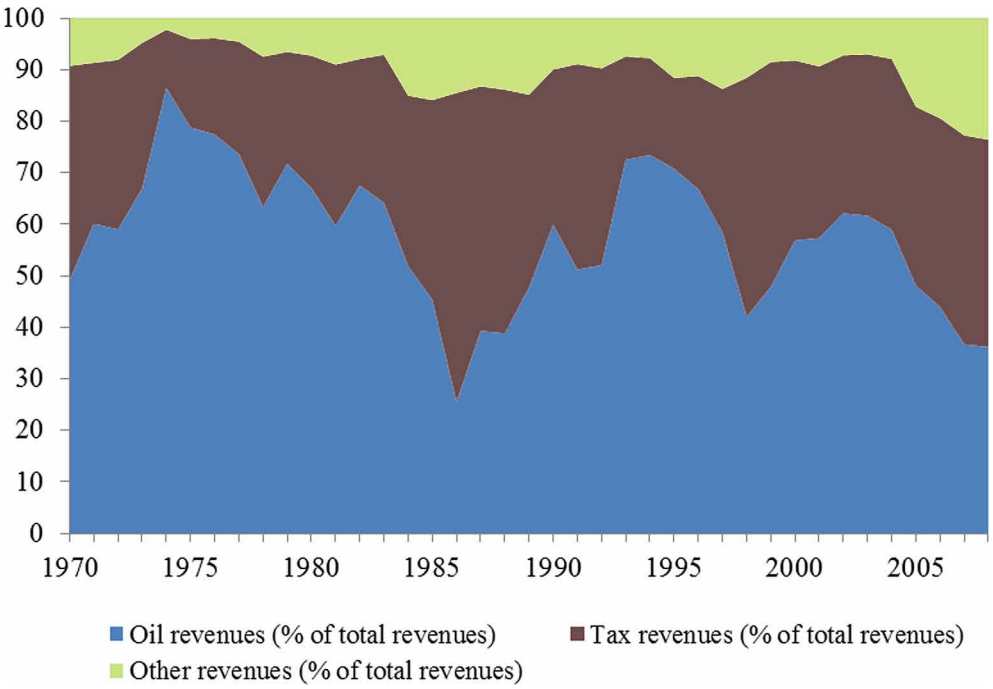
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Share of Natural Resource Export Revenues in Total Government Revenues:** This variable shows the degree of dependency of government's budget to the resource rents.

For natural resource abundance we usually use the natural resource reserves per capita. This shows the potential of a country for future resource production and export. It needs however investment, technology and skilled labor force for realizing this potential. Thus a country may be resource abundance but still the flow of resource money is missing or insignificant in the economy. Which indicator can be used to measure: What rulers can spend to keep themselves in office, either by co-opting, rewarding or coercing their citizens? How many oil dollars a regime can direct at each citizen, for public goods, patronage and so on? The most proper indicator for measuring the questioned issues is the per capita resource revenues. It shows the availability of resource revenues per each citizen, on average. Rulers in two countries *with identical oil export* revenues and *similar GDPs*, but with *very different population* sizes, would have equally different rent capacities to be employed for *patronage* or *coercion* (or modernization). Iran with 75 million population with Kuwait with about 3 millions! The difference in what each regime can pay into affecting citizens' political behavior, by whatever means, is massive. See for example Figure 12 in which per capita oil rents in Iran is compared with per capita oil rents in Saudi Arabia.

The government budget and social welfare system is also highly sensitive against the positive and negative shocks in the global oil markets. More than 90% of foreign exchange revenues of Iran come from oil exports and about 60% of government revenues in annual budgets depend on oil revenues (Farzanegan, 2011). The share of total tax revenues in GDP in Iran is lower than any other developed and non-oil developing country. This causes the financial independency of the state from contributions

*Figure 12. Affecting citizens' political behavior: Oil rent per capita (US $)*
*Source: data.worldbank.org/sites/default/files/subsoil_and_forest_rents.xls*



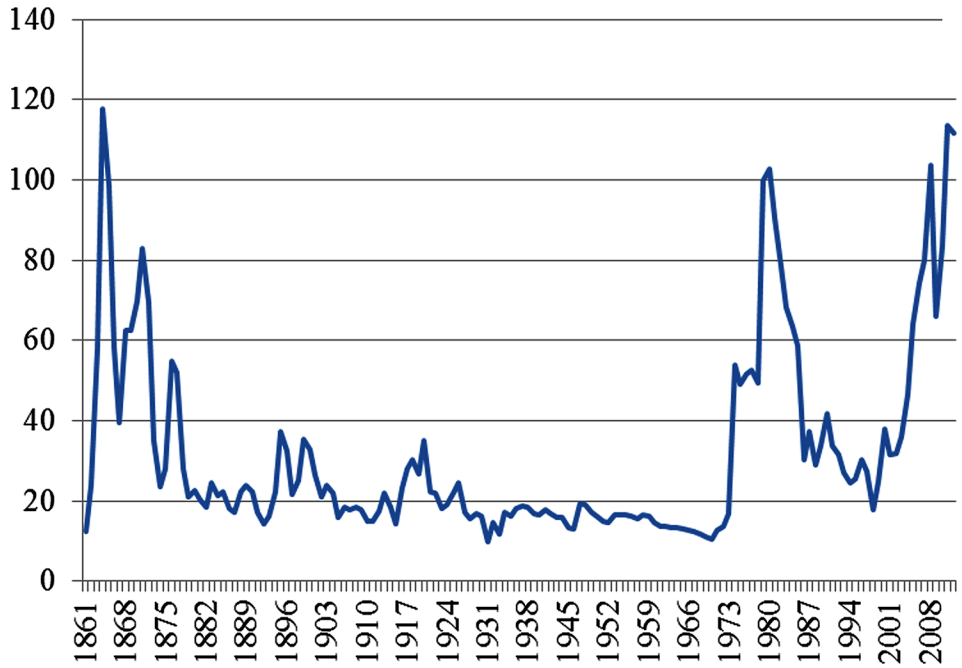
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

through taxes. It also creates a lack of accountability of state to people. The average share of tax revenues in GDP of Iran from 2001 to 2009 is 6.8% while the average world for the same period is 14.8%. (World Bank, 2013).

Figure 13 shows the relative share of oil, tax and other revenues in the annual budget of the Iranian government from 1970-2008. Interestingly, the correlation between the relative share of oil revenues and tax revenues in the government budgets is strongly negative (-95%). In general, oil revenues have substituted the tax revenues, leading to less degree of dependency of government to citizens. Figure 13. shows that whenever the government faces a negative oil shocks such reduction of oil prices in 1986 (introduction of netback-pricing arrangements to maintain market share by the OPEC and increase of oil production) and 1997 (financial crisis in South East Asia), the government expand his tax sources and diversifying the economy with more emphasize on non-oil exports and production.

In the Iranian National Accounts, however, oil value added accounted for just about 20% of total GDP in the past years, comparable to figures of Norway and Venezuela. This is in contrast with the higher share of oil GDP in the other oil exporter of the Middle East region. This is partly because of the more diversified economy of Iran, especially in agriculture, compared to the Arab oil rich economies. The low share of oil value added in the Iranian GDP can also be attributed to heavy price distortions of energy products in Iran. The massive subsidies on domestic sale of crude oil and oil products underestimate the real share of oil GDP in the economy.[6] Nevertheless, the major share of state foreign revenues still comes from oil exports and a significant share of current and capital expenditures of state finance through the petrodollars.

*Figure 13. Share of oil and tax revenues in the budgets (1970-2008). Source (CBI, 2013)*



EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Dependence on oil and mineral resources can cause a problem for the economic development, the so-called "resource curse." On average, resource rich economies have a slower income growth in long term compared with resource poor economies. The curse of resources are transferred to the national economy through different channels such as Dutch disease, conflicts, rent-seeking and corruption, neglecting investment in human capital and weak quality of institutions. A country dependent on oil and mineral resources is highly vulnerable to asymmetric resource price shocks, especially for the case of petroleum. The volatile oil market is depicted in Figure 14. Farzanegan and Markwardt (2009) and Farzanegan (2011) examine the different effects of oil price shocks on the Iranian economy.

Besides the high dependency of Iranian economy and government budget to oil revenues, corruption and lack of transparency in oil industry add to the problem. Counties can still benefit from their natural resources if right policies exist and if transparency and free flow of information are working. This is shown in previous estimation results in this study. According to the 2013 Resource Governance Index (RGI) which measures the quality of governance in the oil, gas and mining sector of 58 countries, Iran's ranking is 53. This composite index covers performance of countries regarding their natural resources in 4 dimensions: *Institutional & Legal Setting, Reporting Practices, Safeguards & Quality Controls, and Enabling Environment*.[7] Iran received a "failing" score on all four components, leading to a composite score of 28 and a ranking of 53rd out of 58 countries.

## 5. SOLUTIONS AND RECOMMENDATION, FUTURE TREND AND CONCLUSION

This paper examines the economic and political drivers of demographic transition and role of natural resource dependency, economic and political institutions and macroeconomic instability in the final effect of demographic transition on economic development and internal conflict.

We use worldwide data for more than 100 countries from 1984-2012 and find robust evidence for our main hypotheses: *demographic transition does not lead to demographic bonus automatically*. This process needs good quality institutions, macroeconomic stability and diversified economy (less dependence on oil rents). We also look at blessing or curse of increasing working age population from conflict perspective which is also our contribution. Increasing working age population as a proxy for demographic transition can increase national income if the right policies and institutions are working, inflation is under control, and economy is protected from asymmetric shocks of resource rents. All these factors stimulate the process of investment and production, increasing productive employment opportunities for the increasing number of young and educated population.

Using empirical findings from global sample with various robustness tests, we examine the situation of institutional and resource dependency in Iran in addition to its demographic changes. *We conclude that given the history of weak economic and political institutions, chronic inflation, and less diversified economy; the Iranian economy may not reap its demographic dividend*. The possibility of facing demographic curse in which economic growth reduces and internal instability increases will be high.

*What are the urgent solutions and recommendation for the case of Iran?* Increasing working age population in Iran needs productive job and long run prosperity. This requires investment and investment requires good policies. An ongoing challenge is international economic sanctions imposed on Iran due to its nuclear programs. These sanctions have reduced foreign exchange reserves by restricting oil exports and increasing transaction costs in general. Sanctions have affected the currency market in Iran, increasing exchange rate and thus making imports more expensive. Given the dependence of domestic industrial production to imported goods this means higher production costs while prices of final goods are often controlled by the state. As a result, profit margin of manufacturing units is decreasing, reducing also employment opportunities and increasing unemployment rate. Increasing inflation rate following sanctions has been significant. All these direct and indirect effects of sanctions lead to decreasing disposable income of Iranians and more engagements in the shadow economy (Farzanegan, 2013 has investigated the shadow economy effects of sanctions in Iran). Jobs in the shadow economy suffer from long term prosperity and security.

Sanctions are also affecting the housing prices and rents by increasing the costs of production in the housing branch. Increasing housing costs have been shown to be one of the main reasons behind increasing divorce and reducing of marriage rates in Iran, amplifying the social crisis in the young population of Iran (see Farzanegan and Gholipour 2015 a &b). Fragile family structure also reduces the possibility of benefiting from demographic transition in Iran. In addition to necessity of improving international diplomacy, Iranian state needs to address the curse of oil by reducing the vulnerability of economic system to oil revenues shocks. One of the main reasons behind the youth unemployment in Iran is dependence of economy to oil rents which crowds out the productive manufacturing sector in long run. By increasing rent-seeking behavior, it also dampens to entrepreneurship activities and private business formation. Increasing working age population in an oil based economy has less chance of working in productive fields, reducing the manifestation of demographic bonus (see Farzanegan, 2014 for entrepreneurship effects of oil rents). Corruption among other dimensions of quality of governance plays a key role in

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

political stability effects of demographic transition. Farzanegan and Witthuhn (2014) use panel data from 2002–2012 for more than 150 countries and show a negative interaction effect between the relative size of the youth population within the total working age population and corruption on political stability. In other words, demographic transition can lead to instability in corrupt countries. Thus, the Iranian state and civil society need to care about control of corruption in order to reduce the risk of demographic curse for political stability of country.

Future research should take into account the role of increasing informal economy in final effects of demographic transition on conflict and economic growth. The informal economy which is evading formal regulations and monitoring is feeding a large number of population in developing countries, providing employment opportunities for a large army of unemployed in the formal economy. This may have crucial implications for the internal stability, income distribution and economic development (Badreldin and Farzanegan, 2014).

## ENDNOTES

1 For application of Polity index as an indicator for quality of political institutions in different contexts see for example, Buehn and Farzanegan (2013), Biswas, Farzanegan and Thum (2012), Bjorvatn and Farzanegan (2013), Bjorvatn, Farzanegan and Schneider (2012).

2 For a sufficiently large time horizon, the bias from fixed effects dynamic panel data model is supposed to be small (Nickell, 1981).

3 The discussion on Vanhanen Index is based on Bjorvatn, Farzanegan and Schneider (2013)

4 http://www.prsgroup.com/ICRG_Methodology.aspx

5 More information: http://info.worldbank.org/governance/wgi/index.asp

6 Kramarenko et al. (2008) estimated the size of implicit subsidies in the energy sector of Iran. According to their estimation, forgone revenue due to domestic sales (in billions USD) which is highly subsidized amounted to 11.9, 10.9 and 11.2% from 2005-2007. This corresponds to a loss of 22,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

24, and 32 billion USD in government revenues through selling energy products with subsidized prices. These massive implicit subsidies on energy products distort the real size of dependency of the Iranian economy and government budget to oil revenues.

# Chapter 69
# Green Convergence in Emerging Nations:
## The Determinants and the Possibilities

**Gagari Chakrabarti**
*Presidency University, India*

**Chitrakalpa Sen**
*BML Munjal University, India*

## ABSTRACT

*Convergence in growth for emerging nations has always been an important topic of economic discourse. This study looks into the growth convergence of selected basket of emerging nations towards selected basket of developed nations using Autoregressive Distributed Lag (ARDL) framework. The findings of the study show that not only the economic indicators of the respective emerging nations are responsible towards narrowing the per capita GDP differential between developed and emerging nations, but also the differentials of economic indicators between developed and emerging nations are important. This helps towards answering the paradoxical question why in spite of taking the best measures the developing countries are unable to match up with their developed counterparts' per capita GDP. Finally, the study shows significant positive relationship between GDP growth rate and carbon dioxide emission.*

## INTRODUCTION

The theory of economic convergence suggests that economies with similar population growth and technological knowhow will exhibit similar levels of productivity and per capita GDP in the long run. Therefore, countries with lower capital stock will grow more rapidly than countries with higher capital stock, closing the income gap eventually (Mankiw, 2012).In recent years, convergence of markets in the emerging nations has garnered significant attention. However, empirical studies have repeatedly shown less than desired results of convergence. The explanations for this phenomenon are a much debated topic.

Jeffrey Sachs (1997) blamed the trade policies of developing countries for the slowdown off convergence, while the Lucas Paradox (1990) tried to explain the non-convergence with the fact that capital doesn't move from developed countries to developing countries. According to a 2011 study by investment firm BlackRock, "by 2020 the investment world is expected to be spending even more time on the emerging markets … developments in Beijing, Mumbai and Sao Paolo will … require as much study as those in New York, London and Frankfurt" (Blackrock Investment Institute, 2011). However, more recent studies have found evidences of slowdown of the emerging markets in the catching-up game (Amaya & Iwanicki, 2014) in the short run. However, the possibility of long run convergence could not be refuted. Therefore, it would be interesting to examine from both an academic as well as investment perspective to identify the reasons behind the convergence performance of emerging markets.

In Figure 1, the per capita GDP of eight emerging nations (four Asian economies: India, Indonesia, Malaysia and China and for Latin American economies: Mexico, Argentina, Brazil and Chile) for 2000-2013 are plotted. The plot shows a clear trend. Starting from 2000, the Latin American economies have experienced a higher per capita GDP than the Asian economies except Malaysia. Of the four Asian economies, India, Indonesia and China started from less than a thousand dollars of per capita GDP in 2000. Of these three, the per capita GDP of India has grown the slowest over the next 13 years while China has grown faster than these two, especially after 2006. However, a clear outlier in the Asian economies is Malaysia. Even in 2000, the per capita GDP of Malaysia was significantly higher than that of India, Indonesia and China. While in 2000, all the three nations had a per capita GDP of less than $ 1000; Malaysia was enjoying a per capita GDP of slightly more than $ 4000. Malaysia is clearly in the league of the Latin American economies of Mexico, Argentina, Brazil and Chile. In fact, after 2009, Malaysia's GDP has grown similar to Mexico. Among the Asian economies, only China has been successful in significantly closing the per capita GDP Gap with the Latin American economies.

In figure 2, the per capita GDP for eight developed countries, UK, USA, Belgium, Japan, Canada, Germany, France and Switzerland has been plotted. The figure shows that the per capita GDP of the developed countries have moved more or less similarly over the years.

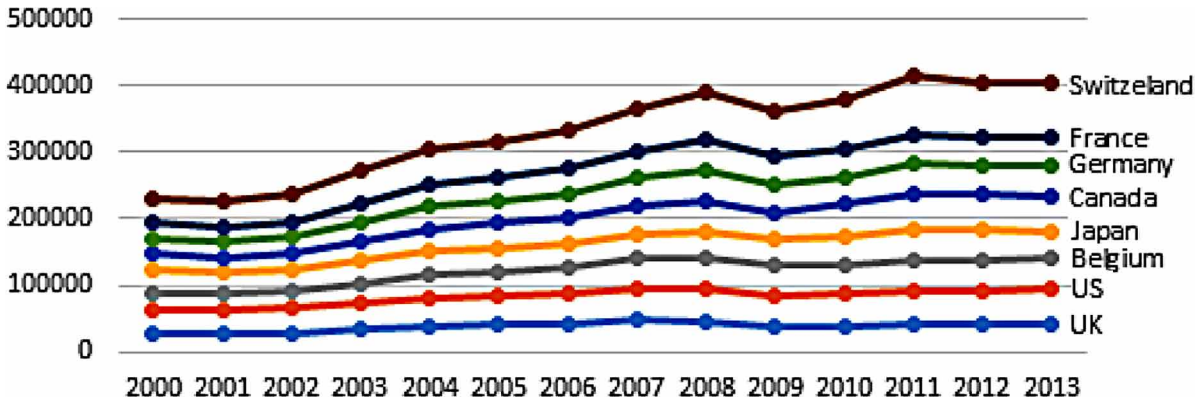

*Figure 1. Per capita GDP across emerging nations: 2000-2013*

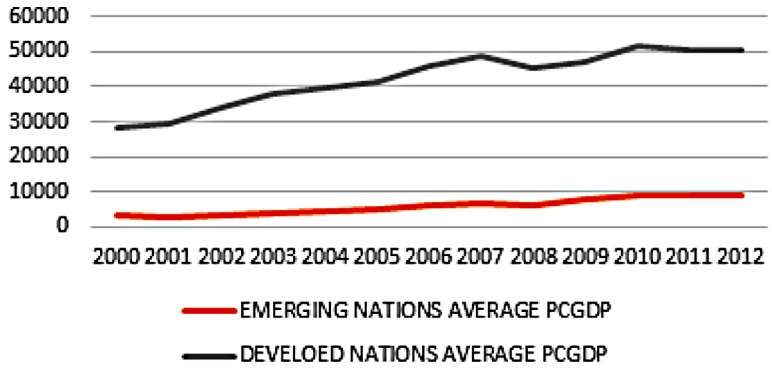
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 2. Per capita GDP of developed nations: 2000-2013*

A quick look at the two figures makes two things clear. First, among the selected emerging nations, some countries perform significantly better in terms of achieving a higher per capita income than the others. Second, there is a drastic gap between the per capita income of the emerging nations and the developed nations. Among our selected emerging nations, in 2013 the country with the highest per capita GDP is Chile with $15732.5 while among the developed nations, the country with the lowest per capita GDP in 2013 is Japan with $38633.7, more than twice of Chile's per capita GDP. Switzerland has the highest per capita GDP in 2013, $847 48.4, almost seven and a half time higher than that of Chile's.

The obvious question that comes at this point of time is whether these huge gap between the per capita GDP of emerging and developed nations decreasing, pointing towards a possible convergence. To understand the trend, the average per capita GDP for eight emerging countries and the average per capita GDP for the developed countries have been calculated for all 14 years in question. These two are then plotted in figure 3. It is quite evident from figure 3that, on an average, the gap between the per capita GDP of developed and emerging nations not only did not decrease, it actually increased significantly. This points towards the idea against convergence which says that capital accumulation leads to increasing returns to scale and therefore, economies that start with greater capital stock will eventually diverge from the poorer nations, typically with smaller capital stock.



## EARLIER WORKS

There has been a vast body of literature trying to identify the impact of performance variables on the growth rate. Empirically, some of the major positive determinants of economic growth have been found out to be in human capital (Lucas, 1993; Barro, 1998), technology (Kuznets, 1966), trade openness (Lockwood, 1954; Rodrik, 1999), institutions (North, 1990;Olson, Sarna & Swamy 1998; Acemouglu, Johnsonn & Robinson, 2001). However, the relationship of FDI and financial system with growth has been largely mixed (Borensztein, Gregorio & Lee, 1998; Campos & Kinoshita, 2002; Aziz & Duenwald, 2002; Mehl, Vespro & Winkler, 2006).While Barro and Sala-i-Martin (1999) have shown evidence of a negative impact of political instability on the growth rate, Kaufmann, Kray and Mastruzzi (1999) provided evidence for a significant influence of quality of governance on the per capita GDP. Barro's (2003) paper

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 3. Comparison of average per capita GDP of emerging and developed nations*

considered 113 countries and showed that "growth rate rises when the initial level of real per capita GDP is low relative to the starting amount of human capital in the forms of educational attainment and health and for given values of other variables that reflect policies, institutions, and national characteristic".

Borys, Polgár and Zlate (2008) conducted a panel data analysis on EU candidate and potential candidate countries to see the impact on growth. They considered variables such as impact of initial GDP per capita, investment, initial FDI stock, inflation, government balance as a percentage of GDP, economic freedom, exchange rate regime, trade openness, terms of trade, EBRD transition indicator, claims on the private sector as a percentage of GDP and a crisis dummy and found a significant impact of most of the variables on the growth rate.

However, one must also keep in mind the negative externalities of growth on the environment. Therefore, assessing growth merely in terms of per capita income may very well be misleading. The environmental Kuznets curve shows a negative relationship between environmental degradation and income growth. The seminal study by Grossman and Krueger (1995) has shown that the level of pollution and contamination of the environment is inversely proportional with the growth level, at least in the short run. According to Grossman and Krueger (1995), the improvement in the growth level doesn't take place till the per capita income hits $8000, which is a far cry from the current Indian per capita income. For a country like India, which is poised to touch double digit growth rate in near future (Business Standard, February 27, 2015), emphasis on the green convergence is of utmost importance.

However, the empirical evidences of the relationship between emissions and economic growth are mostly mixed. Zhang and Cheng (2009) found no significant relationship between emissions and growth in the long run in context of China over the period 1960 – 2007. Soytas, Sari and Ewing (2007) also found no discernible relationship between income and carbon emissions. Halicioglu (2009) provided evidence for a bidirectional causal relationship between carbon emissions and income growth in Turkey. Song, Zheng & Tong (2008) found strong relationship between environmental degradation and economic growth in context of China.

## OBJECTIVE OF THE STUDY

The objective of this study is to:

- Identify the long run equilibrium relationship between the growth rate and selected economic and institutional indicators for emerging countries and developed countries
- To identify any discernible pattern in the long run relationship for emerging countries and developed countries
- To identify whether on an average, the indicators play a significant role in changing the per capita GDP differential between emerging and developed nations in the desired direction
- To identify whether on for each individual emerging nation, the indicators play a significant role in changing the per capita GDP differential between emerging and developed nations in the desired direction
- Having identified the determinants of growth convergence, to identify whether the growth in emerging nations also cause a reduction in carbon dioxide emission.

## VARIABLES AND SAMPLE PERIODS

For the purpose of this study, the following variables have been selected:

1. Per capita GDP (PCGDP). According to the convergence theory, countries with lower per capita income will grow faster. Therefore, having it as the dependent variable help identify the determinants of per capita GDP. This data is collected from the Central Banks websites of the respective countries.
2. GDP growth rate (GDPGR): A higher and sustained GDP growth rate would help speed up the convergence. Calculated as the percentage change of GDP from previous year.This data is collected from the Central Banks websites of the respective countries.
3. Gross fixed capital formation as a percentage of GDP (GFCF) is included in the model as an independent variable to measure the overall level of investment in the country. This data is collected from World Bank's website.
4. Foreign direct investment, net inflows in current US dollars (FDI) is another independent variable that captures the investment in the country. Foreign direct investment has played a significant role in the growth dynamics of emerging nations. In countries like India, the growth in the last decade has been largely fueled by massive foreign direct investments. Foreign direct investment and directly influence growth and real convergence in two ways, first by allowing technological spillover accelerate growth and second by providing much-needed capital which is instrumental for growth. This data is collected from the Central Banks websites of the respective countries.
5. Rate of inflation (INFL) is included as an independent variable to control for the macroeconomic stabilization policies. Calculated as the percentage change of consumer price index from the previous year. This data is collected from the Central Banks websites of the respective countries.
6. International trade as a percentage of GDP (TRADE) is included as an independent variable to account for the trade openness of the country. This data is collected from the Central Banks websites of the respective countries.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

7. Net barter terms of trade index (TOT) have been included as an independent variable to capture the income position of the country's residents. The terms of trade index is calculated as the price of exports in terms of the price of imports. Therefore if the terms of trade index increases, the imports will become relatively cheaper and the income position of the country would improve, which in turn would translate into higher growth. This data is collected from World Bank's website.
8. Index of economic Freedom (FREE): The role of institutions has always been debated in growth theory. To measure the quality of institutions, the index of economic Freedom published by the Heritage Foundation is included as one of the independent variables.
9. All the variables are collected from 2000-2012, subjected to data availability.

## AUTOREGRESSIVE DISTRIBUTED LAG MODEL AND BOUNDS TEST

To estimate a long run relationship among the selected variables, an autoregressive distributed lag (ARDL) model is used. In this particular dataset, an ARDL model would be more appropriate than another dynamic panel data model such as an error correction model as the number of time series observations are relatively small, which may lead to complexities in modeling long run relationships using a ECM (Oxera, 2010). In an ARDL model, the dependent variable is expressed as a function of its own lagged terms as well as the current and past valued of a set of other regressors. A basic ARDL(p,q,q,…q) model with t = 1, 2, ….., T time periods and i = 1, 2, …., N groups, can be expressed as –

$$y_t = \beta_0 + \beta_1 y_{t-1} + ..... + \beta_k y_{t-p} + \alpha_0 x_t + \alpha_1 x_{t-1} + \alpha_2 x_{t-2} + ..... + \alpha_q x_{t-q} + \varepsilon_t,$$

or,

$$y_t = \sum_{j=1}^{p} \beta_j y_{t-j} + \sum_{j=0}^{q} \alpha_j x_{t-j} + \beta_0 + \varepsilon_t$$

where $x_t(k\times1)$ $\left(k\times1\right)$ is a vector of regressors for group i,

$\beta_0$ represents the fixed effect
$\beta_j$ are scalars, and coefficients of lagged $y_t$
$\alpha_j$ are coefficient vectors (k x 1)
$\varepsilon_t$ is the random error term

The ARDL/Bounds test methodology as suggested by Pesaran and Shin (1999) and Pesaran, Shin and Smith (2001) has additional advantages over other tests of cointegration as the long run estimated coefficients are efficient, even if the regressors are I(0) or I(1) or a mix (Pesaran and Shin, 1995). However, in presence of I(2) regressors the model will not work (Giles, web).

For any I(d) variable, (where d = 0 or 1), the bounds test provides a lower value of F-statistic assuming a I(0) process and a upper value of F-statistic assuming a I(1) process. It tests the null hypothesis of $\beta_j=\alpha_j=0$ or no significant long run relationship against the alternate hypothesis $\beta_j\neq\alpha_j\neq0$ or significant

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

long run relationship. If the calculated F-statistic is greater than the upper bound, the null hypothesis of no long run equilibrium relationship can be rejected and if the calculated F-statistic is less than the lower bound, the null hypothesis of no long run equilibrium relationshipcannot be rejected.For any F-value that fall within the bound, the result is inconclusive.

To understand the long run dynamics between the growth and economic indicators, the study estimates three ARDL models.

**Model 1:** Convergence indicator: Growth rate.

This model estimates two independent ARDL models. The first model tries to examine the long run equilibrium relationship between growth rate of emerging nations (dependent variable) and the selected indicators from the emerging nations (independent variable). The second model examines the same long run relationship, but in context of developed countries.

The models can be expressed as –

**Model 1.1:**

$$GDPGR_{it-1}^{EMER} = \beta_0 + \sum_{j=1}^{p}\beta_1 GDPGR_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_1 GFCF_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_2 FDI_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_3 INFL_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_4 TRADE_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_5 TOT_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_6 FREE_{it-1}^{EMER} + \varepsilon_t$$

**Model 1.2:**

$$GDPGR_{it-1}^{DEV} = \beta_0 + \sum_{j=1}^{p}\beta_1 GDPGR_{it-1}^{DEV} + \sum_{j=0}^{q}\alpha_1 GFCF_{it-1}^{DEV} + \sum_{j=0}^{q}\alpha_2 FDI_{it-1}^{DEV} + \sum_{j=0}^{q}\alpha_3 INFL_{it-1}^{DEV} + \sum_{j=0}^{q}\alpha_4 TRADE_{it-1}^{DEV} + \sum_{j=0}^{q}\alpha_5 TOT_{it-1}^{DEV} + \sum_{j=0}^{q}\alpha_6 FREE_{it-1}^{DEV} + \varepsilon_t$$

**Model 2:** Rather than looking only at the emerging or developed countries growth pattern, it is often useful to take a look at the per capita GDP gap between developed and developing nations to understand whether the developing nations are indeed marching towards the developed ones. The second model attempts to examine the long run relationship between the per capitaGDP differential between developed and emerging nations (*PCGDP_D:*dependent variable) and individual emerging country indicators (independent variables). For that purpose, the study estimates an ARDL model.

$$PCGDP_{Dit} = \beta_0 + \sum_{j=1}^{p}\beta_1 PCGDP_{Dt-j} + \sum_{j=0}^{q}\alpha_1 GFCF_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_2 FDI_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_3 INFL_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_4 TRADE_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_5 TOT_{it-1}^{EMER} + \sum_{j=0}^{q}\alpha_6 FREE_{it-1}^{EMER} + \varepsilon_t$$

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

If the coefficients are found to be significant, it implies that by controlling the country's own economic policies it is possible to control the GDP gap between developed and emerging nations.

**Model 3:** The third model attempts to examine the long run relationship between the per capita GDP differential between developed and emerging nations (dependent variable) and differences in indicators for individual emerging country and developed country (independent variables). For that purpose, the study estimates an ARDL model.

$$PCGDP_D_{it} = \beta_0 + \sum_{j=1}^{p}\beta_1 PCGDP_D_{t-j} + \sum_{j=0}^{q}\alpha_1 GFCF_D_{t-j} + \sum_{j=0}^{q}\alpha_2 FDI_D_{t-j} + \sum_{j=0}^{q}\alpha_3 INFL_D_{t-j} + \sum_{j=0}^{q}\alpha_4 TRADE_D_{t-j} + \sum_{j=0}^{q}\alpha_5 TOT_D_{t-j} + \sum_{j=0}^{q}\alpha_6 FREE_D_{t-j} + \varepsilon_t$$

where,

PCGDP_D (dependent variable): average per capita GDP of developed countries less the average per capita GDP of emerging countries.

INFL_D (independent variable): average rate of inflation in developed countries less the average rate of inflation in emerging countries.

GFCF_D (independent variable): average gross fixed capital formation as a percentage of GDP in developed countries less the average gross fixed capital formation as a percentage of GDP emerging countries.

FDI_D (independent variable): average foreign direct investment in developed countries less the foreign direct investment in emerging countries.

TRADE_D (independent variable): average international trade as a percentage of GDP in developed countries less the average international trade as a percentage of GDP in emerging countries.

TOT_D (independent variable): average terms of trade developed countries less the average terms of trade in emerging countries.

FREE_D (independent variable): average index of economic freedom in developed countries less the average index of economic freedom in emerging countries.

**Model 4:** The growth pattern in the emerging nations has largely been inefficient and unsustainable. Green growth has always been an important objective for the emerging countries to achieve. Although the emissions by emerging nations remain smaller than that of the developed nations, in the last few decades, the emission done by the emerging nations have increased significantly. In recent past, in the wake of significant global warming, it is of utmost importance for all the nations to reduce their carbon footprints. The onus is more so on the emerging nations because their emissions are usually higher than the developed countries. However, straddled with low per capita income and a target keep up with a satisfactory GDP growth rate year by year, it gives the poorer emerging nations little headspace to adopt greener technologies, which are more expensive and not immediately profitable. Therefore, the invariable question remains, whether maintain a satisfactory GDP growth rate, the emerging nations compromise with their emissions.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Continuous environmental degradation, eventually leading to scarcity of food, clean water and energy will have significant socio-economic impact. Therefore, to achieve green growth, efficient planning is of paramount importance. A study by Gramkow (2012), in the context of Brazil, has in fact provided evidence towards the fact that by taking correct fiscal policy, green growth can be achieved. However, given constrained resources and often failed governance, achieving green growth has remained quite elusive for the emerging nations (Worldbank, 2012). Hynes and Wang (2012) have exhaustively outlined the outcomes of green growth, especially in context of emerging nations. Their paper has divided the benefits into three categories, economic, environmental and social. The economic benefits are - higher and more equitable distribution of GDP, boost in the production of ecosystem services and therefore revenues brought by them, economic diversification of risk, greater innovation towards development of green technologies. The environmental benefits are - increased productivity and more efficient use of natural resources, usage of natural capital win within the limit, greater usage of nonrenewable capital and reduction of adverse environmental impact on the economy. The social benefits are - better standard of living especially for the poor through new job creation and higher income, enhanced social, human and knowledge capital and reduction in inequality of income.

The question remains, are the fast growth in emerging nations necessarily green growths? Or do they promote a higher level of emissions?To answer this question, this study investigates the relationship between growth rate and environment friendliness of emerging nations, a ARDL model with carbon dioxide emission from energy usage as the dependent variable and GDP growth rate as an independent variable is estimated.

$$GDPGR_{it-1}^{EMER} = \beta_0 + \sum_{j=1}^{p} \beta_1 GDPGR_{it-1}^{EMER} + \sum_{j=0}^{q} \alpha_1 EMISSION_{it-1}^{EMER} + \varepsilon_t$$

For the ARDL models, the bounds test will test for the joint significance of the lagged variables using an F test and the following hypothesis,

**$H_0$:** $\beta_1 = \alpha_1 = \alpha_2 = \alpha_3 = \alpha_4 = \alpha_5 = \alpha_6 = 0$
**$H_0$:** $\beta_1 \neq \alpha_1 \neq \alpha_2 \neq \alpha_3 \neq \alpha_4 \neq \alpha_5 \neq \alpha_6 \neq 0$

## RESULTS

### Stationarity

First, stationarity of the variables are checked using the Augmented Dickey Fuller test. Table 1 and table 2 below shows the results for the emerging country variables and the developed country variables respectively. From table 1, it can be seen that except GDP growth rate, all other variables are I(1), while GDP growth rate is I(0). For the developed country variables as presented in table 2, except inflation all the variables are I (1) while inflation is I(0). All that is statistics are significant at a strong 1% level. As there is no I (2) variable, the data are for use in an ARDL model.

## Model 1.1: ARDL and Bounds test for Emerging Countries

The ARDL model is estimated for the emerging country variables. The appropriate order of the model is selected using the Akaike information criteria. The model with the lowest AIC is chosen (Figure 4). In this case, the selected model is ARDL (1, 0, 1, 3, 0, 1, 2). The result from the estimated ARDL model is summarized in Table 3. as it can be seen, one period lagged gdp growth rate, foreign direct investment (current, first lag and third lagged), terms of trade (current and one period lagged) and one period lagged economic freedom have significant impact on current gdp growth rate in the emerging countries. to be noted here, although the impact of fdi looks very small, this is due to the unit selected (fdi is considered as us $, so the impact of an increase of $1 million us$ would have an impact 1,000,000 times larger.

an important condition for the estimated parameters to be consistent is that there should not be any serial correlation among the error terms of the model. to check it, the autocorrelation and partial autocorrelation till 15 lags have been checked. based on the q statistics and the corresponding probability values, no significant evidence of autocorrelation is found. the result is summarized in Table 4.

In the final step, the bounds test is performed. The result is summarized in Table 5. The F statistic is clearly higher than the 5% significance level per pound and therefore the null hypothesis of no long run relationship can be rejected.

To summarize, it can be concluded that for emerging economies, there exists a long run equilibrium relationship between the growth rates and the selected variables with appropriate lags. However, the impacts of all the variables at all the lags are not statistically significant.

## Model 1.2: ARDL and Bounds Test for Developed Countries

As a natural progression of the study, the long run relationship between growth rate and the selected variables for developed countries are also examined. The purpose is to identify any discernible difference in the relationship among the variables than in the emerging countries. In the next steps, the ARDL process is repeated for developed countries. The optimum estimated model is ARDL(1, 3, 2, 1, 0, 0, 0), the lag length is selected based on the minimum Akaike information criteria (Figure 2).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 3. Result of ARDL model for relationship between growth rate of emerging nations and the selected indicators from the emerging nations (model 1.1)*

| **Selected Model: ARDL(1, 0, 1, 3, 0, 1, 2)** | |
|---|---|
| **Variable** | **Coefficient** |
| gdpgr(-1) | 0.2334** |
| infl | -0.0359 |
| gfcf | 0.0211 |
| gfcf(-1) | 0.1809 |
| fdi | 2.46e-11** |
| fdi(-1) | -2.96e-11** |
| fdi(-2) | 8.90e-12 |
| fdi(-3) | -1.63e-11** |
| trade | 0.0019 |
| tot | 0.0681*** |
| tot(-1) | -0.0721*** |

| free(-1) | -0.3781*** |
| free(-2) | 0.1351 |
| c | 3.6753 |
| akaike info criterion | 4.732526 |
| adjusted r-squared | 0.4779 |
| f-statistic | 7.538168 |
| prob(f-statistic) | 0 |

***, **and * implies significance at 1%, 5% and 10% level respectively

Table 6 below shows the results from the ARDL estimation. Inflation (current and one period lagged), current GFCF and the current terms of trade have significant impact (at 5% level) on the current growth rate. Although FDI (current and 1 period lagged) also have some impact, it is significant only at 10% level. For the variables which are indeed significant, the magnitude of the impact is significantly higher than in the emerging countries. The correlogram in table 7 suggests that there is no significant autocorrelation till 15 past lags. Therefore, the estimated coefficients presented in table 6 are indeed efficient.

The F statistic found from the bounds test is higher than the upper bound at 5% level (table 8) and as a result, the now hypothesis of no long-run relationship is rejected.

To summarize, there exists a long-run equilibrium relationship between the growth rate and the selected variables in context of developed countries. However, very few variables are in fact significant in their impact on the current growth rate.

Before model 2 and model 3 are run, which involve the difference variables, their stationarity is tested to ensure usability for the ARDL model. The result of ADF test for the difference variables are summarized below in Table 9.

## Model 2: ARDL and Bounds Test for Estimating the Long Run Relationship Between the Per Capital GDP Differential Between Developed and Emerging Nations and Individual Emerging Country Indicators

Next, the study estimates model 2 in order to estimate long run relationship between the per capital GDP differential between developed and emerging nations and individual emerging country indicators. The selected model is ARDL(2, 0, 1, 1, 0, 1, 2) as per the Akaike information criteria (Figure 3). The results from the ARDL model (table 10) suggest that per capita GDP (1 and 2 period lagged), previous year's inflation, FDI (current and 1 period lagged), GFCF (current and 1 period lagged), terms of trade (current

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 6. Result of ARDL model for relationship between the GDP growth rate between developed and emerging nations and individual emerging country indicators (model 1.2)*

*Figure 5. Akaike criteria to estimate ARDL model using developed country variables (Model 1.2)*

and 1 period lagged) and economic freedom (2 period lagged) play a significant role in determining the per capita GDP differential.

The correlogram suggests no autocorrelation till 15 lags (Table 11), so bounds test is employed (Table 12).

The results from bounds test show that the F-statistic is clearly higher than the 1% upper bound, therefore it can be concluded that there exists a significant long run equilibrium relationship in the long run.

## Model 3: ARDL and Bounds Test for Estimating the Long Run Relationship Between the Per Capita GDP Differential Between Developed and Emerging Nations and Differences in Indicators for Individual Emerging Country and Developed Country

Results from the ARDL model for long run relationship between per capita GDP differential between developed and emerging nations and differences in indicators for individual emerging country and developed country are summarized in table 13. The result shows that per capita GDP gap in current period is dependent on past periods GDP differentials (up to 4 lags, all significant at 1%), gross fixed capital formation differential (first lag), foreign direct investment differentials (up to 3 lags, all significant at 1%) and terms of trade differentials (current, first and third lag).

The estimated model is ARDL(4, 2, 1, 3, 0, 3, 0), selected on the basis of Akaike Information Criteria (Figure 4). Also, the correlogram suggest no serial autocorrelation till 12 lags (Table 14).

The bounds test result (Table 15) shows that the F statistic is greater than the 1% upper bound, therefore rejecting the null of no long run equilibrium relationship.

## Model 4. ARDL Model With Emission Differential and Per Capita GDP Gap Between Developed and Emerging Nations

Having clearly established the possible determinants of the growth rate and the GDP differential, the study now shift towards estimating the impact of growth on the emerging countries carbon footprints. For this purpose, a ARDL model is estimated with per capita GDP for emerging nations and the annual carbon dioxide emission from energy usage in emerging nations, with the emission differential as the dependent variable. The emission data turns out to be I(1), as suggested by the result of the unit root test (Table 16) and therefore is fit to be estimated using ARDL model.

Table 17 summarizes the result of the ARDL model. The result shows that current year's differential in emission in emerging countries is significantly (at a strong 1% level) influenced by previous year's emission and current year's GDP growth rate. The suitable model is ARDL(1, 2), according to Akaike information criteria (Figure 5).

*Figure 7. Akaike Information Criteria for Model 3*

As a part of post estimation testing, the correlogram in table 18 shows that even till 15 lags, there is no sign of any significant autocorrelation.

The result from the bounds test shows that the F statistic is greater than the I(1) bound therefore confirming a stable long run equilibrium relationship between the growth rate and carbon dioxide emission in the emerging nations.

## CONCLUSION AND FURTHER ISSUES TO EXPLORE

Widening per capita GDP gap with developed nations has long been one of the most talked about problems for the emerging nations. Paradoxically enough, often it has been seen that in spite of the right policy mix adopted by the governments, the gap does not narrow down. This study wanted to look at that problem in the light of dynamic ARDL model. To look at the problem, the study fits four ARDL models.

The first model looked at the problem from an absolute perspective. It investigated, from both emerging as well as developed nations' perspective, the contributors to economic growth. The results showed that for emerging nations, current GDP growth rate is significantly dependent on the GDP growth rate from the immediately previous year, FDI (current year, one lagged year and third lagged year), terms of trade (current and previous year) and economic freedom (immediately previous year). The bounds test

suggests that there exists a significant long term equilibrium relationship. For the developed nations, GDP growth rate is significantly dependent on the GDP growth rate from the immediately previous year, FDI (current and two period lagged), current terms of trade, current economic freedom and gross fixed capital formation (one period lagged).

The second model emphasized on per capita GDP differential rather than the country's own per capita GDP. In the process, it estimates long run relationship between the per capital GDP differential between developed and emerging nations and individual emerging country indicators. The results show that per

capita GDP (1 and 2 period lagged), previous year's inflation, FDI (current and 1 period lagged), GFCF (current and 1 period lagged), terms of trade (current and 1 period lagged) and economic freedom (2 period lagged) play a significant role in determining the per capita GDP differential and also, the relationship is stable in the long run. Both emerging and developed nations' growth rate are significantly guided by a number of economic variables' current and lagged values. Also, the per capita GDP differentials for emerging countries are significantly influenced by the economic indicators of the emerging nations

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

themselves. This finding has a significant policy implication as it points towards the fact that by changing the policy variables in the desired direction, it is possible to control the widening per capita GDP. The onus in this case, remains entirely with the emerging nations' governments to take the steps in the right direction towards minimizing the worrying per capita GDP gap.

The thirdmodel narrowed down the focus even more and tries to see if the per capita GDP differentials are influenced significantly by the differentials in the indicators themselves. The results show that per capita GDP gap in current period is dependent on past periods GDP differentials (upto 4 lags, all significant at 1%), gross fixed capital formation differential (first lag), foreign direct investment differentials (up to 3 lags, all significant at 1%) and terms of trade differentials (current, first and third lag). This result gives an important insight regarding possible policy measures. According to this result, the difference in indicators is most important. Therefore, it gives the emerging countries governments a little head space, as if the developed nation's policies change in the desired direction, it is possible for the per capita GDP gap to narrow down, even if the developed countries do not take any action themselves. However, this also has a flip side. Even if the emerging nations to everything right by taking policies in the right direction, the per capita GDP gap may widen due to undesirable movement in the policy variables in the developed nations. In a nutshell, rather than absolute values of the variables themselves the gap or the differential plays a more significant role.

Having identified the determinants of growth and per capita GDP differentials, the study focused on the possibility of green growth among emerging nations. Even if an emerging country's per capita GDP increases, does it come at the cost of its environment friendliness? To answer this question the long-term relationship between carbon dioxide emissions and GDP growth rate for emerging nations, with the emissions being the dependent variable. The result shows that there is a significant positive relationship between growth rate and emissions. Therefore, the study highlights the dilemma of choice for policymakers. On one hand, the importance of a higher growth rate to ensure higher per capita GDP and a better standard of living is well understood, but also the high growth rate brings in higher emissions. How to control the correct policy variables which will have a negative impact on the emissions but a positive impact on the growth rate, remains to be investigated in future research.

## KEY TERMS AND DEFINITIONS

**ARDL Model:** Autoregressive distributed lag model, where the dependent variable is a function of its own past lagged values as well as current and past values of other explanatory variables.

**Convergence:** The phenomenon of poorer economy's' per capita GDP growing faster than developed countries' per capita GDP before eventually catching up.

**Emerging Nation Growth:** In this study, the emerging nations' (the eight emerging nations selected) growth is calculated by the percentage change in GDP from previous year.

**Green Growth:** Is the GDP growth that is consistent with low GHG gas emissions.

**Gross Fixed Capital Formation:** It is a measurement of the net increase in the capital stock in a particular period. The calculation excludes depreciation or land purchases.

**Index of Economic Freedom:** The Index of economic Freedom is an annual index used to measure the degree of economic freedom in 186 countries calculated using 10 factors of economic freedom such as business freedom, fiscal freedom, property rights etc.

**Index of Economic Freedom:** The Index of economic Freedom is an annual index used to measure the degree of economic freedom in 186 countries calculated using 10 factors of economic freedom such as business freedom, fiscal freedom, property rights etc.

**Net Barter Terms of Trade Index:** Defined as the ratio of a country's exports price index to its imports price index.

**Per Capita GDP Differential:** The per capita GDP differential is calculated by subtracting per capita GDP of emerging nations from per capita GDP of developed nations.

# Chapter 70
# M&A Deals and Corporate Governance Framework:
## A Study in Indian Telecom Sector

**Sohini Ghosh**
*Birla Institute of Technology, Mesra, Kolkata Campus, Kokata, India*

**Sraboni Dutta**
*Birla Institute of Technology, Mesra, Kolkata Campus, Kolkata, India*

## ABSTRACT

*The escalating importance of mergers and acquisitions (M&A) has coincided with concerns about corporate governance issues. This article investigates how corporate governance mechanisms along with firm-specific control variables impact performance during M&A deals occurring between 2000-2012 in acquiring Indian telecom companies. In this research, firm performance has been measured via accounting based, market based and qualitative performance dimensions, represented by Return on Capital Employed (ROCE), Tobin's Q and Human Capital Return on Investment (HCROI) respectively. Panel data regression techniques was employed for the analysis. The learning from this study reveals that board size and firm size have significant positive relationships with ROCE and HCROI. Chairperson-CEO duality also has positive significant association with ROCE. Shareholding percentage of institutional investors was found to have a significant negative relationship with HCROI. Board independence, firm size and market share significantly affect Tobin's Q.*

## INTRODUCTION

Corporate governance broadly refers to a set of exercises that is designed to govern the behavior of corporate enterprises. It aims to promote healthier corporate practices and check the felonious firms. Board of directors of a firm have the fiduciary duty to play an important role in all vital firm decisions. Board characteristics that affect the effectiveness of the directors can potentially influence firm performance.

Keeping in view the emerging importance of corporate governance mechanisms in determining firm performance, several corporate governance guidelines have been framed worldwide since the 1990s. Some of the noteworthy reports are Cadbury Committee Report (1992), Market Specific Principles- Japan and Germany (1997), Core Principles and Guidelines- USA (April 1998), Hampel Report on Corporate Governance- UK (January 1998), The Sarbanes-Oxley Act – USA (August 2002) and The Higgs Report- UK (January 2003).

The first formal and exhaustive endeavour to evolve a code of corporate governance for Indian companies was undertaken by Securities and Exchange Board of India (SEBI). Thereafter the Ministry of Corporate Affairs recommended changes in diverse areas of corporate audit and governance and highlighted the role of independent directors. SEBI also made recommendations with respect to financial and non-financial disclosures, independent auditing and board oversight of management. Clause 49 of the Listing Agreement issued by SEBI makes it mandatory for the listed firms to disclose their ownership data of promoters and non-promoters separately. The improvement in corporate governance standards in India during the recent years as a result of numerous initiatives undertaken by the government, has been disclosed in the World Bank's Doing Business Report. Over the past decade, India significantly bettered its rank amongst other nations, with respect to protection of investor and minority rights. According to the report, India ranked seventh among all economies surveyed in 2015 and is ahead of several developed economies. Stringent audit and reporting standards as required by the amended Companies Act, 2013 have increased disclosures in India. Moreover, the market regulator SEBI's tightening of the rules relating to protection of minority shareholders' interests along with an escalation of investor activism have resulted in an improved corporate governance environment in India. It is thus needless to say that this constantly evolving governance framework in a developing nation like India draws academic attention towards examining the role of corporate governance mechanism in Indian corporations and its implications thereof.

The other focus area of this paper are mergers and acquisitions (M&As) which have increasingly become an effective tool for corporate restructuring. M&A decisions are critical to the success of corporations as they are instrumental in achieving greater efficiency by exploiting synergies and growth opportunities. These events are noteworthy not only because of the high levels of financial investment involved but also may be due to their failure rates. No more than 50% of M&As attain the level of success initially predicted (Cartwright & Cooper, 1996). The authors feel that it is important to examine if corporate governance mechanism which entails an effective and suitable board structure along with the role of institutional investors can enhance corporate performance and maximise shareholder value consequent to mergers.

The reason for focusing specially on mergers in the Indian telecom sector requires deliberation. Firstly it needs to be pointed out that India is on a growth trajectory resulting in a rapidly emerging and diversified business environment. In 2017, American Foreign Policy Magazine has ranked India sixth amongst eight great powers in the world. According to The World Bank, Indian economy is expected to grow at 7.9% in 2017-18. The germination of this growth can be traced back to the Liberalisation, Privatisation, Globalisation (LPG) model embarked upon by the Indian government in 1991. This has led to a radical transformation in the business scenario of the nation, enabling the Indian firms to grow extensively as well as drawn the attention of the multinational corporations in India as an investment avenue. The United Nations Conference on Trade and Development (UNCTAD) World Investment Report 2016 announced that India has secured the sixth position as the most preferred investment destination nations, attracting largest FDI inflows across the world in 2015. In fact, the Indian service sector received the highest FDI

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

(US$ 7553 million) among the other sectors in 2016-2017 with telecommunication accounting for US$ 5539 million. It is also noteworthy that the fiscal year 2016-2017 has struck a record number of M&A deals worth $61.26 billion in India. The significant rise was owing to intense buying interest of foreign buyers and consolidation proceedings across different sectors including telecom. Experts are of the opinion that the M&A activities in 2017 is expected to grow due to unrelenting attention of financial and strategic investors in the Indian economy.

The motive behind considering the Indian telecom sector as the domain of study in this paper, can be attributed to its phenomenal growth, making India the world's second-largest telecommunications market during 2016-2017. It is also predicted to grow at 10.3% annually to reach US$ 103.9 billion by 2020. Moreover, the International Data Corporation (IDC) predicts India to overtake US as the second-largest smartphone market globally by 2017. The business milieu in the Indian telecom sector has shown fundamental expansion due to the reforms implemented by Telecom Regulatory Authority of India (TRAI) and Department of Telecommunications (DoT) post 1991. This study has chosen to examine M&As in this sector because many Indian telecom companies have opted for the inorganic growth strategy of M&As to enhance their performance. The telecom sector has witnessed some of the biggest M&A deals in India namely Vodafone–Hutchison Essar merger in 2007, Idea Cellular merger with Spice Communications in 2008 and Reliance Industries–Infotel merger in 2010. Some of the forthcoming deals that have drawn attention recently are the Reliance Communications and Aircel merger and Vodafone – Idea merger.

This paper has concentrated on 16 M&A deals in the BSE-listed Indian telecom companies during a timeframe spanning from 2000-2012 to determine how the events of M&As have brought about changes, if any, in the business performance of the acquirers. This study probes the relationship between corporate governance profiles of firms and performance changes concomitant with M&A. Focusing solely on the accounting measures like ROCE (Return on Capital Employed) does not give a comprehensive and holistic view of a firm's performance. Thus this study has found it prudent to also include measures which reflect market based as well as qualitative performance in the form of Tobin's Q and HCROI (Human Capital Return on Investment) respectively. The data was analysed using panel data regression technique. By combining time series of cross-section observations, panel data give "more informative data, more variability, less collinearity among variables, more degrees of freedom and more efficiency." By studying the repeated cross section of observations, panel data are better suited to study the dynamics of change.

## LITERATURE REVIEW

Corporate governance practices during an M&A have attracted considerable academic interest. Several theories have been proposed in this regard. The theories that are relevant to this study are Stewardship Theory and Resource Dependency Theory. Stewardship theory presents a model of management where managers are considered as good stewards who will act in the preeminent concern of the owners. According to the resource dependency role, the directors bring resources and legitimacy that will reduce uncertainty, thus justifying the appointment of directors to multiple boards because of their opportunities to gather information and network.

Corporate governance practices prevalent in an organisation are regarded to have a noteworthy influence on the performance and growth of the firm. The variables which are of relevance in this study are: board size, chairperson-CEO duality, institutional investors and board independence. Empirical studies on how these variables affect firm performance have been discussed hereafter.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The impact of board size on firm performance is one of the most debatable issues in corporate governance. A constructive board structure is essential for augmenting firm performance as well as enhancing its stability. Research findings reveal mixed results regarding board size affecting firm performance. While researchers like Cheng et. al. (2008), Coles et. al. (2008), Guest (2009), Gill and Mathur (2011), Afzal and Nazir (2012), Gill and Obradovich (2012), Liu and Wang (2013) and Chu et. al. (2016) reported negative influence of board size on firm performance, Wintoki (2007) and Bennedsen et. al. (2008) divulged no relationship between these variables. Howeve,r Adams and Mehran (2005), Beiner et. al. (2006) and Dixit (2015) found a positive relationship.

Abdelkarim and Alawneh (2009) suggested that ownership concentration is negatively related to firm value. Pant and Pattanayak (2007) also pointed out this negative relationship when promoters' ownership is in the range of 0-49% while a positive relationship exists beyond that. On the contrary, Pattanayak (2008) and Ryu and Yoo (2011) identified a positive relationship between firm value and increment of insiders in ownership. With respect to ownership of institutional investors, Liu and Wang (2013) and Dixit (2015) observed that institutional investors had a positive influence on M&A performance. Ferreira et. al. (2010) and Andriosopoulos and Yang (2014) found that larger presence of institutional investors increases the probability of cross-border M&As because of reduction in information asymmetries and agency costs. Njah and Jarboui (2013) however, suggested that increased monitoring by institutional investors reduced the prospects of earnings during M&As.

The studies undertaken by Ramdani and Witteloostuijn (2010), Gill and Mathur (2011) and Rouf (2011), Gill and Obradovich (2012) and Liu and Wang (2013) stressed on a positive relationship between CEO duality and firm value. However, Mausulis et al. (2007), Afzal and Nazir (2012) and Dixit (2015) contented for separate positions for CEO and chairperson. Kim et al. (2008) inferred that CEO duality in firms leads to greater levels of unrelated diversification.

Finance theory predicts that board independence is not always in the shareholders' interest. Schmidt (2014) found that more friendly boards which are deemed as less independent enhance shareholder returns of firms engaging in acquisitions. However, when monitoring the CEO is of greater concern, social ties have a negative effect on the acquirer's performance. A positive influence on independent boards on firm value were reported by Afzal and Nazir (2012), Black and Kim (2012) and Claessens and Yurtoglu (2013). Gieben (2013) also declared that a board independence level of 61% to 70% will positively relate to M&A performance.

## Research Methodology

The research work is empirical and database oriented. Secondary data have been collected from the database Prowess, version 4.15 maintained by Centre for Monitoring Indian Economy Pvt. Ltd. (CMIE). These facts have been supplemented by information from different business magazines and government and respective company websites.

The data collected pertained to that of acquiring companies, as all relevant information of target firms was unavailable. 11 BSE-listed telecom companies have undergone 27 M&As in this timeframe. Many firms were engaged in a series of M&A activities over the observed time period. Thus, it is difficult to isolate the influence of a single M&A event. As a result, those overlapping M&As are not considered. Moreover, complete data for all the required parameters were unavailable for all the deals. Complete

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

data was obtained for 16 M&A deals. Thus 16 M&A contracts, representing 59.26% of the population, constitute the sample for this study. We collected data for four years, i.e. the year of M&A (t) and 3 consecutive years post-M&A (t+1, t+2, t+3).

The motive of this study is to evaluate the impact of corporate governance mechanisms on firm performance post-M&As for all the BSE-listed Indian telecom companies which underwent mergers during 2000-2012. We intend to capture firm performance from three dimensions, namely financial measures, HR measures and market performance measures. On the foundation of literature survey, we have selected three dependent variables for three models, viz- ROCE-Return on Capital Employed, HCROI-Human Capital Return on Investment and Tobin's Q. The formulae of each are shown below-

ROCE= Earnings Before Interest And Tax / Capital Employed
HCROI= [Revenue-(Operating Expenses –Compensation)]/Compensation
Tobin's Q= Market Value/Book Value

The independent variables, considered in our study, can be divided into corporate governance variables and control variables. The corporate governance variables comprise board size, CEO-chairperson duality status, institutional investors and board independence. Now we define the different corporate governance variables contemplated in this study. Board size represents the total number of directors on the board. Chairperson-CEO duality status is indicated by checking whether the chairperson and CEO is the same person, where one denotes duality and zero otherwise. Institutional investors are organisations that invest on behalf of its members which include endowment funds, commercial banks, mutual funds and hedge funds. Board independence specifies the number of independent directors divided by the total number of directors in the company. The control variables consist of firm age, firm size, leverage, current ratio, growth in turnover and market share. Firm age is calculated by the day the firm got listed in BSE till the day of M&A. Firm size is denoted by log of total assets. Leverage is measured by debt divided by equity. Current ratio is ascertained by current assets divided by current liabilities. Growth in turnover is represented by the formula- [{(Income in year t –(t-1)}/Income in t]X100 and market share is captured by the formula- [Firm's total income/Industry's total income) X 100].

This study aims to answer the following research questions via three regression models:

1. Effect of corporate governance parameters on ROCE during the merger event.
2. Effect of corporate governance parameters on HCROI during the merger event
3. Effect of corporate governance parameters on Tobin's Q during the merger event

We have employed panel data regression for analysis. The regression equations of the above mentioned three models are outlined as follows:

$$ROCE = \alpha + \beta_1 Board\ Size_{it} + \beta_2 Chairperson\text{-}CEO\ Duality_{it} + \beta_3 Institutional\ Investors_{it} + \beta_4 Board\ Independence_{it} + \beta_5 Firm\ Age_{it} + \beta_6 Firm\ Size_{it} + \beta_7 Leverage_{it} + \beta_8 Current\ Ratio_{it} + \beta_9 Growth\ in\ Turnover_{it} + \varepsilon_{it}$$

$$HCROI = \alpha + \beta_1 Board\ Size_{it} + \beta_2 Chairperson\text{-}CEO\ Duality_{it} + \beta_3 Institutional\ Investors_{it} + \beta_4 Board\ Independence_{it} + \beta_5 Firm\ Age_{it} + \beta_6 Firm\ Size_{it} + \beta_7 Leverage_{it} + \beta_8 Current\ Ratio_{it} + \beta_9 Growth\ in\ Turnover_{it} + \varepsilon_{it}$$

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{Tobin's Q} = \alpha + \beta_1 \text{Board Size}_{it} + \beta_2 \text{Chairperson-CEO Duality}_{it} + \beta_3 \text{Institutional Investors}_{it} + \beta_4 \text{Board Independence}_{it} + \beta_5 \text{Firm Age}_{it} + \beta_6 \text{Firm Size}_{it} + \beta_7 \text{Market Share}_{it} + \beta_8 \text{Leverage}_{it} + \beta_9 \text{Current Ratio}_{it} + \beta_{10} \text{Growth in Turnover}_{it} + \varepsilon_{it}$$

The data was analyzed with the help of MS-Excel and statistical software STATA.

## ANALYSIS AND DISCUSSION

The result of panel data analysis is displayed in the tables.

Table 1 titled, "Impact of Corporate Governance Variables on ROCE", reports an R square of 0.6221 and Wald Chi Square of 53.00 and denoted a significant impact of corporate governance variables on ROCE. The result points out that two independent corporate governance variables i.e. board size and chairperson-CEO duality are significant at 5% and 1% levels respectively. Both these variables are found to have a positive association with ROCE. This denotes that firms with larger boards enjoy a greater ROCE. Moreover, if the same person holds the dual positions of chairperson and CEO, ROCE of those firms are better. Among the control variables, firm size is significant at 5% level.

Table 2 titled "Impact of Corporate Governance Variables on HCROI" reports an R square of 0.4696 and Wald Chi Square of 30.10 depicted a significant impact of corporate governance variables on HCROI. Both board size and percentage of equity ownership held by institutional investors were the two corporate governance parameters found to be significant at 1% level. In this case too, we posit that firms having bigger board size impact HCROI more during the event of a merger. However, firms which have institutional investors holding substantial equity ownership report lower HCROI during the merger event. Firm size is the only control variable found to be significant at 1% level.

R square: 0.3021 Wald Chi Square: 9.09 Probability> Chi Square: 0.5237

Table 3 titled "Impact of Corporate Governance Variables on Tobin's Q" reported an R square of 0.3021 and Wald Chi Square of 9.09 In this regression, board independence is the sole corporate governance variable found to have a significant impact on Tobin's Q at 5% level. Among the control variables, both firm size and market share are significant at 10% levels as the dependent variable.

From this study, it was observed that companies comprising larger board size enjoyed better performance post-M&A. The possible cause for the success of larger board is that greater number of members enhances diversity in terms of skill sets as well as perspectives and may be considerably better equipped to handle organizational complexity. This helps to induce better brainstorming during decision making process and culminates in ratifying decisions which yield higher probability of success.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Stewardship theory of corporate governance reinforces that when the dual positions of CEO and chairperson are held by a single person, it enhances the firm performance. It can be concluded from this study that existence of CEO duality positively impacts the return parameters. The possible cause of this might be that if the same person holds dual positions, it facilitates prompt decision making and undertaking of calculative risks without unnecessary interventions.

Available literature suggests that presence of institutional investors facilitates M&As by connecting firms and thereby lowering the allied bargaining and transaction costs. These investors have bigger role to play in a developing country like India which is characterized by weaker legal frameworks, less developed capital markets and information asymmetry. However, results of this study do not conform to the existing literature. With larger presence of institutional investors, corporate governance mechanisms tend to be restrictive in nature and decisions which are risk averse in nature have higher probability of being undertaken, especially during a transition phase post-M&As. So this may be the reason why equity ownership of institutional investors has a negative association with return parameters such as HCROI.

This study reports that larger number of independent directors on board better the Tobin's Q measure of performance. This may be because the presence of independent directors on the board is found to enhance the decision-making process. These directors provide an imperative internal governance instrument for protecting shareholders' interests, especially in transactions such as mergers. While it is possible for insider directors to uphold specific interests/groups which they represent, it may be claimed that independent directors would most probably inject an element of objectivity in the decision-making processes in the board. This would help to endorse the general interests of the firm by enhancing performance parameters and thus benefit the interests of the smaller shareholders.

Among the control variables, firm size has been found to be significant in all of the three regression analyses discussed above. Positive relationship of firm size with the performance parameters reveal that M&As in larger firms tend to yield better returns in the post-merger phase. Firms with substantial asset base have the ability to enjoy economies of scale which become more enhanced after acquiring companies, thus resulting in increase in the market share of the firm. The large size of the acquirer firm helps it to realize benefits of synergies from M&As.

## CONCLUSION

Numerous researches pointed out that most M&A deals fail to be a success. This study tried to gain more insight into the problem so as to suggest a potential solution. In existing literature, there is evidence of studies focusing on the performance of companies, post the M&A event. The impact of corporate governance on firm performance has also been researched upon separately. However, research endeavour emphasizing the effect of corporate governance practices on firm performance during an event of M&A is scarce. This study attempts to address this research gap. Over here, an effort has been made to capture the consequence of corporate governance variables on firm performance during the phenomenon of M&A. Moreover, studies have mostly focused on financial outcomes of M&As. A research reflecting a holistic view of the performance of firms from three dimensions, namely-accounting, market based and qualitative based is a novel attempt. In India research on the impact of M&As in the service sectors is sparse. Those available, have focused on the banking and financial sectors. Thus, this research attempt exclusively dealing with the Indian telecom sector is a neoteric proposal. This study has consequently contributed new knowledge in the fields of corporate governance and M&A. Based on these results,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

telecom companies will get an opportunity to amend their corporate governance mechanisms in order to improve their M&A deal performance.

From this study, it can be safely pointed out that, firms having larger board size yield better results in the post-merger phase. Where the dual positions of CEO and chairperson are enjoyed by a single person, a positive significant association is found with the return parameters. It was concluded that the presence of independent directors in the board is found to enhance the decision-making process. Contrary to existing literature, the results reveal that greater presence of institutional investors has a significant negative impact on firm performance. Amongst the control variables included in the model, only firm size reported a positive and significant relationship with the dependent variables.

A constraint encountered in this research is the time span of the study. This study was restricted to a twelve-year time limit spanning from 2000-2012. No control group was used in the study. The target firms which had undergone M&A were not considered in the study due to apparent paucity of data.

The results of this study not only clarified concepts but also generated certain interesting queries. It might be thought-provoking to execute an analogous study on M&A deals in other sectors. A comparative analysis among different other sectors along the lines of this study could be carried out in future. Profile of CEOs influencing firm performance has been researched upon. However, as a way forward, future researchers could effectuate a study to see how individual differences between CEOs, in terms of age or education impact performance during M&A deals. This study paves a path towards further research on M&A performances using longer timeframe and also encourages inclusion of several other aspects of corporate governance that may affect the events of M&As.

# Chapter 71
# Strategic-Spatial Analysis of the Implementation of Business Opening Politics of Mexico

**José G. Vargas-Hernández**
https://orcid.org/0000-0003-0938-4197
*University of Guadalajara, Mexico*

## ABSTRACT

*The aim of this present chapter is to analyze the Mexican implementation strategy of trade policy openness due to the globalization trend, urging the country to create a series of trade agreements and treaties on free movement of goods and regional integration, becoming the country with the network of the world's largest trade agreements, increasing its presence and Mexican companies in international markets. Similarly, a spatial analysis of the last five governmental periods, comprising 26 years of foreign trade policies and its impact on foreign investments, foreign trade and main multinationals in Mexico, are done forcing them to centering in competitive productive processes and improving their internal organization, innovation and development.*

## INTRODUCTION

Deriving from globalization of foreign trade has created a series of trade agreements and treaties on free movement of goods, regional integration and economic integration processes between countries. This phenomenon has increased in most countries and Mexico is no exception. Mexico has experienced a steady increase in the internationalization of Mexican companies. This increase is largely due to the openness of trade policy adopted by the country. Following the entry of Mexico to the General Agreement on Tariffs Trade (GATT) in 1986, the country adopted business trends on multilateralism and regionalism, which has led to an increase in the internationalization of Mexican companies.

In light of the foregoing, from the late 1990's, Mexico has experienced an increase in investment abroad from large Mexican companies which have managed to cope with changes in international markets and structural adjustment policies (Vargas-Hernandez, 2011), so it follows that the support of the Mexican government to Mexican companies, as well as the impact of trade globalization, results in a sustained internationalization of Mexican companies increase.

## ADOPTION OF OPENNESS TRADE POLICIES

In the eighties, it was created the economic and political framework for the US and international organizations like the World Bank actively promote implementation of neoliberal policies in developing countries, among them, Mexico (Ruiz-Nápoles, 2004). Undoubtedly one of the most important neoliberal policies of that time was the adoption by Mexico to the GATT in 1986, -today World Trade Organization (WTO) - which resulted in the adoption of trade openness policy. Among the main commitments assumed by Mexico, was the gradual reduction of tariffs on trade as well as the adoption of trade policies of non-discrimination, within which include national treatment and most- favored-nation generating with this, greater trade openness in Mexico.

Derived from the developments described above, the Mexican government, in compliance with the economic policy of former president Carlos Salinas de Gortari (1988-1994), conducted a series of privatizations of state enterprises and subsequently opened a new concept of national economic growth that oriented production outward to export. In the context of trade liberalization and large-scale tariff dismantling, Mexico opted for the free trade area with Canada and the United States, leading to the signing of the Free Trade Agreement with North America (NAFTA, or NAFTA for its acronym in English) by Salinas de Gortari, the December 17, 1992,

### A. Agreements and Treaties Signed by Mexico

The Mexican government has a number of international positions and legal figures to give special treatment to foreign direct investment in the country. These provide security to investors and promote investment flows. The legal framework that helps the country to promote foreign investment is mainly based on free trade agreements, mechanisms of protection of foreign investment, bilateral investment promotion and finally the federal law and the laws and regulations of each state.Mexico has a network of 10 free trade agreements (FTAs) with 45 countries (FTAs), 30 Agreements for the Promotion and Reciprocal Protection of Investments (BITs) and 9 limited arrangements (Economic Complementation Agreement and partial scope agreements) under the Latin American Integration Association (LAIA).

In addition, Mexico actively participates in multilateral and regional organizations and forums such as the World Trade Organization (WTO), the Asia-Pacific Economic Cooperation (APEC) Mechanism, the Organization for Economic Cooperation and Development (OECD), the Latin American Association integration (ALADI), Alliance Pacific, Latin American Pacific Arch (Arco Forum), Project Mesoamerica integration and Development (Mesoamerica Project), the Trans-Pacific Strategic Partnership (TTP), among others.

*Figure 1. Map of Mexico commercial*
*Source: Based on information from the Ministry of Economy (Secretaría de Economía2015)*

## Free Trade Agreements

As seen in Table 1, Mexico has a network of 10 FTAs with 45 countries (FTAs), according to the Ministry of Economy (Secretaría de Economía, 2015). In these trade agreements, already including the new TLC Mexico – Central America, which entered into enforce on 31 August, 2012. In FTA México- Central America are included Mexico, Costa Rica, Nicaragua, El Salvador, Guatemala and Honduras. This treaty, replaced the three existing trade agreements with Central American countries that had Mexico (NAFTA Mexico - Costa Rica 1995 Mexico-Nicaragua in 1998 and TLC North Triangle - Mexico in 2001). The result is a total of 10 FTAs with 45 countries.Were eliminated from the list, FTAs Mexico, Venezuela and Colombia (1995) and NAFTA Mexico-Bolivia (1995), as both trade agreements were repealed and left without effect by presidential decree last year 2006 for the first and in 2010 the second.

The first FTA after having signed membership to the General Agreement on Tariffs Trade (GATT), now the World Trade Organization (WTO) was the NAFTA (1994), from there, Mexico, began a race to sign trade agreements and treaties with over 45 countries, being until today, the country with the larger network of the world trade agreements (Secretaría de Economía, 2015). Mexico began to hold practically a trade treaty by year: Costa Rica (1995), the Group of Three (1995), Bolivia (1995), European Union (1997), Nicaragua (1998), Chile (1999), Israel (2000), Northern Triangle (2001), EFTA (2001), Uruguay (2004) and Japan (2005). During the second half of the last decade there was a small decrease in the commercial policy of Mexico, to resume the conclusion of treaties and retaking with the signing of the FTAs with Colombia (2011), Central America (2012), Peru (2015) and Panama already in force.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The FTAs with Central American countries were homologated and approved last August 2012 by a new FTA Mexico-Central America. However, have not been derogated by the signatory countries therefore remain in status of enforcement. On the other hand, on June 29, 2012 it was published a decree abrogating the various establishing the Applicable Rate of General Import Tax for goods originating in certain countries with which Mexico has concluded FTAs, endorsing them in the new Treaty of Free Trade Mexico-Central America.This point does not omit to note that the Agreement for the Strengthening of the Economic Partnership between the United States of Mexico and Japan (EPA) enforced since January 2005 and the Trade Integration Agreement (AIC) signed between Mexico and Peru in force since 1 February 2015.

These FTA are listed under the heading of FTAs because they are much more complex than a simple agreement, presenting the same characteristics of a treaty, such as: full trade liberalization in goods and services, unification of tariffs, rules of origin, customs procedures, safeguards, sanitary and phytosanitary measures, means of dispute settlement, among others.The same applies to the Economic Partnership, Political Coordination and Cooperation Agreement between Mexico and the European Union and its members, effective since December 8, 1997. This instrument it is also known as "Global Agreement" for full coverage on its three areas: political, economic partnership and cooperation.

The Global Agreement is comprised of two main instruments, called "Joint Decisions". One relates to the liberalization of trade in goods, in effect from July 1, 2000 and, secondly, the liberalization of trade in services and disciplines on capital movements, investment and intellectual property issues enforced from of 1 March 2001. These Joint Decisions, also known as the Free Trade Agreement between Mexico and the European Union (FTA), that have been modified in response to increases in the number of Member States of the EU, changes in production processes updates and tariff classifications (Secretaría de Economía, 2015).It will be pending to annex to this list of trade agreements the recent Free Trade Agreement Mexico-Panama, as in April 2014 was signed by the presidents of both countries, pending its ratification and entry into force by the signatory countries.

## Partial Scope Agreements (AAP) and Economic Complementation Agreement (ACE)

The partial scope agreements are those agreements in which two or more member countries participate. These agreements may be commercial, economic complementarity, trade promotion, among others. Because of its flexibility, these agreements have become the most widely used in regional integration, hence the negotiated trade agreements such as this has been that showed greater dynamism within the set of intraregional trade (ALADI, 20).

The Latin American Integration Association (LAIA), of which Mexico is a party, since December 1980, when it was approved by Mexico on the Treaty of Montevideo (1980), is an association of Latin American states formed by Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, Mexico, Paraguay, Peru, Uruguay, Venezuela, Cuba and Nicaragua Panama in order to pursue the process of Latin American integration and establish a long-term common market (ALADI, 2015). Based on Article 25 of the 1980 Montevideo Treaty, the government of Mexico began to sign partial scope agreements and economic complementarity agreements with several Latin American countries, with the aim of creating areas of economic integration in Latin America and achieve the following objectives:

1. Strengthen and streamline trade flows between countries;

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. Promote to the greatest extent the participation of commodities and manufactured goods in such trade;
3. Consider the special situation of some products of interest of signer´s countries; take action and develop appropriate actions to streamline the process of integration in Latin America;
4. To promote and diversify trade between countries, through the reduction or elimination of tariffs and other import restrictions.

Mexico currently has 10 Economic Complementation Agreements and 3 Partial Scope Agreements, most of them within the framework of the Latin American Integration Association. Out of these, the ECA's with Spain (1978), Denmark (1981) and France (1982) are no longer viable because it was held in 1997 the Agreement on Economic Partnership, Political Coordination and Cooperation Agreement with the European Union and its 28 member states, although, these ECA´s have not been derogated.

*Table 2. Economic Complementation Agreement and partial scope agreements*

| Signatory countries and bodies | Title | Enactment date | Short name |
|---|---|---|---|
| Spain | Agreement on Economic and Trade Cooperation between the United Mexican States and the Kingdom of Spain | 21/April/ 1978 | ECA México-Spain |
| Denmark | Economic Cooperation Agreement between the United Mexican States and the Kingdom of Denmark | 2/march/ 1981 | ECA México-Denmark |
| France | Economic Cooperation Agreement between Mexico and France | 4/march/ 1982 | ECA México-France |
| Panama | Partial Scope Agreement between Mexico and Panama | 23/ November/1998 | AAP 14 |
| Paraguay | Partial Agreement between Mexico and Paraguay | 17/April/ 2000 | AAP 38 |

### International Investment Agreements (IIA)

According to the Ministry of Economy (Secretaría de Economía, 2015), International Investment Agreements (IIA) are agreements on foreign investment, designed to promote and protect foreign investment in Mexico and Mexicans abroad, which contribute to creating a favorable business climate. These agreements provide for recourse to dispute settlement mechanisms between states or between an investor and the state. Within these agreements include 30 Agreements for the Reciprocal Promotion and Protection of Investments (BIT's) signed by Mexico with various countries regularly with those that have not signed an FTA or a trade agreement described above.

Agreements for the Promotion and Reciprocal Protection of Investments (IPRPAs) are international treaties on foreign investment concluded between Mexico and any other country in order to protect capital flows and provide legal certainty to investments of both nations. Both IPRPAs as FTAs in which Mexico is a part, are an efficient means to achieve a variety or diversity of foreign direct investment into the country, thus giving greater effectiveness to the policy of economic openness and non-discrimination in the area of investment.

## B. Regional Integration Initiatives

The main benefits of regional integration are promoting interregional trade, modernization of infrastructure and the promotion of integrated production systems. Overall, regional integration contributes to the stabilization of the foreign policies allowing countries to improve their ability to adapt to the requirements of a globalized market economy. The integration and regional cooperation are taking an accelerated growth in Latin America, in recent years. They have advanced more in real integration of Latin American economies during the past three decades. As stated by Klaveren (1997), a series of regional, sub regional and bilateral agreements are achieving political and economic cooperation and increasing mutual liberalization of trade between nations, as it can be seen in Figure 2.

Mexico's participation in global markets has relied on strategic ties with other countries and regions of high economic growth. In addition to its extensive network of trade agreements, Mexico participates actively in multilateral trade negotiations under the World Trade Organization (WTO), the Organization for Economic Cooperation and Development (OECD), the Asia-Pacific Economic Cooperation (APEC), the Latin American Integration Association (LAIA), Alliance Pacific, Latin American Pacific Arch (Arco Forum) Mesoamerica Integration and Development Project (Mesoamerica Project), Trans-Pacific Strategic Partnership (TTP).Similarly, as discussed in previous lines, Mexico maintains business through trade agreements and treaties with members of the Southern Common Market (MERCOSUR), Central American Block, NAFTA, European Free Trade Association (EFTA) and European Union (EU), among others.

Even though, Mexico belongs to several multilateral organizations in various fields, such as the World Bank (WB), International Monetary Fund (IMF), the Group of 20 (G20), Organization of American States (OEI), Organization of American States (OAS), the Free Trade Area of the Americas (FTAA), Inter-American Development Bank (IDB), among many others, it has been decided to enlist in Table 4 only to agencies where the Mexican government actively participates derived from current foreign policy of President Peña Nieto (2012-2018) and his drive for regional initiatives such as Alliance Pacific Economic Cooperation Forum Asia - Pacific and NAFTA Mexico - Central America.

President Enrique Peña Nieto expressed in his book "Mexico, the great hope" (2011); there has been a significant deterioration in the Mexican foreign policy. The country must regain its global leadership and emphasizes to use foreign policy as a tool for economic development. In the section about "Mexico, global actor" lists seven areas of strategic action: promoting better integration with the region of North America; strengthen cooperation with Central America and the Caribbean; restore effective

*Source: Based on information from the Ministry of Economy*

dialogue with South America; consolidation as Latin American cultural power; consolidate the alliance with Asia-Pacific; promote effective multilateralism and energize and deepen the relationship with the European Union (EU).

The foreign policy of the current administration aims to have a closer relationship with the United States, with the aim of promoting and expanding a better regional integration to compete with Asia, specifically China.It also intends to lead efforts in investment, trade, migration international waters, environment, border and energy development and infrastructure (National Development Plan 2013-2018). Another priority of the federal government will strengthen cooperation with Central America, especially to address effectively transnational organized crime which has reduced the nascent institutions of Central American countries and causing instability in the area.

## FOREIGN POLICY OF MEXICO

In today's globalized scenario, international events have a greater impact nationally. This is why foreign policy is a vital tool to promote social, political and economic development in Mexico. In Mexico, the Ministry of Foreign Affairs (SRE) is responsible for conducting foreign policy, and must fulfill two essential functions: to represent and coordinate the interests of all actors in the international arena. The normative principles to be observed by the Federal Executive to conduct foreign policy are incorporated in Article 89; section X, of the Political Constitution of the Mexican United States.

## A. Comparative Foreign Policy in the Last Five Presidential Terms

Mexico's foreign policy, from the point of view of foreign trade, has always been of vital importance in the political agenda of the Mexican government. However, there have been periods within the Mexican politics much more prolific than others. Following the last five governmental periods, comprising 26 years of foreign trade policy are discussed: 1988-1994 President Carlos Salinas de Gortari, 1994-2000 President Ernesto Zedillo Ponce de León, 2000-2006 President Vicente Fox Quesada, 2006-2012 President Felipe Calderon Hinojosa and the current period 2012-2018 President Enrique Peña Nieto.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## 1. 1988-1994: President Carlos Salinas de Gortari

In the area of trade liberalization and export promotion achieved greater macroeconomic stability and greater openness, promoting agreements to open foreign markets and deregulation of the domestic market, thus raising the country's export capacity. In his last State of the Union (Informe de Gobierno, 1994), provided:"... Exports increased from just over 30,000 million in 1988 to almost 52 000 million in 1993 and in the first eight months of 1994 reached 39,000 million. Imports have also presented a significant growth since 28 000 million US dollars in 1988 reached 65,000 million in 1993, and now total almost 51,000 million to August 1994, and intermediate goods and capital account almost 90% of the import bill "(Sexto Informe de Gobierno, 1994).

This period was crucial to the process of trade liberalization and internationalization of the country since the first commercial treaty signed by Mexico was the North American Free Trade Agreement between the US, Canada and Mexico (NAFTA) in January 1994. The integration between the United States and Canada began to materialize in 1965 with the signing of the Automotive Pact between the two countries. Meanwhile, between Mexico and the United States began to develop this integration also more clearly in the same year when is established the maquiladora program in northern Mexico started, which achieves to promote a major integration between the two countries. On June 11, 1990 start the trilateral work with the aim of creating a free trade zone in North America. In 1991 the presidents of the three countries announced their decision to negotiate the North American Free Trade Agreement.

After several years of debate and creating an appropriate legislative framework to be consistent with the other two countries, the Law of Treaties on January 2, 1992 was enacted in order to regulate the conclusion of treaties and interagency agreements in the international arena. Similarly were performed structural reforms to the Ministry of Finance and Public Credit, adding and abrogating provisions and functions of the Secretariat, creating the Directorate General of Customs in 1993 and establishing the jurisdiction of the 45 customs in the country. Subsequently, it was published in 1995 the reform of the Customs Act, changes included the introduction of mechanisms to assess the goods in accordance with the provisions of the GATT, as well as changing the random system for more efficient automated system (Aduanas de México, 2015).

Finally, the trade agreement was signed by the three countries in December 1992 and in 1993 was approved by the legislatures of Canada, Mexico and the United States and entered into force on January 1, 1994. Although during this period, while many treaties and trade agreements have not materialized, it was laid the foundations of openness trade policy Mexico. New business partnerships in the country as the North American Free Trade Agreement (NAFTA) were created.

The formation of the Group of Three, comprising Mexico, Colombia and Venezuela; free trade agreements with Chile, Costa Rica and Bolivia; admission to the Organization for Economic Cooperation and Development (OECD), which includes the largest economies in the world, and the Forum of Asia Pacific Economic Cooperation (APEC), and the participation in the European Bank for Reconstruction and Development show the new importance of the country (National Development Plan, Plan Nacional de Desarrollo, 1989-1994).

## 2. 1994-2000: President Ernesto Zedillo Ponce de León.

Within its National Development Plan (1995-2000) in foreign policy sought to promote sub regional forums in Latin America, Mexico and Spain as they are in dialogue bridges between continents and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

economic regions. The foreign policy sought to establish a new comprehensive agreement with the European Union giving priority to reach a treaty of free and fair trade.

In his message on the occasion of its Sixth Report, President Ernesto Zedillo government asserted that economic growth achieved by the country since 1996 has made Mexico a real exporter worldwide. In his speech stated:"... We have deployed a strategy of diplomatic and economic negotiations with other countries, unprecedented in its intensity and diversity. This strategy has two equally important pillars: the defense of our foreign policy principles, which fortunately coincide substantially with international law, and promoting the interests of the country. Mexicans can rest assured that Mexico is now a stronger nation; more respected and recognized around the world ... "(Zedillo, 2000).

During his tenure were created conditions for free trade with 27 countries managing to be the only country in the world with a network of agreements on that scale, being able to position Mexican products more competitive in international markets and making products accessible to advantage created by so many national markets. In line with changes in international trade and in order to give greater modernization to the Mexican government structure, on foreign trade, structural reform to the Secretary of Finance in July 1997 was performed, creating the Tax Administration Service (SAT), to which was attached the General Administration of Customs. In 1998 the Customs Act was amended again in order to strengthen the control mechanisms and thus combat evasion of payment of contributions, increased regulatory compliance and non-tariff restrictions and customs fraud in general (Adana de México, 2015)

Free trade agreements with North America (1994), Costa Rica (1995), the Group of Three (1995), Bolivia (1995), European Union (1997), Nicaragua (1998), Chile (1999) were enacted and Israel (2000), the Economic Complementation Agreement with Panama (1998) and the Partial Agreement with Paraguay (2000) was enacted; further negotiations and signature of trade agreements with Northern Triangle (2001) and the European Free Trade Association (EFTA) in 2001. In the area of investments were made Agreements for the Promotion and Reciprocal Protection signed investment Treaties (BIT) with Switzerland in 1996, Argentina in 1998 and the Netherlands in 1999.

## 3. 2000-2006: President Vicente Fox Quesada.

The main objective during his administration was to update the foreign policy of Mexico to the new political realities. Foreign policy sought to strengthen trade relations with the United States. However, a series of diplomatic setbacks as the lack of support and lack of solidarity from Mexico in the events of September 11 in the US or the severance of diplomatic relations with Cuba by the American position on human rights issues and the internal situation of the island, prevented the country achieve greater trade openness. Nevertheless, it was signed with Cuba an Economic Cooperation Agreement between Mexico-Cuba (ACE 51) in September 2001.

As it can be seen in the National Development Plan (2001-2006), foreign trade was never a priority for government. This plan established three broad areas of action: social and human development, order, and respect and quality growth in the latter. The objectives were: driving responsibly economic progress of the country, raise and extend the country's competitiveness, ensure development inclusive and create conditions for sustainable development (National Development Plan 2001-2006).However, the FTA with Uruguay (2004) and the Agreement to Strengthen Economic Partnership with Japan (2005) were enacted. In addition, the Economic Complementation Agreement with Argentina (2001) was held and the Economic Complementation Agreement with the Southern Common Market (MERCOSUR): ECA Framework Agreement 54 (2002) and ECA Automotive Sector Agreement 55 (2003).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The last year in office, foreign policy left without effect by presidential decree on TLC Mexico, Venezuela and Colombia (1995). Even though, it was highlighted the continuing diplomatic setbacks, foreign policy focused on supporting foreign investment through signing agreements for the Reciprocal Promotion and Protection of Investments (BIT's) with different nations, agreements whose only function is to protect capital flows and provide legal certainty to investments of both nations. BIT's were signed with Finland, Portugal, Denmark and France in 2000; Germany, Austria, Sweden in 2001; Cuba, Uruguay, South Korea, Greece and Italy in 2002; Belgium-Luxembourg Economic Union in 2003, Czech Republic in 2004, Iceland and Panama in 2006. Not fails to mention, the low viability of such agreements, as with most of them already had broader trade agreements.

## 4. 2006-2012: Presidency of Felipe Calderon Hinojosa.

The National Development Plan (2007-2012) sought to reap the benefits of globalization in order to promote national development and project Mexico's interests abroad. Mexico's foreign policy was not a priority in public policy for the government of President Calderon. In order to resolve the diplomatic crisis and disputes inherited from the administration of President Fox, a foreign policy of relatively low profile was raised, his government was mainly focused on combating drug trafficking and organized crime. Foreign policy, instead of creating business relationships with strategic partners, made her way to creating bilateral, regional and multilateral cooperation agreements on security, as the case of the Merida Initiative.

Of the periods analyzed, this was the least effective in issues of agreements and trade agreements. The FTA with Colombia (2011) was enacted as a treaty that was clear of the Free Trade Agreement with the Group of Three, signed in 1995 and left without effect by presidential decree in 2006. Just as the free trade agreement with Central America (2012) was enacted, a treaty that unifies previously concluded trade agreements with Central American countries. It welcomed the Partial Agreement with Ecuador (2007), the Economic Complementation Agreement with Hungary (2009), unnecessary agreement because its sole purpose is to strengthen and increase economic relations and business cooperation of the two countries, coupled with that Hungary is part of the European Union, a region that already has a trade agreement. Also, the Economic Complementation Agreement with Bolivia (2010) was held after annul by presidential decree of the Free Trade Mexico-Bolivia (1995).

In terms of investment, Agreements for the Promotion and Reciprocal Protection of Investments (BIT) with Australia, UK and Trinidad and Tobago in 2007 were held, as well as India and Spain in 2008; Slovakia, China and Belarus in 2009 and Singapore in 2011. Mexico joined multilateral organizations like the Latin American Pacific Agreement (Arco Forum) in 2007 and the Mesoamerican Integration and Development in 2008.Mexico hosted in June 2012 the Seventh Summit of the Group of 20 (G-20) serving as president of the group during the year.

## 5. 2012-2018: President Enrique Peña Nieto

The objectives of the National Development Plan (2013-2018) are about five strategic areas: Mexico in peace, inclusive Mexico, Mexico with education of quality, prosperous Mexico and Mexico with global responsibility. In the latter, it provides as follows: "... The fifth goal of the National Development Plan 2013-2018 includes the policies of the Government of the Republic aimed at defending and promoting the national interest abroad, and contributes to meeting the development objectives of Mexico, through

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

close relationships, mutually beneficial and productive with other countries, underpinned by a strong, substantive and active foreign policy. Mexico in a Global Responsibility seeks to expand and strengthen the country's presence in the world. Mexico reaffirms its commitment to free trade, capital mobility and productive integration; to promote the value of the nation in the world through economic, tourist and cultural dissemination, and ensure the interests of Mexicans abroad (National Development Plan 2013-2018).

As it can be seen, within the current National Development Plan, foreign policy is essential for the government as part of one of the five areas in which his entire administration versa. In the current administration, mainly include 11 structural reforms promoted by government, approved in the first 20 months of the current administration. For Mexico, it was essential to create a suitable environment to remain globally competitive, even though our economy opened to the world generating competitive industries, such as automotive and aerospace. Over the past 20 years, economic growth of Mexico was only 2.4 percent per year (Secretaría de Economía, 2015).The 11 structural reforms of the country pursue three main objectives: raising productivity in Mexico, triggering growth and economic development; strengthen and expand the rights of Mexicans; and strengthen democratic freedoms and regime.

In the present matter, the foreign trade, it is highlighted the energy reform. It introduces a profound transformation in the Mexican oil industry and activities of the National Electric System, opening the sector to competition to attract both domestic and foreign investment. Therefore on economic competition updated legislation and extensive catalog of anticompetitive practices tightening sanctions on them. The reform in telecommunications and broadcasting strengthens and promotes the development of these sectors. Similarly, it highlights the financial reform and tax reform, thus enhancing competitiveness of the financial sector, with the first, as well as increased revenue for the federal government with the second.

To date, Mexico has celebrated the FTA with Peru (2015) and the FTA with Panama, enact pending. Further regional agreements with LAIA members signed: Bolivia, Argentina, Brazil, Colombia, Chile, Ecuador, Paraguay, Peru, Uruguay, Venezuela, Cuba and Panama (Agreement No. 4 and No. 7).In terms of investment, Agreements for the Reciprocal Promotion and Protection of Investments (BIT) with Bahrain in 2014 and Turkey and not yet in force with Kuwait were held. Similarly, it was encouraged Pacific Alliance, composed of Peru, Chile, Colombia and Mexico regional bloc.

## Internationalization of Mexican Companies

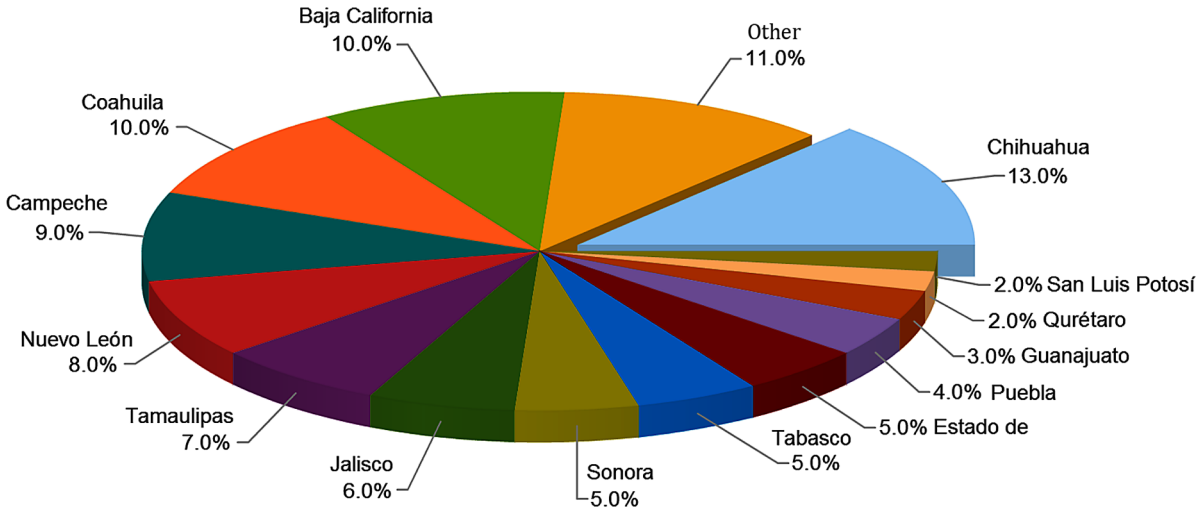
### A. Mexican Exports

The current process of trade liberalization in Mexico, launched in 1986 to join the GATT and deepened in 1994 with the celebration of NAFTA has been reflected in the flow of Mexican exports. Today, these exports are seven times those of 1994. Regarding foreign investment, are four times higher. However, despite these achievements and current openness of the country, Mexico remains dependent on its main trading partner, the United States, where over 70 percent of exports go to them. Mexico's trade still has enormous potential, the emergence of new trading blocs represent an opportunity for Mexican companies who want to position their products in those markets.

Currently, 60 products of the manufacturing, mining, food processing, petrochemical, are representing over 60% of total Mexican exports. The manufacturing sectors with higher exports and positioning in international markets are aerospace electrical and electronics industry, the automotive and medical equipment industries. Top ten products exported by Mexico are cars, trucks and tractors, cell phones,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

computers, electrical transformers, medical devices, televisions, refrigerators, auto parts, among others. The energy and mining sectors remain the main sources of exports. Natural gas, oil, fuel, oils, lubricants are currently exports, among others, as well as gold, silver, copper, lead, sulfur, aluminum and iron.



As shown in the following chart (Figure 3), in 2012, the federal state with the highest percentage of exports was Chihuahua with 13%, followed by Baja California and Coahuila with 10% each, Campeche with 9% and closely followed by Nuevo León 8%, 7% Tamaulipas and Sonora with 6%. These data show that the country's exporting entitiesare precisely the Border States. With the exception of Campeche, the six surrounding states with the United Statesare representing 54% of total exports in 2012, while the rest of exports distributed in other important institutions such as Jalisco, Tabasco, Guanajuato, Queretaro and San Luis Potosi.

As discussed in previous lines, manufacturing accounts for nearly 90% of exports of the country, becoming the main export sector and followed by exports of crude oil, representing a distant 5.9 percent and the agricultural sector by 3.2 percent of products exported by Mexico (Figure 4, 2014). According to data from the Ministry of Economy (Secretaría de Economía, 2015), the strategic sectors for Mexico are aerospace, automotive, medical devices, electronics, automotive parts, organic coffee and silver. This, as currently, aerospace exports have increased 140% over the past 5 years.

Moreover, is the 6th largest exporter of tools and appliances used in medical, surgical, dental and veterinary medicine, the 2nd largest exporter of world TV, 1 worldwide producer of organic coffee and the 3rd largest producer of silver -16% of world production of gold. Conducting a more detailed analysis the main exports of manufacturing, it has 29.8% of Mexican manufacturing exports are automotive products, equipment and appliances that account for 23%, machinery and special equipment for various industries 15.3% professional and scientific equipment 4.4% and that of other manufacturing industries 3.8 percent of total imports in 2014 (INEGI, 2015).

The Mexican Association of the Automotive Industry (2014) established that the Mexican automotive sector accounted for 3 percent of GDP and 14 percent of Mexican manufacturing. Mexico is among the 10 largest world producers of cars, trucks, parts and components for cars, the 6th producer of commercial

cars and 2nd car producer in Latin America.As for the food industry, the main economic activity in the state of Sinaloa is decreasing the percentage of export share as it is being displaced by manufactured products.Even so, a large percentage of products exported as vegetables with 49% beef with 11.1%, fish and shellfish with 6.6% of total exports in 2014, as well as products such as coffee, cocoa, dairy products, among others (INEGI, 2015).

However, as shown in the following chart (Figure 7), the main products exported under the Harmonized Commodity Description and Coding (SADCM) are Chapter 85: machinery and electrical equipment with 22.5% of total exports, followed by chapter 87: land vehicles and parts with 20.6% and third is Chapter 84: mechanical appliances, boilers and parts with 16.3%.

In the following Figure 8, a detailed analysis is performed by tariff and the breakdown of the first ten non-oil products exported in Mexico, where the following products are included: motor vehicles for the transport of persons, raw gold, automatic processing data machines, its units and machinery and electrical

equipment. In 2012 the exported non-oil products totaled 78,700,881 million, while in 2013, reached the sum total of 81,749,713 million and, for the period from January to November 2014, products exported reached amount of 79,370,716 million. The main importers of these products are USA, Canada, Brazil, Colombia, Spain, Germany and China.

With ten existing trade agreements, most exports from Mexico in 2014 were segmented into four regions. The US is the largest recipient of Mexican exports, oil and non-oil, with 80.2 percent of total exports, as may be seen in Figure 9. Secondly, Canada receives 2.7 percent, China with 1.5%, Spain with 1 percent and the rest of the world 15.6 percent (INEGI, 2015).

As discussed in previous lines, Mexico is going through various processes of economic integration, creating trading partners with trade blocs, within which include the American continent: the NAFTA bloc, Alliance Pacific, Central block and LAIA region destination 89.3% of Mexican exports, followed by the European continent, composed of the EU and EFTA, with 5.7% of total exports and Asia which highlights the APEC with 4.5% of Mexican exports in 2014 (INEGI, 2015) (See figure 10).

## B. Mexican Imports

In the area of imports, Mexico, unlike its export sector has diversified as to the destination of the same, reflecting a productive integration with global markets, specifically in the Asian market. According to the sixth report of President Calderón (2012), United States gradually ceases to be the leading provider of Mexico, from 76 percent of total imports in the nineties to less than 50 percent products in 2014. The main suppliers of Mexico remains first US with 48.8 percent of total imports, followed by China with 16.6%, in third place is Japan with 4.4% and the rest of the world are distributed with the remaining 30.2% of total Mexican imports in 2014.

Analyzed by regions of Mexico, imported products come mainly from NAFTA - United States and Canada with 48.8% and if the LAIA members are added, the Americas region represents 55.2% of total Mexican imports, followed by the Asia - Pacific (China, Japan, Malaysia, South Korea and Taiwan) with 31.9%. Third the European Union, mainly from Germany, Spain and Italy finds 12.3% of total Mexican imports (INEGI, 2014).

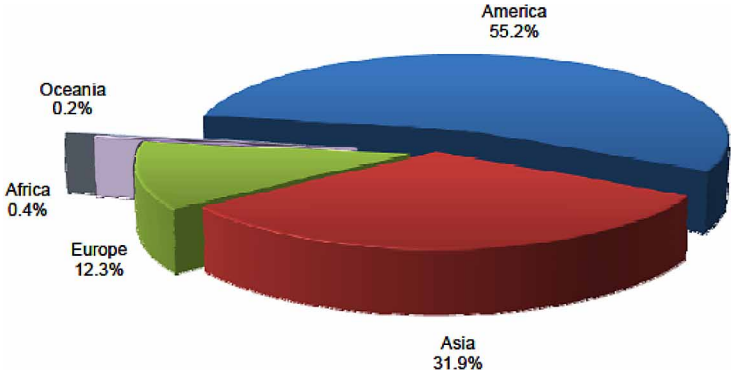

*Figure 11. Percentage share of imports by main countries (2014)*

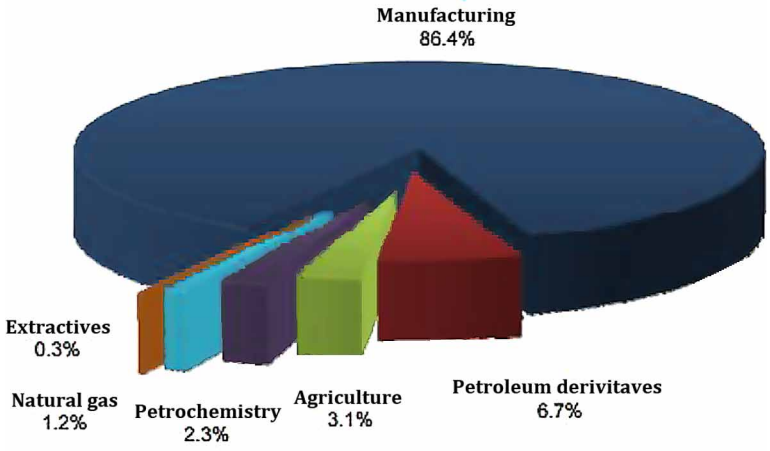
*Figure 12. Percentage share by imports by continents (2014)*
*Source: INEGI (2015)*



Mexico has become a producer of manufactured goods, which requires inputs for the production of this sector. As shown in the following chart (figure 13), more than three-quarters of Mexican imports were inputs for the manufacturing sector, accounting for 86.4 percent of total imports, while 10.2% are for oil products - natural gas, petrochemicals and derivative of oil, and 3.1 percent for agricultural sector products. The main imported products are gasoline, automobiles, monolithic integrated circuits, diesel, electronic integrated circuits and parts for monitors and projectors (INEGI, 2014).

As seen in the chart (Figure 13), manufactures account for 86.4 percent of total imports into Mexico. The main products purchased by the country are equipment and electrical and electronic equipment with 24 percent, followed by machinery and special equipment for various industries with 17.8% and third place are the automotive partswith12.9% of the total imported in 2014.

The agricultural sector accounts for only 3.1% of total imports. This is due to the high productive capacity in this sector, mainly products such as vegetables, beef, coffee, and cocoa, among others. However, owing to the large population and increasing demand for agricultural products, Mexico, does

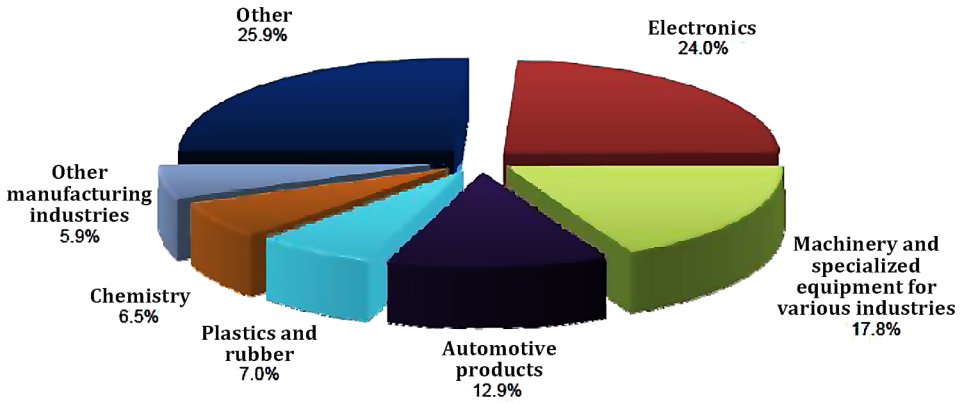


*Figure 13. Percentage share of oil and non-oil imports by sector (2014)*

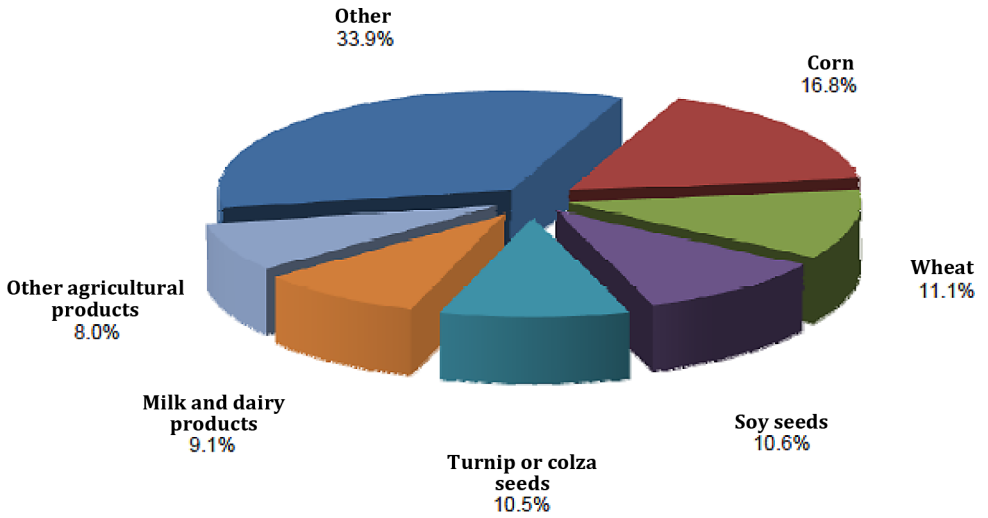

*Figure 14. Percentage share of imports by major manufactures (2014)*
*Source: INEGI (2015)*

not have the capacity to meet demand required in the sector, so it has to import products such as corn, product representing16.8% of total imports by Mexico in the agricultural sector; wheat with 11.1%, rape seed or canola with 10.5 percent, among others.

As shown in Figure 15, the main products imported under the Harmonized Commodity Description and Coding (SADCM) is Chapter 85: machinery and electrical equipment with 21.1% of total imports, followed by chapter 84: mechanical appliances, boilers and parts with 17.2% and thirdly Chapter 87: land vehicles and parts with 8.3%.

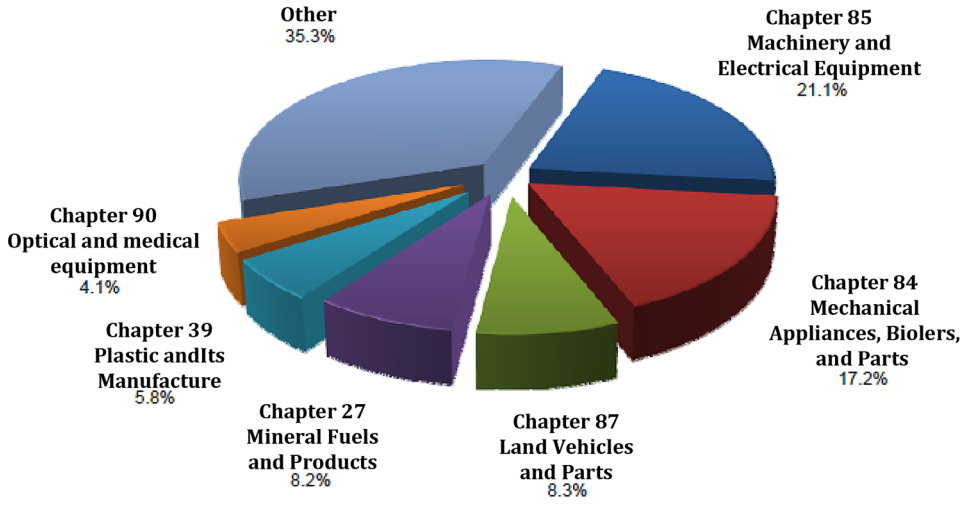

*Figure 15. Percentage share of imports by main agricultural products (2014)*

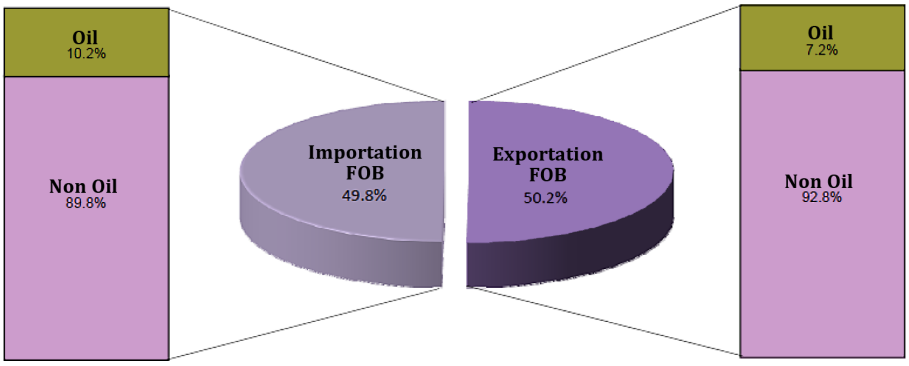
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 16. Percentage share of imports of goods by main chapters of the Harmonized System (2014)*
*Source: INEGI (2015)*

However, reviewing exports in 2014 according to the Harmonized Commodity Description and Coding (SADCM) and imports the same period, it can be seen that the chapter 85: machinery and electrical equipment, Chapter 87: Land vehicles and parts and Chapter 84: Mechanical appliances and boilers; match between the main products imported and exported from the country. This is because Mexico is a country producer of manufacturing, which imports products from certain sector, gives manufacturing the value added and exports abroad.

## C. Trade Balance



Mexico plays a key role on the international stage. In 2012, the country ranked fourteenth in the amount of gross domestic product, the sixteenth to the value of its trade and fourteenth for investment by nationals abroad also lies in eleventh place by size population (NDP 2013-2018). The balance of payments is the systematic search conducted by the Bank of Mexico (Banxico) of all economic transactions between residents of the country and the world. Its main components are the current account, the capital account and the account of official reserves. The trade balance is the part of the balance of payments that includes imports and exports of goods. For this investigation, data provided by the Bank of Mexico, in quarterly reports called "Information Revised Foreign Trade" are used.

In 2014 Mexico's trade balance showed a deficit of 2.442 billion, which compares with 1,184 million recorded in 2013. This variation resulted from the decline in the surplus of oil products, which increased from 8,625 million in 2013 to 1,489,000 dollars in 2014, and a reduction of non-oil deficit, which decreased from 9.809 million dollars in 2013 to 3,931,000 dollars in 2014 as seen in graph 14 (Banxico, 2015).In the period under review, 2014, exports of goods reached 397.535 million dollars, among which 42.979 million dollars correspond to oil exports while 354.556 million dollars correspond to non-oil. In this period, total exports had an annual growth of 4.6%, which was a result of increased 7.3 percent in non-oil exports and a decrease of 13.2 percent in oil (Banxico, 2015).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 17. Percentage share of exports and imports oil and non-oil (2014)*
*Source: Banxico (2015)*

In the same period, total imports amounted to 399.977 million dollars, an amount which suffered a 4.9% increase compared to 2013. The increase in total imports originated from the 5.3% increase in non-oil imports and 1.5% of oil (Banxico, 2015).

The revised information on foreign trade in 2014, reveals that the accumulated value of oil exports reached US $ 42.979 million, lower than 49.493 million dollars observed in 2013. The average price of Mexican crude mix of export level in 2014 was $ 86.94, lower dollar figure in 11.52 dollars at the average presented in the previous year. In relation to the volume of oil exported in 2014, it reached a level of 1.142 million barrels a day, down from 1.189 million daily barrels in 2013 (Banxico, 2015) level (figure 19).

Oil imports in 2014 totaled 41.490 million, while in 2013 were of 40.868 million dollars. Thus, in 2014 the foreign trade surplus of oil products stood at 1.489 million dollars, while in 2013 was 8.625 million as shown in Graph 16 (Banxico, 2015).

In the Figure 20, the trade balance of Mexico is analyzed by the structure of the value of exports, i.e., capital goods, understood as the set of goods that serve as a means to produce other goods such as machinery and equipment transport; consumer goods, which are goods used for immediate consumption either perishable or non-perishable. Finally, the intermediate goods, defined as those incorporated into the production process by which experience changes in their status, composition, shape or simply integrate other assets in order to create a new product, for example, raw materials used in transformation industry.

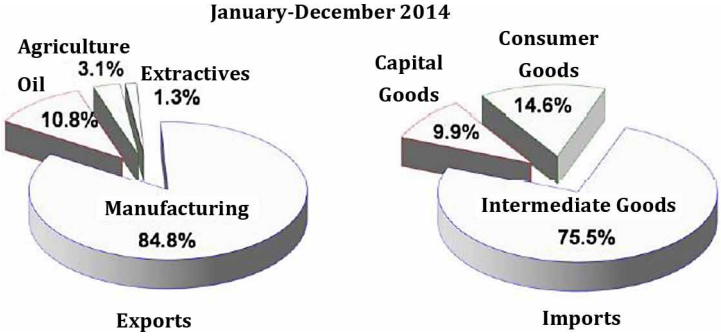
The structure of the value of merchandise exports in 2014 was as follows: manufactured goods, 84.8%; petroleum products, 10.8%; agricultural goods, 3.1%; extractive and non-oil products, 1.3% (Banxico, 2015). The structure of the value of imports of goods in2014was as follows: intermediate goods, 75.5%; consumer goods, 14.6%; and capital goods9.9% of total Mexican imports (Banxico, 2015). The cumulative value of total merchandise imports in2014wasUS $399.977 million, i.e.4.9% increase compared to that observed in 2013. In the reference period, imports of consumer goodsrose1.7%, intermediate goods rose 6% and capital goods increased1.5% of Mexican imports (Banxico, 2015).



## D. Foreign Direct Investment in Mexico

According to the Ministry of Economy (Secretaría de Economía, 2015), the main function of Foreign Direct Investment (FDI) is to create a lasting interest and business or economic long term ends by the foreign investor in the host country being the case Mexico. Foreign investments stimulate competition, encourage the transfer of new technologies, boosting exports, and generate foreign exchange earnings, employment generated; positively affecting the country.

*Figure 21. Structure of exports and imports of goods (2014)*
*Source: Banxico (2015)*

The bodies responsible for managing and operating the National Register of Foreign Investment (NREN) in Mexico are the Directorate General of Foreign Investment (DGIE) belonging to the Ministry of Economy. Likewise, it represents Mexico in international investment forums, support Pro Mexico in promoting and attracting investments, disseminate information and studies on FDI in the country. Quarterly Secretary of Economy (SE) through the National Foreign Investment Commission (FIC), produced Statistical Report on the Performance of Foreign Direct Investment in Mexico (January-December 2014); with support from the Bank of Mexico (Banxico) and following the recommendations of international organizations: Organization for Economic Co-operation and Development (OECD): *Benchmark Definition of Foreign Direct Investment* (2008); and the International Monetary Fund (IMF) Balance of Payments Manual (1993).

According to the statistical report, in 2014, the amount of FDI recorded in Mexico amounted to 22,568.4 million dollars, lower than in 2013 amount to 35,188.4 million dollars. The reported amount of FDI in 2014 was reported by 4,310 Mexican companies with FDI in its capital, in addition to trusts and foreign legal persons conducting business as usual in Mexico. Now, of 22,568.4 million dollars registered, 12768.6 million dollars originated from reinvested earnings, 5565.2 million dollars of intercompany accounts and 4234.6 million dollars of new investment (Table 8).

Foreign investment flows are mainly divided into manufacturing with 12,869.9 million dollars, followed by financial services with 5556.6 million dollars, third the mining sector with 2215.2 million dollars, trade with 1954.3 and finally the construction sector with 872.6 million dollars; the field of mass media information suffered a cumulative divestment in 2014 of 4152.5 billion (Figure 23).

*Figure 22. Comparison of FDI 2013-2014*

*Figure 23. Sectorial distribution of FDI 2014*
*Source: Ministry of Economy (2015)*

Performing a division of investment flows are analyzed by the agricultural, industrial and service sectors. The first, the FDI inflows reached 57.1 million dollars for agriculture and 41.5 million dollars for services related to farming and forest, while breeding and export of animals suffered a decrease of 14.3 million dollars. For the industrial sector, it was recorded that 77.7 percent of FDI flows were for the subsector of manufacturing, 13.4% for the mining and 5.3% for construction. Finally, the services sector had a record of 5556.6 million dollars for financial services, while trading record 1954.3 million dollars and as commented in previous lines, the subsector of information in mass media suffered a decrease of 4152.5 million dollars. This subsector was affected by an atypical transaction: FDI decreased by 5,496 million dollars due to withdrawal from AT& T as a shareholder of América Móvil (see figure 24).

Flows of foreign direct investment are diversified, because as shown in the following chart (Figure 25), FDI comes from several countries, First, from the main trading partner, the United States, with an investment in 2014 to 6516.4 million dollars. Secondly, Spain with 4092.9 million dollars, and thirdly, Canada 2421.4 million dollars, followed by Germany with 1546.2 million dollars, Netherlands with 1489.6 million dollars and Japan with 1433.7 million dollars, it should be noted that FDI comes mainly from countries with which Mexico has an existing trade agreement.

The Ministry of Economy performs an analysis of the historical evolution of the foreign direct investment into the country from 2000 to 2014. Results show that US is the largest investor in Mexico with a cumulative total of 171.543 million dollars, followed by the Netherlands with 49.514 million dollars, third is Spain with 48.121 million dollars, and Canada fourth with 22.781 and fifth Belgium with

15,999 billion (figure 26). Such flows of foreign direct investment rebounded towards mainly manufacturingwith46.1% of the cumulative total from 2000 to 2014, followed by financial serviceswith17.6 percent, third trading with an8.3%, and fourthminingwith5.9and fifth, and sector of the mass media with a4.1cumulative total (Figure 27).

At the international level, according to the United Nations Conference on Trade and Development (UNCTAD for its acronym in English) in 2013, Mexico won the tenth place as the recipient of foreign direct investment country, with a share of 2.6 percent from total world FDI flows. The annual report of UNCTAD publishes the World Investment Prospects Survey which positions Mexico as the 13th most attractive economy to invest in the next three years economy.

As shown in the graph above, of the countries surveyed by the United Nations Conference on Trade and Development (UNCTAD), in 2013, China won first place as a recipient of foreign direct investment, followed closely by US. Third is Indonesia, India fourth and fifth Brazil; Mexico happened to be in the 7th place last year, now to 13th place in the survey.

## E. Business in Mexico

According to the National Statistics Directory of Economic Units (DENUE), the National Institute of Statistics and Geography (INEGI) in 2014 recognized 4 925 012 business in Mexico.

As shown in the above table, the thickness of economic units lies with the total of accounted 4,349,900 that have 0-5 employees. However, for this research, it was decided to consult only the companies with more than 6 workers since they are considered susceptible of being internationalized, 575, 112 total economic units were recorded in Mexico.

*Figure 29. Economic units in Mexico by size*
*Source: Based on data from DENUE (2015)*

There have been selected small and medium enterprises with export activities, belonging to the most representative productive sectors, with reference to the information recorded in the National Bank for Foreign Trade of Mexico, at the time to validate the information obtained in the course of the investigation.

## Companies Exporting

According to the Mexican Business Information System (SIEM) belonging to the Ministry of Economy, in 2015, a total of 612.061 exporting and importing companies in Mexico were registered. Following, companies are broken down by state. Note that the information pertains only to the registered companies SIEM and not all existing in the country.

From the above table shows that of the total registered companies, only 5,294 are exporters, which represent 13.50% of the total number of companies. Similarly, 13,297 companies have imported goods representing 21.70%.

States with the most companies exporting are Jalisco with21%, Coahuila with 20%, 15% Baja California, and Chihuahua with 14%, and the states of Guanajuato, Mexico City and the State of Mexico with 10% each exporting companies registered in the country. In the case of the State of Sinaloa, there are only 55 exporting companies and 14,452 who do not. However, according to the Directory of Exporters (DIEX) of ProMéxico, belonging to the Ministry of Economy in 2014, exporting firms belong to the following sectors:

The sector that is more engaged in exporting is the food innovation with 734registered companies, followed by the food industry with 578 companies. A third sector is the chemical-plastic with 560, followed by the metalworking with 529and fifth sector of construction materials and hardwarewith503 companies. Of the total registered Promexico enterprises, the predominant sector in exports is the food - Food Innovation and agri-foodstuffs, with 41 percent, followed by plastic chemist with 17 percent and third sector and construction materials hardware with 15 percent of all businesses.

## Companies Maquilador as in Mexico

One of the main reasons why NAFTA was signed between México, United States and Canada was precisely by the manufacturing sector and is currently the export maquiladora that represents a major source of foreign exchange for the country, as well as creating jobs, mainly in the border states of Mexico. The maquiladora industry in Mexico has shown an exponential growth and increasing demand for foreign markets. This industry has allowed the country to have a constant technological development and constant training to workers who are employed in industries. During 2013, 80 percent of the recorded investment in this period was for the manufacturing sector, mainly par subsectors in the metalworking industries, machinery and equipment and automotive sector.

In 1994 the number of maquiladoras in Mexico was 2,085 establishments with occupancy of 583.044 employees. 20 years later, in August 2013, the number of maquiladoras grew to 5,049 companies and 2,095,799 employees in the manufacturing sector in Mexico. That is, in Mexico the number of maquiladoras and employment multiplied by factors of 2.5 and 3.6 respectively (INEGI, 2015).However, according to the Integral Statistics Program of the Manufacturing, Maquiladora and Export Services INEGI, in 2015, were registered 5,006 manufacturing establishments in Mexico.

As seen in the table, during the years 2008 and 2009 there was an increase in the number of manufacturing establishments in the country, experiencing a gradual decline from the year 2010, caused mainly by the decline in foreign investment to the country, derived from the global economic crisis of 2009 and the emergence of new competitive emerging markets, the main event, China.

Also in 2014, there are counted 1,121 manufacturing establishments enrolled in Manufacturing, Maquiladora and Export Services Program (IMMEX), so that in total, the maquiladora industry is represented by 6,127 manufacturing and non-manufacturing firms.

## Economic Report 2014 Maquiladoras

The document "Economic Report maquiladoras" by Banco Base and disseminated by the National Council of the Maquiladora and Export Manufacturing in February 2015; notes that in November 2014, the manufacturing sector showed an annual increase of 5.31 percent. The subsectors with greater dynamism over the same period of 2013 were the manufacture of machinery and equipment, clothing apparel, electronics, among others. In the case of chemical and paper industry, showed deterioration in performance compared to the same period last year.

During 2014, gross fixed investment, comprising investment in machinery and equipment, as well as in construction, had an annual increase of 7.14 percent compared with the same period last year. In relation to the investment of imported origin, it experienced an increase of 17.11 percent. The construction sector had an increase of 5.03 percent over the same period last year, while the mining sector had a diminution in performance ending the year with an annual decrease of 5.71 percent. The analysis makes manifest that in relation to 2014 manufacturing exports metal, machinery and equipment, are the same products contributing the largest share of manufacturing exports showed an annual growth of 5.9% on its most important component, automotive parts, had an annual increase of 9.75 percent.

## RESULTS

In order to make a comparison between the last five presidential administrations, exclusively in relation to foreign policy and trade policy, in order to ascertain that period had a positive impact on trade liberalization in Mexico and increased foreign investment, is showed in the following table of results:

As seen from Tables 9-13, after making a comparison of the last five presidential administrations in Mexico, it can be seen that the busiest period in foreign policy and foreign trade was the period 1994-2000 under the President Ernesto Zedillo. It was the period with more free trade agreements and treaties signed, likewise, it was one that was focused more in this sector, enacting and amending laws of matter and structural reform to the government organization in order to be more competitive with foreign markets. These achievements definitely could not have been carried out but for the former president, i.e. the period1988-1994 under the President Salinas deGortari, since its administration laid the foundations of trade policy openness of Mexico creating and negotiating new trade alliances with foreign partners.

*Table 9. Comparison of foreign policy in presidential periods Period 1988-1884. President Carlos Salinas*

| | |
|---|---|
| National Development Plan: Foreign Policy | The NDP (1989-1994) proposes that other countries apply to our trade regulations similar to those reported here that have been implemented, increasing the potential for economic complementarity with the countries of Latin America and promoting bilateral and multilateral agreements with new poles of global growth, the European Economic Community and the Pacific Rim. The foreign trade policy will be aimed at promoting the modernization of the productive apparatus and foreign investment is promoted through financing economic activity, access to markets and technology. |
| Agreements and treaties enacted | The North American Free Trade Agreement (NAFTA) was enacted. Negotiations for the formation of the Group of Three, comprising Mexico, Colombia and Venezuela and free trade agreements with Chile, Costa Rica and Bolivia were performed. |
| Objectives achieved to the end of the period | 1. Creation of the regulatory framework of foreign trade: structural Customs Law of Treaties reforms, among others.<br>2. Greater macroeconomic stability and greater trade liberalization was achieved by promoting agreements to open foreign markets and deregulation of the domestic market, thus raising the country's export capacity.<br>3. The basis of trade policy openness sat Mexico and new business partnerships were created.<br>4. Admission to the Organization for Economic Cooperation and Development (OECD) and the Forum of Asia Pacific Economic Cooperation (APEC), and its participation in the European Bank for Reconstruction and Development. |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 10. 1994-2000 Ernesto Zedillo Ponce de León*

| | |
|---|---|
| National development plan: Foreign policy | The NDP (1995-2000) sought to promote sub regional forums in Latin America, Mexico and Spain as they are bridges in dialogue between continents and economic regions.<br>Sought to establish a new comprehensive agreement with the European Union giving priority to reach a treaty of free and fair trade with the EU. |
| Agreements and treaties enacted | Free trade agreements with North America (1994), Costa Rica (1995), the Group of Three (1995), Bolivia (1995), European Union (1997), Nicaragua (1998), Chile (1999) and Israel (2000) were enacted.<br>Economic Complementation Agreement with Panama (1998) and the Partial Agreement with Paraguay (2000) were enacted.<br>Negotiations and signature of trade agreements with the Northern Triangle (2001) and the European Free Trade Association (EFTA) in 2001 were performed.<br>Investment agreements for the Promotion and Reciprocal Protection of Investments (BIT) with Switzerland (1996), Argentina (1998) and the Netherlands were signed (1999). |
| Objectives achieved to the end of the period | Mexico joined the Organization for Economic Cooperation and Development (OECD) in 1994 and the World Trade Organization (WTO) in 1995.<br>1. During this period were created conditions under free trade with 27 nations managing to be the only country in the world with a network of agreements on that scale, being able to position Mexican products more competitive in international markets and making its products more accessible to many national markets.<br>2. In order to give greater modernity to the Mexican government structure, a structural reform of the Ministry of Finance in July 1997 was performed, creating the Tax Administration Service (SAT), to which was attached the Administration General of Customs.<br>3. In 1998 it was amended again the Customs Act, with the aim of strengthening the control mechanisms and thus combat evasion of payment of contributions, increased regulatory compliance and non-tariff restrictions and customs fraud in general (Customs Mexico, Aduanas de México, 2015). |

*Table 11. 2000-2006 Vicente Fox Quezada*

| | |
|---|---|
| National development plan: Foreign policy | The NDP (2001-2006) established three broad areas of action: social and human development, order and respect and growth with quality. In the latter, the objectives were: responsibly conduct the economic progress of the country, elevate and extend competitiveness, ensuring inclusive development and create conditions for sustainable development. |
| Agreements and treaties enacted | It was proposed to update the foreign policy of Mexico to the new political realities.<br>The FTA with Uruguay (2004) and the Agreement to Strengthen Economic Partnership with Japan (2005) were enacted.<br>The Economic Complementation Agreement with Argentina (2001) and ECA's with MERCOSUR was held: ECA Framework Agreement 54 (2002) and ACE Automotive Sector Agreement 55 (2003):<br>BIT's were signed with Finland, Portugal, Denmark and France in 2000; Germany, Austria, Sweden in 2001; Cuba, Uruguay, South Korea, Greece and Italy in 2002; Belgium-Luxembourg Economic Union in 2003, Czech Republic in 2004, Iceland and Panama in 2006. |
| Objectives achieved to the end of the period | 1. As it can be seen in the National Development Plan (2001-2006), foreign trade was never a priority for the government during this period.<br>2. Suffered a series of setbacks with US diplomats and the severance of diplomatic relations with Cuba, preventing the country to achieve greater trade openness; nevertheless, the Economic Cooperation Agreement between Mexico and Cuba (ECA 51) in September 2001 was signed.<br>3. In 2006, it was left without effect by presidential decree on the TLC Mexico, Venezuela and Colombia (1995). |

*Table 12. Felipe Calderon Hinojosa 2006-2012*

| | |
|---|---|
| National development plan: Foreign policy | The NDP (2007-2012), sought to reap the benefits of globalization in order to promote national development and project Mexico's interests abroad.<br>Mexico's foreign policy was not a priority in public policy for the government of President Calderón.<br>In order to resolve the diplomatic crisis and disputes inherited from the administration of President Fox, a foreign policy of relatively low profile was raised. Government was mainly focused on combating drug trafficking and organized crime. |
| Agreements and treaties enacted | The FTA with Colombia (2011) was enacted following the FTA with the Group of Three (1995) left without effect by presidential decree in 2006. Also, a FTA was enacted with Central America (2012), a treaty that unifies previously concluded trade agreements with Central American countries.<br>They were enacted the Partial Agreement with Ecuador (2007), the Economic Complementation Agreement with Hungary (2009) and Bolivia (2010), the latter, after annul by presidential decree on TLC with Bolivia (1995).<br>In terms of investment, BIT's were enacted with Australia, UK and Trinidad and Tobago in 2007; India and Spain in 2008; Slovakia, China and Belarus in 2009 and Singapore in 2011. |
| Objectives achieved to the end of the period | 1. Foreign policy, instead of creating business relationships with strategic partners, it made her way to creating bilateral, regional and multilateral cooperation agreements on security, as the case Mérida Initiative.<br>2. Joined multilateral organizations like the Latin American Pacific Agreement (Arco Forum) in 2007 and the Project Mesoamerica Integration and Development in 2008. Also Mexico was thehost country in June 2012 of the seventh summit of the Group of 20 (G -20) serving as president of the group during the year.<br>3. In the periods analyzed, President Calderón was the least effective in matters of holding trade agreements and treaties. |

*Table 13. Enrique Peña Nieto 2012-2018*

| | |
|---|---|
| National development plan: Foreign policy | The objectives of the NDP (2013-2018) are about five strategic areas: Mexico in peace, inclusive Mexico, Mexico with quality education, prosperous and Mexico with global responsibility.<br>The aim is to defend and promote the national interest abroad, seeks to expand and strengthen the country's presence in the world; Mexico reaffirm commitment to free trade, capital mobility and production integration (Plan Nacional de Desarrollo, 2013-2018). |
| Agreements and treaties enacted | To date, Mexico has celebrated the FTA with Peru (2015) and the FTA with Panama is pending of enactment.<br>There were signed the Regional Agreement on Cooperation and Trade in Goods in the Cultural, Educational and Scientific areas with members of LAIA (Agreement 7) and the Regional Agreement with Bolivia, Argentina, Brazil, Colombia, Chile, Ecuador, Paraguay, Peru, Uruguay, Venezuela, Cuba and Panama (Agreement 4).<br>In terms of investment, BIT's were held with Bahrain (2014), Turkey and Kuwait (pending). |
| Objectives achieved to the end of the period | 1. Highlights 11 structural reforms promoted by President Peña Nieto, approved in the first 20 months of the current administration. For Mexico, it was essential to create a suitable environment to remain competitive globally.<br>2. The energy reform: transforms the Mexican oil industry and the national electrical system, opening the sector to competition to attract investment. The reform on economic competition updates legislation and expands the catalog of anticompetitive practices tightening sanctions on them. The reform in telecommunications and broadcasting strengthens and encourages the development of these sectors. Similarly, highlights the financial reform and tax reform. |

The least productive period in foreign policy was that of President Calderón (2006-2012), as its public policy focused on the war on drugs, in addition to inheriting the previous period (2000-2006) various conflicts and diplomatic friction with partners. It will be pending to analyze the period of the current president, once he finishes office (2012-2018). However, as seen in its National Development Plan for Mexico's foreign policy is, and will be a priority. During the first three years of his government has already held two FTAs: Peru (2015) and Panama (pending) and integrated regional initiatives: Alliance Pacific (2012) and Transpacific Strategic Economic Partnership Agreement (2012).

## CONCLUSION

It is imperative that foreign policy is an essential and central component in the national project, through innovation and creating strategic alliances with foreign partners is possible to turn foreign policy into a linchpin of the development of Mexico, affecting well in the economic, commercial, political and social development.

Unfortunately Mexican trade policy, despite having ten existing trade treaties, has focused on a single trading partner, the United States, as it is the main recipient of Mexican exports - oil and non-oil companies- with 77.5% of the total exported in 2013. Second and far away as Canada with 2.9% of exports, followed by Spain with 1.9% and the rest of the world with 17.7%. That is, there is little point having 45 partners, with tariff and non-tariff preferences if, 80.4 percent of Mexican exports depend on a single trade agreement, NAFTA (Secretaría de Economía, 2015).

The task of the Mexican state should be to achieve a deeper approach to markets with greater dynamism and growth opportunity, as in the case of the group, BRICS, Brazil, Russia, India, China and South Africa, or the Asian Tigers-South Korea, Taiwan, Hong Kong and Singapore, regions where there has no signed trade agreement. In the Asian market, not just the only trade agreement with which Mexico has in the-Agreement area for Strengthening Economic Partnership with Japan, it is necessary to develop a trade agenda with China, who is currently the second largest trading partner Mexico, as well as members of the Association of Southeast Asian Nations (ASEAN) or the Forum of Asia Pacific Economic Cooperation (APEC).

## KEY TERMS AND DEFINITIONS

**Business Politics:** It is the pursuit of individual agendas and self-interest in an organization without regard to their effect on the organization's efforts to achieve its goals.

**Globalization:** It refers to the opening up of the domestic economy into the face of the global world. It enhances in the cross country flow of goods and services.

**Internationalization:** It is the process of increasing involvement of enterprizes in international markets. There are several internationalization theories which try to explain why there are international activities.

**Multilateralism:** It is a trading system that facilitates the exchange of financial instruments between multiple parties.

**Multinationals:** It is an enterprise operating in several countries but managed from one country which is called the home country.

**Regionalism:** It is the expression of a common sense of identity and purpose combined with the creation and implementation of institutions that express a particular identity and shape collective action within a geographical region.

**Trade Policy:** It is the policy that includes the use of tariffs and other trade barriers, such as restrictions on what goods can be imported or exported, and which countries are allowed to import or export goods to the home country.

# Chapter 72
# Transcontinental Strategies and Strategic Choices

**Reza Aboutalebi**
*University of Surrey, UK*

**Hui Tan**
*Royal Holloway, University of London, UK*

**Reshma Trupti Lobo**
*University of South Wales, UK*

## ABSTRACT

*This paper searches for a possible Asian way for internationalization and the theoretical bases behind these transcontinental strategies and strategic choices. In particular, this paper explores the dominant modes of outward foreign direct investment (OFDI) employed by Indian enterprises in the UK. It also assesses their competitive advantages in various industries, and the link between strategic aspirations and post-entry performance. This study employs a mixed methodology using a combination of questionnaires and semi-structured interviews for data collection from 124 companies. Mergers and acquisitions are revealed to be the preferred mode of entry into the UK. However, the study found that not all theoretical predictions are supported. Although from a financial point of view India's OFDI in the UK is not fully justifiable, from a strategic development aspect, it has satisfied the investors.*

## INTRODUCTION

While transcontinental trade can be traced back more than a millennium, advanced transcontinental strategies or strategic choices are a relatively new phenomena. The theories behind these strategies may be in need of revisiting (Aboutalebi, 2016b) to adjust them to the recent surge in the cross-continental internationalization of Asian multinational enterprises. Late industrialized countries in general and Asian countries in particular tend to follow different paths towards economic development, compare with those

of the early developed ones. This research is an attempt to shed light on the preferred modes, strategies and strategic choices of Indian companies for internationalization and to assess the suitability of current theories to explain these preferences.

Foreign Direct Investment (FDI) as one of the common mode of internationalization refers to "an investment made to acquire lasting interest in enterprises operating outside of the economy of the investor" (International Monetary Fund, 2015). Recently, Outward FDI (OFDI) from Asian countries into the developed countries has fast been gaining momentum. A report by the Organisation for Economic Cooperation and Development (OECD) shows that Asia's developing countries are the first major source of OFDI (see Figure 1). The recent World Investment Report (2015) by the United Nations Conference on Trade and Development (UNCTAD) indicates that not only is there a growing trend of OFDI from Asian economies, more interestingly, there has been a dramatic increase in the number of enterprises originated from developing economies investing in *developed* host countries. This 'reverse' globalization has been termed 'unconventional' (Kedia, Gaffney & Clampit, 2012), as it does not follow the conventional internationalization path previously predicted based on the experiences of firms out of developed (primarily Western) economies.

Several Asian economy proponents have argued that the traditional theories fall short in explaining the FDI patterns from Asian economies. The emergence of these new multinational enterprises (MNEs) raises the need for further study and the development of new theories. A few renowned management advisory organizations have published informative reports (BCG, 2015; Price WaterhouseCoopers, 2010) and attempted to predict the possible long-term consequences. The structure of the paper is as follows: after the theoretical frameworks that highlight internationalization theories regarding multinationals from Asian economies, Indian multinationals in the United Kingdom (UK), research methodology and finally discussions and findings are presented.

*Figure 1. Sources and trend of OFDI (billions of dollars)*

## BACKGROUND

India is currently one of the fastest growing economies, with the second highest growth rate in the world, at roughly 8% (World Bank Data, 2016), just behind China. The Asian enterprises from India are ambitious, seeking to increase visibility and brand recognition on the global business scene (BCG, 2015; PWC, 2010). The recent spate of cross-border acquisitions of global brands by Indian companies – such as Tata's acquisition of Jaguar/Land-Rover and Ranbaxy's acquisition of generic pharmaceutical brands in Germany, Italy and the USA – has prompted business professionals to predict that by 2018, the number of Indian multinationals would far exceed the rest of the Asian countries (PWC, 2010). Needless to say, it is not only very interesting but also important to study the activities and the underlying patterns of OFDI by Indian companies.

The UK, a developed economy, has become the third most favored destination for Indian FDI, after the Netherlands and the USA, according to leading financial and economic newspapers in the recent past (World Investment Report, 2015). Moreover, there has been constant and active collaboration between India and UK with respect to business connections between the two countries; the most recent evidence being a diplomatic visit by the India Prime Minister with the largest delegation of business leaders to the UK.

This study is important for several reasons: despite close collaboration between India and the UK, there is limited academic research conducted on the factors that have influenced this exponential increase in trade between the two countries. Existing literature has mainly looked at either the country-specific or industry-specific push factors for Asian MNEs, and very little research has been dedicated to the pull factors. Furthermore, research on the subsequent success or failure of the intrepid Asian MNEs in *developed* economies has been painfully limited (Ramamurti, 2009). There is also scarce literature on comparative studies of various industries from a single Asian economy investing in a single developed recipient economy (Aboutalebi, 2016c; Aboutalebi, Tan & Dyerson, 2016).

Following recent trends in extant literature that there is a marked increase in OFDI by Indian (a developing country) enterprises into the UK (a developed economy) over the last decade, this chapter will address the weaknesses by examining the strategic behaviors of Indian firms in the UK. It focuses in particular on the preferred entry strategies for Indian enterprises in the UK and how this reflects on subsequent strategic success.

## THEORETICAL FRAMEWORKS

### Modes of Internationalization

The issue of the modes of internationalization has been discussed since the 1960s (e.g., Hymer, 1976) so it is a familiar field of study. As Nummela and Saarenketo (2012) state, the choice of the internationalization mode has been examined from varied dimensions, including the steps of internationalization (Johanson & Vahlne, 1977; Johanson & Vahlne, 1990), the drives of internationalization (Dunning, 1981; Mathews, 2006), internationalization and transaction costs (Kogut & Singh, 1998), supply chain (Aboutalebi, 2016a) and knowledge-seeking (Kedia et al., 2012). However, almost all of them have been developed based on studies regarding companies in Western and developed countries.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although there is a considerable degree of agreement among scholars regarding the existing modes of internationalizations such as direct export, FDI, or franchising (Nummela & Saarenketo, 2012), a noticeable discrepancy is evident in terms of classifying these foreign entry modes. While Daniels and Radebaugh (2004) classify entry mode choices into three groups including export (direct and indirect), licensing (franchising, management contract, and turnkey), and investment (portfolio and FDI), Kotler et al. (2008) group direct and indirect exports as *exporting*, licensing, contract manufacturing, management contracting, joint ownership as *joint venturing*, and assembly facilities as well as manufacturing facilities as *direct investment*. The focus of this research has been mainly on direct investment by Indian MNEs in the UK.

According to Hattari and Rajan (2010, p. 504), while the first wave of outward FDI from India was organic development via a greenfield mode, "the focus of the second wave of Indian OFDI appears to have shifted to overseas acquisitions globally as a mode of foreign market entry and inorganic growth".

## MNE 'Evolution'

Built on Mathews' (2006) "linkage, leverage, and learning" framework, Ramamurti (2009) cautions that the very context of globalization for present-day Asian multinational enterprises (AMNEs) is different, which, therefore, necessitates new reasoning to understand the current stage of individual firms. Contradicting all previous theories (as demonstrated in the evolution chart below), he points out that MNEs from Asian economies are largely 'infant MNEs' or 'adolescent MNEs' (in some cases), and therefore, it is inappropriate to measure them on the same platform (competencies, advantages, strategies) as 'mature MNEs' from the West. Stal and Cuervo-Cazurra (2011) stated a similar opinion in their research papers that studied diverse organizations from South East Asia and Latin America.

On a different note, although extant international business models are more pertinent to early mover MNEs (i.e., developed economies), these traditional theories could be juxtaposed with the new international business theories to complement each other (Li, 2010). This is especially the case since neither the new nor the old models appear capable of explaining all phases of internationalization, as each model caters to just one aspect of the MNE and internationalization evolution process. Li goes on to propose that 'learning' is the single most unifying concept, with the vital contrast that the early MNEs engaged in '*exploitative* learning', while the latecomer AMNEs engage in '*exploratory* learning'.

Many traditional internationalization theories exist on why and how firms internationalize. However, these are contradicted by newer theories that focus on internationalization by Asian economy firms. Diverse scholarly opinions abound on why firms from Asian economies 'frog-leap' (Mathews, 2006; Ramamurti, 2009) into the international domain, some even before establishing themselves in their home market.

## Motivations of AMNEs

UNCTAD (2006, p. 54) defines Asian markets as "low income, high growth economies that are using market liberalization as their main means of growth" (such as Japan, South Korea, India, and China). Some motives for internationalization of AMNEs are internal, such as "institutional reform within the home country, increased competition, and increased opportunity" (Peng et al., 2008, p. 12). Others can be the offered advantages in host countries, such as the availability of the required knowledge or technology (Kedia et al., 2012).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

A desire for rapid expansion and going global are two other strong drivers of AMNEs. Two push factors that speed up the internationalization of companies from Asian economies are 'pro-market reforms', which boost companies' capabilities, and the other factor is 'institutional void' that frees the firms from the avoidable misguided regulations of their home countries (Stal & Cuervo-Cazurra, 2011, p. 209).

Rugman (2009, p. 53) claims these foreign investments by AMNEs "reveal a search for the technology, management and strategy skills missing in these firms". The objection to this claim is that if these companies really lack management capabilities, how can they so successfully beat their Western MNEs counterparts? In contrast to Rugman's claim, research by Stal and Cuervo-Cazurra (2011, p. 209) shows that "as countries develop, their firms will develop sophisticated capabilities and eventually become multinational firms". So if companies do not have the required capabilities in the first place, they cannot become international enterprises.

Kedia et al. (2012), who have more realistic perspectives, state that AMNEs rely on home-country location advantages (e.g., access to low-interest loans, low-cost labor, or supportive national governments) that are different from the advantages available to MNEs in developed countries. These competitive advantages help AMNEs to "seek and build knowledge-based firm-specific advantages through FDI" (Kedia et al., 2012, p. 156). Although these MNEs initially exploit their own home-country location advantages, the big ambitions of these companies cannot be fulfilled fully so they need much more than what is available in their home counties.

According to Kumar (2008), seven main drivers for the internationalization of Indian companies are expanding their brand recognition, product mix development, resource, technology and research and development (R&D), market, risk diversification and efficiency-seeking. A lesser known factor in attracting Indian OFDI into the Western countries is the possible role of Indian immigrants who settled in developed countries. Amar and Mazhar (2013, p. 944) believe that Indian diasporas "facilitate acquisition and exchange of technical knowhow, market information and physical capital".

## Industry Factors in Attracting OFDI by AMNEs

It is not strange to see that a considerable number of AMNEs invest in similar industries abroad, such as the investment by Lenovo, a Chinese computer company, in IBM. However, some AMNEs built on their diversification strategy, and have invested in varied industries, some of which are related industries and others unrelated, such as Tata, an Indian conglomerate (Kumar, 2008).

In the context of India, which is the focus of this research, when compared with previous decades, manufacturing declined severely while services increasingly showed an upward trend. However, after the turn of the century, manufacturing made a comeback, albeit in different sectors from before (Athukorala, 2009) as illustrated in Table 1.

To begin, the extractive sector comprised of oil and gas firms and their affiliates, have gained a greater share in outbound FDI (Kumar, 2008), which is not surprising considering the heavy domestic demand of India's burgeoning economy. While the traditional role of leather goods and textiles has diminished in the manufacturing sector, chemicals and fertilizers have once again risen in prominence. The manufacturing segment itself is rising in the ranks compared to the previous wave and has been part of a lot of OFDI, notably in the automobile and industrial ancillaries' manufacturing market (Ray & Gubbi, 2009). The acquisition of Jaguar and Range Rover by Tata Motors in 2008 has become an iconic transaction between an Asian enterprise and a global brand in a developed market. Other notable

activities have been in aluminum, steel, electrical equipment and similar industries by Tata Steel, Punj Lloyd, Essar Group, Hindustan Dorr and others.

It is also clear a 'knowledge-based' global economy and the pace at which the Indian economy is merging with the global knowledge economy have resulted in yet another shift in the dominance of industries (Athukorala, 2009). In conjunction with chemicals, in the last decade healthcare manufacturing comprising of pharmaceuticals, drugs and related biotechnology has been one of the foremost industries to expand across borders, especially in the USA and Europe (Chittoor & Ray, 2007; Chittoor et al., 2008). This is evidenced by the increasing surplus in yearly exports as well as several cross-border ventures of Indian pharmaceutical companies such as Wockhardt, Ranbaxy, Dabur and Dr. Reddy's Labs, largely in the USA, Germany, and the UK (Ray & Gubbi, 2009).

The services segment has been represented progressively by new sectors in software and media, publishing and broadcasting services (Kumar, 2008). This is reasonable considering the boom in IT outsourcing and software, as well as the globally recognized Indian specialty firms in cinema and broadcasting – where arguably, Indian firms may have some competitive advantage. Notably, firms in the information technology (IT) sector and its related services of consulting, outsourcing and media (IT enabled services – ITES) have internationalized far in excess of other industries. This is clearly evidenced by the foray of IT giants such as Infosys, Wipro, NIIT and several smaller firms into the Western hemisphere through mergers, acquisitions and joint ventures.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to the report by BCG (2015), currently the top three globalizing industries from India in order are automotive equipments and parts, IT services/ITES and pharmaceuticals, based on their internationalization activity in developed countries, primarily the USA.

## Challenges and Barriers for AMNEs

It is evident there is a large diversity in the MNEs rising from Asian economies, not only in terms of region, but also in terms of firm size, sector/industry, motivations, preferred strategies and entry modes and destinations. It is a painstaking process and yet, apart from the economic costs of internationalizing that were pointed out by Athukorala (2009) and subsequently explored by some scholars, very few studies have been conducted in recent times in the area of the *challenges* that Asian economies face (more so while investing in economies far more developed than they are). There are also the operational *barriers* that they are subjected to due to bias, discriminatory policies, market response or other social constructs (Eden & Miller, 2004).

While authors such as Ramamurti (2009) propose that AMNEs have unconventional advantages, others such as Rugman and Collinson (2012) insist that the primary challenge that Asian economy enterprises face is due to their lack of many advantages in the global market. Furthermore, not only do these Asian multinationals have difficulties competing globally, but when their home markets liberalize, they are further set back in their domestic markets by the entry of stronger foreign multinationals. Other challenges that have been emphasized include the challenges of accessing capital for expansion or R&D compared to Western multinationals and the lack of a supportive and institutional infrastructure and managerial talent pool (Rugman & Collinson, 2012).

Li (2010) propose that internationalizing companies are subjected to the "liability of foreignness" which goes beyond the obvious costs to companies and encompasses the "unfamiliarity, relational and discriminatory hazards" (Eden & Miller, 2004, p. 2) that enterprises face in the host markets. Differentiating this from the operational and economic challenges which arise due to geographical distance, Eden and Miller (2004) propose that the liability of foreignness arises due to the psychic and cultural/institutional distance of the host and home markets.

Although all cross-border business results in some liabilities, it is more pronounced in the case of the challenges faced by Asian economy enterprises, possibly fed by Western prejudices towards so-called "Third-World" countries (Li, 2010), the assumed lack of genuineness of foreign enterprises, and geocentricism (Rugman & Collinson, 2012). The case of the introduction of the first Japanese automobiles into the US markets and their reception (or rather the lack thereof in the host market) could be quoted as a classic example of this social liability of foreignness.

Shareholder confidence is affected due to the poor reputation that some AMNEs hold. Issues such as accountability and corporate governance systems may be differently managed compared to their Western counterparts, resulting in trust issues by the host country policymakers and authorities (Ramamurti, 2009). Therefore, in order to compensate for these liabilities or to effectively manage them, not only do the strategies and entry modes employed by AMNEs become critical in determining their acceptance and their success in foreign economies (Eden & Miller, 2004) but they also differ from and for different host regions (Peng et al., 2008).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although in recent decades pro-market policies in India have led to an unprecedented level of investment by Indian enterprises abroad (Hattari & Rajan, 2010), the government of India exercises some controls over the overall amount of investment annually to maintain a balance between the inflow and outflow of different types of investment (Rugman & Collinson, 2012).

## Post-Entry Performance of AMNEs

Unfortunately, there is a very limited number of studies on the post-entry performance of Indian firms in any host country. This is not unexpected considering that such heavyweight international expansion from an economically poor country is a relatively new occurrence. Moreover, the few studies on post-entry performance that do exist are all over a decade old, restricted to the activities of OECD countries only (see Geringer & Herbert, 1991; Wagner, 1994); or specifically on international joint ventures (IJV) (Amar & Mazhar, 2013) or exports (Chittoor et al., 2008). Of those, fewer still agree on the resultant outcomes.

Geringer and Herbert (1991) highlight there are many practical difficulties in measuring the performance of IJVs. Finances pertaining to contracts, management fees and technology licensing fees, for example, are almost never included in performance calculations, which, in turn, distort data obtained through studies. Moreover, although an event study of the stock market may provide some evidence, the fluctuations associated with the stock market often lead to unreliable indicators.

Despite the drawbacks, a few researchers have studied the performance of AMNEs in the context of mergers or acquisitions, and find that a large percentage of these ventures are abandoned or fail to achieve their goals (Chittoor et al., 2008). The failure rate is attributed to either a lack of synergy between the target and the acquirer or to a failure on the part of the management team to effectively manage the subsidiary (Kale, 2009). In addition, out of the acquisitions that are completed, the average shareholder value was found to be only slightly over 2% during the first five years. However, from the aforementioned studies, it can be safely assumed that immediately after entry, the financial performance of the firm may decline before a reasonable upturn can be demonstrated (Kumar, 2008).

## Foreign Direct Investment in the UK

The UK Office for National Statistics (UKONS) (2015) reports that during the last decade, FDI in Britain has risen twice compared to the decade before. That is to say the post-recession IFDI into the UK is still well below pre-recession levels, especially during 2005-2007. "The continued fall to the balance of earnings on direct investment since late 2011 actually resulted in a direct investment deficit for the third quarter and the fourth quarter of 2014, the first such deficit since the fourth quarter of 2008. This deterioration is attributed to both subdued earnings for UK residents' from direct investment abroad and an increase in foreign earnings on direct investment in the UK. The balance of earnings on foreign direct investment has since rebounded slightly, returning to a surplus in the first quarter of 2015 and has continued to improve throughout 2015" (UKONS, 2016, p. 4).

## Net IFDI Positions in the UK by Parts and Sectors

FDI has three main types or parts including portfolios or having shares of foreign companies, inter-firm transactions between companies in different countries, and intra-firm transfers of money between a foreign parent and its subsidiaries (Kedia et al., 2012; UKONS, 2015). That is to say, many scholars do

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

not consider portfolio investment as a form of FDI (Kumar, 2008; Rugman, 2009). In many reports and studies, just the overall FDI is being reported without breaking FDI down into its components; however, UKONS makes separations among these three parts of FDI. Considering portfolio investment as a type of FDI has created a huge gap between the reported figures by UKONS and other reporters (e.g. World Bank, IMF) that do not recognize portfolio investment as part of FDI.

According to the Office for National Statistics (2015) "in 2014, the international investment position in the UK increased from £910.3 billion in 2013 to £1,034.4 billion in 2014. Despite a decline seen in the international investment position in 2013, the international investment position has been increasing on an annual basis for over a decade. Foreign companies' share of the UK company's share capital and reserves was the component driving the increase in 2014, rising from £804.5 billion in 2013 to £908.9 billion in 2014" (UKONS, 2015, p. 16).

Regarding the position of IFDI in the UK in terms of sectors, it can be said the two main industry sectors (services and manufacturing) receive very different amounts of investment. The services sector has always been the main recipient of OFDI from around the world into the UK (UKONS, 2015). The gap between the amount of foreign investment in the UK's services sector and production sector has increased sharply and steadily. The manufacturing (production) sector with a relatively slow but continuous growth has received less IFDI compared with the IFDI for the production sector (UKONS, 2015). As stated by the Office for National Statistics (2015) "the inward investment position within the services industries improved in 2014, increasing from £568.0 billion to £671.3 billion.

The increase was mainly due to Europe and the Americas where positions increased by £47.6 billion and £40.4 billion, respectively. Within the production industries, the investment position in the UK increased from £339.4 billion in 2013 to £359.9 billion in 2014. The increase was mainly due to the Americas and Europe, which increased by £18.7 billion and £7.1 billion respectively" (UKONS, 2015, p. 17). The UK's manufacturing sector is capable of absorbing a much bigger portion of foreign investment if the UK government promotes this sector properly. The next section's discussion would be regarding the role of OFDI from Indian MNEs that are equally interested in the services and manufacturing sectors of the UK.

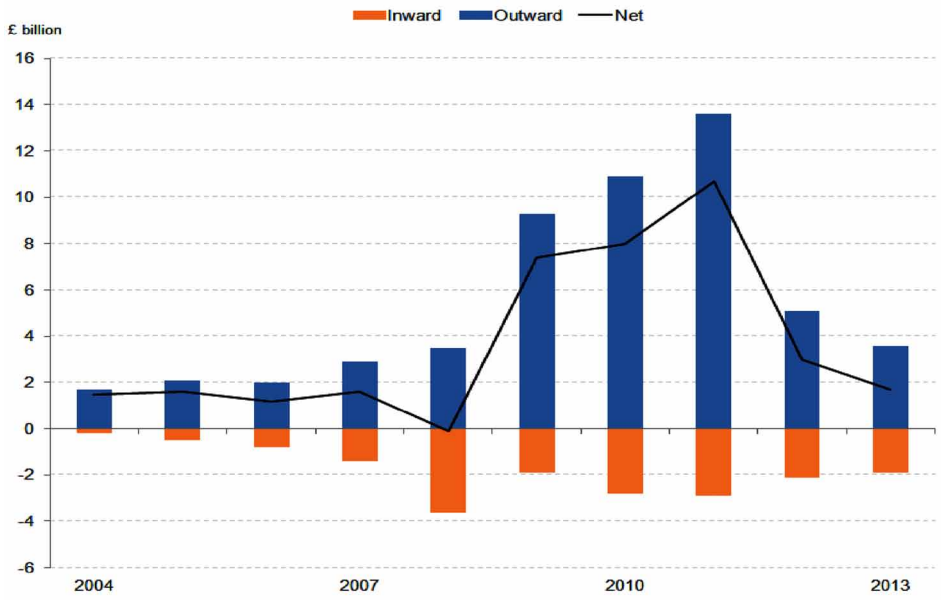
## Outward FDI of Indian Multinationals

The Reserve Bank of India (2014) classifies capital outflow from India into four groups: FDI, portfolio (trading shares), debt flow (paying loans to foreign firms), and others (e.g., donations). As a country with the second highest population and GDP growth in the world (World Bank, 2015), India has attracted the attention of the business world for over a decade. Although Indian enterprises have been investing internationally for several years at a very low volume (Rajan, 2009), the last decade has witnessed a tremendous increase.

Due to its rapid industrialization and economic growth, India has made a significant impact on the world economy, prompting several speculative studies on its Asian firms. An industry analysis model by PWC (2010) that extrapolates the growth patterns for Asian countries based on their GDP growth rate, predicts that China and India will give rise to the highest number of multinationals between 2010 and 2024; and that India may overtake China in the next decade.

According to the Office for National Statistics (2015) "the value of the stock of UK Foreign Direct Investment in India (outward FDI) more than doubled between 2004 and 2013, from £1.7 billion to £3.6 billion. However, there has been a notable decline since 2011, when the stock of FDI was £13.6 billion.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



The largest industry grouping in India receiving UK FDI was financial services (18% of total UK FDI into India in 2013). The value of Indian FDI into the UK (inward FDI) has experienced a notable increase between 2004 and 2013, from £164 million to £1.9 billion. However, the level of FDI in 2013 is lower than the £3.6 billion recorded in 2008. The largest industry grouping in the UK receiving Indian FDI was information and communication (30% of total UK FDI into India in 2013). Since the value of the value the UK's FDI in India was larger than India's FDI in the UK, the UK's net FDI position with India recorded a £1.7 billion surplus in 2013, as shown in Figure 2.

Whereas formerly Indian enterprises focused on developing economies that were similar to themselves for expansion, they are increasingly investing in economically developed countries like the USA, Canada, the UK, and the Netherlands (Gopalan & Rajan, 2010). The aggressive growth of Indian firms and their propensity to expand beyond their borders, combined with their remarkable impact on globalization deserves an extensive study considering various respects, and are bound to throw light on the internationalization of developing-world MNCs in general (Goldstein, 2007; Kumar, 2008; Ramamurti, 2009; UNCTAD, 2004).

## The United Kingdom as a Trading Partner of India

The UK is the sixth largest exporter of goods to India at 2.3% of the total exports and the fifth largest importer of goods from India, at nearly 4.0% of its total imports. In services too, India makes a significant contribution towards the UK's economy. Bilateral relationships between India and the UK have increased steadily for several years, not only in terms of trade and commerce but also in the fields of education, technology, tourism and cultural exchange (Indian Ministry of External Affairs, 2010). According to recent news from the UKTI (2011), India is the third biggest investor in the UK, and the UK

*Figure 2. UK FDI positions with India (£ billions) 2004 to 2013*
*Source: UK Office for National Statistics (2015).*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

receives over 50% of India's investment in Europe. According to the Commonwealth Business Council (CBC), the UK is the fifth largest economy in terms of market exchange rates with favorable investment policies and an open market. It is also one of the strongest economies within the European Union, with considerable trade connections with the EU.

Therefore, for the purposes of this paper on Indian Outward FDI, research was restricted to the investment in the UK. This is mainly due to the increasing political and economic emphasis on bilateral trade and investment between the two countries (British High Commission, 2010), the elevated status of the strategic partnership of the two countries since 2004 (UKTI, 2010) and the current lack of literature on the UK-India relationship.

## RESEARCH METHODOLOGY

Although both quantitative and qualitative approaches have their merits, in keeping with the aforementioned pragmatist philosophy, a stance of mixed approaches could have greater benefits (Tashakkori & Teddlie 2010) for this particular research. An integrated research philosophy of critical realism, incorporating qualitative as well as quantitative aspects into the data collection and analysis (i.e. mixed method design) could provide the best insight for the research on the FDI activities of Asian enterprises within the larger internationalization sphere (Nummela & Saarenketo, 2012).

Reflecting on the nature of the research and the research philosophy, the research strategy is a survey. Although surveys are used for large amount of data sampling through questionnaires, it also caters for smaller sampling in terms of in-depth interviews (Saunders et al., 2012). This research was conducted in two phases and through a combination of primary as well as secondary data. The first phase involved gaining access to relevant databases pertaining to firms of Indian origin in the UK. Sampling was conducted to estimate sample sizes and acceptable response rates in preparation for the second phase. The second phase involved a survey of executives through online questionnaires and semi-structured interviews.

Semi-structured questionnaire surveys as well as semi-structured interviews were employed for the primary data collection to benefit from the combination of these two complementary research instruments. According to Saunders and his co-authors (2012, p. 142) "the use of interviews can help to gather valid and reliable data that are relevant to your research question (s) and objectives". Nine managers (three from each of the top three industries) were interviewed. Seven questions were asked in the interviews. These questions covered three main issues including the motives behind FDI in the UK, the utilized strategies for investment, and finally, the post-FDI financial and strategic performance in the UK.

The survey questionnaires were deployed through an online webhost to randomly sampled respondents from software and IT services, industrial goods and cyclic consumer services (CCS). A total of 400 survey invitations (a proportionate number to the FDI intensity in each sector) were sent by emails to upper or senior executives in all three sectors. One hundred twenty-four (124) responses were obtained, calculated as a response rate of 31%, which is higher than what Cooper and Schindler (2008) state as reasonably sufficient for such social research. Hence, the responses that were obtained can be assumed to be representative of the sample and can be used to make some generalizations within the industries.

Although several international business studies on Asian economy enterprises have been conducted through the cluster sampling technique (for example, Chittoor & Ray, 2007), some argued this could result in decreased accuracy (Cooper & Schindler, 2008), besides being time consuming and complex to apply. Since this research seeks to compare and analyze the individual industry sectors, a sampling

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

technique that provides the equal representation of these sectors is essential to ensure validity. Consequently, in the interests of simplicity as well as the greater precision of the groups, the Stratified-Random sampling method would be most appropriate (Saunders et al., 2012, p. 233). This choice is supported by Cooper and Schindler, who state that stratified sampling is the most suitable method of sampling in order to gain efficiency and "to provide adequate data for analyzing the various subpopulations or strata" (Cooper & Schindler, 2008, p. 169). This study investigates FDI-related issues in three different industries and each industry is a separate stratum, so stratified sampling was deemed the best sampling method for this research.

The data collected from the questionnaires was categorically analyzed. The central tendencies of response were calculated in order to demonstrate the most common responses and attitudes of the respondents (Tashakkori & Teddlie, 2010). The transcribed notes of the interviews were analyzed and coded. These codes were subjected to a comparative analysis, developed into themes, followed by a descriptive and explanatory approach.

## FINDINGS AND DISCUSSIONS

### Recipients of FDIs

The challenges in collecting and analyzing FDI data concerning Asian economies has been well documented by Hoskisson, Eden, Lau, and Wright (2000), and more recently by Aykut and Goldstein (2006). Of particular concern are the issues of the currency of recorded data, due to constantly changing market dynamics, thereby affecting accuracy. Keeping these in mind, secondary data on Indian enterprises in the UK was procured from the Capital-IQ database and then cross-referenced with the one available from the UK Office of National Statistics.

As shown in the pie chart (see Figure 3), the major industry categories were industrials (36 deals), consumer discretionary (35 deals) and IT (32 deals). However, this categorization method is internal to Capital-IQ and not globally utilized as an exhaustive classification. Therefore, the individual firms were re-classified manually, based on the standardized and more widely-used Thomson Reuters Business Classification (TRBC) codes index (Thomson Reuters, 2009).

At 31 deals, software and IT services (also called IT enabled services or ITES), had the highest FDI intensity in terms of volume and value between 2001 and 2010 from Indian firms in the UK. Industrial goods (henceforth 'industrials' or IG), at 20 deals was second highest, and cyclic consumer services (henceforth coded as 'Cons Serv' or CCS) at 11 deals had the third highest FDI intensity.

### Motivation for FDI in Specific Industries

According to the UK Office for National Statistics (2015), the decision of foreign companies to invest in the UK is heavily influenced by the potential financial outcomes of a specific industry. "This has meant that rising FDI in the UK has not been evenly distributed across industries". While IFDI has shrunk in the retail and transportation industries, financial services have been the biggest beneficiary of inward FDI from abroad (see Figure 4). Our findings do not support UKONS's assumption that the financial output of an industry is the major motivation for investment by Indian MNEs (see Figure 5).

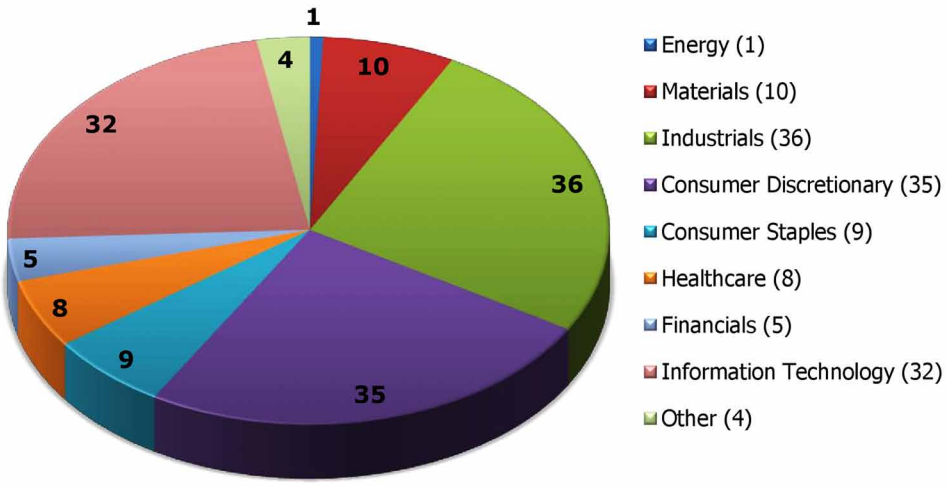
*Source: Capital IQ (2011).*



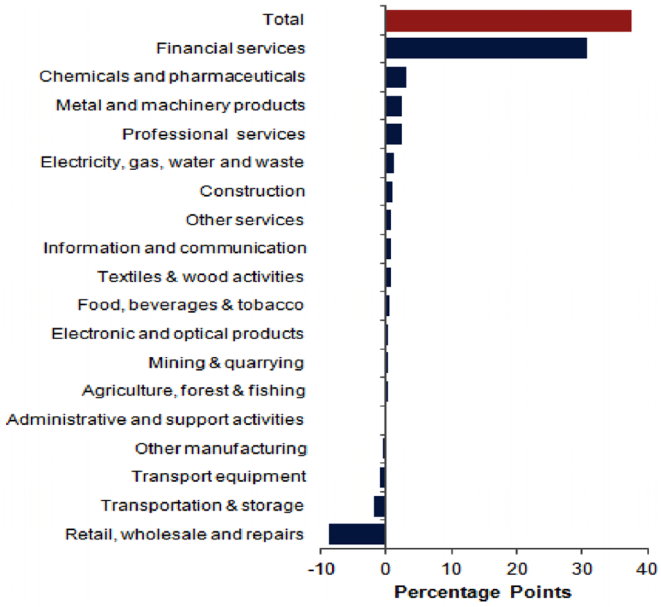


*Figure 4. FDI contributions to growth of different industries in the UK, 2012-2015*
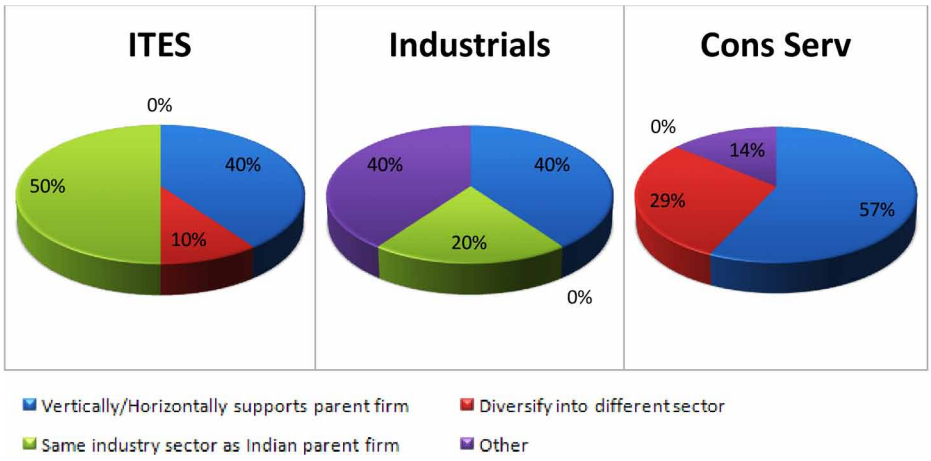
*Source: UK Office for National Statistics (2015).*



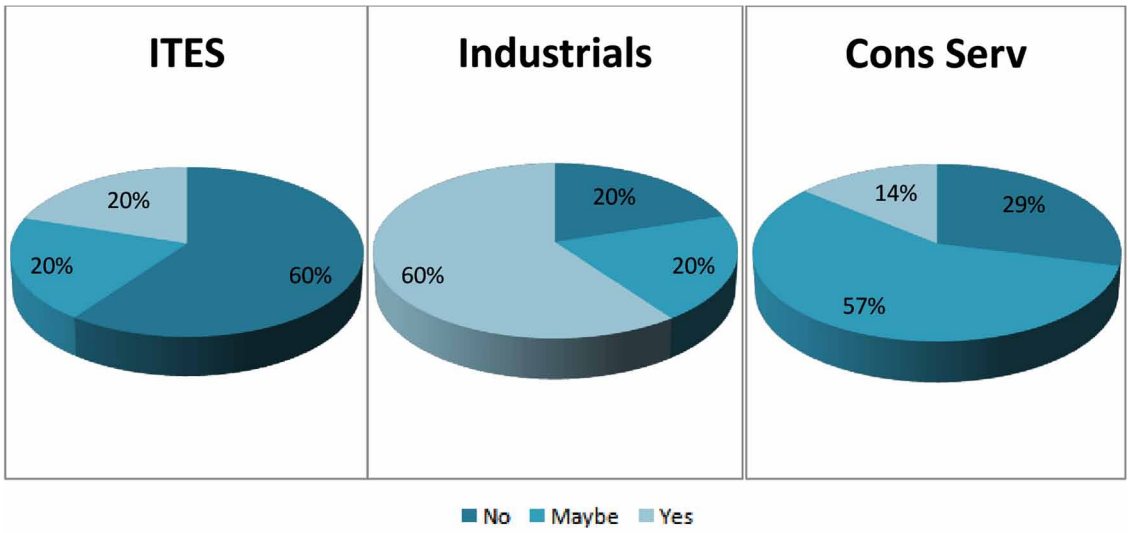
A comparison of the three industries in Figure 5 showed that firms in the ITES business sector tended to invest in acquisitions of firms that function in the same industry (50%) or acquisitions that would assist the vertical or horizontal integration of the Indian parent firm. Contrastingly, while nearly a third (29%) of CCS responses indicate diversification into a different industry as a driver, none of the industrials responses indicated that it mattered.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 5. Reasons to invest in a particular industry sector in the UK*

Delving further into this theme through interviews, respondents elaborated there were multiple aspects to the FDI strategy. While at a macro level the aforementioned reasons were the drivers to internationalization, at the industry and firm levels there were several other influencing factors. For instance, while nearly a third of the researched CCS firms had diversified their portfolio during internationalization, the majority of ITES remained in the same specialty within the sector. The overriding factor for all three sectors was the fact that the acquired firm vertically/horizontally supported the functions and capabilities of the parent firm. In other words, the acquired firm had *complementary capabilities* and was capable of adding to the *value chain* of the parent rather than simply compensating for the capabilities that the parent did not possess.

## Competitive Advantages



Dunning's OLI framework (1979) in particular vehemently stresses the influence of ownership advantages in determining the internationalization paths and strategies of firms. Although Dunning's later works (2008) have been modified to encompass the changing nature of global business dynamics, he asserts that without ownership advantages, it is impossible for expanding firms to achieve any form of success in foreign soil. He further posits that Asian economy firms do not have any of the competitive advantages that would ensure sustained success across borders.

However, when surveyed and interviewed, a majority of the participants in this research in all the three sectors quoted that they strongly believed that their organization possessed some form of competitive advantage. These findings are demonstrated in Figure 6. When asked to elaborate briefly, the keywords such as 'niche industry specialists', 'reputable business/conglomerate' 'global brand name', emerged with the CCS. 'Strong engineering reputation', 'high quality accreditations', 'global presence', 'domain expertise' were the main themes from the IG sector; while 'leading diversified IT company', 'global delivery model' and 'CMMi Level 5 accreditation' emerged as themes from the ITES responses. Our findings support the study by Stal and Cuervo-Cazurra (2011, p. 209) that found "as countries develop, their firms will develop sophisticated capabilities".

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

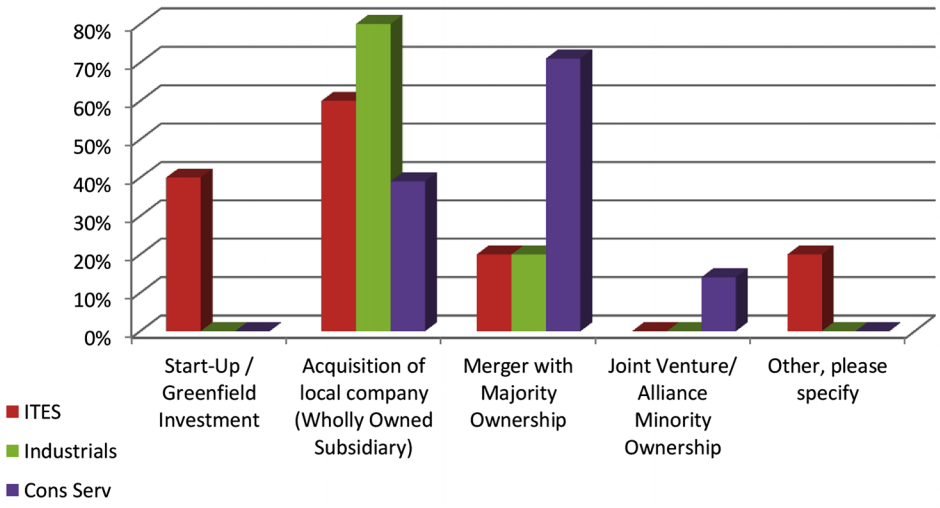
*Figure 6. Did your competitive advantages play an important role in selecting UK for investment?*

These responses may be moderated by the subjective nature of the question and whether all the respondents in question were actually privy to the level of the strategic decision-making process within the organization. Nevertheless, the prominent observation was the conspicuous contradiction to what most theorists in the literature review (e.g., Rugman, 2009; Rugman & Collinson, 2012) claimed on the supposed lack of competitive advantages that Asian MNCs possess.

Conversely, however, upon questioning whether their competitive advantage played an important role in their decision to undertake FDI in the UK, a significant number of respondents (with the exception of industrials) believed that their choice to invest in the UK was not influenced by the firm's competitive advantages. However, in the industrials sector more than half the respondents felt that their competitive advantage was important for their FDI strategy in the UK. Thus, this finding contradicts one of the three pillars of Dunning's OLI theory that claims ownership of a competitive advantage is one of the main motives of internationalization in general and FDI in particular.

## Dominant Modes of FDI

### Choice of Entry Strategy



A total of 80% of the industrial goods sector responded that the acquisition of a local company (wholly-owned subsidiary) was the only mode that was considered. In ITES, 60% indicated acquisition while 40% indicated a Greenfield investment, although a small percentage of this sector also indicated that acquisitions in the UK as well as in the USA were being considered (see Figure 7).

During the data sample procurement, it became evident that not only did mergers and acquisitions greatly outnumber the other modes of FDI but they also had the most accurate record-keeping. Eliminating the minority modes of FDI, mergers and acquisitions (M&A) was determined to be the preferred mode of investment. The data available was in the form of completed M&A deals involving Indian buyers and UK sellers between the years 2001 and 2010.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

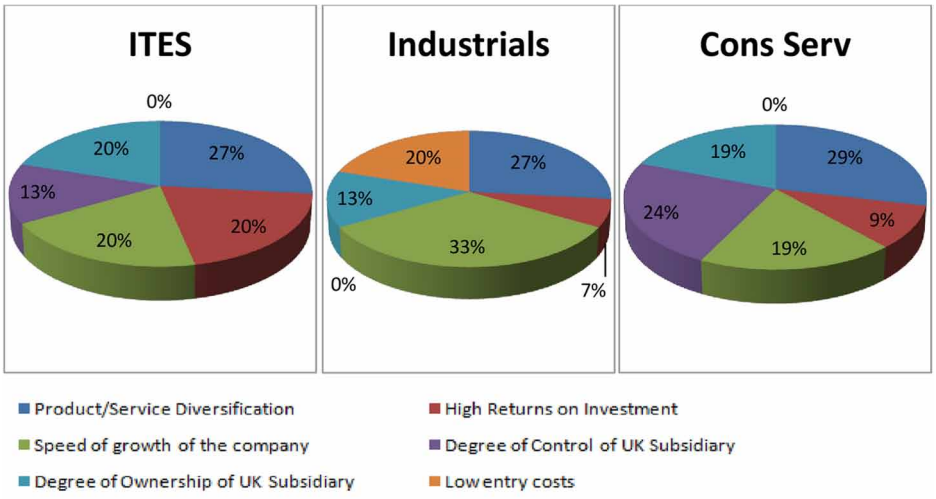


*Figure 7. Choice of entry strategy in the UK*

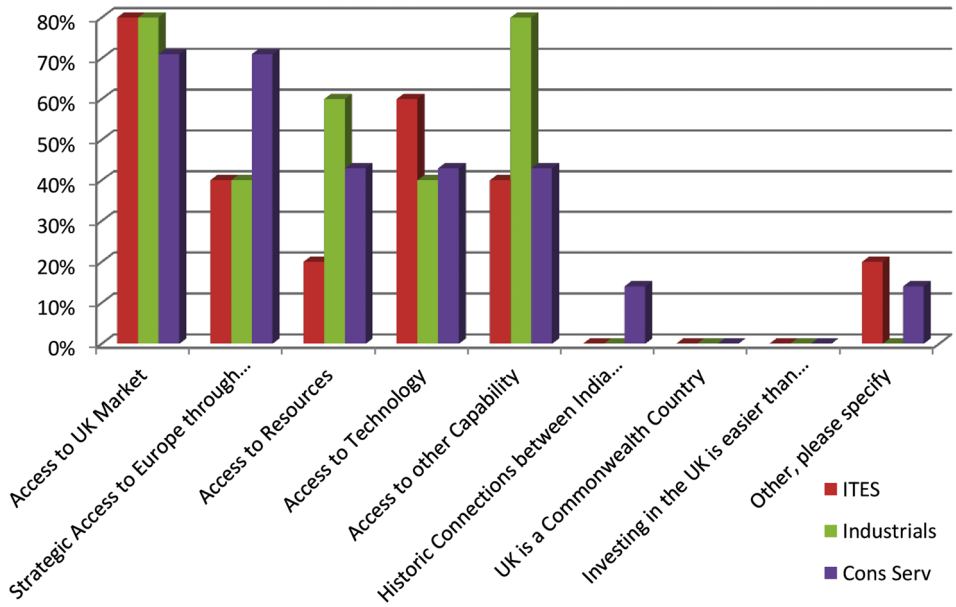
This study shows that acquisitions or whole ownership followed by mergers are the primary and secondary common modes of OFDI by Indian MNEs in the UK, respectively. Our findings are in contrast with the claim by Hattari and Rajan (2010) that predicted acquisitions are a less desirable option due to their high costs and high risks. The drivers influenced their choice of entry strategy for the UK. The respondents were asked to choose the three points they felt had the most impact on strategic decisions. The responses are shown in Figure 8.

It was found that opinion was divided between the three sectors as well as within the sectors. 'Speed of growth of the company' was the largest majority in the IG sector at 33%, while 'product/service diversification' had the majority (29%) in CCS and ITES (27%). Based on a review of extant literature, it was predicted that access to technology, capabilities, and strategic assets were primary motivations for

*Figure 8. The top motivations for choosing particular mode of entry*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the internationalization strategies of Indian enterprises. The fact that the majority of respondents cited 'access to UK markets/strategic access to EU' and 'access to capability' as reasons for FDI in the UK, more or less strengthens the extant literature on this topic.



Furthermore, while 'access to resources' was an important consideration for industrials, 'technology' was at the corresponding level of importance for the ITES segment. This is understandable as technology is a vital element of India's burgeoning IT services industry, as are manufacturing facilities and networks for the industrial goods segment. Therefore, although asset augmentation (WIR, 2006) is known as a critical factor in driving OFDI, the influence of 'industry effects' (Gupta & Wang, 2009; Zahra, 2005) appears to be equally crucial in the decision to internationalize.

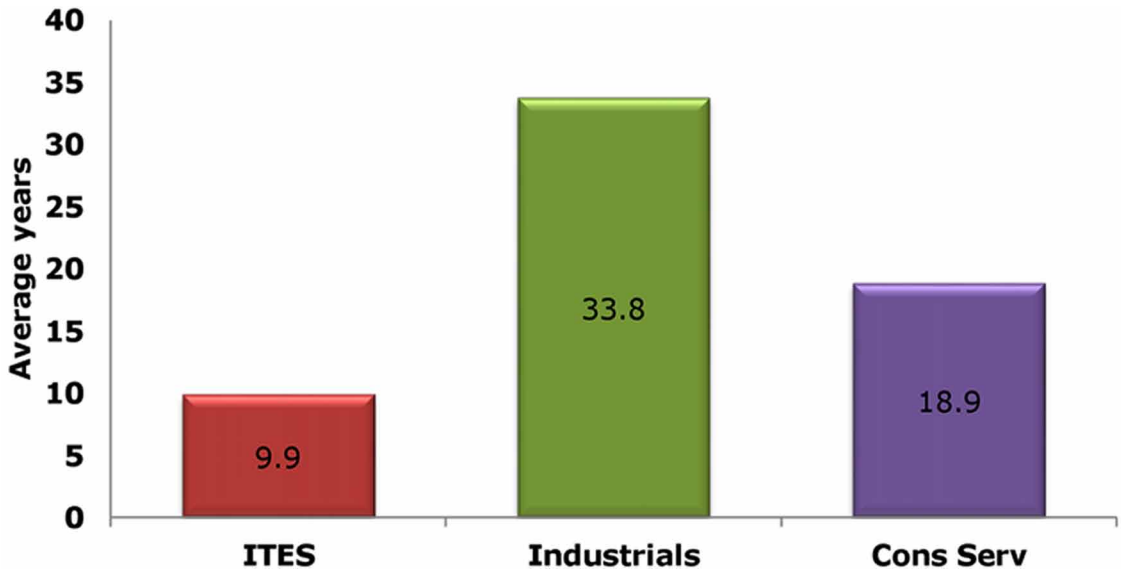
## Drivers for FDI in the UK

Regarding the reasons for investment in the UK, respondents were asked to choose the three most important reasons for their FDI in the UK from a list of eight options. A text box as 'other' was provided in order to encourage respondents to elaborate on their answers.

Figure 9 charts out the percentage responses of the three sectors. As evident from the chart, 'access to the UK market' at nearly 80% was the most important motivation for the ITES industry, followed by 'access to technology' at just under 60%. In the industrial goods sector, access to the UK market and access to certain 'capabilities' were equally important, followed by 'access to resources'. The CCS was the only sector to cite access to the UK as well as strategic access to the European markets as top motivations. 'Access to resources, technology and capability' were equally important drivers, though secondary when compared to the former. Overall, 'access to the UK market' was the top-cited motivation in all sectors.

*Figure 9. Main reasons for Indian OFDI in the UK*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



Our findings are partly different from that of Hattari and Rajan (2010, p. 497) that showed OFDI from India is not entirely different from that of other countries in that they are motivated by many common factors. There is evidence, however, that Indian OFDI is more market- and resource-seeking than OFDI from most other countries. Unlike Hattari and Rajan's findings, our study has demonstrated the importance of access to technology and other capabilities as drivers for FDI. According to Kumar (2008) the seven main drivers of internationalization of Indian companies are expanding their brand recognition, product mixes development, resource, technology and R&D, market, risk diversification, and efficiency-seeking. Kumar's claim is not based on empirical research. In practice, our research highlighted the importance of just four motives. Furthermore, our study does not support the findings of Amar and Mazhar (2013, p. 944) that "the presence of Indian diaspora has a substantial positive effect on the volume of Indian overseas investments in the developed countries".

## Firm Age and Internationalization

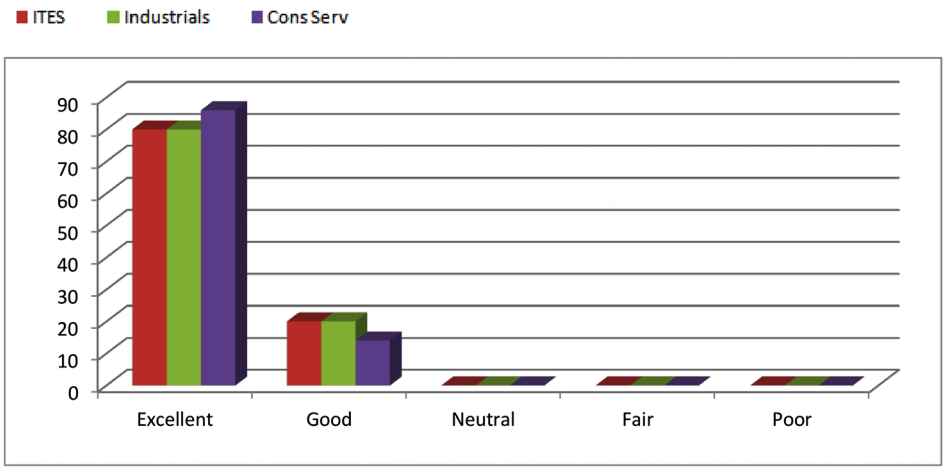
One of the questions asked the respondents to input the number of years the Indian enterprise had been in existence before internationalizing in the UK, with a view to test the claim of some authors that Indian enterprises that have internationalized into a developed economy were predominantly young enterprises. It is important to note that this question focuses on age while first entering the UK, and not age while first investing abroad. Therefore, it is possible that these companies have subsidiaries elsewhere in the developing or even developed countries *before* entering the UK. Related findings are illustrated in Figure 10.

Based on several traditional as well as modern FDI theories, it is believed that Indian enterprises that had undertaken FDI in the UK were probably 'young' MNEs (Singh, 2008). However, at an average age of 33.8 years (industrial goods) and 18.9 years (CCS) and 9.9 years (ITES), the age of the firm appears to refute theories of 'international new ventures' and 'born-global' (Oviatt & McDougall, 1994) that assert the surmise that Asian MNE firms are always young while undertaking cross-border investment.

*Figure 10. Average firm age in the three sectors when first investing in the UK*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Evidently, at 33.8 years, the industrials sector is nearly two and a half times older than the average of ITES firms – a technology- and time-intensive sector that is comparatively speaking, 'the new kid on the block'. Yet, the ITES sector has ventured abroad much earlier and with greater intensity than the other two sectors.



The maturity of the industries is not just based on age. Although the average age of 9.9 years for the ITES industry seemingly represents a very young sector, industry-based theories explain something different. An examination of the theory of industry life cycles (Klepper, 1997) or firm life cycles (Miller & Friesen, 1984) brings a contrasting perspective. The theory posits that industries undergo various stages from birth to maturity to decline, similar to that of the life cycle of products. If this concept is applied in juxtaposition with Ramamurti's theory of MNE evolution (Ramamurti, 2009; Ramamurti & Singh, 2008), the ITES firms are actually mature MNEs in light of the nature of the industry, their "entrepreneurial and strategic postures" (Melen & Nordman, 2009) and the normally shorter industrial life cycle they undergo.

## Post-Entry Performance

The post-entry performance of the parent firms was measured from two aspects: the extent to which the *strategic* aspirations of the firm were met, and the extent to which the *financial* aspirations were met. These questions were specifically to obtain subjective responses (Elango & Chinmay, 2007; Geringer & Hebert, 1991). The fact that nearly 80% of the participants considers the realization of their strategic objectives to be 'excellent' is striking (see Figure 11). This response is even more significant given that there was not a single participant in any of the three sectors that indicated dissatisfaction. Most of the respondents believed that they had either achieved (the older firms) or were in the process of achieving (the newer firms) the foothold that they needed in the European markets.

As reflected in Figure 12, in terms of post-investment financial performance, achievements are satisfactory but not great.

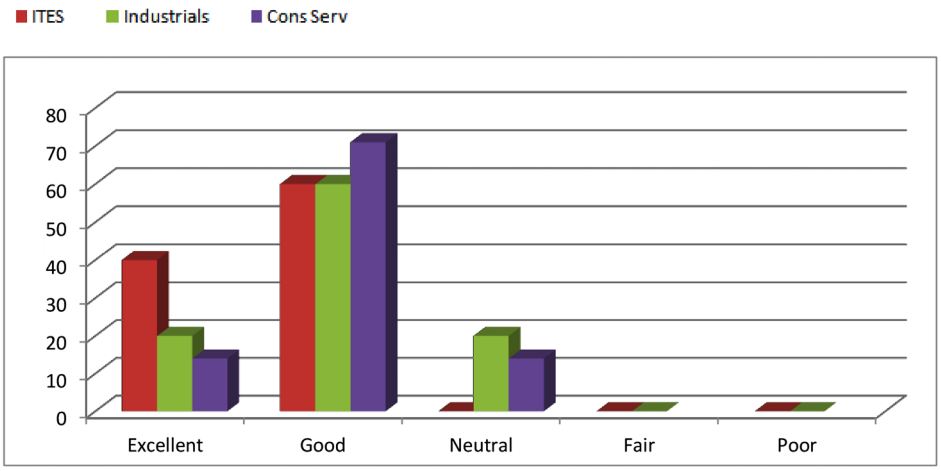


*Figure 11. Executives' perspectives on post-entry realisation of strategic objectives*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 12. Executives' perspectives on post-entry realisation of financial objectives*

The fact that a majority of the participants are satisfied with the post-entry performance (mainly strategic objectives) despite a very slow recovery after the global recession causing an overall poorer financial performance of most large, medium or small enterprises worldwide, is noteworthy. Assuming that to some extent this situation was aided by the financial crisis affecting the survival of developed country firms, it can only be speculated whether this would not have continued to be the case, had there been no financial recession. Although the financial post-entry performance of some Indian MNEs in the UK is not so satisfactory, the investors are happy with the fulfillment of other strategic objectives.

The reason is "many Indian enterprises view OFDI as an important dimension of their corporate strategies" (Hattari & Rajan, 2010, p. 497). Therefore, it is possible that certain cultural aspects may have enhanced the chances of successful ventures across borders for Indian enterprises. Some of the cultural dimensions that are especially extreme in Indian culture (including business culture) are uncertainty avoidance and long-term orientation (Hofstede, 1984).

## LIMITATIONS, RECOMMENDATIONS, AND CONCLUSION

### Limitations

The primary data of this research is limited to Indian MNEs, so the findings cannot be generalized to all Asian MNEs. The results of this investigation may not be representative of the transcontinental strategies and strategic choices of all Indian MNEs around the world, due to the fact that the findings are about Indian MNEs in the UK. This study focused on major issues regarding the internationalization of Indian companies; thus, it is possible that some minor factors with influence in internationalization decisions were left out. In terms of research methodology, the subjective nature of interviews can limit the possibility of generalizing the findings. This research employed a mixed method research design to minimize shortcomings of conducting interviews. Although this research could not cover all existing shortcomings regarding the Asian way of internationalization, it hopefully clarified some aspects of this phenomenon.

## Recommendations

It is evident the internationalization trends of Indian enterprises shall remain; therefore, certain theories and generalization can be built around the themes that emerged through this chapter. Based on the findings of this research the following recommendations are provided. Host countries that wish to continue attracting FDI are urged to keep these dynamics in mind while formulating trade policies. International organizations such as the UNCTAD can act as an essential platform in this context by providing relevant analyses and assistance in order to exploit these Asian and developed economy synergies.

It is also common knowledge that the activities of cross-border FDI for Asian enterprises are especially challenging due to their liability of foreignness. Decision-makers in industry as well as trade authorities are urged to formulate favorable trade policies that encourage increasing commerce from AMNEs. The OECD countries in particular are encouraged to harness the opportunities that Asian enterprises could create within developed economies. This study has found that despite sub-par economic conditions, Indian enterprises have continued to flourish and have reported a satisfactory post-entry strategic and financial performance. This clearly demonstrates that there is definitely a place for more firms within the knowledge-based industries, such as software and IT and service-based industries, such as hospitality and media.

AMNEs are advised to consider current negative issues in the UK including the growing anti-immigration atmosphere, the possibility of leaving the European Union in the near future and very slow post-recession recovery that may jeopardize AMNEs' investment. Thus, it is recommended that AMNEs in general and Indian firms in particular that are eager to expand in the UK markets exercise caution, especially in any non-dominant business sectors. Further, it is suggested that companies from Asian economies undertake expansion into developed countries *only* if they possess the essential core competencies to compete with rivals in the new markets.

Due to the fact that the financial performance during the first few years of post-entry into the developed countries may pose an imminent threat and burden (no profits or marginal profitability), companies from Asian economies should be in a sustainable situation financially with considerable capital before expanding into the developed countries' markets. Researchers are urged to undertake further research focusing on the pull factors of country-specific and industry-specific origin that contribute towards the globalization of Asian MNEs. While some generalizations have been made, greater study is required into the internationalization dynamics of other Asian economies such as Japan, China, and South Korea.

## CONCLUSION

This research has gone beyond the traditional perspectives of the globalization of Western economies or MNCs into Asian markets, rather viewing the developed economies as receptors of OFDI from the very economies that, until recently, were considered weak. Furthermore, this study has taken the stance of evaluating the pull factors rather than the push factors that the Asian economy proponents have thus far focused on. In these two aspects, this study is unique and contributes towards new insights in globalization trends.

A majority of the extant literature claimed that Indian enterprises in the UK were only aggressive young MNCs that invested in the UK because they mostly lacked competitive advantages. However, through this research it has been established that this is not necessarily so, and that the majority of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

surveyed enterprises strongly believe that they had significant advantages in comparison to their rivals. Regarding the preferred mode of Indian FDI in the UK, through archival study and the record-keeping of trade firms cross-referenced with the data from the Office of the National Statistics (UKONS), it was found that acquisitions (and mergers as second to the acquisitions) were the favored form of FDI for many reasons. Furthermore, it was found that software and IT, industrial goods and CCS were the fastest growing sectors that receive the highest FDI volume and intensity. Speed of growth of the company and increasing product/service diversification are two strategic motivations for choosing to invest in the UK.

The subsequent post-entry performance of the Indian MNEs in the UK has been satisfactory and promising. Unlike Western investors, financial outcomes are a secondary issue for Indian MNEs. Other strategic objectives such as being present in the UK market, and access to technology are more important motivations for Indian investors into the UK. There is in existence noticeable differences between investors from Asian economies in general and Indian MNEs in particular with their Western counterparts in terms of motivation for internationalization, the preferred modes of internationalization, the target countries and industries for investment, the portfolios of investment and even the characteristics of MNEs such as their age and size. Therefore, it would be reasonable to develop exclusive internationalization theories for MNEs or would-be MNEs from Asian economies.

## KEY TERMS AND DEFINITIONS

**Foreign Direct Investment:** A long-lasting investment in foreign enterprises that influences the management of the established or acquired entities.

**Internationalization:** A process in which a domestic company becomes international by expanding its activities beyond its home country.

**Inward Foreign Direct Investment:** Receiving long-lasting investments from foreign investors.

**Multinational Enterprise:** A company that is active in at least two different countries.

**Outward Foreign Direct Investment:** Establishing or acquiring entities in foreign countries by investors from the home country.

**Transcontinental Strategy:** A strategy for cross-continental internationalization.

# Chapter 73
# Securitization and the Economy of Risks:
## Decision-Making in the Eurasian Union

**Oxana Karnaukhova**
*Southern Federal University, Russia*

## ABSTRACT

*In the beginning of the 21st century the society of the Second Modernity with incalculable risks marks human conditions in orientation and self-categorization on the basis of historical memory. The dichotomy "We-Other" influences strategic risk decisions. Security is becoming the umbrella topic referring to public goods, transnational markets, "the specific way of life". In the context of different agreements and regulations co-existence (such as European Economic Area, Eurasian Economic Union, BRIC etc.) claims for personal and collective safety together with the rhetoric of memorization influences decision-making process and becomes a burden of securitization. The "Eurasian" project of integration is observed in its transformation from being based on the post-Soviet memory toward economically beneficial cooperation. Still the Eurasian Economic Union is seen as vague in its goals and instruments, relying on the approach to economic integration with the reference to the common past, memories and identity.*

## INTRODUCTION

Since the second half of the 1980s, the approach to the institutional history of developing industrial society is observed as stretching, which sounds as a conflict-burdened process of establishing a system of rules, defined in the fight against dangerous and risky situations. Such situations are created by modern industries. Later, the rhetoric of security and risks sends our thoughts toward the conception of the risk society and culture of symbolic exchange (Beck, 1992; Baudrillard, 1993). The economy of risks relies on future contracts with long-duree effects, influencing economic perspectives at the micro- and macro-levels. However, these perspectives are defined and clarified by the cosmopolitan culture of symbolic exchange. Risk is positioned as the residual inevitability, the backside of incredible prosperity, and existence of welfare states.

The nature of contemporary risks lies in its global catastrophic effects, irreversible damage and, simultaneously, invisibility. Such risks are becoming visible only through the system of knowledge and, more detailed, through social definition and articulation. In comparison with pre-industrial and industrial stages the post-industrial risk is the result of decision-making process in which corporations and state governments bear responsibilities. Such responsibility goes hand-at-hand with the need to launch a set of controlling measures over elements involved in the economy of risk and security.

The most important for the industrial and postindustrial society is its capacity to apply to an uncertain future. Dealing with the basic ideas of globalised economic policy, Rothstein and Downer (2008, p. 6) assume that 'at its simplest, risk-based policy-making is the practice of targeting policy in proportion to potential threats to society, considering both their likelihood and consequences'. Risk calculation transforms future events and processes into present activities. An issue moves from untouchable danger into profitable security "for sale". This is how the society of risk is becoming the society without guaranties. As Beck (1992) stated, contemporary times with the constituting principle of uncertainty gains its counter-principle in a social pact against dangers and damage. Therefore, this pact is the internal logic of the common agreement on economic progress.

Two opposite lines were crossed in Europe at the end of the 20th century; namely, the line of development and security based on the performance of technological and bureaucratic norms and controlling tools, and the line of dangers and historically new damages stretching which extend through the borders of legitimacy and politics (Giddens, 2007; Beck, 2010). This contradiction is of social and political character which is hidden in a mixture of epochs. Such a situation will last as long as industrial stereotypes and symbols of control exist. Among these symbols are emblems of historical and cultural memory.

The comparative studies of the European Union (EU) and neighbouring countries in the beginning of the 21st century are grounded in the so-called "new regionalism approach" (Makarychev, 2008), according to which intra-regional relations could be defined along security as well as economic, political and communication lines. Regions with strong "security" direction are mostly based on We-Other emotional patterns. This leads us to the follow hypothesis. By case participants of security regions could securitize external relations as threatening and at the same time a necessary element of their regional identity.

Among such regions are different geographical and suprageographical configurations with active and emblematic engagement of Russia – the Black Sea region, the Eurasian Union (EAU), and so forth. For some obvious reasons, the situation around the EAU could be described as "symmetric securitization" (Makarychev, 2008). The mechanism of the process can be assumed as follows: Russia faces alienation and securitization from the EU and the North Atlantic Treaty Organization (NATO) and launches similar mechanisms against them. At the same time, the EU itself follows the logic of symmetrical securitization.

## THEORETICAL FRAMEWORK

According to classical economic theory, human decision-making process is based on the rational choice made by an individual. This choice is calculated as the estimation of outcomes and their value. Therefore, economists suggest that behavior is pressed by willingness to maximize potential benefits from a scope of possible decisions and practical steps. However, in reality human behavior deviates regularly from a rational choice. Behavioral economics attempts to overcome the contradiction between classical theory and biases, originated from the psychological nature of human behavior, via emphasis on emotional and even irrational character of decision-making process.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

One of the first critics of economic theories based on the exclusively rational choice of decision-drivers was Simon (1957), who in his work "Model of Man" has questioned the view that organizations are driven by intention to maximize profit. Instead, he assumed that because of members' bounded rationality they have different goals, and organizations reach decisions as a consensus but not always as the best option. At the same time, the economist Becker (1957) has doubted the standard utility function in the traditional economics by also covering non-economic motivation to explain human economic behavior.

Later, considering the contextuality of economic behavior, Tversky and Kahneman (1979) highlighted effect as one of the pillars in the decision-making process. They have witnessed violations of expected utility and suggested a theory, grounded in psychological principles of cognition, in order to explain the violations. Since the 1980s, many non-economic motivations have been considered as influencial for economic analysis and understanding of decision-making processes at the macro-level. In this chapter, the ideas of identity economics are used as a corner-stone of the explanatory model. Identity economics brings social context into analysis. Akerlof and Kranton (2000, 2010) have presented the general framework for identity economics by expanding Becker's concepts. They base the concept of identity on self-categorization of people and social norms of behavior through which they define their belonging to a certain group. The concept of social identity explains a lot about economic behavior at the inter-group level of communication and decision-making process.

Agreeing with Akerlof and Kranton on the influence of social identity on behavioral patterns, we add to this theory the category of cultural identity which could be used as a part of an explanatory model for economic behavior. One of the most valuable ideas derived from social and cultural identity is that of categorization and normative patterns existing implicitly. Risk-security could be mentioned among such patterns. Following this idea the role of affect in risky situations is discussed as a background for the risk-feeling model (Loewenstein, Weber, Hsee, & Welch, 2001). Focusing at the risk-feeling level explains behavior in emotionally complicated situations. It means that decision is made on the basis of culturally - psychological perceptions of uncertainty and possible threats.

As Samson (2014) stressed, behavioral economics provides a set of ideas which could assist in understanding government decisions and global economic shapes; namely:

- Small changes can lead to large effects.
- Psychology is important.
- Decisions and steps made by people do not always have a rational explanation.
- Decisions are made in a social and cultural context.
- Trust does not help, but commitment is is important.

Finally, behavioral economics assumes that a human individual makes decisions not in isolation but rather in a specific context where norms play a crucial role in the definition of acceptable and unacceptable behavior. This context also includes historical memory which is extremely important at the macro-level of decision-making processes. In discussion of risk perception, we pay attention to the second part of the binary opposition – security. But the notion of security is used as "a contextualized soft security"; namely, securitization. Considering the theoretical foundation of the economic securitization hypothesis and mutual alienation of the EU and the EAU, the chapter follows ideas of the Paris School of Security Studies.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Since the second half of the 1990s, a number of European scholars applied the conception of speech act as the core driver of security (Buzan 1989; Buzan, Wæver, & de Wilde 1998; Wæver, 1995). According to them, an issue demonstrates itself as a security problem through the discursive politics of security. Security is not of interest as a sign that refers to something more real; the utterance itself is the act (Wæver, 1995, p. 55). Securitization mostly concerns the question how security issues emerge, clash, and dissolve. Securitization theory argues that language constitutes the very social reality. According to the Copenhagen School, an issue demonstrates itself as a security problem through the discursive politics of security, constructed by actors coalition. The interest of such coalition is to form distinctive practices and effects (Bigo, 2008).

Usually the Copenhagen School operates with political acts and political discourses as objects of feasible securitization. It is not easy to place economy as an object of securitization. While economic security is seen as state of anxiety/feeling, to see securitization as social/political acts is more complex. On the individual level, the economic security refers to a relative freedom from poverty, while at the state level it refers to economic independence and productivity; and as such, it is reproduced in a National Security Strategy. The controversy lies in the idea that economic security is provided by routine political activity of governance, whereas securitization applies to extraordinary steps and a specific national security strategy. That is why the definition of securitization as of dependent on audience acceptance of a speech-act is not satisfying.

Concurrently, the theory of securitization as a speech act is criticized from the position of the so-called "Paris School of Security" (Balzacq, 2010; Bigo, 2004), which emphasizes securitization as a pragmatic act that is a sustained argumentative practice aimed at convincing a target audience to accept, based on what it knows about the world, the claim that a specific development is threatening enough to deserve an immediate policy to curb it (Balzacq, 2010). In other words, a speech act itself does not make an issue securitized, but it should have a specific context and power to do so.

Securitization could be seen as a process of argumentation. If securitization needs reasoning, it means intersubjective communication and agreement on a set of principles – what to consider as a threat, risk, security, and so forth. Consequently, while an issue is to be securitized, it should be located within a specific context and articulated by specific powerful actors, prompting an issue as threatening to a society.

Balzacq (2005) highlights that securitization is characterized by:

- Cognitive patterns (e.g., metaphors, visualization repertoires, analogies, stereotypes, emotions).
- Mobilization within the definite context, approved by a recognized agent.
- Prompting a target audience to build a coherent network of implications (e.g., feelings, thoughts, and intuitions) that give reasons for actions.
- Investing an issue and a referent subject with an aura of unprecedented threat.
- Demanding immediate political act to block its threatening development.

As a new agenda demands a certain level of prioritizing, constructed through discursive practices of commemoration, communication and representation and justifies a high level of resources and immediate response (albeit mostly a political one). This situation concerns non-traditional areas of security – economy, climate, poverty, diversity, and so forth.

Pragmatism posits that cognitive structure – a coherent but flexible set of modes of thought, motivations, and reasons for action – have a real impact on discourse (Balzacq, 2010). One of the contextual drivers of securitization is collective memories which could be used within the decision-making process.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In some sense, structural characteristics of collective memory are rooted in specific cultural forms which influence communication, cognitive construction, representation and perception of risks and threats. At the same time, intersectionality of securitization and memorization flows into economy of risks, where security is not just an emotion on what is thought as a risk or potential danger, but rather a contract. And as such, it can be traded and obtain a market value.

Economic securitization is produced through discursive practices of those groups which have an access to social, cultural, and political power. At the highest level of the political decision-making process, the issue of economic securitization is coined as a line of global political decisions in which all other groups are distributed over or behind.

## METHODOLOGY

The analysis of the EAU documents comes from ideas of the Historical Discourse Approach (HDA) which came into being in the end of 1990s among other Critical Discourse Studies (Wodak, 1999; Wodak, 2001). Besides critical orientation toward the problem-based approach, it deals with the so-called historical dimension of the discourse. Specificity concerns wide use of diverse information resources in order to follow the development of specific relationships or repertoire. The attractiveness of this comprehensive approach lies in its fluidity and flexibility. The analytical procedure goes through a set of levels; namely, linguistic analysis of text, discourse theory with its attention to intertextuality and relationships between texts and articulations, and a meta-theory with application in socio-political, historical, and cultural contexts.

In examining the topic of memory and discourse through the conception of securitization over the period 1992-2014, the study has different genres and theories from different disciplines and uses a set of categories. Data for the analysis were gathered among written texts of different genres – official documents initiating and legitimizing the Eurasian Economic Union; texts coming from different expert communities – Europe, Russia, and beyond; finally, media texts published in different sorts of resources.

Among founding texts for analysis are the National Security Strategy of Russia, the Treaty of the Eurasian Economic Union, and annual expert reports (ERBD). Beyond this it entails speeches of officials concerning issues of economic integration and major political decisions. Finally, media and academic comments and reports on benefits and expenses of unions' existence and literature from international organizations, such as the Organization for Economic and Cooperative Development (OECD), concludes the corpus. Close attention is paid to texts coming from the Russian side, as Russia plays the dominating role in promotion of the Eurasian integration project.

Following the collection of data from different sources and critical reading of it, semantic-discursive categories were established. These categories compose the lexicon and could be analyzed and used to fetch an essence of texts. Examples of such semantic-discursive categories are community, unity, commonality, the Past, post-Soviet, and so forth. Consequently, these categories are used in the discursive strategies, implemented in the written form; the focus is on the strategies of legitimation which are hidden in the corpus of official documents (the National Security Strategy, Treaty of the Eurasian Economic Union, etc.). The pragmatic act of securitization and legitimation is the core activity of a powerful actor to inject a "threatening" characteristic of an object into the public discourse. That is why we see legitimation as a framework for analysis of how discourse of securitization builds legitimation/delegitimation for public communication on issues of economy of risks.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The framework (Van Leeuwen, 2007) distinguishes between four categories of (de)ligitimation: authorization, moral evaluation, rationalization, and mythopoesis. Authorization is delegitimation by reference to the authority of tradition, custom, and common law; (de)legitimation by moral evaluation occurs in case of reference to value system; rationalization is (de)legitimation by reference to use of institutionalized social action and through a system of knowledge and cognitive patterns; deligitimation by mythopoesis goes through narratives of awarded and punishable actions.

Obviously, categories mentioned ealier do not exist separately. In spite of this, they include some characteristics borrowed from another type. Actions and their representations with interpretations are correlated within a specific discourse. As we suggest, analysis of legitimation strategies enables identification of the plot through which the demand for positive attribute of Union governance and negative attributes of insecurity, requiring immediate response from decision-making structures and actors, are justified. While examining the corpus of documents, we defined indicators through which legitimation strategies and plots are manifested and realization of them in other spheres – media, expert communities. Among indicators metaphors could be included.

The importance of metaphore in the political and social constructions has been acknowledged since 1980s. There a set of analytical reports on consistent use of metaphoric constructions for particular articulations of the world events and processes and responses to them through the official media channels. Interestingly, there are some recounts of metaphors in politics, announced by the leaders of world states, such as Thatcher, who remarked:

*… anyone dealing with the European Community should pay careful attention to metaphors. We in Britain were inclined to minimize their significance […]. We had to learn the hard way that by agreement to what were apparently empty generalizations or vague aspirations we were held to have committed ourselves to political structures which were contrary to our interests. (Thatcher, 1993: 319)*

The reason for metaphor use is the idea that political metaphors combine an integral argumentation and reasoning which aim to approve a contested issue and legitimize a direction of action. Therefore, metaphors in the political discourse play the role warrants, emblematizing an issue as an object for securitzation. That is to say, the metaphor has an ideological core and is linked with the process of legitimation. Therefore, analysis of metaphors aims to demonstrate specific securitization policy.

## SECURITIZATION AND THE ECONOMICS OF RISKS IN 1994-2014

The recently signed Declaration on Eurasian Economic Integration provides new life to discussions around the problems of European integration and security of cooperation between inner and outer members of the global welfare system (Eurasian Economic Commission, 2014). Following the global quest for a new pattern of strategic development, a number of states, united by the common soviet memory, seek consolidation and reconstituation of the regional union. This impetus results from the global financial crisis in 2008 that demanded to recall rhetoric of security and rescue the ideology of welfare and economic prosperity. Concurrently, critical voices are being heard which equally suspicious toward European integration success and Eurasian. “The gulf between EU institutions and the European public appears to

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

be as wide as it has ever been. Surprisingly (or perhaps not), a similar scenario is rapidly consolidating in 'post-Soviet' Eurasia" (Anceschi, 2014). In these circumstances we have to deepen our knowledge on the workload of Eurasian integration and their rhetoric.

Dealing with the basic idea of the globalised economic policy, Rothstein and Downer (2008, p. 6) assume that 'at its simplest, risk-based policy-making is the practice of targeting policy in proportion to potential threats to society, considering both their likelihood and consequences'. The rhetoric of security lies in the creation of different networks (such as the European and Eurasian Economic Unions), proclaiming common ground for communities, and living together. Community-building requires the dissolution of institutionalized orders based on fixed notions of 'We' and 'Other', mostly because 'Other' can easily be represented as 'Alien'. In addition, such type of communities means the replacement of notions of 'security from others' with 'security with others'. 'Other' in this case has something in common with 'Us' (Couldry, 2000). At the same time, security-building process requires that 'We' have something of 'Others', that is some of identity.

We could observe the symbolic competition between "European" and "Eurasian" projects of economic integration, where the Eurasian Economic Union is seen as vague in its goals and instruments as its European counterpart. We will follow the post-Soviet approach to the economic integration with the reference to the common past, memories, and identity. Securitization is the procedure defined by those who obtain power. Therefore, the discourse of securitization is the power discourse. In this case, the creation and development of the Eurasian Economic Union is inscribed in the discourse of risks and securitization. The question is about the ability of Russia to consider its own identity beyond the discourse of risks and securitization in relation with the former Soviet republics.

The foundation of the Eurasian integration dates back to the 1990s and links with the clash inside the Soviet Union and post-Soviet political and economic development. The first stage relates to arrival of the Commonwealth Independent States (CIS) in 1991. It was aimed at political and economic reintegration in this region. In 1994, the term Eurasian Economic Community was pronounced by Nursultan Nazarbayev, the President of Kazakhstan. Therefore, after 1994 the idea to build a separate (to the European Union) block of states became more obvious. Although a Free Trade Agreement (FTA) was signed in the framework of the CIS, it did not enter into force until 2003. To the contrary, the reunion process began with bilateral agreements between almost all member states.

The new impetus was made in 1996 when Russia, Belarus, and Kazakhstan signed the agreement on integration in economic and humanitarian areas. But only in 1999 did Russia, Belarus, Kazakhstan, Kyrgyzstan, and Tajikistan agreed to sign a document on formation and implementation of the Custom Union and the Single Economic Space. Subsequently, in 2000 these five states established the Eurasian Economic Community (EurAsEC). Interestingly, in the Treaty the dominant role in percentage of participation (a total of 40% of voters), budget, and so forth was meant for Russia. However, the most significant was determining the Russian language as the official legislative language of the Union (Treaty of the EURASEC, 2000).

Since 2001, the idea of the regional integration has escaped post-Soviet states such as Russia, Belorussia, and Kazakhstan. The urgency of this step was encouraged by internal and external circumstances in 2004 such as the enlargement of NATO and the EU over time in Bulgaria, Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Romania, Slovakia, and Slovenia.

In 2003, Armenia joined the EurAsEC as an observer; Uzbekistan joined this community in 2006. In 2010, as a result of the efforts made during the period of formation, the Eurasian Customs Union (EACU) was finally established with membership of Belarus, Kazakhstan, and Russia. In November,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

2011, these three countries signed the Declaration on Eurasian Economic Integration. In 2012, the Eurasian Economic Commission (EEC) was established. It was based on the experience and under the influence of the European Commission. In September, 2013, Armenia announced its willingness to join the EACU, and very quickly the Supreme Eurasian Economic Council confirmed the "roadmap" for Armenia's accession to the union.

Consequently, on May 29, 2014, the presidents of Russia, Belarus, and Kazakhstan signed the Treaty on Establishment of the Eurasian Economic Union (EEU). It is expected the EEU after ratification in compliance with national regulations of the states will come to force from January 1, 2015. In October, 2014, Armenia hjoined this union, as well as Kyrgyzstan on May 21, 2015. The EAEU now has five member states. Tajikistan and Vietnam are on the enlargement list of the potential member states.

The question of economic security immediately appeared. The anxiety about economic benefits of the Eurasian integration derives from official sources, provided by the EBRD, OECD, and so forth, and the idea that the Eurasian reunion is beneficial only for relatively small, former Soviet republics. For instance, according to the Armenia Economic Report (2014), the inflow of non-trade private remittances in 2013 totalled to US$1.87 billion, a total of 86% of US$1.6 billion originated in Russia. Total inflows of remittances in 2013 grew by 10.8% over the previous year, while they grew by 14.4% compared to 2008.

As the EBRD Report (2012) concludes, import tariff revenues accrue to national budgets in predetermined proportions (with Russia entitled to 88%, Kazakhstan to 7% and Belarus to 5%). The Russian and Belarusian markets were fairly integrated even before the launching of the EAU by direct investments from Russia into the Belarus economy in which Russia accounts for 75% of foreign direct investments (FDI) into Belarus.

The asymmetry in the economic situation within the member-states of the Eurasian Union is obvious. The disparity in the economic size of the largest state, Russia, and that of the other members is perhaps greater than in any other regional economic grouping; namely, Kazakhstan's population and gross domestic product (GDP) are around one-tenth of those of Russia, and those of Belarus are lower still (EBRD, 2012). The forcast for 2014 growth among members of the EAU is following: growth in Russia will remain low (1.3%), while it will accelerate by 0.7 percentage points in Belarus and is projected to slow down by 0.3 percentage points in Kazakhstan. Although some experts conclude the economic nature of the Eurasian Union (Carbone, 2013), the data demonstrates unclear benefits and definite risks for states of the Eurasian Union, particular for Russia. Simultaneously, the initiator and energetic promoter of further intergration Russian Federation is underlined. Therefore, while economic benefits of the EAU are limited, they could be considered in the context of extraeconomic indicators.

In order to understand roots and logic of economic security articulation, as well as memorization practices, the process of securitization should be analized from the National Security Strategy as a corner-stone document. In 1997, the Russian Federation presented the new National Security Strategy (NSS) with the conception of the "multipolar world", whereas NATO expansion and the EU enlargement to the East were perceived as core threats to the potential re-integration of the Commonwealth of Independent States and national security of Russia (NSS, 1997).

In order to ensure regional economic integration in favourable direction, Russia is supposed to need reconstruction of its political influence in the region. Therefore, the 2000 National Security Concept (NSC, 2000) identified the reinvigoration and adaptation of the CIS mechanisms as the preferred way to achieve 'integration processes ... that meet the interest of Russia' (National Security Concept of the Russian Federation, 2000).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Analysis of two editions of the Russian national security strategies revealed key semantic-discursive categories in both documents: security, stability, and sovereignty. Security-related terms (e.g., insecurity, security threat, security challenges, and instability) were salient as it was expected in the given genre of the official government discourse. In comparative terms, the 2006 NSC demonstrated a 'negative connotations' to security by discussing in terms of threats and absence of security (insecurity), whereas the 1997 NSS often mentioned security challenges. Stability was maintained in relatively similar salience in both documents. At the same time, sovereignty suggests lifted topical prominence in the 2006 document. Moreover, stability as well as sovereignty concerned to the binary opposition of security – insecurity.

In the expert reports effects of introduction and promotion of the Eurasian Union are often declared in categories benefits – risks with negative connotations of inevitability. As cited in the Armenia Report (2014):

*Armenia's membership of the EAEU is a most crucial event. Its short term economic benefits are not clear whereas negative consumption impact is inevitable. The long term developments, opportunities for realisation of economic benefits and risks are not defined. There is great need for follow-up research and evaluations.*

The second type of document is Foreign Policy Concepts (FPC) which answer the changing situation. For instance, the FPC of the Russian Federation (2000) renewed symbolic presentation of integration by pointing attention toward security aspects of the Eurasian integration and CIS in particular. In the FPC of 2013, it is mentioned that one of the core priorities is border security through cooperation with former Soviet states. Another concept is to keep mutuality and sovereignty of all states which join the Eurasian zone of integration, but with added value of shared cultural heritage of the CIS members. Finally, the Russian-Belorussian union is highlighted as an example of good practice of integrity. Simultaneously, Russia strengthened its position by bilateral agreements, deepening integration with individual countries.

In 2008, the revised FPC again awakened the issue of regional integration. The more important became the question of security in Middle Asia by which the topic of economic and political cooperation was raised to the top of the list. The Collective Security Treaty Organization (CSTO, 1992) was also mentioned as a consistent part of the strategy. On the eve of the NATO–Russia Summit in Rome, Italy, the creation of the CSTO was meant to mark a new line for Russia's vital interests and to reduce effects of the second round of NATO enlargement.

Finally, in the FPC of 2013, the idea of responsibility of Russia for activities and security on the territory of states is used, tightly connected by agreements. Moreover, this version excluded the goal of creating bilateral and multilateral agreements to make the position of the Russian Federation more resistant to world challenges. Despite this fact, the new goal to strengthen the position of Russia in trade and world economy, to avoid possible discrimination in economic relations, was added (FPC, 2013). As the Concept stresses, the role of Russia is to work on anticipation and leading the events.

Looking from another angle, economic integration is seen as a step toward security in the unstable world and under pressure of Europe and the NATO. Economic benefits are considered as desirable, but less important aims, of the Eurasian Union. Seeking a distant position from the USA or the EU, member-states of the EAU use a political and economic model well-known from the recent past: the buffer-zone. At this line political decision-making is much more important. At the symbolic level, the semantic-discursive category of sovereignty is crucial. Interestingly, in a set of expert reports and analysis (Greene, 2012)

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the terms 'integration' and 'security' are used in application to explanation of predominance of Russian political thoughts, 'ideologically weak' regime. The weakness is strongly connected with "repackaging" of the Soviet and post-Soviet space (CIS).

The idea of the buffer-zone is partly transformed into the positively connotated "bridge", giving new life to the well-known formula West-Russia-East in which Russia plays a distinctive role between two different (even opposite) worlds. In November, 2014, the head of Ministry of International Affairs, Sergey Lavrov, has rearticulated the mission of the Euroasian Economic Union as a specific bridge between Europe and Asian-regions: the Euroasian Union will be a very serious element of the bridge between Europe and Asian-and Far-East region. According to Lavrov, Europe graciously and arrogantly relates to this integration union, although many states, combining the Eurasian Economic Union, *have much more common* then member-states of the European Union (from the interview with S. Lavrov)[1].

This "bridging" strategy of Russia (or, more precisely, 'near abroad') is combined with efforts to use the resource of regional elites through economic, cultural and political dependency. The logic is the same with domestic strategy, logically flowing out of the post-Soviet period (Greene, 2012). Eurasian cooperation is based on sympathetic ties with cultural, linguistic, and historical memories. This step could be described as securitization of the cultural identity through antipathy toward Europe in the Western value system.

As "cultural templates" govern behavior, intervention strategy is based on the idea to accommodate people who could map a local knowledge system and cultural ties and make possible weakening of the Other. By 'cultural templates', the coined allusions of the Eurasian Union (Russia, Belorussia, Kazakhstan) is witnessed to a centre and two peripheries (Isakova, Plekhanov, 2012; Pomfret, 2014). By this a supraterritorial buffer-zone is created in which sovereignty is understood as an opposition to "Western democracy".

In support of this passage, the speech of the Kazakhstan president Nursultan Nazarbayev in 1994 could be mentioned who, for the first time, announced the idea of Eurasian regional integration as the basis for the new Kazakh identity[2]. In 2011, another president, Vladimir Putin, in his speech argued the idea of Eurasian integrity as a collective project by referring to economic benefits for all member-states[3]. It was correlated with the example of the EU, but distinguished as the case, located between politically challenging Europe and economically pressuring China. In these circumstances, the Eurasian Union seemed inevitable.

Returning to semantic-discursive categories used in texts of Eurasian integration, we could assume that securitization processes through silencing political opposition, controlling security regimes, and maintaining a state sovereignty on the international arena; and that helps to support political stability. However, dependency on other countries (as it is the case of Eurasian Union) in terms of national security and economic prosperity could seriously undermine legitimacy of extraordinary decisions in the context of extraordinary threats and spark social and political stability. This is the case of Uzbekistan, which is suspitious on benefits of Eurasian Economic Union, tightly linking economic and political effects of any steps toward integration. One of the reasons is potential threat for domestic labour market and extra-migration to Russia, which makes difficult for the country to be a sovereign economic actor. Recently the president of Uzbekistan coined Uzbek migrants in Russia 'lazy', revealing highest concern in securitization of it.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

If to consider securitization as a fact of acceptance by audience, in the current economic situation, the Eurasian Union hardly can become as integrated as the EU. At the same time, it has purposefulness in stabilization of the context and facilitation of cooperation, applying to the common ground, memory, and heritage. As proclaimed opposite to the EU, the project of the Eurasian Union is becoming attractive for non-European surrounding states (as it is seen in the Russia-Vietnam or Russia-China agreements).

## CONCLUSION

The search of possible connections between cultural memory, insecurity, economy of risks, and global decision-making is vital for the future directions of securitization studies. However, it is important to reflect upon how these connections are being publicly articulated and the impact these discursive representations have upon international policy areas.

Our discursive historical approach confirms the hypothesis that the Eurasian Economic Union has been securitized by application of historical memory of the common Soviet Past and have been shaped through the relevant policy domains. Our intentions of casting light on the process of influence of communicative discourse on economic securitization have been approved. Our analysis of the Russian National Security Strategy suggests this process was explicit. This was justified by relatively low number of applications toward Soviet memories as a semantic-discursive category. But instead of it there are some practices: 1) demonization of Russia as a dominator which is the component of the topic of tyranny; 2) escapism as a tendency in policy-making; 3) implicit representation of security in the context of economy of risks and global threats, and as a part of it legitimizing strategic and immediate policy decisions and moral imperatives.

Documents analyzed develop intuitive connections between memory and insecurity, and a new economic union as a beneficial solution to economic risks and associated threats. To some extent, these documents demonstrate tautological arguments through representation of the Past as a component of welfare. Finally, the analysis demonstrates the importance of context in the success of securitization of the risk economy, and Crimea acceleration of the paradigm for European and Eurasian discursive treatment of economic integration. We suggest that a communicative discourse has constituted integration and security as an issue for European and Eurasian elites.

It could be understood only through application to the social, cultural and political context of recent events. The significant period is observed as 2004-2014 as the time when NATO and the EU enlargement struck the Russian and partnering lands and generated a new sense of vulnerability and anxiety. This situatation created a specific political climate in which the priorities were detailed and revised together with greater resources. Insecurity had to be addressed through revised policy and new level of investments which, in turn, demanded a new type of discourse, forceful and sustained. The discourse of economic integration constitutes a security and moral impreratives for the Eurasian region, and legitimizes connection of memory-insecurity-integration. In this case, the final stage of securitization demands a receptive audience for whom such discourse is delivered.

# Chapter 74
# Firm-Level Determinants of Foreign Investment and M&A Activity: Evidence from Turkey

**Mine Uğurlu**
*Boğaziçi University, Turkey*

## ABSTRACT

*The last decade is marked with acceleration of mergers, corporate restructuring and governance activities. M&A activity has been driven by factors such as technological change, globalization, free trade, deregulation, attempts to attain economies of scale, rise in entrepreneurship, and economic growth. Corporations need to adjust to the change in the environment and expand their markets to achieve growth and protection against volatile economic conditions. Firms can achieve international expansion through foreign direct investments (FDIs) which can take the form of cross-border acquisitions (brownfield investments) and Greenfield investments. This chapter covers an overview of the literature on the determinants of FDI forms of entry, and M&A activity followed with an empirical investigation of the firm-level determinants of foreign investment in Turkey with emphasis on cross-border acquisitions and Greenfield investments. Summary of the findings is followed with the economic implications of forms of FDI entry. The concluding remarks cover the implications of the results for policy makers.*

## INTRODUCTION

Increasing volatility and complexity of the business environment forces companies to reduce their vulnerability to adverse changes and enhance their competitiveness in the market. In addition to the emergence of new industries like e-commerce and biotechnology, old industries are being transformed. The high rate of technological change and development in transportation and communications have increased the pace of globalization. The intensity of competition in global markets has led to deregulation in airlines,

financial services, telecommunications, electricity and other utilities industries. Globalization is driven by reduced barriers to the free flow of goods and services and technological advancements that lead to better communication, information processing and transportation technologies (Hill, 2006). Firms can expand into international markets in a variety of ways such as licensing, franchising, strategic alliances exporting and through foreign direct investments (FDIs) with either a wholly- or partially-owned local enterprise.

Firms have economic and strategic motives for participating in mergers and acquisitions (M&As). The economic motive is to create value for shareholders through the realization of synergies that stem from additional revenues and savings in costs. Strategic motives aim to improve the strategic positioning of the firm to achieve long-term growth and protection against volatile conditions in the region. The quest to survive in the global market is a strategic driver of cross-border M&As.

The first part of this chapter includes a theoretical overview that covers country-level determinants of M&A activity and foreign direct investment (FDI), integrated with evidence from firm-level drivers of M&As and foreign investment. The second part of the chapter documents an empirical study that displays firm-level determinants of M&A activity and foreign investment in the 500 largest firms of the Istanbul Chamber of Industry in Turkey. The initial part of the empirical study focuses on the determinants of the M&A activity in the sample. The second part displays the foreign investment determinants with a comparative analysis of drivers of cross-border mergers and Greenfield investments. A summary of the findings is followed by a section that elaborates on the economic implications of the evidence on FDI and its forms of entry. Concluding remarks cover the implications of the results for policymakers of the host country.

There are several contributions of this study. While most of the studies on M&A activity rely on data from developed countries, this study documents differences in firm-level determinants of M&A activity and FDI modes of entry in an emerging country. Unlike most of the studies in this field, the sample for this study includes unlisted firms which are surrounded by higher information asymmetry and documents the differences in firm-level drivers of M&As and foreign investment for private and publicly traded firms.

The results have implications for policymakers of the host country and firm managers that aim to attract FDI. The higher likelihood of foreign investment in R&D-intensive firms implies the need to increase R&D efforts at the country level. The findings, therefore, point to the need for government investment in accumulating knowledge and human capital that will serve to reduce the technological gap between foreign investors and local firms. The results indicate that M&A involvement is a means of sharing risks and attaining improvements in efficiency for corporations. Foreign investment seems to be driven by high exports, R&D intensity, production of high value added goods, and existence of operational efficiency in local firms. These findings reveal the need for local firms to focus on productivity and innovativeness in the products and services they provide to generate high value added output that will increase their competitive advantage in global markets.

## THEORETICAL BACKGROUND

The studies on determinants of mergers and acquisitions can be grouped as those that focus on country-level drivers of M&A activity and firm-level analyses. After an overview of the literature on the country-level drivers of M&A activity, the theoretical background covers evidence on firm-level determinants of M&A activity with an emphasis on cross-border mergers and Greenfield investments.

## Country-Level Determinants of FDI

The existing literature on FDI determinants has generally focused on macroeconomic factors that affect the FDI flows and their effects on M&A decisions of local firms. One study employs panel data of M&A deals for the 1990-1999 period and documents that the size of financial markets and the level of financial development have significant positive effects in terms of encouraging domestic firms to invest abroad (diGiovanni, 2005). Empirical evidence shows that market size is a determinant of FDI (Love & Lage-Hidalgo, 2000; Chakrabarti, 2001; Lipsey, 1999; Tuman & Emmert, 1999). Research on the effects of economic policy indicators on FDI shows that tax incentives are important in attracting FDI (Tung & Cho, 2001) as well as macroeconomic stability (Obwona, 2001; Lipsey, 1999; McMillan, 1999; Barry & Bradley, 1997). Noorbakhsh et al. (2001) provide evidence that human capital attracts FDI. A recent study, employing a Bayesian model, displays that more than half of the previously suggested FDI determinants are not robust (Eicher et al., 2011). The authors claim that trade agreements and currency unions encourage FDI in specific instances and market potential is no longer an FDI determinant since cost advantages of the producer drives FDI. On the other hand, some factors may lead to a decline in capacity to attract FDI. Debt overhang and sovereign risk reduce FDI (Nunnenkamp, 1991, 1997). Similarly, there is evidence that exchange rate volatility can be detrimental to FDI in developing countries (Benassy-Quere et al., 2001). Furthermore, Xiaoying and Xiamug (2005) test the effects of FDI using data from 66 developing countries and document that macroeconomic policies and institutional stability are preconditions for FDI driven growth to materialize. They document that a low inflation rate, government consumption, and taxes all have significant effects on FDI.

The most common country-level factors that attract FDI are competition intensity and the market structure of the host country (Buckley & Casson, 1998), country-specific culture (Kogut & Singh, 1988; Barkhema et al, 1996) and transaction costs resulting from economic and political uncertainty (Brouthers et al., 2003). An increase in the host country population, market size, per capita income and decreases in tax rates attract both cross-border M&As and greenfield FDI to the country (Nagano, 2013; Neto et. al., 2008). Entry through Greenfield investment increases local capacity and intensifies competition, whereas cross- border acquisitions do not have these effects (Buckley & Casson, 1998). They maintain that governments often attempt to attract Greenfield investments while restricting acquisitions. The governance system prevailing in the host country affects the mode of entry. A home-country firm tends to choose Greenfield FDI when the host country adequately enforces intellectual property rights (Nagano, 2013). A similar study that investigates the macroeconomic determinants of cross-border M&As in European countries uses GDP, stock market capitalization, and credit to the private sector as well as institutional factors related to legal and regulatory environment (Manchin, 2004). The study finds support for the outcome hypothesis (Rossi & Volpin, 2002) which posits that good domestic M&As are more intense in countries where investor protection is better. Weaker governance leads to fewer M&As (Dyck & Zingales, 2001). Manchin (2004) also provides support for the governance hypothesis which predicts that M&As occur in corporations that have different levels of governance. An inefficiently managed firm becomes a target and creates value after restructuring. Differences between countries in laws, regulations and their enforcement might increase transaction costs and asymmetries in information, which can explain characteristics of cross-border M&As. Target firms adopt the governance practices of the acquirer. If certain factors such as corruption are inherent in the country where the target operates, these companies benefit less from M&As. Results confirm that companies listed in countries with a higher quality of regulatory environment and higher economic freedom are more likely targets than those in countries with greater

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

government involvement in the economy in the form of tax policies and lower levels of openness. The industry-level determinants of FDI seem to be technological intensity along with advertising, sales force and competition intensity in the sector (Neto et al., 2008).

## Determinants of FDI in Emerging Markets

Most emerging markets are characterized by rapid economic development, weak corporate governance, inadequate shareholder protection, poor legal enforcement and high stock market volatility (Gibson, 2003; Bekaert & Harvey, 2003; Dennis & McConnell, 2003). The evidence on M&As in emerging markets reveals that, although the determinants of M&As in European transition economies are similar to those in developed economies, governance variables display a highly significant positive correlation with the M&A activity, implying that the rule of law and control of corruption are more important than financial variables (Visic & Skabic, 2010). Another research based on Korean firms displays that information asymmetry is one of the strongest determinants of M&A activity in the country (Choe et al., 2010). These authors show that firms facing high information asymmetry are those that are small in size, are in the high growth stage and face financial constraints such as high leverage and low cash flows. Companies surrounded by high information asymmetry tend to acquire companies with low information asymmetry. Nagano (2013) has studied the determinants of cross-border M&As and greenfield investments, focusing on Japanese firms pursuing FDI in emerging countries in Asia and Oceania. The evidence shows that a firm pursuing a cross-border M&A achieves higher cumulative returns in stocks following the investment, while a firm pursuing a Greenfield investment experiences an increase in stock prices immediately before the investment. In a study of FDI in Taiwan, foreign ownership was found to be significantly associated with increased R&D expenditures and improved performance as measured by Tobin's Q and accounting returns (Huang & Shiu, 2009). The authors argue that this may be because foreign investors possess superior stock selection ability or they are able to positively influence management.

### Determinants of FDI in Turkey

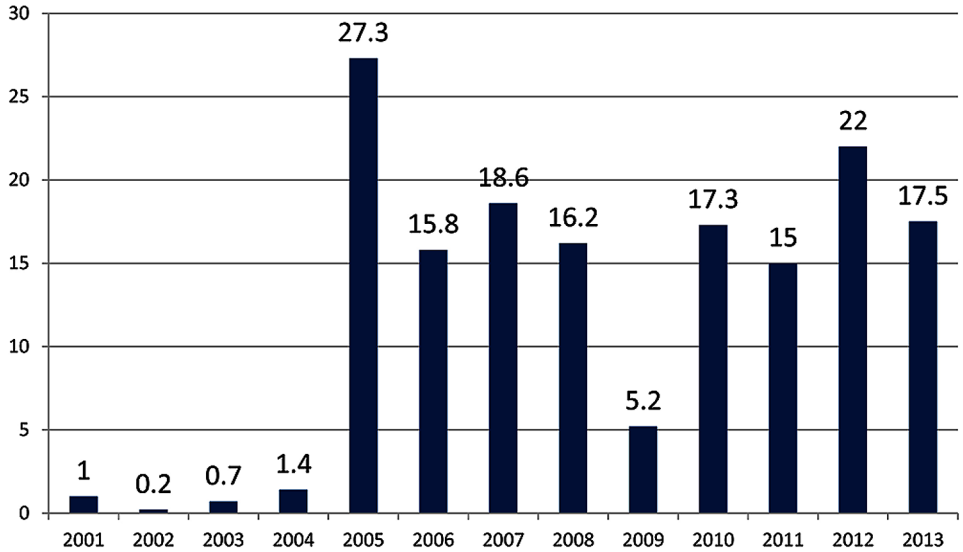
There are empirical studies and surveys that shed light on the macroeconomic determinants of FDI in Turkey. Deichmann et al. (2003) find that agglomeration, depth of local financial markets, human capital and coastal access dominate the location decision for the sample of foreign investment in Turkey. Erden (1996) finds that multinational firms are attracted to Turkey by its market potential, geographic proximity, and low labor costs. Tatoğlu and Glaister (1998), studying multinational firm location factors in Turkey, reveal that Turkey's most important assets include market size, economic growth, and government policy towards FDI, including repatriability of profits. Ernst & Young's attractiveness survey of Turkey (2013), resting on results of 201 foreign firms operating in 29 countries, reveals similar findings. The survey results confirm the previous empirical findings and reveal that the most important factors that make Turkey appealing to foreign investors are, in order of importance, geographical location, size of the domestic market, and reasonable labor costs. 65% of the foreign investors included in the survey (Ernst &Young, 2013) are established in Turkey and the rest operate outside the country. Foreign firms have expressed their preferred forms of investment are shown in Table 1.

Thus, 45.5% of respondents established in Turkey revealed plans for expanding their existing operations, while the majority (69.2%) of firms established outside Turkey declared their investment plans as joint ventures, M&As, and greenfield investments. Only 21.5% of existing foreign investors plan to

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 1. Preferred forms of investment*

| Foreign Firms Established In Turkey | | Foreign Firms Established Outside Turkey | |
|---|---|---|---|
| Expansion of facility | 45.5% | Joint ventures /alliances | 47.6% |
| Increasing labor force | 16.6% | M&As | 9.6% |
| Joint ventures/alliances | 7.7% | Greenfield investments | 12.0% |
| M&As | 7.0% | | |
| Greenfield investments | 6.8% | | |
| Other | 10.6% | | 14.5% |
| Can't say | 5.8% | | 16.3% |
| Total | 100.0% | | 100.0% |



be involved in M&As, JVs, or Greenfield investments. The value of M&A deals in Turkey reached its peak in 2005, followed by a significant drop in 2006, as illustrated in Figure 1. The total value of M&A deals reached $17.5 billion in 2013.

When total M&A activity/GDP is analyzed, Turkey seems to lag behind APAC and EMEA countries, although it has made a significant increase since 2011. The value of M&A activity/GDP dropped slightly to 2.16% in 2013.

## Evidence on Firm-Level Determinants of M&As and FDI Modes of Entry

Firms have multiple possibilities to reach a target market beyond their national borders, the most direct of which are foreign acquisitions (cross-border acquisitions) and foreign start-ups (Greenfield investments). The factors that affect the choice of cross-border acquisitions (brownfield investments) or greenfield

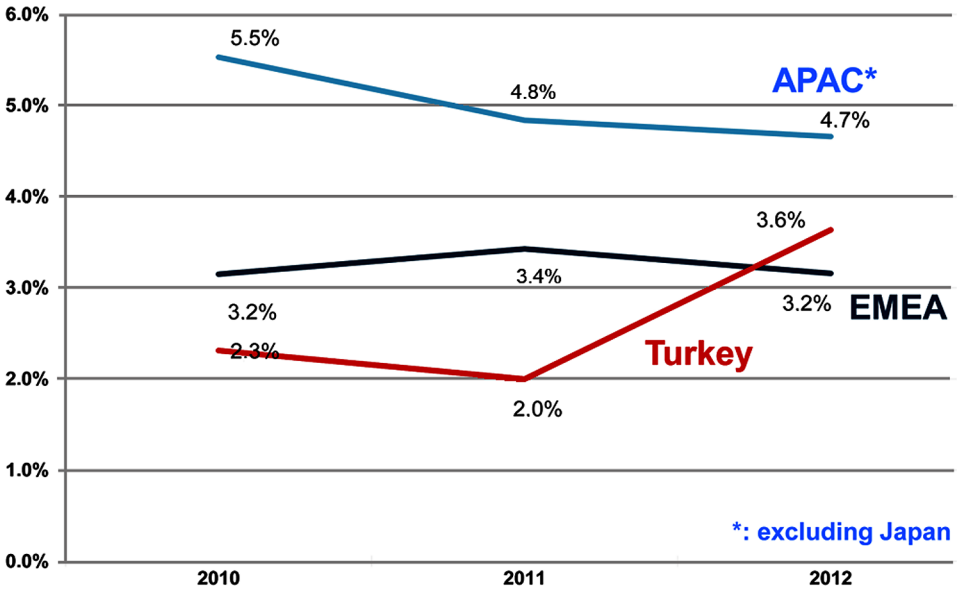


*Figure 1. Total values of deals in Turkey*
*Source: EIU, Deloitte Analysis, ISPAT.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 2. Total M&A activity / GDP*
*Source: IMF, Mergermarket.*

investments can be classified as country-level, industry-level and firm-level factors (Neto et al., 2008). There are numerous firm-level determinants that affect the choice of entry mode between cross-border M&As and greenfield investments. The level of technological advancement of the firm over its competitors in the foreign market affects the entry mode. A high technological gap leads to greenfield investments since they are less dependent on technological capabilities of existing firms (Hennart & Park, 1993). Evidence shows that the R&D intensity of investors affect the choice of the entry mode (Harzing, 2002; Hennart & Park, 1993) and that R&D intensive investors prefer Greenfield investments.

Organizational culture and product diversification are other firm-level factors that affect the choice of entry mode. In their research, Mudambi and Mudambi (2001) show that a younger age of the parent, a lower degree of multinational experience of the parent, and a narrow scope of output indicate a higher level of home country risk and make the choice of greenfield investment more likely. Transferring technological capabilities and organizational culture from the parent to the subsidiary can be challenging in brownfield investments (Hill, 2006). In the case of greater cultural distance between the firm and the host country, Greenfield investments are more likely (Kogut & Singh, 1988).

Transaction costs of the firm also affect the mode of FDI entry. Transaction costs are affected by asset specificity, behavioral uncertainty of partners or stakeholders as well as economic uncertainty. Transaction cost theory does not a priori prescribe a preference for either brownfield or Greenfield investment. A firm's multinational diversity leading to development of its technological capabilities pushes the firm toward setting up a new operation abroad rather than acquiring a new venture (Barkhema & Vermeulen, 1998). A firm tends to choose Greenfield FDI when it has regional networks in the host country and it chooses cross-border M&As when its purpose is to establish sales distribution channels (Nagano, 2013).

M&As are an effective means of resolving corporate financial distress (Jensen, 2001). Research on distressed acquisitions is scarce and is concentrated on the comparison between acquisitions in bankruptcy and acquisitions outside bankruptcy (Hotchkiss & Moordian, 1998) or the study of acquisitions

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

of distressed companies (Clark & Ofek, 1997), or on the comparison of acquisition and bankruptcies as exit strategies (Bergstrom et al, 2005). M&As were an exit route for companies in financial distress during the 2007-2008 financial crisis. The question of whether a distressed M&A can be a value-generating strategy for either the buying or selling counterparty is unanswered. Faelten and Vitkova (2014) show that newly combined firms where the target is either distressed or bankrupt generally benefit from an improvement in performance in the long run compared to their combined pre-bid performance, indicating synergy effects. However, the authors report a deterioration of the combined post acquisition performance of the acquirer compared to its pre-bid performance. Hotchkiss and Mooradian (1998) find positive abnormal returns for the acquirer and the bankrupt target. Bergstrom et al. (2005) and Buehler et al. (2006) compare mergers and bankruptcies and reveal that the financially distressed firms are more likely to merge than to file for bankruptcy. Faccio et al. (2006) who analyze the relationship between the target's leverage and the likelihood of emerging from distress through bankruptcy or M&A find that the likelihood of merger during the Asian crisis increases with the target's leverage.

Evidence shows that one of the strongest determinants of M&A activity and FDI in emerging markets is information asymmetry between investors and the firms (Choe et al., 2010). Investors tend to prefer firms with low information asymmetry. In the finance literature, firm characteristics used as proxies of information asymmetry between investors and controlling shareholders show variety. Some common firm-specific measures of information asymmetry displayed in the literature are size (Poulsen & Stegemoller, 2008; Scherr & Hulburt, 2001), asset growth (Poulsen and Stegemoller, 2008; Bris et al., 2004), profitability (Poulsen & Stegemoller, 2008), growth opportunities (Pagano et al., 1998; Brau et al., 2003; Smith & Watts, 1992) and export sales (Dahlquist & Robertsson, 2001). As size, profitability and export sales increase, information asymmetry between insiders and investors is expected to decrease. Growth, R&D intensity and variability of returns increase information asymmetry.

There is a growing body of research on information asymmetry between domestic and foreign investors. Kang and Stulz (1997) have documented the "home bias" of foreign investors resulting from information asymmetry between domestic and foreign firms in Japan The authors measure how well known a firm is to its foreign investors with the extent to which a firm exports and document that foreign ownership rises with the exports/sales ratio significantly for small firms, but the relationship disappears in large firms. They use a model in which foreign investors know more about large domestic firms than small domestic firms. Firms undertake M&As to reach a critical size to survive the intense competition. Foreign investors know large, profitable firms that export goods and services and tend to invest in the firms they are familiar with (French & Poterba, 1991; Lewis, 1999). Domestic investors may have more information about the local environment or business firms but foreigners may have better technological, financial or human expertise, experience or resources. These advantages may provide a stronger reputation and credibility to foreigners than domestic investors and may be more important when target firms are from emerging markets. The evidence on foreign investment is mixed. Some evidence documents that foreigners are better able to select winners (Grinblatt & Keloharju, 2000; Huang & Shiu, 2009) while conflicting evidence exists from South Korean stocks (Choe et al., 2005). In a recent study, Dvorak (2005) documents that while domestic individuals possess an information advantage, global brokerages are better able to pick long-term winners. Evidence on Swedish firms reveals that foreign firms show a preference for large firms, firms paying low dividends and firms with large cash positions (Dahlquist & Robertsson, 2001). The authors find that market liquidity, presence in international markets measured through export sales or listings on other exchanges seem to identify foreign investors. Furthermore, they document that foreign investors avoid firms with a dominant owner. They conclude that there is

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

an institutional bias rather than a foreign investor bias. Other evidence reveals that foreign investors are associated with higher R&D expenditures and have an ability to select high performing firms for investment (Huang & Shiu, 2009).

The information asymmetry between insiders and capital market investors or potential acquirers is the key driver of the public ownership decision. Chemmanur and Fulghieri (1999) show that in an IPO, a large number of investors need to be convinced about the value of a firm in an M&A transaction and these costs can lead to a reduction in share price. However, it is also possible that an acquirer can extract value from a target when there are a few potential competing acquirers resulting in lower price (Poulsen & Stegemoller, 2008). M&A decisions in firms with concentrated ownership may lead to agency issues for minority shareholders, especially in an environment where corporations have pyramidal structures. Concentrated ownership may reduce trading activity and reduce market liquidity (Coffee, 1991). While the expropriation of minority shareholders may be an issue that involves both listed and unlisted firms, there is evidence that listed firms are more concerned about minority shareholders, disclose more information, and have better performance than unlisted firms (Loderer & Waelchli, 2010).

Recent literature focuses on merger-motivated IPOs where the main motive for corporate listing is to facilitate subsequent mergers and acquisitions (Çelikyurt et al. 2010; Hovakimian & Hutton, 2010). Evidence documents that initial public offerings facilitate acquisitions in a number of ways. Hovakimian and Hutton (2010) find that firms that undertake IPOs benefit from the cash raised in the IPO and have easier access to debt and equity markets. Public ownership enables exchange of publicly traded stocks in subsequent acquisitions. So, merger motive is a primary consideration for IPO firms (Çelikyurt et al., 2010; Hovakimian & Hutton, 2010). Public ownership facilitates acquisitions by relaxing financial constraints that may impede a private firm's ability to acquire attractive targets and allows faster growth, by pursuit of more acquisitions that lead firms to bid very large targets that could be out of their reach because of the extensive borrowing requirements beyond their financial capacity (Hovakimian & Hutton, 2010). Netter et al. (2011) note that the correlation between IPO and acquisition activity displayed by Çelikyurt et al. (2010) and Hovakimian and Hutton (2010) depends on the breadth of the sample. They document that the correlation between current acquisition and lagged IPO activity act drops from 0.584 for publicly traded acquirers to 0.152 when all acquirers are included. Nitter et al. (2011) work on a large sample of mergers and acquisitions from 1992 to 2009, including private bidders and small targets, and they document some differences in their findings than those which utilize only large deals involving public firms. The-finding that mergers occur in waves is attenuated by the presence of smaller and/or not publicly traded firms, and it is noted that the clustering of mergers is driven by the acquisition of publicly traded firms.

## Firm-Level Determinants of FDI and M&A Activity in Turkey: An Empirical Study

This section displays empirical research that aims to reveal firm performance indicators that affect the likelihood of involvement in mergers and acquisitions (M&As) and FDI in Turkey. Foreign investment determinants are analyzed and the differences and similarities of determinants of cross-border mergers and Greenfield investments are displayed.

The measures of information asymmetry used in the analyses include profitability, size, growth, export sales and variability of profits, following Li and Zhao (2008). Listing on the stock exchange is also an indicator of the degree of information asymmetry surrounding the organization since publicly traded firms disclose more information and are more transparent in their operations than unlisted firms. The

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

study aims to reveal whether the determinants of M&A involvement differ among listed and unlisted firms to control for the effects of public ownership on corporate M&A activity.

## Measurement of Information Asymmetry

### *Size Measures*

1. Log sales
2. Number of employees working for the firm *(EMPLOYEE).* As firm size grows, information asymmetry decreases.

### *Export Sales (EXSALES)*

Export sales reflect the globalization of the firm and its reputation abroad. EXSALES is measured as export sales divided by total sales. Higher export sales reflect lower information asymmetry between a firm's foreign investors and blockholders.

### *Growth Measures*

1. Growth in sales *(SGROW)*
2. Growth in assets *(AGROW)* measured as change in total assets divided by total assets.

Some evidence reveals that firms choose to go public, leading to high information disclosure after achieving high growth (Pagano et al., 1998; Smith & Watts, 1992) while some studies reveal contrary findings (Brau et al., 2003). Firms with higher growth rates tend to go public and are more likely to undertake an IPO. Firms with higher growth opportunities are more likely to use equity financing than those with fewer growth opportunities (Myers, 1984).

### *Profitability Measures*

1. *ROA* is measured as net income divided by total assets.
2. Profit margin is measured as net income divided by sales *(PMARGIN)*

Higher profitability reduces the information asymmetry for the investors.

### *Public Ownership*

The firms are classified using a binary variable that equals one if the firm is listed in BIST and zero otherwise.

### *Distress Measures*

Evidence reveals that M&As provide a means of distress resolution for corporations. The study employs several measures of financial distress as determinants of M&A activity and foreign investment. Equity to total assets is used as a solvency measure (Ravid & Sundgren, 1998). In addition, having at least two years of consecutive losses is used to indicate the level of financial distress faced by companies

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

(DeAngelo & DeAngelo, 1990). Leverage is also used as an indicator of financial distress which makes mergers more likely for the target firms (Faccio et al., 2006).

### *Equity Erosion*

This solvency indicator is measured using total equity divided by total assets to reflect the vulnerability of firms to distress when leverage is not included in the analyses. The firms having equity to assets above the median are healthy firms. Table 8 displays that 24% of the firms below the median are distressed firms, which constitute 11.7% of the sample. Those firms that are below the median and have an equity to total assets between 24% and 50% are vulnerable firms denoted as $FINDIST_2$. These constitute 37.3% of the sample.

### *Consecutive Losses*

Firms that have at least two years of consecutive losses are treated as distressed firms ($FINDIST_1$). This is a dummy variable that equals one if the firm is distressed and zero otherwise. The distressed group constitutes 11.7% of the sample.

### *Leverage*

Leverage is used as an indicator of financial distress and is measured as the book value of debt divided by book value of assets.

### *Other Risk Measures – Corporate Stand-Alone (Total) Risk*

The total risk of the company is measured by the standard deviation of return on equity (*RISK),* which reflects the stand-alone or total risk of the firms.

## Empirical Predictions

***$H_1$*:** Listed firms are more likely to be involved in M&As than unlisted firms. Public ownership facilitates M&A activity in several ways (Hovakimian & Hutton, 2010; Çelikyurt et al, 2010). There is a strong contemporaneous relationship between acquisition activity and IPO activity for publicly traded acquirers (Netter et al., 2011).

***$H_2$*:** Highly levered firms that have exhausted their debt capacity are more likely to engage in M&A activity (Jensen, 2001; Bergstrom et al., 2005; Buehler et al., 200; Faccio et al., 2006). This relationship is expected to be stronger for unlisted firms that have limited access to debt and capital markets.

***$H_3$*:** The likelihood of foreign investment increases as export sales rise. High export sales increase the familiarity of foreign investors with the firms and reduces information asymmetry (Dahlquist & Robertsson, 2001; Hung & Shiu, 2009, Kang & Stulz, 1997).

## Empirical Design

The analyses rest on data of the M&A activity of the 500 largest firms of the Istanbul Chamber of Industry during the 2005-2010 period. For firms that have been involved in more than one M&A transaction, the first M&A transaction is used in the analyses. The M&A data covers domestic and foreign firms. The

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

determinants of merger likelihood are studied separately in Equation (1), where M&A is the dependent variable, while listing and foreign ownership are independent variables. This intends to disclose whether acquisitions are motivated by public ownership of the firm, which enables a fair value to be set in the market. Financial distress is included in the equations to detect whether M&A activity is a means of distress resolution for the firms involved.

Foreign investment is studied separately in Equation (2) to reveal differences in determinants of foreign ownership, if any, than those that are detected when all M&As are involved. Listing and M&A activity are included as independent variables, and having foreign investors is a dummy used as dependent variable in Equation (2). Furthermore, the equation is run separately for cross-border M&As in listed and unlisted firms and direct foreign investment.

$$\text{M\& A:} = a_0 + a_1\,\text{LISTING}_{i,t} + a_2\,\text{FOREIGN}_{i,t} + a_3\,\text{EXSALES}_{i,t} + a_4\,\text{FINDIST}_{12i,t} + a_5\,\text{FINDIST}_{2i,t} + a_6\,\text{LEV}_{i,t} + a_7\,\text{PMARGIN}_{i,t} + a_8\,\text{VAD}_{i,t} + a_9\,\text{SIZE}_{i,t} + a_{10}\,AGROWTH_{i,t} + a_{11}\,IND + a_{12}\,TAT_{i,t} + a_{13}\,SGROW_{i,t} + e \quad (1)$$

$$\text{FOREIGN:} = b_0 + b_1\,\text{LISTING}_{i,t} + b_2\,\text{M\&A}_{i,t} + b_3\,\text{EXSALES}_{i,t} + b_4\,\text{FINDIST}_{1i,t} + b_5\,\text{FINDIST}_{2i,t} + b_6\,\text{LEV}_{i,t} + b_7\,\text{RISK}_{i,t} + b_8\,\text{PMARGIN}_{i,t} + b_9\,\text{VAD}_{i,t} + b_{10}\,\text{SIZE}_{i,t} + b_{11}\,\text{IND} + b_{12}\,\text{AGROWTH}_{i,t} + b_{13}\,\text{TAT}_{i,t} + e \quad (2)$$

*LISTING* is a dummy variable that has a value of one if the firm is listed and zero otherwise. *FOREIGN* is a dummy variable that equals one if the firm has a foreign investor and zero otherwise. The *M&A* dummy equals one if the firm had M&A activity during the period and zero otherwise. *EXSALES* is export sales divided by sales. *TAT* is total asset turnover and is equal to sales divided by total assets. $FINDIST_1$ is a dummy for financial distress that equals one if the firm has consecutive losses over at least two years. $FINDIST_2$ reflects vulnerability to financial distress and equals one if the equity to total assets ratio is below the median and above 24%, which is the threshold value for distress obtained from frequency of the data. *LEV* is leverage and is calculated as the ratio of book value of total debt to total assets. *RISK* is a measure of total risk and measured as standard deviation of return on equity. *PMARGIN* is net income divided by sales. *VAD* is value added measured as EBIT + interest payments + gross wages and salaries – income besides main operations + allowances. It is a dummy that equals one if the firm's value added is above the median and zero otherwise. *SIZE* is log sales. *AGROWTH* is change in total assets divided by total assets. *SGROW i*s the growth in sales. *IND* is a dummy for industry that equals one if it is an R&D intensive sector and zero otherwise.

We aim to investigate whether listing increases the likelihood of foreign investment due to lower information asymmetry attained by the disclosure of data related to the public firm. The second stage of the analysis includes dividing the sample into three as listed firms, listed firms involved in M&As, and unlisted firms involved in M&As. Firms that have neither public ownership nor M&As are used for a robustness check of the findings. Foreign investment likelihood is further analyzed for cross-border mergers and Greenfield investments.

## DATA AND METHODOLOGY

### The Data

This research rests on a sample of the 500 largest industrial firms of the Istanbul Chamber of Industry during the 2005-2010 period. The firms that have existed in four years of the six-year period are included. Thus, the sample size was reduced to 453 firms. The classification of the manufacturing firms according to Standard Industrial Classification (SIC) codes is presented in the Appendix (see Table 12). Pharmaceuticals, chemicals and vehicles industries are placed in the R&D-intensive group in the analyses.

Since only 18.5% of these industrial firms are listed on Borsa Istanbul, the analyses rest mainly on the data of unlisted companies. Financial statements of these firms are not disclosed. Only some selected accounts from the balance sheet and income statement are published. Ownership data is not disclosed except for the percentage of foreign shareholdings. The M&A activity data (Table 2) is derived from the Dealwatch database. The 2005-2010 period was selected because of the availability of standardized financial tables of listed companies after 2005.

Within the sample, only 93 firms (20.5%) had at least one M&A during the period of analysis. If a firm had more than one M&A during the period, the first M&A transaction was used (Table 3).

Firms that are involved in M&A can be classified as domestic or foreign. Most of the M&A activity (55%) has been with a foreign investor, and 45% has been among domestic institutions. The proportion of M&As in unlisted firms (50.5%) is slightly higher than those in listed firms (49.5%) for the period of analysis (Table 4).

When missing firms are eliminated, mean foreign ownership is 62.3% and the median is 63.7% (n=654). However, when only those firms between 15% and 85% of foreign shareholdings are included in the preliminary analyses, mean and median foreign ownership become 50% (n=312). If the missing

*Table 2. M&A activity of listed and unlisted firms*

| Ownership Characteristics | | No. of Observations | % |
|---|---|---|---|
| I. Listed Firms | | 84 | 18.5 |
| Had M&A<br>Did not have M&A | 46<br>38 | | |
| II. Unlisted Firms | | 369 | 81.5 |
| Had M&A<br>No M&A | 47<br>322 | | |
| Total | | 453 | 100.0 |

*Table 3. Cross-border and domestic M&As*

| Breakdown of M&A Activity | No. of Firms | % |
|---|---|---|
| M&A with foreign firms | 51 | 55 |
| M&A with domestic firms | 42 | 45.0 |
| Total | 93 | 100.0 |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 4. Foreign Ownership and Control*

| Foreign Ownership Percentages | N | % |
|---|---|---|
| 0.00-0.49 | 43 | 33.0 |
| 0.50 | 14 | 11.0 |
| 0.51-0.85 | 19 | 14.0 |
| 0.86-0.98 | 9 | 7.0 |
| 0.99-1.00 | 45 | 35.0 |
| Total | 130 | 100.0 |

values are treated as zero, the mean drops to 18% (n=2361), as indicated in Table 8. A breakdown of foreign investors' shareholdings reveals that approximately 35% of foreign investments are Greenfield FDI. Breakdown of Foreign Ownership in Listed and Unlisted Firms is shown in Table 5.

The majority of foreign investment has occurred in unlisted firms. As documented in Table 8, 68% of the firms involved in M&As are targets. The rest of constitute Greenfield investments. In 85% of the private sale cases, the acquirer has purchased a controlling stake. The descriptive statistics are presented in Table 7 and a summary of binary variables is presented in Table 8. Financial distress data is reflected in Table 6 and Table 8. The FINDIST variable includes two different proxies of distress. $FINDIST_2$ indicates vulnerable firms that have equity to total assets below the median and above the lowest threshold of 24%, which is derived from the frequency of data. Those firms that have equity to total assets below 24% are distressed firms (11.7%). $FINDIST_1$ is a proxy for firms that have losses over two consecutive periods. These firms constitute 11.7% of the sample. As can be observed in Table 6, 75% of the distressed firms are unlisted.

7% of the listed firms are distressed while 13% of the unlisted firms are classified as distressed. So, unlisted firms have a higher proportion of distressed firms than listed firms.

## Variables

The variables used in the analyses can be grouped as those that reflect performance, ownership structure and firm characteristics that affect information asymmetry between investors and blockholders. The descriptive statistics of the variables are presented in Table 7 and Table 8.

*Table 5. Foreign ownership and listing*

| | N | % |
|---|---|---|
| Unlisted | 187 | 62 |
| Listed | 116 | 38 |
| Total | 303 | 100 |

## METHODOLOGY

In the first part of this paper, univariate *t*-tests are used to reveal the significant variables that can be used in regression analyses. The second part involves use of logistic regressions and least squares regressions. The regressions are checked for multicollinearity. The first two logistic regressions involve total M&A activity and foreign investment as dependent variables, respectively. The regressions rely on panel data for the six-year period. In the second stage, logistic regressions are run for listed M&As and unlisted M&As. The group that has neither M&As nor public ownership is analyzed for robustness check. We expect to have similar significant variables only with opposite signs to verify our findings. The results in Table 10 show that the relations we find are robust. Similarly, FDI is analyzed as listed cross-border M&As, unlisted brownfield investment and greenfield investments. These logistic regressions reveal results for different modes of entry of foreign investment.

The problem of endogeneity may arise when both ownership and performance are determined by omitted variables (Huang & Shiu, 2009). Foreign ownership may be endogenous when performance affects ownership. To eliminate the probability of endogenoity, we have adopted two- stage probit regression analyses in this study. All the performance indicators are regressed against $FINDIST_1$ and $FINDIST_2$ and the fitted values of $FINDIST_1$ and $FINDIST_2$ are placed in Equation (1) and Equation (2). The two-stage probit results reveal that variables which significantly affect merger activity and foreign ownership are the same as the previous results. The analyses can be provided upon request.

## EMPIRICAL FINDINGS

### Univariate Tests

The univariate *t*-test results are presented in the Appendix. When total M&A activity is analyzed, firms that are involved in an M&A activity are shown to have a significantly higher return on assets, value added and are larger in size than the firms that are not involved in any M&A transaction. These firms are significantly large and have lower exports and asset turnover than firms that are not involved in any M&A activity. The results are displayed in Table 13 in the Appendix. Listed M&As have lower leverage and asset turnover than unlisted M&As. However, listed M&As are larger and have higher equity to total assets (above the median) than unlisted M&As as displayed in Table 14.

### Multivariate Results

Determinants of total M&A activity are analyzed making use of Equation (1) and foreign investment are investigated using Equation (2). The results are displayed in Table 9. The determinants of M&A involvement and foreign investment are analyzed using logistic regression equations.

The results displayed in Table 9 reveal that the firm-level determinants of M&A activity differ from foreign investment. Foreign investors seem to prefer firms that have high export sales and value added and operate in R&D intensive industries. A factor that affects M&A activity but is insignificant in foreign investment regression is leverage. The likelihood of M&A activity increases as leverage rises. This

documents that firms with high leverage are more likely to be involved in M&As to resolve financial distress, which supports the evidence in the literature (Jensen, 2001; Bergstrom et al., 2005; Buehler et al., 2006; Faccio et al., 2006).

The factors that are common to both, although with opposite signs, are public ownership, size and efficiency. M&A activity for listed firms is more likely for firms that are large but have lower efficiency. These M&As aim to attain economies of scale and improvement of efficiency from synergy effects. On the other hand, foreign investment is more likely for unlisted, small firms that have high efficiency in asset utilization. Asset growth seems to be insignificant in both regressions. Public ownership is positively related to M&A activity but reveals a negative relationship with foreign investment.

The firms from high-tech industries have higher information asymmetry surrounding them. Their operations are less transparent due to the fact that high-tech firms are more unique in their operations, which gives them a higher competitive advantage. The combined effect of these features on the likelihood of involvement in M&A activity is ambiguous, as documented by Hovakimian and Hutton (2010). However, findings reveal that firms in high-tech industries are more likely to be involved in cross-border mergers.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The determinants of foreign investment are investigated using Equation (2). Unlisted firms have a higher likelihood of private sale to foreign investors. This may reflect the fact that foreign investors possess an information advantage through their familiarity with the firm in previous years or through globalization of the firm with high export sales. Export sales are significantly positively related with foreign investment, supporting Dahlquist and Robertsson (2001) and Huang and Shiu (2009). Consequently, hypothesis three is accepted

Public ownership is positively related to M&A activity in Equation (1). Listing on the stock exchange increases the likelihood of M&As, supporting Hovakimian and Hutton (2010) and Çelikyurt et al. (2010). Public ownership facilitates acquisitions by relaxing financial constraints, creating a fair value for the firms, and allows faster growth by pursuit of more acquisitions that would be out of reach for private acquirers. Firms that go public benefit from the cash raised and exchange publicly traded stock in subsequent acquisitions. So, hypothesis one is accepted, supporting Hovakimian and Hutton (2010) and Çelikyurt et al. (2010).

Leverage has high marginal effects on M&A activity. The findings in Table 9 reveal that as leverage rises, the likelihood of M&A activity increases, supporting the evidence in the literature (Jensen, 2001; Bergstrom et al., 2005; Buehler et al., 2006; Faccio et al., 2006). The positive relationship holds for the total M&A sample and unlisted M&As, as displayed in column (3) of Table 10, leading to the acceptance of hypothesis two.

As Netter et al. (2011) document, our findings seem to be affected by the nature of the sample used in the analyses. Table 9 shows that IPOs and M&As reveal a positive contemporaneous relationship when the total sample is analyzed but reveal a negative contemporaneous relationship when only foreign acquirers are included in the sample. Similarly, Table 10 documents that mergers may be a means of reducing financial constraints for unlisted firms that face difficulty in accessing debt and capital markets. As shown in Table 10, the sign of the leverage variable is significantly positive in column (3) for unlisted M&As while it is negative for listed M&As as displayed in column (1). Findings indicate that public ownership mitigates the relationship between M&A activity and leverage.

The positive relationship between risk and public ownership suggests that M&As with listed firms constitute a means of risk sharing and supports the evidence in the literature (Anderson & Dyl, 2008; Scherr & Hulburt, 2001). This relationship is insignificant in mergers with unlisted firms.

The regressions of cross-border M&As and greenfield investments in Table 11 document a significant negative relationship between risk and foreign ownership only in greenfield investments. This implies that foreign investors tend to avoid firms with high stand-alone risk, and financial distress supporting Dahlquist and Robertsson (2001). The drivers of cross-border M&As seem to differ from greenfield investments in several ways. The results are displayed in Table 11.

Table 11 displays the determinants of FDI classified as cross-border M&As, with listed and unlisted firms, and greenfield investments. All cross-border M&As and greenfield investments tend to take place in R&D-intensive industries. So the R&D intensity of the sector is an industry-level characteristic that is common to all foreign investments.

Greenfield investments have several drivers in common with cross-border M&As of unlisted firms. Export sales, efficiency of asset utilization, and R&D intensity of industry are positively related to both cross-border M&As of unlisted firms and greenfield investments. As size gets smaller, the likelihood of mergers increases.

Greenfield investments reveal a strong negative relationship to financial distress and stand-alone risk. Since Greenfield investment indicates a foreign start-up, corporate risk has no relevance for well diversified international investors. There is no significant relationship between corporate risk, financial distress and cross-border M&As.

Results reveal that FDI is more likely for firms that have high exports, value added and efficiency because foreign investors prefer to invest in firms that they are familiar with from international markets through their export sales. They tend to prefer small firms for which the significance of exports is higher, supporting Kang and Stulz (1997). These findings support the evidence that foreign investors focus on firm characteristics that reduce information asymmetry surrounding the firms (French & Poterba, 2001; Lewis, 1999; Dahlquist & Robertsson, 2001).

## SUMMARY OF FINDINGS

This chapter provides evidence on the firm-level determinants of M&As and foreign investments with emphasis on cross-border M&As and greenfield investments. The determinants of M&As, including domestic mergers, reveal similarities to those of foreign investment. The factors that are common to both, although with opposite signs, are public ownership, size and efficiency of asset utilization. The likelihood of M&A activity rises as firm size increases but efficiency decreases. These M&As aim to attain

economies of scale and efficiency improvements arising from synergy effects. On the other hand, foreign investment is more likely for unlisted small firms that have high efficiency. Asset growth is insignificant in all the analyses, revealing that growth is not an important motive for M&As and foreign investment.

Foreign investment determinants are different from those of M&A activity. Foreign investors focus on firm characteristics that reduce the information asymmetry surrounding the firm's environment. The results reveal that FDI is more likely for firms that have high exports, value added, and efficiency. This evidence supports the premise that foreign investors prefer to invest in firms they are familiar with from international markets, their past relationships and export sales (French & Poterba, 2001; Lewis, 1999; Dahlquist & Robertsson, 2001; Huang & Shiu, 2009). Foreign investment is negatively related to size and public ownership. Export sales is a strong driving force in cross-border mergers involving unlisted companies and Greenfield investments. Exports are more important for unlisted firms and substitute for the smaller size of the unlisted firms in reducing the information asymmetry, supporting Kang and Stulz (1997). Export sales become insignificant in cross-border mergers of listed firms, indicating that public ownership increases the familiarity of investors with the firms, and substitutes for the effects of exports. Since there is a positive relationship between the size of the firm and listing on the stock exchange, the significance of exports may have disappeared in the sample of listed firms due to their larger size, as Kang and Stulz (1997) indicate. Similarly, other information asymmetry measures such as profitability and risk are insignificant in the group of listed firms.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

A factor that affects M&A activity but is insignificant in foreign investment is leverage. Leverage is positively related to the total sample of M&As. This shows that highly levered firms which face distress are more likely to be involved in M&As and supports the evidence in the literature (Jensen, 2001; Berkstrom et al., 2005; Buehler et al., 2006; Faccio et al., 2006). M&A activity is a means of reducing financial constraints only for unlisted firms that have limited access to debt and equity markets. As these firms exhaust their debt capacity and need to make use of higher debt capacity of the parent firm and the internal capital market of the acquirer, they tend to be involved in an M&A transaction. The relationship between leverage and M&A activity is negative for listed firms revealing that listing mitigates the relationship between M&As and leverage. However, FDI is not significantly related to leverage in any of the analyses.

FDIs, including cross-border M&As and greenfield investments, are more likely to emerge in R&D intensive industries. This industry-level characteristic is common to all foreign investments, supporting Huang & Shiu (2009).

Greenfield investments have several drivers in common with cross-border M&As of unlisted firms. Export sales, efficiency of asset utilization, value added generated by firms, and R&D intensity of industry are positively related to both cross-border M&As of unlisted firms and greenfield investments. Consequently, foreign investors seem to invest in good performers. Value added, export sales of firms and R&D intensity in the industry are not significant determinants of M&A activity for the sample where domestic acquisitions are included.

FDI modes of entry have different drivers. There are some differences in determinants between cross-border mergers and Greenfield investments. Greenfield investments reveal a strong negative relationship to financial distress and stand-alone risk. There is no significant relationship between corporate risk, financial distress and the likelihood of cross-border M&As. Leverage is insignificant in all FDI regressions.

This study rests on a sample of firms which represents a small (18.5%) portion of listed firms and the data that is disclosed for unlisted firms is not sufficient for a more detailed breakdown of ownership among domestic firms that are group-affiliated and those that are stand-alone firms. The M&A involvement may be studied separately for acquirers and targets, provided that all financial data is available for both groups. The breadth of data employed in the analyses might affect the results, as indicated by Netter et al. (2011).

## Economic Implications of FDI Forms of Entry

Recent researches provide mixed evidence on the economic effects of Greenfield investments and cross-border mergers. Some studies that focus on the relationship between FDI and economic growth find a positive impact of FDI on economic growth (Borensztein et al., 1998; Pain, 2001; Neuhaus, 2006), while others find a negative relationship (Kim, 2009; Mencinger, 2003). Further studies document that cross-border M&As are less beneficial for economic development than entry by setting up new facilities (Mencinger, 2003; Wang & Wong, 2009; Harms & Meon, 2011; Kim, 2009). Foreign acquisitions often transfer domestic ownership and control to foreign hands, accompanied by layoff of employees and the closing down of production activities. Hence FDI through M&As may correspond to lower level of productive investments than the same amount of greenfield investments, or none at all (Harms & Meon, 2011). However, Greenfield investments can be welfare-improving when the technology advance of the investor is higher than the critical value (Kim, 2009). The mixed evidence on the effect of FDI on economic growth results from combining effects of cross-border M&As and greenfield investment,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

which offset each other (Mencinger, 2003). Cross-border M&As often lead to employment loss and can be used to reduce competition. They tend strengthen market power through increasing concentration and lead to anti-competitive results. Greenfield FDI increases the number of firms in existence and does not increase market concentration upon entry. The effects of cross-border M&As on competition can be influenced by policies adopted by the governments of the host countries. With the emergence of global markets for firms, this may require cooperation of authorities at international sphere.

The effect of FDI on total factor productivity is shaped by technology transfers as well as the intensity of the market competition. FDI is expected to increase factor productivity through transfer of technological and managerial knowledge. Some evidence displays that cross-border M&As have higher R&D intensity and positive impact on total factor productivity of the host country in developed countries while greenfield investment has no significant effects (Bertrand et al., 2007, 2012; Ashraf et al., 2014). Ashraf et al. (2014) conclude that restricting M&As in favor of greenfield investments could reduce FDI-related transfers to host countries. Contrary evidence suggests that cross-border M&As are less likely to transfer new or better technologies or skills than greenfield FDI (Liu & Zou, 2008). The authors document that there are inter-industry and intra-industry spillovers from Greenfield investments, but only inter-industry M&A spillovers.

Most of the shortcomings of FDI through M&As as opposed to greenfield FDI relate to effects at entry or soon thereafter. In the longer term, many differences between the impacts of the cross-border M&As and greenfield investments diminish or disappear. Evidence shows that higher cross-border M&As are followed by higher greenfield investments in industrial and developing countries. The subsequent expansion of Greenfield FDI is at least as large as the initial increase in cross-border M&As in developing economies (Calderon et al, 2004). The authors note that, in the long run, cross-border M&As lead to increased investments and manufacturing, which may be followed by technology transfer and increased employment if later investments are made.

## CONCLUDING REMARKS

This empirical study reveals that foreign investors are able to choose high performing firms that have efficiency and value added above the median, supporting the evidence provided in the literature (Grinblatt & Keloharju, 2000; Huang & Shiu, 2009). These advantages may provide stronger credibility to foreigners than to domestic investors and may create favorable signals to minority shareholders and investors in the market regarding the prospects of the firms that foreign investors choose (Huang & Shiu, 2009). The favorable signals may result from a variety of factors such as the ability of foreign investors to pick good performers, the adoption of strong governance systems of the foreign investors by the targets, and the ability of foreign investors to positively influence management of the acquired firm. This signaling effect may be important if the target firm is unlisted and prevails in the asymmetric information environment of an emerging market (Huang & Shiu, 2009). The majority of the investments by foreign investors in the sample were controlling stake acquisitions and Greenfield investments where they were able to exert substantial monitoring, impose changes and make improvements in the governance systems of the corporations and the host country.

The strategic implications of the findings for the management of a firm that aims to attract foreign investors include attempts to increase the production of high value added products in the sales mix, to emphasize efficiency-improving restructuring of assets and operations, to stimulate export sales and

to increase R&D investments. Investment in human capital seems to be an important factor that will contribute to the accumulation of technological and managerial knowledge and a reduction in the gap between foreign investors and the firms in the host country.

The findings of this study are similar to the existing evidence in terms of the implications for policymakers of the host country. Besides the assurance of the factors that stimulate FDI inflow such as economic stability, level of financial development, tax policies, higher quality of the legal and regulatory environment, economic freedom, and well-functioning markets, governments of the host countries need to work on enhancing the accumulation of technological know-how and human capital in the domestic market to reduce the gap between the foreign investors and targets in the host country. Policymakers should allocate more capital to reach a threshold of human capital, enhance domestic technology by establishing R&D centers to stimulate innovation, and assure free mobility of R&D personnel. For FDI to create technological spillovers and productivity in the host country, innovation in the domestic firms and competitiveness in the market should be encouraged by the policymakers of the host country. As FDI restrictions are liberalized worldwide, these should not be replaced by anti-competitive practices. Efforts to attract FDI should be complemented by policies that restrict anti-competitive practices of cross-border M&As. This requires international cooperation among all countries, including the smaller emerging markets for which competition policy is an important concern.

## KEY TERMS AND DEFINITIONS

**Cross-Border Mergers:** A cross-border merger is a transaction in which the assets and operations of two firms belonging to or registered in two different countries are combined to establish a new legal entity. The control of assets or operations is transferred from a local to a foreign company, with the former becoming an affiliate of the latter.

**Greenfield Investment:** A form of foreign direct investment where a parent company starts a new venture in a foreign country by constructing new operational facilities. In addition to building new facilities, most parent companies create long-term jobs in the host country by hiring new employees.

**Public Ownership:** This term implies that a portion of a corporation's stock is publicly traded. It can be used synonymously with stock market listing, which is being on the official list of stocks that can be bought or sold on a stock exchange.

## ABSTRACT

*If audits serve as formidable internal monitoring tools which facilitate corporate governance, and Corporate Social Responsibility has been proven to serve as "an extension of corporate governance", as well as a signaling device, are both tools not instrumental in promoting Foreign Direct Investment? Through an analysis and evaluation of the literature relating to audits and Corporate Social Responsibility, this chapter aims to investigate the above claim and question on how Corporate Social Responsibility, as "an extension of corporate governance", as well as a signaling mechanism, could facilitate and promote Foreign Direct Investment.*

## INTRODUCTION

The role of the emerging and BRICS economies in propelling global growth, as well as determining and forecasting the direction of stock markets, is increasingly becoming apparent. This change in the previous trend which was previously dictated by the state of the United States economy, also presents a source of concern given apparent uncertainty and political tensions between certain leading economies and the United States. In addition to the leading and pivoting role assumed by China, the influence and impact

of oil prices on stock markets has been witnessed and observed with increased interest since the end of October 2014. The importance of financial disclosure and transparency in leading market economies – particularly for institutional investors has continually and persistently been brought to the fore. Owing to concerns of steep drops in the Dow and persistent uncertainty about the future and not the current state of the United States economy, on the 24th August 2015, a massive sell-out was instigated following a dip of about 1000 points.[1] This being attributed not only to dipping commodities such as oil prices, but primarily in response to observations that prognosis on China's growth was weaker than forecasted, as well as concerns about extent of cover ups about actual state of China's economy.

The vital question remains the extent to which BRICS are able to sustain the expected momentum as propellers of growth and Foreign Direct Investment – at a global level - as merely opposed to a regional level. Furthermore, was the massive sell out which followed in response to the Dow's loss, an over-reaction to China's stock market figures and the fact that expected prognosis about growth, particularly within China's manufacturing sector, may not be as robust as initially anticipated? Or is a combination of other factors such as uncertainty over the hike in interest rates by the Fed Reserve, as well as policy responses by other central banks attributable to the panic?

Is a slow down or bust period approaching in China or the BRICS economies – particularly having experienced a boom cycle whereby China was able to resist the pressures encountered by many other advanced economies following the Financial Crisis of 2008? Such bust cycle periods having been evidenced in the Asian Financial Crisis of 1997 and then a decade later when the 2008 Global Financial Crisis was preceded by a boom period in the housing markets?

This chapter aims to contribute to the literature on how Corporate Social Responsibility, as "an extension of corporate governance" (Sacconi, 2004:6), as well as a signaling mechanism (Goyal, 2006:4), can facilitate and promote Foreign Direct Investment.

## Background and Literature Review

In addition to UNCTAD reports following post 2012 decline – with inflows rising 9 per cent in 2013, to $1.45 trillion, and projections, that FDI flows could rise to $1.6 trillion in 2014, $1.7 trillion in 2015 and $1.8 trillion in 2016, with relatively larger increases in developed countries, the following key observations were also made (UNCTAD, 2014):

- FDI flows to developed countries increased by 9 per cent to $566 billion, leaving them at 39 per cent of global flows, while those to developing economies reached a new high of $778 billion, or 54 per cent of the total.
- FDI outflows from developing countries also reaching record levels with developing and transition economies together investing $553 billion, or 39 per cent of global FDI outflows, compared with only 12 per cent at the beginning of the 2000s.
- Megaregional groupings' impact on global FDI – with Asia-Pacific Economic Cooperation (APEC) remaining the largest regional economic cooperation grouping, with 54 per cent of global inflows.
- The poorest countries are becoming less and less dependent on extractive industry investment and natural resources – with manufacturing and services now make up about 90 per cent of the value of announced projects both in Africa and in LDCs.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The highlighted observations (above) can be contrasted with the following observations provided by Goyal (2006:2):

*The economic size and potential growth of a developing country are the major determinants of the foreign capital it attracts. There is intense competition to attract FDI. Liberalization, incentives such as lower tax rates, and investment targeting are among the measures governments are taking. After the East Asian crisis, FDI has been recognized as a more stable component of foreign inflows. But the developing country share of FDI has never recovered its peak share of 44% reached in 1997, and aggregate FDI has continued to be below the dollar 1.4 trillion reached in 2000. However, UNCTAD, based on its surveys, expects FDI to rise again in 2004 and a renewed surge to follow in the next few years, especially in the services sector. There are signs that this is materializing.*

According to 2014 UNCTAD data and figures, at regional level (UNCTAD, 2014):

- FDI inflows to Africa rose by 4 per cent to $57 billion, driven by international and regional market-seeking and infrastructure investments with expectations for sustained growth of an emerging middle class being cited as contributory factors in the attraction of FDI in consumer-oriented industries: including food, IT, tourism, finance and retail. The overall increase was driven by the Eastern and Southern African sub-regions, as others saw falling investments. In Southern Africa flows almost doubled to $13 billion, mainly due to record-high flows to South Africa and Mozambique. In both countries, infrastructure was the main attraction, with investments in the gas sector in Mozambique also playing a role. In East Africa, FDI increased by 15 per cent to $6.2 billion as a result of rising flows to Ethiopia and Kenya. Kenya is becoming a favored business hub, not only for oil and gas exploration but also for manufacturing and transport. Intra-African investments are increasing, led by South African, Kenyan, and Nigerian TNCs.
- With total FDI inflows of $426 billion in 2013, developing Asia accounted for nearly 30 per cent of the global total and remained the world's number one recipient region. Whilst FDI inflows to East Asia is reported to have risen by 2 per cent to $221 billion, inflows to South-East Asia is also recorded to have increased by 7 per cent to $125 billion. Inflows to South Asia rose by 10 per cent to $36 billion in 2013 - the largest recipient of FDI in the sub region, being India. Most notable are reports of FDI flows to West Asia having decreased in 2013 by 9 per cent to $44 billion – with failure to recover for the fifth consecutive year.
- Elsewhere, uneven growth in FDI was reported for Latin America and the Caribbean. Whilst flows to Central America and the Caribbean (excluding offshore financial centers) are reported to have increased by 64 per cent to $49 billion, and FDI outflows from Latin America and the Caribbean (excluding offshore financial centers) are reported to have declined by 31 per cent to $33 billion, a slight decline was reported in relation to Brazil - a slight decline by 2 per cent, despite a reported 86 per cent increase in flows to the primary sector. FDI in Chile and Argentina are also reported to have declined by 29 per cent and 25 per cent to $20 billion and $9 billion, respectively, due to lower inflows in the mining sector. [2]

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Further evidence of persistent regional tensions and political uncertainties as being contributory to holding back investors – even though differences are reported between countries (UNCTAD, 2014:xx) are currently being witnessed in recent news and stock market reports – impacted by declining oil prices and the difficulties encountered by BRICS in sustaining the forecasted acceleration of growth.

Timokhina (n.d.)h ighlights the role and vital importance assumed by BRICS - as well as the resilience of China through the recent global financial economic crisis:

*Brazil, Russia, India, China and South Africa – so-called BRICS countries became significant capital exporters in the last 20 years. Abbreviation "BRIC" appeared in 2001, when it was suggested that by 2050 aggregate GDP of these countries will exceed the corresponding indicator of the developed economies, and South Africa joined the group in 2011.*

China's strategic role – not only as a vital propeller and accelerator of global growth, but also its influence in its "economic role to promote Africa's development" is highlighted (Timokhina, n.d.).

Goyal (2006) argues that CSR works as a form of signaling and that since it reduces the returns from non-cooperative strategies it implements an efficient equilibrium.[3] In capital markets where so much uncertainty and asymmetric information is involved, reliable signaling mechanisms in the form of audits also serve as vital corporate governance mechanisms.

## ISSUES, CONTROVERSIES, PROBLEMS

### The Significance and Impact of Reliable Signaling Mechanisms in Capital and Stock Market Economies

Recent stock market crashes end of August 2015[4] at the New York Stock Exchange, are not only indicative of panic and loss of investor confidence, but also a huge degree of uncertainty hovering over the markets. Amidst very high volume trading on the NYSE and explanations of a possible market correction, the consolation that trading markets worldwide were also affected by the crash in China's stock markets, and based on the dynamics which were in operation with major Financial Crises in the two previous decades, it was concluded and predicted that a rebound in the stock markets would take place.

A rebound in the stock markets did take place – however temporarily. Even though the NYSE closed on the 24th August 2015 with a loss of 588 points, following an initially devastating drop to 1000 points in the first few minutes of the opening bell, there was a temporary rebound the following day. Following a move by the Chinese central bank to lower interest rates, a measure prompted by the stock market crash, following the "Black Monday" in China, stocks in Wall Street and other major stock markets temporarily rebounded as evidenced from data generated across global stock markets. However the Dow ended the day, 25th August 2015, with a loss of 205 points. Based on the previous trading figures from the previous five days,[5] an aggregate loss of 1850 points was recorded and a 3000 point drop in three months from the all-time high which was registered on the 19th May 2015.

Issues impacting loss of investor confidence in the Chinese stock markets can certainly be attributed to the lack of transparency in the markets, uncertainty, the reliability of accounting data emanating from the markets and consequently, how to adequately price shares and stocks. Even though the "stock market correction" which occurred on the 24th August 2015 in the NYSE was considered by many analysts and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

some investors as an inevitable and anticipated event which was also widely considered necessary within the NYSE, the massive sell off, panic, and surprise – even to traders, could also be explained by the differences in operating dynamics when compared with the 1997 Asian Financial Crisis and the 2008 Global Financial Crisis. In comparison to the 2008 Financial Crisis where financial structural issues within the banking system and regulatory issues were contributory, massive regulatory reforms have been operating since then to bolster Tier One capital as well as other measures implemented following Basel III reforms. The extent of the surprise could also partially be explained by the fact that the Chinese economy, in contrast to its counterparts and other leading economies, had maintained resilience through the 2008 Financial Crisis – having weathered the storms and turbulence of the recent Financial Crisis which culminated in September 2008.

The uncertainty of data emanating from China was not the only factor which was contributory to the Dow's plunge. As highlighted, falling commodity prices in oil, as well as uncertainty surrounding interest rate hikes, all played a role in the massive stock market sell off in the week beginning 24th August. This happening despite the fact that the build up to China's slow down had been evident for months. Such expectancy is also reflected in the distinction between the fundamentals of the US economy and present occurrences in Wall Street.

The current reasonably healthy state of the United States economy – as evidenced by relatively low unemployment rates, low interest rates, lower household debt was highlighted.

Even though uncertainty currently hovers over global stock markets, it is argued by many analysts that there should be no cause for concerns – particularly based on results from previous stock market crashes and financial crises. Whether the present situation will draw similar and comparable repercussions remains to be seen. Present concerns are certainly justified – not only given the slow-down in the BRICS anticipated growth – and the consequent big worries emanating from these emerging markets, but also worries over oil and oil exporting countries. Oil was not the only commodity affected in the Dow's plunge, but also other commodities such as gold and silver – so-called safe haven for investors. Certainly China's role as a major player and its impact and 15% assumption of the world economy, places global markets in a very vulnerable and volatile situation where its economy is affected – as demonstrated by recent events. The dynamics have certainly changed over the years. Policy responses by major economies will certainly play crucial roles in addressing the present stock market uncertainties.

The present situation with global financial markets is further compounded by the fact that many governments cannot lower interest rates than the present levels. Hopefully the worst fears surrounding the extent of the slow-down in the emerging economies will not materialize. Is the market melt-down over yet? Can the emerging economies sustain their expected momentum? It will be interesting to see what unfolds in the months to come – particularly the policy response of the Fed Reserve in September 2015. Whilst the United States economic fundamentals remain solid – or relatively robust, and the high likelihood that Federal Reserve will not raise interest rates in September 2015 persists,[6] policy responses from leading economies still justify the concerns and volatile reactions in the markets.

Maybe the recent events[7] at Wall Street and the "correction" may be just what is needed to bring many investors, analysts, and traders to the reality of what should be expected and be better prepared to deal with asset bubbles.

## SOLUTIONS AND RECOMMENDATIONS

As highlighted by Ojo (n.d.), the crucial factors fueling panics and sudden crashes, frequently boils down to information asymmetries, extent of uncertainty, and lack of transparency and disclosure of vital financial data. Improving Foreign Direct Investment, will therefore require increased transparency, disclosure of financial information and data as a means of addressing information asymmetries between the principal and the agent. Further, with broader stakeholders who fall within the scope and ambit of the stakeholder theory, such asymmetries can be mitigated as proposed by Sacconi (2004) under his model of Corporate Social Responsibility as a tool of extended corporate governance.

According to Sacconi (2004:6), corporate social responsibility can be defined as:

*a model of extended corporate governance whereby those in control of the firm have responsibilities that range from the fulfillment of their fiduciary duties owed towards the owners (principal) to the fulfillment of analogous fiduciary duties owed towards all the firm's stakeholders."*

The engagement of stakeholders as proposed under the model, as well as

*the engagement of stakeholders at appropriate stages, as well as the incorporation of applicable and most suitable forms of rules during such phases of the mediation process between agents and stakeholders, such that flexibility is facilitated in the process to allow for contingencies whilst also compelling effective enforcement and compliance mechanisms, corporate social responsibility should be fostered through the outcomes emanating from better, focused planning, control, decision making, as well as more effective accountability, compliance and enforcement mechanisms, (Ojo, 2016)*

would considerably address information asymmetries between the principal and investors – whether such investors fall within the scope of the traditional principal agent theory or whether they fall under the broader stakeholder theory.

## FUTURE RESEARCH DIRECTIONS

In order to address information asymmetries which contribute to considerable uncertainty, lack of transparency and disclosure in financial markets, considerable measures are being undertaken to enhance audit quality – particularly aspects relating to the provision of certain categories of non-audit services, pursuant to the Sarbanes Oxley Act – which was implemented in 2002, in the aftermath of Enron. The provision of such categories of non-audit services by audit firms, being considered to impair auditors' independence and objectivity. However it has also been argued that the provision of non-audit services by audit firms contributes to knowledge spill overs which are acquired where an audit firm has acquired certain knowledge and skills – as a result of the provision of such non audit services and that such spillovers result in savings and cost reductions which would not otherwise be acquired by engaging a different audit firm. The engagement of a different firm implying that more costs would be employed in such a firm's acquisition of new knowledge. It is therefore also argued that greater focus should revolve around the proportion of non-audit fees generated by an audit firm – in relation to the audit fees earned.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Where such a proportion of non-audit fees in relation to audit fees is considerably high, then it can reasonably be inferred that undue reliance is being placed by the audit firm on its client and hence, greater likelihood that the audit firm's objectivity and independence is likely to be compromised.

In addition to above arguments, and lack of concrete empirical data and research to support the claims that the provision of non-audit services by an audit firm, are detrimental to the extent that such firm's objectivity and independence are compromised, a focus on audit quality has been propounded.

Similar arguments which apply to the provision of non-audit services can be related to another factor which is considered to affect and impair auditors' independence and objectivity, namely, mandatory rotation of audit firms. Whilst a failure to rotate its auditors within an acceptable and stipulated time period is attributable to many corporate collapses, as well as facilitating an environment where creative accounting practices which distort the reliability and relevance of accounting information are practised, it is also argued that an appropriate balance needs to be struck such that auditors are not so frequently rotated that knowledge has to be re-learned by new audit firm – to the detriment and cost disadvantage of the client corporate firm. Whilst ten years, appears to be a growing consensus for the period of mandatory audit rotation, particularly in Europe, other jurisdictions are not of the same opinion.

In various jurisdictions such as South Africa and Malaysia, partial mandatory audit firm rotation is considered a more flexible and feasible option.

As a result of the need for consensus, on a global level, in matters relating to factors which impair audit objectivity and independence, particularly the issue of mandatory audit firm rotation, such factors also contributing to audit quality and the relevance, accuracy and reliability of accounting information generated through financial statements, further efforts aimed at arriving on such a global consensus are required.

## CONCLUSION

Whilst lack of transparency, disclosure of financial and accounting information have been proven to contribute to information asymmetries, uncertainty and panics in financial markets, it also needs to be highlighted that accuracy, reliability and relevance of accounting information is of paramount importance – such that this vital information can be reasonably relied upon by investors.

For these reasons, the focus on audit quality, as well as the importance of audits as vital signaling mechanisms, continue to constitute significant areas – both in terms of Corporate Social Responsibility, as well as factors which determine and influence Foreign Direct Investment in matters of uncertainty and forecasted growth in financial global markets.

As highlighted under the literature review, maybe the recent events at Wall Street and the "correction" may be just what is needed to bring many investors, analysts, and traders to the reality of what should be expected and be better prepared to deal with asset bubbles. It is certainly the case that a great deal of uncertainty persists as regards the actual pace of economic growth in emerging economies, as well as the degree of reliability to be placed on financial data and accounting information in certain economies.

Recent events in global financial markets – particularly with January 2016 heralding a very volatile start to the year, indicate that issues relating to doubts and uncertainty surrounding financial information and the actual pace of global growth are not just temporary one-off events. With the Dow having plunged by more than 300 points to -364.8 during the second week of January 2016[8] – and with all three major indices (the Dow Industrial, S& P 500 and NASDAQ) going into correction zones – and the S&P 500

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

reaching its lowest level since September 2015, the volatility resonating around and within financial markets is certainly not solely restricted to the United States, but also to other major European. Asian financial markets and other leading economies, who have witnessed plunges during the first months of 2016.

The falling oil prices - as well as the response undertaken by OPEC and oil cartels, China's growth and that of other emerging economies, certainly constitute vital areas of attention during 2016. So is the response undertaken in the areas of monetary policy – and also measures aimed at bolstering audit quality and facilitating financial transparency and disclosure.

## ENDNOTES

1. A plunge of about 1078 points (-1078) at the beginning of the day – which ended with a recovery of about 700 points by the end of the day.
2. "Flows to Peru also decreased, by 17 per cent to $10 billion. In contrast, FDI flows to Colombia increased by 8 per cent to $17 billion, largely due to cross-border M&As in the electricity and banking industries." See ibid at page xx
3. A Goyal (2006), "Corporate Social Responsibility as a Signaling Device for Foreign Direct Investment", at page 4
   It is also added that "CSR may serve as a credible signal of a firm's type. Although the country prefers the cooperative strategy it opts for the non-cooperative one if that is the dominating strategy for the firm, but signaling expenditure can change the payoffs to the firm, so that cooperation becomes its dominant strategy. This binding to cooperation makes the efficient equilibrium possible. The accommodating firm has the capacity to design credible signals of its type if it has a longer-term commitment to a business plan, since it is then willing to amortize its signaling expenditure over a longer period." Ibid at page 6
4. 24th August 2015
5. With losses of 163, 358, 531, 588 and 205 points

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

6 On the 31st August 2015, Dow capped worst month in five years – dropping 15 points that day to end August with the worst monthly percentage since 2010. In August 2015, Dow lost 6+% of its value. The following day, the 1st September 2015, China's worst manufacturing results in 3 years sent Dow plunging down at 400+ points (-467) amidst revelation of reports. On the 17th September, interest rates were retained unchanged by the Federal Reserve. Fed Reserve said that rates would remain near zero because present global developments may restrain economic activity.

7 As of the 7th January 2016, shares experienced steep plunges and dives following a continuation of incidents attributed to a slowdown of China's economy – as well as plunging oil prices which reached their lowest levels in 12 years. Following announcements by Chinese regulators that they would "pull the plug on circuit breakers" which had been implemented seven days before, US investors were engaged in massive sell offs which were also triggered by the fear of resulting losses which could occur if swift action to sell was not undertaken before stocks stopped trading. The Dow and shares on the NYSE not only witnessed a 2.4% drop – but also impacts of the global slowdown – which were experienced in other major financial markets around the world.

8 The 13th January 2016

## ABSTRACT

*Role of institutional owners is becoming vital regarding strategic decision making in modern day business corporations. Financial institutions are capable to monitor the empowered company insiders and to regulate the capital market positioning of firms due to their specialized expertise and low cost of monitoring the managers. This article is an attempt to investigate the role of institutional owners on firms' risk-taking behavior in an emerging market. By using the sample of 58 non-financial firms listed at Karachi Stock Exchane-100 (KSE-100) index for a period of 2010 to 2017, these results revealed that institutional ownership can influence firms risk taking decisions. This influence depends on type of institutional ownership; passive owners play negative role in risk taking while active owners play a positive role in risk taking. Size of institutional ownership does not matter in risk taking.*

## 1. INTRODUCTION

Failure of some giant corporations such as WorldCom, Enron, Anderson Global Crossing, Etoys, Merrill Lynch created awareness among investors and corporate regulators regarding the ethical collapse of organizations. These corporate failures astounded the world by their plethora of unethical and unlawful activities and ignited discussions about governance issues in business firms. These corporate failures are attributed to malpractices such as dubious accounting standards, conflict of interest, lucrative compensation management, deceitful operations, power abuses, raw directors, unequal voting rights and free rider problems (Afza & Nazir, 2015). This vulnerability damages economic system and undermine investors return significantly. Moreover, the global financial crisis of 2007-2009 also highlighted several flaws in governance mechanisms regulating the business firms in developed and emerging economics (Akbar et al., 2017).

Corporate governance has a significant impact on strategic business decisions like external financing, risk bearing policies and investment portfolios (Huang et al., 2016; Srivastav & Hagendroff, 2016). Some core ingredients of corporate governance are: responsibilities of board and managers, transparent conduct and accountability, information flow, regulatory and legal environment, and authentic risk management parameters. Implementation of corporate governance is a real task because having rules and regulations is not enough, but implementation is the real milestone to be attained. The amalgam of ethical and legal mechanism to guarantee the business probity proves to be the best remedy of corporate dilemmas. Application of such mechanism comes in various forms of conflicts named as agency conflicts, evoked by (Berle & Means, 1932). Berle and Means (1932) provided evidence to portray such conflicts which are rooted in separation of ownership and control, further refined by Jensen and Meckling (1976) into Agency Theory. These conflicts can arise among shareholders and managers, minority shareholders and large shareholders, managers and debt holders as well so they can be of any nature.

Corporate risk-taking has been a topic of research since last many decades and it is a well-recognized issue. As investors take a high risk to earn more profits, whereas this same kind of trade-off exists at firm level. Managers should invest in those projects which have high idiosyncratic risk to maximize the shareholders wealth in corroboration of "High risk - High return", but reality is very different where managers are hesitant to invest in risky projects to safeguard their personal interests and their risk averse nature (Fama, 1980). Shareholders have options to diversify away the firm specific risk, but managers do not want that, and they even gave up risky but rewarding projects due to their conservative underinvestment approach. The first preference of the managers is their personal wellbeing as compared to the firm profits, continuing with this behavior, their decision-making is in personal favor by lowering down the firm's risk profile and also decreasing shareholders wealth (May, 1995; Holmstrom, 1999). According to Bertrand and Mullainathan (2003) whenever there is an opportunity to take risk, managers always go for less risk. On the similar lines, Amihud and Lev (1981) purposed that sometimes managers support unrelated mergers to lower the risk related to human capital, but such mergers are precarious for corporate health and devastate shareholders wealth.

However, In the corporate governance context ownership structure plays a vital role in shaping up risk-taking behavior of firms. It is an effective mechanism to monitor the risk-taking decisions of the firms and help in reducing agency conflicts between managers and shareholders (Barbosa & Louri, 2002). According to agency theory, managers are conventionally risk-averse, and they prefer their job security over not opting for risky but rewarding projects leading to underinvestment (Akbar et al., 2017). Presence of institutional shareholders with large equity stakes can be a powerful source to constrain detrimental

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

risk-taking. Shleifer and Vishny (1986) proposed that large institutional blockholders have an opportunity to monitor the managerial activities and influence their decisions with respect to undertaking risky but rewarding projects. Similarly, Jarrell and Poulsen (1987) reported that sophisticated and well-informed institutional investors owners can vote in favor of their economic interests as compared to less informed shareholders who follow managers (active monitoring hypothesis vs. passive voting hypothesis). Moreover, Holderness and Sheehan (1988) narrated that blockholders and institutional investors promote shareholders driven business strategies and have influential power to enhance firm performance. While according to Eling and Marek (2012), high level of monitoring, increased compensation and more blockholders are negatively associated with risk-taking. Moreover, the active role played by financial institutions also add value in firm decision making as financial institutions provide managerial and skill resources to the firm by their active participation in board meetings. In this context, Cheng et al. (2011) also found a significant relationship between institutional ownership and risk-taking of insurance firms. Institutional shareholders having greater proportion can better monitor managers and restrain mangers to protect their own personal benefits (Brickley et.al, 1988). Some institutional owners are active and vigilantly favor the shareholders' interests as they can influence managers directly by voting power and indirectly by trading of shares in capital markets (Baysinger et al., 1991; Bushee & Noe, 2000; Wahal & McConnell, 2000; Navissi & Naiker, 2006; Afza & Nazir, 2015). But passive institutional shareholders might have a strategic alliance with insiders and they vote in favor of managers by setting aside the interests of true owners (Gillan & Starks, 2000; 2003; 2007). The above discussion highlights the existing evidence that institutional ownership might influence the level of risk-taking behavior of firms. As per the authors' best knowledge, little attention has been given to this area of study in the context of Pakistan. As the number of institutional owners is increasing day by day their role in corporate decision making cannot be ignored, hence, this article can be considered pioneer in its nature to investigate the impact of institutional ownership on the risk-taking behaviors of firms in Pakistan, which focuses on size and type of institutional owners. The significant contribution of this paper is to highlight the role of institutional investors in devising the risk-taking behavior of the non-financial firms listed on Pakistan Stock Exchange. In addition, by categorizing the institutional investor in the active and passive investors, we tried to investigate that whether the degree of influence is dependent on the type (passive and active) and the proportion of the institutional investors. Hence, this paper is unique in this perspective aimed at to investigate to find out effect of ownership proportion held by institutional owners and to figure the interactive effect of type and proportion of institutional ownership on risk-taking of Pakistani firms.

## 2. LITERATURE REVIEW

Fama and Jensen (1983) developed agency theory to answer the issues raised by Berle and Means (1932) and Jensen and Meckling (1976). The theory focused on contracting environment of the organizations because the organization is a nexus of written and non-written contracts. This theory focused on the decision processes, allocation of residuals claim and devices to control agency conflict which is borne by separation of ownership and control. They purposed two complementary hypotheses regarding decision management (commencement and execution) and decision control (approval and monitoring). Due to this separation of ownership and control in business firms, the conflict of interests arises between managers and shareholders due to different objectives. Managers want perquisites from their job, whereas shareholders need appropriate rate of return on their invested capital (Nazir, 2016). The literature on

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

corporate governance proposes that these diverged interests can be converted by the implementing the effective corporate governance system in the organizations either through incentive alignment or effective monitoring (Jensen & Meckling, 1976; Hubbard & Palia, 1999; Dalton et al., 2003).

Under the incentive alignment hypotheses of agency theory framework, many earlier researchers have cited corporate managers as risk-averse because of employment and reputational risks, and firms do offer their managers compensation plans to align their interests with those of shareholders (Jensen & Meckling, 1976; Fama, 1980), which motivate their managers to undertake risky but rewarding projects to increase the corporate value (Jensen & Murphy, 1990; Baysinger & Hoskisson, 1990). However, the literature has also documented that these large and attractive financial compensation packages also led the mangers to focus on short term personal objectives on the cost of long term value goals and to undertake unnecessary risk and overinvestment which was considered as the one the sources of global financial crisis of 2008 (Kirkpatrick, 2009; Pathan, 2009; Minton et al., 2014). Hence, certain other monitoring governance mechanism could be more appropriate, such as internal board structures or external monitoring by financial institutions and blockholders, in pursuing the manager to undertake optimal risk-taking for increasing corporate value in long term (Staikouras et al., 2007; De Andres & Vallelado, 2008; Belghitar & Clark, 2015).

With respect to efficient monitoring hypothesis by external shareholders, it has been argued that "Bigger is always better" (Afza & Nazir, 2015). In this context, diversified large investors and risk-taking attitude, Gorden (2010, p. 4) narrated "Competitors of the failed firm may do better; suppliers to the failed firm may do worse, but the consequences are 'unbiased.' If all firms are taking good bets, however, then on average the diversified investor will be better off." As institutional investors are large shareholders and they can diversify their risk by investing in different stocks, their anticipation about greater future returns induces them to motivate corporate managers to prefer more risk which enhances corporate risk taking (Pathan, 2009). Moreover, according to Shleifer and Vishney (1986), large institutional shareholders propose a tender offer to replace incumbent management. They also suggest that the tender offer is not the only way to improve performance, but mechanism "Jaw Boning" i.e. negotiations with the management to replace policy can also be used. Finally, they revealed that large shareholders prefer dividends over capital gains due to tax deductions while small shareholders favor capital gains which induce managers to take long term projects instead of short term speculation.

In addition, it has been argued in literature that financial institutions need to show the return performance to their shareholder. This pressure of short term performance induces them to motivate the corporate managers of their investee firms to take risky projects (Baysinger et al., 1991; Aquilera et al., 2007). Financial institutional investors are inclined to immediate short term returns such as maintenance of short term competitiveness, or by mergers and acquisitions instead of considering the long-term value associated with investing decisions (Graves, 1988). They may persuade managers to risk taking by their proxy voting, as they have a large stake in the organization (Johnson et al., 2010; Callen & Fang, 2013).

Considering the risk averse behavior of manager as reported by Jensen and Meckling (1976), Subramaniam et al. (2009) argued that without the efficient monitoring, the managers might reject risky but rewarding projects to avoid their employment risk, however, such projects could be beneficial to long term value of the company. They further narrated that institutional investors should encourage decision makers to undertake all the business ventures which are providing the firms with positive cash flows despite of the chances of their likely failures. In this context, Agrawal and Mandelker (1990) conducted a study to explore the two alternate hypotheses related to institutional investment in firms, namely, "active monitoring hypothesis" and "passive voting hypothesis". They suggested that the presence of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

active institutional owners (active monitoring hypothesis) positively affect the stock returns when anti-takeover amendments are presented whereas passive institutional owners (passive voting hypothesis) and managerial equity have no relation with stock price variations.

Moreover, Cheng et al. (2011) conducted a study to explore the relationship of institutional ownership, managerial ownership and risk-taking in the insurance sector. The results highlighted that stable institutional ownership directs toward lower investment and underwriting risk while the presence of active institutional owners reduces total risk and increase systematic risk. In addition, Deng et al. (2007) studied the role of institutional owners in risk-taking activities of bank holding companies and argued that diversification is an instrument which is used by institutional owners to reduce risk taking of bank holding companies. Contrary to earlier studies, they considered both proportion and stability of institutional ownership to explore their monitoring effects on managers and influence on risk-taking decisions through diversification. Hence, their overall results reported that the institutional owners with a larger equity stake for longer periods are in the better position to scan mangers decisions and can support diversified investments to undertake optimal risk taking by the sample firms.

There has been a tremendous increase in number of institutional investors over the last decade with the growth of investment companies and establishment of treasury departments within commercial banks in Pakistan, where institutional investors ownership increased from 5.94% in 2005 to 32.09% in 2015 (Nazir, 2013). Therefore, firms cannot ignore their presence and monitoring role which making any short or long term strategic investment decisions (Hutchinston et al., 2015) which is also providing rationale for the present study to investigate the role of institutional ownership in corporate risk-taking. Keeping in view the above discussed literature, the idea of the present research study is twofold; whether size of institutional investors is affecting the level of risk-taking by the firm; and how the type of institutional investors (i.e. active/passive institutional investors) effect this risk-taking behavior of firms in Pakistan.

## 3. METHODOLOGY

Population of the study is listed firms on Pakistan Stock Exchange (PSX), (formerly Karachi Stock Exchange, KSE) and indexed in Karachi Stock Exchange-100 (KSE-100) index for a period of 2010 to 2017. Out of 100 companies of KSE-100 index, 42 companies are disqualified from the preliminary sample as they either belong to the financial sector, which does not fall under the scope of the study due to different reporting structure in Pakistan or excluded due to the unavailability of data required for this analysis. Final sample is restricted to 464 firm-year observations representing 58 firms for eight years. Data is collected from multiple sources. Ownership and other financial variables are collected from the published annual reports. Daily stock prices of the firms are taken from the daily quotations from PSX (www.psx.com.pk) whereas KSE-100 index values are retrieved from Vital Information Service investor database (www.jcrvis.com.pk).

This research aims to find out the impact of size and type of institutional ownership on corporate risk-taking. Following the literature, this study proxies risk by both market measures and balance sheet/accounting measures of risk-taking. To measure risk, we took five risk measures:

- Total Risk (TR)
- Systematic Risk (SYSR)
- Idiosyncratic Risk (IDOR)

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Earnings Volatility (σROA)
- Z-Score

Total risk (TR) is measured by annual standard deviation of daily stock returns with a maximum 248 days and minimum 30 days in a year following the study of Pathan (2009). As we assumed stock price reflects the activities of the firm so volatility in stock prices represent the risk taken by firms. It is most popular proxy of total risk adopted by firms, confirmed from many prior studies (Nguyen, 2012; Knof & Teal, 1996). In addition, systematic risk (SYSR) is measured by beta coefficient of single index market model by using KSE 100 index daily returns and daily stock returns of particularly company. Anderson and Fraser (2000) and Gadhoum and Aydi (2003) also employed single index market model to calculate the systematic and firm specific risk. The two-factor market model could also be used, but in that there is a problem of the autocorrelation and the possibility of the relationship between interest rate changes and market return changes. Although such relation between interest rate and market returns can be neutralized by orthogonalization (i.e. E(Yit, Xit) = 0) (Chance & Lane, 1980) but it also reports some biasness (Kane & Unal, 1988). Hence, we go for the simple single index model because there is no significant difference in results (Anderson & Fraser, 2000). The single factor market model is:

$$R_{it} = \alpha_i + \beta_i R_{mt} + \varepsilon_{it}$$

where *i* and *t* denotes the firm and time respectively $R_{it}$ is equity return of firm and $R_{mt}$ is the return on KSE-100 market index. The α is the intercept term, β is systematic risk and related to movement in market factors. It underlies economic and financial conditions of a particular industry and shows sensitivity of firm stock in relation to the market and can be proxied for perception of investors about a firm stock. Idiosyncratic/ firm specific (IDOR) risk is measured by the standard deviation of residuals of above mentioned single index model, consistent with numerous previous studies (Anderson & Fraser, 2000; Pathan, 2009).

Moreover, balance sheet measures of risk are also considered because it gives insight regarding internal risk of the firm and study has used earnings volatility and Z-score as balance sheet measures of risk. Following Laeven and Levine (2009), earnings volatility is calculated by standard deviation of Returns on Assets (ROA). Earnings volatility can be also used to check out the earnings smoothing and fair practices of managers in the presence of disclosure requirements. Moreover, Z-score is a composite measure of risk of firm's insolvency as proposed by Roy (1952) and used by other researchers (Laeven & Levine, 2009; Houston et al., 2010; Vyas, 2011). It is situation when losses are more than profits and firm is not able to pay its debt. It shows that how stable the firm is, high value of Z-score indicates more stability and less risk. It is calculated as:

$$Z - Score = \left(ROA + CAR\right) / \sigma ROA$$

In case of financial institutional ownership, we consider two dimensions. Firstly, the fraction of shares held by institutions as (IOS) measured by the number of shares held by financial institutions divided by the total outstanding shares and, secondly type of institutional ownership (IOTYP) which is either active and or passive institutions because both these types separately affect risk taking of firm. Active intuitional shareholders are those which have a nominee director on the board in which they have their

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

ownership stake whereas other financial institutions are passive if they just have invested and staying behind the wall (Navassi & Naiker, 2006). If a firm has active institutional owners, it holds a value of 1 and 0 otherwise. We also employed five control variables namely size, liquidity, leverage, Tobin's Q, and profitability to control the impact of firm-specific factors other than institutional shareholdings on corporate risk-taking behavior. The econometric form of the model is:

$$RISK_{it} = \alpha_1 + \alpha_2 IOTYP_{it} + \beta_1 IOS_{it} + \beta_2 (IOS_{it} * IOTYP_{it}) + \beta_3 Size_{it} + \beta_4 LIQ_{it} + \beta_5 LEV_{it} + \beta_6 \text{ Tobin's } Q_{it} + \beta_7 PROF_{it} + \varepsilon_{it}$$

where:

i = 1, 2, 3……58 (it is cross sectional identifier)
t = time-series identifier from period 2010 to 2017)
RISK = risk is taken as total risk (TR), Systematic risk (SYSR) and Idiosyncratic risk (IDOR) forms (market measures) and volatility of earnings by Standard deviation of ROA (accounting measure). Z-score is a composite measure of risk
IOS = institutional Ownership; it is divided in two dimensions: one % of shares held (IOS) and second type of institutional owners (IOTYP)
Tobin's Q =is growth opportunity and measured by Market Value of equity + debt/total assets
Size = Firm Size measured by log of total assets
LIQ = Liquidity measured by ratio of current assets and current liabilities
LEV = leverage measured by ratio of debt and total assets
PROF = profitability of the firm taken by ROA

Keeping the pooled time series characteristics of present study data where we have 464 firm year observation for 58 firms over eight years, we have used panel regression analysis to check whether ownership variables cause cross sectional variation in risk over time. As our data is pooled over different cross sections of business firms and has different time series, the best estimation technique is to use panel data models (Hsiao et al., 1999). The model discussed in Eq. (i) can be estimated by Ordinary Least Square (OLS) as well as Generalized Least Square (GLS). OLS is a best linear unbiased estimate for fixed effects models, while GLS is the best linear unbiased linear estimates for random effects models. In fixed effects models, it is assumed that the intercept term of the model is invariant, and it does not vary over time whereas this is not an assumption in random effects models (Gujarati, 2003). Moreover, to choose for the best model between REM and FEM for the present study, we employed Hausman specification test.

## 4. ANALYSIS AND DISCUSSION

Table 1 reports the descriptive statistics for the sample 58 non-financial firms listed on the Pakistan Stock Exchange (KSE) for the period of 2010 to 2017 for the study variables. The mean value of value of total risk is 4.2% per annum whereas the mean of idiosyncratic risk is also 4.2%, however systematic risk is greater than firm specific risk. Systematic risk is averaged at 0.79, but dispersion in total and idiosyncratic risk is more than market risk. The total risk level in Pakistani non-financial firms is quite

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

less than other economies as reported by Nguyen (2011). Conversely, total risk in US firms is less than Pakistani firms which is 2.13% (Anderson & Fraser, 2000). The average volatility in balance sheet earnings is 3.8% which is less than market risk. The mean (median) value of Z-score is 3.775 (15.80) with a minimum of -1.42 and maximum value of 4059.35. There are significant changes in risk levels (measured by different formulas) over the study period. Results reported in Table 2 show the significance of joint effect of years and industry on different risk measures and outlay that risk level changes from year to year and industry to industry.

With respect to financial institutional ownership in the sample firms, the average level of equity stake held by financial institutions in Pakistan is 14.5% of total shares issued by the firm. It shows that sample firms have significant share of financial institutions in their businesses. Moreover, 66.4% of the sample firms have passive institutional shareholders and 33.6% of the firms have active institutional shareholders. Large active institutional shareholders have power to influence managers to take short term actions to optimize business decisions (Hutchinson et al., 2015). Growth of institutional investors in corporate sector is unprecedented so their presence in capital markets cannot be ignored. Institutional investors are involved in corporate decision that we cannot disregard their role while discussing corporate risk taking.

Table 1 also portrays the characteristics of control variables. The average size of sample firms in terms of total assets is 28 billion PKR with the minimum value of 212.713 million and the largest firm in the sample possesses total assets worth of 36.267 billion PKR. The average of LIQ is 2.011 which is quite good and represents a healthy liquidity position of the sample firms. Moreover, the mean (median) of leverage ratio is 0.246 (0.136) depicts that the sample firms have financed one-fourth of their total assets with the help of short and long-term debt obtained from the debt market. Moreover, the sample firms are moderately profitable with average ROA of 11.3%, whereas their growth prospects as perceived by capital market participants and measured by Tobin's q are also good as average Q value is 1.688

*Table 1. Descriptive statistics*

| Variables | Mean | S.D. | Min. | 1st Quartile | Median | 3rd Quartile | Max. |

| Institutional Type | Freq. | Percent | | | | | |
| Active | 156 | 33.6 | | | | | |
| Passive | 308 | 66.4 | | | | | |
| Total | 464 | 100 | | | | | |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

which is quite higher than the standard threshold of 1. In addition, Table 2 presents the results of Wald test of joint significance run for year and industry dummy to test whether study control variables are varying over time and across different industries. Except leverage and liquidity, other control variables experienced significant time changes and vary over the study period. Moreover, Table 2 also indicates that, except LEV, other control variables also differ across different industries.

Table 3 reports the empirical results estimated for probing the relationship between financial institutional ownership and risk-taking behavior of sample firms. Panel A of Table 3 reports the initial results in which only level of institutional shareholdings is regressed against the different measures of risk taking. F-value is statistically significant for total risk, idiosyncratic risk and earnings volatility (σROA) which is the indication of the mathematical appropriateness of these models. Hausman test statistics point out that the results of fixed effect regression should be interpreted; hence, only those results have been reported in the Panel A of Table 3. The variable coefficients are robust as these have been estimated by adjusted clustered standard errors. It is evident that higher level of financial institutions equity stake in companies is statistically related to total risk, systematic risk and the earnings volatility risk of the firms. In case of total and market risk, institutional ownership has significant positive impact on firm's risk-taking. Institutional owners have the capability and power to influence and monitor managers in a better way and induce them to work in favor of shareholders value maximization. They are in a better position to direct managers to undertake risky but rewarding projects to increase the returns of shareholders, and managers under the monitoring of institutional investors work more prudently and vigilantly as compare to other equity stakeholders (Cebenoyan et al. 1995). This result is consistent with the results of Shleifer and Vishny (1986), Hutchinson et.al (2015) and Shah et al. (2012) who also found similar positive results.

However, in case of internal risk measures of risk, only earnings volatility, as measured by variations in ROA, is found to be statistically and negatively significant at the 5% level. Earnings volatility of the companies which is directly related to the operations of the business, its investments and then return on these operations with the help of the assets induction are found to be negatively influenced by equity ownership by financial institutions. As discussed earlier, institutional owners make managers more

*Table 2. Joint significant test for year and industry fixed effects*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

vigilant in selecting projects, the managers undertake the projects with positive net present value or the projects increasing the long term economic value of firms, which, in turn, smooth the cash flows of the firms and reduce earnings volatility.

The role of institutional investors in corporate sector is unprecedented so their presence in capital markets cannot be ignored. Institutional investors have significant impact on corporate decisions and one cannot omit their role while discussing corporate risk-taking. Keeping in view their importance and statistically more robust results, we divided institutional owners into two categories, active and passive. Active institutional investors have their representation on the board of directors in which they have an equity stake through nominee directorship, whereas passive investors do not have this representation and participation in corporate decision making in board of directors. We created a dummy variable to check the effect of the type of institutional owners and interaction of level and type of institutional owners so that we come to know that whether large and active owners positively affect risk taking of the firm or vice versa. We developed an ANCOVA regression model which is a mixture of qualitative (dummy) variable and quantitative regressors (covariates), it is developed by extending ANOVA model which only takes dummy variables (Gujarati, 2003).

With the help of the Hausman test, we checked the appropriateness of the best fit model to our data between fixed and random effect generalized least square regression. The results of estimated models are presented in the Panel B of Table 3 where Model 1-5 report the results of institutional ownership on different types of market and internal risk. As indicated by Hausman test statistics, fixed effect estimations are more appropriate in case of SYSR, IDOR, Z-score and σROA, whereas the random effect model is the best fit for TR. All models are mathematically best fitted as indicated by Wald $\chi^2$ and F-values.

With respect to coefficient results, the level of shareholdings by financial institutions (IOS) is found to be insignificant for all risk measures. Without considering the effect of control variables, the estimated equations for different dependent variables measurements of risk would be like:

$$RISK_{it} = \alpha_1 + \alpha_2 IOTYP_{it} + \beta_1 IOS_{it} + \beta_2 \left(IOS_{it} * IOTYP_{it}\right) + \varepsilon_{it} \tag{1}$$

where mean function of risk for passive investors would be:

$$E\left(RISK|IOTYP_{it} = 0, IOS_{it}\right) = \alpha_1 + \beta_1 IOS_{it} \tag{2}$$

and mean function of risk for active investors would be:

$$E\left(RISK|IOTYP_{it} = 1, IOS_{it}\right) = \left(\alpha_1 + \alpha_2\right) + \left(\beta_1 + \beta_2\right) IOS_{it} \tag{3}$$

In Equation (1), $\alpha_2$ is the differential intercept and $\beta_2$ is the differential slope coefficient (also named as slope drifter), indicating that how much is the effect of active institutional owners (when dummy variable is one) on corporate risk taking differs from the passive investors. The introduction of dummy variable in interactive form enables us to find out difference of impact of both type institutional owners on corporate risk taking. However, in additive form it enables us to distinguish the intercept of both ownership types (Gujarati, 2003). If we look at the regression results in Table 3, we can infer that passive institutional owners have negative effect on all type of risk measures because $\alpha_1$ has negative coefficients

***, **,* indicate statistical significance at 0.01, 0.05 and 0.1 levels respectively. Figures in the parenthesis are t-statistics.

in all cases except Z-score and all coefficients are statistically significant as well. In model 4 of Z-score, it is positive that means presence of passive institutional owners make the firm more stable. Passive institutional owners may have strategic alliance and relationship ties with managers and their effective monitoring role suffers (Brickley et al., 1988).

The coefficient of IOS is insignificant in all regression. It means the size of passive institutional owners do not matter because they remain passive whether their investment in firms increase or not. Differential intercept $\alpha_2$ is only significant for σROA and Z-score which is an indication that active

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

institutional owners positively affect corporate risk taking regardless of their level of ownership as they can influence firms directly by monitoring managers and indirectly by trading shares (Gillan & Starks, 2003). Active institutional owners effect managers to produce a short-term return by adopting risky projects (Hutchinson et al., 2015). The coefficient of $\beta_2$, which is the differential slope (interaction) coefficient, is insignificant in all regression positing that size of institutional ownership do not moderate the relationship between level of institutional shareholding and risk-taking behavior of firms in Pakistan. If the institutions are active, they the level risk-taking (earnings volatility) decreases and it also increase the long-term sustainability of the organizations (z-score). Hence, presence of active institutional owners improves the internal risk position of the company. These results are also robust to the problem of endogeneity[1]. As suggested by Gujarati (2003), this type of estimation is called parallel regression in which intercept differential is significant and slope differential is insignificant.

Overall, panel A of Table 3 indicates that institutional ownership is positively and significantly related to total and systematic risk of the firm which is consistent with the findings of Cebenoyan et al. (1995). One unexpected result we found is coefficient of institutional ownership which is negative and statistically significant when we take σROA as an internal risk measure. One reasonable explanation could be that institutional owners make managers so vigilant and prudent in selection of positive net present value projects that reduces that earnings volatility. Although, it secures the future cash flow of projects but, so much certainty in projects selection leads towards redundant projects which expose firms to more market/systematic risk. Most institutional investors are those institutions which have to show progress to their investors on quarterly basis such as asset management companies and mutual funds (Baysinger et al., 1991; Graves, 1988). Hence, in achieving their goals, they pursue corporate managers for short term returns goals with high and certain results, which ultimately make firm more sensitive to market risk and increase overall level of risk. Considering the type of institutional ownership, the results show that regardless of their level of ownership, active financial institutional shareholders reduces the earnings volatility of firm's long-term solvency increases.

With respect to control variables of study, size has expected results proved from previous researches. Larger firms are low level of total and firm specific risk because of their ability to diversify away the risk through different business lines and geographic diversification (Gursoy & Aydogan, 1998; Nguyen, 2011). But systematic risk is positively related to Size, larger firms are more exposed due to market changes as compare to smaller firms as the level of information asymmetry is quite higher in large firms as compared to their smaller counterparts. Tobin's Q is also positively and significantly related to systematic risk as growth firms are more volatile because of their ability to take risky project in order to achieve growth.

## 5. CONCLUSION

Corporate risk-taking is an important phenomenon and it is critical to firm performance. Optimal level of risk-taking is decided by multiple parties, and one of the key players are institutional owners. They are key participants of capital markets and their role is unprecedented in current era. Institutional owners are substitute for external corporate governance mechanism and they monitor manager in order to run an organization in a better way. The present study is aimed at to investigate the role of institutional owners in devising firm risk-taking behavior. Study findings revealed that the institutional ownership is positively related with external measures of risk and negatively related with internal measure of corporate risk-taking. Overall, institutional owners have the positive and significant effect on the total and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

systematic risk of the firm and play a significant role in monitoring managerial decisions and guide them to undertake risky and rewarding projects which reduces the cashflow volatility but enhances market vulnerability. The robustness of the results has been examined by dividing the institutional owners into active and passive category. The results further provided evidence that, regardless of the size of the institutional owners, active owners negatively affect the earnings volatility and positively influence long term solvency, as measured by z-score.

The results of the present study provide practical implications for managers. From the managerial point of view, corporate insiders can understand the importance of effective monitoring by active financial institutions and their participatory role in decision making while selecting and undertaking business projects. As active institutional shareholders and blockholders are in a better position to monitor managerial decisions, their expertise can be utilized for the evaluation of the business venture. The study also has certain limitations which can be addressed by future research. We just considered non-financial firms listed on KSE-100 index. Because of the difference of risk measures, same theoretical models with bank specific risk measures can be extended to the financial sector of Pakistan. Furthermore, our results showed that risk practices and ownership structure vary from industry to industry, however, we just studied the combined effects. With the help of least square dummy variable model, individual industrial difference can also be obtained and interpreted. Future research should also consider these industry differences, because it will help in understanding each industry risk pattern in more comprehensive form. Finally, cross country comparison can be performed by using country level governance and institutional framework of shareholdings.

## ENDNOTE

[1] Endogeneity between the study variables have been tested using Hausman Specification Test. To detect endogeneity between institutional ownership and risk-taking, the present study estimated Eq. (i) as; $Risk_{it} = \alpha + \beta_1(IOS_{it}) + \varepsilon_{it}$ (i) The unstandardized predicted values of IOS and residual are saved as IOS_pre and IOS_res. At the second stage Eq. (ii) is estimated as; $IOS_{it} = \alpha + \gamma_1 IOS_pre_{it} + \gamma_1 IOS_res + \varepsilon_{it}$ (ii) The coefficient $\gamma 2$ is found statistically insignificant, that means that there is no endogeneity between IOS and different variables of risk and both, dependent and independent variables are being exogenously determined.

# Chapter 77
# Making Innovation Development Policies Work for MENA:
## The Need for Entrepreneurship

**Mehtap Isik**
*Bogazici University, Turkey*

## ABSTRACT

*This chapter analyzes the Middle Eastern North African economies' growth prospects and investigates the role of entrepreneurial activities in achieving sustainable economic growth and social development. It explores the existing macroeconomic, political and social characteristics of the region and brings the different literatures together to understand the policy implications of theory and practices. The chapter shows that entrepreneurial activities can cure a lot of problem in the region as long as supported by the central authorities, and the region has a strong potential to be used by the entrepreneurs.*

## INTRODUCTION

This chapter aims to raise practical solutions to the major development and growth problems of the Middle Eastern North African region (MENA), which are theoretically supported. The main answers revealed by the theoretical surroundings are gathered around the entrepreneurial activities. Thus, the chapter proposes that the entrepreneurial activities are not only important for the individuals in the economy, but also for the salvation of the whole economy, in the development perspective. The study is based upon the strong connection between microeconomic and macroeconomic measures and emphasizes the importance of investing on entrepreneurship in MENA. Our analysis calls the policy makers to finance entrepreneurial activities and claims that it worth, because it pays back with economic development and growth at the same time both in the short and long run time.

To this aim, this chapter investigates the forces which drive trade and global integration in fostering economic development for the special case of MENA region. The extent to which we can attribute economic development to economic growth is a question on the one hand; we ask which structural reforms

are actually missing in the region to achieve a faster economic growth and whether the pointed structural changes affect the economic measures as would be expected. A detailed investigation on the macroeconomic measures lead us to an answer where microeconomic approaches are required: Entrepreneurship.

Taking the new growth theories into account, the innovation and technological improvements are suggested as the main cure in most of the recipes for triggering development and economic growth at once. Then, the key ingredient in the production process becomes the entrepreneurial ability. In that respect, the institutional design in providing the required support for the innovational activities has to be at the center of the discussions, because the fulfillment of infrastructural necessities are significantly important especially if the macroeconomic environment is not ready for the entrepreneurial activities.

When it comes to Middle Eastern North African (MENA) countries, even in the process of identifying the major problems of the region, entrepreneurship arise as a major answer to many problems of the region. This study questions the existence of appropriate macro environment to support micro decisions of individuals and firms regarding to start-up new businesses and to investments on research and development activities which leads the economic growth and development, eventually.

The first section takes a macroeconomic snapshot of the region to observe its current economic situation in the world. The picture clues in on surprising facts regarding the links between development and growth. Controlling almost 60% of the world's oil, being controlled mostly by very strong autocratic governments, including the world's richest countries and some of the poorest countries together, being in a chronic post-conflict context, having a segmented and highly regulated labor markets, with social relations mainly shaped by Islamic rules, a huge unregistered economic production and almost lack of financial markets, the region differ from other developing regions sharply. Although there are considerable differences among countries in the region, the 90's data on the income inequality, poverty and health care demonstrate relatively low levels of poverty and equitable income distribution in compared to other developing regions. On the other hand, a more recent data shows a relative degradation with an accelerating growth of the other developing regions. In compared to countries in other regions at similar levels of income, the governments in MENA region look like more effective in distributing the social services and aids, but inadequate to support the accumulation of the capital required in manufacturing.

It is widely agreed upon that the economic growth generates suitable but not sufficient conditions for economic development. The poverty and inequality are linked to economic growth in an ambiguous way. Many works following Kuznet (1955) study how the economic growth affects inequality. While many studies shows a negative relation between economic growth and inequality (e.g. Perotti, 1996), some empirical works suggest that economic growth increases the inequality (e.g. Forbes, 2000). Indeed, Panizza (2002) shows that the method of measuring the inequality result in differences in the estimated relationship between inequality and growth. Recent works focus on how inequality affects the growth (Galor, 2011). Doyle and Stiglitz (2014) claim that inequality drags down growth in oppose to Krugman (Budis, 2014).

The way of causality between is not clear. However, empirical evidences show that East Asia has experienced a rapid growth and a relatively low level of income inequality at the same time. In contrast, Latin America and Caribbean region has experienced high levels of income inequality and almost zero economic growth over the same period of time (Birdsall et al., 1995). In the same period, the measures in the MENA region are surprising. Poverty indicators exhibit low levels of poverty and Gini coefficients which are similar to those of Europe with very low rates of GDP growth. (Adams and Page, 2003)

This study takes the tension between income inequality and economic growth into consideration, following Ravillion (2001) who explains how the gains from an economic expansion are utilized by dif-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

ferent income groups differ across the countries. In this respect, micro and country-specific approaches can more successfully explain the interaction between economic growth and development in the country at issue. Therefore, economic growth and development policies suggested to a country or a region has to take social and structural elements of the country into account. MENA is a region of its own characteristics in many respects and policies that do not take these specialties into account are off their target. The study claims that policies sourced from new growth theories may be successful, if they are complemented by appropriate structural reforms. Growth strategies should target to balance the speed of growth and well-being of the region. The study analyzes the current financial markets, labor markets and the post-conflict political environment of the region. Also, it is discussed how the oil revenue surplus can be managed so that the infrastructural needs of the region can be fulfilled. In order to compare the macroeconomic conditions of the countries with each other, with European countries and with other developing regions, the data from World's Bank and IMF reports and some cases from countries are used. The effects of Islamic rules on development indices and how these rules would affect the development policies at issue are also discussed, in this chapter.

We organize the rest of the work as follows: In the next section, economic facts about the region are collected. Then, the impacts of political and cultural structure of the region on economic performance are discussed. The next section focuses on why the region needs some policy reforms in its growth and development process, theoretically. The last section, questions the adaptation process and emphasize the need for searching a bunch of compatible policies which respect the distinctive characteristics of the region.

## REGIONAL OUTLOOK

### Economic Measures

A region is defined by the cultural, social and geographical elements. In that respect different classifications of the countries can be considered. Moreover, different mathematical techniques which handle the time series and cross sectional data of the countries are used to construct the regional data. (Hančlová,et al. 2004, Nielsen, 2011) Due to the reliability and comparability issues, this study mainly focuses on data provided by World Bank to analyze regions' economic activity. The regions are defined geographically as North America, Europe and Central Asia, East Asia and the Pacific, South Asia, Latin America and Caribbean, Middle East and North Africa, Sub-Saharan Africa. As it is defined by World Bank, Middle East North Africa (MENA) region includes high-income countries Bahrain, Israel, Kuwait, Oman, Qatar, Saudi Arabia, and United Arab Emirates together with 13 developing countries Algeria, Jordan, Tunisia, Djibouti, Lebanon, West Bank and Gaza, Egypt, Libya, Yemen, Iran, Morocco, Iraq and Syria.[1]

The countries in MENA region are so diversified that the region can be segmented into subgroups according to various variables such as resource endowments, geographical distances, economic relations and trade unions etc. This study mainly follows the classifications by World Bank and assumes that the region is developing one, but takes the diversification into account and uses the subgroups in analysis.

Figure 1 and Figure 2 shows GDP per capita and GDP per capita growth of the region including all income level countries versus the only developing countries, respectively. The difference between the two groups in GDP per capita income decreases in 1980's and increases from 1990's and on. The GDP growth of developing countries which is significantly higher in early 1980's decrease suddenly and small deviations are seen until recent years. The effect of 2008 crisis is higher on growth of developing coun-

tries in the region. The relative position of the region's GDP per capita with respect to the other regions in the world is read from Figure3. Even though the regional data include high income level countries, the regional income gaps between MENA and North America and MENA and Europe and Central Asia are significant. The position of average income of MENA economies change starting in 1990's with the growth of East Asian and Pacific economies. While the East Asian and Pacific region and South Asian region has been decreasing the income gaps with other regions, MENA and Latin America and Caribbean region couldn't achieve such growth trend. Average income of MENA region is behind the World average and the difference has not been decreasing since 1980's.

Figure 4 demonstrates the average GDP per capita growth rates over 10-year periods of the regions between 1980 and 2013. Besides the negative average of 80's GDP per capita growth, the sharp recovery of 90's is also striking. In Figure 2, we see a continuous decrease in the late 90's, but the growth rate fluctuates around 0.5% and 3.5% until 2000's and stays close to world's average. In the first decade of 2000's, region's growth is slightly higher than the world's average. The V-shape growth rates between 2008 and 2010 point out the 08' crisis. In 2013, GDP per capita growth is negative on the average for developing countries in the region and significantly lower than the rest of the world even though all income levels are included. The recovery period after the 08' crisis looks like not completed yet in any regions. However, MENA and Europe and Central Asia regions are the only ones which experience almost zero growth by the end of 2013. Over the period, MENA's growth rate ranges from -4.8% to 6.7% which is the widest interval that no other region experienced. Although the negative growth rates of 80's are not observed in later years, the sharp decrease at 2012 together with political instability of the region is ringing the alarm bells.

Some major indices regarding the economic growth and development of the countries in MENA as of 2013 are listed in Table 1. A very wide range of countries is observed in which world's richest countries Kuwait, Oman, United Arab Emirates, Saudi Arabia and almost the poorest countries Djibouti, Yemen exist.

Why MENA is a very much diversified region economically and how the policies should be shaped in accordance, cannot be analyzed without understanding the differences in terms of resource endowments, government structures, religious beliefs, cultural values.

## Resource Endowments

MENA includes the richest countries in oil, gas and mineral reserves. Other than the fact that the countries in the MENA region own 59% of the world proven crude oil reserves, and 45% of the gas proven reserves, minerals such as phosphate (76%), sulfur (18%), bars (15%), strontium (13%), and iron ore (4.3%) in addition to copper, gold and silver constitutes a significant portion of global reserves.[2] In Figure 5, we see that total natural resource rents as percentage of GDP's which are the sum of oil rents, natural gas rents, coal rents (hard and soft), mineral rents, and forest rents is the highest for MENA. Yet, neither the mining activities nor oil and gas productions are effective as they are expected with the available capacity. The natural resource endowments of the countries are diversified within the region.

The mismanagement and corruption in revenue management have many consequences on overall economy. Indeed, not only in the MENA region, but many countries all around the world are not able to govern their abundant natural resources, efficiently. In most of the cases, revenues cannot be collected. Even when revenue objectives are achieved, governments take policy actions with respect to the short-term interest. Resource Governance Index (RGI) measures the quality of governance in the oil, gas and

mining sector of 58 countries.[3] Norway is the first and Myanmar is the last in the RGI ranking list of the 2013 Resource Governance Index Report. In Table 2, we list the RGI rankings of countries in the MENA region. Those countries appear in *italics* are defined as resource-rich by IMF. Most of the countries in MENA are resource-rich but not able to manage a good governance of resources.

Data given leads to conclude that even though the share of the natural resources on GDP is high, revenues obtained from these resources do not always lead to growth. Indeed, considering that the oil is almost the most crucial factor of production, an obvious question is why all countries endowed with oil are neither the richest nor the most developed ones in the world. Among many other causes that are underlined in the later sections, an economic phenomenon which is named as Dutch Diseases has a crucial role to this end. Corden and Neary (1982) show the effect of revenue surplus obtained from a natural resource on the relative decline of internationally tradable manufacture sectors with respect to the non-tradable good's sector. The model explains that as a result of the boom in natural resource sector real income and so the demand for non-tradable service increases. With increasing prices in service sector, real exchange rate appreciates and the tradable manufacture sector lags behind. Indeed, we observe that the developing countries are mainly endowed with a certain natural resource and /or a

primary product which constitute a highly significant share of exports. However, variety and maturity of exported products are important variables of income derived from international trade. As the product matures in production process, in other words as the product gets more differentiable, higher profit can be expected. In that respect, considering the role of international trade on economic growth, the natural resources may be considered as a curse rather than a blessing. (Auty R., 1993) Yet, this study suggests that whether the natural resource is a curse or blessing mostly depends on the governments' policies. The analysis shows that the mismanagement of the revenues and the lack of infrastructure required for the development of the lagging tradable sectors are the main cause of the problem.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although the region has abundant oil, natural gas and mining, the scarcity of water and arable land which are main resources in agricultural production creates a dependency on the imported food and give rise to one of the major policy challenges in the region. Being the most water scarce region in the world, MENA's average water availability per person is approximately 1,200m3/person/year whereas the world's average is approximately 7,000m3/person/year. One half of MENA's population lives under conditions of water stress. Moreover, the population of 300 million today is expected to be around 500 million in 2025 and the per capita availability of water is expected to halve by 2050. The pollution of water resources is another dimension of the problem. Most of the water need is obtained from the Nile, the Jordan and the Tigris-Euphrates river systems. The rest is from winter rain and underground layer of water-bearing porous stone, earth, or gravel. Despite the scarcity, the fact that rivers and lakes in the region are polluted mainly by industrial and domestic wastes is dramatic. (Bakir, 2001) The Nile basin has a large drainage basin and nine countries share it, the Euphrates and Tigris are shared by Turkey, Iraq and Syria and Turkey, Syria, Iraq and Iran, respectively. The Jordan River is one of the small international basins in the world shared by Syria, Jordan, Israel and Lebanon. However, the scarcity of the water supply brings complexities to allocation problem and it adds to Arab –Israeli conflict. (Kliot, 2005)

The use of total water supply in agricultural production, 80%, is significantly higher than the domestic (17%) and industrial use (17%). The mismanagement of agricultural activity plays a crucial role on the water security issue.

The data available in The Statistical Year Book 2012 and 2013 of Food and Agriculture Organization of the United Nations (FAO), shows that in the recent decade the international food and agricultural markets have been experiencing very high price volatilities, directly and adversely affecting the importer countries' food security. Creating a self-sufficient food market is seen as an important task in the region. Governments provide subsidies to the market which amounts to $21.6 billion or 0.7% of the total GDP in 2011 and the irrigation water charges are negligible in most of the countries. The agrarian reform of 50's and 60's which redistributed the land to peasants to smooth out the income inequality and to please an important proportion of the society was mainly targeting to increase the agricultural production. (Warriner, 1962) Although the emancipation of peasantry was resulted to an extent, the targeted level of agricultural production efficiency was not achieved. (Clawson et al., 1971, Springborg, 1977)

Today, governments in the region exerts efforts to improve water supply by investing on large-scaled projects such as desalination, dam construction, inter-basin water transfers, tapping fossil ground water aquifers, and importing virtual water. Sowers et al. (2011) discuss the efficiency of the supply side policies and emphasize the importance of management of water demand. Our investigation on the regional data and theoretical literature points that which of the supply or demand side of water problem should be focused in policies depend on other regional structures. Solving the water and food security problem is one of the most important steps taken in the way of achieving a sustainable growth.

Policies that are provided to cure problems of market economies supported by the growth theories should be carefully updated for the region taking the differences of the region. Indeed, the case of the emancipation of peasantry and the land reform of 50's and 60's can be interpreted as a good step in providing support to entrepreneurial activities. However, missing the creation of individual incentives to achieve profit together with lack of know-how of the new landowners in managing the agricultural activities drew the limits of the production efficiency. Similarly, the privatization of many sectors would share the same destiny with agrarian reform. In that respect, not only the fiscal and monetary policies, but also the supportive/complementary policies to create the pre-conditions for economic growth play crucial role to foster economic growth and development.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

How the policies are practiced by the governments in the region is also of significant importance. The governmental structures in MENA countries are highly dominated by autocracies, religious principles affect economic decisions in the region as well as the cultural life, markets lack basic mechanisms, and most of all, conflicts in the region is the biggest obstacle that prevents any kind of development.

## Governance in MENA

Governance is broadly defined as "The traditions and institutions by which authority in a country is exercised" by Kaufmann et al (1999). United Nations Development Programme (UNDP) defines governance as "The exercise of economic, political, and administrative authority to manage a country's affairs at all levels." According to the International Institute of Administrative Sciences, the governance is different than government, and it involves the interaction between the formal institutions and the civil society.

Defining the "good" governance is not a straight forward issue. UNDP (1997) emphasizes the importance of participatory, transparent, accountable, effective and equitable governance. A good governance is supposed to be supported by the rule of law. Representation of each and every different layers of the society in the reallocation process in achieving social and economic development is critical. Public sector management, accountability, legal framework for development, and transparency and information are the key concepts in defining the good governance. Interesting more on the policy management requirements of the governance, World Bank provides a set of governance indicators developed by Kaufmann et al. (2010). Worldwide Governance Indicators (WGI) aim to assess the quality of governance using a research data set provided by a large number of enterprise, citizen and expert survey respondents in industrial and developing countries is used. WGI has six dimensions: Voice and Accountability, Political Stability and Absence of Violence, Government Effectiveness, Regulatory Quality, Rule of Law, Control of Corruption. Estimates are degreed from -2.5 (weakest) to 2.5 (strongest). Table 3 shows the regional averages constructed from the data provided by World Bank. MENA has significantly less scores in all dimensions in compared to other developing regions.

Whether the democracy is both a necessary and sufficient condition for economic growth is another question, it obviously offers suitable conditions for a market economy to grow. In that respect, questioning the existence of democracy in the region is an important issue, although the answer is obvious. Even in a most broad definition, democracy requires the supreme power to be vested in the people and exercised

*Table 3. World Governance Index (WGI) estimate scores*

| Averages / Dimensions | MENA | Latin America and Caribbean | South Asia | Sub-Saharan Africa | Europe and Central Asia | North America | East Asia and Pacific |
|---|---|---|---|---|---|---|---|
| Control of Corruption | -0,2 | 0,1 | -0,6 | -0,6 | 0,4 | 1,5 | 0,2 |
| Government Effectiveness | -0,8 | 0,1 | -0,5 | -0,7 | 0,6 | 1,4 | 0,1 |
| Political Stability and Absence of Violence/Terrorism | -0,3 | 0,2 | -1,1 | -0,5 | 0,4 | 0,9 | 0,5 |
| Regulatory Quality | -0,2 | 0,0 | -0,7 | -0,6 | 0,6 | 1,4 | 0,0 |
| Voice and Accountability | -1,0 | 0,2 | -0,5 | -0,7 | 0,4 | 1,2 | 0,2 |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

directly by them or by their elected agents under a free electoral system. However, the practical issues regarding how the power is vested in the people and exercised by them or by representative agents cause a lot of trouble in defining and measuring the democracy in a country. Dahl (1971) points out that the democracy has two dimensions; one is related with public contestation and the other is related with public participation. After Dahl's set of indices, (followed by Gasil 1991, Bollen 1980, 1991, Hadenius 1992) many other measures attempt to scale democracy in countries over years: Economist Intelligence Unit Democracy Index (EIU), Freedom House Index, Neuer Index der Demokratie, Polity index, Polyarchy Dataset, Unified Democracy Scores, Vanhanen's Index of Democracy. Although the list is not full, democracy scores related to MENA are significantly beyond the average. Table 4 shows the three years of EIU Democracy Index which ranges between 0 (most authoritarian) to 10 (most democratic). MENA is the least democratic region in the world. Similarly, Freedom House Index which classifies countries as "free", "partly free" and "not free", measures only Israel as free, Kuwait, Lebanon, Morocco, Tunisia and Egypt as partly free and the rest as not free in 2013.

Once the constitutional democracy is set naturally in a society as it is the case for Western societies, the market economy may be expected to work, properly - Even though the 2008 crisis makes one think about it twice. However, it is not easy to enforce democracy in societies where the preconditions for constitutional democracy are not fulfilled, and it is naïve to wait for a quick positive result. Zakaria (1997) discusses how promotion of democracy in developing countries may cause democracy without constitutional liberalism that produces centralized regimes, ethnic competition, conflict and war.

International democracy aids aim to develop democracy. Huber (2008) defines democracy assistance as "the type of foreign policy that aims explicitly at positively and actively initiating democratization, supporting democratization or strengthening democracy, as well as human rights in foreign countries." He compares the democracy assistance by the US and the EU with respect to the substance, method and recipient of the aids. Both support NGO's related to women, the media and human rights. In general, aids are provided for civil society, political parties and elections and state institutions. Even though it fluctuates over time, the US democracy assistance has been continued since 1990. At the beginning of 2014, in order to support the democracy and governance programming in MENA region, the Obama administration requested $298.3 million from the congress which is almost 2/3 of the one in previous fiscal year. It looks like that the failure of Arab Spring or in most optimistic view the sluggish stage of region's democratization process make international actors to hesitate over democracy assistance.

*Table 4. EIU Democracy Index across regions*

| Region | 2010 | 2011 | 2012 |
|---|---|---|---|
| North America | 8,63 | 8,59 | 8,59 |
| Western Europe | 8,45 | 8,4 | 8,44 |
| Latin America and Carribean | 6,37 | 6,35 | 6,36 |
| Asia and Austraila | 5,53 | 5,51 | 5,56 |
| Central and Eastern Europe | 5,55 | 5,5 | 5,51 |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Arab Spring which refers a series of revolutionary anti-government non-violent and violent protests and demonstrations, uprisings and armed rebellion that started at the end of 2013 was a breakthrough event and had sharp economic, political and social effects on the region. Protests gave rise to economic, political and in some cases governmental changes in Libya, Egypt, Tunisia, Kuwait, Yemen, Jordan Saudi Arabia, Morocco, Bahrein and Oman. Major conflicts in Sudan and civil war in Iraq and Syria are still going on. The last wave of Israel- Palestine conflict which dates back late 1940's and is very wide-ranging, inflamed the quarrels among the other countries in region. The civil wars and conflicts causing a lot of deaths are turning the hopes on democratization process off.

Along the history of the MENA region, governance of countries changes in a wide range of political regimes which does not include the democracy. After the socialist waves between late 50's and late 90's, which is different from all other forms of socialism in the world and shaped by the Islamic rules, monarchies, dictatorships, autocratic regimes are mostly dominant in the region. After the World War I, the fall of Ottoman Empire and the rise of Republic of Turkey have changed the future of the region forever. The world's superpowers interest on the region with a lot of subsequent political, economic and even cultural interventions that were generally not focused on the region's existing inner dynamics gave rise today's economic and politic conditions with an extraordinary and complex national relations in the region.

## Post-Conflict Environment and Government Policies

MENA has always been a scene for, and sometimes subject of, conflicts and wars which give rise today's very complex and confusing economic, political and cultural network under the effect of external forces and internal dynamics. A wide range of religion and ethnic roots have crucial roles in this dynamic. Islam with its different sects is the major religion. Besides the three Abrahamic religions, minorities such as Druze, Yazidi, Baha'i and Zoroastrianism exist. Arabs, Jews, Kurds, Egyptians and Persians live together, not peacefully sometimes. Recent conflicts between two major sects of Islam, Sunni and Shi'a, and between Kurds and Arabs are being most influential than any other time.

Each and every conflict and war have characteristics that are both unique and generic to others in the region. Analysis of these characteristics is beyond the aim of this study. However, the social and economic reasons and results of the conflicts are directly related to policy making process. The policy makers act regarding the short-term conflict resolutions instead of the long-term growth and development. Considering the Iran-Iraq war between 1980-1988, Gulf War between 1990-1991, Iraq war between 2003-2011, Arab-Israeli conflicts beginning with War in 1948, civil wars following Arab spring or the recent ISIS war, it is not wrong to claim that the allocation of natural resources such as oil and especially scarce water sources or fertile arable lands among different religious and ethnic groups has been and is the main cause of conflicts and wars throughout the history. On the other hand, even after the colonial period, first the United Kingdom and then the United States and former USSR (United Soviet Socialist Republics) and now Russia and China are being effective and competing against each other for having potent in the region.

MENA economies are sharply affected by the conflicts in terms of both explicit costs such as loss of labor, physical and human capital, increases in health spending, decreases in productivities, and increases in international debts, and implicit costs such as environmental pollution, high risks of epidemic diseases, decreases in motivation to produce, weakening international trade relations, increase in transaction costs and concessions on policies to resolve conflicts.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The government policies are directed to solve conflicts and post-conflict problems regarding both the domestic politics and international relations. High level of military expenses, the requirement to focus on short-term policies in order to ease the effect of conflicts and wars such as providing huge amount of energy and food subsidies, restrictions in generating government's revenue, pervasive trade policies because of post-conflict political restrictions are only measurable effects on government policies. Conflicts and post-conflict problems challenge the long-term development policies that require increasing investments on specific fields such as education, human rights and necessary institutions for development.

Explicitly, the region has the highest military expenditure per GDP throughout the history since the data is available. The Table 5 shows the years of highest and lowest military expenses of MENA as a percent of GDP, comparing with the other regions. Almost 6% share of military expense in GDP and its growth rate starting from 2008 is certainly remarkable. According to the IHS Jane's Annual Defence Budgets Review in February 2014, defense spending across the MENA region grew by %12.1 which is the highest growth rate of defense spending in the world. The report reveals that Saudi Arabia, Oman, Iraq and Bahrain are featured in the top five growth markets, and defense spending in MENA accounts for %7.8 of worldwide expenditure in 2014.

Being surrounded by a post-conflict environment, the subsidies are widely used by governments to provide short term resolution to social problems. Especially, subsidies in food and energy sectors have a significant part in governments' budget in the region. In natural resource abundant countries, high level of subsidies is related to the redistribution of surplus created by the abundant resource. Governments aim to reduce shocking impacts of large swings in commodity prices on society. Especially in the post- conflict context, public's expectation to share countries' wealth is generally fulfilled via subsidies. However, subsidy policies are neither oriented for social protection, nor cost-effective. The lack of comprehensive social security system is balanced by supported real wages and incomes and low prices on widely consumed products, so that the governments save the day instead of investing on intensive social security policies that may have permanent resolutions only in the long-term. Similarly, the industrial subsidies such as below-market-price energy inputs are used in order to support certain industries. In some cases, the target is to provide protection to employment in the private sector and in other cases, it is to recover the losses incurred by state-owned enterprises that results from inefficient market structures and subsidized prices. (Sdralevic et al. 2014)

*Table 5. Military expenses (% GDP)*

| Country Name | 1988 | 1991 | 1996 | 2001 | 2008 | 2009 | 2011 | 2013 |
|---|---|---|---|---|---|---|---|---|
| East Asia & Pacific | 1,41 | 1,46 | 1,44 | 1,47 | 1,63 | 1,74 | 1,65 | 1,73 |

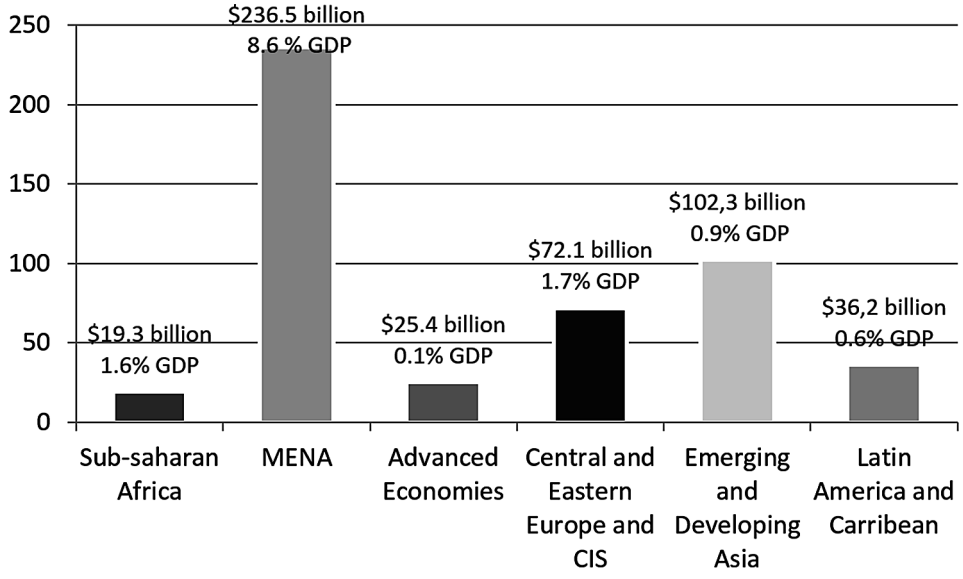
Figure 6 shows that including only petroleum, electricity, natural gas and coal, the pretax subsidies, in the region amounted to 48% of world subsidies. Petroleum products have the highest share, which is about 50%, of the total cost of pretax energy subsidies ($119.3 billion or 4.3% of GDP). Natural gas with 23% ($55.2 billion or 2% of GDP) and electricity with 26% ($62 billion or 2.3% of GDP) follow. On the other hand, food subsidies amounts to $21.6 billion or 0.7% of GDP in 2011. Subsidies on water, financial products, medicines, housing, and other products and services that are difficult to measure are maintained in the region, but are not included in the overall estimates of IMF.



Government revenues are generated from mostly oil, natural resources, tax revenues and grants. The distribution of sources varies across countries. Especially in GCC, the share of tax in total revenue is not significant. Figure 7 shows the average value of tax share in government revenue which is the percentage of the total revenue excluding the grants between 2008 and 2012. The oil and other natural resources are the main sources in countries such as Kuwait, Oman, UAE, Iran and Qatar. There are additional fees, fines and rents such as revenue obtained from Suez Canal in Egypt.

## Business Environment, Financial Markets, and Islamic Rules' Effects

The role of financial markets in raising the productivity of investments, supporting a strong business environment is crucial for both entrepreneurs and the macroeconomic growth and social development. There exists a two way relation between financial markets and firms: As the firms demand higher investment, financial markets expand, and as the financial markets support higher level of investment, the firm activity accelerates in the economy.

The commercial laws that are defined as a transpose of the European rules by Mallat (2000) and regulations in the region shape the private sector. Governments are dominant and regulatory. State –owned enterprises are significant, and family firms that operate in highly protected markets constitute a large

*Figure 7. Average tax revenues as a percentage of total government revenue, 2008-2011*
*Source: http://data.worldbank.org/*

part of the existing private sector. Because of the weak enforcement and laws relating to bankruptcy and liquidation, the exit of firms from business is restricted as well as the entry. Licensing and inspection rules are strict and enforcements of these rules are unpredictable. Allocation of key resources such as credits, physical inputs and infrastructural needs is regulated. Governments apply price controls to subsidize the consumers. In this business environment, it is not easy to find the appropriate conditions to start a business for an entrepreneur. Entrepreneurs are old and had paid jobs before becoming entrepreneurs. Firms are either small with less than 10 workers or very large. Firms report low productivity of labor and capital. (Fawzy, 2002, MacElwee and Al-Riyami, 2003) Especially after the onset of Arab Spring, with undermined business confidence, affected tourist arrivals, and depressed domestic and foreign direct investment, incentives of entrepreneurs to start and run a business is lower. (Yusuf, 2014)

Access to industrial land is a problem in the region. Land markets are segmented with large price differences between privately and publicly owned land and between rural and urban areas. Most of the economic activity is clustered in big cities where the land is restricted. Although the land is limited, there exist idle land because of many reasons such as that the public enterprise that own the land is bankrupt or that the private owner hold the land to increase the price. (Devlin, 2010) Access to credit is another problem. On the average 40% of the firms reveals the credit access as a major constraint. (Beck & Honohan, 2008).

In this type of business environment where a lot of uncertainty exits, the weakness of financial markets is not surprising. Existing studies that are of limited number shows that financial markets are thin and strongly regulated, as the governments impose restrictions and price controls. Creane et al. (2006) develop a comprehensive set of indices to assess the financial market's development in the region. Financial structure is diversified. The GCC countries, especially Bahrain, are in a different position then the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

rest of the region, in terms of the institutional environment, financial openness and use of the monetary policies which guarantee the long term development of markets. However, government ownership is significant, and market forces cannot properly work in the whole region.

Pearce (2011) investigates the state of financial inclusion in the region, and shows that MENA is behind the regions of similar income on the key indicators of bank deposits and loans accounts per population. World Bank report (2012) shows that credit to private sector ranges from 60% of GDP (Jordan, Kuwait, Lebanon) to 30% of GDP (Algeria, Syria, Yemen). In MENA, the number of firms that use the financial institutions to finance their investment demand is relatively lower than the number of firms in other developing regions. Firms confront much higher collateral requirements to access loans, in compared to their comparators.

Stock markets in the region are small and highly volatile. The share of Foreign Direct Investment (FDI) net inflows in GDP in 2013 is 1,68% in MENA in compared to 3,5% in Latin America and Caribbean and 3,1% in East Asia and Pacific. Iqbal and Nabli (2004) point that non-GCC countries, received net inflows of FDI of about $2.2 billion in 2000 which is nine times less than $19 billion that the group of five Eastern European countries (Czech Republic, Hungary, Poland, Turkey and Russia) together received, three times less than $8 billion what the three East Asian countries (Malaysia, Philippines, and Thailand) received, and twenty two times less than $50 billion what the group of four Latin American countries (Bolivia, Chile, Mexico, and Brazil) received. It shows the potential of the region. However, as Chau et.al (2014) shows that that political uncertainty increased after Arab Spring contributes to the financial volatility. Malik and Awadallah (2013) claim that Arab Spring causes the replacement of old political players with new ones. However, it only led to re-configuration of political power leaving the economic and institutional problems unsolved. With an increasing political uncertainty neither the financial markets completed its global integration nor the business environment improved.

The commercial law that highly influences and shapes the business environment in MENA strongly reflects the effects of Islam which is the widest religion in MENA region. Saudi Arabia, Sudan, Iran, United Arab Emirates and Qatar are governed by Islamic law, sharia. In Algeria, Djibouti, Egypt, Lebanon, Morocco, Tunisia sharia applies in some issues such as marriage, divorce and inheritance. In general, the effect of religious culture on economy is significant all around the region. Qur'an which doesn't include many economic regulations, specifies rules related to the inheritance in detail. Because the extended relatives also reserve a specified amount, the accumulation of capital over generations is prevented. Although a system called waqif which does not exist in Qur'an was created over time to keep family money over generations being tax-free, it never became an efficient way of accumulating the capital. Kuran (2003) discusses the role of Islamic inheritance law on capital accumulation. The lack of corporate structures in Islamic law gave rise of the waqif which are not sufficient to create the conditions for a strong private sector and human and physical capital accumulation. In this regard, the main reason of why MENA economies transferred from reasonable to sluggish levels throughout the 18th century can be identified as the legal infrastructural stagnation. Indeed, Islamic rules of Qur'an do not directly manage the economy either at a macro or a micro level. Two principals regarding the economic decisions were followed in the region: The first one was provisionism that focused on the supplies of essential commodities required for urban life favoring the imports. The second one was fiscalism that mainly focused on raising the revenue in the treasury. Instead of governmental infrastructural investments, the state was directly financing the public goods such as mosques, hospitals and schools. Mainly, waqif founded by rich families were managing the financial flow to support who needed the offered service. They were responsible from the redistribution of income. By the rules, it was possible to protect

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the family's money from taxes and inheritance rules. Although the system worked partially, it distorted the reallocation of the surplus created by the production. Because the founders of waqif were mainly the close relatives of the rulers and highest officials, they took decisions parallel with ruler's interest. However, they were helping just enough so that an alternative system was not strongly questioned and civil societies couldn't become powerful.

While the market economy was rooting in the Western Europe by naturally finding necessary preconditions, the most of the Middle Eastern countries' private sectors, except the oil market, isolated from the international markets. The absence of skills, know-how and accumulated capital and cultural reluctance to be in a network with Western societies worsened the backwards of economies. It should be emphasized that there is no rule against the market economy in Islamic law. Islamic law does not conflict with modern economic developments except issues regarding the interest rates and extreme consumerism. Although creation of the preconditions for market economy such as existence of financial markets, property rights and the entrepreneurial abilities have been prevented in the region, that was most probably not because of the Islamic law itself. The state-centered development policies compatible with Islamic law were not enough to create the required incentives for the development of human capital and financial markets. Moreover, some economic reforms regarding the banking system, stock markets and trade agreements bring the MENA economies closer to the international markets.

Although Islamic banking majorly centers on the GCC countries, Iran and Malesia and constitutes only 1% of the global financial assets, it is a growing sector at an annual rate of approximately 18% between 2009 and 2013, and is projected to grow by an average of almost 20% a year to 2018. Islamic finance assets grew from almost US$200 billion in 2003 to almost US$1.8 trillion in 2013 (International Monetary Fund, 2015). It's not hard to understand why in Cameron's administration finds the future of Islamic finance bright and London volunteers to become a center for it (UK Excellence in Islamic Finance, n.d.).

## Labor Market

The region has the highest unemployment rate following Sub-Saharan Africa and it almost doubles the world's average in 2013. World Bank data shows that the unemployment rates are not volatile since 1990 and are between 10% and 11%. As of 2013, the youth unemployment in the region is so severe that it increases up to 51% in Libya. The percentage of unemployed women in the female labor force is more than 20%.

The most significant characteristic of the labor market in the region is that it is dominated by the public sector. In the GCC countries, public employment is an important way of distributing oil revenues to nationals. Having small populations, the GCC countries have been applying open door policies in the labor market for a long time period. IMF data shows that the expatriate labor ranges from 50% of labor in Saudi Arabia to 90% in United Arab Emirates in early 2000's. (Fasano and Goyal, 2004). The labor policies have changed starting from late 1980's. At first, governments and state-owned enterprises took the leading role. Then, in order to nationalize the private sector workforce, mandatory measures such as quantitative regulations have been used. However, enforcing the use of national labor force in private sector had its own drawbacks and created some complexities especially in the long-run. Lower productivities of the nationals together with easy access of private companies to expatriate labor challenge the nationalization policy in labor market. The nationalization policies followed by countries diversify in the region and named after the country such as Emiratization, Omanization etc. The size of labor force

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

and unemployment rates are the effective variables on policies followed. From Bahrein, Oman, Saudi Arabia to Qatar practices different types of mandatory measures. However, neither the job creation process nor the management of existing business environment looks sufficient to realize the nationalization programs. (Al-Waqfi et al., 2014)

The dominance of the government in markets through regulatory actions and state-owned enterprises leads the segmentation of the labor market. Fasano and Goyal (2004) shows that most of the new jobs created by the private sector is in non-oil, services sectors. Paying low wages and requiring low skilled labor, these jobs do not appeal the nationals. Due to high regulation in most of the region, the informality increases. At the same time, the adjustment of the labor market is prevented. Highly protected jobs make the labor almost a fixed input in the production. Thus, firms hesitate to offer new jobs causing higher unemployment rates and segmentation in the market. It also effects the motivation of nationals in taking education. Protected jobs offered by governments have high demand and nationals do not have the incentive to improve their skills over the levels required by these jobs.

The World Bank data shows that the percentage of the population age 15 and above who can, with understanding, read and write a short, simple statement on their everyday life was only about 80% and 5% less than the world's average in 2010. As of 2013, the MENA region has 17 students for every one teacher (a pupil-teacher ratio of 17:1) compared to the world average of 24:1. However, the knowledge level is lower compared to their counterparts in the developed countries as it is justified by international test scores. The quality of teachers is a main explanatory variable. Countries in the region face shortage of teachers. Therefore, those hired to serve as teachers are often not adequately qualified for the position. Most of the countries in the region support the private schools and paid education. The private education sector in MENA is the fastest growing according to report 'Trends in Private Education Investment and Expansion in MENA 2014' by Education Investment.

## A QUICK LOOK INTO GROWTH THEORIES

Practices over years have evidently shown that policies which follow Solow's growth model (1956), mainly based upon physical capital accumulation were not sustainable. As the economic structure has changed all around the world, new insights have been required in explaining, analyzing and designing economic theories, policies and practices.

New growth theories following Romer (1989) and Barro (1991) define the growth as a perpetual motion machine. The key concept of the theory is knowledge which is not subject to diminishing returns. Accumulated human capital causes innovations to occur which make capital and labor more productive, and which affect consumption side of the economy as well. The growth is claimed to be self-feeding and sustainable with a strong emphasis on human capital. (Barro et al., 1995; Benhabib & Spiegel,1994; Temple, 1999, 2001a; Easterly & Levine, 2001; Vandenbussche et al., 2006; Cohen & Soto, 2007). Most of the endogenous growth models take for granted the incentives to innovate and to earn higher profits. Indeed, what makes the growth sustainable are mostly the incentives and accumulation of human capital.

More recent criticisms on the growth theories focus on the missing explanation of how the stable equilibrium can be achieved. The strong relation between technologies, institutions and industry are neglected. Institutions related to markets, property rights, monetary exchange and international trade as well as the education and health programs are crucial for creating the proper incentives and fostering the human capital productivity. In that respect, central authorities' direct control over economies can be

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

criticized, and use of policies in action which provide appropriate conditions for individual producers to innovate and to produce effectively can be suggested. The independent and reliable institutions are supposed to govern the required systems such as financial and legal systems. (Nelson, 2005)

There exist substantial theoretical and empirical studies suggesting that financial systems become more developed as countries get richer. At the same time, financial developments accelerate the economic growth. A weakness in the financial system can cause systematic problems for the whole economy. Differences between growth rates of market-oriented economies and of centrally planned economies are put forward by many studies. (Demirgüç-Kunt & Levine, 2004; Stiglitz, 2000; Alfaro et al., 2004; Bruno et al., 2012) In addition to open financial systems, the positive impact of international trade on economic growth through efficient use of resources is theoretically accepted. (Krugman P., & Obsfeld M., 2000) Although the empirical studies in the literature does not fully support the theories (Frankel, J. A. & Romer, D., 1999; Yanıkkaya, 2003; Rodrik, 2005; Herzer D., 2013; Shahbaz,, 2012), existence of the long-run positive effects and that the extend of trade impact on growth is highly related to the policies on education, technology and institutional quality is widely accepted.

Starting from 80's, including MENA economies; many developing countries and centrally-planned economies in Europe shifted their growth strategies towards market-orientation. Complementary policies that support development of financial systems, openness to trade and accumulation of human capital were enacted. (Devlin, 2010) Some of developing countries such as China seem like to achieve growth targets. However, inequality and poverty measures do not mostly follow the fast growth trend. (Kenwood et al., 2013; Kanbur, 2008) Indeed, according to neoclassical growth theories; because accumulation of physical capital is provided by increasing propensity to save, the growth process is stimulated by income inequality. Therefore, a tolerable level of income inequality has a positive impact on physical capital accumulation. However, when human capital is replaced by physical capital, inequality is not anymore a binding constraint for growth. (Galor & Moav, 2004) In this respect, creation of the preconditions for entrepreneurial activities is of crucial importance. As long as the supportive policies for small firms and entrepreneurs are practiced by governments, the economic growth that is achieved by economic activity triggered by human capital, technological advances and profit oriented entrepreneurs can be accompanied by social development and improvements in income equality.

Whether centrally planned or not, the use of government expenditures is always effective in growth and development. Literature shows that the effect of government expenditures on the economic growth is ambiguous. Recent studies shows the importance of type of expenditures in identifying the relationship. Expenditures in the form of investments that provide the required infrastructural structures and accelerate the accumulation of physical capital and labor, increase the quantity and efficiency of factors of production and lead to higher growth. Expenditures on health, education and other services supports the accumulation of human capital, increase the productivity and lead to higher growth. However, beyond an optimal level, the government expenditures may crowd out the private spending and cause inefficiencies in both the factor markets and the final goods markets. According to neoclassical approach increasing tax rates negatively affects the supply side of the economy and it distorts the markets so that economic activity decreases. With respect to the new growth theory, the negative effect of higher tax rates is even higher because the level of technology is negatively affected. However, what Barro (1990) calls as productive government spending may lead to higher level of human capital accumulation and technological improvements offset the negative effects of taxes on the economic activity. (Bergh et al., 2011) Berg and Henrekson (2011) provides a survey on the relation between the government size and the economic growth. They also provides an explanation to the contradictory results in the literature.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

They suggest that social trust increases the big governments' impact on economic growth. Moreover, market-friendly policies followed by big governments compensate the inefficiencies in the markets created by the high taxes and expenditures.

## ENTREPRENEURSHIP AS A GROWTH ENGINE IN MENA

This study brings different literatures together in analyzing the importance of entrepreneurial activities for a sustainable economic growth accompanied by social development. The needs of MENA region in its growth and development process are questioned by taking the existing macroeconomic, political and cultural measures into account. An overall look of the region shows that the countries are from a very wide range of variety and it is almost impossible to adopt a unique formula prepared for economic growth or social development. Especially, the practiced receipts of Western or East Asian world are likely to fall far away from the target. Yet, the measures of region shows us that the entrepreneurial activities may be an answer to many problems at once: Economic growth, income equality and social development. Besides, MENA region has a strong potential to host and enjoy the entrepreneurial activities.

In the region, rich natural resource sectors, oil, gas and minerals, are dominant and creates a pervasive revenue effect in economic activity. The giant governments create an inefficient production process and labor markets are segmented. The unemployment, especially youth unemployment is a major problem not only in economic terms but also accelerating the social unrest and political instability. The scarcity of arable land and water adds a lot of trouble to the existing religious, ethnical and historical conflicts between different groups and countries in the region. Climate change and estimated average temperatures within 30 years which is not suitable to live in makes the problems even worse.

In this respect, the entrepreneurial activities supported by governments in non-oil sectors may solve the problems. Specifically, some sectors have a strong capacity to be expanded by entrepreneurs. Although it is not a complete list, the solar energy, biotechnology, chemical industries, water and air cleaning, agricultural production, Islamic finance, private education are all the sectors on which entrepreneurs can find profit opportunities when the required regulations and policies are supported by the governments. Supporting the infrastructural necessities for human capital and technology required in these sectors and proving the protective and encouraging laws for the entrepreneurs, the central authorities' destructive power is transformed into a creative one. Particularly, the support provided to small and medium enterprises, women and youth plays a crucial role. The successful start-ups would boost the profit incentives of new entrepreneurs and start a perpetual motion in growth accompanied by social development.

The study shows that the use of policies which accelerates the innovation and technology creation in the specified industries enlightens the way to growth and development. However, the microeconomic conditions of each sector and how the firms, new entrepreneurs and governments should proceed in their own decision making process by taking both the individual and social interests into consideration should be analyzed industry by industry and country by country. This type of microeconomic analysis are very much valuable for the macroeconomic policies.

# Chapter 78
# Major Macroeconomic Dynamics for Labor Market in Turkey: A Causality Analysis

**Mustafa Karabacak**
*Uşak University, Turkey*

**Oytun Meçik**
*Eskişehir Osmangazi University, Turkey*

## ABSTRACT

*The relationship among inflation, unemployment, and economic growth can be treated as a trade-off in general. When the economy is in recession, inflationary pressures are expected to decrease while unemployment is increasing. On the contrary, a decrease is expected while inflationary pressures are rising. Thus the relation between these twin macroeconomic variables and their relation to economic growth are a focal point for developing countries. The aim of this study is analyzing the relationship among unemployment, inflation, and economic growth in Turkey by alternative methods. Thus the causality among these variables is tested with modified Wald statistic developed by Toda-Yamamoto. Findings obtained from causality test will provide policy recommendations for Turkish economy on a macroeconomic level.*

## INTRODUCTION

As the basic economic indicators of modern economic conditions, the concepts of unemployment, inflation, and economic growth are macroeconomic variables which are often analyzed and of which relations among themselves are studied in detail in the context of interaction. Whereas an economic growth could occur as a result of financial activity level in an economy, an inflationary setting and/or high unemployment rates could also be observed.

To the extent that the mutual trade-off among those principal macroeconomic variables has generally been accepted, the likelihood of being subject to the different type of interaction in the whole country or different time period is stronger. Hence, it is needed to analyze the relationship among mentioned variables by focusing on especially the country and period which are wanted to be studied.

Regarding the recent past of the Turkish economy, high unemployment, inflation and low economic growth keep remaining on the agenda as the common problems. Beyond any doubt, ensuring a sustainable economic growth in an economy is based on primarily ensuring economic stabilization. Like Turkey's, in an economy which is equipped with both powerful and treating features in terms of labor force, the interaction demonstrated by those three outstanding variables gains great importance.

In the present chapter, it is aimed to analyze the relationship among variables about annual economic growth in the period of 1960-2014, inflation rate and unemployment data in Turkey through modified Wald statistics developed by Toda-Yamamoto[1] and to present political suggestions in the level of macroeconomy for the economy of Turkey in the light of those findings. Accordingly, the literature review about causality relation of those three major macroeconomic variables mentioned in the present study was given, the macroeconomic developments in the related period were analyzed, and the findings of causality analysis which was conducted in the light of data were presented.

## LITERATURE REVIEW

Being major macroeconomic variables of an economy, unemployment, inflation, and economic growth relation are often discussed in the literature, though they might be in the characteristic of variability from period to period. Like all of the other economies in the world, it is seen that the literature searching the causality relation among those factors which regard financial and real dimensions of the economy as well as in Turkey supports the stated evaluation. Focusing the literature in terms of unemployment, inflation, economic growth and the constraint of Turkish economy; the outstanding findings could be summarized as:

Uysal and Erdoğan (2003, p. 45) focused on the relation between the unemployment rates and price level in Turkey between 1980 and 2002. In the study, the related time period was evaluated according to different periods. Hereunder, the fact that there is a positive relation among variables in the 80s whereas there is a negative between 1990 and 2002 is remarkable. Karaca (2003, p. 254) searched the relation between inflation and growth in Turkey using quarterly data for the period of 1987-2002 and observed the existence of one-way Granger causality from inflation to growth. It is emphasized that the inflation in the economy of Turkey in the related period downgraded the growth rate.

Berber and Artan (2004, p. 115) analyzed the relation between inflation and economic growth in Turkey for the period of 1987-2003 and they found out one-way causality relation from inflation to economic growth. Furthermore, it is also a remarkable finding that inflation influences economic growth negatively. On the other hand, Terzi and Oltulular (2004, p. 31) analyzed the relation between the inflation and growth rates at the sectoral level in the economy of Turkey with annual data in the period of 1923-2003. The findings point out a negative causality relation from inflation to sectoral growth. Considering those findings, it is emphasized that inflation is a considerable obstacle to growth and price stabilization is significant in this respect.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Göktaş Yılmaz (2005, p. 74) performed Granger and Hsiao causality tests in order to specify the causality relation between the growth and unemployment rates in Turkey in the period of 1978-2004. The findings show that the causality relation is only from unemployment rate to growth rate. Thereby, for the related periods, unemployment is among the factors influencing economic growth and in response to this, it is seen that economic growth cannot decrease unemployment rate. On the other hand, Yapraklı (2007, p. 297) analyzed the relation between inflation and economic growth in Turkey with the quarterly data for the period of 1987-2007 by using Granger causality test. Accordingly, in the related period, inflation influences economic growth while economic growth does not affect inflation.

Uysal, Mucuk, and Alptekin (2008, p. 66) found out that there is a one-way Granger causality from inflation to economic growth in the period of 1950-2006 according to the results of Granger causality test analyzing the relation between inflation and economic growth in Turkey. Karaçor, Şaylan, and Üçler (2009, p. 71) conducted Granger causality test by using quarterly data of the 1990-2005 period of the Turkish economy and reached the conclusion that there is a double way interaction between growth and inflation rates.

Şentürk and Akbaş (2014, p. 9) analyzed the relation between economic growth and unemployment rate represented with industrial production index in the economy of Turkey from 2005 to 2012 and inflation rate by using Toda-Yamamoto causality test. Accordingly, it is seen that there is a two-way causality relation between the industrial production index and the unemployment rate in the related period and inflation rate. Süleymanov and Nadirov (2014, p. 123) studied the inflation-growth relation in the Turkish economy in the period of 2003-2013, and they found a one-way causality relation from growth to inflation. Similarly, Akan and Kanca (2015, p. 17) reached a finding of one-way causality relation from growth rate to inflation in the period of 1980-2013 in the Turkish economy.

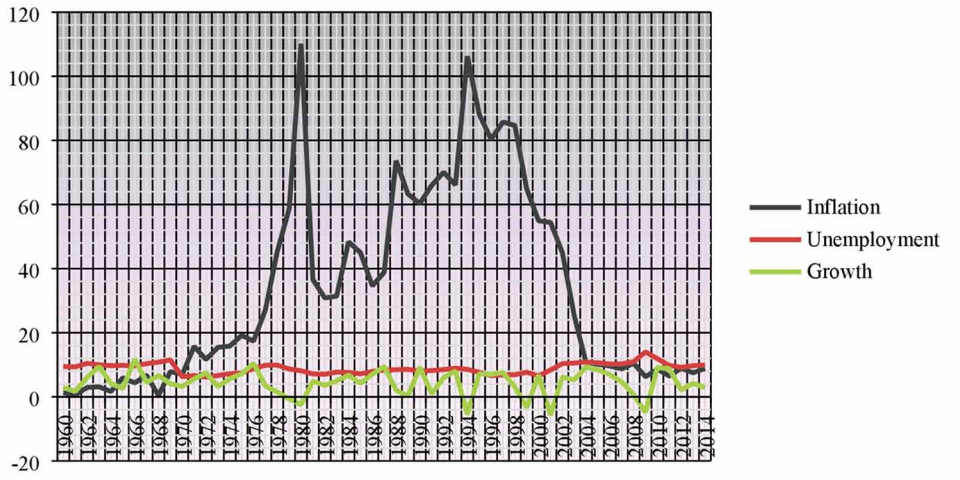
Focusing on the literature, as stated commonly in the studies supported by empirical findings, it is seen that the relationship among unemployment, inflation, and economic growth variables may vary according to studied period. Hence, analyzing the relations among those variables through a different and new method for the Turkish economy has a great significance in terms of empowering the information scale in the literature as well.

## THREE MAJOR MACROECONOMIC VARIABLES IN TURKEY

In the economy of Turkey, the observation of macroeconomic developments for the period of 1960-2014 will end up with some evaluations. The most significant of all is, no doubt, the Turkish economy which suffered from high inflation in a considerable part of this period and which came up against more fragility as its own integration to global economy got stronger.

In Figure 1, the process of inflation, unemployment and economic growth series as the three major macroeconomic variables of Turkish economy in the period of 1960-2014 is shown. The process of inflation and economic growth in the figure points out a significant relation between those macroeconomic variables in the related period. Likewise, while there is an inflationary process going on in an economy, and annual gross domestic product (GDP) is growing in real terms, it is possible to mention growth with inflation. And it stands out that there is that kind of relation for a considerable period except for the years in which some crisis effects are observed for the Turkish economy. It could be stated that the process of the unemployment rate in the related period is more stable than the other variables.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



Since Figure 1 reflects a long period of time, it enables to specify the developments which end up with dramatic results clearly in the economy as well. For instance, the fact that the oil crisis which broke out as a result of oil embargo declared by Organization of Arab Petroleum Exporting Countries [OAPEC][2] on 15th October 1973, caused an increase in the world oil price and peaked in 1979 caused one of the most dramatic inflation increases in the economy of Turkey reflects the graphic. This period took its place on the stage of history as a time in which the world experienced stagflation at the same time, questioned the aspect of 'activist government interventionism' and new alternative trends came out.

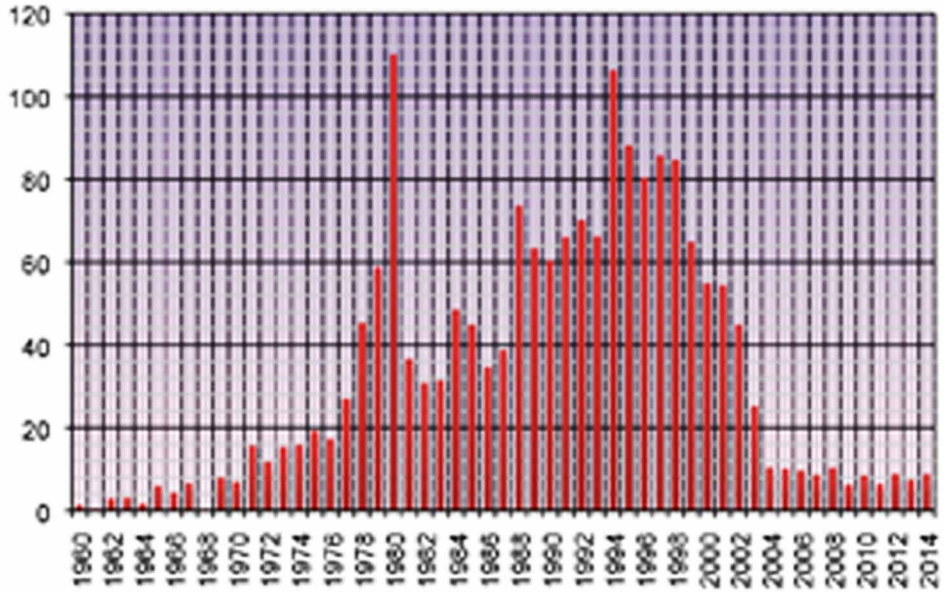
The year 1980 represents a process in which the economy of Turkey came to the new path and the drift in the financial politics differentiated from the previous periods with the experienced paradigm shift. The effects of fluctuation and developments observed in the world economy as a result of constraint abolition on the capital movements in 1989 were started to be seen in the economy extremely. 1993 and 1994 were the years of devaluation and economic crisis. 1999 corresponds to the effects of great Marmara earthquake which stroke breeder power directly and 2000-02 correspond to the periods in which backstopping negotiations were being made with International Monetary Fund (IMF), and economic crisis were observed.

Since the declaration of "Transition to the Strong Economy Program" in 2001, great structural reforms, which first interest financial sector and aim radical changes and transformations in the medium-long terms, have been made (Taşar, 2012, p. 84). It is possible to associate the general level of prices and positive progress in the economic growth in the 2000s to the acquisitions in the same period. However, it is not possible to state that the positive developments in GDP, industrial production, the rates of capacity utilization and foreign trade created a significant acceleration for the indicators to employment (Kol & Karaçor, 2012, p. 392).

The developments related to prices in Turkey for the period of 1960-2014 are seen in Figure 2. It is observed that increasing inflation in the economy of Turkey with the stagflation atmosphere which the world economy came across in the 1970s starts to influence the growth in a negative way. Thus, Turkey met two digit inflation in the 1970s and in the following process, due to the rapid increase in the infla-

*Figure 1. Three major macroeconomic variables in Turkey: 1960-2014*
*Source: Republic of Turkey Ministry of Development, Turkstat, Organization for Economic Co-operation and Development [OECD] Statistics.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



tion, economic and social uncertainties came out, which ended up with a regression in the potential revenue of the economy. During this process, the fact that the inflation reached three digit numbers in February-October 1980, January 1998 and the period between April 1994 and March 1995 reflected the history books. However, in return for this, it could be expressed that crazy inflations which marked the parts of Latin American and European countries have not been seen in any periods of Turkish economy (Özatay, 2011, p. 248).

After Turkey had experienced the transition process to the inflation targeting in the period of 2002-2005, it went into inflation targeting period. Thus, a process in which direct inflation was aimed by the Central Bank of the Republic of Turkey (CBRT) without using any intermediate objective started (Kara & Orak, 2008, p. 60). The main aim of practicing inflation targeting process in the economy of Turkey is to provide price stabilization and from this point of view, economic stabilization. It is discussed that inflation targeting process which has been in practice in Turkey recently results in an average inflation decrease which has positive effects on economic growth with its dimensions of financial sector development and financial deepening (Meçik & Karabacak, 2011).

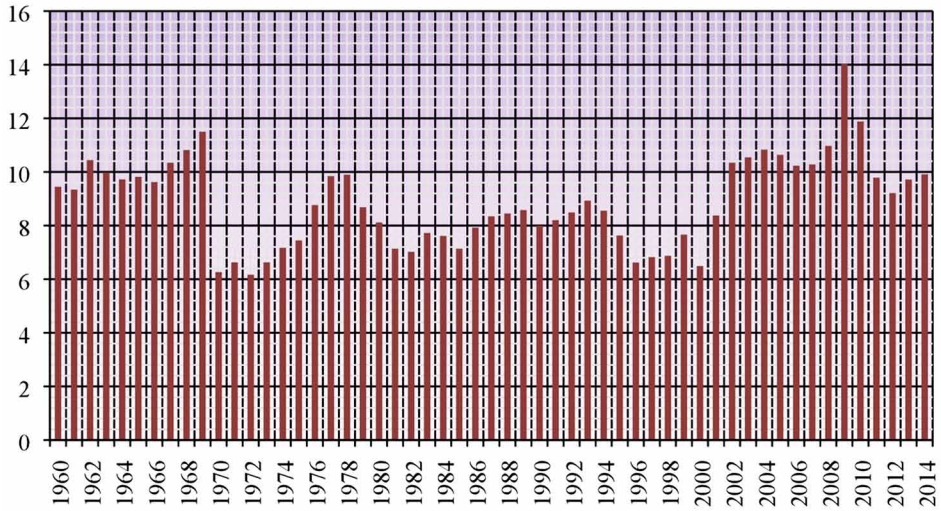
Inflation targeting regime, for the period after 2002 in which political stabilization was enabled with convenient global economic developments, ensured the inflation separated from the previous periods and approached one digit levels. However, it is hard to say that monetary authority was successful when descending to the particulars of inflation targeting process. Yet, as seen clearly in the graphic, it is possible to say that the process of inflation which did not show fluctuation relatively in the 2000s is a significant acquirance compared to the previous periods.

The unemployment rates in the related period are available in Figure 3. It is seen that the unemployment rate has relatively a low process between the 1970s and the 2000s. When this period is evaluated with the movement resulted from the increase in the general prices level in Figure 2, the trade-off rela-

*Figure 2. Inflation rate in Turkey: 1960-2014*
*Source: OECD Statistics.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion between inflation and unemployment is striking. The inference made with the annual average data for Turkey reminds the theoretical relation which is framed with Phillips curve[3].



It is seen that the ability of Turkey to generate employment did not change especially after the 1980s and consequently the developments which could decrease unemployment did not occur. Beyond any doubt, monetary and fiscal policies have a great role for this reality. Likewise, the fact that monetary authority adopted inflation targeting regime and the fact that fiscal policies focused on budget deficits and creating primary surplus caused a significant decrease in the generation of employment power (Köksel and Fisunoğlu, 2013, p. 45).

The fact that unemployment in the Turkish economy displays a non-decreasing characteristic requires the questioning of the traditional politics aimed to solve this problem. In this context, it should be noted that the politics which could decrease unemployment should require the sustainability of economic growth. It should be emphasized that first of all there should be a paradigm shift in the labor force market and a process which includes education policies aiming flexible employment and decrease in cost burden at micro level and aiming increase in the quality at macro level (Türk Sanayicileri ve İşadamları Derneği [TUSİAD], 2002, p. 235).

Economic growth, defined as the positive increase in the GDP and per capita GDP from one year to the other, reflects the Figure 4 as below for the period 1960-2014 in Turkey. According to this, on a yearly basis, it stands out that economic growth has a floating and low potential process in general.

The paradigm shift in 1980 and the drift in economic policies distinguished this period from the previous ones and the effects of fluctuation and developments observed in the world after the abolition of constraints on capital movements in 1989 on the economy were started to be felt considerably. As a result, in this process, it is seen that economy went into an unsteady growth process with fluctuation in capital movements at an increasing level (Boratav, 2008, p. 172). As well as the fact that Turkey started to face instability more often under international capital movements with the free capital mobility of Turkey increased the fragility in the economy, it also caused discussions about applications like Tobin tax[4] (Meçik, 2014, p. 362). However, the most significant condition, in order to empower the economic

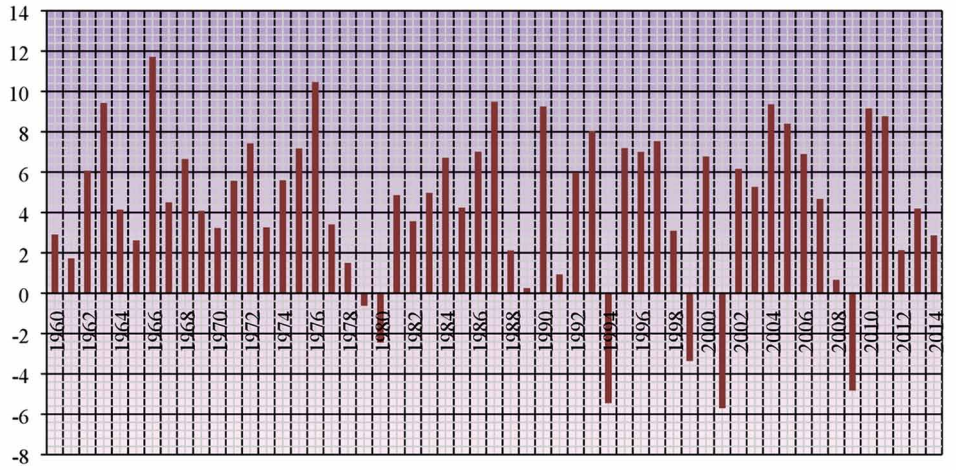


*Figure 3. Unemployment rate in Turkey: 1960-2014*

*Figure 4. Economic growth rate in Turkey: 1960-2014*
*Source: Republic of Turkey Ministry of Development, Turkstat.*

growth in Turkey, should be rendering sustainable growth. Likewise, the recent empirical findings remark joint relation of economic growth and employment. Especially, the fact that the countries with high-income level reach a better employment level and the role of economic growth in this reality is emphasized (Ghose, Majid, & Ernst, 2010, p. 99). It is a well-accepted reality that a sustainable economic growth is based on the technology keeping up with the present era and also the production of technology (Kepenek & Yentürk, 2005, p. 636).

Evaluating the Turkish economy for the period of 1960-2014 in terms of macroeconomic variables such as unemployment, inflation, and economic growth; it is possible to state that the introvert, protective and interfering industrialization model of the 1930s yielded to opening foreign countries in the frame of market-friendly neoliberal politics after 1980. During this period, it is seen that the average growth speed of Turkish economy resembled the developing countries while macroeconomic performance did not develop significantly in spite of paradigm change and political choices (Pamuk, 2014, p. 346).

The Turkish economy is in a period of change related to sectoral based labor productivity which is under the effect of not only global developments but also development acceleration of the economy. Therefore, it is seen that the percentage of the agricultural sector in the revenue and employment regressed while the percentage of the service sector came into prominence. In the same process, while the sectoral distribution of labor force was getting changed, resistance seen in the rates of unemployment in spite of all developments leads to inferences on jobless growth[5] (Meçik & Afşar, 2014, p. 19).

## THE MODEL

### Data

In the empirical analysis; the data of annual inflation rate, unemployment rate, and economic growth were used as three major macroeconomic variables for the Turkish economy in the 1960-2014 period. Whereas inflation rate data (INF) was taken as the general level of prices rate of increase series which

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

was calculated by OECD[6] for the base year 2010 Consumer Price Index (CPI) series, the unemployment rate data (UN) was provided from the series presented in the OECD Statistics database. The economic growth series is the numbers of growth speed taken from Republic of Turkey Ministry of Development web page and calculated for GDP series harmonized with Turkish Statistical Institute (Turkstat) data.

## Methodology

The methodology in the present chapter was developed according to Granger causality testing which a statistical hypothesis is testing in order to find out whether a time series is useful in forecasting another time series. Such cause and effect relations among economic variables are analyzed with causality tests in a frame of economic theory (Tarı, 2010, p. 437).

Even though the applicability of the causality test developed by Granger (1969) is high, there is a need to make some pre-testings about stationarity and cointegration. The Granger methodology is highly sensitive to the characteristics such as stationarity and cointegration of series. Since series with unit root do not have standard distribution as stated in Gujarati (1995), F test procedure and Granger methodology will not be valid.

On the other hand, dynamic causality test developed by Granger (1988) which enables to test the causality through a vector error correction mechanism, requires all of the series to be integrated I(1) order one. It does not allow testing the causality among the series at different integration orders (Büyükakın, Bozkurt & Cengiz, 2009, p. 111). Hence, Toda and Yamamoto (1995) developed a test which provides an analysis of causality relation without regarding the integration orders of series and the existence of cointegration relation.

Toda-Yamamoto test developed according to a VAR model requires the estimation of VAR ($p$+$d$) model given in equation (1) while $p$ is the optimal lag length and $d$ is maximum integration order[7]. In the equation (1), $A$ represents parameters matrix while $x$ a vector consist of $k$ variable and ε and υ represent error terms vector and constants vector respectively (Akçay, 2011, p. 84).

$$x_t = v + A_1 x_{t-1} + \ldots + A_p x_{t-p} + \ldots + A_{p+1} x_{t-p-d} + \varepsilon \quad (1)$$

The null hypothesis on the non-existence of Granger causality is tested by practicing a constraint supposing the first $p$ parameter in the equation (1) equals to zero. MWALD (Modified Wald) statistics obtained from the estimation equation (1) has an asymptotic chi-square distribution (Kar, Nazlıoğlu, & Ağır, 2014, p. 69). However, Hacker and Hatemi-J (2006) suggested applying the test based on bootstrap distribution instead of standard chi-square distribution since the performance of MWALD statistics with standard chi-square standard is weak when the sample size is small. Likewise, bootstrap distribution displays a better performance when applied to both small and big samples compared to asymptotic chi-square distribution.

## Empirical Evidence

There is no precondition for the variables in leveraged bootstrap Toda-Yamamoto causality test developed by Hacker and Hatemi-J (2006) such as being stationary or cointegrated. However, maximum integration order of the variables should be known in order to apply the test (Büyükakın, Bozkurt & Cengiz,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

2009, p. 111). Because of it, Augmented Dickey-Fuller and Phillips-Perron unit root tests were applied in order to find out the integration order of the variables involved in the analysis. According to the results acquired from the Unit root test, the maximum integration order of the variables was defined as "1".

AS stated beforehand, the causality analysis developed by Hacker and Hatemi-J (2006) is based on a VAR ($p+d$) model estimation. Thereby, first of all, a VAR ($p$) model should be specified providing stability condition and necessary assumptions in order to analyze the causality between variables. In this context, after necessary testings, it was concluded that VAR (10) model is appropriate for the analysis of relation between inflation and economic growth; VAR (3) model for the analysis of relation between unemployment and inflation and again VAR (10) model for the analysis of relation between inflation and unemployment.

According to the results given in Table 2 about causality analysis, there is only one-way causality from economic growth to inflation. Since MWALD statistics obtained from causality tests applied for the other variables are smaller than the bootstrap critic values, the null hypothesis cannot be rejected. That is, it is not possible to refer to causality between unemployment and inflation.

## CONCLUSION

Unemployment, inflation and economic growth could be listed as the most significant indicators of an economy at the macroeconomic level. It is known that there exists some trade-off among those variables proposed in the theoretical framework. According to this, while unemployment rate decreases in an economy, it could be expected that inflationary pressures may increase.

In the present chapter, it is aimed to analyze the relation among the economic growth, unemployment rate and inflation variables for the period of 1960-2014 in Turkey and in consideration of the findings, to present some policy suggestions at macroeconomic level for the Turkish economy.

As emphasized in the literature, since those relationships could vary from period to period, analyzing this relation through different and new methods has a supportive quality to empower the knowledge in the literature. Though findings of the analysis suggest that there is one-way causality from economic growth to inflation, it is not possible to state that there is a causality relation between unemployment and growth; and unemployment and inflation. So, like the statement in the literature and emphasized commonly in the studies about unemployment, inflation and economic growth relation; the relation among unemployment, inflation, and economic growth variables could vary from period to period; and the findings of the present study about the 1960-2014 period of Turkish economy could be taken confirmatory since they are parallel to the findings of the studies about the same period performed by Süleymanov and Nadirov (2014) and Akan and Kanca (2015).

In accordance with the findings of the analysis, it is possible to speculate that the growth process in the related period is in the manner of creating inflation and corresponds to an inflationary growth process as a characteristic. Additionally, it is also observed that the conditions created by the global economic crisis in the last period of Turkish economy cyclically changed the mentioned relation for a while.

In the light of the findings acquired from the time series analysis, it is possible to emphasize that policymakers should be in an approach regarding the structural features of the economic growth dynamics in the framework of price stability. Therefore, the need for structural reforms which has been discussed very often recently in the Turkish economy should be highlighted once more. Likewise, the present situation shows that the economic growth process should well-analyzed in terms of problem solutions such as unemployment and inflation.

In order to keep the growth process sustainable, the economy of Turkey should be built in a manner of promoting growth dynamics; based on technology and meanwhile not only importing technology but also producing it. It is obvious that it will bring new requirements in the context of the labor market, quality and productivity increase.

It is expected that bringing about sustainable economic growth will be effective to empower the economy in terms of finance; to support price stability and to diminish unemployment problem. Thus, it could be noted that permanent political designs which are for medium or long terms should be formed for the economy of Turkey instead of short term solutions.

## KEY TERMS AND DEFINITIONS

**Economic Growth:** The increase in an economy's production possibilities frontier over time. There are three main causes of economic growth: increases in the stock of capital; technological progress embodied in new capital equipment; and growth in labor input due primarily to population growth, immigration, and changes in participation rates.

**Granger Causality:** The Granger causality test is a statistical hypothesis test for determining whether one time series is useful in forecasting another, first proposed in 1969. The intuition behind the Granger causality test is the quite straightforward. Ordinarily, regressions reflect "mere" correlations, but C. Granger argued that causality in economics could be tested for by measuring the ability to predict the future values of a time series using prior values of another time series.

**Inflation Rate:** The annual percentage increase of the cost of living as measured by the consumer price index. Consumer price indices are based on a representative basket of goods and services purchased by consumers in an economy. Composition and relative weights of the basket are reviewed periodically.

**Inflation Targeting:** Inflation targeting is a monetary policy in which a central bank has an explicit target inflation rate for the medium term and announces this inflation target to the public. The assumption is that the best that monetary policy can do to support the long-term growth of the economy is to maintain price stability. The central bank uses interest rates as its main short-term monetary instrument.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**Phillips Curve:** The Phillips curve is a single-equation empirical model, named after A. W. Phillips. Phillips curve states the negative correlation between the unemployment rate and rate of inflation. The decreases in unemployment will end up higher rates of inflation.

**Unemployment Rate:** Unemployment rate is the number of unemployed people as a percentage of the labor force, where the latter consists of the unemployed plus those in paid or self-employment.

## ENDNOTES

1 For further information: Toda and Yamamoto (1995).

2 OAPEC is a regional Arab organization of an international character specializes in the affairs of oil. For further information: www.oapecorg.org.

3 For further information: Phillips (1958).

4 A means of taxing spot currency conversions that was originally suggested by James Tobin. The Tobin tax was developed with the intention of penalizing short-term currency speculation, and to place a tax on all spot conversions of currency.

5 Growth without creation of proportionate employment opportunities is called "jobless growth". Machinery and capital when displaces labor (and not helps it) in production, results in an increase in unemployment and causes "jobless growth".

6 The mission of the OECD is to promote policies that will improve the economic and social well-being of people around the world.

7 Maximum lag of the series should not exceed the optimal lag of count of VAR model. Otherwise Toda-Yamamoto causality test should not be applied.

# Chapter 79
# Does Trust Matter for Foreign Direct Investment Decisions?

**Sibel Bali Eryigit**
*Uludag University, Turkey*

## ABSTRACT

*Factors affecting the investment decisions of multinational companies are heavily researched in the literature. However, the number of studies dealing with the socio-cultural characteristics of host countries among these factors is quite limited. Among the cultural characteristics affecting location decisions, one of the primary cultural characteristics is the general level of trust between individuals. In this scope, this chapter intends to research whether the general level of trust in a society has an effect on the location decisions of foreign investors. In line with this objective, an analysis will be conducted by employing the panel data method for 39 emerging market countries for the period between 1998 and 2011. According to the results of the study, a low general level of trust in the host country represents a significant disadvantage for the attraction of foreign direct investments.*

## 1. INTRODUCTION

The impact of foreign direct investments (FDIs) on economic development is intensively researched in the literature. The relevant literature has proven many times that FDI promotes economic growth in the host country by providing the transfer of new knowledge and technologies, creating employment opportunities and increasing capital accumulation. Thus, FDIs are particularly important for emerging markets, as they do not have sufficient capital accumulation for industrialization. Due to the importance of FDIs, the literature has heavily researched the factors affecting FDI decisions. The studies underline that there are many factors that influence multinational firms' decisions about FDIs, such as the host country's market size the distance to other markets, openness, and incentives given to foreign investors, macroeconomic stability, tax advantages, human capital, and infrastructure quality. However, there are quite a few studies on the impacts of the socio-cultural dynamics of host countries on FDI decisions in the relevant literature.

Among the socio-cultural characteristics of host countries that affect location decisions, one of the primary cultural characteristics is the general level of trust between individuals. So, the primary objective of this study is to assess the impact of the general level of trust in the host country on the FDI decisions in that country. As there are quite few studies conducted in this sphere, it is thought that this study will contribute significantly to the literature. In line with this objective, an analysis will be conducted by employing the panel data method for 39 emerging market countries for the period between 1998 and 2011.

The plan of this study is as follows: The introduction section will present the subject and aim of the study, as well as its contributions to the literature. The theoretical background and related literature section will deal with the place and importance of trust in economics, and it will also address the impact of the level of trust on investment relations by discussing the impact mechanisms. The third section will deal with the empirical methodology employed in the study. The fourth section presents the model and data. The fifth section will present the empirical findings. Lastly, the empirical results obtained under the title conclusions are discussed.

## 2. THEORETICAL BACKGROUND AND RELATED LITERATURE

According to Fukuyama (1995), a nation's well-being, as well as its ability to compete, is conditioned by a single pervasive cultural characteristic, which is the level of trust inherent in the society. As communities rely on association based on trust, and *trust is determined by culture*, it may be said that the general level of trust differs in distinct cultures. In fact, there are many studies in the literature advocating that trust and, particularly, the level of social trust are important determinants of the performance of economies.

The first study known to comprehensively address the effects of mutual trust on the economy is "The Moral Basis of Backward Society", conducted by Banfield and published in 1958. Banfield (1958) attributes the economic backwardness of Southern Italy, in comparison with Northern Italy, to the low general level of trust in the south. Family ties in Southern Italy are very strong, but the other individuals of the society beyond the family exhibit a low level of mutual trust. According to Banfield (1958), the poor general level of trust hampers the communication, cooperation, and interaction between individuals. This prevents the creation of large organizations that would promote economic development. Similarly, La Porta et al. (1997) stated that in large organizations and social structures in which the members interact with each other infrequently, trust was needed to support cooperation. In fact, La Porta et al. (1997) supported this claim by detailing empirical evidence as well.

According to Arrow (1972), the lack of trust plays a significant role in economic backwardness and underdevelopment. Arrow (1972) emphasizes that each commercial transaction relies, in itself, on trust, and that each transaction will definitely come to an end within a given period. Simply, the level of mutual trust is important for the formation of a market. This is because the future involves uncertainty and risk, and economic activities require that economic units trust the future behaviors of others. The linking of supply and demand implies that there has been an explicit or implicit mutual agreement in the background. Economic units that comply with their contracts and thus have gained trust in the market are forced to resort to legal action when the other party fails to comply with the conditions set, which causes significant losses for the complying party in terms of time and money. In other words, the low level of general trust in a society is expected to increase the cost of transactions due to asymmetric information and associated market distortions.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The relationship between the level of trust and FDIs is based on cooperative behavior, market distortions, and the costs arising from them. In the location decisions of multinational companies for the FDI, the perception of risk regarding the host country and the ensuing costs have an important role to play. As is the case with all economic exchanges, each party in a given FDI possesses special information, resulting in information asymmetry. However, this information asymmetry is greater due to the differences in social-cultural, economic, and legal structures of countries involved, especially with respect to foreign investments. Accordingly, it is possible to say that multinational companies may encounter greater uncertainty and risks when they make investments in another country in comparison to the ones they make at home. Contracts, which bind multiple parties in legal agreement over the transaction period, represent an attempt to mitigate the problem of asymmetric information and uncertainty. However, all of these contracts result in significant incremental costs that may eventually impact the location decisions of multinational companies (Bhadwarj et al. 2007; Kukharsky, 2012).

The general level of trust in a society is the result of the mutual experiences of its members. High interpersonal trust is expected to be created in an orderly, honest, and cooperative society, relying on norms mutually shared by its members. In other words, in order to attain a high level of interpersonal trust in a society, the relationships must be based on cooperation, and they should avoid opportunistic behavior (Fukuyama, 1995; Bhadwarj et al., 2007). In other words, each and every transaction has intrinsic information asymmetry; however, the societies with high generalized trust have a lower tendency to take advantage of this information for their own advantage. Accordingly, the monitoring and transaction costs are expected to be lower in societies with a high level of trust than in those societies with a low level of trust (Butter and Mosh, 2003).

People who do not trust each other in societies with a low level of trust will conduct their business relations within a system of formal rules, which ultimately pushes them to negotiate, come to terms with, and bring actions against others. This process considerably increases the transaction costs. This also indicates that the quality of functioning of the formal institutions becomes even more important in communities with a low level of trust. Nevertheless, a high level of trust is expected to substantially eliminate the adverse effects of an underdeveloped institutional environment on the location decisions made by the FDI's decision makers (Delios and Henizs, 2003; Kolstad and Villanger, 2004). For instance, despite the fact that the formal institutions of China are not sufficiently developed, its economy has grown so rapidly and has attracted FDI based on its high level of social trust. Given the fact that law and enforcement in developing countries in general are relatively weak, it is possible to say that the high level of general trust in the host country may reduce the perception of risk among foreign investors (Ang et al., 2009).

In conclusion, the steps that must be taken in order to consider and prevent any problems that could arise from a low level of trust do not only increase transaction costs, but they also result in significant opportunity costs for multinational companies in an environment where global competition is on the rise. The perception that opportunistic behavior is rarer in societies with a high level of trust and therefore the transaction costs will be lower and information sharing will be higher thanks to cooperative behavior, is expected to affect the location decisions of multinational companies. This high level of trust not only reduces the contractual costs, but it also decreases litigiousness, thus cutting legal transaction costs (Bhadwarj et al., 2007; Dearmon and Grier, 2009; Durlauf and Fafchamps, 2005)

However, the number of studies on this subject in the relevant literature is quite limited. The first known study to empirically research the effect of trust on bilateral trade was conducted by Butter and Mosch (2003). They determined that increasing trust by one standard deviation can encourage changes of up to 90-150% in bilateral trade. Guiso et al. (2004) found that the level of trade, portfolio invest-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

ments, and direct investments are at a lower level in countries where the level of mutual trust is low. As far as known, this is the first study investigating the effects of trust on FDIs. Moreover, Bhardwarj et al. (2007), Bottazzi et al. (2007) and Zhao (2011) noted that a high level of trust in the host country is an important determinant for the location decisions in relation to FDI. Additionally, Botazzi et al. (2007) stated that education and work experience reduce the effect of trust but do not eliminate it. Finally, Kukharsky (2012) found that a 1% increase in a country's level of trust leads to a more than 3% increase of the US FDI in this country.

## 3. EMPIRICAL METHODOLOGY

This study employs the dynamic panel approach. Many economic behaviors substantially involve a dynamic structure. As such, panel data may be extended in such way where economic behaviors can be adjusted dynamically at the individual level. At this point, with the inclusion of the lagged values of the dependent variable into the model as regressors, dynamic relationships are distinguished from the static panel data approach:

$$Y_{it} = \delta Y_{i,t-1} + X_{it}^{'}\beta + \mu_{it}\,,\ i\in\{1,2,\ldots,N\},\ \text{and}\ t\in\{1,2,\ldots,T\} \tag{1}$$

Here, *i* denotes the units such as individuals, countries, regions, etc. – in other words, the cross-section dimension of the panel data. Further, *t* denotes the time and is the time-series dimension of the panel data, $Y_{it}$ denotes the dependent variable vector, $X_{it}$ denotes the explanatory variables matrix, β denotes the parameter vector, $\mu_i$ denotes the unobservable unit specific impact, and $\mu_{it}$ denotes the error term. δ is a constant and denotes the dynamic adjustment. The error term is as follows:

$$\mu_{it} = \mu_i + \varepsilon_t + \nu_{it}\,. \tag{2}$$

Here, $\mu_i \sim iid\left(0,\sigma_{\mu}^2\right)$, $\varepsilon_i \sim iid\left(0,\sigma_{\varepsilon}^2\right)$ and $\nu_i \sim iid\left(0,\sigma_{\nu}^2\right)$ apply and are independent from each other.

In dynamic models, there may be a correlation between $Y_{i,t-1}$ and $\mu_{i,t-1}$ due to the impact of past shocks. Additionally, as $Y_{it}$ is a function of $\mu_i$ in panel data models, $Y_{i,t-1}$ is also a function of $\mu_i$. Therefore, for the model given in (1), $Y_{i,t-1}$ is correlated with the error term containing $\mu_i$. So, the assumption of strict exogeneity, which implies uncorrelatedness between the regressors and the error term, is invalid. Therefore, the estimators are not unbiased and consistent.

Arellano and Bond (1991) suggested the use of the generalized moments method (GMM) for dynamic panel data. This approach is also known as "two-stage instrumental variables" approach. The first-differenced model with the general instrumental variable can be written as:

$$Z'\Delta Y = \Delta Y_{-1}\delta + Z'\Delta X\beta + Z'\Delta u_{it} \tag{3}$$

or

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$Z'\Delta Y = \Delta Y_{-1}\delta + Z'\Delta X\beta + Z'\Delta u_{it} \tag{4}$$

again, where $\Delta X = \left[\left(Y_{i,t-1} - Y_{i,t-2}\right), \left(X'_{it} - X'_{i,t-1}\right)\right]$. Accordingly, the GMM estimator can be obtained as:

$$\tilde{\Theta} = \left[\Delta X'Z\left(Z'\Omega Z\right)^{-1}Z'\Delta X\right]^{-1}\Delta X'Z\left(Z'Z\right)^{-1}Z'\Delta Y, \tag{5}$$

where Ω is the variance–covariance matrix.

To test the validity of the set of instruments, the Sargan (1958) test can be applied for GMM estimation. Additionally, the use of GMM requires the assumption that the first difference of the error term does not have a second-order serial correlation. The invalidity of this assumption implies that the lagged instrumental variables have not been set correctly. It is natural for the model to have first-order autocorrelation when the model includes the one lagged value of the dependent variable; this does not imply the presence of a specification error. Thus, it is important to test the presence of a second-order autocorrelation. For this purpose, the Arrelano-Bond (1991) *m*2 autocorrelation test is widely used.

## 4. MODEL AND DATA

For the objective of this study, this section delves into the effects of trust in emerging-market countries on FDI within the framework of a dynamic panel data model. The dynamic panel data model that was set up in line with this objective is as follows:

$$\begin{aligned} fdi_{it} &= \beta_0 + \delta fd_{i,t-1} + \beta_1 trst_{it} + \beta_2 \inf_{it} + \beta_3 \ln gdp_{it} \\ &\quad + \beta_4 gfc_{it} + \beta_5 invpr_{it} + \beta_6 enr_{it} + \beta_7 tax_{it} + \beta_8 opn_{it} + u_{it} \end{aligned}, \tag{6}$$

where $fdi_{it}$ represents the percentage of inward FDI to GDP, δ is the coefficient indicating the dynamic adjustment for FDI, and $\beta_k (k=0,1,\ldots,S)$ is the coefficient vector of the explanatory variables. Furthermore, $u_{it}=\mu_i+\varepsilon_t+v_{it}$ denotes the error term involving country- and time-specific effects.

This approach inevitably includes the control variables in the model for the accurate estimation of the effect of the level of trust in emerging market countries on FDI. Based on this, information regarding the effects of the control variables on the attraction of FDI and the dataset used is given below.[1]

- ***Trust*** ($trust_{it}$) represents the general level of trust in a given society, and the present study uses the Gallup World Poll's measure of trust as data. The dataset from 2011 was used, as it is the most comprehensive dataset for the countries within the scope of this research. Interpersonal trust is measured using the question, "*Generally speaking, would you say that most people can be trusted or that you can't be too careful in dealing with people*?" Trust is the percentage of respondents in each country replying, "*most people can be trusted*".

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- ***Inflation*** ($inf_{it}$) was added into the model to represent macro-economic stability. Kairuki (2015) notes that high inflation may increase the foreign companies' costs of doing business. A high inflation rate in the host country may also deter foreign investment, as the real local currency value of capital is already invested, and future returns may become smaller due to high inflation (Hayakawa et al., 2013). Additionally, inflation causes the prices to lose their signaling function. This makes it more difficult for foreign investors to make cost/profit predictions and long-term plans (Lewandowski, 1997). Gedik (2013) claims that policies aiming at reducing inflation have demand-restricting effects, and that this may adversely affect the decisions of foreign investors.
- ***Real per capita GDP*** ($gdp_{it}$) is widely used as a proxy for market size in host countries. Market size represents the domestic demand, and therefore the volume of sales. It is an important determinant, especially when the reason underlying the FDI decision of multinational companies is the market-seeking strategy. In other words, when multinational companies intend to carry out production for domestic demand, the market size and growth potential of the host country become more important (Busse and Hefeker, 2007). In this context, FDI becomes economically sensible, only when the volume exceeds a level at which the average cost of serving the market through exports exceeds the average cost of production within the market (Davidson, 1980). However, there are also views holding that market size does not affect or adversely affect investment decisions. Loree and Guisinger (1995) assert that factors affecting location decisions vary de pending on the FDI strategy used, and that location decisions of export-oriented FDIs are affected by costs rather than the market size. According to Asiedu (2004), who holds a different viewpoint, foreign investors tend toward economies where the return on capital is high. Since capital is scarce in countries in which the income per capita is relatively low, the return on capital is higher. In conclusion, when it comes to export-oriented foreign investments, a high GDP per capita is expected to negatively affect the FDI decisions.
- ***Gross fixed capital formation*** ($gfc_{it}$) is used as a proxy for infrastructure in the host country. Insufficient infrastructure causes disruption at each stage of production, thus increasing costs. On the other hand, with good infrastructure, it becomes more efficient to transport goods from one place to another, communicate with people involved in business operations through the use of technology, have buildings that are well set up and have uninterrupted power, and have ample water supplies (Kariuki, 2015). Therefore, it is thought that the high level of infrastructure in the host country positively affects the location decisions of foreign investors.
- ***Investment profile*** ($invpr_{it}$) includes the factors related to the risk of investment that are not covered by other financial and economic risk components. The investment profile index was derived from the dataset of the International Country Risk Guide (ICRG), provided by the PRS Group. The investment profile rating assigned is the sum of three subcomponents (Contract Viability / Expropriation, Profits Repatriation, and Payment Delays), each with a maximum score of 4 points and a minimum score of 0 points. A score of 4 points equates to Very Low Risk and a score of 0 points to Very High Risk. As high values of the investor profile imply low risk, high index values are expected to positively affect FDI decisions.
- ***Secondary school enrolment rate*** ($enr_{it}$) is used to represent the level of human capital in the country. High skills and trained labor are expected to reduce the transaction costs, as they minimize the duration of training required for the use of new production techniques and new technologies. Furthermore, the level of human capital is determinative of management skills, communication in business relationships, and the effectiveness of decision-making processes. In conclusion,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

a low level of human capital is expected to adversely affect location decisions since it reduces the efficiency and profitability of investments.

- ***Taxes*** ($tax_{it}$) are one of the basic factors taken into account by foreign investors in their assessments, which are based on costs. The model uses the corporate tax rate of the host country to represent the taxes. High tax rates are expected to adversely affect location decisions.
- ***Openness*** ($opn_{it}$) refers to the trade openness of the host country. The ratio of the sum of imports and exports to GDP was used to represent openness. In the case of export-oriented FDI (called vertical FDI), foreign investors prefer more open economies, as trade restrictions substantially increase transaction costs. However, according to the tariff-jumping hypothesis, in horizontal FDIs, foreign investors tend to prefer less open economies to protect against the competition brought about by imports. In line with these explanations, it may be said that the effect of openness on the decisions of foreign investors varies depending on the country in question.

## 5. EMPIRICAL RESULTS

The model given in equation (11) in the study is estimated to take into account the annual panel data for 39 emerging market countries for the period between 1998 and 2011.[2] Table 1 gives the descriptive statistics for the variables.

Examining Table 1, it is evident that the null hypothesis that all variables in the model are normally distributed is rejected. The estimation results of the dynamic model given in Equation (6) are shown in Table 2.

Paying close attention, one can see that the model is estimated by adding the one-period lagged values of all variables, excluding trust. This is related to the purpose of eliminating the potential problem of endogeneity among the variables, and to the expectation that investment decisions will be taken with a delay (see Asiedu and Lien, 2004; Naude and Krugell, 2007; Majocchi and Presutti, 2009; Anyanwu, 2011).

Examining the estimation results, it can be seen that the general level of trust in the host country is a significant determinant of the FDIs flowing into the country. In other words, economies with a low level of trust have a significant disadvantage in attracting FDIs. This finding is consistent with the find-

*Table 1. Descriptive statistics*

| | Mean | Median | Max. | Min. | Std. Dev. | Skewness | Kurtosis | Jarque-Bera | p-value |

ings of Guiso, Sapienza, and Zingales (2004), Botazzi et al. (2006), Bhardwarj et al. (2007), Ang et al. (2009), Zhao (2011), and Kukharsky (2012). As stated in Ang et al. (2009), high general levels of trust in a society facilitates social exchange by reducing the need for time-consuming and costly monitoring, and therefore makes it possible for more efficient economic exchanges in a more favorable business environment that attracts foreign investors. Besides, level of generalized trust in host country for foreign investors determines perception of their risk of dealing with strangers in host country. Additionally, it was observed that the high general level of trust in emerging markets was better able to attract FDIs than macroeconomic stability, trade openness and human capital. As stated above, since institutional and legal environments of emerging economies are not sufficiently development, this finding indicates that general level of trust in host country has a greater effect on location decisions of foreign investor.

Assessing the control variables in the model, it can be seen that all variables, excluding inflation, are individually significant and generally fit the expectations. However, the parameter concerning the inflation rates variable is significant only at a significance level of 10%, but it may be said to fit the expectations. The finding that inflation adversely affects the location decisions of a given FDI is consistent with the findings of Kolstad and Villanger (2004). Furthermore, Naude and Krugel (2007) and Demirhan and Masca (2008) estimated that the sign of inflation is negative at a level of significance of 10%, which

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

is similar to the findings of our study. Kok and Acikgoz Ersoy (2009) found that the effect of inflation was negative, although very minor. Finally, Schneider and Frey (1985), Vijaakumar et al. (2010), and Mhlanga et al. (2010) could not find a statistically significant relationship.

The sign of real GDP per capita, which represents the market size, is negative according to the model estimation. Asiedu (2002) states that foreign investors prefer those countries where the return on capital is high. Since the capital is scarce in the countries where the GDP per capita is low, the return on capital in these countries is higher. In other words, since the return on capital is lower in the countries where the GDP per capita is high, there is an inverse relationship between real GDP per capita and FDI. On the other hand, according to Asiedu (2004), in order for the real GDP per capita to positively affect FDI decisions, it must exceed a certain threshold. The findings of this study are consistent with the findings of Edwards (1992), Jaspersen et al. (2000), and Asiedu (2002; 2004) in that real GDP per capita is inversely related to FDI/GDP.

It is clear from the model findings that gross fixed capital formation, which represents the infrastructure of the host country, is a crucial determinant of location decisions. According to the model results, the infrastructure of the host country has a greater effect on location decisions than all other explanatory variables, excluding the investor profile. This finding indicates that the transportation, communication, and technological facilities of the host country substantially contribute to the attraction of FDI. This finding is consistent with the findings of Habib and Zurawick (2002), Kariku (2015), Kok and Acikgöz Esoy (2009), Awan et al. (2011), and Gichamo (2012).

With respect to the investor profile index, it can be seen that its sign is positive and that it is the factor with the greatest effect on investment decisions within the framework of the model.[3] High values of the investor profile index, consisting of three subcomponents – namely, contract viability, profit repatriation, and payment delays – represent low investment risk. As the host country's risk decreases in terms of these three subcomponents, it has greater advantages for attracting FDIs. Since the effect of the investor profile index is positive, and given that this effect is relatively high, the findings of this study are consistent with those of Busse and Hefeker (2007), and Baek and Qian (2011).

According to the results of the model, human capital has a positive effect on FDIs. This finding verifies the opinions of Lucas (1990) and Dunning (1988), in that a low level of human capital increases transaction costs and decreases efficiency, thereby detracting from the return on FDI. This finding is also consistent with the findings of Noorbakhsh, et al. (2001), Asiedu (2006), Bhadwarj et al. (2007), Dutta and Osei-Yeboah (2010), and Kim and Park (2013).

With respect to taxes, it is seen that environments where high taxes are imposed adversely affect the location decisions of foreign investors, which is in accordance with expectations. This finding is consistent with those of Demirhan and Masca (2008), Tang (2012), and Gedik (2013). Additionally, tax policies have a greater effect on location decisions than human capital, macroeconomic stability, and even trade openness.

It can be seen that trade openness has a positive effect on FDI. It was previously noted that there are different views in the literature regarding the effect of trade openness on location decisions, and that the results vary depending on the countries and FDI strategies. In the model that was formulated, trade openness positively affects location decisions. This finding verifies the view that foreign companies intending to make export-oriented FDIs prefer countries that have higher trade openness, which is based on the idea that trade restrictions increase transaction costs. The finding that trade openness contributes to the attraction of FDIs is consistent with the findings of Asiedu (2006), Kariuki (2015), and Janicki and Wunnava (2004).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, the high adjusted determination coefficient in the model implies that the changes in the explanatory variables substantially account for the changes in the dependent variable, and that the null hypothesis where the coefficients for the Wald test are simultaneously equal to zero is rejected in favor of the alternative hypothesis that the model is generally significant. Additionally, the Sargan test statistic calculated for the model fails to provide sufficient evidence for the rejection of the null hypothesis, which implies the suitability of the instrumental variables used to estimate the dynamic model. That is, the instrumental variables used for the dynamic panel GMM estimations are suitable. Moreover, when the $m2$ serial correlation test statistic proposed by Arellano and Bond (1991) – as required by the use of second lags as instrumental variables for GMM estimations – is examined, the null hypothesis implying that none of the models have serial correlations cannot be rejected. Accordingly, this means that there is no second-order serial correlation problem in the model.

## 6. CONCLUSION

In addition to its contribution to capital accumulation and employment, FDI also provides important advantages for emerging economies, such as the transfer of technology, management, and organization applications. In their location decisions, foreign companies tend to gravitate toward countries that would provide them with various advantages. The factors that have an effect on FDI decisions are widely researched in the literature. Characteristics of host countries, such as the presence of domestic demand, proximity to markets, and costs, are heavily researched. However, the number of studies on the cultural identities of countries is quite limited.

The primary characteristic among the cultural characteristics that affect location decisions is the general level of trust between the individuals in the host country. Each commercial transaction is based on the mutual trust between parties. The lack of trust between parties requires that various measures be taken for the accomplishment of the commercial transaction. Each measure taken will increase the transaction costs. In FDIs, it is difficult for the home country to know and assess to the full extent of all legislations and procedures in the host countries. In addition to the knowledge of legal processes, it is necessary to assess the quality of functioning of the legal processes as well. In other words, the presence of laws does not necessarily mean that the enforcement of law is satisfactory.

At this point, the importance of interpersonal trust for commercial relationships becomes more obvious. The level of interpersonal trust results from the mutual experiences of individuals in the society. A high general level of trust in a given society indicates that the parties are unlikely to act contrary to expectations. In societies where the general level of trust is low, the problems arising out of the information asymmetry between parties are more serious. Information asymmetry exists in any society, irrespective of whether they have low or high levels of trust. However, societies with a low level of trust are more likely to suffer from problems arising from information asymmetry. Such an environment increases transaction costs, and it also makes it more difficult to carry out management/organization activities and to make predictions and long-term plans. Consequently, a low general level of trust in a society puts that country at a disadvantage in relation to the location decisions for FDI. The model that was set up for 39 emerging economies also shows that a low level of interpersonal trust poses a serious disadvantage in attracting FDIs.

## ABSTRACT

*Perception and preference factor plays an important role and help the investor to understand and make the meaningful investment decisions. These two factors are highly influenced by demographic differences of an investor. The present study aims to examine the perception and preference factors influencing the investment behavior of an investor based on various demographics differences. Survey method of primary data collection techniques was adopted to collect responses of 750 respondents from Eastern India particularly (state capital or satellite towns having the population of 10,00,000) Bihar, Jharkhand, Odisha, West Bengal, Sikkim and Assam. Results of the present study suggest that significant demographics differences occur in investment perceptions and preferences towards tax saving mutual fund investments among the investors.*

## INTRODUCTION

India's financial market has gone through tremendous changes either in terms of regulatory framework, stakeholders' participation, its size, efficiency or effectiveness and outreach to the bottom of pyramid. The Government understand the vulnerability of investors and hence introduced better protection norms for them as financial markets otherwise has had a long history of frauds and deception. Regulatory bodies have also introduced laws that have resulted in speedy settlement and reduced costs. Settlement time has been brought down to overnight from seven days as it existed earlier. Regulatory bodies have also launched awareness campaigns that are expected to make new investors careful and confident. The recent thrust of financial inclusion policies has further enriched the scope of economy leading to a sea change in the financial market. Throughout the world financial markets are becoming well-organized and providing more encouraging solutions to the investors. Consistent with this evolution, Indian Mutual Funds industry has also witnessed a rapid growth and opened new vistas to millions of investors by virtually taking investment to their doorstep. The Mutual Fund Industry in India has grown tremendously and the assets and under management has increased from Rs. 90,587 crores in 2001 to Rs. 9,05,120 in 2014. Although the Indian Mutual Funds Industry has understood the importance of investor's perception and preference towards high return; professional management; trust and long term financial benefits, still they continue to differentiate their products as a response to the economic changes. It, therefore, became important to understand and examine investor's perception and preference, and disclose some valuable information to support meaningful investment decisions. This is considered important from regulatory bodies, investors and AMCs point of view. The question we have explored is "what perceptions investors as of now have vis-à-vis trust, long-term safety, risk, returns and other relevant parameters. Gender, geographical location, age, education, occupation, income, saving and marital status have been studied as moderating variables. Study aims to investigate and identify the small active investor's perception and preference for Tax Saving Mutual funds particularly in eastern India. Further the study also examines the various factors that small investor takes into consideration before investing in a Tax Saving Mutual fund schemes. The study is concentrating on the behavior of small active investors and hence it is a part of behavioral finance area.

## REVIEW OF LITERATURE

This literature review has been undertaken to understand the various demographic factors having influences on investor's perception and preference to towards mutual funds. Jambodekar (1996) studied to explore the awareness about Mutual Funds among investors and to identify the factors which encourage the purchasing decision and the selection of a specific fund in India. Findings suggest that newspapers and magazines are the main source of information through for investors to get the details about Mutual fund schemes and fund provider service. Sundar (1998) conducted a survey to understand an insight into the functioning of private mutual fund company based in India with reference to Kothari Pioneer Mutual Fund. Findings suggest that the mutual fund agents and distributors play a significant role in spreading the Mutual Fund investment culture whereas small investors' age and income are the two important factors in the choice of scheme selection. However, fund return and brand image are the key considerations while purchasing of Mutual Fund Schemes. Panda and Tripathy (2001) used factor analysis and principal component analysis for survey based study to explore the factors affecting investors

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

purchasing and preference decision based on a sample size of 300 respondents. The factors affecting the purchasing decision of the investor were hassle free trading, brand name and lock in period. Safety, liquidity, regular income and tax benefits acts as determinants of preferences of the investors for mutual fund. Singh and Vanita (2002) have conducted a survey of 150 investors in Delhi. The study has revealed that the investors' favored to invest in public sector mutual funds companies with an investment objective of availing tax exemptions benefits. The study further concluded that the majority of the investors were dissatisfied with the performance of their Mutual Funds who had opted for growth schemes. Wilcox (2003) in his study examined how investors choose a Mutual Fund within a given range of funds/ schemes. The key findings are that investors pay a great deal of attention to past performance. Investors vastly overweight loads relative to expense ratios when estimating a fund's overall fee structure. He also found that investors with knowledge of basic finance are less likely, not more likely, to make rational fund choices. Singh and Chander (2004) have conducted research to find the significant factors affecting perception of investors of Mutual Funds. The study has surveyed 400 investors and infers that middle class investors preferred to invest in Mutual Funds in order to get tax benefits. Further it was found that Mutual Funds to be better investment alternative and public sector investments to be less risky for small investors. Ranganathan (2006) has examined the related characteristics of the fund selection behavior of individual investors towards mutual funds. The study highlights that the individual investor's investment objective was to save for retirement purpose. The author argued that low awareness level regarding the mutual funds may be one of the reasons for not preferring mutual funds as a viable option for their portfolio investment. The author adds that the mutual fund industry players should understand the individual behavior before it introduces different types of funds to penetrate the market successfully and to improve their professional management skills as investors are apprehensive to invest in mutual funds due to lack of professional management. Walia and Kiran (2009) in their study have tried to identify critical gaps in the existing structure for mutual funds. The study also extends to understand the need of redesigning existing mutual fund services by Acknowledging Investor Oriented Service Quality Arrangements in order to understand investor's behavior while introducing any financial innovations. Rao & Parashar (2010) in his study made an attempt to identify the factors affecting the perception of investors regarding mutual funds investment. They concluded that tax incentive was one of the important factors affecting the retail investors while investing in mutual fund. Saini, Anjum and Saini (2011) have analyzed the investors' awareness and perception regarding investing in mutual funds and studied the investors' opinion regarding main deficiencies in the working of the Mutual Fund industry. The present investigation outlined that mostly the investors have positive attitude towards mutual funds investment. In order to maintain their confidence in mutual funds they should be provided proper and systematic information relating to different developments and changes in the Mutual Fund industry. Singh (2012) argued that the majority of the respondents' lack knowledge regarding functioning of mutual funds. He further suggested that demographic variables (gender, income and qualification) have significantly influence the investors' attitude towards mutual funds. In an advanced the benefits provided by mutual funds are concerned, return prospective and liquidity are considered as the most important factors by the investors followed by transparency, flexibility, and affordability. Rathnamani (2013) suggested that the investors prefer to invest in Mutual Funds in order to have high return at low level of risk, liquidity and safety of investment. The study further concluded that the Mutual Fund as an investment option is catching the attention of various segments of the society, for investors, professional, industrialists, academicians, financial intermediaries and regulators for varied reasons. Bhuvaneswari (2014) confirmed that funds rate of return, liquidity, and market share act as the major factors influencing the perception

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

of investors. Sharma and Agrawal (2015) analyzed the impact of demographic factors in influencing buyers' decision and to identify the intensity of various factors that positively and adversely affect their decision. Findings suggest that the success depends upon high return, and professional competence of fund managers. However, liquidity, flexibility, tax savings, service quality and transparency etc. are some of the factors which have a higher impact on perception of investors.

From the literature review we find that hardly any such studies have been conducted for the eastern India that may differ from other regions of India. Our research gaps hence may be summarized as:

Geographical Gap: No such study, to the best of literature survey conducted, has been undertaken about Tax Saving Mutual Fund, and its perceptions and preferences in Eastern India. Government focuses towards financial inclusion particularly for the bottom of pyramids at the national level can't be fulfilled without understanding the investor's perception and preferences in this part of the country.

Time Gap: Study on the Small Active Investors (SAI) is contemporary (Current data collected is during 2013-14). As the investors' perceptions and preferences are dynamic in nature it is important to undertake such studies recurrently. Allocation of funds and performance of AMCs (offering Tax-Saving Mutual Fund schemes) have been studied for period 2004-05 to 2013-14.

Activity Gap: Perception and Preference of SAI for Tax-Saving Mutual Funds, Investment Objectives, Decision-influencers and Reason for Investment. Performance Measuring Techniques: In all, four techniques Sharpe, Treynor, Jensen, and Eugene FAMA models have been used to analyze the performance of the Tax-Saving Mutual Fund scheme. By using these technical models, systematic and unsystematic risks associated with the selected schemes have been highlighted.

## Research Design

The research is based on exploratory and conclusive research designs. Explorations are needed to develop all-inclusive understanding of a problem that needs to be comprehended. It is exploratory study which helped us to determine the best research design, data collection method and selection of subjects. The study is descriptive also as the work required describing certain trends, and beliefs. Descriptive study has helped us to arrive at conclusions. This research design has helped the researcher in enhancing familiarity with the problem under investigation and to clarify concepts. Since conclusive research tests the hypothesis of the research problem and draws definite conclusion for implementation, thus, our research is also conclusive in nature. Analytical and evaluative techniques have been employed for analysis and to arrive at the conclusions and hence the study design is analytical and evaluative also. Study employs descriptive statistics (Mean, Standard Deviation), Independent Sample t-test and ANOVA for the analysis of respondent's response.

## Limitations of the Study

As the study focus mainly on eight cities of Eastern India consisting of 1 metro, 5 state capital or 2 satellite cities, empirical findings should be interpreted with care. Further, study does not further classify the investors in high net worth, or retail investors. The second limitation of the study is that from the available source of perception and preference, only ten major sources have been selected for the study. This list may not be exhaustive. Perception has been measured on the basis of expressed belief which may or may not be accurate in all cases. Care has been taken to utilize appropriate sampling procedure but it has not been possible to establish that it represents the population.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## OBJECTIVES OF THE STUDY

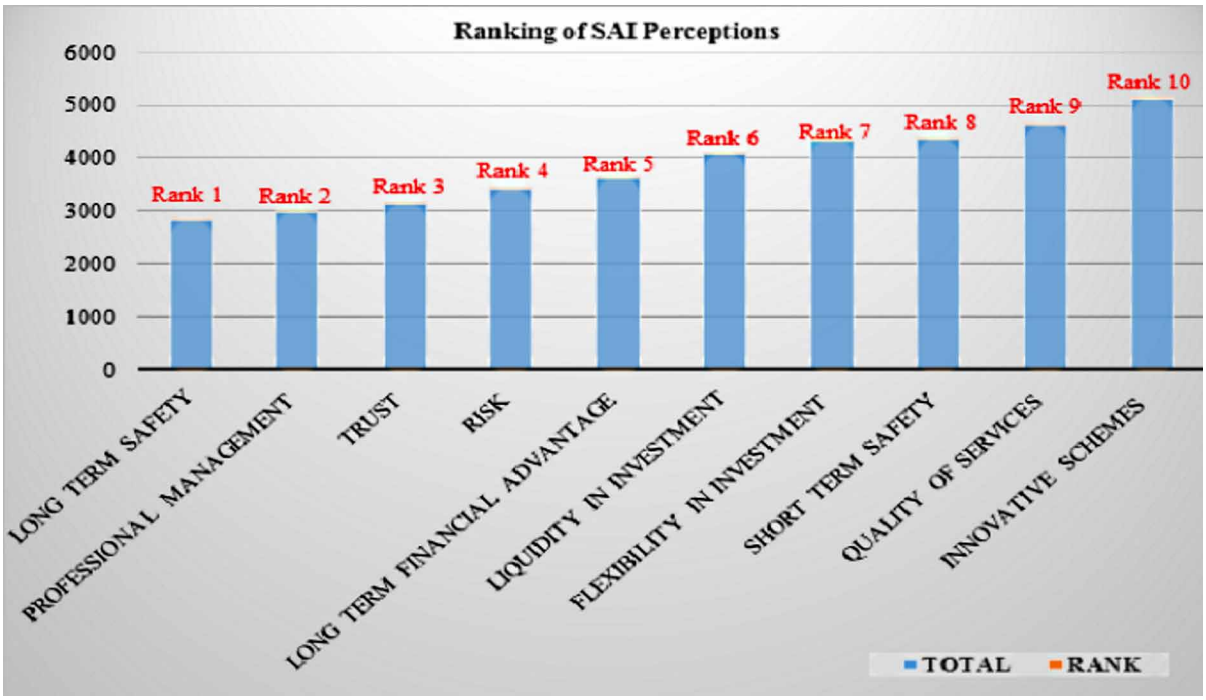
The objective of the study is to measure the small active investors' perceptions and preference towards Tax-Saving Mutual Fund Schemes of selected urban and sub-urban towns of Eastern India. Thus, corresponding null hypothesis is no significant difference in investment perception and preference among the Small Active Investors on the basis of their Geography, Gender, Age, Marital Status, Qualification, Occupation, Income, Saving, and Investment Objective.

Being exploratory and empirical in nature, study mainly focuses on small active investors who are investing on their own, having stock market or mutual fund market experiences \ with a threshold portfolio value of Rs. 20,000 per annum in the Eastern India particularly state capital or satellite towns (having the population of 10,00,000) Bihar[1], Jharkhand[2], Odisha[3], West Bengal[4], Sikkim[5] and Assam[6]. The cities selected were either state capital or satellite town having population 10.00.000 or more. The number of respondents approached was 825 comprising of Bhubaneswar (125), Ganagtok (75), Guwahati (50), Kolkata (125), Muzaffarpur (100), Patna (125), Ranchi (125), and Siliguri (100) respectively. However, analysis has been performed on the sample size of 700 respondents after final sorting. Further, respondent's selection was purely based on convenience sampling available through individuals networking.

## RESULTS AND DISCUSSION

### Descriptive Measures

Investment decision of small active investors (SAI) for Tax-Saving Mutual Fund Schemes has been discussed with respect to perception of SAI towards Tax-Saving Mutual Fund Schemes. Perception factors have been evaluated on the basis of Rank (1 being the most important and 10 being the least import criteria). The objective behind this data collection was to test the reliability of the responses of the study. Further, Preference factors have been evaluated on the basis of Rank only (1 being the most important and 10 being the least import criteria). Figure 1 reflects ranking of SAI Perception towards investment in mutual funds. Findings suggest that Long Term Safety placed on the first rank is the most important perception towards investment in Mutual fund by SAI followed by Professional Management, Trust, Risk, Long Term Financial Advantage, Liquidity in Investment, Flexibility in Investment, Short Term Safety, Quality of Services, Innovative Schemes as second third, fourth, fifth, sixth, seventh, eighth, ninth and tenth rank respectively.



### Statistical Measures

As null hypothesis is no significant difference in investment perceptions among the Small Active Investors' on the basis of various demographic categories. This has been analyzed with respect to the following Investment Perceptions namely Trust, Long Term Safety, Short Term Safety, Risk, Long Term Financial Advantage, Liquidity in Investment, Professional Management, Flexibility in Investment, Quality of Services and Innovative Schemes. This part of the analysis is further supplemented with respect to different demographic categories. More specifically, t-tests have been employed to test the null hypothesis for variables Gender and Marital Status. The tabulated value for t statistic (at degree of freedom above 200) is 1.96. Null hypothesis, therefore, will be rejected if the t statistic value is more than 1.96 and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 1. Ranking of SAI Perception towards investment in mutual funds*

corresponding p-value is below 0.05. Gender has significant impact only on three investment perceptions namely short term safety, flexibility in investment and innovative schemes in deciding investment strategy. These are quite common in Indian perspectives because females intend to be little bit more conservative towards investment since beginning. However, marital status has no significant impact on investment perceptions except in case professional management because of more conservative approach towards investment in post marital life (see Table 1).

This part of the analysis is further discussed with respect to different demographic categories namely geography, age, occupation, education, income and saving. One-way ANOVA has also been employed to test the null hypothesis. The tabulated value of F statistic for requisite degree of freedom is 2.6 for geography and 2.37 for education, occupation, income and saving, and 2.21 for age respectively. Null hypothesis, therefore, will be rejected if the F-value is more than the tabulated value and corresponding

Note: √ shows statistically significant at 5% significance level; × shows statistically insignificant at 5% significance level.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 2. Investment Perceptions (One-way ANOVA)*

| Demographic Categories | Trust | Long Term Safety | Short Term Safety | Risk | Long Term Financial Advantage | Liquidity in Investment | Professional Management | Flexibility in Investment | Quality of Services | Innovative Schemes |
|---|---|---|---|---|---|---|---|---|---|---|
| Geography | × | × | √ | × | × | √ | √ | × | × | × |
| Age | √ | × | × | √ | √ | √ | √ | √ | √ | × |
| Occupation | × | √ | × | × | × | √ | √ | √ | × | √ |
| Education | × | × | √ | × | × | × | √ | × | × | √ |
| Income | × | √ | √ | × | √ | √ | × | × | × | √ |
| Saving | × | × | × | × | √ | √ | √ | × | × | × |

Source: Author's Estimation,
Note: √ shows statistically significant at 5% significance level; × shows statistically insignificant at 5% significance level

p-value in all cases is below 0.05. Demographic variations like geography, age, occupation, education, income and savings have moderate to high impact on the various investment perceptions particularly risk, quality of services, trust, long term safety, short term safety, flexibility in investment, long term financial advantage, liquidity in investment, innovative schemes selections etc. Age, education and saving have the maximum impact as investment objectives and expected outcome depends mainly upon one's age, education and saving potentials. However, occupation, income and age have least impact on investment perceptions (see Table 2).

## Descriptive Statistics

Rank of Criteria on the basis of Preference affecting Investment Decision of SAI for Tax-Saving Mutual Fund Schemes

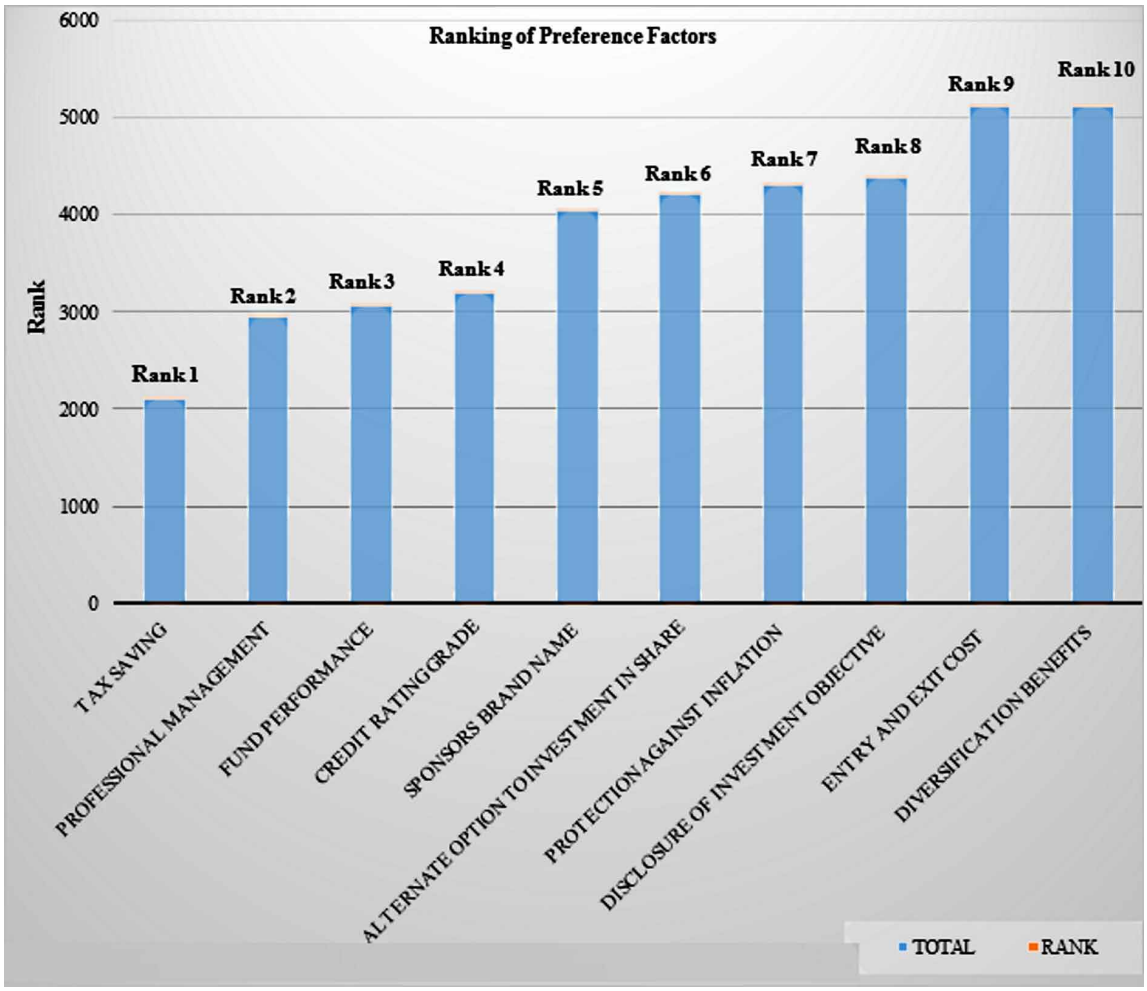

Figure 2 shows ranking of preference factors towards Investment in mutual funds. Study finds that tax-saving has been given first rank i.e. the most important preference towards investment in mutual funds by SAI followed by professional management, fund performance, credit rating, sponsors brand name, alternate option to investment in shares, protection against inflation, disclosure of investment objective, entry and exit cost, diversification benefits as second third, fourth, fifth, sixth, seventh, eighth, ninth and tenth rank respectively.

**Statistical Measure:** Null hypothesis is validated on the basis of various demographic categories. Gender has no significant impact on investment preference parameters except in case of sponsor's brand name. That means fund performance, tax benefits, professional management, alternative investment options, inflation, diversification; entry and exit loads are common features which are important to all investors irrespective to gender. However, marital status has significant impact on the investment preferences particularly fund performance, disclosure of investment objectives, tax benefits, and diversification aspects. Probably, marital status puts some consideration in investment strategy for safer returns (see Table 3 and Table 4).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 2. Ranking of Preference Factors*

This part of the analysis is further discussed with respect to different demographic categories using t-statistics findings for variables Gender and Marital Status. The tabulated value for t (at degree of freedom above 200) is 1.96. Null hypothesis, therefore, will be rejected if the t value is more than 1.96 and corresponding p-value is below 0.05.

This part of the analysis is further discussed with respect to different demographic categories namely Geography, Age, Occupation, Education, Income and Saving based on One-Way ANOVA employed for examining the null hypothesis. Demographic variations like geography, age, occupation, education, income and savings have low to very high impact on the various investment perceptions particularly fund performance, disclosure of investment objectives, tax-saving, credit rating grade, sponsors brand name, professional management, alternate option to investment in share, protection against Inflation, diversification benefits, and entry and exit loads. Geography has minimum impact followed by age, occupation, savings, education and income. Thus, Income acts as most significant demographic categories for investment preferences. Fund performance is the most sensitive aspects for investors based on the demographic aspects whereas disclosure of investment objectives is least important for the investors.

## CONCLUSION AND IMPLICATIONS

The existing theory suggests that decision to invest in a particular mutual fund is influenced by demographic factors. In present study it is found that gender-based differences are significant in case of short term safety, flexibility in investment and innovative schemes in deciding investment strategy. This could be because women small-active-investors are more conservative and patient towards investment decisions. Further they show a distinct preference for diverse schemes which may be due to their proclivity for larger number of options in other respects also. In case of marital-based differences status has no significant impact on investment perceptions except in case professional management. This may be because of need for more traditional approach towards investment in post marital life. Difference arising due to age, education and saving have been found to be significant in the context of investment objectives as well as expected outcome. This could be because investment objectives are dependent upon differing needs during human life cycle characterized by age. Education may have impact because of varied earning capacity dependent on education and also perhaps because of varying investment information. Savings may play a role in determining investment objectives because of greater options available with higher savings. In case of preference towards mutual fund investment, demographics variable gender has no significant impact on investment preference parameters except in case of sponsor's brand name perhaps because brand names reflect greater credibility and are considered less risky. Marital status has been found to exert significant impact on the investment preferences particularly fund performance, disclosure of investment objectives, tax benefits, and diversification aspects. This could again be influenced because of the differing needs, perceptions and preferences of people having differing marital status. It is also found that geography has minimum impact followed by age, occupation, savings, education and income. Income acts as most significant demographic categories for investment preferences. Fund performance is the most sensitive aspects for investors based on the demographic aspects. Investor expects good rate of return thus fund manager should meet their expectation by their expertise knowledge and skills. However, disclosure of investment objectives is least important for the investors thus a customized training and workshop should be provided to small active investor to understand the fund's overall objectives, investment pattern and Risk appetite for optimal investment decisions. Our study has brought forth the investment patterns (in tax saving mutual funds) of a particular group of investors whom we have named as small active investors and who are a sub-group of retail investors. Such studies need to be repeated to establish its generalizability with ore structured tools to enhance validity and reliability. The present research work has implications for mutual funds industries, small investors and the regulators. The companies may factor Investment Advisor as the dominant force for SAI decision making as it has emerged as the most important source of information. They may also utilize advertisement and return on schemes to meet existing investor perceptions. Regulatory bodies must continue to ensure protection of the investors, particularly for the vulnerable sections such as women, old people and middle-income groups. Even the companies should sensitively design the Mutual fund products and selling for these vulnerable sections. As Tax Saving Schemes and Long term safety of investment critical for SAI, this may be taken into consideration by fiscal policy makers and RBI. Implications for the investors are that they must evolve their behaviour based on their differing needs that may emanate from their demographic realities. Appropriate investment has been a function of demographic realities and hence must be consistent with them.

# Chapter 81
# Basic Types of Project Initiators: Contributor Relations in Platform-Based Online Crowdfunding

**Javier Vidal-García**
*University of Valladolid, Spain*

**Marta Vidal**
*Complutense University of Madrid, Spain*

## ABSTRACT

*Crowdfunding has helped many businesses and projects to take off easily and is replacing the traditional methods of fundraising since more platforms are being created. Evaluation of the risk for both the borrower and the donor is important before investing or borrowing to ensure that the project is a success. Crowdfunding is changing the way that projects and startups get funded. Most of crowdfunding money is raised on reward-based platforms, although equity crowdfunding is growing quickly. It can be expected that crowdfunding will become more popular, with many crowdfunding new opportunities available, which will make not easy for potential investors to choose what to support. In this chapter, we introduce the reader to the basic types of project initiators-contributor relations in online crowdfunding. We review the current literature identifying the research questions relevant for our purpose. We subsequently conduct a research method of systematic review to identify the relevant papers that address those research questions.*

## INTRODUCTION

People have many business ideas and innovations that are usually delayed or crippled due to lack of funds. There are many ways of raising money towards a given venture in order to kick-start a project. If an individual does not have the necessary funds, one of the alternative ways to raise funds is through fund-raising platforms. The money raised through a fundraising may it be through donation or on debt

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

and it should only be used to successfully start the targeted project. The money raised can be through donations, mainly reward-based, equity-based or credit-based, all of which have to give some form of compensation to the contributor (Outlaw, 2013, p. 5).

It is very difficult to maintain an adequate long and short term financial plan when there is a shortage of funds for any particular business or a new venture. Furthermore, the working capital management will need to have adequate funds in order to cover the short term expenses. It is also possible that the creditors can demand payment at any time for the goods delivered to the business by them and for that is necessary to maintain the working capital or adequacy of the funds. Fundraising can also help the business to maintain the effectiveness of the business on a long term basis and the example could be related to the purchase of a new machine (Steinberg et. al., 2012, p. 35)

A new startup needs some amount of funds in order to get the business started. In order to transform the entrepreneurial project into a reality, then it is necessary to have adequate cash to execute all such plans. Moreover, the fundraising will help the entrepreneur to develop the business model for the growth of the project and a successful business marketing plan (Damus, 2014, p. 32)

The technological advancement and the use of the Internet have raised a new platform for fundraising known as crowdfunding. Crowdfunding involves three parties: the project initiator or owner who needs funding, the contributor who is willing to give their money and the moderating organization that facilitates the engagement between the contributor and the initiator (Young, 2013, p. 33). Moderation can also be done through technology by the project initiator himself, using Web 2.0 and outside of platforms (see for example Gerber & Hui, 2013 for a definition including such practices). The platform involves entrepreneurs or potential business owners asking for funding for their projects from the "crowd" or users from all over the world who may be interested in supporting their cause or business. Crowdfunding allow individuals the possibility to develop into their business ideas, even if it is only with a small amount of money. Governments encourage crowdfunding due to its positive impact on the economy as a whole, as it creates new jobs and fosters the economic growth of countries.

This chapter seeks to introduce the reader to the basic types of project initiators-contributor relations in online crowdfunding. For this, we have reviewed the current literature identifying the research questions relevant for our purpose. We subsequently conduct a research method of systematic review to identify the relevant papers that address our research questions.

## BACKGROUND

Although the name of crowdfunding and its use of the Internet are new concepts to the market and the population, it is usually mentioned that the construction of the Statue of Liberty's Pedestal took up the same idea. John Pulitzer, who was then a publisher, used his newspaper to rally up people donate money for the construction of the Pedestal, a project that later raised 100.000 dollars in six months. Pulitzer raised a fund and promised to print the identity of each donor, regardless of the amount of the donation. In August 1885, Pulitzer was finally able to announce that he had raised the final $100.000 for the statue's pedestal. The next year the Statue of Liberty, which had arrived from France packed in crates, was erected on top. (See Young, 2013 for more details). Crowdfunding is becoming hugely popular in many parts of the world and the Internet platforms that are being used for contributions are on the rise.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In 2013, Crowdfunding raised over 5.1 billion dollars to help people in various projects all over the world and the figure is projected to increase in the future with the new platforms becoming more popular (See Crowdfunding Industry Report from Research firm Massolution). The new law of the Jumpstart Our Business Startups (JOBS) by President Obama in 2012 introduced a regulatory framework. Most of it still has to be translated into active regulatory elements to this date, protecting donors to crowdfunding projects and enabling businesses to use crowdfunding as a real source of funding. The Act enhanced the credibility of the platforms for crowdfunding while at the same time ensuring that the project owners or entrepreneurs had a viable and a good source of funding for their projects. Kickstarter and Indiegogo are some of the most popular platforms boasting of members in millions of all parts of the world, these websites have enough people to pool huge amounts of resources for the funding of their businesses. See Assadi in this book (In search of business models of crowdfunding) for a complete explanation of the business models of online crowdfunding websites.

The chapter starts describing the different types of crowdfunding and continues explaining the different types of relations between project initiators and contributor in online crowdfunding such as reward-based crowdfunding, equity-based crowdfunding, and credit-based crowdfunding.

## MAIN FOCUS OF THE CHAPTER

### 1. Reward-Based Crowdfunding

The reward-based form of crowdfunding is the most popular type with most contributors and initiators preferring this method due to the security of their funds under this method (See Crowdfunding Industry Report from Research firm Massolution, 2014). In reward-based crowdfunding, the target amount has to be established first for the completion of the project (Steinberg, 2012, p. 97). Then, the person or organization sets up donation amounts with an attached incentive that is proportional to the amount donated for the project. This method is hugely popular for artists, movie directors and other projects that have an aesthetic or prestigious value to the donor. For instance, if an artist was looking for a donation to help with a tour of Europe, he may offer signing autographs to people that will contribute $500 and backstage preparation with the cost to people contributing $1,000. These incentives ensure that the enthusiasts and the music lovers are motivated to donate to the cause (Young, 2013, p. 79). One of the unique characteristics with this method is that if the set platform allows for the project owner to get the amount only after the targeted amount is reached, he/she cannot be awarded the amount collected in case the donors do not raise all amounts. The donors can therefore get their money back and they have the confidence of recovery of the raised amount as a result (Agrawal, Catalini, & Goldfard (2015))

One of the major benefits of reward-based crowdfunding is that it has low risks for the promoter or the company that is behind the campaign to raise funds or donated amounts. Once a company has raised the required amount for the project and they may have had the donations only with a special clause for the specific project they are able to avoid dealing with debts, credit implications or interest that is attached to the loans or government grants. The reward-based crowdfunding method offers the chance to completely avoid all these problems and start their business or project without any possibility of future shortcomings due to any changes in the plans or the success of the project. The reward-based method also runs on low cost with the project owners being offered a chance to showcase their projects for only a small fee of their total collection and there are no high costs of managing the platform. As opposed

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

to raising money through other conventional methods, where a person could end-up incurring a lot of costs for setting up the funds, crowdfunding sets this up at only a small fee and the project is viewed and supported by millions from all over the world (Roebuck, 2011, p. 104). The reward-based method also offers the donors a chance to gain a personal connection with the project they have donated towards and the people they have funded.

Given the nature of their agreement or the incentives that have accompanied a specific project the donors get a chance to meet with their project initiators and owners in some of the project or are offered a form of memorabilia that offers them a personal connection to the projects. (Roebuck, 2011, p. 108).

One should examine the project and the rewards that they have offered the people in order to ensure that they feel attracted enough to the project to offer their funds. As much as the project owner has to assess the amount of money that they need for their project, it is equally important to draft the best reward that is irresistible for the targeted crowd. The reward is very important to the project since it is the attractive aspect of the project and the main reason why people are interested in investing. The company has also to ensure that the reward selected does not detrimentally affect the project since they may end up spending a lot of time to give their rewards infringing on the results of the targeted project. (Young, 2013, p. 85).

The experiences and rewards that companies set for the people need to be measured and evaluated for their practicality since they may cripple the success of the project in the long-run. It is therefore advisable to limit the premium awards to only few elite and people that have hugely contributed towards the project. Depending on the amount that the project needs to be successful the owner should come up with premium rewards that are set to mirror the amount that he/she wants to raise (Young, 2013, p. 90). This means that the rewards for small projects should not have high premium awards in comparison to the rewards for a huge project that needs a lot of money.

Drafting a good plan to help with selling the project to the people in the right way to attract potential investors is also critical in a reward-based method. The right plan should consist of the ways to market the project and also the right rewards to the donors who have contributed to the project. Prior planning ensures coming up with the best strategy for marketing and representing the project in addition to the project itself (Roebuck, 2011, p. 139). It is also advisable to hire professional marketers in the event that the project is large and requires a lot of resources to ensure that it gets the amount of funding to complete it successfully. Professional crowdfunding marketers are essential in guiding and ensuring that the company has captured the main attributes of their project and that it may be attractive to donors. Giving incisive information on the best rewards for a given project are also some of the factors that may help in directing and giving a project owner. Generating a buzz for the project leads to funding and therefore the project should generate the buzz that is achieved through personally promoting the product across multiple channels and trying to forge personal connections with people to rally them behind the cause (Roebuck, 2011, p. 141). The reward-based method is regularly used, especially due to the fact that the project owner does not have to incur any financial loss in the undertaking, apart from a small amount that they pay to the platform owners once it is fully financed. Table 1 shows the advantages and disadvantages of this type of crowdfunding.

The crowdfunding platforms such as Indiegogo, Kickstarter, RocketHub, and Eppela host many reward-based projects. Moreover, an individual can establish a project that incorporates a text, video, and reward perks that will be accessed by a backer when the money is pledged by them to the initiative. Therefore, it can be said that these platforms are available to fund new innovative projects. Kickstarter is the pioneer in reward-based crowdfunding online platforms, where over $1 billion has been raised to projects. The online platform Kickstarter is the most creative way to provide funding for the creative projects.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The platform Indiegogo is suitable for any kind of project. The most important fact is that it has attained more recognition worldwide and even more than Kickstarter. Initially, it used to fund theatre based projects, but then it expanded its development and made it open to almost any project.

Rockethub is another similar company that was originally meant for the artists, but later transformed to include the sciences and scientists' projects, especially after the launch of its SciFund Challenge (Roebuck, 2011, p. 32).

Eppela is a platform founded in 2011 in Italy (Tuscany) for projects in the fields of design, art and culture, technology, food, non-profit, sustainability, and social innovation. The platform mainly targets potential artists, writers, film makers, or designers. Eppela charges 5% of the sum raised to cover operating costs. 40% of projects posted on Eppela are successful, it has more than 90,000 registered users, a successful project raises an average of 6,500 euros. Some of the most successful projects of reward-based crowdfunding funded through Kickstarter include Coolest Cooler, a company started in 2014 and located in Portland (Coolest, 2014), which is the largest reward-based crowdfunding campaign to date. The project involves the design of a portable cooler, which include blended drinks and music. This project has received donations from 62,642 investors for a total of 13,285,226 dollars. Another successful project, and currently the most funded, is Pebble, which is a customizable watch, with many downloadable watchfaces and internet-connected applications. The company is headquartered in California, its watches can be purchased online at (Getpebble, 2015). Pebble can connect to iPhone and Android smartphones using Bluetooth, alerting customers with a vibration for incoming calls, emails and messages. The project was funded in 2012 and attracted 68,929 investors, raising a total of 10,266,845 dollars. Ouya is another prosperous project funded in 2012, it is a microconsole with its own version of the Android operating system. The console was released to the general public on June 2013, together with Ouya stores for applications and games designed for the Ouya platform, its products can also be purchased online. A total of 63,146 investors supported the project, which raised a total of 8,596,474 dollars. Another of the most funded project is Pono Music, funded in 2014 in San Francisco, California (Ponomusic, 2014), which is an audio player using high quality recordings sold through the PonoMusicstore. The project gained support from leading record labels such as Warner, Sony, and Universal, and has signed a full agreement with Warner. The company was fully funded in one day after launching its crowdfunding campaign, 18,220 people invested in the company raising 6,225,354 dollars.

## 2. The Equity-Based Crowdfunding

Equity-based crowdfunding is a form of crowdfunding where the contributors become part-owners of the company raising funds. Equity-based is not a popular form of crowdfunding since the majority of the projects are not huge companies that donors and people funding the projects can get a stake and own part of (Douw, 2012, p. 60). Most of the projects are by entrepreneurs who do not have shares that the

*Table 1. Reward-based crowdfunding in balance*

| Advantages | Disadvantages |
|---|---|
| • Raising money for the project or business without selling off an equity stake in the business.<br>• Getting hundreds or thousands of people committed to the success of the campaign. | • Once an individual has successfully raised money, he has got to ship whatever he is producing.<br>• The dock is ticking and it is no surprise that many of the top crowdfunding projects are very late in getting delivered to donors. |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

investors can invest in. However, since the enactment of the Act in 2012 this form of crowdfunding has gained popularity with most people seeing it as an investment opportunity for the interested investors in lucrative projects that the investors deem to pick up and be beneficial in a near future. This is offered at very low rates as compared to the market rate since the project owners will need to make their proposal and project attractive to the potential investors through their competitive prices and growth potential in the future (Douw, 2012, p. 60).

Equity-based form of crowdfunding is slowly catching up with the other methods of crowdfunding. It is, however, a safe and viable method to raise money for the company and beneficial for the donor if the company makes profits in the future and they gain from the dividends or distribution. Equity-based crowdfunding can also be used to create a venture finance market. Equity crowdfunding does not only involve the shares as the only forms of securities, but also debt notes, convertible notes, and hybrid forms of equity and debt (see Freedman & Nutting, 2015, p. 5). In addition, there are some forms of partnerships that qualify as securities in equity-based crowdfunding. One of the main attributes of equity-based crowdfunding in creating venture-based market is its ability to connect startup business and the medium businesses to the larger investor community. Equity-based crowdfunding offers a platform to reach out to the companies through a single advertisement on the web. It ensures that the information reaches out to interested potential buyers and sells the business to the investors (Mollick (2014)). The venture space is therefore in ensuring that the investors and the business people meet. In addition, the venture space ensures that people with similar businesses and ideas can interact and advise each other on the best practices and the best ways to improve the businesses. The venture space is not only useful in raising the funds, but also ideas and plans on the best ways to improve the business given that there are other members of the crowd with the same ideas. It can also lead to mergers and amalgamation of two or more different venture businesses since the equity-based crowdfunding targets the business people who are interested in increasing their venture capital either through shares or other securities. The equity-based finance structure has a pool of professional small and large businesses that need a regular appraisal either through funding or through further investments (Steinberg, 2012, p. 113). Economic growth is also a factor that is hugely influenced by the success of the equity-based crowdfunding, since the growth of business companies contribute to the economic growth of the country. Most governments all over the world are taking up the new platforms and legislations have already been passed to ensure that crowdfunding for businesses and individual projects help the larger financial community that is the whole country. The venture finance marketplace has therefore transformed the equity-based crowdfunding concept to rally the support of the government and security legislations since it has been viewed as a milestone and a new trend in the financial sector.

These platforms offer companies to obtain extra funding for their product without having to go through the normal bureaucratic procedures that tie up an Initial Public Offer or the sale agreements with the shareholders in a company. It is therefore a platform for buyers and sellers to meet as much it is a fundraising project since the donors stand to gain from their investment decisions (Dresner, 2014, p. 85). The Jumpstart Our Business Startups Act of 2012 has increased the number of people who are interested in investing in the projects as they are assured of getting a return on their investments. The process is similar to the reward-based method since one has to broadcast and market their project to many people in order to ensure that they get enough "crowd" to fully fund their projects. It is therefore essential that the company plans for the ways to sell the project and make it attractive to potential investors that invest in the company in the hope of getting returns on the investments in the form of dividends or distribution. Similar to reward-based crowdfunding sorting help from professionals, on crowdfunding

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

under this method is also necessary since they need to generate enough buzz to ensure that their projects are funded. This implies a low risk as compared to get money through other channels such as debt financing since the shares are the tokens that are offered to the investors of the new project. In addition, the costs are also relatively low since instead of going through the usual channels and processes that require a lot of resources the company generates the funds at a very low cost with the only requirement being the small fee (ranging from 7% to 12%) charged by the platform operators. Although the investors are offered a stake in the company, the amount of stocks that are offered for a given amount needs to be proportional to their contribution (Dresner, 2014, p. 57). It is important to note the purpose of the project to the company and the implications of offering new members a part of the company keeping in mind that it should be high enough to attract new investors but should be financially feasible to ensure that the company remains in a competitive position. Offering too many shares for a lower amount may result to problems in the company due to one project and as a result, it is advisable to ensure that the amount given is managed by the company and does not cause any problems in the long-run.

The investors, however, bear the risk of losing if the company does not do well in the projects that it has invested in. As opposed to the reward-based method where the donors do not expect rewards that have a monetary value, although reward-based campaigns offer products as rewards, in equity-based method the donors take the risk of losing the money if the project or the company fails in the market. The opposite is true if the company performs well, investors are likely to get return on their investments from the project. The owners of the project are also able to pool the funds that they could not have accessed due to their financial constraints easily and more efficiently (Lawton & Dan, 2013, p. 86). Table 2 shows the advantages and disadvantages of this type of crowdfunding.

There are several online platforms that facilitate equity-based crowdfunding. They are IPOVillage.com, Seedrs, Crowdcube, Earlyshares.com, and MicroVentures.com. Their details are shared below:

IPO Village is the platform that utilizes equity-based crowdfunding in order to provide retail investors with exclusive IPOs emulated by the allowance of Main Street investors to get an access to the stock that was for Wall Street elites.

Cedars is the FSA regulated platform in the UK. It provides services for investments in the startups that includes equity-based crowdfunding investments as well. This platform lets the individuals to look for rewarding, tangible, places to get their money invested.

Crowdcube is another way to provide money to the startups and expand the business through equity-based crowdfunding while providing the entrepreneurs with a great platform to get connected with the ordinary people and ultimately give a raise to the venture capital.

A sample of recently funded projects funded through Seedrs includes Chapel Down (Chapeldown, 2015), a Premier English sparkling wine and beer producer based in Kent, England, admitted to trading on the ISDX Growth Market. The Company raised £4,350,000 through an equity issue in 2013 when it was funded, supported mainly by large investors and institutions. The company has launched a new equity issue in 2014. The company has been admitted to trading on the ISDX Growth Market and it is the first listed company that has undertaken an equity crowdfunding campaign anywhere in the world. Seedrs is also an example of a leading company funded by equity crowdfunding, the company is an online, cross-border platform for investing in startups (Seedrs, 2015). It aims to provide the infrastructure for private investments in early-stage businesses. They are looking to process and administer angel and group transactions and to create products and structures to provide a range of investor types exposure to startups. The company was launched in 2012 and has raised £2,583,420 since then with an equity offer of 33% of the company. NearDesk is another example of successful equity-funded company, the com-

*Table 2. Equity-based crowdfunding in balance*

| Advantages | Disadvantages |
|---|---|
| • By taking angel investing (individuals investing in startups) online, equity crowdfunding has opened up this type of investing to more and more people. There are very accomplished investors using these platforms whose contribution may add to the success of the business long term.<br>• Equity crowdfunding allows raising money in a fast way on websites without the need to agree to fundraising commitments of venture capital companies.<br>• It would also allow entrepreneurs more freedom to set their own commitments compared to selling publicly traded stocks.<br>• Attracting hundreds of investors online also means gaining online popularity for a startup company. | • Not all entrepreneurs are comfortable posting their financial and business plans online for investors to see. Getting comfortable with equity crowdfunding means one must get comfortable with increased transparency into the business.<br>• Equity crowdfunding might not be able to compete with the experience and expertise in business growth that venture capitalists could bring to startups.<br>• As crowdfunding investors might have not much knowledge about the risks of online investment, it may be difficult for entrepreneurs to deal with investors' expectations.<br>• Equity crowdfunding (by non-accredited investors) is not yet legal in the United States as it is prohibited by the Securities Act of 1933 |

pany lets users rent desk and meeting space by the hour at different locations around the UK, it is based in London and its cards can be purchased through its website (Neardesk, 2015). Thus, customers only pay for the time they use, with a single monthly invoice. Cards are issued by NearDesk and by partners who provide co-branded cards. The company has raised £1.000.012 in 2014 with an equity offering of 22% in its third round. Another company worth mentioning is Shareeight, an application available to download on the iPhone and iPad that aims to bring together all of the major brands and retailers in one place. Shareeight is a unique search method to reach the top 500 retail search terms in just three taps, the interface organizes the results into manageable chunks of 8. Shareeight aims to bring all the major stores together to benefit both customers and shops. So far, more than 80 retailers and over 8.000 brands have joined Shareeight. The company was founded in 2014, it is based in London and its applications can be downloaded from its website (Shareeight, 2015). They have had two rounds of financing, in the first one they raised £605.000, equivalent to the 16% of the company, and a second round raising $1,000,000 in just 24 hours.

## 3. Credit-Based Crowdfunding

Credit-based crowdfunding is a method where the donors to a specific project loan out money to the person in the hope of future repayment of the amount owed. This is the safest method of crowdfunding for the donors since in case the project owner defaults in payment of the advanced loans the platform is liable for the payment of the loan to the donor (Tomczak & Alexamder, 2013, p. 341). Under this method the borrowers submit an amount that they wish to be loaned and the donors interested in the specific project advance the borrower the amount with a promise of repayment at a future date. The platform acts as the intermediary and or surety for the borrower and the donor to ensure that the donor gets the amount back and facilitate the pooling of funds for the borrower. The borrowers find crowdfunding attractive since it has very low or no interest rates for the borrowers and they only have to incur a fee to process the funds by the platform and agree on a flexible payment plan to refund the amount forwarded. In the event that there is any interest to be charged on the amount of money borrowed the borrower sets the interest to be charged that they are comfortable and can guarantee a refund within the stipulated time period (Mollick, 2014). This makes the method attractive for the borrowers since they are not required to pay a minimum or set interest rate that is predetermined and as a result they can guarantee payment.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The lenders on the other hand have to evaluate the project for its risks or benefits and potential and establish if they are willing to lend money at the interest rate set by the borrower. The arrangement is similar to that of a bank loans with the main difference being the predetermined interest rates. Whereas in credit-based crowdfunding the borrower sets the interest rates, inviting donors to fund the project in a bank loan the borrower must agree to the terms set by the bank or the authorities involved (Althoff & Leskovec (2015)).

One of the main advantages is that the borrower does not have to give any form of collateral to the lender and they transact only in terms of good faith from the borrower and the donor of the project. The donor funds the borrower in the hope that they will repay the money not because they have a history of repaying or they have presented evidence to suggest that they are capable of repaying the money but only on faith they have on their project. This ensures that the platform eradicates many processes of loan funding and borrowing that would slow the timeline of acquiring a loan. Background checks run by the banks and also the examination of the presented information are a large part of the processing process making it tedious and time consuming. The process also rules out borrowing from poor and new business people that are looking for money to kick start their business and have no collateral or no history to guarantee payment of the amount that they have borrowed. Crowdfunding offers such people a chance to borrow even huge amounts of money without any form of guarantees and guarantors. Credit-based crowdfunding has been immense in eliminating the factors that hinder borrowing and lending since there are none in crowdfunding. The project and presentation of the ideas are the most important aspects of a project if one aims to be funded for a project accordingly. It is therefore advisable for one to lend both their time and resources in the presentation of the project to as many people as possible. Hiring professionals to market the product is necessary for a borrower that looks to get money for their project and within a specific timeline since the professionals are able to market the product to the potential lenders using the best techniques while also offering advice on aspects such as the interest rate that stands to attract investors in the market (Tomczak & Alexander, 2013, p. 350). Proper planning is also important for the borrower if they are to make the intended amount within the set timelines and be able to pay specific installments that they have set. Unlike the other two methods where awards are given to the people who invest in the project, the credit-based method requires an individual to have a well-structured plan on the mechanisms of payment. Table 3 shows the advantages and disadvantages of this type of crowdfunding.

Just like the above two crowdfunding platforms, there are several examples of online credit-based crowdfunding platforms. They are named as Funding Circle, Lending Club, Prosper, Zidisha and Index Ventures.

Funding Circle was developed with a big idea in order to revolutionize the outdated banking system and maintain a better deal for every individual. They have helped the businesses grow with thousands of loans along with the facilitation to let the investors prosper and stabilize the economy. It is the leading lender in the online marketplace which targets small business.

On the other hand, Lending Club got the status of an establishment as an alternative to the conventional banking system in that provides loans to the borrowers at a low interest rate and better returns to the investors. It is America's dominant online credit platform and has been pioneer in transforming the way the lending operates.

Index Ventures is the leading international capital firm with branches located in London, Geneva and San Francisco. They provide support to the companies and founders who look to become the Fortune 500 for the upcoming 50 years.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Credit-based crowdfunding present some interesting statistics, Funding Circle (Fundingcircle, 2015) reports that 34,322 British investors have lent to business through their website and a total of £417,602,420 have been lent to British businesses since 2010. An average investor achieves an average return after fees and bad debts of 7.6%. Lending Club (Lendingclub, 2015) is the world's leading online credit marketplace, they have a simple credit marketplace, customers interested in a loan fill an application, the company examines the information, determines an interest rate and presents some offers to borrowers, then investors select loans in which to invest and can earn monthly returns. Lending Club has donated $6,205,366,548 in loans, and has paid $595,817,848 to investors. 83.17% of borrowers report using their loans to refinance existing loans or pay off their credit cards. The company has grown at more than 100% per year over the last few years. Prosper (Prosper, 2015) is America's first peer-to-peer lending marketplace, it has more than 2 million members and has funded more than $2,000,000,000 loans. Borrowers request loans between $2,000 and $35,000 and lenders invest from $25 in each loan listing selected, investors can see credit scores, rating and histories, as well as borrowers' personal loan descriptions, endorsements from friends, and community affiliations. The company reports an average return of 8.89% for investors. Zidisha (Zidisha, 2015) is the first online microlending community that matches lenders and borrowers, the company has raised $2,308,144 so far and has funded 8,127 projects, with a total of 9,504 lenders and 6,141 borrowers from 141 countries. Index ventures (Indexventures, 2015) is the oldest of the companies, founded 1996, they have funded 140 companies in 38 countries. The company has raised several venture funds, from Index Ventures I through VI; Index Growth 1 and 2; and a $200 million life sciences fund with the support of GlaxoSmithKline and Johnson & Johnson.

## 4. Donation-Based Crowdfunding

Donation-based crowdfunding is the last method available for funding new initiatives. In this method, funds are raised for an initiative of public interest, although there is no economic benefit to the community financing the initiative. One of the greatest challenges of social entrepreneurs today is accessing startup capital, that's why donation-based crowdfunding makes this method an interesting financing solution. One example of donation-based crowdfunding is the 2008 election campaign of President Obama, the campaign team collected more than $137 million by this method.

One of the risks in a crowdfunding initiative is targeting and unrealistic financing initiative, as crowdfunding platforms charge a larger percentage fee if the target is not met, failing to deliver on the project's promise will negatively affect the project's reputation. Thus, it is very important to engage the potential community into the project and design the project according to their interests. That's why advertising the campaign is an important part of the crowdfunding process, always keeping costs in mind, it is important to advertise the campaign through several channels and reaching the largest possible

*Table 3. Credit-based crowdfunding in balance*

| Advantages | Disadvantages |
|---|---|
| • Possibility of raising capital without giving away company's shares of capital.<br>• Funds are disbursed as personal loans through internet without financial intermediation.<br>• The fact that small sums are made to individual loans minimises losses. | • Less important contributor's involvement than in equity-based crowdfunding<br>• No pre-sale/audience building element as in donation-based crowdfunding.<br>• Funds are disbursed without collateral, with high risks involved. |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

potential supporters. Most donations-based crowdfunding initiatives reward donors with something in exchange for their contribution. Typically this is some kind of perk, this is usually the most expensive part of the crowdfunding campaign. The most challenging part of the crowdfunding process is moving from the zero donation phase, as potential donors usually imitate what other supporters did, then a potential donor might be not willing to give funding to a project when no money has been raised yet. Encouraging close friends and contacts to contribute in the initial stages of the campaign will be helpful. The Regional Studies Association (RSA) explains that the most critical zone is when the 10%-50% of the initiative has been funded, as most unsuccessful campaigns fail somewhere in this range. Thus, in order to take the initiative to reality it is essential to push the campaign after the launch with advertising and showing previous donations. In initiatives involving social entrepreneurship like the ones involving this type of crowdfunding it is more important to have the certainty that it is a feasible project, as a poor crowdfunding campaign could harm the reputation of the company and affect future initiatives to get funding. Another important issue to consider is that the amount raised can be affected by declined funds later on coming from credit cards, wrong donations, or fraud.

Not all of the main crowdfunding portals are suitable for social entrepreneurs. For example, Kickstarter is designed only for creative projects and is not aimed for social businesses or nonprofits. GoFundMe is the world's leading personal fundraising website, it is based in San Diego, California, and it was launched in 2010 (Gofundme, 2015). It has become the leading fundraising site for personal causes and life-events. It has raised $550 million from 8 million donors since inception. Some example websites that are usually employed by social business include: Indiegogo, which we already mentioned above, although the company was not created for social entrepreneurs it allows almost all donations-based initiatives. It has become a large network for social businesses and ONGs due to its flexibility and international recognition. Another platform for causes and charities is Crowdrise, which employs a specific system to advertise the charitable impact of social organizations. Rockethub jointly in partnership with A&E Project Start Up also offers donation-based crowdfunding services funding innovative projects for social entrepreneurs. Another portal which operates in a different way of the others listed above is Invested.in, this website offers the opportunity to social ventures to create its own crowdfunding community for donation-based fundraising. The platform argues that its procedure to raise money is simpler than other portals and its transaction fees are lower than the competition. Table 4 presents the advantages and disadvantages of this type of crowdfunding.

The most common examples of donation-based crowdfunding are projects involving some kind of community fundraising: improvement to schools, improvements to churches, financing for children school ground, or financing facilities for sports clubs. The initiatives that raised the largest amounts from the platform GoFundMe include "Saving Eliza" (SavingEliza, 2015), which is a campaign to save a 8 year old girl, who was diagnosed with a rare terminal genetic disease. The campaign has raised $1,758,500 from 32,794 people. Another campaign is "Bucks for Bauman", which helps a man injured in the Boston marathon attacks to pay for his medical bills, the campaign has raised $809,035 from 16,491 people. Also related to the Boston marathon attack is the "Celeste and Sydney Recovery Fund", which is a fund to recover both ladies physically and emotionally from the attack in Boston. The initiative has raised $794,934 from 11,271 people.

*Table 4. Donation-based crowdfunding in balance*

| Advantages | Disadvantages |
|---|---|
| • There are usually no tax implications when receiving large sums of money in this kind of initiatives.<br>• No need to give up partial ownership of the company (although in many cases of donation-based crowdfunding there is not a company involved).<br>• Limited regulatory restrictions.<br>• Donors are assured that their money is put to good use.<br>• It provides a platform for many short-term and easy to measure social projects, which are initiated soon. | • The main disadvantage is that social entrepreneurs might be limited by the amount of money they raise, as this kind of initiative usually attract less money than other types of crowdfunding, the amount collected might not be enough for an ambitious initiative.<br>• People are reluctant to support a project if they do not obtain a financial return on their donation, this should be taken into account in the initial plan.<br>• Especially important for social projects is that the number of participants in these initiatives decreases in proportion to the likelihood of fraud.<br>• Reward initiatives can be expensive.<br>• It is difficult to differentiate a social project from others and get attention from the crowd given that barriers to entry are low. |

## CONCLUSION

In conclusion, crowdfunding has helped many businesses and projects to take off easily and is replacing the traditional methods of fundraising since more platforms are being created. Evaluation of the risk for both the borrower and the donor is important before investing or borrowing to ensure that the project is a success. The legislation of the Act has enabled the platforms to conduct business better and have a larger crowd since the donors have the backing of the government and the law while engaging in the business.

Crowdfunding is changing the way that projects and startups get funded. Most of crowdfunding money is raised on reward-based platforms, although equity crowdfunding is growing quickly. It can be expected that crowdfunding will become more popular, with many crowdfunding new opportunities available, which will make not easy for potential investors to choose what to support. A new business that seeks funds through the crowdfunding process comes out stronger as for the questions that has to answer and the scrutiny that it is put under, compared to convince a single angel investor. It is worth mentioning that because a startup does not obtain crowdfunding does not necessarily mean that the business is not viable. It might be that investors may not be on that platform or perhaps is not the right time. One of the biggest challenges ahead will be communicating efficiently and engaging with investors after successful funding. Investors will possibly be interested in the big numbers and updates instead of the news from daily operations. Investors will be more likely to reinvest if they are kept engaged and the company is looking after them. Creating a mutual interest might foster that investors act as ongoing mentors in the business.

It is widely believed that crowdfunding will democratize the investment market. The question remains if the sector will continue acting in a fair and trustworthy way in the future, or will make the same mistakes as banks during the financial crisis, in that case the sector can lose its credibility. In this sense, Crowdfunding research website TheCrowdCafe explained that there are no cases of fraud in the six main platforms monitored by them. Fraud means creating fake campaigns or companies. Although the number of fraud cases and scams in the crowdfunding industry has been recently growing, recent cases include: GoBe, Anonabox, Scribble or Holovision. Thus, investors should examine the project thoroughly before investing as the possibilities of fraud will increase in the near future as the industry grows.

Each type of crowdfunding has itws own advantages. Reward-based crowdfunding can raise money for the project or business without selling off an equity stake in the business, as well as getting hundreds or thousands of people committed to the success of the campaign. Equity-based crowdfunding attracts

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

accomplished investors using these platforms whose contribution may add to the success of the business long term. It allows raising money in a fast way on websites without the need to agree to fundraising commitments of venture capital companies, and also allow entrepreneurs more freedom to set their own commitments compared to selling publicly traded stocks. Credit-based crowdfunding offers the possibility of raising capital without giving away company's shares of capital. Funds are disbursed as personal loans through internet without financial intermediation, and the fact that small sums are made to individual loans minimises losses. Finally, Donation-based crowdfunding offers no tax implications when receiving large sums of money in this kind of initiatives, with no need to give up partial ownership of the company, limited regulatory restrictions, while donors are assured that their money is put to good use.

While in the US, companies using crowdfunding platforms have to disclose their finances to potential investors and regulators, in European equity crowdfunding platforms are still approaching important concerns like transparency for potential investors. American crowdfunding platforms typically look for financial projections of companies and examine their business plans. The lack of crowdfunding legislation in Europe is an important obstacle in the advancement of this way of financing. In Europe, small and medium companies represent 99% of businesses and 67% of all jobs. According to the European Central Bank, bank loans decreased sharply after 2008 by 29%. Crowdfunding is a possible solution for the problems of financing small and medium-sized companies, but the existing regulations prevent growth in this market. Furthermore, the lack of integration of European regulation limits crowdfunding to national borders, which means that operating in a small market will make more difficult for small companies to satisfy their capital requirement.

In Europe, there are 28 different legal crowdfunding frameworks for one market, this fragmentation is the key problem for crowdfunding growth. Cross-border transactions will face problems with this situation. Thus, many investors are excluded from investing in crowdfunding projects due to their location in the UE. Many countries are pushing the European Commission to create a pan-European regulatory framework to foster growth in the sector. This problem has been clearly recognized in the United States, with the Jumpstart Our Business Startups Act', or the 'JOBS Act', a uniform regulation for crowdfunding has been created. According to Masssolution Market Researcher, Europe will represent 26% of the crowdfunding total market. Only in 2012, the European market handled transaction for 925 million, while the American market for crowdfunding managed 16 billion dollars. Europe will not be able to follow the United States when it comes to crowdfunding until a uniform legislation is created (Bruntje & Gajda 2016).

Finally, it is worth mentioning that many crowdfunding proposals do not go through the crowdfunding platforms, many companies prefer to launch their crowdfunding campaigns through their websites. One example is Lockitron, which was rejected by Kickstarter. The company, which makes electronic door locks, launched a campaign on its website and raised more than $2,000,000 in 30 days.

## KEY TERMS AND DEFINITIONS

**Angel Investor:** An investor who provides funding for small startups or entrepreneurs.

**Credit-Based Crowdfunding:** Credit-based crowdfunding is a method where the donors to a specific project loan out money to the person in the hope of future repayment of the amount owed.

**Crowdfunding Platform:** Internet platforms which enable companies to advertise over the internet and obtain investments from registered users in return.

**Donation-Based Crowdfunding:** In this method, funds are raised for an initiative of public interest, although there is no economic benefit to the community financing the initiative.

**Equity-Based Crowdfunding:** Equity-based crowdfunding is a form of crowdfunding where the contributors become part-owners of the company raising funds.

**Jumpstart Our Business Startups (JOBS):** A regulatory framework, protecting donors to crowdfunding projects and enabling businesses to use crowdfunding as a real source of funding.

**Reward-Based Crowdfunding:** In reward-based crowdfunding, the target amount has to be established first for the completion of the project. Then, the person or organization sets up donation amounts with an attached incentive that is proportional to the amount donated for the project.

# Chapter 82
# Shadow Economy:
## An Analysis for EU-27 and Turkey

**Hale Akbulut**
*Hacettepe University, Turkey*

## ABSTRACT

*The aim of this chapter is to investigate shadow economy on an EU-27 and Turkey basis. For this purpose, firstly the definition, causes\ and consequences of shadow economy together with its relationship with tax evasion are discussed. In addition, the causes of shadow economy are examined for EU-27 during the period 2003-2012. It was done both statistically and empirically by employing scatter plot diagrams and the random effects model. While empirical findings confirm the effects of taxes, income level, trade and population on the shadow economy, statistical findings mention the effects of governance related indicators. Another main finding of this chapter is about Turkey. Accordingly, shadow economy in Turkey is observed to be higher than in the EU-27 and taking into consideration the comparative statistical findings about the causes of shadow economy, the main reasons of shadow economy in Turkey are thought to be governance related.*

## INTRODUCTION

Today a large share of economic activities performs in the so-called "shadow economy" in both developed and developing countries. In addition to its large volume, the shadow economy is usually perceived as an economic problem as it has harmful effects on the economy such as distorting taxation justice and decreasing the efficiency of economic policies. These circumstances, together with some increasing economic problems such as budget deficit and unemployment, increased the concerns about shadow economy. However, the definition, structure and the causes of shadow economy are still not clear. This chapter investigates related deficiencies on an EU-27 and Turkey basis.

The chapter is built on three main aims. The first aim of the chapter is to clarify the definition and the structure of shadow economy. For that purpose, previous studies together with the work of the OECD (2002) are employed and the structure of shadow economy, its specific characteristics, its relationship with

DOI: 10.4018/978-1-7998-2448-0.ch082

Copyright © 2020, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

other non-observed economic activities, and tax evasion are investigated. The causes and consequences of shadow economy are discussed and its measurement is given. The second aim of the chapter is to explore shadow economy and its causes in the EU-27. In line with these, both statistical and empirical relationships between shadow economy and various indicators are examined by using data from the period 2003-2012. The correlation between the shadow economy and some economic and governance related indicators are examined by employing scatter plots diagrams.

The last aim of the chapter is to explore the shadow economy in Turkey. The trend of the shadow economy in Turkey for the period 2003-2012 is given and a comparison with the EU-27 is made in order to have more rational inferences. The data of possible factors that cause shadow economy is compared with EU-27 averages. This chapter also presents a modest guide for policy makers as it relatively presents the effects of both economic and governance related indicators which would be beneficial while struggling with the shadow economy among the countries in question.

The chapter is organized as follows. It starts with the definition and some characteristics of the shadow economy and the impacts of shadow economy including both benefits and harms are also discussed. The causes and consequences of shadow economy are also given in that section. The following section investigates the measurement of the shadow economy and problems of data and measurement are given. In order to clarify the definition and structure of the shadow economy even further, its relationship with tax evasion is presented. The next section presents a detailed analysis of the shadow economy in the EU-27 and followed by an exploration of the structure of shadow economy in Turkey. The next section includes an empirical analysis which examines the relationship between shadow economy and its causes in the EU-27. Concluding remarks and views are provided in the last section.

## BACKGROUND

### Shadow Economy: Definition, Causes and Consequences

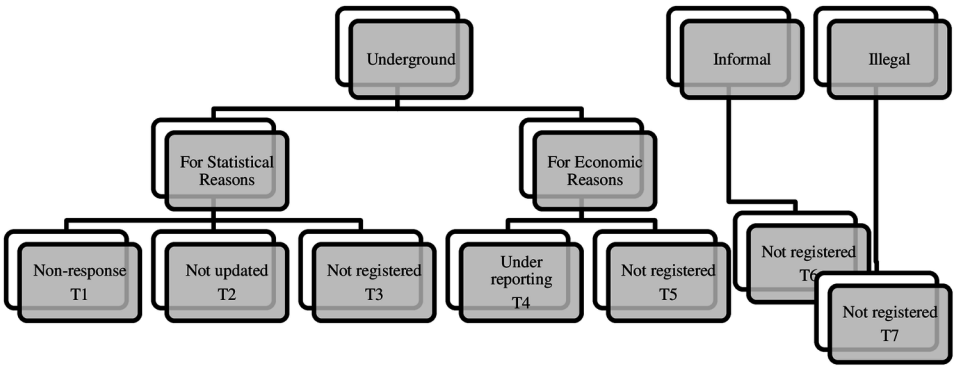
The shadow economy is one of the main problems of many countries in different forms and degrees. An important share of economic activities occurs in a shadow economy in both developed and developing countries. In addition, some economic problems such as the need for public finance, high unemployment rates, and budget deficit have increased the concerns about the shadow economy. However, a clear definition of shadow economy has not yet been formulated. Schneider and Enste (2000, p. 78) stated one commonly used definition of the shadow economy as "all economic activities that contribute to the officially calculated (or observed) gross national product but are currently unregistered." Choi and Thum (2002, p. 2) states that in simple term the shadow economy "constitutes activities that are not recorded in the government statistics."

Economists usually use different terms such as "shadow economy," "underground economy," "informal economy" or "hidden economy" without always clarifying what they mean. The OECD handbook for "Measuring the Non-Observed Economy" (2002, p.36) is a beneficial source that shed some light on the definition of shadow economy and its relationship with some other non-observed economic activities. The handbook states that "the groups of activities most likely to be non-observed are those that are underground, illegal, informal sector, or undertaken by households for their own final use." And "the deficiencies in the basic data collection program" are also admitted as being a part of non-observed economy.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Accordingly, non-observed economy consists of five main areas: (i) underground production; (ii) illegal production; (iii) informal sector production; (iv) household production for own final use; and (v) production missed due to deficiencies in data collection program[1].

The shadow economy takes part in a non-observed economy and is especially related to underground and informal economy and usually considers T4, T5, and T6 in Figure 1 which is solely the economic part of the non-observed economy (Garvanlieva, Andonov, & Nikolov, 2012, p.8).



The shadow economy is usually related to low income levels; however, it is not a set of survival activities performed by destitute people. Yet, in some situations the shadow economy has been intertwined with the formal economy. Individual workers may switch between the two sectors even during the same workday. Thus, the shadow economy is not an individual condition, but rather a process of income-generation characterized by one feature: it is unregulated by the institutions of the society, in a legal and social environment in which similar activities are regulated (Castells & Portes, 1989, p. 12).

We can define some special characteristics for shadow economy by benefiting from related literature. First, the shadow economic activity must create economic value. However, it is not a sufficient condition in order to qualify an economic activity as shadow economic activity because shadow economic activities are not included in national accounts (Danopoulos & Znidaric, 2007, p.70), and government fails to measure actual volume of production activities. Even if labor force shifts from shadow economy to formal sector, measure of Gross Domestic Product (GDP) growth rates will be misleading.

Because the increase in growth rate has been caused by decreasing shadow economy, and the real growth in total income has been considerably smaller than indicated by the GDP (Feige, 1979; Petersen, Thiessen, & Wohlleben, 2010, p. 425). Secondly, as shadow economic activities cannot be observed and reported to governmental organizations, they do not constitute a tax base for government. Thus, while shadow economic activities increase net real income of workers, they distort government revenues and increase tax burden on the official sector. Thirdly, shadow economic activities are irregular. There are no rules for shadow economic activities such as minimum wage standard or job security, and workers in the shadow economy cannot benefit from various opportunities such as retirement benefits and health insurance.

Another feature of the shadow economy concerns the characteristic of labor. Workers usually receive fewer benefits or less wage accompanied with worse working conditions and these characteristics can be subsumed under the general heading of "*down-graded labor*" (Castells & Portes, 1989, p. 26). And

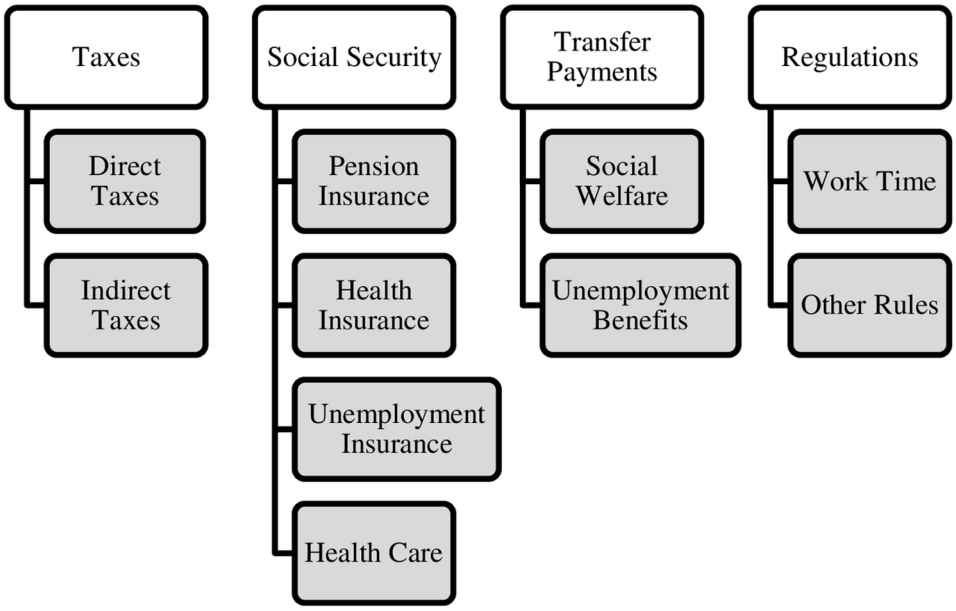
last, although the shadow economy is irregular and not included in national accounts, as Castells and Portes (1989, p. 26) suggested "it is an integral component of total national economies, rather than a marginal appendix to them." Thus, shadow economy and formal economy seems to have a systemic connection. The causes of shadow economy are not clearly defined, and there are different views about them. Schneider and Enste (2002) divided the economic causes of shadow economy into four groups: taxes, social security, transfer payments and regulations.

High tax rates are seen as one of the main causes of the shadow economy in a number of studies such as Schneider (1986, 2005, 2007), and that inference may be related to the inverse U shaped Laffer-Curve (Laffer, 1979, p. 75) which shows the relationship between tax rates and tax revenues. Accordingly, increasing tax rates will increase tax revenues; however, this is valid only up to a certain maximum tax rate level. Increasing tax rates beyond this level will result in tax evasion and avoidance and hence decrease in tax revenues. Gutmann (1981) modified the Laffer-Curve by including the shadow economy. For the economy consisting of the public sector, the official sector, and the shadow economy, he suggests that increasing tax rates beyond a certain level will result in a growing shadow economy. Indeed, as Petersen, Thiessen and Wohlleben (2010, p. 422) suggest, increasing burdens of direct and indirect taxes have created incentives to reduce labor supply and consumption in the official markets as governments often consider observable income and consumption as the major taxation base of the state.

Social security and transfer payments are seen as another main cause of the shadow economy as they break down the working incentives of people by guarantying a certain standard of living without any working obligation. In addition, Schneider and Enste (2002, p. 123) suggest that one of the incentives for transfer payment recipients to work illicitly is the increase in opportunity in finding a future regular job through contacts made during this occupation. The regulations especially aimed at labor markets create working disincentives for both employers and employees in the official sector, by increasing costs (Schneider, Buehn, & Montenegro, 2010, p. 445). Similarly, regulations about production such as license fees and registration requirements will increase production costs and tend people to work in shadow economy. Schneider (2012, p. 13) highlights that transition countries have higher levels of regulation and, hence, a higher shadow economy. Figure 2 gives an overview of the economic causes.



Besides tax and social security burdens, Dreher, Kotsogiannis, and McCorriston (2005, p. 2) suggest there is another school of thought that identifies institutional bureaucracy, regulatory discretion, corruption and weak legal system as the main causes of the shadow economy. Danopoulos and Znidaric (2007, p. 71) point to the fact that weak state institutions, official corruption, anemic or inconsistent law enforcement, and lack of political will on the part of the political system attract potential law breakers. There are a number of studies (Dreher, Kotsogiannis, & McCorriston, 2005; Torgler & Schneider, 2007a; Karlinger, 2009) which test the relationship between those factors and shadow economy empirically. Of those, Dreher, Kotsogiannis, and McCorriston (2005) and Torgler and Schneider (2007a) suggest that increase in institutional quality leads to a smaller shadow economy. Karlinger (2009) points to the effect of competition on shadow economy in countries having a different size of corruption.

Last, the volume of the shadow economy is affected by some macroeconomic variables such as inflation, unemployment, per capita income, and income equality. In addition, economic instability, uncertainty, and low standard of living increase tendency of people to work without records. Moreover, Castells, and Portes (1989, p. 28) point to the effects of international competition. Domestic production cannot compete with imports from countries which have low labor costs. This will inevitably tend domestic firms to either close down or to operate in the shadow economy.

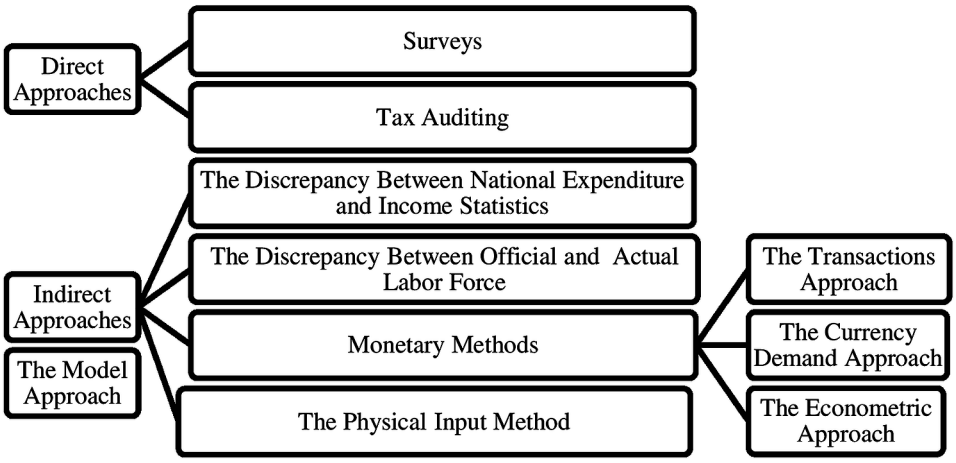
*Figure 2. Economic causes for the shadow economy*
*Source: Schneider and Enste (2002, p. 104).*

There are contradicting arguments about the effects of the shadow economy on overall economy and the basic arguments for and against it can be summarized as follows. The supporters of shadow economy argue that governments sometimes indulge in excessive and wasteful spending and also establish unnecessary and inefficient regulation in the economy. Shadow economy that arises from high tax rates makes governments to realize that there is a limit for how much they can spend (Spiro, 2005, p. 180). Another advantage of the shadow economy arises if there are many unnecessary and inefficient regulations. The shadow economy reduces the cost of bureaucracy and labor which in turn contribute to growth. As it decreased labor costs and creates new job opportunities, the shadow economy serves to decrease unemployment, thus forcing the official sector to reduce costs and improve quality due to competition.

However, the shadow economy contains some disadvantages. If tax revenues are decreased by tax evasion arising from high tax rates, governments may choose to increase tax rates in order to increase revenues. This policy will result in increasing tax burden on the formal sector and distort taxation justice. In addition, the shadow economy makes statistics less reliable and this may lead to incorrect economic policies. Danopoulos and Znidaric (2007, pp. 71-72) states the shadow economy renders government fiscal policy ineffective due to uncertainty about the actual amount of revenue. Last, as the shadow economy is easy to operate in small scaled firms, it is usually unproductive and less efficient.



## How to Measure the Shadow Economy?

As mentioned in the previous section, the shadow economy is a critical issue and its incorrect measurement will distort the effectiveness of economic policies. As the size of shadow economy is still an unresolved issue, there are also difficulties in measuring it. Figure 3 gives the summary of all approaches including sub-categories.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 3. A summary of approaches to estimate the size of shadow economy*
*Source: Frey and Pommerehne (1984), Schneider and Enste (2000), and Schneider and Enste (2002).*

Direct approaches are microeconomic approaches which depend on either surveys or samples based on voluntary replies, or tax auditing and other compliance methods. Direct approaches provide detailed information on the structure of the shadow economy. The main disadvantage of this method is its dependency upon the individuals questioned. The individuals in the sample may not reflect the whole population and they may prefer to hide their behaviors. Moreover, even if individuals in the sample are honest, they may be uninformed about the shadow economy and the results are sensitive to their understanding. Some kind of household production may be mistaken as shadow economic activities (Petersen, Thiessen, & Wohlleben, 2010, p. 432).

The results of direct approaches are also sensitive to the feature of the survey. Isachsen and Strom (1989) found out that almost twice as many people admitted to operating in shadow activity by mail after being interviewed. Direct approach is also leads only to point estimates and is unable to provide estimates of the shadow economy over a longer period of time. Isaschsen, Knovland, and Strom (1982), Isaschsen and Strom (1985), Mogensen, Kvist, Kormendi and Pedersen (1995), and Feld and Larsen (2005, 2008, 2009) are examples of studies which employ sample surveys in order to measure shadow economy (Schneider & Enste, 2000, pp. 91-92; Schneider, 2014, p. 10).

Indirect approaches are macro-economic in nature which use different indicators in order to measure the shadow economy. Four indirect approaches are commonly used: the discrepancy between national expenditure and income statistics, the discrepancy between the official and actual labor force, monetary methods and physical input approach. The first approach is based on the presumption that the discrepancy between the expenditure and income reflects the shadow economy. However, Frey and Pommerehne (1984, p. 6) point to many other factors influencing the national accounts calculations. The discrepancy between expenditure and income may reflect omissions, errors and tax authorities' behavior. In that context, results are not completely reliable.

Measuring the shadow economy by the discrepancy between the official and actual labor force is based on the idea of a decline in labor force participation will reflect an increase in the shadow economy. However, Schneider and Enste (2002, p. 17) suggest that differences in the rate of participation may also have other causes and individuals may simultaneously work in both official sector and shadow economy.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, the estimation results of this approach are not completely reliable. Monetary approach is based on the assumption that shadow economic activities are usually settled by paying cash. This assumption is reasonable as transactions paid in cash are easy to be hidden from fiscal administrations. Schneider and Enste (2002, p. 17) suggest that "if the demand for cash rises above the 'normal' relative or absolute value, one concludes that shadow economic activities are increasing." And, if the amount of currency used to make hidden transactions can be estimated, then it could be multiplied by the income-velocity of money in order to get a measure of the size of the shadow economy (Ahumada, Alvaredo, & Canavese, 2008, p. 97).

The size of shadow economy can be measured by monetary approach with three different methods: fixed ratio approach, transactions approach, and econometric approach. The first method assumes that the ratio between currency demand and money is fixed and the excess currency may reflect the size of shadow economy. This approach is first used by Cagan (1958) and it followed by Gutmann (1977) and Tanzi (1980). While Gutmann (1977) used statistical analysis, Tanzi (1980) estimated a currency demand function econometrically. The currency demand approach is employed by later studies (Tanzi, 1983; Bhattacharyya, 1990, 1999) and became the most commonly used methods. However, it has been criticized for the following reasons. Factors that cause shadow economic activity other than tax burden are ignored and, moreover, the assumption of equal velocity of money for both types of economies is suspicious. In addition, cash is not spent in the shadow sector only, but in the official sector. Therefore, the cash circulation in the shadow economy is much lower than in the official sector. However, shadow economic activities are usually paid immediately because of distrust, so money circulation in shadow sector may be faster than in the official sectors, too (Petersen, Thiessen & Wohlleben, 2010, p. 434).

The transactions approach was first developed by Feige (1979). This approach is based on an assumption that the relationship between the volume of transaction and money is constant over time. If this relationship holds, then the total stock of money gives an indication of total transactions in both the official and hidden economy. Relating total nominal Gross National Product (GNP) to total transactions, the hidden economy's GNP can be derived residually by subtracting officially measured GNP from total GNP (Frey & Pommerehne, 1984, p. 6).

The last monetary approach is the econometric approach. As there are a number of factors that affect currency demand other than shadow economy, recent studies have intensified effort to control these factors and ensure that the "extra" currency can really be attributed to the working of the underground economy (Frey & Pommerehne, 1984, p. 10). This approach is pioneered by Tanzi (1980) and Klovland (1980) and followed by some later studies (Tanzi, 1983; Isachsen, Klovland, & Strom, 1982; Langfeldt, 1982). It is assumed that shadow economic activities are paid for in cash and the velocity of money in both shadow and official sector are assumed to be equal. The main cause of shadow economy is assumed to be taxation and the discrepancy between currency demand with and without taxation is employed in order to measure shadow economy. However, this approach has been criticized for its unrealistic assumptions.

The last indirect measurement method which is the physical input method can be divided into two different methods. The first method is *Kaufmann-Kaliberda Method* and it is based on the assumption that electricity consumption is the single best physical indicator of overall economic activity (Kaufmann & Kaliberda, 1996). By employing electricity consumption they estimate a proxy for the overall economy and compare it with the official statistics. The difference between the growth of official GDP and the growth of electricity consumption is attributed to the growth of the shadow economy. However, it has also been criticized because all economic activities does not require electricity consumption. In addi-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion, technical progress has been ignored and there may be considerable differences in the elasticity of electricity/GDP across countries or changes over time (Schneider & Enste, 2000, p. 96).

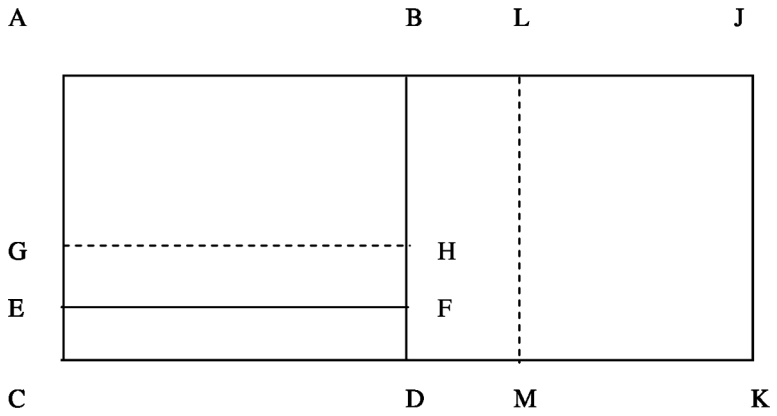
The second physical input method is the *Lacko Method.* In this method, it is assumed that a certain part of the shadow economy is associated with the household consumption of electricity. In order to measure the actual size of shadow economy, one should know how much GDP is produced by one unit of electricity in the shadow economy of each country. However, as it is not known, she takes the result of the known shadow economy and applies it to the other countries. This method again has been criticized because it only considers the shadow economy occurring in the household sector and as it employs a base value for shadow economy the results may not be reliable (Schneider & Enste, 2002, pp. 23-24).

The last approach in order to measure the shadow economy is the model approach. Direct and indirect approaches assume that only one indicator reflects the size of shadow economy, however the shadow economy is affected by various factors. The model firstly links the unobserved variables to observed indicators and the model approach considers the multiple causes that contribute to the growth of the hidden economy as well as its multiple effects (Karaboytcheva & Andrada, 2012, pp. 168). Secondly, the casual relationships among the unobserved variable (the shadow economy) are specified (Schneider & Enste, 2000, p. 98). In summary, there are various methods that can be used to measure the shadow economy and each of them has their own advantages and disadvantages.

## MAIN FOCUS OF THE CHAPTER

### Shadow Economy and Tax Evasion: Distinctions and Linkages

The shadow economy and tax evasion are related concerns, but the linkages and distinctions between them have to be clarified. We can start by mentioning different sectors in which productive activities take place. Human productive activities[2] are taking place in the household sector, the market sector, and the shadow economy. Figure 4 represents different types of economic sectors. The right rectangle (MKJL) represents the subsistence economy or household production. Household production is exemplified by Ironmonger (1999, p. 3) as the provision of meals, child care, clean clothes, accommodation, shopping, voluntary work and self education. The left rectangle (ABCD) represents the market sector or formal sector which consists of public and private sector and the rectangle (BLDM) which is between market production and household production represents the shadow economy.



In the System of National Accounts (SNA) literature, household production together with shadow economy is considered as informal sector (BDKJ). However, household production was almost neglected in theoretical and empirical economics (Petersen, Thiessen, & Wohlleben, 2010, p. 425).

As the income from the shadow economy and household sector is unobservable, only the market income remains as a base for taxation. However, people may earn a remarkable amount of income from these sectors, so they must also be considered. Due to difficulties in determining these income generating activities, tax burden usually falls on the formal sector. In that context, increasing tendency of tax evasion may lead people from the official sector to the shadow economy again. Therefore, the shadow economy and tax evasion are interpenetrating subjects. Nevertheless, the informal sector, which consists of the shadow economy and household production is not the only source of tax evasion and tax avoidance[3].

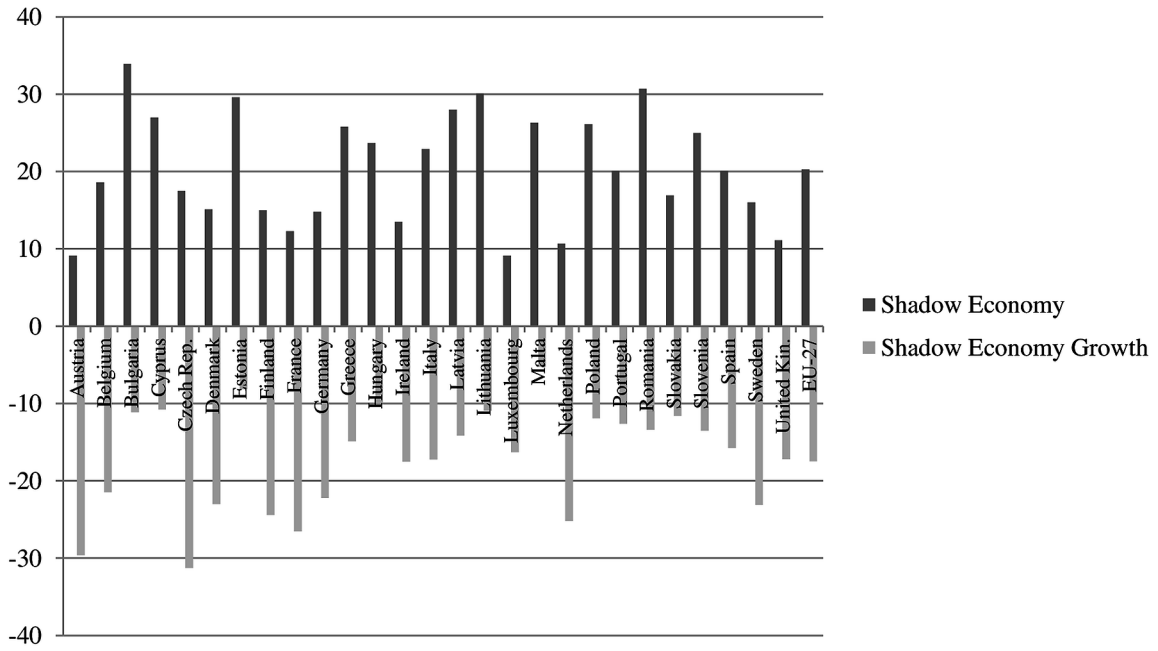
EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 4. Components of total income or wealth*
*Source: Petersen, Thiessen & Wohlleben (2010, p. 425).*

In Figure 4, one part of the market sector is legally withdrawn from the income tax base due to the existing tax allowances and exemptions (CDEF) while another part is illegally withdrawn from the income tax base (EFGH) in favor of tax evasion. This part (EFGH) is measured in the SNA, but not reported to the fiscal administration. The tax base here is hidden from tax authorities by underreporting incomes or overvaluing costs. A number of economic agents prefer this method in order to reduce production costs. Therefore, the size of tax distortion arising from formal economic activities is tidy.

However, many individuals engage in shadow economy depending on some reasons other than evading taxes. These reasons which have been discussed previously may include the intensity of regulations, distrust of public authority, dissatisfaction of public services and institutional quality, and avoiding international competition (Castells & Portes, 1989; Schneider & Enste, 2002; Dreher, Kotsogiannis, & McCorriston, 2005). In addition, Sam (2010, p. 168-172) suggests that while attempts to reduce shadow economy contribute to the government's revenue, measures to reduce tax evasion do not necessarily reduce tax evasion from the shadow economy. He also pays attention to the difference between taxable income and non-taxable income in the shadow economy. Accordingly, all economic activities are not taxable for example small enterprises are hardly taxed because their income is often below the tax threshold income level. In conclusion, tax evasion and shadow economy are intertwined; however, they do not reflect exactly same subjects.

## The Shadow Economy and Causes in The EU-27



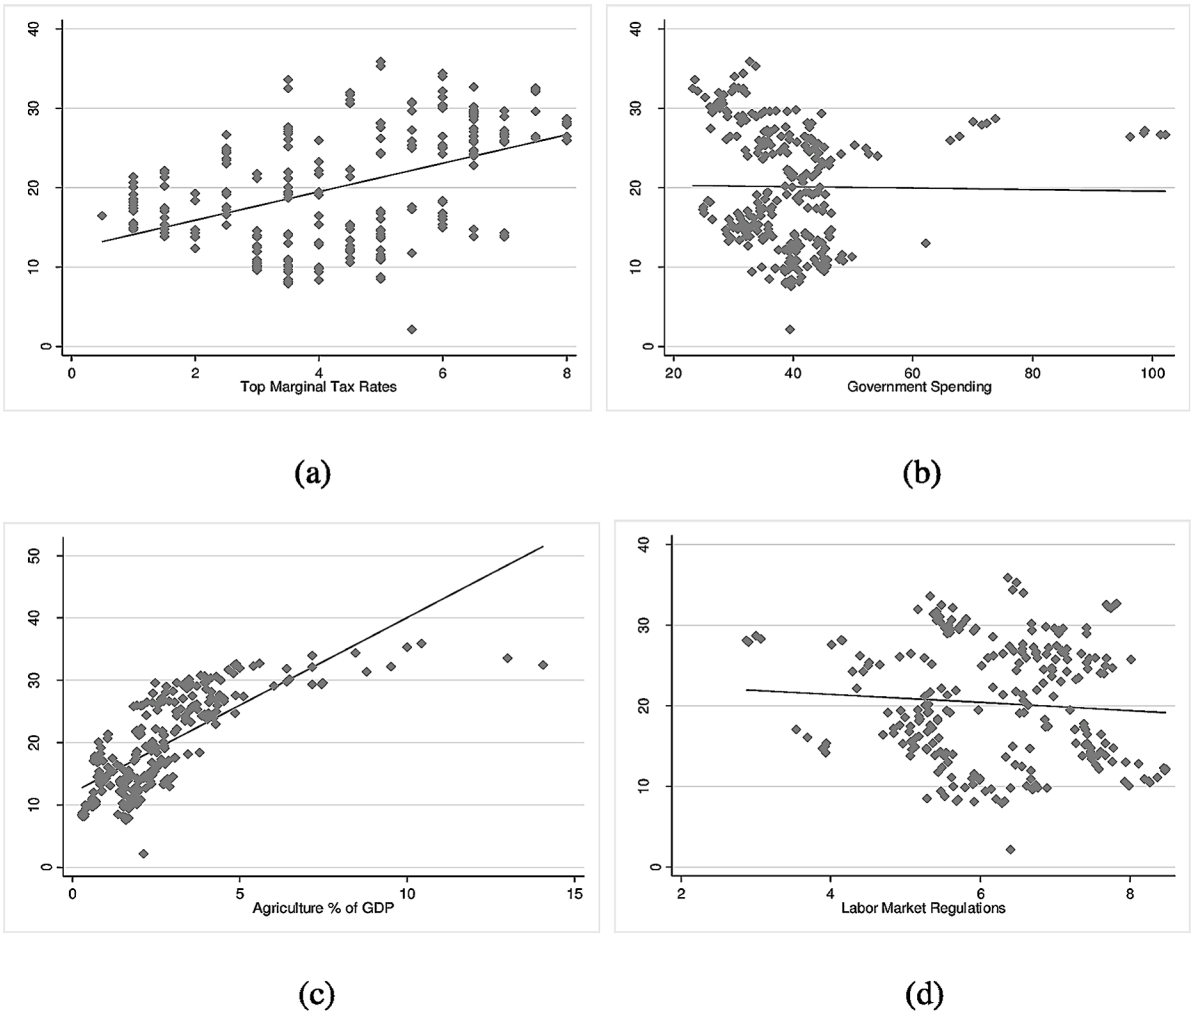
The shadow economy is sometimes perceived as the problem of developing countries; however, it is still a worthwhile issue for developed countries. On average across the EU-27, the shadow economy is as large as 18.4% of the economic activity in 2012 (Schneider, 2013). Figure 5 shows the size of shadow economies in 2012 and growth rates of shadow economy during the period 2003-2012 in the EU-27 countries.

As can be seen in Figure 5, Bulgaria (33.9%), Romania (30.7%), and Lithuania (30.1%) have the largest shares, while Austria (9.1%), Luxembourg (9.1%) and Netherlands (10.7%) have the smallest size of shadow economies. In general, the share of shadow economy increases from West Europe to East Europe. Overall, the EU-27 countries have negative growth rates for shadow economy, so size of shadow economies are decreased during 2003-2012 in all EU-27 countries. However, the size of shadow

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 5. Shadow economy (in % of official GDP (2003-2012 Averages)) and shadow economy growth (2003-2012) in EU-27*
*Source: Schneider (2013).*

economy in EU-27 is 20.3% of the official economy on the average which can still be interpreted as a high percentage rating. As the structure and the size of shadow economies vary in different EU-27 countries, different policy measures have been used in order to reduce the size of shadow economy. These policy measures include improved detection, increased penalties, promoting benefits of formal work etc. and more detailed information about some specific measures can be found in Eurofound (2008, 2009), Jensen and Wohlbier (2012), Packard, Koettl, and Montenegro (2012) and Schneider and Williams (2013).



Different points such as government expenditures, tax burden, regulations, and institutional quality were listed as causes of shadow economy in the previous section. These factors are examined here to locate the main causes of the shadow economy in the EU-27, while scatter plots diagram is employed in order to observe the relationship between shadow economy and the other causes in question by using 2003-2012 data. As high tax burden is admitted as one of the main causes of the shadow economic activities, the correlation between top marginal tax rates and shadow economy is handled first. Although the relationship does not appear strong, a positive relationship is observed between top marginal tax rates and the size of shadow economy (Figure 6a). Therefore, countries with higher top marginal tax rates have larger size of shadow economies which is also consistent with our previous debates.

One of the other main causes of the shadow economy is huge government expenditures. It was mentioned above that the tendency to shadow economy may be caused by some kind of protest of people who think that government expenditures are excessive and wasteful. There seems no correlation between shadow economy and government spending (Figure 6b). Even so, Cyprus and Malta, both which have the highest government spending, face a high shadow economy. An interesting relationship is observed for

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 6. Scatter plots of shadow economy and some selected indicators*
*Sources: Fraser Institute (EFW, 2013), Schneider (2013), Heritage Foundation (2014) and World Development Indicators (WB, 2014).*

agricultural shares (Figure 6c). Accordingly, an increase in the share of agriculture in GDP is positively related to shadow economy but only up to a certain level. Beyond this level of agricultural share, the size of shadow economy seems uncorrelated with the agricultural share.

Additionally, it is worth mentioning that countries found in that region of the diagram which is denoted by largest agricultural share include Bulgaria and Romania, the two biggest shadow economies in the EU-27. Regulations especially related to labor markets are mentioned as important cause of shadow economy. The relationship between labor market regulations and shadow economy is observed to have weak correlation with the shadow economy (Figure 6d). Even Greece with lowest level of labor market regulations (4.34% for 2003-2012) still is one of the biggest shadow economies in Europe while the opposite is true for United Kingdom with highest level of labor market regulations (8.26% for 2003-2012).

Thus, labor market regulations are not a strong determinant of the shadow economy in the EU-27.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition to economic indicators such as taxes and expenses, the sectoral composition of the economy and regulations; indicators related to governance may be effectively based on the size of shadow economy. In that context, World Governance Indicators (WB, 2013) are employed here and the relationship between shadow economy and different governance indicators are observed. World Governance Indicators[4] include six main topics: control of corruption, political stability and absence of violence/terrorism, regulatory quality, rule of law, voice and accountability and government effectiveness[5]. The relationship between control of corruption and shadow economy is observed as negative (Figure 7a) and this finding is consistent with the expectations.

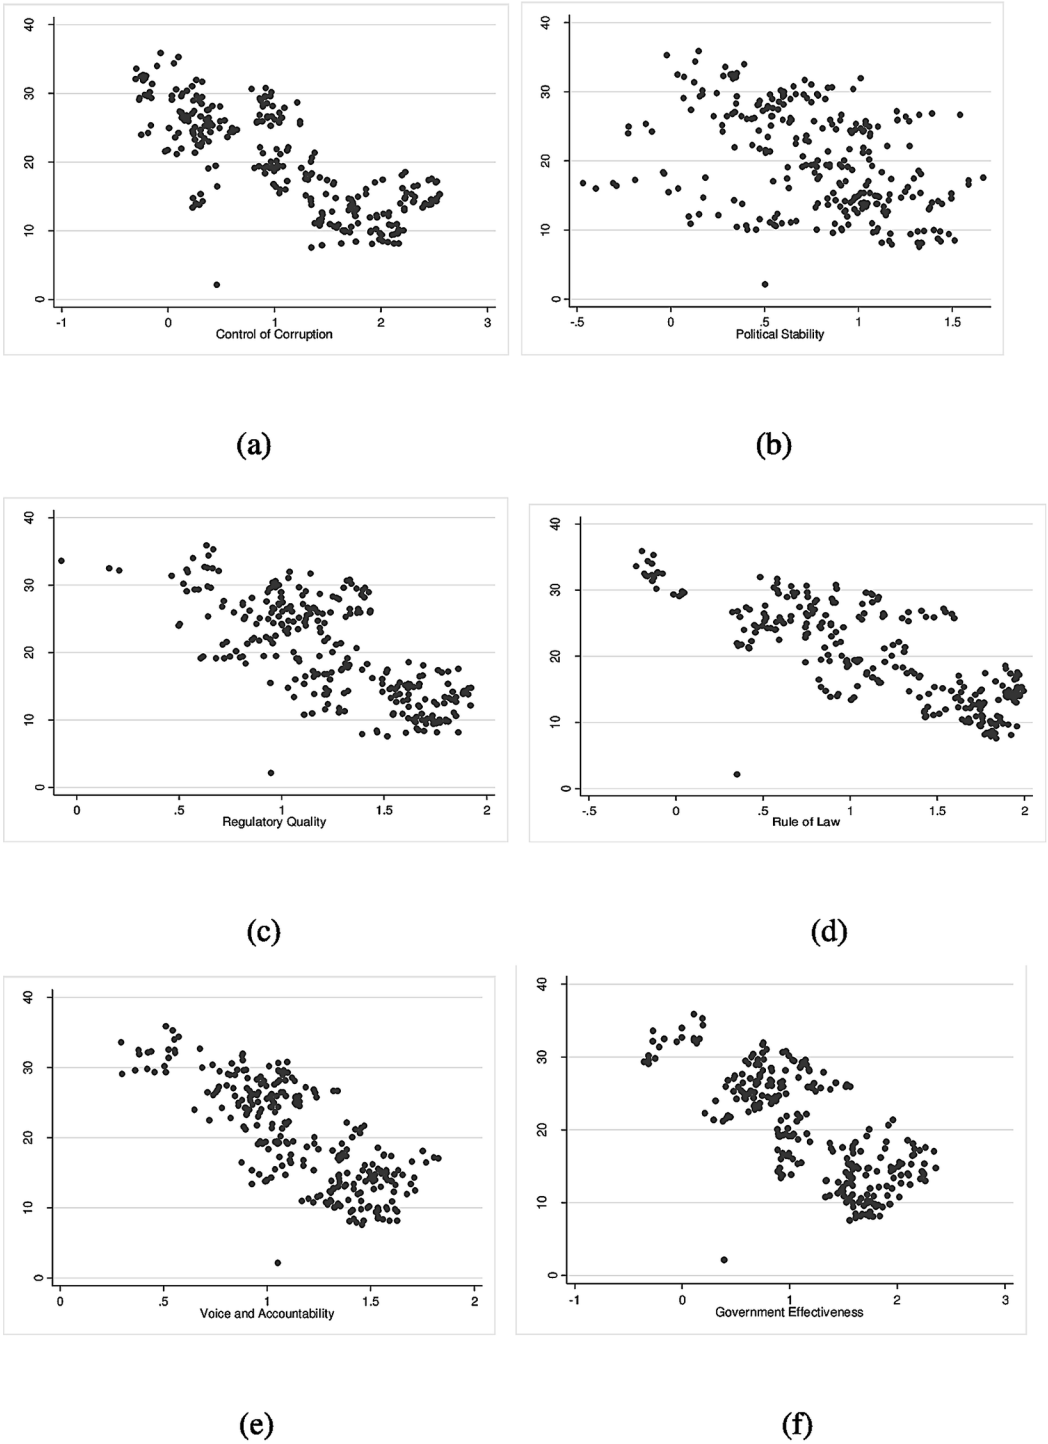
In addition, Bulgaria and Romania which have large size of shadow economies, are the two countries that have lowest index rates for control of corruption on average (-0.1467 for Bulgaria, and -0.2192 for Romania). Similarly Austria, Luxembourg, and the Netherlands with small size of shadow economies have high index rates for control of corruption on average (1.8403 for Austria, 1.9529 for Luxembourg, and 2.1151 for the Netherlands).

All of other governance indicators again have a negative relationship with the size of shadow economy in EU-27 (Figure 7). However, the correlations of some indicators are not so strong. The index of political stability and absence of violence/terrorism has the weakest relationship with shadow economy. On the other hand, stronger relationships are observed for rule of law, voice and accountability and government effectiveness in the EU-27 countries.

In summary, control of corruption, regulatory quality, rule of law, voice and accountability and government effectiveness were observed to have stronger relationships with the size of shadow economies in the EU-27 compared to the political stability indicator. In addition, they seem also more effective when compared to economic indicators - top marginal tax rates, government spending and labor market regulations. These findings are important with respect to policy making and dealing with indicators which have stronger correlations with the shadow economy and they are recommended as a weapon which can be used to fight against shadow economy in the EU-27.

## Some Notes on Shadow Economy in Turkey

Although Turkey managed to decrease the share of shadow economy to GDP especially after 2003, nevertheless it still maintains to be one of the main economic problems. Schneider (2013) estimated the share of shadow economy in 2012 (in % of GDP) as 27.2% which is higher than the EU-27 averages. Figure 8 shows the trend of the shadow economy in Turkey (in % of GDP) which is always higher than the EU-27 average. Although the shadow economy in Turkey is very large compared to the EU average, it is smaller than the EU-27's largest shadow economy – Bulgaria. Nevertheless, this does not mean that shadow economic activities in Turkey are low. Especially in recent years, several measures have been taken effect such as "KADIM - The Project of Struggling Against Informal Employment" by the Ministry of Labor and Social Security and "The Action Plan of Struggling Against Shadow Economy" by the Finance Ministry[6]. In addition to some other ministries, governmental and sometimes non-governmental organizations also help to serve combating shadow economy.



When we further make comparisons for tax evasion, a worse situation is observed in terms of Turkey. Figure 9 shows the trend of tax evasion (in % of GDP) in Turkey and the EU-27.

Although Turkey managed to decrease the share of tax evasion up to the global 2008 crisis, it started to increase again after that date depending on high inflation and decrease in the purchasing power of individuals. The difference between tax evasion shares of Turkey and Luxembourg which has lowest

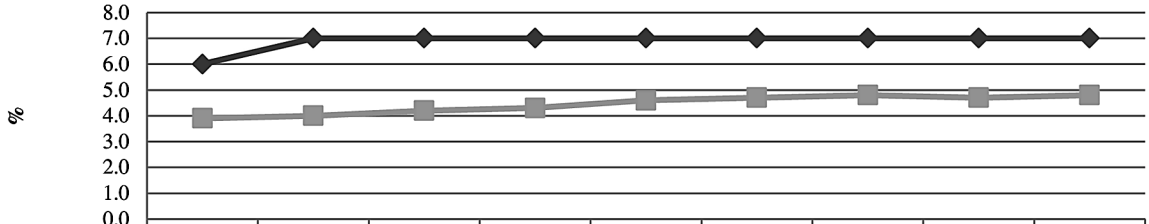
| Luxembourg | 1.4 | 1.4 | 1.4 | 1.3 | 1.2 | 1.1 | 1.0 | 1.2 |
| Turkey | 7.5 | 7.1 | 6.8 | 6.3 | 5.7 | 5.3 | 5.3 | 5.7 |
| EU-27 | 3.6 | 3.5 | 3.4 | 3.2 | 3.9 | 2.7 | 2.6 | 2.8 |



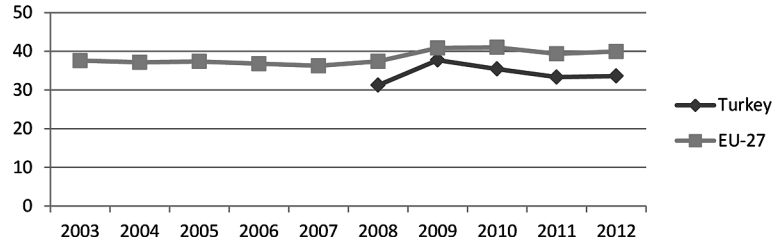
level of tax evasion share (as an average for the period of 2003-2012) seems worthwhile. In addition, average tax evasion in Turkey is higher than the EU-27 average and Romania which has highest level on average. The causes of the shadow economy in the EU-27 are examined by using scatter plots diagrams in the previous section, however as there is no large scale of data, this method is not preferred for Turkey. The magnitudes and trend of possible causes are rather compared with EU-27 averages. Figure 10 shows top marginal tax rates for Turkey and the EU-27. While EU-27 countries have a top marginal tax rate of 4.44% on average, the rate is 6.88% in Turkey.

Additionally, rates are always higher than in the EU-27 within the period 2003-2012. However, it is worth noting that the situation differs when tax revenues as a share of GDP is employed. After a change in budget system in Turkey in 2006, tax revenues as a share of GDP become 19.77% (WB, 2014) on average (2003-2012). However, tax revenue share of the EU-27 is 26.65% on average, which is higher than in that of Turkey. One must also note that the composition of taxes have to be considered in order to talk about the effects on the shadow economy.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 10. Top marginal tax rates in Turkey and EU-27 during 2003-2012*
*Source: Fraser Institute (EFW, 2013).*

| | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 |
|---|---|---|---|---|---|---|---|---|---|
| Turkey | 6.0 | 7.0 | 7.0 | 7.0 | 7.0 | 7.0 | 7.0 | 7.0 | 7.0 |
| EU-27 | 3.9 | 4.0 | 4.2 | 4.3 | 4.6 | 4.7 | 4.8 | 4.7 | 4.8 |



Indirect taxes may increase the size of shadow economy as they are more difficult to be retained and controlled. Furthermore, high indirect tax rates in some commodities such as cigarettes, alcohol and fuel oil may encourage smuggling thereby deepening the problem of shadow economy. In EU-27 the share of direct and indirect taxes are quite similar in recent years: the share of indirect taxes as a percentage of total tax burden is 34.5% and the share of direct taxes as a percentage of total tax burden is 33.2% in 2011 (EC, 2013, p. 178-188). However, tax revenues in Turkey depend heavily on indirect taxes. While the share of direct taxes to tax revenues is 32.2%, the share of indirect taxes was 67.6% in 2011. Thus, in Turkey, the composition of taxation may be more explanatory for the shadow economy than its magnitude.

Figure 11 shows the trend of government spending as a share of GDP in Turkey and the EU-27. Figure 11 shows that rates in Turkey are lower than in the EU-27. Considering the weak relationship between government spending and the shadow economy in the EU, it may be suggested that the main cause of shadow economy in Turkey is not government spending.

A weak relationship was observed between labor market regulations and shadow economy in the EU-27. The index rates in Turkey are far below that of EU-27 averages for the period of 2003-2012 (Figure 12). Moreover, the average rate of Turkey which is 4.36% close to the rate of a country which has lowest rate in the EU-27: Greece 4.34%. Thus, the size of labor market regulations does not seem be an important cause of shadow economy in Turkey just as in the EU-27.

Factors related to governance seem quite important for Turkey. Figure 13 shows World Governance Indicators in Turkey and EU-27 as an average for the period of 2003-2012. As can be seen from the figure the quality of governance in Turkey is quite different from the EU-27.

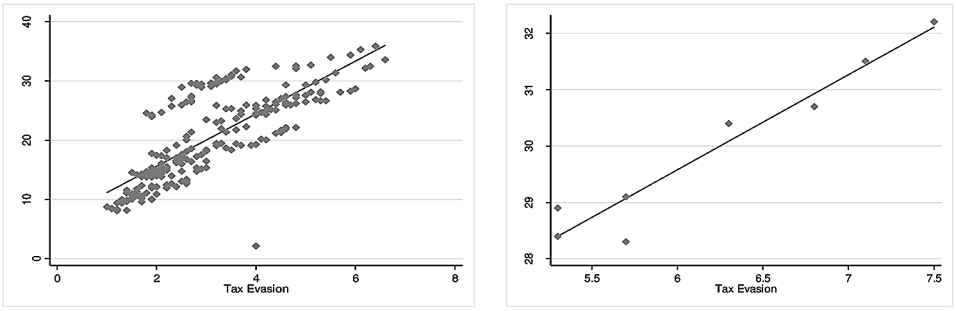
| EU-27 | 5.8 | 5.9 | 6.0 | 6.1 | 6.2 | 6.2 | 6.6 | 6.5 | 6.7 |

*Figure 13. World governance indicators in Turkey and EU-27 as an average of the period 2003-2012*
*Source: World Governance Indicators (WB, 2013).*

All of these indicators have a lower index in Turkey. Even the signs of political stability and absence of violence/terrorism and voice and accountability indexes are negative on the average. The correlation between governance indicators and shadow economy was found to be stronger than economic causes for the EU-27. The effect of these factors may be more severe in Turkey, where a lower level of governance quality is operational. Thus, Turkey has to increase voice and accountability, control of corruption, regulatory quality, government effectiveness and political stability in order to struggle with the shadow economy.

Last, the correlation between tax evasion and shadow economy is examined in the EU-27 (Figure 14a) and Turkey (Figure 14b) by using scatter plots diagram. As can be seen from the figure shadow economy and tax evasion are positively related and the correlation between them seems strong for both the EU-27 and Turkey.



## An Empirical Analysis for EU-27

The causes of shadow economy are discussed in previous sections both theoretically and statistically. In this section, we tried to discover some empirical evidence about the determinants of shadow economy in EU-27. For this purpose, three different econometric models are employed and variables are determined in accordance with Torgler and Schneider (2007a, 2007b), Schneider (1997, 2005), and Schneider, Buehn and Montenegro (2010).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 14. Scatter plots of shadow economy and tax evasion in Turkey and EU-27 for the period of 2003-2010*
*Source: Schneider (2013).*

**(a)** **(b)**

**M1:** $SHADOW_{it} = \beta_0 + \beta_1 TAXE_{it} + \beta_2 LOGGDPPC_{it} + \beta_3 LOGLABOR_{it} + \beta_4 AGR_{it} + \beta_5 LOGPOP_{it} + e_{it}$

**M2:** $SHADOW_{it} = \beta_0 + \beta_1 TAXE_{it} + \beta_2 LOGGDPPC_{it} + \beta_3 LOGLABOR_{it} + \beta_4 AGR_{it} + \beta_5 LOGPOP_{it} + \beta_6 TRADE_{it} + e_{it}$

**M3:** $SHADOW_{it} = \beta_0 + \beta_1 TAXE_{it} + \beta_2 LOGGDPPC_{it} + \beta_3 LOGLABOR_{it} + \beta_4 AGR_{it} + \beta_5 LOGPOP_{it} + \beta_6 TRADE_{it} + \beta_7 ECOFR_{it} + e_{it}$

where $SHADOW_{it}$ is the shadow economy as a percentage of official GDP, $TAXE_{it}$ is the tax evasion as a percentage of GDP, $LOGGDPPC_{it}$ is the log GDP per capita (constant 2005 US dollars), $LOGLABOR_{it}$ is the log of labor force participation rate as a percentage of total population within the age range of 15-64, $AGR_{it}$ is the agriculture value added as a percentage of GDP, $LOGPOP_{it}$ is the log of total population, $TRADE_{it}$ is the trade as a percentage of GDP and $ECOFR_{it}$ is the index of economic freedom.

## Data and Hypothetical Expectations about Coefficients of Variables

The data of GDPPC, LABOR, AGR, POP and TRADE is obtained from World Development Indicators 2014 database (WB, 2014). The data of SHADOW and TAXE is obtained from Schneider (2013). The data of ECOFR is obtained from the 2014 Index of Economic Freedom of Heritage Foundation. The index has four different components: rule of law, government size, regulatory efficiency and market openness[7].

The variable TAXE is expected to have an impact on shadow economy. The data is presented by Schneider (2013) accounts for indirect taxation and self employment. The increasing size of tax evasion may have a negative impact on people that work in the formal sector and may lead them into shadow economic activities. Moreover, statistical data and correlation diagrams have revealed a strong and positive relationship. Thus, the coefficient of TAXE is expected to be positive.

The per capita income level of countries is considered to have an impact on the size of the shadow economy. Low income levels tend people to search for new alternatives. Furthermore, since finding a job in the shadow economy is easier and people already suffer from having low incomes after high taxes, they often are inclined to engage in shadow economic activities. Thus, the coefficient of LOGGDPPC is expected to be positive.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The other factors that may be effective on the size of shadow economy are the demographical factors. As the population increases, it becomes more difficult to sustain a certain standard of living. Moreover, as Bahl (2003, p. 13) suggests, tax systems may lag behind in the ability to capture new taxpayers in some fast growing populations and this may increase the incentives to work in the shadow economy. Thus, the coefficient of LOGPOP is expected to be positive.

The sectoral composition of the economy may have an impact on shadow economy, because the agricultural sector which is often based on self-employed activities is more appropriate to hide the actual income and evade taxes. In addition, if we assume that more agricultural share in GDP means lower income levels, then it will lead to the increase of shadow economy, as well. Thus, the coefficient of LOGGDPPC is expected to be negative.

Torgler and Schneider (2007a, p. 19) indicate that individuals with an occupation have less leisure time at their disposal and, thus, time acts as a restriction to being active in the shadow economy (Schneider & Enste, 2002). Thus, the coefficient of LOGLABOR is expected to be negative. In models (2) and (3), the effect of trade on the size of shadow economy is measured. As hiding activities in trade is more difficult, the coefficient of TRADE is expected to be negative.

Last, in model (3) the effect of the economic freedom on the size of shadow economy is tested. The detail about the index of economic freedom has been supplied previously. Higher economic freedom represented by the variable ECOFR is expected to have a negative impact on the size of shadow economy.

## EMPIRICAL RESULTS AND RECOMMENDATIONS

In this section panel data analysis is employed in order to test the relationship between shadow economy and various indicators in the EU-27 over the period 2003-2012. First, unit and/or time effects are tested using F and LR Tests in order to check the validity of the pooled regression which ignores the panel structure of the data and assumes that coefficient parameters are constant over time and for all units. The estimation results of the tests can be seen in Table 1.

*Table 1. The results of F and LR tests in order to test unit and/or time effects*

| **Model 1** | | **Test Value** | **d.f.** | **p-value** | **Result** |
|---|---|---|---|---|---|
| **LR TEST** | **Unit Effects** | 180.17 | 1 | 0.0000 | Unit effects exist. |
| | **Time Effects** | 0.00 | 1 | 1.0000 | No time effects |
| **F TEST** | **T/U Effects** | 21.20 | F(26,180) | 0.0000 | Time and/or unit effects exist. |
| **Model 2** | | **Test Value** | **d.f.** | **p-value** | **Result** |
| **LR TEST** | **Unit Effects** | 177.83 | 1 | 0.0000 | Unit effects exist. |
| | **Time Effects** | 0.00 | 1 | 1.0000 | No time effects |
| **F TEST** | **T/U Effects** | 20.42 | F(26,179) | 0.0000 | Time and/or unit effects exist. |
| **Model 3** | | **Test Value** | **d.f.** | **p-value** | **Result** |
| **LR TEST** | **Unit Effects** | 170.66 | 1 | 0.0000 | Unit effects exist. |
| | **Time Effects** | 0.00 | 1 | 1.0000 | No time effects |
| **F TEST** | **T/U Effects** | 19.36 | F(26,179) | 0.0000 | Time and/or unit effects exist. |

**Note:** Degrees of freedom in parenthesis.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In all three models, the F tests suggest that pooled regression is not appropriate as coefficient parameters differ according to time/unit effects. Similarly, LR tests suggest that there are unit effects in all models. Thus, the models have to be estimated with fixed effects or random effects model instead of pooled regression.

In the second step, the Hausman Test (1978) is employed in order to decide whether fixed effects or random effects model is suitable. The estimation results are given in Table 2. The test statistics indicate that random effects model is preferable in all of the models.

After determining which regression model to employ, the models were estimated with random effects model. Table 3 presents the estimation results.

As can be seen from Table 3, the coefficients of variables mostly meet expectations; however, the models have to be tested against econometrical problems. Based on this purpose, two common econometrical problems of panel data method - heteroscedasticity and autocorrelation - which may lead to efficiency problems are considered.

*Table 2. Hausman specification tests*

| | **Model 1** | **Model 2** | **Model 3** |
|---|---|---|---|
| **$X^2$(n)** | $X^2(5)=6.01$ | $X^2(6)=4.23$ | $X^2(7)=4.96$ |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In order to test for heteroscedasticity, the test of Levene, Brown, and Forsythe is employed, as it is suitable for random effects regression. In addition, Bhargava, Franzini, and Narendranathan's Durbin-Watson and Baltagi-Wu's Locally Best Invariant (LBI) Tests were employed in order to test for autocorrelation. The related results are given in Table 4.

Table 4. shows that there is a heteroscedasticity problem in all the three models, but there is no autocorrelation problem. Thus, we re-estimate the models of Huber, Eicker and White Estimator which gives robust variances in the case of heteroscedasticity. The robust estimation results are given in Table 5.

Table 5. shows that the coefficient of tax evasion has a positive sign and it is statistically significant at the 0.01 level in all the three models. Thus, in line with our expectations, higher tax evasion is associated with the larger size of the shadow economy. As tax evasion increases tax burden and the dissatisfaction of individuals in the formal economy increases, more people prefer to operate in the shadow economy.

*Table 4. Heteroscedasticity and autocorrelation tests*

| Tests | Model 1 | Model 2 | Model 3 |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The coefficient of LOGGDPPC is always significant and with an expected negative relationship. This relationship indicates that lower level of income meaning a low standard of living will promote shadow economic activities.

On the contrary to our expectations, the coefficients of LOGPOP always have a negative sign. As the sample constitutes of developed countries, the result is not so surprising. Most of the countries in the sample have already high national income and therefore high population may not mean low per capita incomes. In addition, the result is consistent with the finding of Torgler and Schneider (2007b).

The coefficients of LOGLABOR and AGR variables are found to be statistically insignificant thus, having no impact on the size of shadow economy. Similarly, ECOFR which represents economic freedom in Model (3) has no effect on shadow economy. Last, the higher TRADE is associated with lower shadow economy in all the three models and this result is consistent with our expectations.

In summary, the results of the three models suggest that tax evasion has a positive effect on shadow economy in EU-27 countries over the period of 2003-2012. Other determinants of the size of the shadow economy are per capita GDP, population and trade. Economic freedom category seems to have no effect on the size of the shadow economy. However, some of its components may be effective on the size of shadow economy as our statistical findings in previous sections suggests.

## FUTURE RESEARCH DIRECTIONS

The study tries to explore the determinants of shadow economy in the EU-27 and Turkey. As there are insufficient data, econometrical model cannot be estimated for Turkey. However, once the problem of data insufficiency is solved, econometrical analysis may be performed for Turkey. In addition, as the composition of taxation is quite different in Turkey as opposed to the EU-27, an econometrical model may be constituted considering different kinds of taxation such as taxes on income, taxes on wealth and taxes on consumption.

Statistical findings show that the quality of governance has a quite important effect on the size of shadow economy. The study employs economic freedom as an explanatory variable and not different components of governance are used in order to inhibit a decrease in degrees of freedom. However, having sufficient data, testing the effects of different governance related indicators may be worthwhile in future research.

## CONCLUSION

The shadow economy is one of the main economic problems of both developed and developing countries. However, there are difficulties in defining the shadow economy and its structure. Economists sometimes use different terms in literature without explaining what they really mean. OECD (2002) has a clear distinction about shadow economy and other non-observed economic activities. Accordingly, the non-observed economy consist of underground production, illegal production, informal sector production, household production for own final use, production missed due to deficiencies in data collection program, and the shadow economy is involved in the informal and underground economy.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The shadow economy is heavily related with tax evasion, and sometimes they are perceived as similar. Nevertheless, distortion in tax revenues does not always take place in shadow economy. Some kind of tax evasion together with tax avoidance arises in the formal sector. However, statistical and empirical findings suggest they are closely related. The size of the shadow economy in EU-27 is nearly 20% of the official sector during the period 2003-2012, and can be perceived as high. Yet, the size of the shadow economy in Turkey is more than that of the EU-27. Failure to decrease the size of shadow economy necessitates the determination of causes of the shadow economy and their relative effectiveness.

As both statistical and empirical findings of this chapter suggest, there are a number of economic and governance related factors that cause shadow economy and their relative effectiveness varies. Governance related indicators statistically seem more effective on the size of shadow economy as compared to economic indicators such as taxes and spending. Governments have to relate with improving their indicators about governance in order to achieve a decrease in shadow economy. Government effectiveness, accountability, rule of law and control of corruption are critical indicators in particular. To sum up, policy makers have to discern main causes of shadow economy and consider them while struggling with shadow economy.

## KEY TERMS AND DEFINITIONS

**Corruption:** An illegal and dishonest behavior displayed by public authority in order to get private gain.
**Efficiency:** Providing greatest amount of outputs with the lowest amount of inputs.
**Formal Sector:** Sector which generates income on which tax must be paid.
**Governance:** The action of governing.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

**Observable Consumption:** Consumption that is recorded officially by government and constitutes a tax base of the state.

**Observable Income:** Income that is recorded officially by government and constitutes a tax base of the state.

**Tax Evasion:** Illegal behaviors displayed by individuals (both in formal and informal sector) in order to get rid of tax responsibilities.

## ENDNOTES

1 For details see OECD (2002, pp. 37-41).

2 Ironmonger (1999, p.35) states that "Productive activities are those which result in the production of goods or the delivery of services, including goods and services that are not sold, and goods and services that are self-provided; includes preparation of meals, care of children and adults and time spent in educational activities."

3 According to Rosen and Gayer (2008) "Tax avoidance is altering behavior in order to reduce your legal tax liability, if contrast tax evasion is failing to pay legally due taxes" (pp. 370-372).

4 Estimate gives the country's score on the aggregate indicator, in units of a standard normal distribution, i.e. ranging from approximately -2.5 to 2.5 (WB, 2013).

# Chapter 83
# Nationalism and Patriotism in International Business

**Duane Windsor**
https://orcid.org/0000-0003-0406-1030
*Rice University, USA*

## ABSTRACT

*This chapter explores nationalism and patriotism in international business, with attention to implications for diplomacy and geopolitics. Globalization increases economic interactions across national borders through exports, imports, foreign direct investments, and mergers or acquisitions. The World Trade Organization aims at making this global system of economic interactions more protection free. Nationalism is domestic emphasis placed on the country's economic, political, and strategic interests. Nationalism views international business as a zero-sum competition. Patriotism is pro-national behavior of consumers, producers, and other business stakeholders, and also calls for such pro-national behavior. Nationalism and patriotism are partly reactions – varying considerably by country – to domestic effects of this globalization, markedly exacerbated by the unexpected financial crisis and ensuing severe economic recession that emerged in 2008 and continued into 2016. The chapter draws on extant literature to develop a more systematic understanding of nationalism and patriotism.*

## INTRODUCTION

This introductory section explains the perspective and structure of the chapter. The unexpected financial crisis and severe economic recession that suddenly emerged in 2008 and has continued into 2016 has brought about a revival of state protectionism across the globe. Two key dimensions of this revival of state protectionism are nationalism and patriotism. Both phenomena appear to be increasingly important as globalization affects countries, consumers, and producers (Christiansen & Koeman, 2015). This chapter draws on extant literature to develop a more systematic understanding of the increasing roles of nationalism and patriotism in international business. Particular attention is paid to implications for public and business diplomacy and geopolitics.

Nationalism suggests policies and practices that seek to strengthen the country in international business transactions. Nationalism does not automatically require "beggar thy neighbor" policies and practices, but it does tend to encourage exports, discourage imports, and encourage national control of natural resources. Patriotism tends to work in the same direction, by encouraging actions that support the home country and calls on individuals and businesses to act in the national interest.

There are some implications for corporate espionage or cybercrime, as has been suspected of some Chinese firms (Holslag, 2015) as well as of Iran, North Korea, and Russia (see Crosston, 2015; Lucas, 2015; Silver, 2015). These four countries are not members of the 2001 Council of Europe Convention concerning Cybercrime, effective July 1, 2004 (Lucas, 2015). The United States (US) has signed and ratified the convention. Both governments and firms under governmental influence may engage in espionage or cybercrime. Documenting such activity is difficult because of the secrecy involved (Kshetri, 2013; McDougal, 2015).

There are important implications for public diplomacy between countries and business diplomacy by enterprises (Ordeix-Rigo & Duarte, 2009, make this distinction). Geopolitics is the combined influence of demography, geography, and economy on national politics and a country's public diplomacy. Businesses more closely tied to a country or region's geopolitics is more influenced by the same factors. Business diplomacy concerns how enterprises manage interactions with foreign governments, multilateral institutions, and international social movements (see Ordeix-Rigo & Duarte, 2009; Saner & Yiu, 2005; Wolters, 2012). Businesses more closely tied to a country or region will tend to reflect greater nationalism, although there may not be the same relationship to patriotism.

The chapter has several objectives. One objective is to provide working definitions of nationalism and patriotism in international business. Another objective is to assemble a relevant literature, reflected in the set of references. Yet another objective is to develop categories of nationalism and patriotism and to identify available information, or sources of information, about those categories. A final objective is to develop possible solutions and recommendations for addressing nationalism and patriotism in a globalizing world economy.

The remainder of the chapter following this introduction is structured as follows. The Background section provides some broad defines for and places nationalism and patriotism in context. The subsequent main section titled Nationalism and Patriotism discusses some key examples: protectionist policies, resource nationalism, control of cross-border mergers and acquisitions, and corporate inversions and other devices for tax avoidance in violation of economic patriotism. The section ends with a discussion of globally footloose multinational enterprises (MNEs) that are extreme examples of international businesses that exhibit, as a matter of values and strategies, neither nationalism nor patriotism. The subsequent section addresses the political context for nationalism and patriotism in international business. The next section considers Solutions and Recommendations for the problems of nationalism and patriotism. The subsequent section then considers Future Research Directions for this topic. The Conclusion ends the chapter with discussion of the overall coverage of the chapter and concluding remarks.

## BACKGROUND

Some authors may use the terms economic nationalism and economic patriotism more or less interchangeably (see Callaghan & Lagneau-Ymonet, 2012, concerning the Paris Stock Exchange; and Nourry & Jung, 2012, concerning anti-takeover measures in the European Union). There is definitely some

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

overlap. This chapter will use the two terms distinctively. Economic nationalism will mean an emphasis on government policies and practices. Economic patriotism will mean behavior of stakeholders favoring domestic producers, and calls by public officials and others for pro-national behavior by domestic producers and their stakeholders.

Economic nationalism emphasizes why and how a government and any organizations, such as businesses, that it can own, control, or influence should try to protect and guide a relatively open economy against perceived (and possibly objective) negative effects of globalization (Lee & Lee, 2015). Industrial policy and protectionism try to use various incentives, subsidies, and restrictions to protect jobs, firms, industries, government revenues, and stock exchanges (for example) against foreign competition, imports, and investments.

Such industrial policy is alive, if unwell, within the European Union (Lazzarini, 2015; Sokol, 2015; Wruuck, 2006). In the US, there was active Congressional skepticism concerning possible negative effects of the proposed 12-country Trans-Pacific Partnership (TPP) free trade agreement (or Pacific Rim trade deal), agreed in October, 2015. Globalization generates various policy tensions within each country. For instance, antitrust policy should promote consumer welfare, but industrial policy involves active government intervention to protect particular constituencies or industries. Reduction in foreign and domestic competition likely increases prices to consumers. The European Union has been very active in conducting antitrust investigations of some large US firms, and China of foreign firms in certain industries such as auto sales.

Economic nationalism becomes some set of public policies of various types aimed at increasing domestic control of the economy. The selection and implementation of the set of public policies is a matter for each government. Essentially, economic nationalism is imposition of constraints on globalization and/or freer trade. Typical policies may include trade restrictions, protection of domestic industries and firms, efforts at import substitution, and controls on capital flows. There is a wide range of possible policies, including currency valuation efforts.

Economic patriotism is a term that gained political currency after 2000 due to increasing globalization and the 2008 global financial crisis (Grant, 2012; Morgan, 2012; Shapiro, 2012). Patriotism generally has increasing influence (Wang & Jia, 2015); and may serve to reinforce nationalism (Dufy, 2015). The term can have two different meanings, the first substantively explaining why a government and the second rhetorically arguing why a corporation has a primary duty to its country's welfare rather than to global welfare or enterprise profit. The first interpretation is effectively synonymous with economic nationalism, defined as some combination of industrial policy and protectionist policy aimed at asserting partial governmental control of a nation's economy to offset negative effects of free trade in a global economy.

This first interpretation is associated particularly with Western Europe, China, India, and Russia – but exists elsewhere. The other interpretation is political rhetoric concerning the corporate social or citizenship responsibilities of a country's businesses, with particular attention to avoidance of fair taxation through corporate inversions or other maneuvers and to failure to create or protect jobs in the prolonged economic downturn following the 2008 financial crisis. This second interpretation asserts arguments for voluntary pro-social initiatives by companies to avoid adopting public policies of the kind associated with economic nationalism.

A significant feature of economic patriotism is what can be termed ethnocentricity or ethnocentrism in consumer behavior. "Made in America" is a widely embraced movement. There is a growing literature on pro-patriotic consumption occurring in various countries (Cheah & Phau, 2015a, 2015b; Dedeoglu, Savasci, & Ventura, 2005; Harcar & Kaynak, 2015; Lekakis, 2015; Stolle, Hooghe, & Micheletti, 2005).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is an increasing literature addressing nationalism and patriotism in their various forms as affecting international business. The reference set for this chapter assembles key items in that literature. The identified literature defines and documents evidence of nationalism and patriotism.

## NATIONALISM AND PATRIOTISM

### Issues, Controversies, Problems

Nationalism and patriotism in international business are disruptions of an idealized model of free trade – including exports, imports, capital flows, foreign direct investment (FDI), and business restructuring through mergers and acquisitions. The World Trade Organization (WTO) works toward this idealized model through member-state negotiations. Despite certain exceptions for temporary labor, there is no true global labor mobility due to national citizenship and immigration controls – which could be classified under nationalism and patriotism. Rather there is greater focus on global labor standards. There are still in place various protectionist policies throughout the action.

### Protectionist Policies

Protectionism in various forms has long shaped important public policies for centuries. Export-led growth was a key theory of economic development until quite recently (Palley, 2012). Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776) is a criticism of mercantilism and an advocacy of a commercial system of freer markets. Mercantilism was the prevailing economic "theory" and policy in Western Europe during the 16th to 18th centuries, prior to Smith's exposition of a capitalist market economy emphasizing the benefits of unfettered international trade and domestic markets. The essence of mercantilism was to "beggar thy neighbor" by protectionism and export promotion, with specific emphasis on maximizing national possession of precious metals in the form of bullion (gold and silver). Crown monopolies were typically granted to friends of the monarch. One can think of imperial control of foreign colonies – such as India before full independence or Canada before dominion status – as in part a form of resource nationalism. The height of the laissez-faire mythology of the unregulated market economy at the end of the nineteenth century arguably corresponded with American imperialism and protectionism during the period 1890 to 1913 (Palen, 2015).

There have been many instances of protectionist approaches since the decline of mercantilism in favor of first laissez-faire market capitalism succeeded by increased regulation and increased state interventionism in other forms. Subsidies to particular companies or industries remain controversial. A key instance has been the long-term competition between Airbus (Europe) and Boeing (US) in the global aircraft market (Irwin & Pavcnik, 2001). The literature contains various examples of protectionism approaches including industrial policy, currency controls, devaluations, and tariffs.

Some of the freer trade actions and agreements occur regionally rather than through the WTO globally. For instance, cross-labor mobility is a principle of the European Union (EU). However, the immigration crisis of 2015-2016 is placing increased stress on that principle, with the United Kingdom recently signaling the possibility of withdrawal from the EU.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In October 2015, twelve Pacific Rim countries including the United States agreed to a Trans-Pacific Partnership (TPP) trade agreement – to be ratified by each country. The other countries include Australia, Brunei, Canada, Chile, Japan, Malaysia, Mexico, New Zealand, Peru, Singapore, and Vietnam. The TPP includes provisions for trade barrier reductions and investor-state dispute settlement – with states permitted to opt out in the instance of tobacco-related matters. There is relatively serious opposition within Europe to a Transatlantic Trade and Investment Partnership (TTIP) between the United States and the EU, as well as to a proposed Comprehensive Economic and Trade Agreement (CETA) between Canada and the EU.

## Resource Nationalism

There can be overlap between protectionist measures and resource nationalism. A recent illustration concerns the issuance of U.S. regulations concerning offshore ocean fish farming (aquaculture) – which may be followed in due course by similar regulations for other U.S. waters. The information below comes from Burdeau (2016), who interviewed several knowledgeable individuals. New federal regulations permit such fish farming in federal waters in the Gulf of Mexico, despite criticism by fishermen (who predict loss of employment) and environmentalists (who predict harm to the marine environment through pollution and potential effects on wild fish stocks). The director of the U.S. National Oceanic and Atmospheric Administration (NOAA) explained the perceived benefits of expanded offshore fish farming in terms of improved balance of trade, improved food security and safety, new job creation, and supply to U.S. consumers. Presently, an estimated 90 percent of seafood consumed is the US is imported, and more than half of that quantity is farmed. The rationale for increased US aquaculture is partly one of substitution of domestic production for importation – accomplished through new federal regulations. This rationale can be thought of as a variant of resource nationalism, the resource being US waters.

Russia under Vladimir Putin has been asserting increased control over natural resource industries (Rutland, 2015). From 2003, Argentina began a program of renationalizing (in full or through majority ownership) privatized formerly state-owned firms including the water supply company for the capital city Buenos Aires, the Argentine airline Aerolíneas Argentinas, the energy company YPF, and the natural gas distributor Metrogas. Much of the Chinese economy comprises state-owned or state-influenced enterprises, despite increased but controlled privatization. National resources are important assets for various countries (Andreasson, 2015; Carrión, 2015; Wilson, 2015). The Organization of Petroleum Exporting Countries (OPEC) – to which not all oil producing countries belong – is a form of cartel for increasing the relative economic power of the members in international markets. Many oil production enterprises throughout the world remain state-owned or state-dominated.

## Control of Mergers and Acquisitions

There were various instances after 2000 of governments attempting to prevent foreign acquisitions of domestic firms (Babin, 2015; Nourry & Jung, 2012). In steel, France, Luxembourg, and Spain opposed a takeover of Arcelor by the Indian firm Mittal. In food, France classified Danone as a "strategic industry" that should not be acquired by the US firm PepsiCo. There are instances within the European Union itself of attempts to block cross-country acquisitions. A Spanish company Abertis attempted to acquire Autostrade, the Italian toll-road operator. There was a bidding war for Endesa (Spain) between E.ON (Germany) and Gas Natural (Spain); and a bidding war for Suez (France) between Enel (Italy) and Gaz

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

de France (France). In the US, there was strong opposition to a Chinese takeover of Unocal, which was acquired ultimately by Chevron, and in 2006 to selling port management in six major seaports to a company DP World in the United Arab Emirates (UAE). New Zealand prevented the transfer of a majority stake in the Auckland Airport to the Canada Pension Plan Investment Board.

The approach can be indirect in the following sense. In the US, Halliburton plans to acquire Baker Hughes (Blum, 2016). American authorities were already studying the US$35 billion deal; and Halliburton had made various proposals to sell assets to satisfy any regulatory requirements. The regulatory issue is impact of the acquisition on competition in the global oil field services. Halliburton and Baker Hughes are the second and third largest companies in the world, after Schlumberger. In January, the European Union announced a full investigation separately of the proposed deal. All three companies are headquartered in Houston, Texas – although Halliburton moved its corporate headquarters to Dubai, in the United Arab Emirates, in 2007, maintaining dual headquarters locations as a US corporation.

## Corporate Inversions and Other Devices for Tax Avoidance

Patriotism has two meanings. One meaning is actual behavior by consumers and producers on the basis of patriotic sentiments, such as the "Buy American Network." During the Great Depression, the Buy American Act of 1933 (signed by President Herbert Hoover on March 3, 1933, in his last day in office) instructed the U.S. government to prefer US-made products. The Buy America Act, a provision of the Surface Transportation Assistance Act of 1982, applies to mass-transit procurements over US$100,000 and at least partly funded by federal grants. The other meaning is political rhetoric urging that corporate responsibility and citizenship include economic patriotism in the forms particularly of socially desirable job creation and fair share tax payments.

The most politically prominent challenge to calls for economic patriotism is the use of various devices for tax avoidance by privately owned MNEs, both nationally anchored and globally footloose. Tax avoidance is a legal action, to be distinguished from illegal tax evasion. The latter is more likely to occur with individuals, such as the recent set of investigations by the U.S. tax authorities concerning improper concealment of taxable funds in Swiss banks. In this instance, economic patriotism requires firms to make legally avoidable tax payments or face public condemnation. There are disputes within the European Union over whether some member-states are effectively tax havens. Germany and the UK organized a multi-country Global Forum to address tax coordination issues.

Governmental calls for corporate patriotism may reflect real concern about whether domestic businesses – including nationally anchored multinational enterprises – will reliably serve the national interest in cases of conflict with corporate interest (Yosifon, 2016). Key instances affecting US politics have been offshoring of employment, a negative balance of trade (imports exceeding exports) especially with China, and tax avoidance maneuvers. Environmental protection can take on a patriotic interpretation (Gabehart, 2015).

An interesting variation is the Aviation Directive of the European Union (EU). This information comes from Buenger (2013). On January 1, 2012, the EU extended its Emission Trading System (ETS), or carbon market approach, to virtually all commercial aircraft (with few exceptions) departing from or landing in any EU member-state. This extension was both unilateral – against some criticism, and extraterritorial in reach. The extension effectively drives up the financial costs of carbon generating behavior globally but arguably might encourage innovation in emissions reduction.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Firms can be expected to seek profits (see Wilson, 1989), and the shareholder primacy norm strongly influences American corporate governance law and practices (Yosifon, 2016). Justice Strine, previously Chancellor of the Delaware Court of Chancery and now Chief Justice of the Delaware Supreme Court, makes three key points. First, firms are profit-seeking organizations, staffed by profit-oriented people: "Instead of recognizing that for-profit corporations will seek profit for their stockholders using all legal means available, we imbue these corporations with a personality and assume they are moral beings capable of being 'better' in the long-run than the lowest common denominator" (Strine, 2012, p. 136).

Second, the effectiveness of voluntary self-regulation is limited: "In the end, policy makers should not delude themselves about the corporation's ability to police itself; government still has a critical role in setting the rules of the game" (Strine, 2012, p. 136). Third, international cooperation – of the type needed to address regulatory havens – is difficult to achieve: "The coalition- and consensus-building required to develop an effective global (or at the least, OECD-wide) scheme of externality regulation will require enormous leadership and dedication. But it cannot even begin if we delude ourselves into believing that corporations will effectively regulate themselves" (Strine, 2012, p. 172).

The rhetoric of economic patriotism has appeared in both political and academic circles (Obama, 2012: Clift, 2013; Clift & Woll, 2012, 2013). US President Barack Obama used the term economic patriotism in the 2012 presidential campaign about job creation responsibility (Obama, 2012). In July 2014, President Obama emphasized economic patriotism in criticizing US multinational corporations practicing corporate inversion to reduce U.S. tax liability. He noted that "some people" called such firms "corporate deserters" for engaging in legal tax-reduction maneuvers arguably violating asserted ethical standards for corporate citizenship. President Obama stated in a speech at the Los Angles Trade –Technical College that "They're technically renouncing their US citizenship." This use of the term economic patriotism is political rhetoric, but tends to work against a competing notion of global or world citizenship (Croucher, 2015).

On September 22, 2014, in announcing new rules aimed against inversions, Treasury Secretary Jacob Lew stated: "These transactions may be legal, but they're wrong" (Davis, 2014, p. D1). On September 22, 2014, Treasury Secretary Jacob Lew announced rules intended to reduce or eliminate the economic incentives for inversions (Davis, 2014). Reported opinion among corporate advisers was that the effect would be to make inversion deals less lucrative rather than to halt deals (Advisers, 2014). In a letter to the US Congress which is available online for ready access (Lew, July 15, 2014), Lew wrote: "... these firms are attempting to avoid paying taxes here, notwithstanding the benefits they gain from being located in the United States." He characterized the attempt as "effectively renouncing their citizenship to get out of paying taxes" and articulated the notion of economic patriotism: "What we need as a nation is a new sense of economic patriotism, where we all rise or fall together."

Tax avoidance has become a hot topic in the United Kingdom and Europe, and seems particularly directed at US firms and certain tax havens within or near the European Union (Kay, 2013; Krugman, 2013). Preuss (2012) questions whether a tax avoiding firm can claim to be socially responsible (see Jenkins & Newell, 2013). Dowling (2014, p. 173) suggests that tax avoidance is a boundary condition for CSR; but Dowling ties law and CSR to a suggestion "that a company should pay its fair share of tax ..." Fairness of taxation is a controversial question (Aynsley, 2014; Chittenden & Foster, 2008; Mankiw, 2007; Weiss, 1993). One empirical study finds that tax sheltering devices do not on average affect firm value, but do have a positive effect in the presence of good governance of the particular firm (Desai & Dharmapala, 2009). Those authors conclude that tax sheltering is not simply a resource transfer from the state to shareholders.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Starbucks has been a target of expressed concerns (Fairless, 2015). Apple has been another prominent company under public scrutiny (Lochhead, 2013a, 2013b). Chief Executive Officers assert two positions:

1. Tax law compliance (Bloomberg News, 2014a); or
2. Fair share payment, a moral argument (Lochhead, 2013b).

Within the European Union, while not alone Ireland and Luxembourg have been under particular pressure to reform tax policies attracting US companies (EU calls Dutch on carpet over Starbucks taxes, 2014; Ireland, Still Addicted to Tax Breaks, 2014; Luxembourg's tax deals cause global criticism, 2014). This chapter does not undertake to provide a systematic survey.

Corporate inversion is one form of tax avoidance. Other forms include for example "transfer-pricing, re-invoicing, offshore 'special purpose vehicles' ... dubious charitable trusts ..." (Christensen & Murphy, 2004, p. 37). One article by members of the tax justice network argues that many MNEs are structured in such a way as to "enable tax avoidance in every jurisdiction" (Christensen & Murphy, 2004, p. 37). The authors view elaborate and aggressive tax avoidance as tax abuse and a fundamental violation of private and corporate citizenship engagement (Christensen & Murphy, 2004, p. 37). The authors define CSR as publishing "all necessary accounting information" and refraining "from the use of profits-laundering vehicles created without substantial economic purpose" (Christensen & Murphy, 2004, p. 37).

Senator Charles Schumer (D-NY) called for Congressional legislation to stop "earnings stripping" in which a parent company loads a US subsidiary with tax-deductible debt (Davis, 2014, D6). The EU commission finds that low tax treatment for Apple in Ireland, where the firm "funnels the bulk of its international sales through subsidiaries" using "exaggerated transfer pricing" (Baetz, 2014), is state aid that may be illegal under EU law. Ireland prefers to attract foreign businesses to a low tax haven over maximizing tax revenues per business otherwise choosing to locate there. The transfer pricing problem lacks a widely-accepted theoretical solution and is a matter of proposed norm (Baistrocchi, 2006).

Problems in defining policy are that:

1. The arms-length standard (ALS) (Rectenwald, 2012, p. 426) must be estimated as there is no external transaction;
2. There is a cycle of offshore tax deferral while waiting for a repatriation holiday (Rectenwald, 2012, p. 449); and
3. There are disagreements (such as the Irish tax haven policy) hindering intergovernmental cooperation.

In a corporate inversion, a firm merges with a smaller firm in a different country and relocates its legal business address to the other country (Freedman, 2014). Recent inversions include pharmaceuticals AbbVie (Chicago) and Mylan (Pittsburgh) shifting to Europe (Freedman, 2014). Walgreen Co. decided not to invert (Freedman, 2014). It is not strictly established that tax breaks drive corporate inversions (Hall, 2014).

In September, 2014, five liberal US Senators (four Democrats and one Independent) sent a letter to the CEO of Burger King opposing move of its corporate headquarters to Canada from Miami. The letter reads in part: "We believe you will find that turning your back on your loyal US taxpaying customers by renouncing your corporate citizenship is not in the best interest of Burger King or its shareholders." The letter also accuses Burger King in the words of a news report "of trying to avoid paying its fair share for

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

roads and other public services it receives in the United States" (Senators, 2014). The letter contains the following notions: loyalty, corporate citizenship, best interest, fair share, and corporate benefit ("roads and other public services").

In the period preceding the Scottish (referendum) vote on September 18, 2014, on independence from the UK, some important businesses expressed opposition to independence. Standard Life insurance stated it might shift operations and legal entities (Rankin, Carrell, & Monaghan, 2014). Royal Dutch Shell and British Petroleum warned against secession because reportedly concerned by the prospect of increased oil production taxes levied by Scotland (Eaton, 2014b). Two leading banks warned they would move corporate headquarters (Royal Bank of Scotland, which is majority owned by UK taxpayers following the 2008 government bailout) or legal entities (Lloyds Banking Group owner of Halifax and Bank of Scotland) to England (Hui & Kelbie, 2014).

There appear to be three kinds of corporate inversions:

1. To please host country regulators;
2. To reduce aggregate tax liability; and
3. To take advantage of regulation havens.

Burger King's shift to Canada appears to be an instance of pleasing Canadian regulators concerning acquisition of a Canadian firm rather than (2) or (3). There are individual inversions through change in citizenship or residence, or involvement in tax avoidance schemes that have operated through Switzerland for instance. There is an inquiry into so-called "dividend arbitrage" operating mostly through London as a scheme whereby banks temporarily transfer ownership of client shares to a lower-tax jurisdiction when a dividend is expected (Strasburg, 2014).

Accenture, once named Andersen Consulting, relocated to Bermuda in a 2001 inversion and is now incorporated in Ireland (Bump, 2014). Certain oil field services providers originally headquartered in Houston moved early (Freedman, 2014). Transocean moved to the Cayman Islands (1999), and then to Switzerland (2008). Noble Corp. moved to the Cayman Islands (2002), then to Switzerland (2009), and then finally to London (2013). Weatherford International moved to Bermuda (2002) and then to Switzerland (2008) (Eaton, 2014a). The three firms saved an estimated US$2.923 billion in taxes during 2002-2009 (Freedman, 2014). A corporate inversion both saves taxes and facilitates repatriation of foreign earnings to the US (Freedman, 2014). The Congressional Research Service (Marples & Gravelle, 2014) reported 75 firms had made inversions over the past two decades (Freedman, 2014).

The term economic patriotism traces to at least 1985 with William Safire concerning national defense spending (Bump, 2014). Obama used the term in the 2012 presidential campaign (Bump, 2014; Obama, 2012). The notion of "economic patriotism" or "corporate citizenship" as true citizen of a home country is in conflict with realities of global business opportunities (Foroohar, 2012). A rather different view of economic patriotism was expressed by a prominent US banking CEO: "Jamie Dimon, the chief executive of JPMorgan Chase, which last week put aside $1.1bn in fresh provisions for legal expenses, questioned whether it was 'American' to force banks to deal with a number of regulators and their fines" (quoted in Binham, 2015).

Medtronic acquired Covidien, Ireland, for US$43 billion to invert – completing the acquisition in January, 2016. In August, 2014, Medtronic disclosed intention to reimburse its CEO for a US$24.8 million inversion-generated tax bill. The 2004 law imposed a 15 percent tax on stock and option awards given to personnel of inverting companies (Capital Flight, 2014). While the new Treasury rules apparently

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

halted a Salix Pharmaceuticals merger with an Italian drug firm's subsidiary, Medtronic disclosed in September, 2014 that it would borrow part of the funds for the Covidien acquisition (Overseas, 2014). In April, 2014, following issuance of new regulations by the US Department of the Treasury to reduce tax benefits, Pfizer scrapped its planned merger with Allergan.

Fair Tax Mark, launched in February, 2014, is a private certification that a firm complies with standards for fair tax compliance. SSE plc, the second largest UK energy supplier and a FTSE100 company, has Fair Tax accreditation (Fair Tax, n.d.). SSE was the first FTSE100 to earn accreditation (SSE trailblazes, 2014). A study using 217 tax-avoidant and 217 non-tax-avoidant firm-year observations for 2003-2009 from the Kinder, Lydenberg, and Domini database finds that more socially responsible firms display less tax avoidance (Lanis & Richardson, 2015). The CSR categories for community relations and diversity are particularly important in this relationship.

## GLOBALLY FOOTLOOSE MNEs

There is a scattered literature around the idea of globally footloose MNEs (Goerg & Strobl, 2002; Orts, 2002a, 2002b; Van Beveren, 2006) or born-global MNEs (Knight & Cavusgil, 2004; Trudgen & Freeman, 2014). A globally footloose MNE is one owing no loyalty to any particular sovereignty: "Where the corporate globalists seek a competitive global economy ruled by mega-corporations that owe no loyalty to place or person, citizen movements seek a planetary system of economies made up of locally owned enterprises accountable to all their stakeholders" (Cavanagh et al., 2002, p. 6). Decentering and also what the present author will term "wandering" (from location to location) suggest the likelihood of shared sovereignty actors in the middle of a distinction between sovereignty free and sovereignty bound actors (Rosenau, 1990). Fiat's then chief executive reportedly stated that the company is "Italian based but not an Italian company" (*Financial Times*, 2010). MNEs may have a natural tendency to "decenter" (or unbundle) for business purposes (Desai, 2009). Halliburton operates co-offices in Houston (headquarters) and Dubai (field operations).

Table 1 provides a proposed typology of enterprises relevant to the study of nationalism and patriotism in international business. The typology identifies five kinds of enterprises, aligned along the horizontal stub of the table. The five kinds of enterprises involve, as shown down the left-side vertical stub, variations in focus (domestic business versus international business) and ownership (private versus state). State ownership is combined with state domination of formally private enterprises, as in a country like China it is difficult to draw a definite line between what is state-owned and what is, despite formal private ownership, state influence and thus domination in reality.

These variations in focus and ownership define the five kinds of enterprises. The bottom row of the table explains the basic characteristics of each kind of enterprise. As an idealization, a country that has relatively little international business engagement may emphasize a "commercial republic" or a species of "command economy" or some combination of private and state enterprises. Globalization is reducing the likelihood of such isolated countries, although North Korea may be an illustration of the isolated "command economy" approach. Globalization places emphasis on international business activities. China is active in international business, but its economy – while being marketized and privatized – is still strongly state-owned or at least state-dominated. The "commercial republic" when entering international

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

business involves privately-owned MNEs which remain typically nationally anchored in a particular home country. There is an emerging enterprise form which has been labeled in the literature as a globally footloose MNE, meaning effectively owing no real allegiance to a home country.

The "commercial republic" conception (Elkin, 1994, 2001) is illustrated by the following comment: "Google's tax avoidance is called 'capitalism', says Chairman Eric Schmidt" (Google's tax avoidance, 2012). The conception reflects partly the emphasis by the Obama Administration on middle class concerns (see Selznick, 1992).

## THE POLITICAL CONTEXT OF NATIONALISM AND PATRIOTISM

This section examines the political context of nationalism and patriotism, and the implications of that context for some important considerations such as corporate espionage or cybercrime, public diplomacy, and business diplomacy. The section will also address the relationship between the political context and certain aspects of public policy such as international trade effects, government fiscal policies, and the role of civil societies.

Nationalism and patriotism vary across countries, and thus involve varying effects for business corporations. Protectionism may simply vary by country, dependent on national economic conditions and the government in office. Corruption generally appears to be higher in developing and transition countries relative to developed countries. However, corruption by key officials – such as participation in the alleged Panama wealth concealment scheme recently reported by a media consortium – may also vary by country, Argentina, Iceland, China, India, Russia, and the UK having been named (The Panama Papers, 2016).

*Table 1. A basic typology of enterprises classified by type of business and type of ideology*

| **Type of Enterprise** | | | | | |
|---|---|---|---|---|---|
| **Focus** | **Domestic Business** | | **International Business** | | |
| Ownership | **Privately Owned** | **State-Owned or State-Dominated** | **State-Owned or State-Dominated** | **Privately Owned** | |
| Definition | Domestic Commercial Enterprise | Domestic State-Oriented Enterprise | State-Owned or State-Dominated Multinational Enterprise (SMNE) | Nationally Anchored Privately Owned Multinational Enterprise (MNE) | Globally Footloose Multinational Enterprises (MNE) |
| Characteristics | "commercial republic" if:<br>• Very limited state enterprise (typically utilities)<br>• Relatively limited governmental regulation<br>• "Citizenship" activities due to closeness to domestic stakeholders | State-directed economy when:<br>• Very extensive state enterprise going beyond typical utilities<br>• Governmental regulation tends to support state direction | | Political "rules of the game" with home and host countries:<br>• Lobbying governments for firm benefits<br>• Engaging in "citizenship" activities for reputation building | Pure economic self-interest:<br>• Firm may shift location of activities if regulated too closely<br>• Firm may engage in strategic "corporate social responsibility" activities out of prudence |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

A basic dividing line is between democratic societies and authoritarian societies. Democratic societies appear to be more concerned with control of mergers and acquisitions and control of tax avoidance schemes (Dowd, Landefeld, & Moore, 2016). The reason is that democratic societies tend to be participants in the global trading system and thus relatively open to changes in business ownership and mobility of capital. Authoritarian societies are more likely to emphasize state-owned enterprises and resource nationalism. China and Russia have been characterized as authoritarian capitalism systems: the two countries combine, in different patterns, authoritarian political regimes and market-oriented economies although the economies are still arguably dominated by state-owned and state-influenced enterprises (Krastev, 2012). The authoritarian regimes – China, Iran, North Korea, and Russia – are the ones more associated with officially sanctioned or encouraged hacking for both political and economic purposes. The authoritarian regimes generally do not permit foreign acquisitions, as distinct from foreign direct investments. Singapore has also been characterized as an authoritarian capitalism – of a very different stripe (Cassidy, 2015).

## Authoritarian Political Systems and Civil Societies

Knowledgeable readers will have a working understanding of democratic political systems. As noted above, those polities are more open economically, tend to be concerned with control of mergers and acquisitions and control of tax avoidance, and are largely defensive in guarding against foreign espionage – corporate and governmental – and cybercrime. It is the authoritarian political systems – especially those of China and Russia – that require more direct attention here.

The Russian Federation is officially a federal republic of regions and theoretically a parliamentary democracy, with a popularly elected president presently Vladimir Putin (formerly president and then prime minister under Medvedev) and an appointed prime minister (Chairman of the Government of the Russian Federation) presently Dmitry Medvedev (formerly president). Putin's majority ruling party United Russia, founded in 2001, is both conservative and nationalist in orientation. United Russia controls both the national government and the regional parliaments. Given this electoral dominance and nationalist policy orientation, the Putin regime is authoritarian if capitalist in economic approach (Gel'man, 2016; Gel'man & Starodubtsev, 2016; Gill, 2016; Motyl, 2016). There is an important process of internal financial transfers to regional governments to assure loyalty (Ermasova & Mikesell, 2016; Marques, Nazrullaeva, & Yakovlev, 2016; Sharafutdinova & Turovsky, 2016).

The People's Republic of China (PRC) is officially a one-party communist state with provinces and other subordinate entities (several autonomous regions, four direct-control large municipalities, and two special administrative areas). There is both a president presently Xi Jinping and a premier of the State Council presently Li Keqiang. Xi was previously vice president and is general secretary of the Chinese Communist Party (CCP). The National People's Congress elects the president and the premier (Chen, 2016). The premier is the second ranking member of the Politburo Standing Committee, after the president. The premier normally handles the economic affairs of the PRC. The Chinese provincial structure generates internal financial transfers to assure loyalty, similar to the process in Russia (Wang, 2016).

Civil society is generally robust in democratic polities with developed economies. One reasonably subdivides democratic polities into government, business, and civil society sectors. The situation is different in authoritarian regimes such as China and Russia (Poskitt, Shankland, & Taela, 2016). Although

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

those two countries are marketizing and privatizing, state-owned and state-influenced enterprises remain important, political connections link business and state (and party), and civil society remains relatively underdeveloped (An, Chen, Luo, & Zhang, 2016; Chen & Cao, 2016; Yang, 2016).

There are strong ideological and political pressures for value consensus (Hao, 2016, drawing on three surveys of thousands of Chinese respondents). Wang (2016) concludes that prospects for democratization in China are weak; there is more discontent with the present political system, especially within the CCP, than democratic impulses. Veterans' organizations may be influential in Russia (Kulmala & Tarasenko, 2016); anti-corruption, environmental, and human rights organizations are not yet influential in China or Russia (Hawkesworth & Loudiyi, 2016).

## Connections to Corporate Espionage

Competitive intelligence efforts by any firm may slide into stigmatized practices, as found by a study of US firms (Reinmoeller & Ansari, 2016). However, China and Russia are reportedly key players in international espionage and hacking, including efforts to steal commercial as well as political secrets (Benson, 2011; Lewis, 2012). Iran and North Korea are also suspected in such efforts. Economic espionage is an important aspect of Chinese government activities as seen by available reports. There is a growing literature on economic espionage, with emphasis on China and Russia, although those two countries are not alone (P. L. Chen, 2016; Dreyfuss & Lobel, 2016; Rascoff, 2016; Waltz, 2016; Workneh, 2016). The linkage to Chinese and Russian multinationals is difficult to establish, but Chinese state-owned and state-influenced multinationals are an important aspect of international activities. It appears more likely that authoritarian regimes will influence their multinationals, at least indirectly, to engage in at least economic espionage in the national interest.

## Government Fiscal Policies and International Trade Effects

Literature connecting nationalism and patriotism, especially by businesses, to government fiscal policies and international trade effects is limited. The relationship is more direct in democratic polities with open economies; as noted above, these polities are the ones most concerned with mergers and acquisitions and tax avoidance. The worse the trade imbalance, presumably the greater the country's concern over mergers and acquisitions; and the worse the government fiscal deficit and debt, presumably the greater the concern over tax avoidance and corporate inversion. Russia has been particularly affected negatively by sanctions (over its annexation of Crimea in 2015) and falling oil prices, the latter arguably being good for China as an importer (Dreger, Kholodilin, Ulbricht, & Fidrmuc, 2016). Moons and van Bergeijk (2016) conduct a meta-analysis of 32 empirical studies (1986–2011) concerning trade and investment impact of economic diplomacy methods. They report a positive, significant effect (except for state visits) on international economic flows.

## Effects on Public Diplomacy and Business Diplomacy

The term diplomacy can mean public diplomacy – conducted by governments, or business diplomacy – conducted by or through commercial or state-owned enterprises (Poulsen, 2016; Saner, Yiu, & Søndergaard, 2000; Vanc & Fitzpatrick, 2016). The emphasis in this chapter is on economic diplomacy, meaning coordinated public and business diplomacy efforts aimed at international economic goals such

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

as business opportunities in other countries. The most literature is available on China in this regard (Gu, Zhang, Vaz, & Mukwereza, 2016; Jakobson & Manuel, 2016; Strüver, 2016; Zhang, 2016). Fuchs (2016) reports evidence that Chinese diplomatic visits fall in the year of a visit by the Dalai Lama to a country and then rise in the following year.

## SOLUTIONS AND RECOMMENDATIONS

In weighing solutions and recommendations, it is important to consider two fundamental considerations. First, globalization does have negative as well as positive effects; and the balance of these effects can vary greatly by country. There is a marked economic inequality in the world, and this inequality can place strong pressures on national governments for protectionist, resource control, taxation of foreign enterprises, and similar measures (Garavini, 2015; Wilson, 2015). Second, there are profound geopolitical divisions in the world: China, Iran, North Korea, and Russia are not cooperative partners in the international system. Some countries behave extremely nationalistically – that is, beyond what we may typically expect of all countries.

Criticisms of corporate behavior are intended to influence outcomes for proposed policy reforms or to threaten businesses to refrain from maximizing gains out of risk aversion. Strictly legal actions are ethically neutral rather than ethically suspect, although certainly not ethically superior (i.e., virtuous, good, and just). A "loophole" is commonly defined as "A technicality that allows a person or business to avoid the scope of a law or restriction without directly violating the law" (Investopedia, n.d.).

Imperfect tax codes, riddled with loopholes or technicalities and varying globally by jurisdiction, permit persons or entities to minimize tax payments. A tax code is a set of detailed rules, rather than a set of guiding principles. Dworkin (1978) distinguishes among policy, principle, and rule. There is no economic, political, or strategic advantage for a person or an entity to pay any tax beyond legal liability – ignoring risk aversion and reputational considerations. While a person or privately-owned entity might view overpayment (or over-compliance) as a virtue, in a publicly traded entity the notion of fiduciary responsibility to shareholders (whatever its inherent defects) must arguably be strongest in tax decisions.

One solution is international cooperation, such that there is no location advantage with respect to tax liability or regulatory burden. There may be other location advantages, as reflected in Burger King's decision to relocate to Canada. Walgreen's decision not to relocate reflects some balance of considerations. A second solution is some form of domestic tax reform such that the problem of international cooperation does not arise. A third solution is virtuous or responsible management, but virtue or responsibility takes the form of overpayment in violation of fiduciary responsibility. Economic patriotism is meaningful for domestic firms, with no option or interest to operate trans-nationally. The appeal cannot have useful relevance for an MNE operating across multiple jurisdictions. Perfect regulation is unlikely, and virtue or responsibility assumes a peculiar meaning for an MNE. Public policy is open to influence efforts by the very MNEs to be regulated; and those MNEs may have opportunities to shift activities among jurisdictions in competition with one another. An appeal to superior virtue is not a demonstration that harm is occurring in legal compliance.

The most general approach to altering economic inversions would be to reduce corporate tax rates and go to residence-neutral taxation so that location is irrelevant. Mr. Lew's observation (quoted earlier) about benefits suggests benefit taxation (i.e., user charges) rather than ability-to-pay taxation (i.e., deep pockets). The US may have the highest corporate tax rate in the OECD (combining federal, state, and

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

local taxes). Public policy solutions may tend to create new loopholes. A 2004 law attempted to reduce inversions by requiring a 20 percent threshold: former US shareholders must own less than 80 percent of the merged company (Freedman, 2014). Firms introverting prior to the law are not affected by the requirement (Freedman, 2014).

Another possibility to consider is that regulatory havens reflect defects in regulation and/or absence of international coordination. With respect to tax havens (see Ali Abbas et al., 2012; Krugman, 2013), Kay (2013) has recommended a number of possible reforms: "... removing interest deductibility, introducing an allowance for the cost of corporate equity or shifting the tax base towards cash flow rather than accounting profit. ... Opportunities for tax avoidance are everywhere and always the consequence of rules that treat economically similar transactions differently." Additionally, such rules as exist are rarely enforced, as authorities prefer to negotiate (Kay, 2013). Kay advocates taxing shareholders rather than companies, and if necessary for some reason to tax companies then to tax free cash flow or economic rent (i.e., earnings in excess of cost of capital).

The recent spate of corporate inversions in the pharmaceutical industry likely reflects high profitability such that there are significant tax advantages (Professor Mark V. Pauly, quoted in Capital Flight, 2014). One proposed policy option is to reduce the U.S. corporate tax rate and tax code complexity. The Obama administration proposes requiring shareholders to own 50 percent of the new entity, and a so-called "smell test" in which companies operating primarily in the US would be treated for tax purposes as US corporations (Freedman, 2014).

Another proposed policy option is international cooperation (Bank, 2013). OECD is working on plans for exchange of information concerning corporate tax-avoidance strategies (Bloomberg News, 2014b). The OECD Secretary-General stated that MNEs hold an estimated US$2 trillion in low-tax jurisdictions (Bloomberg News, 2014b). In late October, 2014, a total of 51 countries signed an accord to combat tax evasion through automatic exchange of tax information from 2017; however, Switzerland and the US were not signatories. Switzerland maintains marked banking system secrecy, and the US has opted to pursue its own strategy (Smale, 2014). The 51 signatories are members of the 123-country Global Forum organized by Germany and the UK to address tax evasion and fraud (Smale, 2014). The broader policy problem is to coordinate tax policy as distinct from tax enforcement through information exchange.

## FUTURE RESEARCH DIRECTIONS

Nationalism and patriotism are more likely to increase than to decrease in the future. China, Iran, North Korea, and Russia in particular are nationalistic in the classical meaning of that term. There are economic and political stresses between Canada or the US and the EU. Immigration pressures on the US and the EU are leading to increasing discourse about whether stronger barriers to population influxes should be adopted. The continuing economic difficulties since 2008 have, with other factors, increased stresses leading various governments to consider protectionism, industrial policy, and resource nationalism. There are also changes in political regimes toward increased aggressiveness internationally (China and Russia especially) and toward "illiberal democracy" as distinct from conventional dictatorship (Innes, 2015). Country and enterprise studies are particularly desirable.

Research should emphasize defining and illustrating varieties of nationalism and patriotism in international business. The conventional emphasis in literature has been on the advantages of freer trade on the one hand, and on the benefits of international cooperation on the other hand. We need much more

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

inquiry into how causes and effects of nationalism and patriotism by country, the relationships to corporate espionage and cybercrime, and the consequences for public diplomacy and business diplomacy. While a significant literature is accumulating, on the whole nationalism and patriotism are understudied because the research emphasis has been on globalization (the World Trade Organization) and regional integration (the European Union). This emphasis is coming under reevaluation in light of the economic and political developments since 2008.

## CONCLUSION

This chapter has marshaled information and issues concerning nationalism and patriotism in international business. Nationalism is basically a set of policies and practices, most typically adopted by governments. Patriotism is basically a set of beliefs and behaviors by stakeholders of businesses (domestic and international), typically in support directly or indirectly of nationalism policies. The chapter defines nationalism and patriotism as different matters, although often linked or even interdependent.

There are implications for public diplomacy, business diplomacy, corporate espionage, and cybercrime. The three chief examples of nationalism addressed in this chapter are protectionism, resource nationalism, and control of mergers and acquisitions undertaken by foreign businesses – even within the EU. The chief example of proposed patriotism is taxation of enterprises, which frequently engage in legal but politically condemned tax avoidance devices. A recent form of such tax avoidance is corporate inversion, in which a larger firm merges with or acquires a smaller firm in another country for the purpose of shifting formal registration jurisdiction and thus escaping taxation in the home country.

## KEY TERMS AND DEFINITIONS

**Beggar Thy Neighbor:** A protectionist policy typically using currency devaluations (increasing foreign demand for exports) and increased trade barriers (decreasing domestic demand for imports) to gain at the expense of trading partners. The idea occurs in Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), Book IV, Chapter III, Part II.

**Corporate Inversion:** A legally permissible action in which a business from one country merges with a smaller business in a different country and relocates its legal business address to the other country. The larger, inverting business is dominant. Inversions occur principally for purposes of tax liability reduction, but can sometimes occur to obtain business advantages in the other country.

**Corporate Espionage:** Espionage or spying conducted for commercial rather than national security purposes. Governments may conduct or instruct corporations to conduct such espionage for economic gains. Corporations may conduct such espionage for competitive advantages.

**Cybercrime:** Crime involving a computer and/or a communications network, in various forms. The computer and/or network may be an instrument or target of the crime. Hacking, spamming, and child pornography are instances.

**Ethnocentrism:** The ethnic or cultural bias of an individual in which that individual's group is the ideal benchmark against which any other ethnic group or culture is assessed.

**Nationalism:** Nationalism is domestic emphasis placed on the country's economic, political, and strategic interests. Nationalism views the international business system as a zero-sum competition.

**Patriotism:** Patriotism is the pro-national behavior of consumers, producers, and other business stakeholders, and also the calls for such pro-national behavior.

**Pollution Haven:** A country affording foreign businesses lower standards for pollution than they would face at home. The pollution haven jurisdiction derives other non-pollution advantages.

**Resource Nationalism:** Assertion of national (or community) control over natural resources. Pemex (Petróleos Mexicanos), the Mexican state-owned petroleum company, was established in 1938 through nationalization of all private petroleum companies (foreign or domestic) then operating in Mexico.

**Tax Avoidance:** Business decisions undertaken to minimize tax liability in a given country or other tax jurisdiction. Multinational enterprises may be structured to minimize taxes globally. Tax avoidance is legal, if unpopular politically, as distinct from illegal tax evasion.

**Tax Haven:** A country affording foreign individuals and/or businesses low or even zero tax liability without requiring actual residence. The tax haven jurisdiction derives other non-tax-revenue advantages.

# Chapter 84
# Critical Analysis of the Influence of Transnational Capitalism on Institutions and Organizations

**José G. Vargas-Hernández**
https://orcid.org/0000-0003-0938-4197
*University of Guadalajara, Mexico*

## ABSTRACT

*This chapter aims to analyze the development of capitalism and its influences on institutions and organizations from its beginnings to reach the highest stage in the processes of neoliberal economic globalization and the New Economy version with supports of information and communication technologies. In raising this development from a critical analysis, it examines the impacts and effects on individuals, communities and the nation state. Subsequently it is questioned the scope of the imposed transnational neoliberal capitalism model. Finally, it is concluded that it needs a cultural transformation for not accepting the forms of domination, power and alignment of globalizing capitalism and to reconstruct the identity of communities through individual action and asserting collective self-determination, independence and self-management. To a certain extent, this analysis finds that evolution and globalization support divergence more than convergence.*

## THE EMERGENCE OF CAPITALISM

The term capitalism carries an old history of human exploitation, and for a long time, in general, has been omitted from the speeches, although it is accepted the existence of a system that in fact is valid and current with important variations (Jay and Jay, 1986; Tormey, 2012). Weber (1978) defines the spirit of capitalism as the set of elements that inspire ethical entrepreneurs on their shares in favor of capital accumulation. Beginning from this argument, capitalism has embodied entrepreneurial ethical values establishing a new moral relationship between people in their work settings.

The phenomena of economic globalization, as any economic development have had an evolutionary process. Capitalism is an evolutionary process that is touted as an engine of economic progress and development. Economists such as Marx analyze the evolutionary process of capitalism using the dialectic method to describe the negative influences of the modern capitalist engine on labor relationships in industrial organizations created by the economic-based structures. The dialectic method in action used by Marx was used to explain economic relationships of methods of production. A thesis calls for the very opposite, the antithesis and from the struggle process between these two forces both are destroyed giving existence to a new synthesis.

Schumpeter analyzes the innovation and scientific advance supported by a continuous process of creative destruction as the result of technical and technological relationships among with institutional and organizational structures (Nelson, 1990). This continuous process of creative destruction is an in built in force of capitalism, representing the natural selection of institutions and organizations that is the survival of only those that are more fitted to the economic environment.

The evolutionary processes of capitalism have lasted several centuries and have been inherent in the processes of economic globalization, which in turn are the result of processes of capital accumulation. The two shock waves of capitalism inherent to imperialism, took place after the conquest of America and the Industrial Revolution (Amin, 2001). In this first phase of economic globalization a mercantilist system develops but it was opposed by the liberation forces of some colonies such as the British-American, and later the Spanish-Latin-American, the French-American and the Portuguese-Latin-American that defy the logic of production. Capitalism proclaiming freedom overcame unjust economic relations of feudalism but became the justification for the looting of the resources of the less developed peoples for the benefit of the colonial metropolis. The colonial legacy has marked the economic, political, social and cultural rights of colonized peoples giving rise to institutional and organizational relationships and sense of identity.

The Reformation represented a break in confusing ruling classes of their time with the feudal past that according to Weber laid the ideological foundation for the development of capitalism between the emerging bourgeoisie, large landowners and the monarchy that kept under control the threat represented by the poor farmers, the main victims of social transformations. The concurrent rise of capitalism with the phenomenon of modernity separates the political sphere from the economic one. From this alternative perspective, modernization was the wellspring of Western capitalism whose ideological forays into the world kept it in a constant delay.

However, the development of capitalism as an economic system has degraded social development, specifically among those who do not have capital and have to hire their work and also at macro level among colonial territories and less developed countries (Wallerstein, 2001; Thomas, 1980; Mooers, 1991; Grosfoguel & Cervantes-Rodríguez, 2002; Dietererich, 2002). The economic development of England was based on the thesis of classical political economy developed by the English Adam Smith, Thomas R. Malthus, David Ricardo and the Frenchman Jean Baptiste Say based savings, work and free trade. But the application of these theories is contradictory and incompatible with the systematic use of political, military and economic development in praxis of colonialism, exploitation of protectionism and barbarians (Dietererich, 2002).

The monarchy European feudalism in the eighteenth century is resisted and destroyed by capitalist production forms and illustrated movements of the nineteenth century (Wallerstein, 2001; Thomas, 1980; Mooers, 1991; Grosfoguel & Cervantes-Rodríguez, 2002 & Dietererich, 2002). The emergence of capitalism in the late eighteenth and early nineteenth century due to the use of new technologies such

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

as the steam engine and new means of transport such as rail, accelerate the production and trade of the economy and generate enrichment for those who might benefit from these technical advances.

Since then, the capitalism become over time until these days in an increasingly oppressive system of capitalism legitimated by economic liberalism justifying mechanisms influencing institutions and organizations. These mechanisms deprive workers of their means of production. The new owners of means of production exploit their materials and intellectual energies in exchange of wage which is less than the actual values of the goods produced.

Friedrich List, creator of German state capitalism in the late eighteenth and early nineteenth centuries, criticizes the double standard of the English moral. This criticism is synthesized in the analysis of Dietererich (2002) because since the constitution of the modern English state in the developmental dictatorship of Oliver Cromwell as was manifested in the Navigation Act (1651) and the monopoly of the East India Company to the days of the charming Tony Blair, the only real economic growth policy was the protectionist state capitalism (Robinson & Harris, 2000, Mann, 2001-2002). Blair's New Labour government framed by the notion of Competition State adopted a centre-left political strategy to achieve its own economic, social and political objectives (Cemy & Evans, 2004; Cemy & Evans, 2000).

## OBJECTIVE

The objective of this study is to analyze how the development of capitalism had influenced institutions and organizations.

## EXPANSION AND CRISIS OF CAPITALIST IMPERIALISM

The second phase of the expansion of capitalist imperialism began with the industrial revolution, which deepens the polarization that has increased inequality and causes confrontations between the imperialist powers, socialist revolutions and national liberation revolutions that arise in the periphery. Marxism is a dialectical approach to the development of humanity. An approach from historical materialism mark the class struggle of capitalist development that evolves to a socialist society composed of a system of production, distribution and consumption consisting of equal individuals in a democratic State.

The logic of capitalism is the dominant ideology in the West since the Industrial Revolution (Lovins, Lovins & Hawken, 1999) and was promoted heavily in the nineteenth century, based on the accumulation of capital by maximizing profit. The period between 1860 and 1900 is often referred to as the Second Industrial Revolution due to the large number of technologies invented during that time. Those who do not benefit do form a new social class that requires a socialist ideology to oppose capitalism which has its peak in the nineteenth and twentieth century (Chase-Dunn, 2001).

Since the 1929 crisis, the greater challenges that the capitalist system has faced are attributed to liberalism for its confidence in the ability of market mechanisms to overcome economic crises and passive assistance of governments. Reactions to the crisis in confidence condemn the free market. Keynes challenged capitalism to be the best policy for capitalists when he said that full employment is necessary for capitalism to grow and can be achieved only if governments and central banks get more involved into the economic health to increase economic growth and economic distribution.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social welfare policy focuses on state responsibility for providing de commoditization of social benefits on the basis of principles of universality, equality and global coverage. This welfare model is incompatible with the urgent progress of unregulated capitalism, to which adaptive pressures, social welfare orientation of social democracy have redirected actively applying resources and services to young families.

Competitive capitalism became monopoly capitalism during the decolonization processes that occurred in the nineteenth century to strengthen global expansion after World War II through processes of capital accumulation and reproduction (Grosfoguel & Cervantes-Rodríguez, 2002). During the process of decolonization, the name of Third World countries was assumed by the "non-aligned" with the two large hegemonic blocks, socialism and capitalism, so that Latin America was not included. The national liberation movements after World War II end with a system of colonialism. However, the colonial legacy marked the economic, political, social and cultural rights of colonized peoples. These movements joined ethnic and religious communities against capitalism as a common enemy. When national popular movements are strong, they transcend in solidarity internationalism.

## NEOLIBERALISM AS AN IDEOLOGY OF CAPITALISM PULSE

Neoliberalism is imposed as the best alternative to the exhaustion of expansive growth period of greater global economy after World War II, between 1940 and 1970. The economic model based on industrialization by import substitution was exhausted in terms of supporting economic growth. This period was considered as the "golden age of capitalism" with a high global economic growth characterized by industrial expansion of capitalist periphery countries and the strengthening of the economies of the socialist countries.

Globalization processes intensified after World War II with the creation of global institutions as expressions of the transformations undergone production, information and communication systems. The WTO is the successor to the GATT which together with other institutions like the International Monetary Fund and the World Bank emerged after World War II seeking to establish a new world order in global turbulent transition times by the unilateral imposition of capitalism.

Most developed countries promoted these international organizations to ensure their economic interests, hegemonic-based in free trade by promoting a devourer mercantilism under globalization processes with imperialist vocation. These international organizations can grant subsidies and tariffs that benefit only the powerful against the dispossessed and leading to nationalism of the developed world. Thus, globalization represents the most advanced stage of capitalist development which benefits economic elites through global integration processes supported by the doctrine of neoliberalism as an economic and political ideology.

The concept of globalization is ambiguous and it tries always expressing the empirical evidence. The concept of globalization began to be used for academic purposes in the mid-eighties. In any case, the concept of globalization should be reviewed from the ground, as the content and processes that characterize the development of global capitalism and contemporary societies (Aguirre Rojas, 2000). The evolution of transnational capitalism or neo-capitalism has resulted in economic globalization, which in terms of Márquez Ayala (2001) is based on four pillars: first, the ideology that exalts the market; second, the brand is neoliberalism, three, the theoretical is monetarism and four, its slogan is the hope of the village collective access to global prosperity and welfare.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The development in globalization has generally been capital-centered because it places capitalism in the center of the narrative development, thus tending to devalue or marginalize any possibility of non-capitalist development. The naturalness of capitalist identity as a template for all economic identity can be challenged (Gibson- Graham, 1996:146) for various economic development options proper of post development that value the same local models not necessarily complementary, neither opposing nor subordinated to capitalism. The term global village was coined in 1960. The neoliberal model of globalization that seeks to build a global village with global citizens, contradicts itself when it proclaims the opening of borders and the strengthening actually reinforce the essential role of national states.

Other historical interpretations (Reich, 1998) on the development of globalization processes dated to the end, more than half of the seventies and early eighties. These analysis point concurrent events such as the cumulative impact of the second oil crisis, a substantial decline in GDP, rising inflation rates, the traumatic event of the hostages in the U.S. embassy in Iran, the rise to power of Thatcher in Britain, Reagan's U.S. and Kohl in Germany. These events have resulted as part of the impacts of economic globalization processes.

From the eighties, the rise of the conservative right with Thatcher came to power in England, with Reagan and the Republican Party in the United States, and then fully assaulting power with Bush and the Falcons with their reactionary policies imposed unilaterally, dismantle the welfare state. This dismantle can lead to social disaster and jeopardizes not only the world order but the very survival of the capitalist system.

Neoliberalism is defined as the mode of governing through individual freedom that requires people to be free and self managing in different economic, social and political spheres of everyday life in health, education, bureaucracy, the professions (Ong, 2007).

Neoliberalism as hegemonic model of global capitalism was assumed and promoted by Thatcher in Britain and Reagan in the United States with the support of international financial institutions, the International Monetary Fund, the World Bank and the World Trade Organization, who promote policies economic and financial liberalization, deregulation, privatization, opening up of economies to the world market, precarious employment relationships and retraction of state presence in the economy. The manifestations of this development of emerging capitalism fall into the paradox which is that while focusing on self-regulatory role of market mechanisms, on the other hand triggers reactions to counter and offset the perverse effects of market mechanisms.

The processes of creative destruction of capitalism, according to Schumpeter (1994), more accurately explain the development of international capitalism in its highest stage, globalization. The neoliberal interpretation of Hayek (1975) that the employer, under its responsibility, decides which produces, what services offers and how it does it in business activities, it's totally free. Consumers, meanwhile, are free to choose, according to their income, between values and services offered by the employer.

The socialist system was not ready to compete with the creative destruction processes of global financial capitalism that promises prosperity for all. Financial crises are a sign that the capitalist system is in constant transformation and creative destruction, such as the case of the oil crisis of the late seventies, the crisis of globalization in the nineties and the crisis of 2007-2008, no matter where those who harm while benefiting big business. The ideology of neoliberalism was pushed around the globe condemning all public action coming from the nation-state, transferring ownership of public assets to private and employing military intervention to defend their interests. The economic-political elite and their agents are campaigning to legitimize neoliberal ideology of transnational capitalism that promotes free market.

## GLOBALIZATION: THE HIGHEST STAGE OF CAPITALIST IMPERIALISM

Transnational capitalism builds a system of institutions that overcome the structures of the nation state, exceed their functions, facilitate networks of supranational integration between groups belonging to the same stratum, reconfigured global social forces and dominated groups and dominant groups deepening global divide between those who benefit from globalization processes and those without.

However, the globalization of economic activities is promoted by governments, business and other groups. Everyday life changes and makes new systems and transnational forces, transforming the institutions of the societies we live in and has to do with the rise of individualism (Tepoztlán Center, AC. 1999). The emergence of this individualism is due in part to competition extends to the same individuals and is worrisome because it can determine the level of latent authoritarianism inherent in capitalism. Capitalism emerged as the result of individual liberal freedoms to guarantee individual legal and political equality. However, advanced capitalism has become quite adaptable and compatible with authoritarianism with policies suppressing individualism and intellectual freedoms.

This competitive individualism is the foundation of economic crisis of the globalization system. Soros (2002) argues that by stating that the public interest benefits by allowing people to pursue their personal interests, market fundamentalists have blurred the distinction. Those who adhere to this ideology of convenience have no qualms about bending the rules to their advantage. The result is not perfect competition but a cheater capitalism, in which the rich and powerful feel justified in enjoying their privileged position. The mechanisms of competition as a motivation are driven by the imperial rival states and generally by the same imperial system. In the words of Petras (2013b) competition in capitalist terms is mediated, influenced and directed by the states.

To achieve rationality and market efficiency should be with values of democratic culture such as individual freedom, legal and political equality based on competition, under the reasoning that liberal democracy and capitalism are explained by economic reasons and the struggle for recognition. The relationship between the market and democracy is a tortuous relationship while the principles of political economy which underpin transnational capitalism contradict the principles of democratic theory when certain rights are privileged over others. Research shows that the theoretical models based on economic theories are linked to economic growth. Empirical research on the relationship between the market and democracy is very limited to some countries and regions. Rohrschneider (1999) found that the relationship between democratic and economic values as indicators is ($r = .51$). Grosjean and Senik (2007) found simple correlations supporting the relationship between democracy and market although the reverse relationship was not clear-cut.

This liberal democratic theory is founded on the principles of freedom and equality of individuals, where they become more relevant to the communities and their political identities. Thus, democracy has become the perfect tool to maintain the hegemonic power of globalizing capitalism. Around this principle of liberal democracy there is a debate between liberal multiculturalism positions, democratic socialists and communists. Liberal democracies became more advanced social democracies.

In the eighties and nineties it was used the term "informal economy" whose expansion is related to the structural conditions of transnational capitalism that result in increased poverty and marginalization in the global scope. The size of the informal sector is a good indicator of the quality of external institutions, taking into consideration the costs of structuring relationships with external institutions that are related to the proportion of interactions that ensure the design of domestic institutions.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Long before the term globalization, proposed in 1983 by Theodore Levitt to designate a convergence of global markets, and to refer to an object that is elusive and unmanageable, it was a buzzword to mean economic connections, the world were economically and politically interrelated. The term globalization acquired mid-1990 a media attention in the new international order in 1991 that allowed new ideas to the negative image dragged by capitalism.

In the emerging new world order, the State does not disappear but is disaggregating into distinct parts, separated according to their functionality. A new status of nation states emerged in the stratified world political unipolarity. The State is well in captivity, caught in the web of the interests of the dominant national groups seeking trans-nationalization of capital accumulation by penetrating power structures of global capitalism.

The rise in the less developed countries of a new transnational capitalist class connected to international financial circuits, which under a neoliberal hegemonic project, have become the new economic elite that has been the rise to political power and promoted the interests of imperialist capitalism. The economic-political elite and their agents are campaigning to legitimize neoliberal ideology of transnational capitalism that promotes free market.

The rhetoric surrounding the consolidation of the Cold War divided the world according to the degree of development of their economies in those highly developed that made the first world, and those economies that agglutinated around socialism not integrated into the world economy forming the second world. Finally, all other not developed economies were known as the Third World. In the times of the Cold War, the world was divided into bipolar democratic nations with the United States at the front and communist nations aligned around the power of Russia.

The fall of the Berlin Wall and the disappointments that caused nationalist economic policies in many nation-states, it was believed that this represented the triumph of liberal democracy around the world. Similarly, the sharp fall of Soviet socialism and the countries of Eastern Europe, of which curiously, Gorbachov has argued that its essence was competition in the Hegelian-Marxist concept. The collapse of communism legitimized democracy as the political system more viable.

At the end of the eighties, the end of the Soviet bloc gave the final push towards consolidation of neoclassical theory as dominant as the only approach to national development increased with growth strategies focused on the state. Those growth strategies of communist states were discredited. The way was clear for the global expansion of capitalism and with it the hegemony of the theoretical school more market oriented.

Therefore, real socialism entered into a period of total decadence, in a crisis of no return. Against the excesses of capitalism, it is necessary to find explanations and teachings of this fall in order to redefine the new forms of organization. While it must be accepted that socialism did not fail completely because undertook significant contributions to the development of the people who experienced it. Moreover, however, the socialism could not resist the ideological attacks of globalizing capitalism.

With the disappearance of the economies around the real socialism and the opening of Communist China, the second world is made up of a set of economies that have a relevant role and form the periphery. The economies of the second world become more profitable for the first world. The development of capitalism globalization with a new geo-economics is expanded to all corners of the globe. These peripheral economies of the second world have competing interests in terms of negotiations for preferences for their economies.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the world order, two characters appear in capitalism today: first, the use of military power unfettered, and in the second instance the pre-eminence of speculative finance. The defining characteristics of capitalism today are: a) private ownership of the means of production, utilities and strategic natural resources, with a high concentration of multinational companies. b) oligopoly market and dependent on external hegemonic centers, c) extreme commoditization of capital-labor ratio, with the consequent growth of surplus value for the capitalist and the worker's inferiority (Wallerstein, 2001; Amin, 2001; Dietererich, 2002; Galeano, 2002).

The spatial reference of development has moved from the national with the weakening of the nation state to the supranational level and local blocks strengthening regional integration and decentralization of functions to local governments. Only now the phenomenon appears as a true paradigm mounted on several fallacies, myths and slogans that lead to democracy, to the welfare and progress of mankind. A global democratic proposal does not fit local situations and vice versa. Besides, there is a growing tendency to the rights of man and of the property and not to the construction and development of a public space (Laïdi, 2000).

Transnational capital has the ability to dissolve its commitment to the welfare of the working class, which regardless of territorial boundaries; it is a reserve for transnational capitalism. So, at this historical juncture, rather than as a characteristic, transnational capital has broad power over the masses. Financial expansion of capitalism which is based on periodic crises, accelerated mobility processes, concentration and financial performance and questioned the monetary policies of national institutions, leading to a restructuring of production systems on a global scale.

The establishment of blocs linked to free trade agreements (FTAs) ("one market, one currency") increases the risk of instability and international competition, until there is - by necessity - a global reference currency, the one of the country that becomes the leader. The crisis of Fordist capitalism found its own limitations and contradictions as a production system with the processes of capitalist accumulation, was the cause that triggered the scientific and technological revolution reorganizing the production system in multinational agencies that promote the globalization processes.

The technological monopoly of transnational corporations concentrates resources and excludes from the benefits to those without the skills to join the processes of scientific and technological revolution. Thus, without the skills are sentenced to a dependency and in the best of the cases, to be mere repeaters. Business and corporate mergers are a trend of the concentration and accumulation of monopoly capital to address the effect of recurring crises of capitalism. The release of capital of rigid Taylorist, Fordist and Keynesian processes facilitates the emergence of a transnational integration of interests and global movements of political economic elites.

However, they are not the only corporate America winners on the board of globalization as a product of the contradictions in the development of neo-capitalism, of the tensions generated in all areas of human activity, and the side effects of global markets. These large U.S. corporations increased their reliance on foreign subsidiaries to capture profits through export strategies, so they are the primary stakeholders in promoting the adoption of the principles of free market and neoliberal economics. Global corporations are motivated by establishing branches in all corners of the world where the rules of origin are applied to "local content" to meet the requirements of free trade and its major customers (Dietererich, 2002).

Of the 500 corporations more important in the world, 46% are from the United States and in less than a decade have increased their profits by 36 to 43%. Eleven of the 13 world's biggest financial houses are controlled by investors from United States, according to Petras (2013a). In the global economy dominate euroestadounidenses companies. 79% of the 500 largest multinationals are located in the U.S or Europe.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

If it is included Japanese corporations, the percentage increases to 91% (Petras, 2013c). International agreements that are perceived as negative for capturing profits of TNCs and MNCs are rejected, always looking for a justification to "humanitarian purposes."

The capitalist economic growth is linked to imperialist expansion. In the third phase of expansion of globalizing imperialism, its goals remain the control of world markets and the exploitation of the resources of the less developed countries (LDCs). These processes are linked to multi-secularly deployments in polarizing world capitalism. The processes are also compatible with the logic of imperialism for domination and appropriation of surplus (Saxe-Fernández, 1999). The transfer of this surplus is ensured by the design and implementation of policies in conjunction with global power structures. In this phase, the economic globalization equals to imperialist capitalism expansion of global markets.

## THE EMERGENCE OF THE NEW ECONOMY

In the last three decades of the last century (the twentieth century) globalization processes extended and deepened due to a number of factors, including: The technological revolution with its rapid development of telematics, communications, and rapid innovation science and technology base. The interaction of the revolution in information technology and communication, the crisis of the welfare state and capitalism, and the emergence of new social movements have led to the formation of a new hegemonic social structure that Castells (1998) calls the "society-network ", the new economy based on the informational / global and a new culture on the basis of real virtuality.

Economic globalization is a phenomenon that has resulted in the advancement of information and knowledge technologies (IKT) like telecommunications, through the integration of economic activities that occur mainly in the rapid increase of capital mobility. This increase in international capital mobility, along with the increase of strategic alliances, mergers and acquisitions is one of the characteristics of the economic globalization processes.

The so-called New Economy as a development strategy has largely failed in its expectations. Basically, those profitability criteria are the same as the traditional economy based on advanced industrial capitalism that generates goodwill in favor of capital and against the amount of work and information. In addition, the information tends to substitute capital which it is information itself and therefore also tends to replace the work. Creating virtual capital disappears in the digital world the notion of time as a factor for accumulation. Today, the world is witnessing the third great revolution supported by an expanding capitalist imperialist revolution of economic globalization, which is challenged by those promoting the democratic revolution and the transformation of capitalist appropriation forms of surplus value by other more collective forms.

It is at the local, national and regional levels where it is managed the dynamics of transnational deregulation of markets, so it is considered that capitalism as a system is promoted nationally. In part, national economic policies are adjusted to the pressures of national capitalist elites integrated to networks of transnational capitalism, rather than external pressures of global institutions. The expansion of capitalism took advantage that gave it advantage over the spoiled peripheral economies and their dysfunctions. As an example, the payment of the foreign debt of Latin American economies is a priority in their budgets for social spending on education, health, etc.., and infrastructure investments. The support to handle the debt crisis of the least developed countries took advantage of transnational capitalism to impose operating structures and enforce conditions. The strategy worked perfectly to take hostage

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

to countries that refused to accept the implications of the new global development model. While debt relief is made on behalf of poor countries, they get worse if resources are not correctly applied based on programs that are aimed at achieving economic growth as an end in itself. The weakened culture of dependence of the poor is replaced by the impressive hegemonic project of capitalism expansion encouraged by the economic interests of large corporate groups. This program should give credibility to the economic policy implemented.

As a result, even though the upper classes and their servants in government incur in charging large debts in the seventies and eighties, the lower classes have been bearing the burden of debt repayment during the nineties. Since the mid-seventies a new stage in the history of world capitalism important layers of the population ever increasing in number observed and increasingly considered as their working and life conditions deteriorate (Bienefeld, 1991).

The capitalist power or hegemony has the resources and the power to impose such rules as the transnational hegemony of global capitalism development through supranational structures. The governments of the imperialist corporations and international financial institutions most influential share a concept of global development and poverty alleviation centered on unlimited economic expansion of open markets and trade liberalization. The nation state has become an instrument of development cooperation of transnational capitalism. If looking at the neoliberal state as a continuation of the welfare state, it means legitimizing the new correlation of social forces arising from the transformations of capitalism and establishes the framework and infrastructure for creating transnational state.

The transnational capitalist elite requires of regulatory processes to stabilize the capitalist system. The economic elites who rule in market democracies conduct intense campaigning to convince global citizenship in the myth of unprecedented power. The superstructure formed by transnational institutions design policies that nation states must implement. In global markets, the interactions between companies and consumers, cultures and capitalisms, transform to homogenize preferences, which causes people to react positively or negatively in the expressions of fundamentalism. For other, divergence and heterogeneity is a valid form of reaction to the marketization of social life and the trade and financial integration.

## IMPACT ON LATIN AMERICA

The formal implementation of this approach in the Latin American states was called structural adjustment and basically consisted of seven steps: the unilateral opening of foreign markets, extensive privatization of state enterprises, deregulation of goods, services and labor markets, capital market liberalization, with an extensive privatization of pension funds, fiscal adjustment based on a drastic reduction of public spending, restructuring and thinning of social programs supported by the state with a focus d compensatory schemes for the most needy and to industrial policy and any other form of state capitalism and concentration of macroeconomic management (Portes, 1997).

Countries undergoing structural adjustment program accepted institution building related to the interests of transnational capitalism. Structural reforms in labor and social policies encourage de-commoditization, while globalizing capitalism relegated to the role of state attention to sectors excluded by a more competitive labor market and flexible production systems through the hypothesis of inequality compensation levels. This legitimizes the economic and social inequality of capitalism under the guise of development (Thomas, 1989).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The global economy has a tendency to increase productivity levels based on scientific and technological innovation, cheap and flexible labor has to adapt to the conditions of international competitiveness. The mobility of labor has not been liberalized, despite the potential benefits that would bring discipline to the domain of the free market. Since national and local companies lack the means to compete on equal terms with transnational capitalism, they have little choice other than to become the local junior partners.

Galeano (2002) recounts the realism of capitalism in Latin America as economic and political system of Iaocca when he argues in a conference that unemployment is a hard problem. Today we can do twice as many cars with the same number of people. When it comes to improving the educational level of the population, as a solution to the unemployment problem, he always says that he is worried about the memory of what happened in Germany: there education was advertised as a remedy to unemployment, and the result was frustration of hundreds of thousands of professionals who were pushed to socialism and rebellion. I find it hard to say, but I wonder if it would be better for the unemployed act with clarity and leave to find work directly to McDonald's.

Employment is the means of access to markets. Price controls appear to be problems of the past, but terrorism has resurfaced. Above all, the richest countries are also those with the best brands in the business.

## CRITICAL ANALYSIS OF THE EFFECTS OF CAPITALISM

A critical analysis of the effects of capitalism reveals that created extreme inequalities in the region and almost worldwide. Inequality as an inevitable product of postindustrial capitalism is increasing almost everywhere (Muller, 2013). According to the analysis of Piketty (2014) income inequality has grown because "the ratio of wealth to GDP declined in Europe from 6:1 or 7:1 around World War I to 2:1 in the 1960s. It has since rebounded to nearly 6:1. The United States experienced a smaller decline, since its factories were not destroyed by the two wars, but has also experienced a growing wealth-to-GDP ratio of late." Second, r or rate to return to capital or wealth has averaged around 5% over long periods of time in many different countries, while g or growth rate of the economy cannot be expected to grow by much more than 1%.

Those who earned more from the processes of globalization are those that changed their policies to be inserted, than those who did not, according to Lindert and Williamson (2001). Pritchett (1996) recommends forgetting convergence because the evidence suggests that the predominant theme of the modern economy is a massive divergence in per capita between rich and poor, a gap that continues to grow yet.

In other words, globalization is deepening dependency relations and development between the peoples of the world through processes that are of looting, plundering and devastation of natural, human and financial resources. In this regard, Gonzalez Casanova (1997) said that the current globalization reformulates and maintains dependence structures of colonial origin, the equally strong imperialism of the late twentieth century, and the central and peripheral capitalism that was organized between 1930 and 1980.

Moreover, the globalization of capitalism also globalizes misery, even though its aim is reducing the level and severity of poverty by taking advantage of this phenomenon. Clearly, not so much the amount of resources determines the level of poverty in a country but is uses of resources. Poverty has many dimensions, from which they are always hungry, to the lack of development opportunities and lack of access to basic infrastructure, such as lighting, water, etc., to psychological aspects such as impotence, humiliation and dependency. An estimated 40 million people die of hunger every year.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the capitalist system, democracy has serious problems of legitimacy. Covertly legitimate liberal democracy to capitalism in the domain of man by man through the process of developing legal rules to implement the economic policies formulated in the best interest of the structures of economic power of large corporations and transnational speculative financial capital that dominate the international market. They rely on the decisions of the technocrats of undemocratic international financial institutions to impose their guidelines to governments with the consequent loss of sovereignty.

The role of the democratic state conflicts with post industrial capitalism globalization between the processes of commoditization and de-commoditization of social policy. What we are witnessing is a radical change of industrial capitalism to a post industrial conception of economic relations. Nevertheless, as a result of the implementation of programs of economic liberalization, society is polarized reflecting the contradictions of industrial capitalism, to the point where it becomes a dual society in which few have access to the benefits of age information, while others are totally excluded. The processes of neoliberal globalization increases social inequalities that weaken the democratic system sharpen the contradictions and make it incompatible with capitalism.

In the latter part of the twentieth century that balance was broken in favor of markets and here is the result: the loss of public confidence, counterfeiting and fraud destroy capitalism and the free market, and in the long-term the foundations of our society. This has not been said by any dangerous leftist, but by the Federal Reserve former chairman, Alan Greenspan. Did also exaggerates Greenspan? The world systems theory focuses on the study of the social system and their interrelations with the advance of global capitalism as driving forces between the different countries, including the small.

Despite the hegemony of the capitalist system continues to grow, in the last two decades the global economy is constantly deflation threatening large investments from U.S. imperial and capitalist hegemonic interests. Already these interests are in tension and confrontation for a locus of power to maintain an advantageous position that allows them to accelerate capital accumulation. Of course, government can intervene to correct most of the financial crisis, although capitalist hegemonic interests leave small room for maneuvering. The U.S. imperial strategy to reverse the trend of decline of hegemonic capitalism has caused more instability to the global economy and thus some geopolitical arrangements that portend the imminent fall of the imperial hegemony of capitalism.

The crisis of the object capitalism falls more in the realm of use value rather than exchange value. Signs of exhaustion of neoliberalism were presented from regional financial crises started with Mexico in 1994 and the chaos caused by the dynamics of the new economy that tried to be the locomotive of the global economy entered in crisis in 2001. High levels of economic speculation determine vulnerability of the economic system.

It is enough that a national institution has financial difficulties to drag after it a broad sectors and beyond the frontiers, making the regional phenomenon. But the end of the economic crisis means the recovery of the beneficiaries of capitalism and a serious decline in living standards and social benefits of the working classes. The future of workers is very uncertain. The crisis of the object capitalism is presented more in the domain of their use value that in the domain of exchange value.

## QUESTIONS TO NEOLIBERAL ECONOMIC GLOBALIZATION PROCESSES

New social movements against neoliberal globalization, starting from Seattle, consolidate theoretical and practical exhaustion of neoliberalism and question both the effectiveness of these policies as its

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

claim to be the only viable development path. The global justice movement has its roots in the past 20 years in the least developed countries, although there is strong rebellion since Seattle in 1999 in developed countries as a democratization movement that is opposed to the imposition of neoliberal policies. With the ideological crisis of neoliberalism that has implications for the economic and social crisis that weakens the political systems, questioning the free market principles, are promoted civil society actions and claimed the complementary roles of the state. The struggle against neoliberalism is also against the commoditization of the world.

Proponents of global capitalism argue that if the conditions of law and order are maintained, the economic welfare of society will increase, because it is more consistent with human nature, they argue. However, globalizing capitalism is inherently polarizing development of peoples, while being threatened by low economic growth. A critical analysis of the effects of capitalism reveals that it has created extreme inequalities in the region and worldwide. The economic and social inequalities among the world's advanced countries and many Third colonial and semi-colonial worlds are persistent.

The checks and balances are bonds, alternative experiences, establishing solidarity between people. The checks and balances are the many instances in which policy is developed. They are counter-posed fundamental questions about how the world is building capitalism. Forums become symbolic places that are manifested and expressed in the various counter movements in convergence or resistance, with joints from the same basis. The multiplicity of social movements is its strength and what most fear the project of hegemonic ideology of capitalism. Social movements have a role in the findings of a comprehensive response by establishing transnational networks that after mitigate imaginable ethnocentric inclinations; can provide a counterbalance to the globalization of neoliberal capitalism.

The activities of these organizations pose no danger or risk to the power structures of economic and political elites, for the nation state, to international financial institutions, to the imperialist states and transnational corporations. At the heart of the counter-powers develop new strengths, new demands, new political practices, new forms of struggle and life. The drive and creativity are vital in counter-powers (Proceso, 2001). Historically capitalism shows some contradictions that limit growth and threatening the mythology containment policy to enter an uncontrollable crisis of collective empire and to avoid it requires alternative models for a new world order in much will depend on the emerging forces in opposition to the new global colonialism that fits in a cynical, repressive and exclusionary political ideology.

Despite the emergence of a plurality of critical thinking processes in globalization that speak of alternative models, it has not materialized a social organization different from the one that the market-based capitalism promotes. Critical thinking has to consider in theory and experience the weaknesses of capitalism and the design of a new world order as an alternative analysis from the local to the global policy. It should be facilitated by adequate, new practices and strategies of social movements oriented towards the anti systemic design of a democratic and sovereign alternative.

## CONCLUSION

This analysis reaches the conclusion that the primary cause of the extreme social and economic divergence in terms of inequality in anywhere in the world, as it could be in Latin America, is the result of the expansion of capitalism in the world. Thus, contemporary Latin American economies have become an integral part of the new global economic system that is not dominated by nation-states but by large

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

transnational corporations that are major global players in this system. In other words, transnational capitalism has influenced institutions and organizations.

Neoliberal ideology has been used to justify the strategy of restructuring policies and economic adjustment followed in most Latin American countries since the eighties. In fact, globalization processes stimulated by the global expansion of capitalism and development have consistently favored only a limited proportion of the Latin American population while the majority has to suffer the adverse effects of this process.

This political theoretical analysis leads to conclude that there is an increase trend of divergence. There is a tendency for inequality to diverge whenever the rate of return of capital is greater than the rate of economic growth. If the difference is positive and large, it leads to a divergence of wealth between the very rich and the rest of population. The fundamental inequality (p. 25) or the fundamental force of divergence (p. 351) as defined by Piketty (2014) is based on comparing the (real) interest rate of the economy to the growth rate. According to Piketty (2014) the "forces of divergence can at any point regain the upper hand, as seems to be happening now, at the beginning of the twenty-first century," and, "the consequences for the long-term dynamics of the wealth distribution are potentially terrifying."

In other words, it is the subsidiary state, properly a neo-liberal model dependent peripheral capitalism, the dominant ideology and practice in the last 33 years.

It is needed an organizational cultural transformation for not accepting the forms of domination, power and alignment of globalizing capitalism and to reconstruct the identity of communities, institutions and organizations through individual and collective action claiming self-determination, independence and self-management. Capitalism, by itself, has no ethical value. This does not mean that there are no moral capitalist. Morals and Ethics are not synonymous when applied to individuals in institutions and organizations. Its moral molded into human nature towards individualistic and naked singularities most harrowing miseries of men when its project of power has no ethical limits in institutions and organizations.

One solution to break America's dependency relationship is to develop a protectionist capitalism within a trading bloc that facilitates transnational formation of institutions and organizations under different ownership and new forms of governance and under a development strategy that Dietererich (2002) termed as creating research, production and global marketing complex (RPMC), which can be achieved by the union of holdings, part of the global surplus in its market segment.

Finally, some suggestions to eradicate or at least remove misery evolving convergence are:

Sustainable and social responsible business strategies addressing the needs of the bottom of the pyramid markets will help to eradicate, to a certain extent, the global misery evolving convergence.

The beneficiaries of targeted poverty-alleviation programs need more personal capabilities development and political empowerment in order to sustain and maintain the quality of the benefits and services received.

Local governments should design and implement antipoverty social policies targeted to alleviate misery most effectively making sure that support reach the real poor and involving more actions of people involved in poverty alleviation programs.

For real poverty removal and misery evolving convergence it is required to impose increasing fiscal policies and tax systems more tied and corresponding to the increasing levels of income.

## KEY TERMS AND DEFINITIONS

**Capitalism:** It is the set of elements that inspire ethical entrepreneurs on their shares in favor of capital accumulation. Beginning from this argument, capitalism has embodied entrepreneurial ethical values establishing a new moral relationship between people in their work settings.

**Convergence:** It means coming closer over time in respect of any social, economic, political and natural variables.

**Divergence:** It means moving away from each other over time in respect of any social, economic, political and natural variables.

**Globalization:** It means the opening up of the domestic economy into the face of the global world. It enhances in the cross country flow of goods and services.

**Institutions:** It is an organization founded for a religious, educational, professional, or social purpose.

**Neoliberalism:** It is an approach to economics and social studies in which control of economic factors is shifted from the public sector to the private sector.

**Organizations:** An organization is an entity comprising multiple people, such as an institution or an association, that has a collective goal and is linked to an external environment.

**Transnational Capitalism:** The transnational capitalism in neo-Gramscian and other Marxian-influenced analyses of international political economy and globalization, is the global social stratum that controls supranational instruments of the global economy.

# Chapter 85
# Integrated Sustainability Reports:
## Historical Survey, Theoretical Proposals and Best Practices

**Massimo Costa**
*University of Palermo, Italy*

**Giuseppe Valenza**
*University Mediterranea of Reggio Calabria, Italy*

## ABSTRACT

*Disclosure of corporate social and environmental sustainability, resumed in 'sustainability reports', have occupied most of the attention of accounting thought and practice over the last few decades. Evaluation of ecological footprint and social sensitiveness is becoming relevant also for the investors. The chapter presents institutional disclosure concerning social, environmental, and integrated (financial, social and environmental) issues in a threefold perspective. The first is a historical one: after some definitions the birth and development of sustainability reports are presented to the reader. The second is a theoretical one: a paradigm or framework is developed for including what various experiences and literature have supplied until nowadays. The third is an empirical one presenting the main sustainability scoring criteria mostly used today, and an empirical survey on the car industry. Some concluding notes follow from the comparison of the aforementioned perspectives.*

## INTRODUCTION[1]

For many decades the accounting has expanded its content, focusing beyond the narrow field of financial information and considering the social and environmental information. The increased focus on non-financial information is paradoxically started by big company, typically focused on creating shareholder value (Tinker, 1984).

The need for information required by stakeholders (not only shareholders and equity investors) concerned the issue of sustainable development in the second half of the twentieth century. Initially, corporate sustainability has been interpreted as social sustainability against the unacceptable exploitation of workers and social disintegration. Then, corporate sustainability has also been considered as environmental sustainability, so as ecological sustainability for the production of goods and services, to preserve the rapid consumption of non-renewable resources and to reduce the impact of pollution caused by production processes (Mintz, 2014).

The reasons for this need for information are multiple and often conflicting, but they all stem from the opportunity to involve stakeholders in their business to converge corporate goals with stakeholder objectives. Therefore, the first academic studies on this subject were included in the field concerning the stakeholder theory (Freeman, 1984; Freeman & Evan, 1988). Specifically, the need to provide information to the stakeholders is derived from a new social sensitivity towards the issue of sustainability, which is interpreted as: strategy for creating sustainable value added (Figge & Hahn, 2004); social commitment of the company to safeguard the rights of the community (Vallance et al., 2011); request of ethics by the community (van Marrewijk, 2003; Di Giandomenico, 2008); a result of an expansion of the stakeholders (Dawkins, 2003); possibility to ensure human development (Anand & Sen, 2000). Today the communication of information reaches social and environmental objectives that coincide with the goals of investors and management, at least in the most advanced companies and in the advanced countries.

The social and environmental disclosure is traditionally divided into two parts. This distinction is derived from a difference between the two 'new' areas of reporting. Social accounting concerns the reporting of the impact of business on human and social aspects, which can be both economic and non-economic (e.g. value added distribution, employment, social well-being created), instead environmental accounting concerns the reporting of the consequences and any benefits of the business on the ecological environment (e.g. protection of environmental balance, environmental sustainability, use of energy resources) (Gray et al., 1996; Unerman, 2000; Adams, 2004). According to the most recent literature and best practices, the chapter also argue the issue of integrated reporting, which considers financial, social and environmental information, focusing corporate communication towards value creation over time (Busco et al., 2013). Recent literature (Guthrie & Yongvanich, 2006) also highlighted the need to coordinate the Balanced Scorecard, Intellectual Capital and social and environmental reporting to provide more complete account of the management and performance of a corporation.

The expansion of the disclosure from a traditional conception (financial accounting) to a social concept (social accounting) is not simply a generalization of the focus of reporting to other variables. This perspective considers only the formal aspects of the phenomenon. Material aspects depend instead by political and philosophical changes that have encouraged the diffusion of Corporate Social Responsibility (CSR). The principles and structure of CSR have been defined in previous decades, but the latest developments of the debate concerned the implementation of the CSR on corporate performance (Carroll, 1991, 1998, 2000). The empirical literature on CSR has studied many aspects of this issue: e.g. the market reaction to social responsibility disclosures (Patten, 1990) or correlations between CSR and financial performance (McWilliams & Siegel, 2000). Other contributions (Margolis & Walsh, 2001), criticizing the previous studies based on correlations between CSR and financial performance, supported redirecting the empirical analysis of the most useful aspects to guide corporate social initiatives.

CSR begins when the classical economic paradigm (liberalism) is abandoned. According to the liberal paradigm, social welfare is maximized when the selfishness of individuals and competition of businesses are greatest. This paradigm has greatly influenced the development of economics and accounting, thus

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

summarize in a few elements that process of evolution is impossible. However, the most important elements are certainly the neoclassical economic assumptions about profit maximization and competitive markets for the best allocation of economic resources.

Scholars, governments and analysts did not consider the inconsistencies of the classical economic paradigm as abnormal. The assumptions remained valid, therefore the contradictions were considered 'corrections' of a model that was never disputed. Market failures were treated with empirical solutions, often conceived as ethical necessity for the benefit of the community. Alternatives to the individualist paradigm were proposed, some of them disputing any economic organization based on selfishness and market exchanges, such as the Marxist paradigm (the only real alternative to the predominant system).

Accounting followed the economic interests of the companies, thus maximizing the net worth or profit, considering only the perspective of the owners or the companies (conceived as institutions). In the debate of the nineteenth and twentieth centuries the economic postulate was never really criticized.

The egoistic postulate became the *only* economic postulate, designed as a certain and indisputable 'law'. The egoistic limits were seen only as 'constraints' to egoistic actions, established by an external body to protect public interests. The maximization of the utility function was the main objective of economic agents, companies and individuals. Opposite behaviours were considered 'subversive' (Friedman, 1962).

The assumption of this postulate is an economic growth without limits and contradictions of the capitalist system of production, but this assumption is inevitably falsified by logic, and then from history. Economic growth does not seem compatible with the unlimited exploitation of the economic, energy and human resources, because it will inevitably fail. Therefore, the attention of public interest to the community and the environment arose from the observation of the contradictions and inconsistencies of the capitalist system.

The social and environmental reporting stems from the opening of the company aims to altruism and solidarity (collective interests), not denying the egoistical characteristics of the companies related to the achievement of profits. This process is not linear because the 'social welfare' outside the exchange market and financial perspective loses the monetary assessment, which is the unit of measure and the conventional sign for comparing economic resources.

The social and environmental accounting concerns measurement problems of physical, quantitative and qualitative values, which cannot be expressed in a single unit of measurement. The 'quality' is certainly a subjective concept: assessing or measuring quality performance is a process of interpretation, certainly not objective. Therefore, the main problem of social and environmental reporting is not to define principles of objective and universal evaluation (Nicolò, 1997), but to explain and clarify the qualitative assumptions.

Corporate reporting is divided into two sections: (a) accounting and financial statements, which have systematic features; (b) non-accounting reporting (also called statistical reporting), which has fragmented characteristics. Non-accounting reporting is more flexible than financial reporting, therefore it handles better the complexity of qualitative and subjective assessments. It promotes processes of cooperation and expectations between the company and stakeholders, who are promoters of concrete projects for sustainable and socially responsible corporate policies.

Non-financial reporting has serious limitations: different methods, notions, classifications and units of measurement. Financial accounting may instead provide for the systematic integration of data and concepts. It shall be therefore regulated (ex ante) and revised (ex post) to ensure reliability and neutrality of accounting systems, although it is possible that companies intend the financial accounting as a

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

fulfilment. For this reason, the chapter will discuss the social and environmental accounting following a systematic view.

The aim of this chapter is not to deal with the social and environmental aspects included in corporate purposes but to focus on reporting, also analysing the best practices of the companies. A brief diachronic synthesis will follow, also considering literature, historical development, laws, empirical observations, but without providing a comprehensive review.

The chapter aims to explain the historical origin of the social, environmental and integrated reporting, considering successively two points of view: the first one is an integrated reporting based on a systemic approach, while the second one is based on a non-systemic approach. Then, an empirical study will analyse the evaluation of sustainability performance of the companies based on integrated assessment of economic, social and environmental dimensions, according to the criteria of RobecoSAM and Dow Jones Sustainability Indices (DJSI). This study will also show the best practices of companies in the automobile industry. Finally, conclusions will compare theoretical deductions with empirical evidences.

The chapter does not explore some issues because there are space limitations, in particular: (a) a list of legal requirements for social and environmental reporting in the advanced countries, despite its importance; (b) national social and environmental accounting; (c) internal accounting (e.g. cost accounting and management accounting).

For this reason, after this Introduction and before Conclusions, the chapter is articulated into the following sections. Sections 1 and 2 are devoted, respectively, to the birth and diffusion of social reporting and to the following emerging of environmental reporting. They are mainly of historical nature. Sections 3 and 4 concern, respectively, the presentation of social/environmental reporting in corporations, and its strategic role. Section 5 concern the integration between financial, social and environmental reporting. They are mainly of descriptive and theoretical nature. Sections 6 and 7, finally, deal with the best practices, and, respectively, with the international practice of sustainability evaluation in general and with the automobile industry in particular. They are mainly of empirical nature.

## 1. HISTORICAL SURVEY OF SOCIAL REPORTING

The history of social reports is relatively recent: fifty years ago the first studies on this topic spread. The classical accounting developed its scientific theories when the first big companies were born during the second industrial revolution, while the big state administrations were spreading (Lipari & Costa, 2005).

At that time only the financial accounting was predominant. It considered two opposite points of view: the first one was the 'assets and liabilities view' (also called 'balance sheet view'), whose main contributions were proposed by Anthony, Moonitz, Kester, Solomons and Sprouse, instead the second one was the 'revenues and expenses view' (also called 'income statement view'), based on the theories of Brade, Dixon and Paton (Lionzo, 2012). This duality also existed in national variants: 'Statik Bilanz' vs. 'Dinamische Bilanz', in Germany, and 'Sistema del Patrimonio' vs. 'Sistema del Reddito', in Italy.

The social reports, and consequently the social accounting, is explicitly an extension of the traditional field of financial accounting. The spread of Corporate Social Responsibility has been the cause of this extension, therefore there is a strong connection between them. CSR has different definitions and notions, therefore it is impossible to summarize all the literature on this topic. Green Paper (2002) defined CSR as "a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis".

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, this notion seems restrictive and narrow. Therefore, a wider notion could be the following: "a concept whereby companies integrate, among its institutional purposes, social and environmental goals, also considering financial and economic aspects, expanding its range of stakeholders, and adapting their strategies and actions, as well as its corporate communications towards these stakeholders".

In the light of this perspective, social reports express a wide corporate communication, including social information (communication in the strict sense) or social and environmental information (communication in the broad sense), which is a part of the larger CSR. Therefore, business communication and CSR are not the same thing, despite the solid connections between them.

Focusing the discussion on the history, an Italian record is recognized in the field of social reports when other countries did not feel sensitivity to social issues. The generalist approach of the Italian accounting shifted the attention of scholars to the third sector enterprises in the early years of the twentieth century. In those years, the only non-profit organizations were called 'Opere Pie', ie religious institutions of charity, in relation to which it was proposed a report that summarized the results of their mission and purpose. The 'mission report' had very limited impact in other areas different from the non-profit sector. There were no similar experiences outside of Italy, because until the end of World War II there were no conditions for the development of a social sensitiveness in the reporting field.

The Germany showed signs of sensibility on social issues like Italy, where AEG Company published the first Social Report in 1938. At that time there was a culture of corporatism in Italy and Germany, thus the first studies of social economy began to spread, where scholars theorized a 'third way' between socialism and capitalism and the active intervention of States over national economies. It is no coincidence that the first 'business administrations' were born in Germany and Italy, as evolution of the corporate administration and accounting. Both Italian 'Economia aziendale' and German 'Betriebswirtschaftslehre' proposed studies about intermediate economic systems, and their contribution to domestic production (GDP), seen as the predominant purpose with respect to the distribution of profit for shareholders. In this cultural climate the income theories of Gino Zappa (1937) spread, where income was seen as the result of a durable combination of factors of economic production, considering a social and holistic view of the company. As well as the 'Dinamische Bilanz' of Eugen Schmalenbach (1919), which proposed the income statement configured in value and cost of production obtained, indicating the company's social contribution to domestic production. But it would be wrong to attribute this sensibility only to the authoritarian regimes of the past, since similar theoretical and practical experiences are found in socialist countries of Northern Europe, like Sweden, or in countries with a long liberal tradition, like the Netherlands. This sensitivity - as mentioned - does not invest the entire theme of the social report but caused the first phase of the 'socialization' of the traditional report, incorporating indexes and values in it out of the traditional reporting aimed at investors. After World War II the first social democratic governments were born in Europe, therefore the studies about socialized reports continued to major developments (on the concept of 'socialized reports' and 'social reports', see Gabrovec Mei, 1990). The more invasive role in the economy by the states, the growing social sensitivity and trade unionists, strengthen the focus on social reports.

In this light, dirigiste orientations of France and Spain can be interpreted, where the government, through a mandatory accounting plan, proposed to guide the industrial policy of private companies and direct them to national and social purposes.

However, the issue of sustainability has appeared everywhere with social, political and economic movement of the sixties. 1968 is the year in which the cultural process achieved full maturity, it is the moment when the literature and practice on the social statement really began to develop. The Anglo-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Saxon countries were a little back, only in the following decade they remained fully involved in the new cultural scene. The seventies are certainly those in which both the literature and the practice on the social report finally implement their scientific contents. In the United States, following the model of the traditional disclosure, the Survey on Social Responsibility Disclosure is published. Similarly, a White Paper is published in the UK. In Germany, the practice of publishing social reports spreads more, becoming widespread among big companies. In Italy there is a discussion of doctrine, but also the first publication of a social report, by Merloni in 1978. In France, a country of traditional legal regulation, a law on the social report is published.

In summary, the most advanced countries were opened to social reports, each one according to their cultural, economic and legal traditions. The theoretical models are, however, fragmented and undeveloped at that time. The most consistent theoretical model was proposed by Solomons (1974), but it was difficult its practical applicability. This model in fact adopted only the monetary unit of measurement, limiting the field to only those elements capable of economic assessment. In summary, the model can be summarized in the following formal expression:

Overall Value generated by the production process (*Added Value*)
+ External Benefits (for external subjects or for the community)
– External Costs (as before)
= 'Social' Profit/Loss

In the following decade, the scientific debate on the social budget is consolidated. It is important to remember IX International Congress of Strasbourg in 1983, when the first structure of the social report was proposed, based on the German experience. In contrast, there was a reaction of the scholars of the traditional report against all forms of socialization of the financial statements.

This reaction was in accordance with neoliberal environment in those years was consolidated, especially in Anglo-Saxon countries, but it was an opportunity for a complete emancipation of the debate on the social report against the themes of traditional accounting.

The debate on the environmental report was born in the nineties, reducing attention to the social report, which has become mature. The gradual broadening of the range of stakeholders also determined the consideration of 'future citizens', therefore sustainability became an intertemporal concept impacting on the reproduction ability of resources consumed in production processes. In this context, the social report had two meanings: as a broad meaning, the social report considered both social and environmental information; according to a narrow sense, it considered only the social dimension reporting, leaving further information to the environmental report. In the same years the researchers attempted to assess the 'quality' of corporate performance, using non-financial approaches. In this direction, a significant contribution is certainly the balanced scorecard (Kaplan and Norton, 1996). Literature and practice in the last fifteen years are not easily summarized, since the contributions and proposals are very numerous, but here highlighting at least a process of standardization of rules for the preparation of the social report (such as the EU Green Book, 2002).

European Union, which summarizes literatures and practice of European countries, is perhaps the most advanced in the world for attention to social issues. Directive 2003/51/EC regarding the 'Modernization' establishes the need to include financial and economic indicators for better understanding of the development or performance of the company, considering also non-financial indicators (employees and environment) when appropriate. However, all proposals for standardization and promotion of social

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

disclosures have never been legislatively mandatory. The information society is now therefore purely voluntary. The international network of scholars of CSR has been consolidated in recent years. Among these it is important to remember the Encyclopedia of CSR (edited by S. Idowu, 2012) and other publishing initiatives in the same field, as well as the First World Congress on CSR (London, 2014), followed by other world conferences (Nanjing, 2015; Cologne, planned for 2016).

## 2. THE SPRING OF ENVIRONMENTAL REPORTING FROM SOCIAL REPORTING

Environmental Reporting is much shorter and more recent. As it was said before the environmental sensitivity found its way just in the '90s (Amendola, 2006). Scientific studies had already showed that a continuous development would imply a more and more intensive deployment of not renewable resources and a so deep consumption of renewable ones to make them will be not recovered in the future. According to authoritative studies already in 1985 global consumption of renewable resources exceeds the ability to reconstitute them, and since then such a ratio worsened rapidly year by year. Since '90s, then, the public opinion acknowledges the fact an unlimited growth is not sustainable. The same concept of 'sustainable development' was formulated in 1987 'Brundtland Report' (WCED, 1987) by the World Commission on Environment and Development. After some years one arrives to the signature of a joint document among various countries (the so called 'Agenda 21'), in the Rio de Janeiro Conference of 1992: for the first time principles, objectives and actions for a more equilibrated development are determined under an economic, social and environmental perspective. Rio de Janeiro 'Agenda 21' was still a transition document: the unlimited development was not still denied, but it is theorized a possibility for it is sustainable. The same environmental sensitivity is finally outlined, but beside to the more traditional social one, and then it was not still an autonomous field at all.

Anyway, since then a new literature is to be recorded, this time specific to environmental reporting (Harte & Owen, 1991; Roberts, 1991; Lehman, 1995; Gamble et al., 1996; Krut & Moretz, 2000; Wilmshurst & Frost, 2000) and parallel to the 'social' one. It enjoyed a relevant fortune and more rapid growth in attention. The first efforts, however, were driven toward 'environmental accounts' conceived as parallel to the traditional economic ones of the 'national accounting'. 'Environmental accounting' remains along as a branch of statistics, while corporate environmental accounting finds it hard to take on its own identity. Notwithstanding this, after two decades, a literature and a practice is spread so much to allow some comparative valuations respect to the wider literature on 'social accounting'.

A very relevant document, which resumes the actual sensitivity toward sustainability themes, even for its possible reference to every kind of organization is that one issued in 2011 by the FEE (Fédération des Expert Comptable Européens), which gives an introductive framework on integrated disclosure, by means of 'key indicators' on social and environmental issues, as well as on governance, meant as the qualitative side of information on management. In this document is very relevant the distinction between separated sustainability reporting and integrated sustainability reporting, where 'integration' is meant with reference to traditional financial reporting. The document does not want to choose between them, but indicates both as directed to different stakeholders, then indicating both as opportune in different contexts of reporting. One observes an apparent paradox in the not symmetric relationship between the two kinds of sustainability reporting, namely social and environmental, at least in literature. Literature on social reporting tends, in fact, to include environmental one, as one relevant chapter of the former, and, then, it loses its self-sufficiency in a strict 'social' discourse. Of course there are important excep-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

tions in some national traditions, as in the Italian case, where there is a self-sufficient and robust stream of studies on social reports (Vermiglio, 2000). On the contrary literature on environmental accounting indicates a stronger autonomy, tending to reject specifically social issues, even if it was born just from this previous literature. At a simple glance on scientific contributions on main international reviews it is evident a disproportion between the many articles on environmental accounting and the few on social accounting, these last ones often including the previous ones.

Another difference in comparison is the difference on the point of view. Social accounting and reporting is nearly always from a 'corporate' point of view, starting from firms and progressively expanding toward other kinds of organizations. Environmental one, on the contrary, finds hard to distinguish itself from 'national accounting'. The latter shows official documents (even at a UN level) that are absent in the former, but the 'corporate' dimension remains quite atrophic. What both share, anyway, is the inspiration for a systematic language, then by means of true accounts and not by means of statistic tables or rhetoric clauses. The same term 'reports' for both sustainability fields, reveals, more than a full balancing of stocks and flows as in financial reports, a theoretical trend toward integrated or systematic statements.

Inside specific contents of environmental reports (INTOSAI, 2010), willing to give a sort of systematic view, we find some general premises, largely common to social disclosure, but more agreed information, concerning mainly the following 4 fields of disclosure: (1) Flows of resources, energy and similar issues, external to the reporting entity, or between entity and its environment, expressed in non-monetary terms; (2) Distinction of the specific 'environmental' inside financial accounting (e.g. the costs for environmental recovery); (3) Measurement of stocks, or positions, of environmental resources, and of flows, or variations, in parallel physical and monetary terms; (4) Financial measurement for environmental outcome of economic activity, and in terms of not renewable resource consumption, and in terms of production/consumption residuals (solid, liquid, aeriform), and – more rarely – in terms of positive effects of environmental recovery (e.g. a reforestation action).

## 3. SUSTAINABILITY REPORTING IN CORPORATION: GENERAL ASPECTS

Sustainability reporting in practice has followed three different ways in correspondence with the three main groups of organizations: enterprises, public bodies, no profit organizations (Hinna, 2005). In enterprises, and particularly in the big corporations, sustainability disclosure belongs mainly to what is called as Corporate Social Responsibility (about reviews on CSR definition, see: Moir, 2001; Dahlsrud, 2008). It is, then, a tool integrating the more traditional financial disclosure to actual and potential investors, which keeps its core business and role. In a nutshell, sustainability disclosure is, for corporation, a projection of traditional disclosure on a broader scenario (Werther and Chandler, 2011). In our opinion, the full understanding of it need a recall of basic features of its historical precedent.

Classical financial disclosure is 'relevant for economic decisions' (*decision useful approach*), and, secondarily, for the 'discharge of manager responsibility' (*stewardship approach*). These two objectives are reached by a comprehensive disclosure on performance, both in terms of controlled financial stocks (resources, when positive, and claims, when negative), and in terms of cash and economic flows, where 'economic' means 'adjusted for competence' cash flows (income and owners contributions, when positive, and expenses and owners distributions, when negative).

Starting from this resumed framework, CSR imagines a sort of 'social contract' (Gray et al., 1988; Sacconi, 2004), similar but wider than corporation contracts, between corporation and a broad set of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

'investors' and 'stakeholders'. This time 'investment' is no longer only a capital investment, but also an investment in terms of 'job', 'consumption', and, generally speaking, an 'entrustment' respect to wider social ends. Now stakeholders are not only single persons or categories, but also the society as a whole, and even future generations, as when we account for the consumption of not renewable resources. Thus, accountability reporting, in order to address decisions, interests this set of actual and potential users, and who represents institutionally their interests (e.g. 'state' in the name also of future generations, as abstract titular of the 'common wealth'). Which kinds of decisions to address? Of course not only economic decisions, but the basic decision to renew the 'trust' toward the corporation, so allowing its life and development or not. And, furthermore, there is also an appraisal on management performance in sustainability issues, perhaps with rewards and punishments, even of virtual character, like social consensus or blame.

In the specific contents, respectively, of social and environmental statements, it is impossible – at the state of art – to present a generally agreed framework. Moreover, doctrine is not uniform in deciding if it is opportune to set a rigid and homogeneous structure, or, at the contrary, a flexible and heterogeneous one. We can just observe first recurring nuclei of contents among the various theoretical proposals and practical experiences. There is always a 'descriptive' part, where social and/or environmental phenomena are presented qualitatively, on its turn shared into two parts: one concerning what is 'inside' the corporation, the other what concerns 'outside', that is relationships with not directed involved in production stakeholders. There is, more, a quantitative part, on its turn shared according different criteria. A distinction is between the part of reports that is derived form or linked to financial reports, and the part where social/environmental variables and relations are autonomously disclosed. Another distinction, partially similar to the previous one, is the distinction between the monetary and non-monetary part. The former shows issues like the formation and distribution of the added value, the reclassification of expenses according social or environmental criteria, the monetary translation of positive and negative externalities. The latter affects not monetary variables, expressed in physical quantitative terms (like, e.g., in environmental statements, acquisition and consumption of energy) or in qualitative ones. Another distinction, this time inside the only quantitative part of the reports, is between the strict social/environmental statements and the various information, by means of ratios or other not systematic tools, which accounts for social/environmental performance. The lack of a unit of measurement that makes homogeneous and comparable the different variables seems, till now, to represent an obstacle for the affirmation of a systematic tool, which expresses in a 'bottom line' the environmental/social available value created or destroyed in an administrative period.

To give some examples, issues dealt by social reporting concern, typically: ethical codes, employment, distribution of added value by means of wages or other income, work conditions, life conditions inducted by the corporate, professional training activities, industrial relations, and generally speaking external relations, definitions of stakeholders and of specific activity directed to or for involving them, social investments, quality of good/service and related trade initiatives, contributions to consumers' health, and more.

To give other examples, issues dealt by environmental reporting concern, typically: even here themes related to health and security, environmental sustainability for what concerns consumption renewable and not renewable resources, quantification of pollution, environmental expenses or investments, environmental ratios for positions and variations of environmental variables, stocks and flows of employed resources, both in physical quantitative terms and in monetary terms, environmental impact of life cycle of products, and more. Environmental reporting, for its nature, shows a greater degree of structured information

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

and quantitative languages than the social one, and, more, a more incisive intervention by the law, even if still relatively fragmented. When 'environmental costs' are presented, of course in monetary terms, they are classified into the following categories: costs of prevention and environmental protection, costs of environmental management, costs of recovery and reparation, depreciation of environmental assets.

## 4. SUSTAINABILITY REPORTING IN CORPORATION: THE ROLE OF STRATEGY

In recent years the international financial crisis is hampering the development of the real economy. Selfish behaviours of companies and financial organizations have guided their decision to short-term choices aimed at maximizing profits. These choices were guided by a partial view in decision-making, which were based exclusively on economic and financial considerations.

In light of the economic disasters caused by the crisis, companies today are changing their paradigm and points of view. Companies are realizing that the maximization of economic and financial objectives in a short-term perspective is counterproductive for themselves, but also for the ecological and socio-cultural environment. The behaviour of firms oriented only to the achievement of profits could compromise the survival of companies, while also reducing the quality of the ecological environment and the quality of life of the communities. The investment decisions of investors consider not only the economic and financial aspects, but also social and environmental ones. This happens not only for ethical reasons, but mainly because it guarantees more security in the investment risk, closely linked with the long-term durability of the company identified for investment (Krosinsky & Robins 2008; Fulton et al., 2012).

Therefore, the predominant concept of current times is 'sustainable development' (Gladwin et al. 1995; Bansal, 2005; Hopwood et al., 2005; Robert et al., 2005; Steurer et al., 2005; Crowther and Aras, 2009) which implies that in the future investors and shareholders will consider investment decision processes more oriented to a long-term and multidimensional perspective. The sensitivity towards sustainability seems to move with the need for a reporting that considers financial, social and economic parameters.

In addition to problems linked to the economic crisis, companies are competing in increasingly large and globalized markets and competitive sectors, where it is much more difficult to defend their competitive advantages and strengths. According to some authors (Nicolò, 2015), the survival of companies depends mainly on their reputation. Consequently, although economic and financial performance is important for the survival of companies, the importance of social and environmental issues is growing. Current and potential customers are increasingly sensitive to sustainability issues when implementing their purchasing processes: quality and safety of goods and services, conditions of workers and environmental protection are variables that customers consider to orient their purchasing decisions. The workers with excellent skills decide to work in companies that have a high reputation, because they are more reliable in meeting the needs expected from employees. Raw material suppliers, service providers and lenders may decide to lower their contractual claims if the corporate reputation is good and shared between stakeholders (e.g. companies can obtain lower costs or more time to fulfil their obligations). Finally, shareholders may choose to invest in companies with high reputation for two reasons: (a) investors want to reward companies that implement social and environmental objectives within their business strategy; (b) investors see safer companies that follow sustainable development strategies, because shareholder value is better guaranteed by financial risks, business failure risks or environmental and ethical scandals.

Companies must define corporate strategy by incorporating in it financial, social and environmental factors. In this way, the strategy of companies can enhance corporate reputation, creating long-term

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

competitive advantages fully compatible with sustainable development. Therefore, companies have to increase corporate reputation, communicating it adequately to stakeholders.

To achieve these objectives, companies can use sustainability reports used not only to account for and report on financial, social and environmental data, but also as a strategic tool to support corporate communication to achieve an increase in reputation.

Managers should follow the steps below to use sustainability reports for effective corporate communication in support of the reputation of the company:

- Clearly define issues, aspects and objectives of corporate sustainable development;
- Involve internal and external stakeholders in defining the issues above (not only shareholders and investors);
- Explain how the strategy of sustainable development (social and environmental objectives) has a positive impact on financial and economic results;
- Communicate sustainability information to stakeholders;
- Make, year by year, the gap analysis between planned objectives of sustainability and actual results.

In the first step, managers identify the relevant issues regarding their sustainability strategy. Second, companies involve stakeholders in order to understand whether the issues identified are really important and shared by them. In the third step, companies intend to convey to stakeholders, especially investors, the link between sustainability objectives and financial aspects of corporate businesses. Then companies show the information on financial, social and environmental objectives to stakeholders, summarized in the corporate sustainability strategy. Finally, through gap analysis, managers give high credibility to the sustainability report, avoiding the risk of using it as a tool to disseminate news on the corporate objectives not actually pursued.

## 5. TOWARD AN INTEGRATED DISCLOSURE: A PROPOSED MODEL OF SYNTHESIS

All the aforesaid doctrine and practice, as for social accounting and reporting as for environmental accounting and reporting, shares an easily recognizable common denominator.

It is the belonging to all relations, be they internal or external to the entity, of 'not financial' character. In words we are speaking about 'non-financial' accounting. The other main feature is the widening of potential stakeholders, far beyond the classic providers of capital.

The same investors are not only passive subjects respect to sustainability reporting as an external bond, but they are really involved and interested in it, because this is perceived like a tool for evaluating the overall risk of business. Anyway, it is not deniable an evident progressive trend to the integration of various kind of disclosure, between social and environmental reporting for a unique sustainability reporting, and between this last one and traditional financial accounting.

Such an integration has not still got a recognized path. In this section, then, we will try a model of synthesis as a contribution toward a rational and compact synthesis of the three main fields of accountability.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Of course the aim of this proposal is not the pretension to be the 'best way' to consolidation of reports along different sets of variables, but it is assumed as an eventual starting point, among other possible ones, to be criticized and overcome by other more mature approaches. In other words, it is time – in authors' opinion – to go beyond the recurrent vague claims for integration and to experiment concrete operational solutions, even though they could be risky under some methodological points of view.

The first choice we do is toward the privileged single corporate reference. Social reports and, more, environmental reports are to consider distinct from disclosure on a 'national' or 'regional' basis, in order it can be considered to have reached an adequate level of maturity. This means that we neglect flows that are totally external to the organization, because they do not belong to the entity. Flows can concern only either inside the entity or relations between inside and outside, not exclusively outside the entity. These last ones will be able to be considered by a parallel 'national' sustainability accounting, which can share methods and system with corporate accounting (as it happens between classic national accounting and corporate financial accounting). Only by this sharp distinction the corporate dimension could get an adequate methodological development for the required disclosure to stakeholders.

The second choice is the fact that social/environmental disclosure is founded upon some general principles: sustainability, accountability, transparency (Crowther & Aras, 2008). These principles define CSR before the same disclosure on it, and the same business ethics, meant as the discussion on the final ends of corporate. From those ends and from those principles the features of sustainability reporting derive for the benefice of stakeholders.

Every statement of this kind, whichever is its name, looks to have always the following two parts: (1) descriptive part; (2) systematic part.

The former, like in traditional financial statements includes generalities on reporting entity, an introductive part, a definition of entity's social identity, a definition of areas of disclosure and of subjects to whom the information is directed. A broad part of this will be devoted to the tools of implementation for social/environmental policies, to their coordination and finally to their representation and auditing. In it there will be a methodological section that will be the greater the more social and environmental variables communication will not have a generally agreed corpus of representation and communication methodologies.

The latter is made of input/output tables for defined classes of values in their relations between inside the entity and outside it. It is, then, a flow statement, whereas rarer will be the stock accounts, i.e. the accounts representing, in physical unit or in monetary terms, availability of social/environmental value in defined instants of time. This part represents the 'strict' financial statements; it can derive its values from financial accounting by means of satellites accounts, but also charging autonomously other classes of values. The reclassification of accounts from financial accounts is simply the same traditional method adopted by management accounting, on the UN Model of 2003, named IEEA (Integrated Economic and Environmental Accounting).

Social and environmental variables are, and are expressed, both in physical quantities and in monetary terms. The great challenge of the last years is to found a measure, which is both monetary, and then useful for comparisons, and conventional, for including every kind of complexity that is not possible to express in exchange values. Conventions might be the most various, let one thinks at least to the environmental recovery cost, and it is not possible to recall them here. Just for giving a very recognized example of translation of qualitative outcomes to economic proxies we can mention the birth and diffusion of SROI analysis (Social Return on Investments) in the last years.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are not so many attempts to summarize the three traditional domains, economic, social, and environmental, into a unique account or statement, notwithstanding the wide literature on integrated reporting. Until now, unfortunately, integration seems to be only the putting 'side-by-side' the three dimension, even without a common unit for the only social and environmental variables.

An innovative idea might be the one of pursuing a real systemic approach that combines the three dimension each other. Thus, corporate integrated statements should be ideally shared into three parts, each for a class of values. However, all variables, by means of an opportune convention, would be translated in monetary terms.

Let us look, then, at the following proposal:

**Financial Section**
Income
Expenses
= Net Profit or Loss
+ Other Income from Primary Factors of Productions (Earnings not included in Net Profit, Interests, Wages, Rents, Taxes)
= Added Value (AV)

**Social-Ethical Section**
AV
+ Social Benefits in Money Terms

Social Costs in Money Terms
= Social-economic Added Value (SEAV)
**Environmental-Energetic Section**
SEAV
+ Environmental Recovery Actions in Money Terms

Net Consumption of Natural Resources in Money Terms
= Integrated Environmental-Social-Economic Added Value (ISEAV).

The above model deserves some explicative notes.

First of all, this is 'monetary' disclosure, where 'money' is the unit of size selected for measuring well-being. Thus, it has two explicit boundaries. The former is that it does not take into account what does not belong to the domain of 'translatable' to money. The descriptive part of integrated reports serves for such duties. The systematic part, instead, could only concern what is liable to be systemized. The latter is that 'money' is here only a proxy for measuring net benefits; while it measures 'economic dimensions', it does not represent an 'exchange value' as it does in the traditional domain of financial accounting. Its weakness could be the need for a generally agreed convention in defining criteria of translation to monetary proxies; its strength the power allowed by monetary comparisons in space and time.

Secondly, the label adopted try to cover the most general field liable to disclosure. Out of the financial section, one can give information about a potentially unlimited set of variables and indicators. The model tries to gather them into two main classes. The *former* concerns whatever is linked to manhood and society as a whole. It has been named 'social/ethical' because part of literature assesses social variables

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

for what they simply are or seem to be, without no reference to peculiar ideological or cultural points of view, while others assume a defined set of 'value judgments' and evaluates ethically what is being disclosed. The *latter* concerns whatever is linked to physical and natural contexts. It has been named 'environmental/energetic' to stress, in the second term, the recurrent 'input/output' reporting in terms of energy consumed and produced, while in the first term, position and variations in environmental 'net assets' is underlined.

Third, and finally, some criticism about the sum is possible, considered the heterogeneous spring of the different sources. But the comparability of 'money value' deriving from different sources is necessarily to be entrusted to further research, considered that neither financial accounting, nor non-financial one could ever only deal with strictly homogeneous values. In the same traditional financial accounting, in fact, doctrine and practitioners sum each other cash values, exchange values, historical costs and conventional amounts. A strict choice for homogeneous accounting could make accounting regress toward an archaic cash accounting. There is no reason, then, for not undertaking new roads including new fields of disclosure.

It is possible to affirm that today research has not still invested along this direction. We have no available data, but it would be possible that an implementation of the proposed model could lead to unpleasant results, like that ISEAV could be always, in a societal aggregation, negative and then this model gives the analytical proof that unlimited capitalistic development does not belong to the realm of possible and then that it is condemned to a historical failure. Sustainability accounting could give times and costs of this historical failure.

An alternative model of integrated reporting could be a 'non-systemic' one. In this approach the economic domain, even inserted in a broad social reporting, keeps its own autonomy.

The 'not economic', in this model, results shared into the social and environmental fields of reporting.

The 'social' one should concern the following areas of disclosure: distribution of income, acquisition and/or variations in availability for corporation of 'not financial' resources, like, e.g. organization culture or know-how, creation or destruction of job opportunities and professional growth in the social context of relation, creation or destruction of social security, spreading of the corporation culture outside the boundaries of the organization, civic sense or legality promotion, fight against social exclusion, discrimination, marginalization, and similar things. A focus on basic research funding or culture funding or other similar activities of social impact, could be opened; or, otherwise on infrastructure investments, tangible or intangible be they, which are permanent and of social fruition, then distinguished from contingent entity's investments; or, finally, on 'societal influences', that is social and cultural resources absorbed by the organization from its social context.

The 'environmental' one should concern, more, the following areas of disclosure: physical flows of materials, services and energy, inside the corporation and between inside and outside it, reclassification of financial flows (economic or cash) under an environmental point of view, economic measurement of resources withdrawals from environment, renewable or not be they, economic measurement of solid, liquid and gas waste, economic measurement of environmental recovery.

## 6. INTEGRATED ASSESSMENT OF CORPORATE SUSTAINABILITY PERFORMANCE: BEST PRACTICES USED BY INTERNATIONAL RATING AGENCIES AND PERFORMANCE ANALYSIS COMPANIES

The previous sections have shown the historical development of sustainability reports. At first, the accounting considered only financial information, because the reporting was exclusively addressed to the owners of the company (shareholders and investors). Then, social information began to be important, therefore reporting was also addressed to a wider group of stakeholders through social reports (community, employees, trade unions, customers, public bodies, etc.). Finally, environmental information assumed great importance with business increasingly impacts on the ecological environment, therefore reporting was addressed to a group of stakeholders interested in the conditions of the environment (employees, customers, environmental groups, animal rights organizations, non-profit organization, public bodies, etc.). Now, as mentioned, companies are focused on integrated reporting, which jointly considers economic, social and environmental information under the concept of 'sustainability' or 'sustainable development'.

In this section, an empirical study is proposed to analyse approaches and techniques used by international rating agencies and performance analysis companies about the assessment of corporate sustainability. This empirical study allows to identify the best practices used in integrated assessment of sustainability, in order to understand whether the techniques followed are aligned with the theoretical approach proposed in paragraphs (see section 5).

Standard & Poor's prepares the listing of sustainable enterprises by the Dow Jones Sustainability Index (DJSI). Literature has focused on the framework used by the Dow Jones Sustainability Group Index (DJSGI) for identifying and ranking companies according to their corporate sustainability performance (Knoepfel, 2001), while other scholars have proposed different empirical studies on the DJSI (Cerin & Dobers, 2001; López et al., 2007; Robinson et al., 2011). Therefore, one of the best known and highly regarded Socially Responsible Investing (SRI) indexes is the Dow Jones Sustainability World Index (Sariannidis et al., 1999).

The quotations of the sustainability performance consider both global indices (World Index World Enlarged Index, World Developed Index) and area indices (Australia Index, Chile Index, Emerging Markets Index, Europe Index, Eurozone Index, Korea Index, Nordic Index, North America Index, United States Index). In this way, S & P highlights the corporate sustainability performance of sustainable enterprises, including both global perspective and limited geographical areas.

The oscillations of DJS indices measure the performance of sustainability based on an integrated evaluation approach, which considers jointly: (a) economic and financial results; (b) social results; (c) environmental results. Consequently, positive oscillations of DJS indices show an increase of the sustainability performance of listed companies in terms of economic, social and environmental results. Conversely, negative oscillations represent lower integrated sustainability performance.

The listing of the companies and their sustainability performance within 'integrated markets' enables investors, and stakeholders in general, to guide their decision-making process more consciously, giving the company the ability to create reputation and enhance its corporate image.

The 'integrated rating' provides reliable information for the choices of the stakeholders, as the sustainability of companies listed on the DJSI market is subjected to an external evaluation by RobecoSAM. In fact, S&P cooperates with RobecoSAM, company that has the task of developing the criteria for integrated assessment of the sustainability of companies ('Corporate Sustainability Assessment' – CSA).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The techniques used by S & P and RobecoSAM represent international best practices for performance evaluation of corporate sustainability, because the evaluation of sustainability performance is based on the criteria proposed by GRI (Global Reporting Initiative[2]), the international leader in the preparation of the sustainability reporting standards. For this reason, they are generally accepted as international best practices. The literature has highlighted the importance of best practices promoted by the GRI, considering both theoretical and empirical contributions (Hussey et al., 2001; Hedberg & von Malmborg, 2003; Willis, 2003; Brown et al., 2009; Levy et al., 2010; Skouloudis, 2010; Brown, 2011; Marimon et al., 2012; Milne & Gray, 2013). In addition, all the biggest and best-known multinational companies adopt these criteria for the preparation of their sustainability reporting (e.g. 3M Co, Adidas AG, AXA SA, Bayer AG, Bombardier Inc, Bridgestone Corp, Cisco System Inc, Danone, Electrolux AB, Eni SpA, Finmeccanica SpA, Henkel AG & Co KGaA, Hewlett-Packard Co, Intel Corp, Johnson & Johnson, LG Electronics Inc, Panasonic Corp, Pirelli & C. SpA, Samsung Electronics Co Ltd, Sony Corp, Unilever NV).

According to the principles adopted by RobecoSAM in official documents (Measuring Intangibles 2015), sustainability performance of companies are assessed using a 'comprehensive approach' (or 'integrated approach') that considers the overall results that affect corporate sustainable development. In particular, valuation practices adopted are based on:

- Economic, social and environmental results;
- Long-term perspective.

Techniques used by S & P and RobecoSAM are based on an integrated assessment approach that is not restricted only to economic and financial factors, but also extends to social and environmental aspects. In addition to this, performance evaluation involves not only shareholders and investors, but certainly a wider audience of stakeholders, such as customers, employees, communities, institutions and associations that are related to the companies evaluated.

The importance of three different evaluative dimensions (economic, social and environmental) is needed because the only financial factors are not useful in evaluating corporate performance excluding non-financial factors. Only if companies define their competitive strategy according to an integrated vision of sustainability can improve their ability to create shareholder value in the long term (Greenwald, 2015).

Companies subject to integrated assessment of sustainability are those that can identify and exploit business opportunities related to the field of sustainability, taking advantage of the emerging chances within the dynamic of industries and markets in which they operate. Rating is based on 'a truly integrated approach to analysing sustainability performance', since specific scores obtained from the assessment in relation to economic, social and environmental dimensions are summarized in an overall score, called 'Total Sustainability Score'. Companies are classified in a ranking; this allows identification of the the leading companies of sustainability in the international context. Through this assessment, companies can highlight and focus on the sustainability factors associated with their business success and value creation. Companies with a higher Total Sustainability Score have a greater chance of high performance resulting from the adoption of best practices of integrated sustainability.

RobecoSAM identifies 59 economic sectors ('industries'), in which companies listed on S&P's DJSI are classified. Economic, social and environmental aspects of businesses are measured using specific parameters. These parameters are 'general', then valid for all the industries, or 'specific', then only valid

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

for a particular industry (to reflect specific sector characteristics). The parameters are weighted with a specific 'weight' based on the parameter importance within the industry.

Assessment methodology is based on questionnaires in relation to which companies respond to questions. Each answer has to be accompanied by a specific documentation to show proof that supports the veracity of the answers. If the issues are relevant or critical, RobecoSAM also requires that such documents are public, then spread among stakeholders.

Parameters for integrated assessment of sustainability are identified with reference to the G4 Sustainability Reporting Guidelines (2015) issued by GRI. A list given by the GRI organization includes parameters that measure dimensions of the Corporate Sustainability Assessment for all industries. The following list does not include all the parameters, but it is useful to provide an overview of the economic, environmental and social measurements of corporate sustainable development:

- **Economic Dimension:** Antitrust policy; brand management; codes of conduct/compliance/corruption & bribery; corporate governance; customer relationship management; financial stability & systemic risk; health & nutrition; independence of content; IT security & system availability; payment transparency; principles of sustainable insurance; privacy protection; product quality and recall management; risk & crisis management; supply chain management; tax strategy.
- **Environmental Dimension:** Biodiversity; climate strategy; environmental policy/management system; environmental reporting; genetically modified organisms; low carbon strategy; operational eco-efficiency; product stewardship; releases to the environment; resource conservation and resource efficiency; water related risks.
- **Social Dimension:** Bioethics; controversial issues, dilemmas in lending/financing; corporate citizenship and philanthropy; human capital development; Labor Practice Indicators and Human Rights; Local Impact of Business Operations; Occupational Health and Safety; Promoting Responsible Gaming; Responsibility for Alcoholic Products; Responsibility of Content; Responsible Marketing Policies; Social Impacts on Communities; Social Reporting; Stakeholder Engagement; Talent Attraction & Retention.

As mentioned above, some parameters are only used for specific industries. For example, the following fundamental parameters ('highlighted criteria') are considered in relation to the automobile sector (see RobecoSAM Sustainability Yearbook 2015):

- **Economic Dimension:** Health & Nutrition; Innovation Management; Strategy for Emerging Markets.
- **Environmental Dimension:** Climate Strategy; Operational Eco-Efficiency; Water Related Risks.
- **Social Dimension:** Human Capital Development; Labor Practice Indicators and Human Rights; Talent Attraction & Retention.

## 7. PERFORMANCE ASSESSMENT OF INTEGRATED CORPORATE SUSTAINABILITY: INTERNATIONAL REPORTING PRACTICES FROM AUTOMOBILE COMPANIES

This section shows the results from an analysis of the sustainability reports of automobile companies that have achieved the best sustainable development goals. The decision to study automobile industry is justified by the importance of this economic sector for international economies and for the social and environmental impacts on society and territories. Specifically:

- Automobile companies are faced with many challenges, including the need to define and implement a clear strategy of market positioning in a competitive environment with over-capacity, intense competition and the need for large investments in research and development (R & D). These aspects are certainly critical to economic and financial dimensions of corporate sustainable development.
- Increasingly strict regulations on greenhouse gases emissions and air pollutants, as well as dependence on oil, cause management problems for automobile company, which need to improve energy efficiency and reduce the intensity of carbon emissions (the recent scandal involving Volkswagen group is particularly representative). These aspects are important for environmental dimension of corporate sustainability.
- The impact on society of automobile companies activities is remarkable, considering the number of workers, institutions, trade unions, government agencies and associations involved. These factors are relevant for social dimension of sustainable businesses.

Therefore, accounting practices adopted by carmakers are a particularly representative field of investigation to identify international best practices for the preparation of integrated sustainability reports. In this way, the most recent sustainability reports published by companies that have obtained the best results in RobecoSAM evaluations were analysed in their statements, values and parameters. The sustainability reports analyzed are:

- BMW – Bayerische Motoren Werke AG (Germany) – Gold Class [Sustainable Value Report 2014];
- FCA – Fiat Chrysler Automobile NV (United Kingdom) – Silver Class [Sustainability Report 2014];
- Nissan Motor Co Ltd (Japan) – Silver Class [Sustainability Report 2015];
- Peugeot SA (France) – Bronze Class [CSR Report 2014];
- Renault SA (France) – Bronze Class [Registration Document 2014; CSR Report 2013].

All sustainability reports adopt a comprehensive/integrated approach to reporting. The tables below list the economic, environmental and social parameters used in all integrated reports. In this way, best practices of integrated reporting were identified. The terminology used for the parameters were taken from the 'G4 Sustainability Reporting Guidelines'.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 1. Economic aspects and parameters of integrated reporting (best practices)*

| CATEGORY: ECONOMIC |
|---|
| **Aspect: Economic Performance** |
| Direct economic value generated and distributed |
| Financial implications and other risks and opportunities for the organization's activities due to climate change |
| Coverage of the organization's defined benefit plan obligations |
| **Aspect: Indirect Economic Impacts** |
| Development and impact of infrastructure investments and services supported |
| Significant indirect economic impacts, including the extent of impacts |

Besides the parameters shown in the table, some sustainability reports consider additional aspects and parameters. Referring to the economic dimension, some companies also consider the following aspects: market presence (e.g. Proportion of senior management hired from the local community at significant locations of operation); procurement practices (e.g. Proportion of spending on local suppliers at significant locations of operation). Referring to the environmental dimension, additional aspects are considered: overall (e.g. Total environmental protection expenditures and investments by type); Supplier Environmental Assessment (e.g. Percentage of new suppliers that were screened using environmental criteria; Environmental Grievance Mechanisms (e.g. Number of grievances about environmental impacts filed, addressed, and resolved through formal grievance mechanisms). With reference to the social dimension, additional aspects are: Equal Remuneration for Women and Men (e.g. Ratio of basic salary and remuneration of women to men by employee category, by significant locations of operation); Supplier Assessment for Labor Practices (e.g. Percentage of new suppliers that were screened using labor practices criteria); Non-discrimination (e.g. Total number of incidents of discrimination and corrective actions taken); Child Labor (e.g. Operations and suppliers identified as having significant risk for incidents of child labor, and measures taken to contribute to the effective abolition of child labor); Forced or Compulsory Labor (e.g. Operations and suppliers identified as having significant risk for incidents of forced or compulsory labor, and measures to contribute to the elimination of all forms of forced or compulsory labor); Indigenous Rights (e.g. Total number of incidents of violations involving rights of indigenous peoples and actions taken); Local Communities (e.g. Percentage of operations with implemented local community engagement, impact assessments, and development programs); Anti-competitive Behaviour (e.g. Total number of legal actions for anti-competitive behaviour, anti-trust, and monopoly practices and their outcomes); Customer Privacy (e.g. Total number of substantiated complaints regarding breaches of customer privacy and losses of customer data).

Empirical analysis highlights the best international practices, which consider the sustainability performance reporting in accordance with a global vision, measured through multi-dimensional parameters. The *common* aspects and parameters of the five companies observed belonging to automobile industry have identified integrated reporting best practices in this specific industrial sector. Additional parameters identified in some sustainability reports indicate that the integrated reporting practices are still developing, which tend toward expansion of the range of aspects and parameters for measuring corporate sustainability results.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 2. Environmental aspects and parameters of integrated reporting (best practices)*

| CATEGORY: ENVIRONMENTAL |
|---|
| **Aspect: Materials** |
| Materials used by weight or volume |
| Percentage of materials used that are recycled input materials |
| **Aspect: Energy** |
| Energy consumption within the organization |
| Energy consumption outside of the organization |
| Energy intensity |
| Reduction of energy consumption |
| Reductions in energy requirements of products and services |
| **Aspect: Water** |
| Total water withdrawal by source |
| **Aspect: Biodiversity** |
| Operational sites owned, leased, managed in, or adjacent to, protected areas and areas of high biodiversity value outside protected areas |
| **Aspect: Emissions** |
| Direct greenhouse gas (GHG) emissions (Scope 1) |
| Energy indirect greenhouse gas (GHG) emissions (Scope 2) |
| Other indirect greenhouse gas (GHG) emissions (Scope 3) |
| Greenhouse gas (GHG) emissions intensity |
| Reduction of greenhouse gas (GHG) emissions |
| NOX, SOX, and other significant air emissions |
| **Aspect: Effluents and Waste** |
| Total water discharge by quality and destination |
| Total weight of waste by type and disposal method |
| Total number and volume of significant spills |
| **Aspect: Products and Services** |
| Extent of impact mitigation of environmental impacts of products and services |
| **Aspect: Compliance** |
| Monetary value of significant fines and total number of non-monetary sanctions for non-compliance with environmental laws and regulations |
| **Aspect: Transport** |
| Significant environmental impacts of transporting products and other goods and materials for the organization's operations, and transporting members of the workforce |

The results of the empirical analysis of sustainability reports are summarized in the following key points:

- The sustainability reports adopt a holistic approach, according to which sustainability performance is measured by analysing the economic, social and environmental results jointly achieved.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Table 3. Social aspects and parameters of integrated reporting (best practices)*

| **CATEGORY: SOCIAL** |
|---|
| **SUB-CATEGORY: LABOR PRACTICES AND DECENT WORK** |
| **Aspect: Employment** |
| Total number and rates of new employee hires and employee turnover by age group, gender, and region |
| Benefits provided to full-time employees that are not provided to temporary or part-time employees, by significant locations of operation |
| **Aspect: Occupational Health and Safety** |
| Percentage of total workforce represented in formal joint management–worker health and safety committees that help monitor and advise on occupational health and safety programs |
| Type of injury and rates of injury, occupational diseases, lost days, and absenteeism, and total number of workrelated fatalities, by region and by gender |
| Health and safety topics covered in formal agreements with trade unions |
| **Aspect: Training and Education** |
| Average hours of training per year per employee by gender, and by employee category |
| Programs for skills management and lifelong learning that support the continued employability of employees and assist them in managing career endings |
| **Aspect: Diversity and Equal Opportunity** |
| Composition of governance bodies and breakdown of employees per employee category according to gender, age group, minority group membership, and other indicators of diversity |
| **SUB-CATEGORY: HUMAN RIGHTS** |
| **Aspect: Investment** |
| Total hours of employee training on human rights policies or procedures concerning aspects of human rights that are relevant to operations, including the percentage of employees trained |
| **SUB-CATEGORY: SOCIETY** |
| **Aspect: Anti-corruption** |
| Communication and training on anti-corruption policies and procedures |
| **Aspect: Supplier Assessment for Impacts on Society** |
| Significant actual and potential negative impacts on society in the supply chain and actions taken |
| **SUB-CATEGORY: PRODUCT RESPONSIBILITY** |
| **Aspect: Customer Health and Safety** |
| Percentage of significant product and service categories for which health and safety impacts are assessed for improvement |
| **Aspect: Product and Service Labeling** |
| Results of surveys measuring customer satisfaction |

- The sustainability reports analysed contain various types of information: qualitative information (e.g. Descriptions of management approaches and future lines of action); quantitative-monetary information (e.g. investment to ensure safety at workplaces and environmental security); quantitative-technical information (e.g. consumption of energy and natural resources).
- The sustainability reports have two different perspectives: the first one is an 'ex-post reporting' (closing perspective), used by companies to highlight corporate sustainability results achieved; the second one is an 'ex-ante reporting' (preventive perspective), used to program the future goals of corporate sustainable development.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The sustainability reports are aimed at a wide range of stakeholders: not only shareholders, but also employees, customers, suppliers, communities, territories, associations, non-profit organizations, trade unions, non-governmental organizations, public bodies, states and governments.
- The sustainability reports adopt information representation criteria that are also designed for non-expert users, therefore 'user-friendly' information to facilitate their understanding of the content (e.g. digital interaction on the reports contents, summary tables with the most important data, photos, images, graphics, summary and interpretation schemes, description of approaches used to simplify the learning data, interviews, appendices with more detailed information).
- The sustainability reports have characteristics that enable them to support the communication strategy of companies to spread, increase and maintain their corporate reputation.
- The sustainability reports analysed adopt an integrated, but not systemic, approach because there is no single measure that summarizes and expresses economic, social and environmental results achieved.

## CONCLUSION

In this chapter we presented the theme of sustainability reports for as concerns the social dimension, the environmental one, the integrated one (financial-social-environmental). The chapter, then, deals with the corporate institutional communication in a broader sense than the traditional financial disclosure.

The chapter, after having presented and defined its object, shows the historical progress toward the sustainability reports in its different dimensions in the last decades, proposes a theoretical basis for the integrated reports, verifies a correspondence of this last one with general agreed criteria for evaluating the sustainability performance, and, particularly, endeavors an empirical survey on the car production sector, considered one of the most environment sensitive industry of the world.

It is time, now, for some conclusive clauses about the main results of this reconstruction.

Management and accounting literature, in these last years, gave a pressure for broadening disclosure on the social impact of corporate activity.

This broadening, before limited to strict social issues, after to environmental ones, is now generally conceived in a more integrated shape. But the attitude of disclosure is not so different from the traditional one, at least in a logical sense. We observe information useful for decisions (not only and no longer only economic decisions) and we observe information useful for a discharge of responsibility (not only and no longer only toward ownership of corporate). As well as investors entrust their capital to management, so society, in a wider sense, entrusts a role to single corporate.

The set of stakeholders is now greater than in the past, and includes also generic 'subjects' like 'public opinion' or the 'future generations', but social issues matter also for traditional stakeholders, even the same investors who could be very interested on the sustainability of their investment.

Sustainability reports as the main tangible outcome of CSR on one hand discovers a new field for corporate ends, i.e. the business ethics, giving substance and verifiability to it, and, on the other hand, strengthens the traditional ends of value creation, with a long-sighted vision.

Corporations realize, just in the years of the great crisis (after 2007) that a short-sighted perspective can endanger the same long-time survival of themselves. In a more and more integrated and globalized arena, environmental and social reputation becomes a core strategic issue, to which customers (and not

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

only them) are more and more sensitive. The same value of shares looks influenced by the risk of environmental scandals and investing on a social-environmental sustainable corporation is not only a fact of ethics but simply a rational attitude.

Of course sustainability reports may not be kept separated from financial ones. Integration looks the natural outcome for a clear disclosure toward stakeholders.

Focus of disclosure, then, is on the risk it can become a propaganda exercise, not verifiable by an independent auditing.

This risk could be avoided, exactly as happened since '30 years in U.S.A. after the Great Depression in traditional accounting, by a regulation; regulation that now is moving just its first steps.

In any case, regulation needs a doctrinal effort for designing a framework, an ideal model for this integrated reports. Our contribution could be read in this perspective. In this paper we propose two models of integration. A first one – non-systemic – gives a regulation on single items of disclosure but does not integrate the three dimensions into a unique value. A second one – systemic – tries to integrate the three dimensions, expressing in money terms externalities, i.e. benefits and costs for society in the widest sense, financial, social or environmental could they be.

The two theoretical solutions show vantages and disadvantages because the strength of one single bottom line (in the second approach) could face the risk of over-simplification for externalities that, by their nature, cannot be translated in money terms, even by the help of proxies.

Analysis of praxis seems to corroborate our general suggestions. Integration of disclosure is now real, and all three are resumed in a general discourse on sustainability. Scoring of Dow Jones and RobecoSAM seem to enforce the idea that success in competition is due to a harmonic and systematic combination of financial success inside corporation and financial-social-environmental success outside it.

Comparison between theory and law, by one side, and empirical analysis, by the other side, looks a progressive reduction of the gap between what corporations do and what they should. What it is still weak, perhaps, seems the relationship between a defined and clear ex ante perspective (programming, forecasting about social-environmental impact of business activity) and the ex post one (the sustainability reports, in words).

Empirical observation confirms theoretical intuition of the need for a really integrated reporting. Financial, Social and Environmental Reports are generally now parts of integrated 'sustainability' reports. What it is not confirmed, however, is the trend toward what we called the 'systemic approach'. Translation of social and environmental benefits and costs in terms of money or economic proxies is moving just its first steps, being generally preferred what we called the 'non systemic approach'.

Another feature emerging from the survey is the great variance in structure, recognition, evaluation, presentation, disclosure from one corporation to another.

These two main results may suggest two practical indications for research and regulation in this field.

First one is the theoretical investment on the 'systemic approach'. Lack of a unique unit of measurement, in fact, is a weakness for sustainability reporting.

Second one is the need for a compulsory regulation on sustainability reporting, not necessarily only on a global basis, because of the importance of 'national' or 'sector' classes of stakeholders (but here regulation could intervene by means of G.A.A.P.).

The challenge of the next years seems to be the enhancement along these two dimension, in order disclosure in environment and social issues can establish really a link between corporation and stakeholders and not only is an unreliable rhetoric mean of corporation propaganda.

## ABSTRACT

*This chapter explores the tenets and the practice of a transnational initiative to promote local entrepreneurial growth: the Building Global Innovators (BGI) model, a startup accelerator based in Lisbon (Portugal) and in Cambridge (Massachusetts, USA). We examine the pathways through which BGI's process and global network of experts helped two successful Portuguese technology startups grow and scale very quickly – Movvo and Veniam. We combine literatures from strategic management, marketing and economic geography to explore BGI's transnational acceleration model, which taps into global "pipelines" and distant entrepreneurial ecosystems, namely as a way to access the expertise, market opportunities and venture capital that is often unavailable in emergent and policy-sheltered local clusters. We discuss the relevance of such a transnational acceleration model for high-tech startups in peripheral economies.*

## INTRODUCTION

Over the last decade and a half, fostering local entrepreneurial growth has been a major policy objective in Europe. Scholars and policy makers alike agree that technology and knowledge-intensive startups are a key pillar of sustainable economic growth. Given this agreement, it is not surprising that the European Union, in its Entrepreneurship 2020 Action Plan, pushes for "decisive action to unleash Europe's entrepreneurial potential, to remove existing obstacles and to revolutionise the culture of entrepreneurship in Europe". This focus on promoting entrepreneurial growth by promoting knowledge-based and high-technology ventures may seem obvious, but represents a sizable departure from traditional strategies focused on the discovery and funding of large corporations capable of undertaking ambitious research and development projects and the attraction of foreign direct investment (Acs et al., 2008). In recent years, however, several policy makers and think tanks have increasingly recognized early stage high-technology ventures as the key to unlock innovation and economic growth (Audretsch, Keilbach, & Lehmann, 2006; Samila & Sorenson, 2011).

The debate surrounding the relationship between firm size and innovation dates back to the classic work of Schumpeter (1942). Scholars have found mixed evidence regarding the effect of firm size on innovation (Acs & Audretsch, 1987; Cohen & Levin, 1989). While startups typically suffer less from bureaucratic bottlenecks and are thus quick and agile, they often lack the capital and customer access resources of larger corporations. Therefore, there is a growing recognition that successful startups cannot rely solely on internal-to-the-firm capabilities but also need to rely on their external environment (Feldman & Kogler, 2011; Getler, 2003). Consequently, location emerges as a key driver of startup success, a relationship epitomized by the concentration of successful startups in places such as Silicon Valley.

Startups located in high-performing hubs like Silicon Valley benefit from these places' entrepreneurial spirit and from several localized features associated with "being there" (Gertler, 2003), such as access to specialized skills, infrastructure, potential clients, competitors and networks (e.g. Feldman & Kogler, 2011). The success of the "Silicon Valley model" and Michael Porter´s influential book on *The Competitive Advantage of Nations* (1990) sparked an influential stream of entrepreneurship policy focused on embedding startups in "clusters" and local networks of companies and other organizations, as well as on the development of incubators and technology parks. Yet, there is very little evidence that such a recipe actually works across different countries, regions and industries (Martin & Sunley, 2003; Burfitt & McNeill, 2008). In fact, most if not all of the attempts to replicate "Silicon Valley everywhere" have been failing dramatically (Hospers, 2009). In this chapter, we explore the drivers of success (and failure) of startup acceleration models in regions that lack the access to market knowledge and capital that exists in central hubs like Silicon Valley. In particular, our goal is to discuss an emerging model for high-technology entrepreneurship in peripheral European regions.

In peripheral European regions, high-tech entrepreneurship is often very incipient due to lack of sophisticated entrepreneurial ecosystems. For this reason, many authors suggest that an over-localized approach to entrepreneurship support can do more harm than good (e.g. Rodriguez-Pose & Fitjar, 2013; Vale & Carvalho, 2013). Even when local talent is available, such places typically lack access to customers and to market knowledge, and to the resources and institutions that knowledge-based ventures need to start and scale their businesses. Specifically, these regions are distant from advanced customers, business intelligence, and well-functioning innovation and venture capital institutions. Lack of access to these drivers of startup success can render localized networking ineffective in the early stages of the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

development of new companies and industries in peripheral regions (Todtling & Trippl, 2005). During these stages, more transnational models of business incubation, acceleration and networking are required (Gibson & Naquin 2011).

This chapter explores the experience of a particularly innovative, and successful, transnational model to foster local entrepreneurial growth: the *Building Global Innovators* (BGI) model. BGI is technology transfer accelerator initiative based in Lisbon (Portugal) and in Cambridge (Massachusetts, USA). It started in 2010 as a venture competition integrated in the *MIT Portugal* program, a formal 10 year partnership between the Portuguese government and the Massachusetts Institute of Technology (MIT) with the aim to promote research on technology-based innovation and application of such knowledge, for instance through university spinouts. Instead of supporting sub-optimal and locally sheltered environments for startups, BGI aims at rapidly creating links and networks to locations across the globe where complementary expertise can provide the technology-based startups accelerated by BGI with access to customers, market knowledge, relevant startup experience and venture capital.

The guiding principle of BGI's model is to increase competition awareness and promote growth of the new ventures in multiple places and ecosystems, rather than keeping the newly created startups geographically isolated from more central high-performing growth clusters. Thus, the BGI model shows how a global networking model can improve and sustain growth prospects of local startups by helping them to access and bridge to resources that are hardly available in their local ecosystems. To illustrate the functioning of such a model, the chapter presents two case studies of BGI "alumni" companies: *Movvo,* a startup that created a technology that can measure the flow of people in physical spaces, and *Veniam*, a startup that turns vehicles into Wi-Fi hotspots in order to connect infrastructure, people and moving things to each other and to the Internet. The cases are used to exemplify BGI's methods, its achievements and limitations.

The case evidence presented is based on data from the BGI initiative and grounded on two of the authors (Gonçalo Amorim and José Paulo Esperança) experience in developing and managing the initiative since its inception. Methodologically, our analysis follows some of the general principles of the *participatory action research* paradigm (Herr & Anderson, 2005; Miller & Tsang 2010; Ozanne & Saatcioglu, 2008; Reason & Bradbury, 2001; Vermeulen, 2005). Participatory action research is widely accepted as a robust approach to understand complex problems and tap into knowledge and expertise that would be difficult to access with other methodological approaches (Ozanne & Saatcioglu, 2008). An important concern in participatory action research is to ensure an adequate and fair balance between insider and outsider knowledge (Herr & Anderson, 2005)[1].

We selected *Movvo* and *Veniam* for two reasons. First, these were two startups that adhered very closely to BGI's transnational acceleration model philosophy. Based on past experience, it is sometimes easy for first time entrepreneurs to deviate from BGI's philosophy, for instance because their founders may have a tendency to underestimate advice provided by mentors and by BGI. Second, these two startups already have products on the market and have generated sufficient data and history to allow us to examine the outcomes and impacts of the acceleration process. Moreover, focusing on two in-depth cases is typically considered more robust than focusing on a single case (Yin, 1994), providing for more points of comparison and a better illustration of the acceleration processes under study.

The chapter is structured as follows. The next section presents a conceptual background, primarily based on literature from strategic management, marketing and economic geography. It juxtaposes the tenets of localized entrepreneurship and innovation with the relevance for startups to tap into global "pipelines" for accessing multiple resources to grow, such as customer access, market knowledge, tech-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

nology, business networks and (venture) capital. We suggest that the access to such resources through global networks is particularly vital for startups in peripheral countries and regions. Subsequently, the chapter explores the nuts and bolts of the BGI model, and presents the two case studies (Movvo and Veniam). The chapter concludes with suggestions for further research and lessons for entrepreneurship and innovation policy in European peripheral regions.

## BACKGROUND: FROM LOCAL CLUSTERS TO GLOBAL PIPELINES

### Agglomeration, Clusters and Localized Innovation

Firms are basic venues to organize economic activity. Their internal capabilities – e.g. embedded in the entrepreneurs and staff´s knowledge and routines – are widely recognized as key determinants of a firm´s performance and their ability to adapt to new contexts (Grant, 1996; Teece & Pisano, 1994). Knowledge-based startups are important conduits of new knowledge and innovation and are thus crucial for the economic renewal of countries and regions (Stam, 2010). Particularly relevant in this respect are spin-off companies, which re-combine newly available knowledge with inherited competences of "parent" organizations – such as larger/older firms and research institutes – making them particularly apt to tackle new market opportunities (Klepper, 2002).

However, the role of internal capabilities in entrepreneurial success is only a part of the story – the external environment plays an important role as well (Conner & Prahalad, 1996; Lee et al., 2001). Some authors speak about "regional systems of entrepreneurship" to highlight the relevance played by several city and regional level factors that influence "the creation, discovery and exploitation of entrepreneurial activities" (Qian et al., 2013, p. 560). In fact, entrepreneurship rates are highly heterogeneous across space, and some places keep spinning off new high-tech ventures and attracting talent much more than others. Beyond an entrepreneur's personal traits and firms' routines, this phenomenon reflects different places' economic structures and human capital but also, importantly, different institutions and entrepreneurship cultures (e.g. Stam, 2010), as epitomized by the entrepreneurial success and economic renewal of Silicon Valley over the last decades.

According to Michael Porter, this is so because entrepreneurs and new ventures may benefit from being embedded in local "clusters", that is "geographic concentrations of interconnected companies, specialized suppliers, service providers, firms in related industries, and associated institutions (e.g., universities, standards agencies, trade associations) in a particular field that compete but also cooperate" (Porter, 2000, p. 16). Porter and several other scholars inspired by Marshall´s (1920) seminal work on the benefits of agglomeration (e.g., Moulaert & Sekia, 2003) suggest that this is the case due to three types of externalities. First, co-located firms can share a number of production factors; the chief example is specialized labour pooling, as being in clusters increases the chances of good matches and eases the access to related competences. Second, new firms can benefit from being close to specialized suppliers and advanced customers, which facilitates input sharing, competition monitoring and access to market intelligence (Lilien et al., 2002; Santos, Doz & Williamson, 2004; von Hippel, 1986). Third, physical proximity facilitates the access to informal (and often unintended) knowledge spillovers, rumours about the industry and "buzz", which require little specific investments apart from "being there" (Gertler, 2003).

Porter´s (1990; 2000) cluster theory and the literature on localized innovation emphasizes two important dimensions of local entrepreneurial growth. First, they stress the importance for startup suc-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

cess of complementing a firm´s internal capabilities with a more system-like perspective. Second, they highlight the relevance of accessing and monitoring sophisticated and demanding customers. Despite all their impact in our current knowledge, these literature streams also suffer from two major limitations and misconceptions. First, the relevance of Porter´s cluster externalities for startups has been questioned and seems to vary according with the industry´s life cycle. According with Neffke et al. (2011), being part of specialized clusters is more relevant for mature industries. In more dynamic and turbulent sectors, in which designs and products are not stable yet, access to diversified types of skills, partners and customers is more important; moreover, in those cases, a too strong local orientation can lead to employee poaching, knowledge leakage, predatory competition and higher costs for startups. Second, prior research on clusters tends to over-emphasise the role of physical proximity for learning and innovation, overlooking the relevance of long-distance interactions and contact with other "clusters" and ecosystems. In a context of heightened knowledge mobility and international business, the access to knowledge and innovation resources in other geographies can hardly be ignored (Lagendijk & Oinas, 2005; Crevoisier & Jeannerat, 2009; Vale & Caldeira, 2007).

## Global Networks, Pipelines and Local Entrepreneurial Growth

Beyond the local "cluster" approach to understand innovation and entrepreneurial success, a number of recent approaches in economic geography and innovation studies emphasise the role of global networks and "pipelines", defined as channels and conduits through which firms access relevant knowledge and resources to innovate and grow outside clusters (Bathelt et al., 2004; Owen-smith & Powell, 2004). Bathelt et al. (2004) suggest that clusters and pipelines are rather different – yet complementary – ways to access knowledge and resources. Contrarily to just "being there", knowledge and resource access through pipelines is often a much more planned, conscious and structured effort; it requires additional investments, identification of counterparts, and more targeted objectives.

For startups moving from emergence to early growth stages (Hite & Hesterly, 2001), pipelines are important to diversify relationships and facilitate the access to new technology, business and capital networks. It is not reasonable to assume that startups can find such networks and resources locally, within single clusters. Yet, pipelines are also not the only way to access remote knowledge. According with Maskell (2014), pipelines are particular useful when a company knows the type of resources it needs, and *where* they can be found. When that is not the case, pipelines can be complemented – or preceded – by other modes of distant knowledge and resource access, such as the participation in trade fairs, the establishment of "listening posts" or technology scouting units, and even "crowdsourcing" or online problem solving. All these knowledge access models are increasingly relevant for knowledge-based startups, and underpin open-innovation strategies of fast growing companies (Chesbrough, 2003).

For instance, Santos, Doz and Williamson (2004) discuss the case of SAP, a German multinational software company that is, nowadays, the world's largest business software company. In order to grow, SAP proficiently accessed its international network of customers, irrespectively of their location, to gather vital customer and market knowledge. Specifically, SAP "leveraged market knowledge drawn from a far flung group of early, foreign customers – including Britain's ICI and US Chevron Oil – to shape products capable of coping with national differences in accounting conventions and the urgent needs of its multinational customers for cross-border integration of financial data" (Santos, Doz & Williamson, 2004, p. 32). Business-to-consumer firms are also increasingly tapping into the knowledge and expertise of geographically dispersed customers (e.g. Dell's IdeaStorm community, which crowdsources new

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

product ideas from customers, see Bayus, 2013), employees (e.g. Merck KGaA's Innospire, a grassroots innovation process which, in its first edition, gathered ideas from 550 employees from all divisions and from 32 countries all over the world, see Betz et al., 2014) and other experts (e.g. Procter & Gamble's Connect & Develop initiative, see Huston & Sakkab, 2006).

Knowledge accessed through pipelines is perhaps even more important for startups than to established firms, namely when it is related – yet not too similar – to the startup´s internal capabilities. In this sense, pipelines can bring the variety of knowledge that allows companies to identify new business opportunities, develop new products and catalyse their internal resources in novel ways. The innovation literature demonstrates that a company's innovation potential is maximized when they mobilize related but not too similar portfolios of knowledge (Cohen & Levinthal, 1990; Nooteboom, 2000; Wuyts, Dutta, & Stremersch, 2004). More recent studies suggest that innovation requires combinations of dissonant pieces of knowledge, substantially distant from a company´s knowledge repertoire (Stark, 2011). In this sense, too much cognitive and relational proximity between companies and knowledge pieces – as frequently happens in many clusters – can limit innovation potentials (Boschma, 2005).

## Local Entrepreneurial Growth in Peripheral Regions

The limitations of clusters to support local entrepreneurial growth are heightened in peripheral regions. Those places – e.g. in many regions of Southern and Eastern Europe – have relatively weak economies and underdeveloped entrepreneurial innovation systems (Toddling & Trippl, 2005). Obviously, this does not mean that talent does not exist in these regions. However, even if some knowledge-based startups in the periphery may be at the forefront of technological knowledge, their regions lack the markets, advanced users, industrial partners and well-developed venture capital players necessary to innovate and grow (e.g. Vale & Carvalho, 2013). In other words, they lack access to crucial customer and market knowledge and, equally important, to entrepreneurial experience and accessible smart (venture) capital. This is particularly problematic in nascent industries, in which there are no experienced entrepreneurs locally that can play a mentoring role for newcomers and connect them with the networks they need to succeed. As a consequence, an over reliance on local networks may hamper, rather than help, the development of startups, and ultimately, the local formation of new industries.

Under these conditions, facilitating the access to global knowledge networks and advanced users is deemed essential for local entrepreneurial growth (Fontes & Combes, 2001; Vale & Carvalho, 2013). For example, when studying the networking behaviour of biotech startups in Portugal and Southern Italy, Capaldo et al. (2015) concluded that "…the local environment is a lesser determinant for a substantial proportion of firms than would be expected in startups. A distinctive feature of these firms is an extensive reliance on foreign sources, for different purposes and from the very early stages" (p. 1381). Carvalho et al. (2014) reach similar conclusions based on the in-depth study of a leading, born-global startup in "smart-city" technology (Living PlanIT), based in the North of Portugal. Using data for Norwegian firms, Fitjar & Huber (2015) show that more radically innovative firms are more involved in international networks (formal and personal) than non-innovative and incremental innovation companies. Thus, from a policy perspective, Fitjar & Huber (2015) suggest that in smaller and peripheral countries innovation and entrepreneurship policy should facilitate global connections rather than national and regional networking.

In her seminal study on the new "argonauts", Saxenian (2007) shows that the recent growth in the number of successful high-tech and information and telecommunication startups in Taiwan, India or Israel is closely linked with global networks established between its entrepreneurs and places like Silicon

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Valley, in which they gained experience, studied and worked before. These networks have been pivotal to access technology, but equally essential to facilitate access to market exposure, contact with advanced users, entrepreneurship culture and access to venture capital. Yet, questions remain whether such a global network model can be applied everywhere, namely for countries with less social affinity with innovation powerhouses such as Silicon Valley and the United States (Frenken, 2009), and if plugging entrepreneurs in global networks is amenable to policy intervention – and, if yes, how such a model could look like.

In this chapter, we propose that in an increasingly globalized economy, it is not only possible but essential to rapidly promote and establish bridges between the talent and technical knowledge of local entrepreneurs with distant networks capable of unlocking, first, the customer and market knowledge they need to build strong value propositions and, second, the (venture) capital they will need to scale their business. In the next section we describe the transnational acceleration model used by the BGI (Building Global Innovators) network which, from its headquarters in Lisbon, Portugal, aspires to create a new generation of startups with the ambition to become global leaders in the markets they target.

## THE BGI ("BUILDING GLOBAL INNOVATORS") TECHNOLOGY TRANSFER ACCELERATOR (TTA)

### The Roots of BGI: From an Experiment to a Full Blown Accelerator

Building Global Innovators (also known by its shorter acronym BGI) is a global startup technology transfer accelerator (TTA) based in Lisbon (Portugal) and Cambridge (MA-Cambridge/USA). The goal of BGI is to identify aspiring tech entrepreneurs and innovators (high-technology startups and university spin-outs under five years old) and help them scale and prepare a global-oriented market launch. BGI focuses on four domains, or market verticals: (i) medical technologies & health IT, (ii) smart cities & industrial tech, (iii) enterprise IT & smart data and (iv) ocean economy.

Even though BGI was officially founded in March 2010 as the innovation and entrepreneurship arm of the MIT Portugal program (MPP), its roots date back to 2006, when MPP was launched. MIT Portugal was one of five strategic international research programs launched by the Portuguese Government in collaboration with the Massachusetts Institute of Technology (MIT), Harvard University, Carnegie Mellon University, University of Texas at Austin and Fraunhofer Institute (Germany). The goal of these initiatives was to streamline the basic and applied research in the top research and academic institutions in Portugal and foster collaboration with world-class institutions. These international research programs will represent an investment of nearly €300 million over a decade (2006-17).

The MIT Portugal program is an initiative led by the Portuguese Foundation for Science and Technology (FCT) and anchored in a strategic partnership between several Portuguese Universities and Research Centres of the Engineering school of MIT and key partners from industry and government. One of the key goals of the MIT Portugal program is to promote economic growth through selective investment in top-notch science, technology and higher education. Promoting innovation and entrepreneurship was a natural extension of the core MIT Portugal program and, thus, the *Innovation and Entrepreneurship Initiative* within the *MIT Portugal program* (so called MPP-IEI) was born in 2010.

In its first editions, BGI was called "*ISCTE-IUL MIT Portugal Venture Competition,*" an experimental "*beyond the business plan*" competition run at *ISCTE-IUL*[2], one of Portugal's top business schools and the one with the strongest focus on the promotion of innovation and entrepreneurial talent. The pro-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

gram was designed as a hybrid model with elements of two successful innovation and entrepreneurship initiatives at MIT: the *Deshpande's Centre for Technological Innovation grants*[3] (i.e. science grants for de-risking and commercialization activities) and *MIT's 100K*[4] (i.e. a business plan competition run at Sloan's MBA[5]). Since then, the BGI model has continuously evolved to better fit both its mission and the needs of the entrepreneurial ecosystems it supports. Eventually, in early 2013, BGI was incorporated as an independent entity and established its own identity globally.

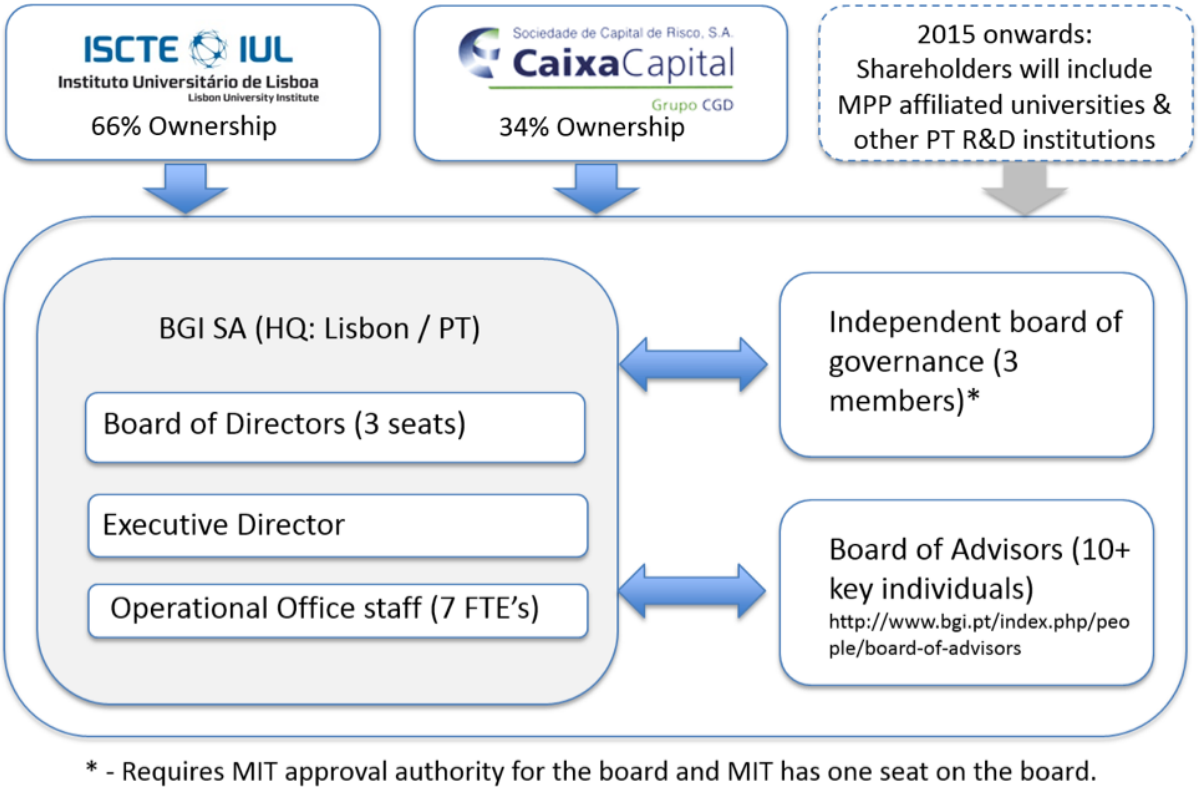
Nowadays, BGI is strongly anchored in the top eight science and engineering universities in Portugal (all of which are integral partners of the MIT Portugal program) and keeps the ambition of strengthening Portugal's startup community. However, since 2010, BGI's network quickly expanded beyond the borders of ISCTE-IUL. Today, BGI counts with key strategic partnerships with *MIT*[6] but also since its inceptions with key local players such as *Caixa Capital* (the venture capital arm of Portugal's state owned bank *Caixa Geral de Depósitos,* with € 650 million in assets under management). The partnership with Caixa Capital allows BGI to offer financial support, in the form of seed capital, to four ventures per year, originally with up to €1 million per edition.

To date BGI counts 80 alumni companies which resulted in the launch of over 30 new ventures, raising close to €30 million in risk financing and creating over 300 highly qualified jobs. These numbers place BGI among the top accelerators in Europe, right after London-based Seedcamp, which has 110 alumni companies and raised close to €60 million in follow-on funding and significantly larger than the Startupbootcamp network, which operates with 10 accelerator programs in 9 locations (Amsterdam, Barcelona, Berlin, Copenhagen, Eindhoven, Israel, Istanbul, London and Singapore) and which has 88 alumni companies but, so far, has raised only about €10 million in follow-on funding (Economist, 2014).

## BGI's Governance Model and Global Network

A key challenge faced by BGI, and by many accelerators located in peripheral regions, is the need to provide globally-oriented support to incubated startups (which is often expensive) while ensuring a lean and financially sustainable operational model. BGI developed an innovative and efficient governance structure to deal with these challenges. Specifically, BGI today consists of a small organisation team with seven full-time equivalent (FTE) employees, which ensure the day-to-day operations and the delivery of the objectives of the MPP-IEI mission. BGI's core activities include:

- Budgeting and reporting to the board as well as other stakeholders including *FCT*, the Portuguese Foundation for Science and Technology;
- Public relations, building a vetted network of experts and dealing with investors;
- Organizing networking & fundraising events for BGI alumni;
- Managing an international yearly call for submissions (innovative startups and spinouts) in the four verticals of the MIT Portugal program (see above);
- Venture acceleration activities and startup training (provided via unique syllabi designed and delivered by ISCTE-IUL & MIT faculty);
- Portfolio management (most active in those where BGI holds an equity stake);
- Management of IT and data platforms;
- Maintaining an Alumni network of companies.



EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

To date, BGI has built a network of over 12,000 stakeholders, including technologists, researchers, entrepreneurs, vetting experts, marketers, legal and financial professionals, mentors, investors and general ecosystem members. The board and board of advisors of BGI counts with the active participation of key people including from the Deshpande Center for Technological Innovation (http://deshpande.mit.edu/), ISCTE-IUL (http://www.iscte-iul.pt/en/), Martin Trust Center for MIT Entrepreneurship (https://entrepreneurship.mit.edu/), Massachusetts Institute of Technology (MIT: http://web.mit.edu/), MIT Portugal (http://www.mitportugal.org/), MIT Sloan School of Management (http://mitsloan.mit.edu/) and UTEN Portugal (University Technology Enterprise Network: http://utenportugal.org/) and Portuguese diaspora representatives. BGI counts, also, with key strategic partners such as Caixa Geral de Depósitos (Portugal's state-owned and largest bank: https://www.cgd.pt/), Caixa Capital (http://caixacapital.pt/), the law firm Cerqueira Gomes & Associados (http://www.cerqueiragomes.pt/pt/) and e+i (Portugal's Strategic Program for Entrepreneurship and Innovation: http://www.ei.gov.pt/index/), and other key stakeholders such as Portuguese Foundation for Science and Technology (FCT: http://www.fct.pt/), to name just a few.

In order to ensure the financial sustainability of its model, again BGI had to create an innovative model (see Figure 1). Unlike the reality in the US, philanthropy is very much underdeveloped in Europe in general, and in peripheral countries, in particular. Besides, alternative sources of funding efforts by private sponsors, originally thought as a good source of funding, have yielded limited success, especially in a context of tough economic environment that Portugal has been undergoing. Such limitations have sparked the need for the operational team to creatively look for and design alternative forms of funding.

*Figure 1. BGI's governance model*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In its first years, the funding of BGI was almost exclusively secured from ISCTE-IUL own sources. This situation, however, is not sustainable in the long term. Therefore, to ensure adequate governance and financial sustainability of its model, in early 2013 BGI span out of ISCTE-IUL and was incorporated as an independent company (BGI) with two founding shareholders, ISCTE-IUL and Caixa Capital (see Figure 1), a structure encouraged by several public stakeholders including MIT Portugal and the Portuguese Foundation for Science and Technology (FCT). Such governance model was designed to guarantee governing stability even when tough structural environment – such as the one that the Portuguese economy is undergoing – pressure the budget of public universities such as ISCTE-IUL.

In 2013, at the launch of the 4th Edition, BGI implemented an innovative equity-sharing model in an effort to seek for the long-term financial sustainability of its model. Specifically, through the current model BGI takes a maximum of 5% post money equity on a valuation of at least €1 million (trigger event) on BGI accelerated companies to which Caixa Capital provided financial support. As off the launch of 5th edition, in 2014, what was before an award (up to 10 year venture loan) similar to a grant, was adapted to a combination of an award (50% of the total in the same terms of the previous 10 year loan) and a convertible debt (the remainder 50%). Unlike the common accelerator model, BGI does not grant the participating companies any stipend monies during the acceleration period nor does the equity right apply to those ventures which are not supported by Caixa Capital. BGI does not charge any of the participating teams any type of fees, overheads or otherwise. However, selected teams have to find their own financial means to support their travel and accommodation.

The 5th edition of BGI marked a major turning point for the national innovation landscape in Portugal, in terms of the maturity of the ecosystem agents (i.e., accelerators). In an effort to position Portugal in the world map of high-technology entrepreneurship and innovation, BGI, Caixa Capital and Caixa Geral de Depósitos (CGD) agreed to adjust the format of BGI's acceleration program in place until the 4th edition, to allow greater specialization of the incubated startups. Specifically, in this new model, the €1 Million financial award previously assigned solely to BGI's top 4 ventures, from 5th ed. onwards was "shared" by other two Portuguese high-tech accelerators, the *Lisbon Challenge* (http://www.lisbonchallenge.com/) - focused on digital and mobile startups (sponsored by Beta–i) - and the *ACT* (https://www.actbycotec.com/en/) - focused on Biotech and sponsored by COTEC Portugal (http://www.cotec.pt/). As such, *BGI*, *Lisbon Challenge* and *ACT* now work in cooperation,, proactively contributing to the consolidation of the field of innovation and technology transfer in Portugal. Consequently, BGI's awards will gradually reduce from up to €1 million to €300,000 (i.e., €500,000 in the 5th ed. and €300,000 in the 6th ed.) in seed investment in the four-most promising ventures per edition. In the new model, duplication of the award is no longer possible and what was a 10-year venture loan at a negligible interest rate, now becomes a convertible note aligned with standard investor terms.

## BGI's Transnational Acceleration Model: Local Talent, Global Ambition

In 2010, when BGI was still giving its first steps, the Portuguese startup "ecosystem" was very incipient. Existing startups faced extreme difficulties and rarely left existing incubators who also struggled for survival or were highly dependent on state subsidies. The limitations of the Portuguese startup "ecosystem" combined with the small market size of the Portuguese economy, made local access to customer and market knowledge and to capital extremely difficult. Israel and Scandinavian countries had faced similar challenges in the past but were able to overcome such challenges by building strong transnational support networks. BGI followed these best practices and adopted, since the beginning, a model that tries

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

to identify entrepreneurial talent but, immediately afterwards, relies on high quality international collaborative partnerships and networks to promote rapid and profitable growth of the accelerated startups.

In order to infuse the transnational philosophy in its structure and organization, BGI's team is based in Lisbon, at ISCTE-IUL, but also in Cambridge (USA) at MIT. Moreover, BGI constantly evaluates and strengthens its network of mentors, advisors and investors in order to offer top-notch support to local entrepreneurial talent. BGI's valuable network of partners and "stakeholders" - which includes top Portuguese and international engineering and science universities and technology incubators, science parks, angel groups and other venture capital and institutional investors - was built, over the years, through a bottom up logic based on the needs of incubated startups (i.e., a user centric perspective). Today, this vast network of partners and "stakeholders" is one of the critical differentiating factors of BGI. BGI leverages this network to achieve four goals which are aligned with its mission finding and supporting local entrepreneurial talent: (i) clarify startups' (unique) value proposition, (ii) translate market and customer knowledge into promising and viable go-to-market plans, (iii) raise the necessary capital to finance the growth of incubated startups, (iv) identify and address major risks facing their technology and market entry strategy and, ultimately, (v) consider and plan successful *exit* scenarios, right from the moment of company inception.

The BGI program runs once a year, and scouting and recruiting entrepreneurial talent starts with an international road show running from March to May, which is the period in which applications are open. Selection takes place during June. From over 100 applications (over 35% of which are international), approximately 50 startup teams are invited for a 25 min. interview by a panel of three to five experts and up to a maximum of 21 startups get accepted in the accelerator. Upon acceptance, participating teams agree that they have to find their own financial means for travel and accommodation in Lisbon and Cambridge. The process is managed through BGI's custom built online platform (called BGI-Hub), an IT platform that BGI uses to keep all data regarding participating startups, including their scores and interview comments. Startup acceleration, in turn, starts in late July and graduation occurs in May/June of the following year. The whole cycle takes then approximately one year, from sending the online application to graduation.

## Clarifying the Business Idea

The philosophy of BGI is to infuse an execution mindset in participating venture teams before they approach potential investors, avoiding premature scaling of startups with a non-validated market fit. Hence, each venture selected to join the BGI accelerator benefits from more than 1,150 hours of expert mentoring aimed at clarifying their unique value proposition. Among other initiatives, BGI's acceleration process includes three intensive training periods (two in Lisbon at ISCTE-IUL's premises in July and November, and one in Cambridge at MIT's premises in May). Selected ventures are requested to attend together with a highly vetted group of mentors these intensive training initiatives, which help focus ventures on the critical steps in successful go-to-market and de-risking strategies. These "intensive training periods," so called *bootcamps*, serve also to educate entrepreneurs and founders on company creation, key decision-making processes and effective communication (e.g., pitching their idea to potential investors). As ventures progress in the acceleration process, BGI gradually introduces founders to the international networks they need to gather (i) customer and market knowledge and (ii) access key (angel) investors and eventually, if appropriate, venture capitalists capable of financing scaling.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Each "intensive training period" takes one to two weeks and is extremely intensive for participants (12+ hours a day). In between these training periods, teams work on specific (weekly) deliverables or activities. Upon graduation (end May), BGI concentrates/limits its support to the most promising and committed teams, 8 to 12 (out of the 21 batch per edition) teams are selected for an extended mentoring period which can extend for a period of up to 5 years, offered in the first 9 to 12 months via a semi-structured catalyst program and continuous coaching over the following years until companies *exit* or *fail* (Table 1 shows the list of selected startups in the first five editions of BGI and their corresponding fate).

*Table 1. Graduated ventures in five editions of BGI*

## Translating Market and Customer Knowledge into a Go-to-Market Plan

A key feature of BGI's transnational accelerator model is the rapid exposure of selected startups to a global network of mentors and advisors that can help shape and improve the commercial prospects of the incubated startups. In the first week after being accepted in the accelerator (July), the BGI team connects selected startups with different sorts of experts (technology, market, regulatory, legal, IP, potential partners) capable of bringing the entrepreneurial expertise and, importantly, the market and customer knowledge firms need to refine their value propositions and de-risk their business.

In the interim periods (August to October and January to June), teams work on a weekly basis and hold 10 structured (Aug-Oct) and non-structured meetings (Jan-Jun) with their assigned mentors, advisors (all teams) and catalysts (selected pool of 8 to 12 teams), depending on stage of development and acceleration phase. Throughout these periods each startup designs and then executes an 18 to 24 month go-to-market plan, which embodies the ideas of transnational acceleration discussed in previous sections of this chapter. It is during this process of writing a go-to-market plan (Aug-Oct) that the benefits, for startups, of BGI's rich network of 200 unique experts become apparent. These experts help startups to rapidly validate their business model and prepare for scaling operations with global aspirations. These experts have been carefully recruited over five years with the help and lobbying support of all involved parties, namely MIT and Portuguese government (FCT). Today, these experts constitute the backbone of BGI's successful model. All experts work with teams on a voluntary, but regular basis[7].

A key delivery for startups, related to the gathering of market and customer knowledge is *BGI's go-to-market plan*. BGI's go-to-market plan, a process that has been improved over the years, is designed to help technology-based venture teams transition from a technology-centric proposition to a commercially viable businesses proposition that can be ready for investment based on each venture's Technology Readiness Level (TRL[8]). Startups accelerated by BGI typically have TRL's ranging from 3 to 6. One of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the key goals of BGI, while guiding teams in the write-up of their go-to-market plans, is to take each team through a process of defining their unique value proposition (quantifiable in terms of monetary savings or value added to a specific target customer segment) and conduct market validation (assessing need strength and awareness, willingness to pay, switching costs, industry/sector dynamics, current and future competition among several other non-obvious factors. The goal is that the execution of such a go-to-market plan (which includes an investor's deck presentation) supports the team in attracting mentors, recruiting top talent (including an advisory board) and eventually in becoming investment ready and attracting the right investors.

## Startup Financing Model

Having clarified their business idea and business model and developed an investor's presentation in their go-to-market plans, each incubated startup needs to be able to raise capital (initially from local investors) to finance the execution of its plan. BGI connects promising local startups with business angels and early stage VC's around the globe, but with a special focus on the US, in order to rapidly mature and validate their value propositions, increasing their odds of becoming a viable business. Each startup's ultimate goal is to identify a profitable exit strategy. Each startup has a limited time (10 weeks) to work with mentors and advisors and gather sufficient customer and market knowledge to develop a clear and convincing business proposition. Very few get presented term sheets by US investors at this stage. Afterwards, each startup is invited to participate in an investor-only event, in Lisbon, where it pitches its business proposition to a panel of international investors. This is the first "formal" opportunity startups have to articulate their value propositions and uniqueness to a professional audience of experts and mostly, local investors.

The process of raising capital, however, typically takes significantly more time and effort (due diligence). Therefore, unlike any other accelerator in the world, BGI supports (pro bono) its alumni for a period after graduation up to five years. This support includes invitation-only events with key ecosystem players, including advisors, customers, partners and investors, among other. Unlike the models in which BGI was inspired (Deshpande's grants and MIT's 100k) - which exist with the sole purpose of supporting teams which are part of the MIT university ecosystem (i.e. technology spinouts where it already holds some IP rights) - BGI was originally conceived as an open model in order to achieve critical mass in its four verticals (i.e. the four domains or tracks introduced earlier). Driven by a management school with little technology focus, BGI concentrates primarily on providing the adequate tools to prove market fit and provide support to fragile new ventures built on technology-based value propositions.

## BGI's Exit Strategy

About 11 out of the 20 accelerated ventures per edition attract some form of venture financing (76.8% non-dilutive and 23.2% risk capital sources). The median venture financing per batch (i.e. BGI graduated companies) is €480,011. To date, 42.2% of BGI batch ventures get funded. The largest cumulative round(s) to date is set at €4.5 million[*3] whereas the smallest is set at €40,000. In Table 2, we summarize the funding raised by startups graduated from BGI (as 31st July, 2015). Of a total of 101 (100%) ventures (incorporated or not) that graduated in five complete editions of BGI (6th Ed. batch will be selected in July 2016), 66 are active companies (65.3%), 11 have failed and were shut down (10.9%), 11 were never incorporated (10.9%) and 9 are considered "zombie" companies (8.9%). The remainder 4 companies (3.9%) correspond to dropouts.

| **Total** | **11.9 M EUR** | **5.7 M EUR** | **31.3 M EUR** | **4.5 M EUR** | **4.9 M EUR** | **35.4 M EUR** |

*1 Funding conditional on achievement of certain milestones

*2 As of 31/07/2015

*3 Data excludes Feedzai series B round of US$17.5 million (May, 2015).

In five editions, BGI has received 515 applications, 35.0% of which were outside Portugal from 36 countries (see Table 3 for the number of submissions per area in BGI's first five editions). Nearly half of the applicants (46.4%) were from Enterprise IT & Smart data, 21.7% from Ocean economy, 17.5% from Medical devices and Health IT and 14.4% from Smart cities and industrial technologies.

In terms of exit strategy, BGI defines an *exit* as an event when any of the following situations takes place: (1) any awarded startup pays back or reimburses Caixa Capital Awards; (2) a startup reaches an accumulated venture financing of at least US$5M (€4 million), in equity and/or convertible debt or venture loans; (3) in the event of an IPO and/or M&A on any of the startups supported by BGI; or (4) a startup reaches a turnover of at least €2.5 million per financial year. Thus far, BGI has had two exits as per the above definition.

## Future Challenges of the BGI Transnational Acceleration Model

Provided the huge effort and commitment to core mentors, considerable attention has been devoted to making such a process replicable and scalable with limited internal resources. In spite of such efforts, further improvements were required in BGI's Mentoring Process. Applicant teams had consistently reported the need for more mentoring activities that could enable them to develop their ventures in a faster and more efficient manner. Also, it has been acknowledged by BGI internal management that further front loading activities need to precede e-teams III in Cambridge final boot camp (May/June) and that mentoring has been too "loosely done". More and better mentoring activities were then needed in BGI and for that reason an improved mentoring process was introduced during BGI's fourth edition (in 2013).

The improved BGI's Mentoring Process (or BMP) launched with the 4th Edition, is a structured process designed to be more efficient, scalable than the previous mentoring process. The BMP lasts 10 weeks with a predefined calendar aimed at "frontloading" teams' work and increasing their chances of successfully proceeding to the next steps. Among other initiatives, the BMP teams and mentors meet once per week for one hour and, two days prior to each meeting, teams need to submit specific weekly deliverables (typically 3 to 5 pages of written material). The BMP builds upon a powerful online, custom built platform (BGI Hub), where teams and mentors, respectively share deliverables and comments. The platform will soon aggregate business (as well as other) intelligence based on a combination of open source and proprietary (artificial) algorithms.

We now turn to the two case studies we use to examine whether our theoretically derived mechanisms work and how BGI's transnational acceleration model just discussed precisely operate in a real setting, controlling for many complex confounding effects and contextual influences (Miller and Tsang 2010).

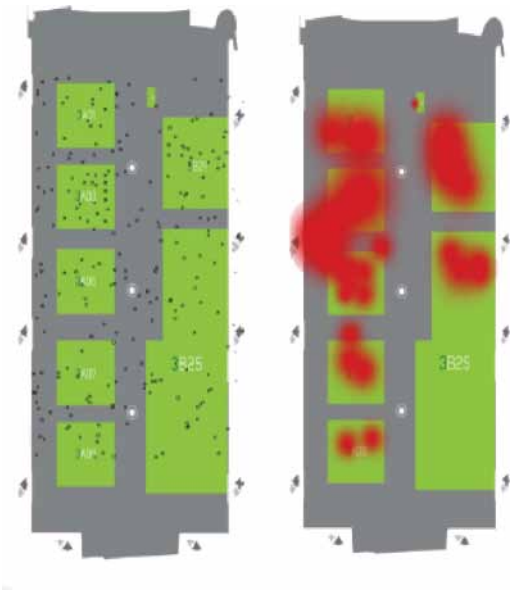
## CASE STUDIES: MOVVO AND VENIAM

### Case Study 1: Movvo[10]

*Movvo* is a fast-growing technology company, dealing with hardware and software solutions to measure the flow of people in physical spaces (such as large retail shops and malls). Movvo was founded in 2009 in Porto, Portugal's second largest city. Part of the idea to develop a technology to capture people's path in physical spaces emerged following a project in which some of the founding team's members had been working on for a corporate client, as interns at INESCTEC, an R&D Centre at the University of Porto (http://www.inesctec.pt/). The project consisted in developing Machine-to-Machine (M2M) solutions for home coffee appliances. The goal of the corporate customer was to incorporate a Bluetooth or 3G enabled device in coffee appliances which could automatically communicate consumer needs to a central database (e.g. to order new coffee capsules).

The project was quite ahead of its time, which may have hampered growth. The team successfully developed a number of prototypes, but the project eventually reached a standstill. Nonetheless their experience in the M2M space convinced them that this was a space ripe for disruption with the advent of the Internet of Things (IoT)[11]. At the same time, other team members who studied at Porto´s School of Sciences were exploring new possibilities in the field of indoor micro-location technologies. As explained by Roberto Ugo, Movvo's CTO and one of the company´s founders:

*we had a professor who disliked shopping very much, so we created an algorithm to help him spend less time in the retail store; but then we started thinking that if people spend less time in shops they would also buy less (…), this was when we became interested in following paths of people in retail shops [through signals in mobile phones] and started working on a Bluetooth prototype.*



Roberto soon started looking at the existing intellectual property in this space. After countless hours searching patent documents, Roberto realized that he and his colleagues had the skills and drive to improve existing technologies in terms of location accuracy. Competing indoor location solutions relied on slow, less accurate, or manual technologies (such as RFID). GPS-based solutions could not be used in very small places or indoor, due to lack of signal and granularity. Movvo's idea was powerful. To use wireless protocols and emissions - like GSM, Bluetooth or Wi-Fi - to anonymously capture the real-time location of mobile phone owners. Moreover, they could do it in a cost effective way, as they knew how to use standard, off-the-shelf technologies and beacons to improve the signal information using trilateration algorithms. This is where the Science background skills of the remainder of the founders, Suzy Vasconcelos and Diana Almeida, also played a key role.

Together, the founding team had the skills and technological knowledge needed to excel in the development of new solutions in this space. Figure 2 shows is an early *heat map* of customer paths in a retail space. It illustrates the type of output that Movvo was able to create with its state-of-the-art indoor mapping technology. However, at this stage (Spring of 2010), despite all their technical talent, the team

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 2. Example output of Movvo's original tagless real-time location technology*

felt overwhelmed by the huge number of potential applications and markets they could potentially focus on. In addition, a number of organizational issues, such as how to finance growth and streamline business development were major obstacles to the successful growth and scaling of their startup.

## Clarifying the Business Idea and Gathering Customer and Market Knowledge

Conscious of these obstacles, as soon as they heard about "ISCTE-IUL MIT Portugal Venture Competition" (now BGI), the team decided to apply (May 2010) and was selected to go through the first edition of BGI's acceleration program, described in previous sections. Movvo considers that this was a turning point in their growth trajectory. They benefitted immensely from intensive mentoring, networking and pitching as well as their hard work during the boot camps in Lisbon and Cambridge. In particular, mentors and advisors helped Movvo choose clear target customers - retailers and malls, understand unmet needs of these customers that could be solved with their technology (customer intelligence, purchasing patterns, optimizing retail space and promotional offers, etc). Movvo's business model, as well as the concrete steps they needed to take to launch their business, became much clear during the process of preparing their international go-to-market plan. Such valuable entrepreneurial lessons and customer and market knowledge that would be hard, if not impossible, to find locally:

*Mentors can choose to cooperate with companies to mentor based on their portfolio.(...) Our mentor was from the MIT and his company was specialized in real time management software for the railway industry, which was very relevant to our field and thus very insightful. This is a very specific type of knowledge. Moreover, he helped us dealing not only with the business plan and other doubts, but also introduced us to people and clients.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Movvo recognizes and praises the value they were able to extract from BGI´s network of mentors and advisors. Moreover, they understood that the incentives for these mentors and advisors were, most of the time, non-monetary, which helped them feel part of a unique group of entrepreneurs who are passionate about their ideas and about changing the world. This was the kind of motivation that made them work hard, but also becoming keen on helping other local entrepreneurs follow their dreams:

*It works like a professor telling their own personal stories. (…). And they do it for free. Of course if there is business in-between the better, and they may become involved in the company in the future as staff or investors, but that's not a major condition. In the US there is a virtuous cycle of entrepreneurs helping each other and giving back to the institutions that helped them out to start their ventures [e.g. MIT], as a sort of philanthropy which is not developed here [in Portugal]. I can imagine that in the future something similar may happen with BGI, with alumni companies helping newcomers.*

## Raising Capital to Grow

Movvo's hard work paid off. In October 2010, Movvo became one of the track awardees of BGI and, one month later, it became a Grand winner which allowed it to raise 200,000 € in a first round investment by Caixa Capital, an investment which nowadays totals 400,000 €, in non-dilutive financing. This process contributed to considerable learning on how to how to approach and deal with new and advanced markets, how to streamline operations, work with lead clients and develop a strong network with potential investors and advisors.

It is interesting to compare Movvo's experience with BGI´s transnational acceleration model and their prior experience in a more locally-oriented incubator. As explained by Roberto Ugo, BGI's transnational philosophy helped the company succeed and overcome challenges in ways that their previous incubator was unable to do:

*[our first] local incubator [in Porto] gave us great support; we were launching our first company and besides the space, they helped us with contracts, local networking and all sorts of daily issues that we didn't know how to deal with. [Yet], BGI linked us up with all their international contacts and potential investors (...). They [BGI] are catalysers for growth, investments and new business opportunities; it is totally different. In their events we get in touch with American investors, investors from Spain, the UK (…). They help us to look to the rest of the world. (…) BGI was also very helpful when we wanted to file in a global patent, linking us to specialized layers in Cambridge.*

## The Long-Term Value of being a BGI Alumni

The support of BGI is not a one-off event. There is a close involvement and follow-up after the venture competition. For example, after winning the competition in mid-2011, Movvo still faced many challenges and uncertainties. Their technology had a high number of applications, ranging from market intelligence (data) for retailers or malls, to safety applications or solutions for transportation companies. The team had to decide where to start, which customer or customers to target first, how to position their offering and how to improve their business and pricing models. Even in the technology front, the team had to

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

work on server integration issues, to ensure a smooth coupling of Movvo's solution with the client's IT systems, and to deal with data privacy issues. These obstacles posed considerable hurdles and delays. BGI tried to facilitate the process by coaching the founders further.

For example, Movvo had applied for a provisional patent during the summer of 2010 but was, at the same time, engaging in important negotiations with key customers, such as large retail corporations both in Portugal and abroad. All these different demands on the team's time and energy required a lot of dedication and rigorous planning. In their customers' interactions, communication would focus primarily on potential applications, and not on the technology itself. At the same time, the team needed to be prepared to answer any questions regarding their technology, patents and complex issues such as their 'hot topics' concerning server integration and privacy issues. In order to avoid any pitfalls, Movvo prepared each meeting very carefully, always considering different scenarios and having contingency plans ready. BGI supported these negotiation processes that required developing specific dashboards according to the company needs. Ultimately, a leading Portuguese retail corporation decided to adopt their solution and to invest in the company, becoming a key shareholder of Movvo.

During 2012-13, Movvo attracted different rounds of angel investment in Portugal and North America, and BGI was, again, instrumental in the process of capturing capital and financing Movvo's scale-up. One of these investors was a Boston-based angel investor, who had an interest to invest and support the team. Another key investor, identified by BGI, consisted of former *Novabase intrapreneurs* (a pioneer Portuguese IT company). One of the latter investors was, one year later, invited to become an interim CEO. The first angel round was also accompanied by the duplication of the 200,000 € award by Caixa Capital resulting in a 600,000 € round which came on top of the 200,000 € already awarded as the Grand winner of the competition.

During this period, Movvo started selling technology overseas and grew from 4 to 32 highly qualified employees, based in Porto – where the company locates and envisions expanding its R&D capacity. Movvo is also present in Cambridge (Cambridge Incubator Centre), right at the heart of MIT, in order to fuel its transnational network of contacts and facilitate networking with Boston's and MIT's entrepreneurial community (the first year was also supported by BGI). These international networks are particularly important to help the company raising further capital and financing and, importantly, gather customer and market know-how and reach potential customers. In the words of Movvo´s CTO, "there are many brains in Portugal, it would make no economic sense to hire them in other places. (…) [However], we [Portugal] are not very good selling our own products".

To this effect, Movvo is planning to establish a global sales and commercial unit in Boston/Cambridge. As Roberto Ugo explained, it is also about marketing and sales acumen: *"it is not only about the credibility, Americans can sell the impossible."* Currently, Movvo also informally supports new local companies starting up their business, and cooperates with local Universities for student´s research projects. This contributes to grow new mentoring and business support ecosystems locally, indirectly influenced by BGI´s experience.

All in all, the case of Movvo shows that a good idea can emerge everywhere, and that top-notch talent and technology does exist in peripheral European economies. However, the right knowledge, mentoring, cultural features and the resources necessary to scale it up and turn it into a viable businesses are much more selective. Thus, the relevance to link promising startups in these places to world class ecosystems through global "pipelines."

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## Case Study 2: Veniam

Veniam, which stands for *VEhicles Networking In A Mesh (VENIAM),* was founded in 2012 by two academic researchers, following their participation in the third edition of Building Global Innovators. João Barros, at the time Associate Professor of Electrical and Computer Engineering at the University of Porto and national director of the Carnegie Mellon University Portugal program (CMU), together with Susana Sargento, a post-doc researcher at the Telecommunications Institute in Aveiro (a city 75 km to the South of Porto), had been working together for several years when they had the breakthrough idea behind Veniam. Together, João and Susana made important scholarly contributions to the field of vehicular networks, namely to the area of self-adjusting nodes and algorithms capable of optimally managing such networks. Consequently, given its roots in academic research, Veniam is formally a spinout resulting from licensing a technology that both founders developed at their academic institutions.

The idea behind Veniam is to commercialize an aftermarket device that turns cars into mobile hotspots. Compared with existing solutions, Veniam leverages vehicle-to-vehicle communication to form a city-scale vehicular mesh network that offers a 10x increase in the range of the WiFi backhaul, a 10x lower cost per megabyte and a unique and simple platform for thousands of new vehicle apps. When they first joined BGI, João and Susana were confident that they were into a huge opportunity. They knew that the megatrend known as the Internet of Things (IoT) would push all kinds of devices - beyond computers, smartphones and other digital communication devices - to be connected to the Internet. They also knew existing solutions were not good enough and were confident their technology was superior to existing alternatives. Yet, they struggled about how to actually turn their idea into a commercially viable offering. What customers to target? How to position and market their product? How do set up distribution channels? And importantly, how to finance such move from the lab to the market?

## Discovering Local Talent with Global Ambition

One may wonder how could such a breakthrough technology originate from research in a peripheral region like Portugal, instead of Silicon Valley or Boston? Two factors were determinant in the case of Veniam: the thought leadership and international network of João Barros and the supportive role of Carnegie Mellon University, through its Portugal Program (CMU).

As a promising "start-scientist" with a degree from the University of Porto, João Barros soon felt the need to collaborate with other prime knowledge centres around the globe, first in Germany and later in the United States. For instance, during his academic studies João studied also at Universitaet Karlsruhe, Germany and then completed a Ph.D. degree at the Technische Universitaet Muenchen (TUM). In 2010, he received the prestigious IEEE Communications Society Young Researcher Award for the Europe, Middle East and Africa region, as well as other distinctive scholarships which allowed him to spend time conducting research at Cornell University and at MIT. Yet, João Barros knew that it would take more than his own talent to bring Veniam to life. Fortunately for Veniam, Portugal does not have a shortage of engineering talent. It has, however, a shortage of marketing and sales expertise for high-technology ventures, or in the words of João Barros:

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Portugal is a great place to have your engineering, because the salaries are 3.5x lower than Silicon Valley and the quality is excellent. [However], it is a terrible place to have your sales, marketing and product management, because there are very few people who know how to address global markets in a high-growth tech startup.*

## The Partnership with Carnegie Mellon University's Portugal Program

The idea of a vehicular mesh networking technology had been pursued by scientists and entrepreneurs worldwide for quite some time but which never materialized. The inexistence of a testbed large enough to take on the challenge of understanding the real-world conditions and the achievable performance of a city-scale vehicular mesh network made it very hard to develop and test such technology. The CMU-Portugal Program (a five-year international partnership between Carnegie Mellon University and 12 Portuguese Universities, headed since 2009 by João Barros), was pivotal in the successful development of such technology. Hence, João Barros' thought leadership, combined with the support of Carnegie Mellon University Portugal Program and the right timing (given the rapid trend towards an Internet of Things) made it possible for Veniam to pioneer the development and pilot the largest test bed in the world based on this technology.

Under the auspices of the CMU program, a number of proprietary technologies were developed with the support of several multi-million euro grants provided by the Portuguese science and technology foundation (*FCT*). The solution Veniam is currently commercializing resulted from five years of R&D efforts and more than 2M EUR of R&D investment. This included the *Drive-In* project, funded by FCT through the Carnegie Mellon Portugal program, which resulted in a large-scale testbed with 465 taxis in Porto, Portugal. The project led to significant advancements in vehicular networking simulation, algorithms and protocols, the backbone of Veniam's technology. Another key project was *MISC*, funded by FCT through the MIT Portugal program, which explored how city buses can be used to gather large quantities of data in a city. CMU Portugal program enabled the development of the largest vehicular network in the world, connecting taxis and buses wirelessly using their uniquely developed IEEE 802.11p compliant driver. Across all these projects, the support of the CMU program was pivotal in allowing João Barros to develop a fast setup for vehicular communications, ensuring reliable and efficient routing of data packets among vehicles, and extending the reach of WiFi hotspots by an order of magnitude. These technological achievements constitute the backbone of Veniam's value proposition.

## BGI: Helping Veniam Clarify its Value proposition

When Veniam entered BGI acceleration program, back in July 2012, it consisted of a typical academic team, with a strong emphasis on academic research and a potentially interesting technology. João Barros, the company's founder and CEO, acknowledges that while Veniam had ample access to engineering and scientific talent, customer and market knowledge was more of an issue:

*Veniam is a tech company that builds on 10 years of R&D in connected vehicles and intelligent transportation systems. We recruited our best MSc and PhD students so access to the right technical knowledge was not an issue. The main challenge was customer and market knowledge.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

This view is corroborated by BGI's leadership and mentors. Everyone who came in contact with Veniam agreed that their scientific know-how, experimental data and the intellectual property were important strengths. Yet, a number of important components in their business idea were still missing. Veniam's pitch missed, for instance, clear information on their choice of target customers and strategy to reach them, the cost of transmitting data over cellular networks, capacity usages, business model and other implementation and operational challenges. BGI and its network of mentors knew this and, therefore, asked Veniam's leadership to roll up their sleeves and start seeing the company from the customer's standpoint. According to João Barros, this customer - and market-focused approach to technology commercialization was very beneficial for Veniam, as "the BGI mentors encouraged us to talk to customers as much as possible and showed us the right questions to ask. This was crucial to the development of our business strategy."

For instance, mentors helped Veniam clarify its competitive landscape and positioning. As Veniam operates in an extremely competitive environment (with large players, including corporate automotive players, each one trying to implement its own proprietary standard to the industry), these aspects needed to be sharpened rapidly. This was not an easy task. With the help of BGI, Veniam was able to connect with key people that brought in the marketing and entrepreneurial skills their high-tech team missed. Specifically, Robin Chase - co-founder and former CEO of Zipcar (sold to Avis for US$491 million) - joined the team as a cofounder and Maria João Souto, a prolific Portuguese high-tech entrepreneur, joined as general manager and director of operations. These were valuable additions to the team, in the words of João Barros:

*Our co-founder Robin Chase was vital, as chairman and strategist. She joined from day one. Our general manager Maria João Souto brought decades of experience in managing the day-to-day activities of startups and growing SMEs.*

BGI's mentors advised the team to map out the competitive landscape to better understand the differentiation potential and the added value of their solutions. The team quickly discovered that companies currently competing in the emerging connected vehicle market can be divided into four different categories: (1) chipset manufacturers, (2) telematics vendors, (3) OEMs and (4) telecom operators. Although some companies already offered a few of the necessary components for vehicular communications, none of the competitors offered a turnkey solution for vehicular mesh networking like the one proposed by Veniam. Moreover, unlike its competitors, Veniam developed its own IEEE 802.11p compliant driver, meaning that the company was able to manufacture its devices at a fraction of the cost using easy-to-access and inexpensive components, such as commodity radios, and leveraging on the existing Wi-Fi infrastructure.

Beyond customer choice and competitive landscaping, BGI also helped Veniam clarifying its go-to-market strategy, as well as ensuring a sense of urgency and focus on the right issues at the right time, which in the words of João Barros were among the crucial advantages of joining the BGI network:

*We benefited a lot from interaction with other entrepreneurs, mostly to boost our confidence and learn from their experience (...) in terms of how they were addressing their markets and going through the process of figuring out what their products could be and how they would sell them. (...) [And], at the end of the day, the biggest benefit of BGI was to impose a timeline and force us to focus on the right issues. It is very easy to get distracted as an entrepreneur, but BGI helped us set the right priorities.*

## BGI: Helping Veniam Raise Money to Grow

Veniam came out of the BGI accelerator as the Grand finalist for the third edition. As already discussed, at this stage the company had two new co-founders, Robin Chase and Roy Russell, ex-founders of Zipcar. Furthermore, as winners of BGI's third edition, the company received prize money of €200,000 in the form of a 10 year venture risk loan, award which could be doubled if, in the subsequent 5 years, Veniam would be able to meet a set of pre agreed technical and commercial milestones, which it indeed met in the spring of 2014. This was an important seed capital for Veniam, according to João Barros:

*The capital that came with the grand prize was helpful in that it bought us some runway and allowed us to close Series A at a higher valuation.*

Veniam also took advantage of BGI's network of investors and was able to pitch its idea to 74 investors in just six months, an impressive count. Yet, Veniam wanted to grow in a capital-intensive space, which meant that they needed access to large venture capitalists in Silicon Valley. Those types of investors are more difficult to find than standard angel investors, even in a network like BGI. João Barros felt that that, indeed, many investors in BGI's network were *"mostly small investors with limited reach"* which made it challenging for the company to find the right ones to finance its growth. Consequently, according to João Barros, for Veniam there was actually no need for so much emphasis on fundraising and connecting with (small) investors within BGI network - it was more important to develop the quality of the business idea:

*My experience is that when you have an amazing opportunity, the right product, a good market understanding, strong team and initial paying customers, the investors will show interest. Therefore, the emphasis should be on checking all the right boxes and building a solid business.*

Despite these challenges, Veniam was able to grow successfully from a four-people team in 2012 to more than 20 employees in three countries by 2014. We now explore Veniam's scaling and go-to-market.

## BGI: Increasing the Chances of Commercial Success of Veniam's Technology

Besides enabling helping Veniam raise capital to scale and coaching the team, BGI also played an important role in streamlining Veniam's market access and commercial success, allocating key resources to business development and gathering customer and market knowledge. Over of the course of just three months (July to November 2012), Veniam conducted extensive customer interviews with major telecommunications operators in Portugal and abroad. At this stage, Veniam was able to quantify exactly customers' unmet needs in different verticals[12]. Such realization gave the team the confidence it needed to leave its comfort zone as established and successful researchers and focus on developing a high risk venture which required them to invest countless hours in a tireless mission to change the way users connect to the network.

With two seasoned entrepreneurs on board as co-founders, a large demonstration pilot and as a BGI grand winner (€400,000 in non-dilutive financing), Veniam was able to quickly gain an international reputation. Such reputation was important to persuade, in a first instance, angel investors based in New York and Silicon Valley to engage in the venture. True ventures and Union Square Ventures along with

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

its angel investors made a series A amounting to US$4.9 million, closed on the 9th August 2014. This would be the turning point for a local company based in peripheral city of Porto to establish itself as an emerging and ambitious global player in telematics.

With its R&D office located in Porto at the University of Porto incubator (UPTEC), Veniam was able to keep its burn rate at fraction of the cost (estimated at 1/5th) compared with what its competitors would be able to located in the West or East coast of the USA. This co-location strategy is a model that BGI strongly and actively supports since a company's inception, whereby co-locating a company's management near a large, vibrant but extremely competitive market - for instance Silicon Valley or Boston in the US. This enabled Veniam to grow quickly. While in 2012 the company had two founders in Portugal and two in the U.S., in 2013 the numbers were 5-9 in Portugal and still two in the U.S. Finally, in 2014 the company doubled its staff in Portugal (to 10-18) and in Silicon Valley (now with four people, including the CEO), and added one more salesperson in Asia.

In sum, Veniam's case is paradigmatic in the sense that the actual deployment of BGI´s transnational acceleration model helped to accelerate its success. Veniam's success also meant that BGI would now be able to showcase Portugal as a reputable and credible hub for efficient R&D, and persuade more international investors to look into Portugal as an origination geography capable of producing strong deal flow at discounted prices when compared, for instance, to the US.

## FUTURE RESEARCH DIRECTIONS

The case of BGI opens new avenues to understand the ways through which startups from small and peripheral economies (like Portugal) benefit from being plugged in different innovation ecosystems, and which types of organizations, business models and policies can be more effective supporting these connections.

In this chapter, in order to explore BGI´s model, we focused only on two very successful "grand winner" startups of BGI´s venture competition, Movvo and Veniam. These two startups operate in very dynamic industrial segments (linked with the "Big Data" and the "Internet of Things"). Thus, it would be important to analyse how the BGI model (and other similar initiatives) work across different sectors and industries, namely as the types of knowledge and resources required to innovate and grow may vary, as well as their sensitivity to geographical location.

In addition, we need large scale empirical studies to better single out the impact of transnational accelerator models, such as BGI, in entrepreneurial success (e.g. access to new markets and networks, capital acquisition and overall growth). For example, more systematic, quantitative analyses that control for firms' internal characteristics (such as the company and entrepreneur´s skills) and for key external factors would be very welcome. Such analyses would allow us to better understand the impacts of transnational accelerator models, such as the BGI process, in different types of startups. Large-scale survey research combined with secondary data, for instance, would allow researchers to flesh out the relevance of entrepreneurs' traits and skills, but also of group dynamics influencing the acceleration program. This type of questions open up several interesting research avenues at the intersection of entrepreneurship studies, economic geography, marketing and even behavioural economics.

From the perspective of local entrepreneurial ecosystems, another issue that would require attention concerns the ways through which knowledge and resources accessed in distant ecosystems becomes "anchored" in the local economy over time. In other words, is it possible that the access to global "pipe-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

lines" dynamically reinforces companies' "out-cluster" orientation, hollowing out local economies (e.g. through early takeovers and transfer of operations to other locations)? The evidence from the case studies suggests complementarity effects and, on the contrary, benefits for local economies - e.g. through the expansion of local R&D staff and the development of new mentoring ecosystems locally (e.g. inspired by the culture and institutions of far away locations). Yet, more research is necessary to fully understand how distant knowledge becomes anchored (or not) in local clusters and how does it vary across places, and what can be the role of transnational networks such as BGI in this respect.

## CONCLUSION

This chapter explored the tenets and the practice of a transnational model for startup acceleration that relies on a global network of experts and investors to promote local entrepreneurial growth in the European periphery: the *Building Global Innovators* (BGI) model. BGI is a Technology Transfer startup accelerator based in Lisbon (Portugal) and in Cambridge (Cambridge, USA) that has successfully incubated several technology-based ventures. In this chapter we discussed the tenets of BGI's model and the pathways through which BGI's global network of experts helped two IP intensive, promising Portuguese-originated startups grow and scale very quickly.

Our findings resonate with recent theses of local entrepreneurial growth in peripheral countries (Fontes & Combes, 2001; Fitjar & Huber, 2015; Vale & Carvalho, 2013). In these contexts, more than struggling to foster local interactions and nurture weak "clusters" (Porter, 1990), it is essential to establish bridges and connectivity between the talent and technical knowledge of local entrepreneurs with global networks capable of unlocking, first, the customer and market knowledge startups need to build convincing business cases and, second, the (venture) capital they will need to scale their businesses. This configures an important lesson for innovation policies in peripheral regions.

Complementarily to previous empirical studies that show how global entrepreneurial linkages emerge in an organic way (Saxenian, 2007), we explored how startup accelerators can deliberately harness such networks to help startups grow rapidly. Today, BGI operates through a partnership between one of Portugal's top business schools (ISCTE-IUL) and a state-owned bank (Caixa Geral de Depósitos). Yet, it started as an entrepreneurship initiative sponsored the Portuguese government and supported by the Massachusetts Institute of Technology (MIT), all within the MIT Portugal program which played a pivotal role in the formation of BGI's vast and high-level network of mentors. Moreover, the startups we explored (namely Veniam) rely on technologies which development strongly benefits from heavy public investments from the Portuguese government in science and innovation, with the aim to support and internationalize top-notch research in Portuguese universities. All in all, this shows that plugging startups in global "pipelines" is amenable to – and may even require – direct policy intervention, but also demand very active, professional and long-term approaches, as shown by the BGI model. The success of such an approach relies on fostering structured learning processes for companies, as well as on the establishment of serious commitments and long-term relations between an accelerator (such as BGI), the startups and the networks of mentors.

The evidence from BGI and the two in-depth case studies we examined show that place matters for entrepreneurship policies. In particular, a well-connected transnational accelerator like BGI can have a very important impact in a startup's internal capabilities and growth prospects. As a matter of fact, the whole international-oriented *modus operandi* of BGI is grounded on the assumption that the geographies

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

in which startups are active are an important driver behind its success. Yet, for entrepreneurship policies and startup accelerators, geography and places should not be understood as points in space, but rather as rich repertoires of actors and networks bind together by culture, routines and institutions, which altogether strongly influence the dynamics of local entrepreneurial systems. In this broader sense of "place", being at the right "place" (e.g. the right accelerator) is a crucial determinant of startup success.

Finally, a transnational model such as the one used by BGI seems to contribute to the formation of new local entrepreneurial and mentoring ecosystems in the periphery. Although testing this proposition would require further research, the evidence from our in-depth case studies show that BGI is not only able to help IP-intensive startups reach clearer business ideas, global networks and capital from distant locations, but also reach new ways of working and entrepreneurial culture. Absence of these factors are among the main hurdles in starting up new high-tech ventures in peripheral economies. Instead of trying to replicate the ecosystem and success factors of startup accelerators in regions like Silicon Valley, peripheral countries should invest in accelerators capable of connecting local startups to more advanced ecosystems is probably one of the most effective ways to support the emergence of "true" clusters and entrepreneurial dynamics in the periphery.

## KEY TERMS AND DEFINITIONS

**BGI - Building Global Innovators:** Technology transfer accelerator initiative based in Lisbon (Portugal) and in Cambridge, Massachusetts (USA). BGI aims at rapidly creating links and networks to locations across the globe, providing startups with access to customers, market knowledge, experienced mentors and venture capital.

**BGI's Go-to-Market Plan:** Process designed to guide startups to evolve from a technology-centric to a commercially viable businesses proposition.

**Clusters:** "Geographic concentrations of interconnected companies, specialized suppliers, service providers, firms in related industries, and associated institutions (e.g., universities, standards agencies, trade associations) in a particular field that compete but also cooperate" (Porter, 2000, p. 16).

**MIT Portugal Programme:** Formal partnership between the Portuguese government and the Massachusetts Institute of Technology (MIT) with the aim to promote innovation and university spinouts. It is led by the Portuguese Foundation for Science and Technology (FCT), and anchored in a strategic partnership between several Portuguese Universities, the MIT and key partners from industry and government.

**Pipelines:** Channels and conduits through which firms access relevant knowledge and resources to innovate and grow outside clusters (Bathelt, Malmberg, & Maskell, 2004).

## ENDNOTES

1 In this article, the first author had no prior knowledge about any of the two startups analysed and the second author had worked with *Movvo* on topics unrelated to startup acceleration (e.g. utilization of their path-level data to understand consumer behaviour and marketing topics), thereby ensuring the independence of their views.

2 ISCTE-IUL is the abbreviation of the school's original name, which was Instituto Superior de Ciências do Trabalho e da Empresa (Higher Institute of Business and Labor Sciences), with the addition of 'Instituto Universitário de Lisboa' (University Institute of Lisbon) added in 2009, to reflect the fact that ISCTE-IUL became one of the three Portuguese universities (along with the University of Porto and the University of Aveiro) which adopted a 'Foundation Regime', which prescribes management according to private law.

[7] Mentors volunteer their time for two reasons. First, with the help of MIT Portugal and the Martin Trust Center for MIT Entrepreneurship, BGI was able to tap into MIT's network of successful entrepreneurs. Unlike the case in Portugal and, perhaps even Europe, these entrepreneurs have a strong philanthropic culture and altruistically offer their time and expertise to help other entrepreneurs grow. Second, some of these advisors make capital investments in the incubated startups, which gives them a stake in their success.

[8] The technology readiness level (TRL) is a method used by institutions such as the U.S. Department of Defense, NASA or the European Spatial Agency, to estimate the maturity of a certain technology. TRL levels ranges from 1 (basic research) to 9 (mature technology, ready for operational testing and market launch).

[9] Dilutive sources include Angel and VC-funding that involves convertible notes, equity or quasi-equity deals.

[10] Formerly known as *Around Knowledge,* the company decided to change its corporate brand in 2014 to *Movvo* to better reflect its value proposition and the way its platform works. See: http://www.movvo.com/.

[11] The Internet of Things is a general term that refers to technological developments that allow building networks of physical objects, i.e. to use electronic sensors, devices and software to connect all kinds of physical objects and appliances to the existing Internet infrastructure. Not only startups but also large companies such as Alcatel-Lucent, Cisco, Ericsson and Google, to name just a few, are leading this revolution.

[12] For instance, Veniam found that an important unmet need of telecommunications operators' private end customers was the cost per MB of their cellular data plans, which varied between €0.02 and €0.08 (e.g. AT&T charges 100 USD for 5GB), whereas over Wi-Fi hotspots the cost is about €0.003 per MB (e.g. ZON FON hotspots, which charge 3 EUR per hour for a 2Mbit/s connection). This meant that offloading traffic from cellular to Wi-Fi hotspots to a vehicular network like the one proposed by Veniam would result in a 5x to 20x cost reduction for end consumers, a major benefit for customers.

# Chapter 87
# Diffusion of Technology via FDI and Convergence of Per Capita Incomes:
## Comparative Analysis on Europe and the MENA Region

**Sumru Oz**
*Koc University, Turkey*

## ABSTRACT

*This chapter analyzes the convergence of incomes towards the FDI home country in Europe and in the MENA region, separately; and the prerequisites to derive benefit from FDI in a comparative manner. The per capita income convergence towards the major FDI home country, US, is estimated higher for Europe compared to the MENA region. However, the differences in the convergence values are not so wide between some sub-groups of these two regions. The absorptive capacity hypothesis, together with the investment capacity explains the discrepancies between not only the two regions as a whole, but also sub-groups within each region. The strong complementary effects between FDI and both absorptive and investment capacity suggest that economic policy aimed at fostering growth should try to benefit more from FDI by increasing the absorptive capacity-enhancing own R&D activities and promoting human capital- as well as by improving investment environment to attract more of it.*

## INTRODUCTION

According to the new growth theory, technological improvement is the main source of economic growth and diffusion of technology is the basic mechanism of per capita income convergence among countries. Therefore, the growth rate of a country depends on the state of domestic technology relative to that of the rest of the world. In this setting, if technology diffusion were national in character, there would be no possibility for convergence of incomes. Each country would grow at a rate determined by its own

research effort. However, in reality research in one country benefits from knowledge created in others, providing a mechanism by which a laggard country would tend to catch up, formulated by the diffusion of technology models of endogenous growth theory.

Strong diffusion is the only force towards convergence because it equalizes differences in technology across countries (Keller, 2001). The reason is that almost the entire Research & Development (R&D) activity in the global economy is concentrated in a small number of industrial countries and, yet, not all of the other countries stagnate relative to the frontier. In a typical model of technology diffusion, the rate of economic growth of a backward country depends on the extent of the adoption and implementation of new technologies that are already in use in leading countries. Therefore, measuring the convergence of per capita incomes is important in order to assess whether comparatively less advanced countries manage to decrease the technological gap with more advanced ones.

The new growth literature underlines international trade and foreign direct investment (FDI) as transmission mechanisms that link a country's growth rate to economic developments in its partners (Grossman & Helpman, 1994). In general, empirical studies on international technology diffusion find evidence that there is significant cross-country technology diffusion via international trade channels. However, evidence related to FDI as a technology diffusion mechanism is ambiguous. On one hand, the results of empirical studies on developed countries show that FDI is a channel through which technology is internationally diffused (Lichtenberg & van Pottelsberghe de la Potterie, 1996; Barrel & Pain, 1997; Barrel & Pain, 1999; Choia, 2004). On the other hand, results of research on relatively less developed countries find no evidence supporting the existence of technology spillovers from foreign firms to domestically owned firms, as shown by Haddad and Harrison (1993) for Morocco or Aitken and Harrison (1999) for Venezuela.

These results imply that only developed countries can benefit from technological spillovers stemming from FDI, leaving no room for developing countries to catch-up. However, Borensztein, de Gregorio, and Lee (1995) empirically examine the role of FDI in the process of technology diffusion and economic growth in developing countries, suggesting that FDI is an important vehicle for the transfer of technology, contributing to growth in larger measure than domestic investment only when the host country has a minimum threshold stock of human capital. Xu (2000) also links the different outcomes obtained for developed and developing countries to the fact that most developing countries fail to reach the minimum human capital threshold level in order to benefit from the technology transfer. Bijsterbosch and Kolasa (2009) affirm the importance of human capital on the effect of FDI on convergence of productivity in the Central and Eastern Europe towards that of the euro area. Similarly, Neto and Veiga (2013) also find a positive effect of FDI on productivity growth and on GDP growth once the initial level of human capital is considered.

Recent studies based on firm-level data confirm that what matters is the absorptive capacity – not only human capital level, but also own R&D activities as implied by the theoretical models of technology diffusion- to benefit from positive spillovers, both for developed and developing countries. Regarding the former, e.g. Ben Hamida (2013) concludes that only local firms which have largely invested in absorptive capacity in Switzerland gain benefit from spillovers, stemming mainly from technology transfer. Similarly, the results of Chen et al. (2010) indicate a general pattern where industries with high absorptive capacity in China are better than low-end industries in absorbing spillovers from foreign-owned firms.

In summary, empirical studies on diffusion of technology confirm that human capital plays an important role in order for a country to benefit from foreign spillovers. Furthermore, they suggest that countries themselves must also engage in R&D activities so that they derive benefit from foreign knowledge. Ac-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

cordingly, human capital and own R&D activities are considered as the two components of the *absorptive capacity*. Apart from the own R&D and human capital, the determinants highlighted by empirical research based on new growth theory as affecting the rate of growth, such as government consumption, price stability and political stability can be considered as comprising a second category that can be called as *investment capacity*, in the sense that they determine the general investment environment of a country.

This chapter hypothesizes that technology diffusion measured by the convergence of per capita incomes depends not only on the absorptive capacity, but also on the investment capacity. To test this hypothesis, the convergence of incomes towards the FDI home countries in Europe and in the Middle East and North Africa (MENA) region are estimated separately and the results are analyzed taking into account the absorptive and investment capacity of these countries in a comparative manner. Therefore, the sections of this chapter are organized as follows. Following the Background Section which surveys the literature on international technology diffusion, the main focus of the chapter is presented. First, the empirical methodology that is used to capture the per capita income convergence towards the FDI home country is discussed. Then, the results of the convergence analysis for the MENA region and Europe are given separately. Finally, the results are scrutinized taking into account the absorptive and investment capacity in both regions comparatively. Conclusions and policy recommendations are presented in the last section.

## BACKGROUND

The extant literature on international technology diffusion mainly investigates international technology spillovers and their effects either on growth directly or on total factor productivity (TFP) – the component of output growth that is not attributable to the accumulation of factor inputs. There are different approaches to study empirically the effect of international technology diffusion. In some of them there is no reliance on any one specific transmission channel. Bloom, Canning, and Sevilla (2002), for example, develop a model which accounts for economic growth by the growth of factor inputs, technological innovation and technological diffusion. The novelty of their approach is the introduction of the effect of technological diffusion on economic growth, which until then, has been decomposed into two components: increases in factor inputs and improvements in TFP.

Their model allows for cross-country differences in the level of TFP and expects that these differences close over time as technology diffuses to the extent that differences in TFP reflect differences in technology. Using cross-country panel data on income growth over the period 1970-1990, they find evidence of conditional convergence in the growth data. The rationale for conditional convergence in their approach is the diffusion of technology between countries unlike that of the neoclassical extension, in which catch-up occurs due to a high rate of investment as the capital stock grows towards its postulated steady-state for countries whose capital stock and output are lower than their steady-state levels. Another example, in which there is no reliance on any one specific transmission channel, is Bernstein and Mohnen (1998). They investigate how a country's R&D capital accumulation affects factor intensities and productivity growth in another – in their case, the USA and Japan, respectively – and conclude that international spillovers exist from the USA to Japan, but not vice versa.

The majority of the empirical studies on international technology diffusion though rely on a specific transmission channel. In general, the weighted sum of foreign R&D is used to reveal the effect of foreign R&D on a country's TFP. The weights vary from study to study to a great extent, because countries are

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

linked through different channels such as foreign trade and foreign direct investment (Mohnen, 2001). International trade is the most preferred one, where each of the foreign country's R&D is weighted with the import share of that country (Coe & Helpman, 1995; Coe, Helpman, & Hoffmaister, 1997; Nadiri & Kim, 1996; Gera, Gu, & Lee, 1999). According to this specification the more a country imports from a foreign country, the more R&D spillover benefits accrue to that country.

In general, empirical studies on international technology diffusion, which rely on a specific transmission channel, find evidence that there is significant cross-country technology diffusion in embodied form. Specifically empirical evidence supporting the international trade channel is rather strong. For example, Coe and Helpman (1995) study whether a country's productivity is increasing in the extent to which it imports from high knowledge countries. They also investigate, for a given composition of imports whether a country's productivity is higher the higher is its overall import share. Their regression results suggest that there is support for both predictions. The authors conclude that not only does a country's total factor productivity depend on its own R&D capital stock, but also depends on the R&D capital stocks of its trade partners. Furthermore, the rate of return on R&D capital is found to be very high both in terms of domestic output and in terms of international spillovers.

Nadiri and Kim (1996) use foreign country's R&D weighted with the import share of that country in order to estimate the effects of international R&D spillovers on TFP growth of the seven largest industrialized (G-7) countries by 1991. They conclude that international R&D spillovers have contributed to narrowing the productivity gap between the US and the other G-7 countries. Coe, Helpman, and Hoffmaister (1997) find evidence that R&D spillovers from developed to developing countries are also substantial. They provide quantitative estimates of spillover effects for a group of 77 developing countries from Africa, Asia, Latin America, and the Middle East. They conclude that R&D spillovers from the industrial countries in the North to the less developed countries in the South are substantial. Their results imply that a developing country's TFP is larger the larger is its foreign R&D capital stock; the more open it is to machinery and equipment imports from the industrial countries; and the more educated is its labor force. In their preferred specification, the foreign R&D capital stock only affects the developing country productivity through its interaction with imports of machinery and equipment, which is consistent with the technology diffusion models.

In general, per capita income convergence fails for broad sample of countries, but there is per capita income convergence among, for example, the OECD countries. This evidence motivated researchers to focus on groups of countries comprising major trade partners with the aim of finding a relationship between per capita income convergence and international trade. An example to this approach is Ben-David (1996). He compares convergence in groups of countries that trade mutually more with different country groupings that are selected randomly and checks whether the former exhibit more income convergence than do the latter. Indeed, if trade plays a role in the convergence process, it should probably be evident among countries that are the principal trade partners of one another. The results indicate that most of the individual trade groups exhibited income convergence. Convergence of his magnitude is not a common outcome among these countries when they are grouped randomly instead of by their trade partners. Ben-David and Kimhi (2000) generalized the findings of Ben-David (1996) by including poorer countries in the analysis. The results indicate that changes in the extent of trade appear to have an effect on the degree of income disparity among countries and increases in intra-group trade intensify the speed of convergence among the group members.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Contrary to the robustness of empirical evidence supporting the international trade channel, the result of empirical studies on foreign direct investment as a technology diffusion mechanism among countries is ambiguous. Suggesting that not only international trade, but also inward and outward FDI might be channels through which technology disseminates across countries, Lichtenberg and van Pottelsberghe de la Potterie (1996) extend Coe and Helpman's (1995) analysis on international trade to include FDI for a sample comprised by the 13 OECD countries, which have the relevant FDI data over the period 1971-90. Their empirical results show that outward FDI flows and import flows are the two simultaneous channels through which technology is internationally diffused. Branstetter (2000) introduces a framework based on patent documents for measuring international spillovers at the firm level and tests the hypothesis that FDI is a channel of knowledge spillovers for Japanese multinationals undertaking direct investments in the USA. He finds evidence that FDI is a significant channel of knowledge spillovers, both from investing firms to indigenous firms and from indigenous firms to investing firms. This evidence emphasizes the potential importance of multinational corporations as channels of knowledge spillovers between advanced economies.

Barrel and Pain (1997) investigate the role of FDI in the diffusion and assimilation of technologies and ideas across borders in Europe. Their main interest lies in the extent to which technology transfers and other spillovers from foreign-owned firms affect the pace of technical change and hence economic growth. Therefore, they assume that technical progress is dependent on the aggregate level of foreign-owned assets together with an exogenous element proxied by a linear time trend. This assumption implies that technical progress will grow at a constant rate if direct investment grows at a constant rate.

Assuming further that the FDI stock enters with a four quarter lag they obtain significant effects from inward FDI for the United Kingdom and Germany. Extending the model in Barrel and Pain (1997) to obtain a panel data analysis of the impact of the economy-wide inward investment on technical change in four European countries – the United Kingdom, Germany, France, and the Netherlands – Barrel and Pain (1999) present empirical evidence of significant spillovers on technical progress, thus important effects on the economic performance of host economies. Expanding the scope of the analysis on interactions between FDI and income convergence to the OECD countries, Choia (2004) finds that income level and growth gaps between source and host countries decrease as bilateral FDI between them increases by using FDI data from 1982 to 1997.

In other words, the level and growth of per capita income converge as bilateral FDI flow increases between any two OECD countries. These findings show that there is empirical evidence related to positive spillovers of foreign investment by transferring technology between developed countries. In contrast, evidence for such spillovers from developed to developing countries is not robust. Haddad and Harrison (1993), for example, employ a unique firm-level dataset to test for such spillovers in the Moroccan manufacturing sector and reject the hypothesis that foreign presence accelerated productivity growth in domestic firms during the second half of the 1980s. Similarly, Aitken and Harrison (1999) find no evidence supporting the existence of technology spillovers from foreign firms to domestically owned firms using a panel of more than 4,000 Venezuelan plants between 1976 and 1989.

These results imply that only developed countries can benefit from technological spillovers stemming from inward FDI, leaving no room for developing countries to catch-up. However, the research covering both developed and developing countries links the different outcomes to the fact that most developing countries lack the necessary human capital level to benefit from the technology transfer. For example, Borensztein, de Gregorio, and Lee (1995) examine empirically the role of FDI in the process of technology diffusion and economic growth in developing countries. They test the effect of FDI on economic

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

growth in a framework of cross-country regressions utilizing data on FDI flows from industrial countries to 69 developing countries from 1970 to 1989. Their results suggest that FDI is an important vehicle for the transfer of technology, contributing to growth in larger measure than domestic investment. However, FDI is more productive than domestic investment only when the host country has a minimum threshold stock of human capital.

Xu (2000) examines the technology diffusion effect of multinational corporations (MNCs) in a multi-country framework, where technology transfer intensity of MNC affiliates is measured by their spending on royalties and license fees as a share of their value added assuming that higher spending by the affiliates on technology transfer corresponds to greater technology diffusion to the host country. The data contain majority-owned affiliates of US MNCs in the manufacturing sector in 40 countries, half of which is comprised of developing countries. Not surprisingly, there is strong evidence of technology diffusion towards developed countries, but weak evidence of that towards developing ones. The reason is that most developing countries fail to reach the minimum human capital threshold level in order to benefit from the technology transfer of US MNCs (Xu, 2000).

Bijsterbosch and Kolasa (2009) also affirm the importance of human capital on the effect of FDI on convergence of productivity in the Central and Eastern Europe (CEE) towards that of the Eurozone. The empirical results point that FDI inflows play an important role in accounting for productivity growth in the CEE region and that the impact of FDI on productivity critically depends on the absorptive capacity of host countries such that the effect of FDI on productivity increases as the productivity differential vis-a-vis the euro area declines. In a recent paper, Neto and Veiga (2013) empirically investigate the role of foreign direct investment on growth through diffusion of technology and innovation using a panel data set covering 139 countries over the period of 1970 - 2009. Utilizing an otherwise standard growth regression and regressions on productivity growth, they introduce a direct effect of foreign direct investment and an indirect effect to capture the role of technological catch-up.

The results show that these two mechanisms have a positive effect on productivity growth and on GDP growth once the initial level of human capital is taken into account. The recent within-country studies based on firm-level data also confirm that what matters is the absorptive capacity -a broader definition covering both human capital and own R&D activities as suggested by the theoretical models- to benefit from technology diffusion. For example, the results of Chen et al. (2010) indicate a general pattern where industries with high absorptive capacity and/or high efficiency in China are better than low-end industries -with low absorptive capacity and/or low degree of efficiency- in absorbing spillovers from foreign-owned firms. Similarly, in a recent paper on Switzerland, Ben Hamida (2013) concludes that only local firms which have largely invested in absorptive capacity gain benefit from spillovers, stemming mainly from technology transfer.

Therefore empirical studies on diffusion of technology confirm that human capital plays an important role in order for a country to benefit from foreign spillovers. As suggested by the diffusion of technology models, countries themselves must engage in R&D activities to implement and adapt foreign technologies so that they derive benefits from them. Accordingly, human capital and own R&D activities are considered as the two components of the *absorptive capacity*. Beyond R&D and human capital, the determinants highlighted by empirical research based on new growth theory as affecting the rate of growth, such as government consumption, price stability and political stability can be considered as comprising a second category that can be called as *investment capacity*, in the sense that they determine the general investment environment of a country.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

This chapter hypothesizes that technology diffusion measured by the convergence of per capita incomes, depends not only on the absorptive capacity, but also on the investment capacity of countries. To test this hypothesis in the context of the countries in Europe and in the MENA Region, this chapter first estimates the convergence of incomes towards the FDI home country in both regions separately, and then analyzes the results with respect to absorptive capacity and investment capacity of all countries in these regions in a comparative manner.

## CONVERGENCE TOWARDS THE FDI HOME COUNTRY IN EUROPE AND IN THE MENA REGION

Whether there is a per capita income convergence or divergence among countries has been a major area of dispute in the empirical growth literature. Empirical research using panel data regressions encouraged by the availability of Summers-Heston data set, which allows making cross-country growth comparisons, is based on two theoretical models of growth. The first one is the neoclassical growth theory developed by Solow (1956) which identifies three sources of growth in the short-run (i.e., during the transitional phase towards steady-state): capital accumulation and growth in labor force which can be combined to give the ratio of capital per worker, and technological progress which is considered exogenous. However, in the long-run it is the effectiveness of labor, in other words exogenous technological progress, which determines growth in output per worker.

The second strand of theoretical models of growth used as a base for empirical research is the endogenous or new growth theory which fills the gap in neoclassical theory by opening up technological progress and innovation to systematic analysis, and studies their effects on growth. Indeed, the endogenous growth theory provides the tools to handle endogenous technological change and innovation within a dynamic general equilibrium setting allowing for the development of tractable models. While the neoclassical theory of growth treats technological progress as an exogenous process and focuses instead on capital accumulation as the main source of output expansion, the new growth theory focuses on technical progress. The studies on the latter, pioneered by Romer (1990), view commercially oriented innovation efforts that respond to economic incentives as the major engine of technological progress and growth. In this view, innovation feeds on knowledge that results from cumulative R&D experience on the one hand, and it contributes to this stock of knowledge on the other.

Consequently an economy's growth depends on its cumulative R&D effort and on its effective stock of knowledge, with the two being interrelated such that the pace of technological progress, thus growth in that economy is determined endogenously. Both strands of theoretical growth models imply that either exogenous or endogenous; technology is the main driving force behind the long-run economic growth. The difference in their approach is that neoclassical models hold that technology is available everywhere to everyone at no cost, while at the other extreme, the endogenous growth theory, as it is first put forward, relates a country's technical advances only to its own innovations (Eaton & Kortum, 1999).

Therefore, the former implies absolute convergence of per capita incomes of countries regardless of their respective characteristics, while the latter has no convergence implications at all. The rationale behind the neoclassical growth model that predicts absolute income convergence among countries (i.e., poorer countries grow faster than richer ones), is the diminishing returns to capital. The evidence for this prediction is not robust though. On one hand, income divergence, or at best, non-convergence, appears

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

to characterize the behavior of most cross-country income differentials, but on the other hand there is evidence of considerable convergence among wealthier countries (e.g., among 20 relatively advanced OECD countries), especially during the postwar period.

When the analysis is broadened to include a wider spectrum of countries, the convergence evidence seems to disappear entirely, even a divergence is observed. However, once determinants of growth, such as human capital, government policies, and other variables put forward by the endogenous growth literature are considered, there appears to be strong evidence of convergence among countries, which is termed as conditional convergence. Within the neoclassical model with exogenously determined identical level of technology among countries, this finding can be interpreted as evidence of diminishing returns to physical or human capital. As Romer (2001) states, running a regression conditioned on these variables and finding that countries with lower initial income grow more rapidly can also be interpreted such that the technology level is lower in a country that starts at a lower level of development which grows faster as better technology diffuses there.

In the endogenous growth framework, if technology diffusion were national in character, there would be no possibility for convergence because each country would grow at a rate determined by its own research effort. But in reality, research in one country benefits from knowledge created in others, providing a mechanism by which a laggard country would tend to catch up, formulated by the diffusion of technology models of endogenous growth theory. Strong diffusion has become the only force towards convergence, because it equalizes differences in technology across countries. In a typical model of technology diffusion, the rate of economic growth of a backward country depends on the extent of the adoption and implementation of new technologies that are already in use in leading countries since almost the entire R&D activity in the world economy is concentrated in a small number of industrial countries and, yet, not all of the other countries stagnated relative to the frontier.

Therefore, the new theory of economic growth underlines international economic relations as transmission mechanisms that link a country's growth rate to economic developments in its trade partners (Grossman & Helpman, 1994). Convergence implications of diffusion of technology models is more convincing theoretically considering that per capita income of countries converge each other as technology diffuses from a technologically more advanced country to a comparatively less advanced one.

In the extant literature on international technology diffusion, technological knowledge is typically the design of a new intermediate product. According to this mechanism, technology diffuses internationally through foreign intermediate goods. The idea is that employing the foreign intermediate good involves the implicit usage of the design knowledge that was created with the R&D investment of the foreign inventor. In this case, the technological knowledge of the design is embodied in the intermediate good. As long as the intermediate good costs less than its opportunity costs – including the R&D costs of product development – there is a gain from having access to foreign intermediate goods. Therefore, improvements in technology have been the main source behind the economic growth, thus diffusion of technology is the basic mechanism of per capita income convergence among countries.

As the survey in the previous section shows, the empirical studies on diffusion of technology confirm that the technology transfer via FDI is not straightforward. The flow of advanced technology brought along by FDI can increase the growth rate of the host economy, hence allow for income convergence between FDI partners only by interacting with that country's absorptive capability. However, there is another prerequisite of deriving benefits from technological spillovers: to attract considerable amount of FDI that involves latest technological improvements. In this respect, the investment environment of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

a country matters as well. Besides the two components of absorptive capacity, the empirical research on growth highlights lower government consumption, price stability, and better governance as affecting the rate of growth of a country.

Accordingly, before analyzing the importance of the investment capacity comprising of these three determinants and the absorptive capacity in accruing benefits from technology transfer via FDI in Europe and in the MENA region comparatively, this section aims to reveal the per capita income convergence dynamics in the two regions towards the FDI home country.

## Measuring Convergence

### Convergence Based on the Neo-classical Growth Model: β-convergence

In the neoclassical growth framework, the average growth rate of per capita output, y, over an initial time 0 to any future time T is derived in Barro and Sala-i-Martin (1995) as

$$(1/T)\bullet\log[y(T)/y(0)] = g + [(1 - e^{-\beta T})/T]\bullet\log[y^*/y(0)]. \quad (1)$$

Equation (1) implies that the average per capita growth rate of output depends negatively on the ratio of y(0) to y* once the steady-state growth rate, g, the convergence speed, β, and the averaging interval, T, are held constant. In other words, the effect of initial position, y(0), is conditioned on the steady state position, y*, implying conditional convergence.

Alternatively, the average growth rate of per capita output of country i, $y_i$, between any time t and a previous time t-T, where T is a time interval, e.g. in years, can be written as

$$(1/T)\bullet\log(y_{i,t}/y_{i,t-T}) = a - [(1 - e^{-\beta T})/T]\bullet[\log(y_{i,t-T})], \quad (2)$$

where $a \equiv g + [(1 - e^{-\beta T})/T]\bullet\log(y_i^*)$, and yi,t-T is per capita income in country i at the beginning of the interval. Similarly, yi,t is per capita income in country i at the end of the interval, T is the length of the interval, and β is the speed of β-convergence, i.e. the catch up speed of the relatively poorer economy to the rich one in terms of the level of per capita income.

Considering that the number of countries in each group is at most 20, the results of the econometric analysis would be hardly reliable if the econometric specification (2) were directly used in regressions. In order to increment the number of observations, this specification is converted to panel data framework following the procedure proposed in Lall and Yilmaz (2001). Assigning value 1 to the time period T in Equation (2) in order to have a panel data framework and rearranging, we end up with the following basic econometric specification, which is used to test β-convergence based on neoclassical growth model.

$$\log(y_{i,t}) = a + b \log(y_{i,t-1}), \quad (3)$$

where the estimated b needs to be translated into speed of β-convergence using the formula

$$\beta = -\log(b). \quad (4)$$

## Convergence in the Diffusion of Technology Models

The first method used to detect per capita income convergence among FDI partners (i.e., β-convergence), is based on the neoclassical growth model, which has no foresight related to the effect of FDI on convergence. It can only signal a form of conditional convergence in a group of countries, where FDI partnership is used to homogenize them. In accordance with the focus of this chapter, which analyzes the convergence implications of foreign direct investment as an international technology diffusion channel, the second convergence method used in this chapter is based on the diffusion of technology model of endogenous growth theory.

Technology diffusion mechanism from developed to less developed countries, which, has less, if not none at all, R&D activity, is modeled in Barro and Sala-i-Martin (1995). The main idea behind the model, referred to as the leader-follower model, is that if the diffusion of technology occurs gradually through international trade, then the follower countries tend to catch up to the leaders because imitation and implementation of discoveries are cheaper than innovation. This model of indirect technology diffusion implies convergence even when diminishing returns do not apply, but requires a form of diminishing returns in imitation such that the cost of imitation rises as the number of goods already adapted increases.

It is straightforward to deduct convergence implications of indirect technology diffusion via the FDI model from Barro and Sala-i-Martin (1995) model of indirect technology diffusion via trade considering that the cost of imitation in the latter model can be replaced by the cost of adaptation in the former since cost of adapting is smaller for the original inventors who are more familiar with the invention. In other words, the form of conditional convergence implied by the technology diffusion via FDI model is based on the assumption that the cost of adaptation is lower than that of innovation when very little has yet been adapted and rises as they are getting adapted. Therefore, relationship between the growth rates of the follower and the leader countries derived in Chapter 8 of Barro and Sala-i-Martin (1995) also applies in case of indirect technology diffusion via FDI, such that

$$\gamma_i \approx \gamma_1 - \mu \bullet \log [(y_i/y_1)/(y_i/y_1)^*], \tag{5}$$

where $\gamma_i$ and $\gamma_1$ are per capita growth rates in follower countries and the leader country, respectively, $\mu$ is the speed of convergence in the diffusion of technology model framework, $y_i$ and $y_1$ are per capita incomes of follower countries and the leader country, respectively, and finally $(y_i/y_1)^*$ is the steady-state ratio of per capita incomes in follower countries and the leader country.

Since the role of FDI as a technology diffusion mechanism is focused in this study, the leader country is considered as the FDI home, whereas the follower ones as the FDI host countries in the MENA region and in Europe. The convergence obtained in this framework is called as μ-convergence (Öz, 2014).

Following the relationship between the growth rates of the follower countries and the leader country in the diffusion of technology framework given in Equation (5), the average growth rate of the FDI host country i between initial time t-T and time t can be written as

$$(1/T)\bullet\log(y_{i,t}/y_{i,t-T}) = (1/T)\bullet\log(y_{1,t}/y_{1,t-T}) - \mu\bullet[\log(y_{i,t}/y_{1,t})] + \mu\bullet[\log(y_i/y_1)^*], \tag{6}$$

where $y_{i,t-T}$ and $y_{1,t-T}$ are per capita income in each of the FDI host country i and that in the FDI home, respectively, at the beginning of the interval. Similarly, $y_{i,t}$ and $y_{1,t}$ are per capita incomes at the end of the interval, T is the length of the interval, and μ is the speed of convergence (i.e., the catch up speed) of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the relatively poorer economy the rich one in terms of the level of per capita income in the diffusion of technology framework of endogenous growth theory. Since the steady-state ratio of per capita incomes in the FDI host and home countries (i.e., $\log(y_i/y_1)^*$)is constant, the Equation (6) can be written as,

$$(1/T)\bullet\log(y_{i,t}/y_{i,t-T}) = a' + (1/T)\bullet\log(y_{1,t}/y_{1,t-T}) - \mu\bullet[\log(y_{i,t}/y_{1,t})] \quad (7)$$

where $a' = \mu\bullet[\log(y_i/y_1)^*]$.

Similar to the procedure followed for the econometric specification (2) based on the neoclassical growth model, Equation (7) can be converted to panel data framework by assigning value 1 to the time period T.

$$\log(y_{i,t}/y_{i,t-1}) = a' + \log(y_{1,t}/y_{1,t-1}) - \mu\bullet[\log(y_{i,t}/y_{1,t})], \quad (8)$$

Rearranging gives,

$$\log(y_{i,t}/y_{1,t}) = a' + b'\bullet\log(y_{i,t-1}/y_{1,t-1}), \quad (9)$$

where the estimated $b'$ needs to be translated into speed of $\mu$-convergence using the formula:

$$\mu = (1/b') - 1. \quad (10)$$

In specification (9), the dependent variable is obtained by taking the log of what is obtained after dividing the per capita income of the FDI host countries by that of the home country 1. The $\mu$-convergence obtained by regressing the log of the lagged value of the ratio of the per capita income of host to home countries on log of its current value shows the host countries' speed of converge towards the FDI home country.

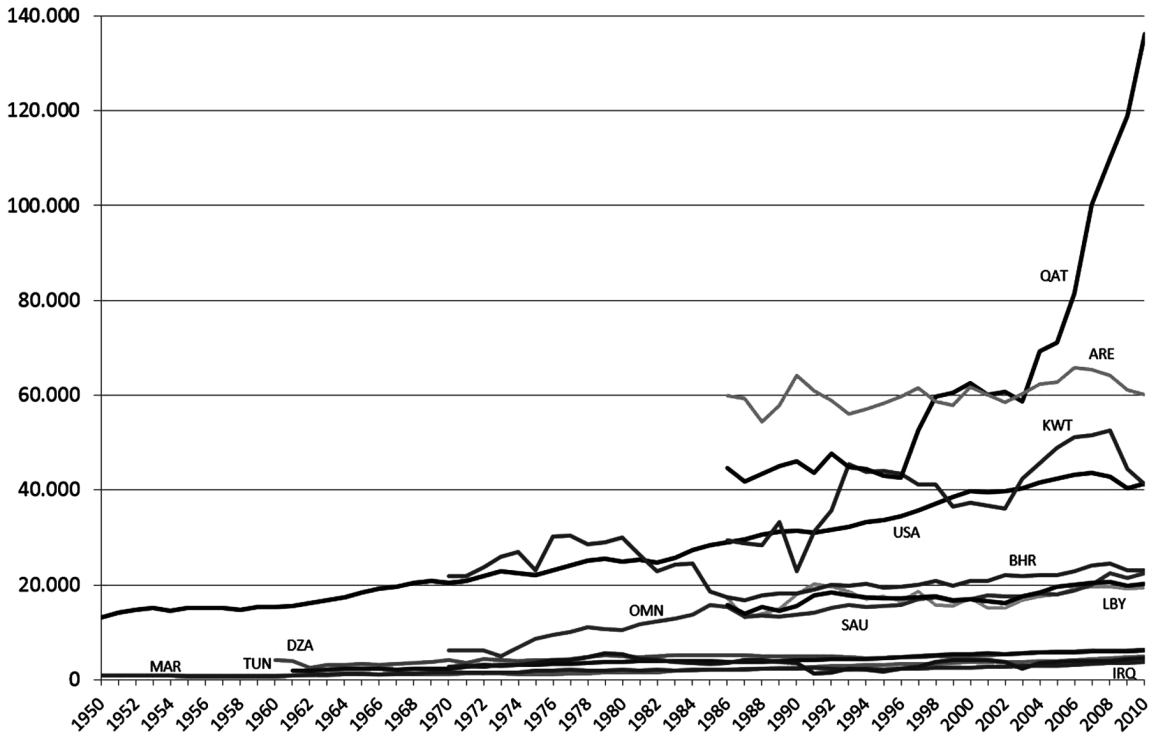
## Convergence in Europe and in the MENA Region

### Data and Methodology

The Foreign Direct Investment (FDI) data are taken from "International Direct Investment Statistics" database of OECD iLibrary. In order to determine the countries that have the highest amount of direct investment in countries in Europe and the MENA region, "Foreign direct investment: positions by partner country" data is used. This data contains the whole outward FDI stock of each OECD member by the end of year 2010. According to this dataset, the USA accounts for the highest FDI not only in European but also in MENA countries. Therefore, the USA is taken as the home country in the convergence analysis below.

Per capita income data of the countries are taken from the "PennWorld Table Version 7.1" (PWT 7.1) by Alan Heston, Robert Summers and Bettina Aten from "Center for International Comparisons of Production, Income and Prices at the University of Pennsylvania" issued in November 2012. The data cover the years 1950-2010, so the empirical analysis is done for this time period. Among the various data presented in PWT 7.1, real GDP per capita (RGDPC) in constant price (Laspeyres) for each country is used in this chapter.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



In order to answer the question whether there has been a per capita income convergence between the FDI home and the countries both in the MENA region and in Europe, they are grouped to form a panel data set, separately. The group for each region consists of the countries in the region and the country that has the highest FDI in the region.

## Results of the Convergence Analysis for the MENA Region

The Gross Domestic Product (GDP) per capita data of all countries in the MENA region are shown in Figure 1 for the period 1950-2010. Qatar turns out to be an apparent outlier in this Figure, thus the regression should be repeated excluding this country in order to avoid bias in the regression analysis.

Figure 1 also shows there are considerable differences in per capita income values of the countries in the MENA region. There is an apparent distinction between the oil producing countries in the Gulf region and the North African countries. Table 1 shows the estimated β- and μ-convergence values for the whole MENA region, as well as for the North African countries and the countries in the Gulf region, separately, towards the main FDI home countries in these regions.

*Figure 1. Real GDP per capita (RGDPC) in constant price in the MENA Region*
*Source: PWT (2012)*
*(*)Though considered as a MENA country geographically, Israel is excluded from the analysis since it differs to a large extent from the other countries in many aspects, including human capital, institutions, culture, etc. Malta and Turkey are also excluded from the analysis for MENA region since they are included in the analysis for the Europe as being an EU member, and a candidate country, respectively.*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In case of the convergence analysis for the MENA region, not only the USA but also France and Great Britain, which have the second and third direct investment stock in the region, are taken as the FDI home country. However, as Table 1 shows, the estimated β-convergence values do not change to a large extent with respect to the choice of the FDI home country within each group. Once all the countries in the MENA region are included in the analysis, the β-convergence is estimated at around 0.17 per cent per year. The estimated β-convergence increases to almost 0.5 per cent when Qatar is excluded. However, the estimated μ-convergence values are not robust to the choice of FDI home country and vary between 0.34 and 0.63 per cent for France and Great Britain, respectively.

The β-convergence in North African countries, estimated at around 0.5 per cent per year, is almost the same as the β-convergence obtained for the whole group excluding Qatar. The μ-convergence, especially towards the USA and Great Britain are much higher, reaching almost 1 per cent in case of the former and 1.23 per cent in case of the latter. The negative convergence values obtained for the Gulf region imply divergence of per capita incomes. But this result should be interpreted with caution since including Qatar data may bias the regression analysis, as mentioned before. Indeed, the Gulf region excluding Qatar is the group where the convergence is highest with respect to both measures. The estimated β-convergence towards the USA is 1.39 per cent per year while that towards France and Great Britain is around 1.5 per cent. The results for μ-convergence are similar to those of β-convergence in the Gulf region excluding Qatar.

*Table 1. Convergence in the MENA Region (1950-2010)*

## Results of the Convergence Analysis for Europe

Considering that there is an ongoing integration process in Europe under the European Union (EU) framework, the convergence analysis is performed in four different groupings to account for the different integration levels among countries. The first group covers non-EU developing countries of Europe; the second group consists of developing EU member states that join EU after 2004, while the third and fourth groups comprise the first fifteen and the six founding EU members, respectively.

The GDP per capita data of all countries in Europe and the USA are shown in Figure 2 for the period 1950-2010. Luxembourg turns out to be an apparent outlier. To consider the risk of bias in regressions stemming from this country, the convergence analysis for industrialized EU members is repeated excluding Luxembourg. The estimated convergence values of the four different groups towards the GDP per capita of the USA are shown in Table 2.

In line with expectations, both β- and μ-convergence values increase as the level of integration in EU increases. This evidence is stronger when Luxembourg is excluded from EU groups that consist of industrialized countries. The estimated β-convergence reaches 2.17 per cent per year for the five founding members of EU while it is 1.73 per cent for EU-15. In case of developing countries of Europe, β-convergence is estimated as 1.36 per cent for EU members and 0.63 for non-EU members.

*Figure 2. Real GDP per capita (RGDPC) in constant price in Europe and in the USA*
*Source: PWT (2012)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The μ-convergence obtained based on the diffusion of technology model of endogenous growth theory is estimated as 2.69 per cent for the five founding EU members. The estimated μ-convergence value is 1.76 per cent for the first 15 members of the EU, while it is 1.37 per cent for the developing countries of Europe which joined EU after 2004. Finally, for the group comprised of developing non-EU European countries, the μ-convergence is estimated as 1.1 per cent. Therefore, high per capita income convergence seems to be a prevailing feature, especially among EU members.

Comparing estimated μ-convergence values of European countries with those for the MENA region, leads to the conclusion that per capita income convergence of EU members towards the FDI home country is higher. Even the lowest μ-convergence value obtained in Europe (for the developing non-EU European countries estimated as 1.1 per cent) is higher than the 0.5 per cent estimated for the whole MENA region excluding Qatar. However, once the sub groups in the MENA region are taken into account, the difference in the convergence values between the two regions diminish. For example, the μ-convergence value towards US estimated for North African countries (0.98 per cent) is close to the value obtained the for the developing non-EU European countries (1.1 per cent). Similarly, 1.37 per cent of μ-convergence prevailing for the Gulf region is close to that of the European countries that joined EU after 2004. These results are deemed eligible for further investigation, which is the concern of the following section.

## Absorptive Capacity and Investment Capacity

Endogenous growth theory stresses R&D and human capital as the major determinants of long-run rate of growth by providing technological progress within a country. These two determinants are also considered as the *absorptive capacity* of a country in the sense that countries themselves must have a certain level of human capital stock and engage in R&D activities in order to be able to absorb technology created in other countries. The empirical studies on diffusion of technology confirm absorption hypothesis that countries themselves must engage in R&D activities to be able to adopt and imitate new technologies. Apart from the own R&D prerequisite, stock of and investment in human capital seem to play an important role in order for a country benefit from foreign spillovers as detailed in the background section.

*Table 2. Convergence in Europe towards USA (1950-2010)*

| | **β-Convergence** | **μ-Convergence** |
|---|---|---|
| **Europe Developing** | | |
| EUR_NON-EU_USA | 0.63 | 1.10 |
| EUR_EU_USA | 1.36 | 1.37 |
| **Europe Industrialized** | | |
| EUR_EU15_USA | 1.23 | 1.11 |
| EUR_EU6_USA | 0.60 | -0.02 |
| **Europe Industrialized Excluding Luxembourg:** | | |
| EUR_EU15_USA | 1.73 | 1.76 |
| EUR_EU6_USA | 2.17 | 2.69 |

Note: Both β- and μ-convergence values are estimated using the between regression (see Öz, 2014 for details).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Borensztein, de Gregorio, and Lee (1995), for example, conclude that FDI has a positive effect on per capita income growth only when the host country has a minimum threshold stock of human capital. Indeed, inclusion of an interaction term between FDI and human capital (the product of these two variables) improves the overall performance of the regression implying that there is a strong complementary effect between FDI and human capital (i.e., the contribution of FDI to economic growth) is enhanced by its interaction with the level of human capital in the host country. The regression coefficients indicate that all countries with secondary school attainment (for male population older than 25) above the range 0.45 will benefit positively from FDI. The human capital threshold value found by the regression results of Xu (2000) is even higher than that of Borensztein, de Gregorio, and Lee (1995).

The male secondary school attainment is estimated to be somewhere between 1.4 and 2.4 years so that the technology transfer of US MNCs enhances the host country productivity. These findings show strong complementary effects between FDI and human capital on the growth rate of income justifying the theory that the flow of advanced technology brought along by FDI can increase the growth rate of the host economy only if the country has enough absorptive capability. Apart from R&D and human capital, the determinants highlighted by empirical research as affecting the rate of growth such as government consumption, price stability and all governance indicators including the political stability comprise the second category that can be called as *investment capacity*, in the sense that they determine the general investment environment of a country.

As Crafts (1995) summarizes, anything which enhances the attractiveness of investment is potentially growth promoting. Investment capacity can be thought to affect the growth rate of a country by affecting the physical capital accumulation through either domestic or foreign investment. This line of thought concurs with Barro (1996), who states that high life-expectancy, high rule-of-law index, low government consumption ratio, and low inflation rate encourage economic growth partly by stimulating investment. The political-stability may also increase the growth rate through its positive effect on incentives to invest (Barro & Sala-i-Martin, 1995).

Furthermore, Benhabib and Spiegel (1994) find that human capital stocks are positively correlated with physical capital accumulation stressing the role of human capital in attracting physical capital besides enhancing the absorptive capacity. Therefore, investment capacity and absorptive capacity determine the rate of per capita income growth to a large extent not only individually, but also by interacting with each other.

## Comparative Analysis Based on Absorptive Capacity

Comparative analysis of absorptive capacity between the countries in Europe and in the MENA region is based on two components: human capital and R&D. The appropriate proxy to represent these components can be drawn from the empirical studies on economic growth. Following the theoretical emphasis related to the role of human capital on growth rate, most cross-country empirical studies of economic growth include some proxy for human capital. The proxies vary to a great extent, including average years of attainment in primary, secondary, or higher schooling at the beginning of each period; contemporaneous changes in schooling; as well as secondary and higher school-enrollment ratios.

The extant literature on growth reveals that three issues should be considered when selecting and using a proxy for human capital. First, it should not be treated as a factor of production like labor and physical capital, because straightforward insertion of some index of educational attainment in the production function might constitute a gross misspecification of the relation between education and the dynamics

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

of production (Nelson & Phelps, 1966). Following the theoretical insights of endogenous growth, human capital should be viewed as affecting growth rate indirectly through technological progress since educated labor force is necessary for innovation, adoption, and imitation of new technologies.

Indeed, Benhabib and Spiegel (1994) find that human capital affects the growth of total factor productivity first by influencing the rate of domestically produced technological innovation, and second, by affecting the speed of adoption of technology from abroad. Eaton and Tamura (1996) approve the conclusion that human capital contributes to productivity of countries by facilitating the adoption of new technology rather than by serving as a standard factor of production. The second issue mentioned also by Nelson and Phelps (1966) is that the progressiveness of technology has implications for the optimal capital structure, particularly, the society may have to build more human capital relative to tangible capital the more dynamic is the technology.

The idea is supported by the model developed in Keller (1996), in which the long-run benefit from technology diffusion depends on whether the rate of human capital formation is increased relative to the increase in the amount of spillovers (e.g., caused by trade liberalization). The reason is that further accumulation of human capital is necessary to implement the newer technologies. If a country fails to increase the rate of human capital formation in accordance with the rate of knowledge spillovers, the new technology cannot be fully absorbed, and the relative lack of human capital forces the growth rate of the economy back to its former level. The findings of Barro (1996) support theories that stress the positive effect of education on an economy's ability to absorb new technologies.

Finally, the proxies used by the cross-country empirical studies of economic growth ignore quality issues, implicitly assuming that any variation in quality of human capital are small relative to the importance and variation in pure quantity of human capital (Hanushek & Kimko, 2000). Once this assumption is relaxed by using labor force quality in regressions, there is evidence that labor force quality has a consistent, stable, and strong relationship with economic growth. Considering further the level of technology attained globally in the 21st century, labor force with tertiary education data in World Development Indicators used in this section is the appropriate proxy for human capital while searching for the reasons of the differences in estimated convergence values for various groupings in the MENA region and Europe.

Patents, R&D expenditures, and number of scientists and engineers are among the proxies used to test the effect of R&D activities on growth. Most of the empirical studies on diffusion of technology, which analyze the total factor productivity differences among countries employ variables related to R&D (e.g., Nadiri & Kim, 1996); Howitt, 2000). In small, high income samples, R&D variables are shown to contribute positively to the explanation of differences in growth across countries. These studies also reveal that the spillovers require some expertise in order to be assimilated. Foreign R&D as well as other sources of technology such as FDI and foreign technology payments can be considered as complementary to own R&D. Therefore, the data for R&D expenditures as percentage of GDP, which is the main proxy to detect R&D activity of a country, is used in this chapter.

In summary, absorptive capacity is the combination of human capital stock and R&D activities performed within a country in order to be able to assimilate foreign technology brought about by FDI. In Table 3 and 4, the share of labor force with tertiary education data in World Development Indicators is used to show human capital stock of the countries in the MENA region and in Europe, respectively. This data allows to take into account not only labor force quantity, but also quality to some extent. These two tables also show the R&D expenditures as percentage of GDP as a proxy for R&D activity in each country involved in the analysis.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3 shows 2000-2010 average of R&D expenditures as a percentage of GDP and labor force with tertiary education as percentage of total for the MENA region. The average of labor force with tertiary education does not differ to a large extent among different groups in the MENA region. This indicator is 13.1, 14.7, and 15.5 percent of total labor force for North Africa, the Gulf area, and the rest of the countries in the region, respectively. In spite of having much higher incomes, Gulf countries spend less on R&D compared to North African countries as well as to Iran and Jordan. Morocco, Tunisia, UAE, Iran, and Jordan have higher R&D activity compared to the rest of the countries in the region.

Table 4 shows the data for absorptive capacity of European countries. The average of labor force with tertiary education is around 26 per cent of total labor force in founding EU members and in the first 15 members of the EU. This indicator falls to 21 per cent for developing EU member countries and drops further to 19 for non-EU developing countries of Europe. On average, it is approximately five percentage points higher in developing countries of Europe compared to the countries in the MENA region. In comparison to the European countries, the R&D expenditures are lower in all three different groupings of the MENA region as well, with 0.48, 0.19, and 0.37, for North Africa, Gulf, and the rest of the countries in the region, respectively. Among the first 15 members of the EU, only Italy, Greece, Portugal and

Source: World Development Indicators

Spain have considerably lower R&D activity compared to the European average. The same is valid for the other indicator of absorptive capacity for Italy and Portugal. Among the European countries, Bosnia Herzegovina and Albania have minimum R&D expenditure level.

In line with the implications of the diffusion of technology model, as average R&D expenditure increases the convergence speed for different country groups within Europe given in Table 2 increases. The finding that the lowest speed of convergence prevails for the group that contains non-EU developing countries of Europe is supported by the absorptive capacity hypothesis, which expects weaker increase in technological level in countries with lower R&D expenditures. The average R&D expenditure as percentage of GDP is lowest in this group with 0.59, which is not much higher than the value obtained for the North African countries (0.48). In fact, the μ-convergence value towards US estimated for the developing non-EU European countries (1.1 per cent) is also not much higher than the value obtained for North African countries (0.98 per cent).

The results for the average of labor force with tertiary education are also in line with the implications of the diffusion of technology model. As the share of labor force with tertiary education increases, the convergence speed for different country groups within Europe given in Table 2 also increases. Although non-EU developing countries' average is 5 percentage points above the MENA average, there are large differences in the indicator among the countries of this group: While Russia's labor force with tertiary education is 44 per cent of its total, the share drops approximately to 12 in Turkey and Bosnia, and further to 8 per cent in Albania.

## Comparative Analysis of Based on Investment Capacity

Comparative analysis of investment capacity between the countries in Europe and in the MENA region is based on three components: Government consumption, price stability, and Worldwide Governance Indicators (WGI). First, a greater volume of nonproductive government spending and the associated taxation is supposed to reduce the growth rate for a given initial value of GDP. Barro (1996) finds a significantly negative effect on growth from the ratio of government consumption. Barro and Sala-i-Martin (1995)

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

also estimate a significantly negative and high coefficient for the ratio of government consumption to GDP. The strong evidence is linked to the political corruption or other aspects of bad government, as well as to direct effects of nonproductive public expenditures and taxation.

Secondly, it has long been found that a higher average rate of inflation accompany a higher volatility in inflation, which – by leading to an unstable economic environment – is detrimental for investment and growth. When Barro (1996) includes inflation rate over each period as an explanatory variable along with other growth determinants, the estimated coefficient of inflation is found as significantly negative. However, once the other growth determinants are held constant, the relation between growth and inflation is found to be statistically insignificant for inflation rates below 20% per year.

This result is robust to the inclusion of instrumental variables such as central bank independence, lagged inflation, and prior colonial status, which are significantly related to inflation and reasonably exogenous. Similarly, Yılmaz and Akçay (2002) find the threshold level of inflation rate below which the negative relationship between inflation and growth becomes insignificant as 13% per year for 29 developing countries. The results do not necessarily mean that this negative effect is small at low rates of inflation.

Besides low government consumption ratio and low inflation rate, *political-stability* is considered to encourage economic growth through its positive effect on incentives to invest since it lowers the probability of threats to property rights through political turmoil. Another growth enhancing factor found in cross-country regressions is the *rule-of-law* index, which gives the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts.

The Worldwide Governance Indicators (WGI) based on Kaufmann et al. (2010) cover not only these two determinants, but also four other factors. *Government effectiveness* reflects perceptions of the quality of public services and civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies. *Regulatory quality* is related to perceptions of the ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development. *Control of corruption* combines perceptions of the extent to which public power is exercised for private gain, including corruption, and "capture" of the state by elites and private interests. Finally, WGI provides *voice and accountability* index, which reflects perceptions of the extent to which a country's citizens are able to participate in selecting their government, as well as freedom of expression, freedom of association, and a free media. These six dimensions of governance are reported in the range from -2.5 (weak) to 2.5 (strong) for 215 economies over the period 1996–2012.

The 2000-2010 average of general government final consumption expenditure as percentage of GDP, inflation rate, and the average of the estimates for six dimensions of WGI as proxies for investment capacity of the countries in the MENA region and in Europe are given in Table 5 and 6, respectively. All country groups in the MENA region have similar government expenditure levels with 15-16% of GDP. Inflation rate is around 3% in North African and Gulf countries, while it is over 9% for the other countries of the MENA region. Average of WGI estimates takes positive value only for the Gulf countries excluding Saudi Arabia. This finding supports investment capacity hypothesis, considering that convergence in Gulf Region (excluding Qatar) is highest in this region.

General government final consumption expenditures in EU members are 21% of GDP, inflation is around 2% on average, and the average of WGI estimates is around 1.5 for EU-15 and 6 founding members of EU. The estimated μ-convergence value is lower for developing countries of EU although

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

general government final consumption expenditure is lower. Therefore, this indicator does not seem to explain differences in convergence values, due probably to the fact that government spending is not non-productive in EU as opposed to the findings of Barro (1996) for a wider spectrum of countries, where political corruption or other aspects of bad government may prevail. On the other hand, WGI estimates seems to explain convergence values in case of EU members, since as the average of WGI estimates fall from 1.5 to 0.8, estimated μ-convergence value falls as well, from 1.76 for industrialized to 1.37 for developing countries of EU. For non-EU developing countries of Europe the average WGI falls further to -0.4 and the μ-convergence is estimated at 1.1. This tendency is valid for inflation rate as well.

Comparing Table 5 and 6 yields the conclusion that the investment capacity explains the differences in μ-convergence values estimated for the countries in the MENA region and in Europe quite plausibly. The lower investment capacity of the countries in the MENA region depicts itself in lower FDI inflows to the region in comparison to those towards the European countries, as well. Indeed, as percentage of GDP, yearly FDI inflows to MENA region is 3.5 per cent while European countries attract FDI that amount to 6.5 per cent on average during 2000-2010. Yearly FDI inflows towards the six founding members of EU reach 8.7 per cent of their GDP in the same period.

## CONCLUSION

As the endogenous growth literature highlights the dependence of growth rates on the state of domestic technology relative to that of the rest of the world, one way for the developing countries to catch up is benefiting as much as possible from technology diffusion. In a typical model of technology diffusion, the rate of economic growth of a backward country depends on the extent of the adoption and implementation of new technologies that are already in use in leading industrial countries. Therefore, measuring the convergence of per capita incomes is important in order to assess whether comparatively less advanced countries manage to decrease the technological gap with more advanced ones through time.

Theoretically, international trade and FDI are considered as technology transmission mechanisms from leader countries to followers. Empirical studies on international technology diffusion confirm that there is significant cross-country technology diffusion via international trade channel, but evidence on FDI channel is ambiguous. The reason is that while empirical studies on developed countries find positive spillovers stemming from FDI, there is no evidence of such spillovers in research on developing countries. This implies that only developed countries can benefit from technological spillovers stemming from inward FDI, leaving no room for developing countries to catch-up.

However, further research which covers both developed and developing countries reveals that these different outcomes are due to the fact that most developing countries lack the absorptive capacity to benefit from the technology transfer. Besides absorptive capacity, a combination of other determinants highlighted by the empirical research based on the new growth theory as affecting the rate of growth, which is termed as investment capacity, should be taken into account when analyzing the convergence process.

This chapter analyzes the validity of the hypothesis that technology diffusion measured by the convergence of per capita incomes, depends not only on the absorptive capacity, but also on the investment capacity in the context of the countries in Europe and in the MENA region. Accordingly, this chapter first estimates the convergence of incomes towards the FDI home country in the MENA region and in Europe separately before analyzing the results with respect to prerequisites to derive benefit from FDI

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

in a comparative manner. In order to detect the per capita income convergence implications of FDI, each region is analyzed using two different measures of convergence, namely β-convergence based on neoclassical growth model and the convergence based on technology diffusion model of endogenous growth theory, which is termed as μ-convergence.

For the MENA region, the countries that have the highest FDI stock in the region as of 2010, the USA, France and Great Britain, are established as the FDI home countries. However, the estimated β-convergence values do not differ to a large extent with respect to the choice of the FDI home country. Once Qatar is excluded from the analysis as being an apparent outlier, both β-convergence and μ-convergence towards the USA are estimated at 0.5 per cent per year. Since there are considerable differences in per capita incomes between oil producing countries in the Gulf area and the North African countries, convergence analysis is repeated for these two sub-groups of the MENA region. The β-convergence value estimated for North African countries is almost the same as that obtained for the whole group, while the μ-convergence towards the USA reaches 1 per cent. The Gulf region excluding Qatar is the sub-group where the convergence is higher with respect to both measures with around 1.4 per cent.

In case of the convergence analysis for Europe, different sub-groups are used as well to account for the ongoing integration process under EU. Plausibly, both β- and μ-convergence values increase as the level of integration in EU increases. This evidence is stronger when the outlier (in this case Luxembourg) is excluded from sub-groups that are composed of industrialized countries of Europe. The estimated β-convergence reaches 2.2 per cent per year for the five founding members of EU while it is 1.7 per cent for the first 15 members of EU. This result is consistent with the conventional speed of conditional convergence of 2 percent obtained in cross sectional studies surveyed in Hauk and Wacziarg (2004).

In the case of developing countries of Europe, β-convergence is estimated as 1.4 per cent for EU members and 0.6 for non-EU ones. The μ-convergence is estimated as 2.7 per cent for the five founding EU members. The estimated μ-convergence value is 1.8 per cent for the first 15 members of the EU, while it is 1.4 per cent for the developing countries of Europe, which joined EU after 2004. Finally, for the group comprised of non-EU developing countries of Europe, the μ-convergence is estimated as 1.1 per cent. Therefore, high per capita income convergence seems to be a prevailing feature, especially among EU members.

The comparison of convergence values between the MENA region and European countries is based on the μ-convergence derived from the diffusion of technology model of endogenous growth theory, since it is more appropriate for this chapter, which analyzes interactions between convergence of per capita incomes and FDI considering the latter as an international technology diffusion channel. Comparing estimated μ-convergence for European countries with those for the MENA region, leads to the conclusion that per capita income convergence of EU members towards the FDI home country (US) is higher. Even the lowest μ-convergence value obtained for subgroups in Europe (for the developing non-EU European countries estimated as 1.1 per cent) is higher than the 0.5 per cent estimated for the whole MENA region excluding Qatar.

However, once the sub groups in the MENA region are taken into account, the discrepancy in the convergence values between the two regions becomes narrower. For example, the μ-convergence value towards US estimated for North African countries (around 1 per cent) is close to the value obtained for the developing non-EU European countries (1.1 per cent). Similarly, 1.4 per cent of μ-convergence prevailing for the Gulf region is close to that of the European countries that joined EU after 2004. These results support the hypothesis that technology diffusion depends not only on the absorptive, but also on the investment capacity of countries as explained below.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

First, in line with the findings of empirical studies on the diffusion of technology model, as average R&D expenditure increases the convergence speed for different country groups within Europe increases. The results for the average of labor force with tertiary education are also in line with the evidence obtained using diffusion of technology models: As the share of labor force with tertiary education increases the convergence speed for different country groups within Europe increases. Second, comparing the absorptive capacity of European countries with that of the MENA region implies that industrialized EU members surpass the MENA average in both components. This fact justifies the absorptive capacity hypothesis considering the high convergence values estimated for EU-6 and EU-15. However, the average R&D expenditures as percentage of GDP in non-EU developing countries of Europe (0.6) is not much higher than the value obtained for the North African countries (0.5). Similarly, the average of labor force with tertiary education is only 6 percentage points lower in North Africa compared to non-EU developing countries of Europe. The similarity in the absorptive capacity of these two regions explains the similarity of the μ-convergence values towards US estimated as 1.1 per cent for the developing non-EU European countries and as one per cent for North African countries.

These findings confirm that technology diffusion measured by the convergence of per capita incomes depends on the absorptive capacity in the context of the countries in Europe and in the MENA Region. However, the similarity of μ-convergence values prevailing for the Gulf region and for the European countries that joined EU after 2004, which is 1.4 per cent for both, cannot be explained by absorptive capacity. The average of labor force with tertiary education is 6 percentage points lower in the Gulf States compared to developing countries of EU and the average R&D expenditures as percentage of GDP in the Gulf States (0.2) is quite lower than the value obtained for developing countries of EU (0.8). In order to explain this fact, investment capacity which covers the determinants of growth other than the ones that comprise absorptive capacity can be used. Especially, the average of WGI estimates component of investment capacity, which is 0.8 for developing countries of EU, is calculated as 0.3 for Gulf States. This indicator is around -0.4 for North African and non-EU developing European countries.

The average of WGI estimates seems to explain differences in convergence values of EU members as well. As the average of WGI estimates falls from 1.5 for industrialized to 0.8 for developing countries of EU, the estimated μ-convergence value falls from 1.8 to 1.4, respectively. Taken together, these findings confirm the validity of the hypothesis that technology diffusion measured by the convergence of per capita incomes, depends not only on the absorptive capacity, but also on the investment capacity.

In summary, both absorptive and investment capacity matter in explaining the differences in convergence speeds estimated not only for countries in the MENA region and in Europe, but also for subgroups within each region. There is evidence that sub-groups including countries with poor absorptive capacity, such as developing non-EU European and North African countries mark the lowest income convergence towards the FDI home country. Therefore, in line with the empirical studies on the diffusion of technology surveyed in the Background section, the technology transfer brought about by FDI, hence the income convergence between FDI partners is not straightforward. This justifies the theory that the flow of advanced technology brought along by FDI can increase the growth rate of the host economy only by interacting with that country's absorptive capability.

Furthermore, the investment environment of the country also matters. The main policy recommendation to the policy makers of the developing countries based on these results is that the economic policy aimed at fostering growth should consider inward FDI not only as a more stable form of capital inflows, but also as a medium of technology transfer and try to benefit as much as possible by enhancing the absorptive capacity of the country. This can be realized by supporting R&D activities, facilitating tech-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

nological implementation, and promoting human capital as well as improving investment environment to attract more FDI. With respect to the latter, avoiding nonproductive government consumption, trying to maintain price stability and ensuring improvement in all aspects of governance indicators are among the main policy recommendations.

## KEY TERMS AND DEFINITIONS

**Absolute Convergence:** Poorer economies tend to grow faster than rich ones without conditioning on any other characteristics of economies.

**Conditional Convergence:** Taking account of the determinants of the long-run per capita income, poorer countries tend to grow faster than richer countries.

**EU:** European Union.

**FDI:** Foreign Direct Investment.

**MNC:** Multi-national Corporation.

**R&D:** Research and Development.

**TFP:** Total Factor Productivity– the component of output growth that is not attributable to the accumulation of factor inputs, such as labor and capital.

**WGI:** Worldwide Governance Indicators.

## ABSTRACT

*This chapter deals with intermediaries in the financial sector such as banks and institutional investors. These actors are expected to play a central role in economic growth via the funding of investment because they are supposed to match creditors' desires (households) with borrowers' needs (firms) at a macroeconomic level. It aims to reassess the theoretical role of financial intermediation related to the allocation of savings in a context of a structural decline in overall investment for thirty years. To achieve this goal, it studies the evolution of financial intermediaries' behaviour in their capacity to finance investment and identifies the weaknesses of our current financial system which does not allocate optimally savings to firms' productive projects. Then it suggests some policy implications defining new forms of financial intermediation in which public financial intermediaries would have to play a greater role.*

## 1. INTRODUCTION

Intermediaries are at the core of economic and social dynamics. When some actors strive for financing and others offer funds, it could be imagined that lenders and borrowers could meet directly. But creditors' desires rarely match borrowers' needs. This is the reason why a third part intrudes in the middle of these relationships: that's what financial intermediation is about. Indeed, borrowers aim to minimize expenses and take on debts in the medium and long term while lenders are concerned with having high yields, minimizing risk and maintaining liquidity by focusing on short-term investments. If, at the microeco-

nomic level, the non-financial agents may have sufficient resources or not to fund their spending plans at a given horizon, at the macroeconomic level, households are agents with funding capacity (potential lenders) and the companies and States, are agents who need funding (potential borrowers). Therefore, this imbalance and diversity of economic agents' financing needs require to put in place a range of institutions and market mechanisms to not only organise the transfer of funds from the agents who save to those who wish to borrow, but also to make compatible their conflicting motivations in terms of price, maturities, yields or liquidity. Among these institutions, there are financial intermediaries which are predominantly banks and institutional investors (pension funds, insurance companies, mutual funds). This transaction mutually proves advantageous in so far as it allows the lifting of the budget constraint[1] from non-financial agents by allowing them a more satisfactory temporal scale of their spending.

By facilitating money transfer between borrowers and lenders, financial system and financial intermediaries in particular are considered to play a positive role in the economy via the funding of productive projects or investment. Financial system is supposed to allow an optimal allocation of savings to firms' productive projects. Indeed, at the macroeconomic level, there is a consensus among economists that investments[2], both private and public, are the driving force of the economy, through the investment multiplier: a rise in investment will increase national income more than proportionally thanks to the operation of a virtuous circle. When firms' investment expenditure increases, there is both an increase in demand for investment goods, and an increase in production of investment goods. Companies will therefore employ and pay income in order to produce. This income will then be spent by households. This will bring a new demand for companies, and companies will have to meet this demand by further increasing the production, that is to say by employing even more and paying more income... Conversely, we would get a vicious circle in case of initial investment decline. Thus investment appears to be the condition which revives strong growth and sustainable job creation.

Such a mechanism had worked well during the post-war boom. During this period, the macroeconomic dynamic was based on the traditional drivers of household consumption and business investment. Household consumption could be dynamic because it was based on the Fordist compromise aligning wage increases with the rate of productivity gains. On the investment side, the dynamics were embodied by business leaders primarily seeking growth. The dynamics of consumption also strengthened investment: businesses accumulate more productive equipment when they are able to increase their sales thanks to consumers whose incomes climb regularly. On the public expenditure side, the contribution was also positive: firstly, because we observe the rise of public expenditure to cover new needs which develop with the general enrichment (health and higher education in particular); secondly, because the constraints on public spending are weak thanks to a funding facilitated by strong economic growth. Externally, competition is low enough for the West, because the newly industrialized Asian countries (South Korea, Hong Kong, Singapore, and Taiwan) are not yet sufficiently developed, with the notable exception of Japan whose rise seemed inexorable at that time.

But from the late 1970s, the post-war boom that had gradually helped to establish a partly socialized economic system in Europe begins to slowdown. Thanks to these apparent limitations of the previous growth regime, radical changes are legitimized and implemented: limiting public spending, the conduct of a tight monetary policy, public finance through market mechanisms that would discipline the State, suppression of wage indexation, individualization of wage negotiations, strengthening control in the distribution of social benefits while exonerating companies, as much as possible, from the weight of social security "contributions"... Economic policies change priority from full-employment to the fight against inflation. The neoliberal revolution is not limited to public policies: corporations are also ordered

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

to change. The capitalist image of management position is no longer the manager who ran the company in the Fordist era, trying to build corporate empires, be it at the expense of returns to shareholders. Now, the manager appears in a new context: with financialization, he has to promote shareholder value, be it with the withdrawal of profitable investment that do not deliver the profitability required by shareholders. Financialization may be defined as a process whereby finance gradually imposes its domination of the real economy (Krippner, 2005), both at the macro-economic level where finance is likely to slow growth and employment, or at the micro-economic level where finance constrains companies to pursue shareholder value, sacrificing investment in favour of dividend distribution.

From 1980, deregulation policies profoundly change the area of possibilities in terms of economic growth. The combination of wage disinflation policies (dis-indexation of wages from price evolution, attacks against trade unions...) and the introduction of competition by globalization held wages in check. This sharp decline in the share of wages in added value was observed around the developed world. If the overall share of wages declines, this does not prevent the highest earners to experience very dynamic growth (particularly in the United States). With wages driven down, the engine of consumption based on income from employment becomes less effective. But the second driver of economic growth, investment, will also experience a significant drop. The slowdown in consumer spending is not conducive to investment spending by businesses.

For thirty years, a structural decline in overall investment is observed. A report by Mc Kinsey (2010) shows that the investment rate decreased from 26.1% in 1974 to 21.8% of GDP in 2009, a loss of about 20 trillion dollars. This decrease which concerns essentially the developed countries has accelerated since the 2007 crisis. See Figure 1. The largest decreases particularly touch the traditional sectors of industry, agriculture, mining and infrastructure from 1980 to 2008. This structural decline in investment is detrimental to economic growth. In the 2000-2008 period, the GDP growth rate of developed countries was 2% against 5.3% over the 1960-1970 period.

As seen in Figure 2, in emerging countries, the development is reversed and more variable with an investment boom in the 2000s. If this rate increases from 28.8% to 48.7% from 1970 to 2009 for China and 14.6% to 37.9% for India, it goes from 19.3% to 24.1% between 2001 and 2008 in Africa, from 21.4% to 26.4% in Central and Eastern Europe as well as in other Asian countries. This boom mainly concern industry, infrastructure (transport, energy, telecommunications) and residential real estate. This trend is expected to continue with the rural exodus that will result in significant infrastructure needs.

In Europe in particular, the issue of lack of investment is a major challenge today, not only for European growth but also for employment. The OECD and the IMF have in fact denounced, during the recent months, the delay in the recovery of investment in Europe compared to the United States. The European Commission (EC) has recently looked into the problem by proposing the implementation of the Juncker plan intended to lead to a 315 billion euro stimulus, over three years, of investment in Europe.

If the decline in investment is damaging to growth, it is all the more so because the world economy has considerable financing requirements, to finance long term investments. In developed countries, structural investment requirements are linked to the necessary adaptation of the productive apparatus to an ageing population and to climate change through projects related to different areas: energy, innovation and growth of SME, universities and research... This is to fund new infrastructures but also to renew existing ones that have become obsolete and unsuited to the climate change. In emerging regions, long-term investments are linked to their pattern of growth. These investments, which are essential in order to catch up with Western living standards, were already important but they are expected to intensify. The progressive ageing of their population should lead to the implementation of social policies and the

introduction of compulsory pension schemes[3]. Indeed, ageing populations imply a profound transformation of their financial systems in the sense of long-term investment, because the role of institutional investors precisely lies in this socialization of risk inherent to public and private social protection systems.

At European level, the Commission considers that investment needs are about 1.6 trillion euro by 2020 for cross-border transport infrastructures of goods and people and energies. Energy transition has a cost: it will take 2 to 3% of GDP per year for ten years, so in the case of Europe, about 3 trillion over a decade. This transition is by nature a long-term investment project with a low financial return: 3% over

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

10 years on average (Giraud, 2012). Thus, we see that the economies that experienced a financialization of their economy do not invest as much as before, even if the needs are great and if savings are abundant in Europe and also in the world thanks to higher Asian savings. Yet an economy that no longer invests is an economy that is no longer preparing for the future, that no longer sees its productivity increase. In short, an economy on the brink of a stagnation that would be secular. Therefore, the study of the causes of this structural decline in investment is crucial.

Several reasons can explain this decrease in investment. First, there are circumstantial factors related to the crisis and differences in economic policy in the developed countries[4]; then there are causes related to financing requests and financing offers that combine with one another. Indeed, investment cannot be decreed, it depends on both the supply of funding and corporate decisions. On the demand side, the decline in investment in Europe would simply be related to the lack of a new Eldorado which inhibits investors/entrepreneurs. On the supply side, it is the financial system and its actors which are at stake. The latter has evolved and the major financial intermediaries which are the banks have had to adapt to a world which is becoming increasingly finance orientated. The banks have participated in this movement by diversifying their traditional activities towards market activities to the detriment of their traditional role of financial intermediary[5] (transformation of deposits into loans). But this decline is also rooted in the organization of the corporate finance system because shareholder power has transformed the strategies of non-financial companies at the expense of productive investment (Auvray et al., 2016) as well as those of financial institutions.

This chapter focuses in particular on the second reason related to the financing supply problem by identifying on the one hand, the weaknesses of our current financial system which does not allocate optimally savings to firms' productive projects and which generates systemic financial crises; and on the other hand, financial mechanisms related to shareholder governance that discourages long term investment projects of listed companies. First, we reassess the theoretical role of financial intermediation related to the allocation of savings and then the funding of investment, and its evolution throughout history. Second, we define and explain the two main mechanisms at work in the current financial intermediation architecture leading to depress investment and employment. Third, we suggest some policy implications defining new forms of financial intermediation in which public financial intermediaries would have to play a greater role in financing the economy.

## 2. BACKGROUND

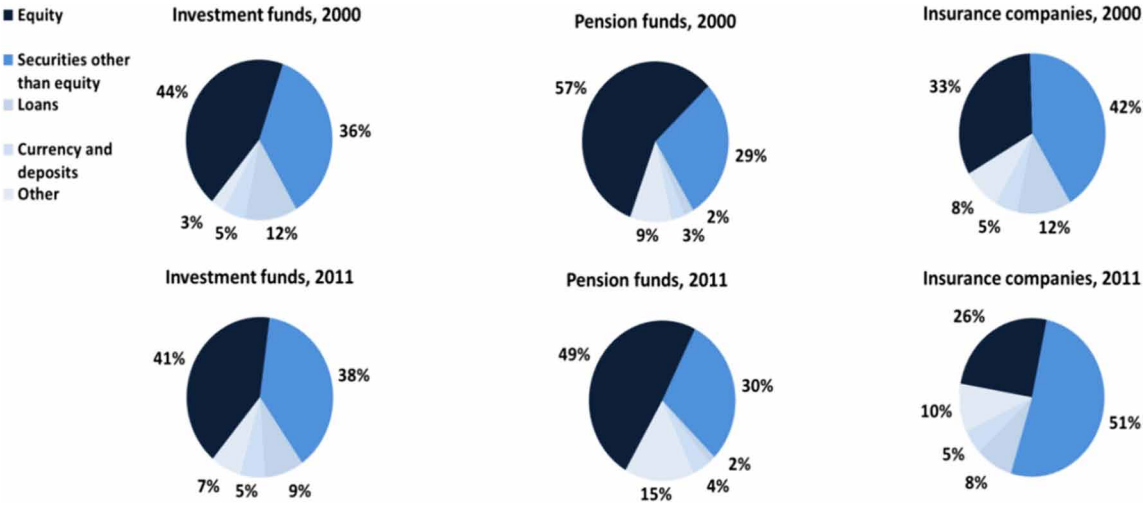
### 2.1. Role and Evolution of the Financial System

Financial intermediation aims at organizing the transfer of funds between borrowers and lenders. According to Gurley and Shaw (1960), this transfer and this adjustment can be provided in two different ways originating from a key distinction between direct and indirect finance and referring to two complementary financing systems. The first takes place on the financial markets directly between the two types of agents with requirements and with financing capacity via the issuing[6] and subscription of financial assets. In the second case, the transfer passes through a third party, a financial intermediary (including banks, insurance companies, pension funds) *via* the issuance of separate securities, thus juxtaposing two contractual relationships. An essential function of financial intermediaries is to make two types of transformations[7] of debt characteristics: a maturity transformation by offering households short term

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

assets, and businesses long-term financing and a transformation thereof by substituting their own debt to that of non-financial agents in deficit. Households within the framework of indirect finance do not hold the corporate debt but the intermediaries' debt. In Europe, funding is mainly done through bank intermediaries. Banks are specific financial intermediaries to the extent that they collect savings (deposits) and provide financing in the form of loans; but above all, they are the only ones to manage the system of means of payment and to create money (loans create deposits).

The purpose of these intermediaries is to be found in the market's imperfection and incompleteness and information asymmetries. Indeed, the existence of financial intermediaries meets a set of imperfections in the field of information distribution, risk allocation or liquidity attributes. If we were in an economic sphere based on pure and perfect competition[8], financial intermediaries would have no reason to exist. It would be simpler and cheaper for primary lenders to acquire directly from an infinite number of final borrowers the securities that match their preferences in terms of yield, maturity risks, liquidity (Leland, Pyle, 1976; Diamond, 1984; Diamond, Dybvig, 1984). The agents in need of financing, who would find themselves in a symmetrical situation, would be certain to find investors who consider their own debt requirements and investment potential attractive.



But economic reality is different and much more complex. In producing information services relating to the selection of borrowers, by specializing in the purchase and sale of financial assets, by treating very high financial volumes coming from or going to large numbers of customers, financial intermediaries access unit costs of collection or loans (operating costs, trading costs or information research costs...) lower than those which apply to individual agents (either lenders or borrowers) in bilateral contracts tied on markets, and therefore achieve benefit. They also develop expertise to manage more effectively the asymmetry of information in the long term. Finally, thanks to their size, financial intermediaries can more easily diversify their portfolios and therefore better allocate all the risks inherent to financial activity. However, far from eliminating market imperfections, they only reduce them. Meanwhile, guaranteeing savings income in a context of uncertainty and in the long term, they set about a socialization of risk. That is why in all developed economies, individuals, naturally more adverse to risk, entrust them with large sums. Thus, investors are expected to play a positive role in the economy by facilitating the distribution of risks and reducing transaction costs and information asymmetries.

To distinguish these financial intermediaries, it is possible to use several criteria of classification: actors can be grouped by institution or profession. If one trusts institutions, monetary financial intermediaries (MFI) must be distinguished from non-monetary ones (NMFI). On the MFI side, one would find mainly banks, whereas on the NMFI side we find the regrouping of insurance companies, pension funds, mutual funds, assets managers... The MFIs and NMFIs do the job of collecting savings and providing funding. But only MFIs can collect deposits and manage means of payment and are able to create money without prior savings. In addition to this capacity of money creation, it is often considered that the opposition between MFIs and NMFIs can be found in the composition of these institutions balance sheet: while MFIs are expected to have liquid liabilities (savings deposits) and assets composed of non-marketable debts (loans), the NMFI tend to have illiquid liabilities (insurance contracts) and an asset based on marketable securities (shares). In this vision, banks would ensure a liquidity provision service whereas NMFI would guarantee a more or less long-term placement of savings. A second level of distinction is often mobilized to organise the different NMFI: it separates institutional investors (insurance companies, pension funds, mutual funds[9]) from other investment funds (in particular hedge funds). The basis for this distinction is regulatory: the "other" investment funds are more recent, and therefore less regulated than institutional investors.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 3. Detention of equities by institutional investors in 2000 and 2011*
*Source: OECD, Institutional Investors database.*

Concretely, the theoretical role in the allocation of savings of financial intermediaries and especially asset managers (also called investment funds) consists of buying financial assets. This is what is shown by Figure 3, that outstanding assets are invested in shares and mainly bonds. It is especially the pension funds and investment funds (mutual funds) that invest in shares, the insurers focus more particularly on public debt securities.

Through their shareholding/ownership, financial intermediaries or investment funds have become major shareholders of listed companies. They represent today, in the United States, 40% of the market capitalization whereas in 1960, 84% of shares were held by individuals. This trend is even more pronounced in the UK where the proportion of shares directly held by individuals decreased from 54% to 11% (Çelik, Isaksson, 2013). Thus, in nearly 50 years, a substantial change is observed in the nature of shareholding/ownership: the main shareholders are now institutional investors rather than individuals. The link between these funds and the companies in which they invest being even more uncertain, these funds allow for the delegation of asset management. Because of the many delegations of asset management (with deposit of funds), we do not really know who is the final beneficiary of a shareholding/ownership. This new shareholder structure will affect the company.

## 2.2. Evolution of the Financial System: Opportunities for Different Economic Actors

More generally, this shift towards an increasingly financialized financial system was reflected differently according to the function of economic agents. Regarding the States, this occurred primarily by the marketisation of public finance, only this could ensure a sufficient depth to attract savings. The States supplied the markets with assets (deemed safe) by placing their debts on the sovereign bond markets. Most countries have seen the ratio of government debts to GDP climb.[10] Thus, for France, the ratio public debt to GDP increased from 20% in 1980 to 95% in 2014, according to figures from the IMF

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*World Economic Outlook*. In the UK, the trend is also upward in the same period: from 47% to 91%. The opening of international financial markets was aimed at enabling the States to finance themselves more economically by wagering on savings that are no longer reduced to only national savings.

From the household perspective, this resulted in a substantial increase of their financial wealth thus benefiting from a growing sophistication of the financial sphere. They invested in financial markets to place their savings, and secure investment incomes. Directly (in the form of individual savings) or indirectly (as mutual funds), households (domestic or foreign) became shareholders of companies. In the French case, households bought massively into shares and life insurance securities. They headed towards riskier and less liquid investments than before, hoping to gain better returns than traditional savings deposits. According to Plihon (2008), while equities and life insurance accounted only for 8.6% and 13.3% of the financial wealth of French households in 1990, they accounted for 23.7% and 34.5% respectively of financial assets in 2007. This growth is notwithstanding highly unequal because only 28.9% of French households hold life insurance products in 1998, and 36.5% in 2015 (INSEE, 2015).

As for firms, they turned towards capital markets to issue financial assets (stocks, bonds, commercial paper) and pay investment income to the holders of these assets (dividends, interest). Recourse to market funding could seem even more profitable to them than the interest rates of bank loans which were high in the 1980s. The initial idea was that financial markets would be more effective than banks to allocate capital to the most innovative companies, companies for whom banks may be cautious at the prospect of higher risk.

For banks, this financialization has resulted in their increasing involvement in the financial markets, which has led to a marketization of their balance sheet. In other words, the balance sheet is becoming more dependent on financial markets on the asset side but also on the passive side. According to Plihon (2013), in France the proportion of loans to customers (households, businesses, and governments) decreased from 84%, to 38% of banks' assets, from 1980 to 2010. Similarly, the proportion of customer deposits in bank liabilities evolved from 73% to 34% between the same dates. The role of banks is no longer primarily to take deposits and make loans. They do more and more intervention in the financial markets by issuing or subscribing securities. The share of securities held in bank assets has thus evolved from 5% in 1980 to 37%, in 2010. Similarly, banks' liabilities resources now come at 42% of shares issued in 2010 against only 6% in 1980. With the movement of financial deregulation, the banks, which saw their role as privileged financier endangered by competition from direct financing, invested in the field of financial markets to re-intermediate the funding via a market intermediation.

In this way, from a neoclassical perspective, the evolution of financial system for thirty years has allowed different economic actors to benefit from financialization. At a global scale, it means that higher savings would lead to higher investment and growth. Thus, a more market oriented financial system should become a necessity in order to stimulate business investment. We think these benefits claimed by this theory deserve to be questioned in particular for corporates. The current architecture of financial system has considerably changed the rules of corporate governance with the rise of new types of shareholders.

## 3. MAIN FOCUS

In the process of financialization, listed companies are ruled from now on by shareholders like pension funds, insurance companies and mutual funds. These financial intermediaries have progressively replaced individual shareholders and they both do not want to be immobilized in a stock and require high yield.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Consequently, firms' investments are suffering from financial pressures with financial intermediaries no longer playing the part of the shock absorber between savers' desire for liquidity and firms' need for stability to carry out its productive project. This part aims at explaining how financialization may damage investment. More precisely, it explains two mechanisms at work: corporate governance, on the one hand and the liquidity of the financial markets, on the other.

## 3.1. Corporate Governance and Liquidity as Disciplining Devices for Managers

One of the fundamental rules of capitalism is the principle of one share - one vote. If shareholders put pressure on companies, it is because they can exercise the voting rights associated with their shares that enable them, in a general meeting, to vote on the amount of dividends and to appoint directors who will in turn vote for CEOs of the companies. Such a mechanism has long been used in corporations all around the world. Nevertheless, since the early 1980s in the United States and in the 2000s in continental Europe, non-financial companies began to bring into their capital large numbers of institutional investors or hedge funds that exert these voting rights. They do so through standardized proxy voting companies on the one hand or directly with the aim to extract rents at the detriments of creditors and employees on the other hand (Coffee, Palia, 2014). In addition to voting in the general meeting, shareholders may leave the capital of a company at any time, if they feel, for example, that a quarterly profit is not high enough. This ability to withdraw from capital is the second channel that oppresses companies and allows shareholders to make increasing demands. Such a mechanism is that of liquidity which Keynes presented as the rationale of the financial markets.

Indeed, liquidity is defined as a capacity which can be converted into currency without delay, cost or risk in losing capital. In this way we establish that an asset will be qualified as liquid if it has two attributes: firstly, an asset is liquid if it is of negotiable character, that is to say the facility to be able to resell the considered assets quickly and free of charge; secondly, an asset is liquid if it has a certain predictability of its future resale value, with a reduced risk of capital loss. Thus, liquidity is at the centre of a specific dialectic. If the financial markets are organized so as to allow everyone to sell their shares at any time, this in fact creates a secondary market where securities are traded continuously, that is to say, an institution (the stock Exchange) is created which reassesses the price of the asset on a daily basis: this consequently creates the risk of seeing the stock prices decline. For shareholders, this means that the existence of stocks markets prompts them to seek to protect themselves against price declines. They do this by getting high dividend payments and by pushing companies to buy back their own shares[11]. Such practices induce an increase in the price of shares that is often well received by the markets. Managers generally respond favourably to this payment of liquidity request, because they benefit from compensation indexed to the share price (as stock options). Conversely, when the price of a listed share declines, this causes not only financing difficulties but also takeover threats. As for the managers, they risk their jobs because a new control system means new shareholders, and consequently new directors who will choose the top management.

Moreover, these dividend payments should not just be important: they should be higher than those of competing companies. For advocates of shareholder value, there would only be creation of the shareholder value when the company did better than the market average. Therefore shareholder value is a powerful tool of profit mobilization for dividend distribution, any company not participating in this race forward would see a disaffection of its stock prices, which would harm both its shareholders (capital losses) and its managers (risk of takeover and replacement by a new team).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thanks to the continuous trading of stock markets, shareholders constantly threaten to leave a company that does not meet with their new requirements. This threat has grown stronger during the past 30 years. The liquidity of financial markets has indeed experienced strong growth since the 1980s and 1990s by extending to various markets (corporate finance, financing of public debt, foreign exchange markets across the world with financial centres interconnected with each other), multiplying the fall-back possibilities, and consequently capital outflow opportunities. With frontiers across different countries' financial markets removed, there is no more obstacle to the free movement of capital, and consequently the liquidity pressure is all the more intense for corporations and workers[12]. While corporate governance rules have not strongly evolved through the ages (one share still is equal to one vote in many cases), capital mobility has really undergone a huge shift since the 1970s and the demise of the Bretton Woods international monetary system.

This structural change is problematic because it has pushed non-financial corporations to overlook profitable investment opportunities in order to pursue shareholder value on financial markets organized for liquidity. The macroeconomic consequence of this shift in focus of companies at the expense of productive investment is a slowing of economic growth and rising unemployment which can only be temporarily dammed, with difficulty, by the establishment of expedients (private and public debts, wealth effect, and trade surpluses) to support the activity. Studies show indeed that American non-financial companies spent an increasingly important share of their profits to buy back their own shares by making cash payments to shareholders (Lazonick, O'Sullivan, 2000; Hecht, 2014). We have now strong evidence that stock markets and impatient institutional investors destroy real investments of non-financial corporations, both in US (Asker et al. 2015) and in Europe (Brossard et al., 2013).

## 3.2. Financial Institutions/Intermediaries: From the Theoretical Shock Absorber to the Practical Shock Amplifier

Financial listed companies are also subjected to the pressure of this new type of shareholder. The effect is even greater because they play a role of financial intermediaries participating in the financing of the economy. By demanding high returns compared with other competitors, shareholders push them to select riskier and more profitable short-term strategies[13] at the expense of less profitable long-term investment projects. One form of investors / shareholders short-termism is revealed in the sharp decline in the holding period of financial assets ownership, an increase in purchase/sale of short-term stocks... For example, on the New York Stock Exchange (NYSE), the average holding period went from five years in 1980 to five months in 2010 (Della Croce et al., 2011). One of the reasons given to explain this short-termism is the many asset delegations to external assets managers who, being in competition, are encouraged to take account of the short-term returns rather than the long term ones. This development of asset managers, by lengthening the investment chain and making it more complex, has not only participated in the lowering of investor involvement in the company but has also induced an increase in costs for agents in need of funding and an dissymmetry in risk taking. The already mentioned proxy advisors represent another type of delegation which institutional investors are fond of. These Proxy advisors outsource the governance of their voting rights in general meetings of companies in which they are shareholders. This demonstrates to what extent institutional investors are no longer involved in the companies.

## 3.3. Liquidity and Short-Termism against Investment

If the liquidity of secondary markets[14] is essential to attract investors, it constitutes a strong constraint and establishes incentives for short-termism. It distorts the way of understanding the real economy. By creating a financial market where companies are listed, we have created the fiction of liquidity of productive investment itself. If we can understand the rationality of investors seeking liquidity for their investments, this liquidity research conflicts with the necessity of their own commitment to productive investment. Indeed, the action of productive investment is often irreversible. It is a way of planning for the future, a time commitment that is not reconcilable with the ongoing search for liquidity inherent to financial markets. Consequently, the company, which is a viscous corporate purpose intended to reproduce itself over time, is influenced by the instability of the financial actors' state of mind. Financial markets often soar, upwards or downwards, for a company, a sector of activity or a particular country. These impulses influence stock prices... but they also change corporate investment behaviour. If the stock market valuation is particularly well oriented, why not agree to a capital increase that would bring new money and enable an investment increase? Conversely, in the case of a pronounced disaffection on the stock exchange, the company and its management team can blame the coup and think, in a pessimistic trend, that it's better to invest less. The opinion of the financial markets reflects on productive business investment and it amplifies the movement, causing episodes of over-accumulation and moments of under-accumulation. The instability of financial agreement contaminates the real economy.

This is even more damaging in that financial opinions are based on conventions, and not on any theoretical value, the fundamental value, as defined in the theory of efficient markets. The hypothesis of informational efficiency postulates that the market price of a security reflects its fundamental value, given the available information (Fama, 1970). In other words, the security would possess an intrinsic value, defined as the future income flow to which it is entitled. In the case of shares, the basic value is equal to the present-day value of the income flow of dividends distributed by the company. Indeed, one share gives the holder a right to future profits. This formula reveals the profound logic of capitalism: capital value is determined by its ability to generate profits over time. The share price should consequently, in this logic, be determined by the future flow of dividends that will define the fundamental value. Thus, the efficient market theory suggests that stock prices represent the intrinsic value of companies, excluding market fluctuations. This intrinsic value is in itself objective in the sense that it is based on the company's characteristics (productivity, production capacity etc.) thus reflecting a fundamentalist logic.

However, calculating the fundamental value is not easy to achieve because future dividends are unknown. They represent a fraction of the profits, which are themselves uncertain because they depend on strategic choices of the company or even macroeconomic developments. Consequently, investors should anticipate such dividends based on the information provided. Thus, informational efficiency is inextricably linked to the formation of expectations on the future developments of variables likely to influence asset prices in the market. What governs the financial agreement is the phenomena of crowd psychology, mimetic behaviour where everyone is watching everyone else in order to form their opinion (Orlean, 1999). On the eve of the sub-prime crisis, all of the rating agencies, supposed to speak the "truth" on the financial markets, thought that the sub-prime products were of high quality. The next day, they had all changed their minds. Similarly, the financial markets myopia had long held the view in the 2000s that it was no more risky to lend to the Greek State than to lend to the German State: the interest rate gap between the two public debts was practically non-existent. There are countless examples where financial markets

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

have been grossly mistaken in their assessments. Therefore, it is really difficult to entrust them with the task of guiding the long-term investment prospects that shape tomorrow's economy... The markets are not inherently good assessment guides.

Since the 1980s, numerous studies have evaluated the negative influence of liquidity and the presence of impatient institutional investors in companies' capital. This influence is most often characterized by the expression "short-termism": companies think at short-term when they pay the shareholders whereas they could use the funds to make a long term investment that would ensure their future prosperity. On this point, there has been, for some time, a certain consensus in academic literature[15] but also awareness on the part of professionals. This is the case of BlackRock's CEO, Larry Fink, one of the leading asset managers in the world, who, in 2014, 2015 and 2016 sent a letter to the largest US companies (S & P 500) to warn them: "giving cash back to shareholders should be part of a balanced strategy; however, when done for the wrong reasons at the expense of productive investment, this can endanger the ability of the company to generate long-term returns." Beyond this warning, many observers perceived these financial excesses since the crisis started in 2007-2008. Some regulators such as Paul Volcker[16] (Former Fed governor) and Lord Adair Turner[17] (Chairman of the Financial Services Authority) called into question in 2009, the economic value of some financial innovations (CDS, CDO...) (Zingales, 2015); while international institutions and academics questioned, using numerous empirical studies, the positive relationship between the size of the financial sector and economic growth (IMF[18], 2014; European Commission[19], 2013; Coeuré, 2014; Philippon and Reshef, 2012; ...). This assessment invites us to reconsider the current financial intermediation forms.

## 4. FUTURE RESEARCH DIRECTIONS

After observation of more than 30 years of financialization during which finance has gradually been emancipated from the real economy and explained the main mechanisms which have led non-financial listed companies to making less productive investment, the issue of guiding principles is raised, for a new financial structure dedicated to serving the economy. Such a reform implies an extension of financial commitment to support productive investment or corporates' productive projects. This part aims to present some policy implications defining new forms of financial intermediation. Two main avenues can be examined related to governance and the control of the financial markets' liquidity, which may be subject of further researches.

### 4.1. Change the Governance

This path of reform concerns the governance of funds and the corporate governance. In the first case, the goal is to encourage institutional investors to adopt long term return oriented strategies more compatible with the investment horizon of the companies they fund. In the second case, it would reduce shareholder pressure on the company by sharing power more equally within the company.

In terms of governance of funds, a solution to financial excesses would be to rely on the virtues of a certain type of investors: long-term investors. These investors, who are generally defined as investors with illiquid resources, have theoretically a strategic advantage over other financial intermediaries such as banks, in that they are less exposed to liquidity risk. Accordingly, they should be less compelled to seek short-term returns. These are for example, pension funds, life insurance companies, sovereign wealth

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

funds... This theoretical category of investor is supposed to represent the good shareholders, that is to say those who do not seek the highest dividends, share buybacks or short-term capital gains because they know that growth opportunities are the key to long-term profits. But the problem associated with this reform strategy by long-term investors is that their behaviour is not always conforming to the theory. In fact, in practice, we observe that their behaviour is no different from short-term investors seeking highest returns in the short term. A study of OECD (Della Croce et al., 2011) shows a long decreasing trend of financial assets holding by institutional investors from 1991 to 2009. Another OECD study (2010) about defined benefit pension funds reveals that US pension funds tended to follow market movements (momentum investment strategies). For example, during the financial crisis in 2008 and 2009, they were net sellers (buyers) of equities (bonds) when market was bear. Such a strategy consequently tends to amplify market trends and is against what we can expect from a long term investor. This last one should rather have a countercyclical strategy.

Another complementary way would be to modify the current corporate governance rules that let shareholders dominate the company. The objective is to reduce the primacy of shareholders on profit reallocation decisions. Three main paths can be considered. The first aims to transform the board of directors into a time supervisory board which allocates profit following arbitration between remunerations of the past (sum payable to shareholders), of the present (to employees) and of the future (to investment financing). According to Morin (2013), no party should therefore impose its views. Another solution would be to grant preferential dividends when the stock holding period lengthens: if you are shareholders of a company for less than a year, you are not entitled to any dividend but after presence in capital of over a year, you start getting a regular dividend. Finally, another path refers to double voting rights: this time it is a question of giving a bonus for seniority, not in terms of income (dividends), but in terms of power in corporate governance. Mayer (2013) proposes to create decreasing voting rights when a shareholder is closed to the exit. This solution is ground on an ex ante agreement which binds the owner to stay in the corporation during a defined time. Otherwise, a more radical solution would be to give the vote only to subscribers of shares on the primary market (the only one that finances the company), and no longer allocate votes to buyers in the secondary market.

## 4.2. Control the Financial Markets' Liquidity

The change in the governance of funds and corporate governance is one of the conditions to ensure that entrepreneurs invest again. But this company reform can only take place in a new financial system involving greater intervention of State. Such objectives include a reduction in the liquidity of financial markets and reconsideration of self-regulation and its underlying foundation: the efficient market theory. Here again we suggest several proposals which would deserve to be dealt in depth.

Behind the fight against liquidity, is the defence of a certain conception of the company. Indeed, for now on, we apply to the company the same imperative that we have towards a financial security, it has to be liquid. Yet, the company cannot be liquid because it aims to reproduce over time. If today's market liquidity allows owners of capital to impose their will on companies and states, it is this liquidity that must be constrained first. This constraint can only be authoritarian. Keynes proposed a solution: the taxation of financial transactions that would put a grain of sand in the cogs of market finance. We support this proposal which is applicable to all financial assets while adjusting the rate in relation to the assets' holding period.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, this liquidity control may involve stricter regulation of financial intermediaries. It has to be noted that since financial institutions are self-regulating, financial stability is undermined (Borio, 2009). In banking sector, this evolution toward self-regulation has begun by the end of the 70's at international level through the intermediary of the Basel Committee which has given to banks more and more leeway to monitor themselves their activities' risks. For example, with the Basel 3 banking prudential requirements (2010), it takes €3 of capital for €100 of activities, but in the 1960s, British banks needed to have €20 of capital for €100 of activities. Self-regulation has mainly allowed financial institutions to increase the leverage effect to have a debt representing 97% of their liabilities, whereas it usually represents only half the liabilities of a non-financial company[20]. We advocate imposing minimum holding periods for long-term institutional investors and / or obliging them to primarily invest on the primary financial markets which are the only ones that offer real financing to the company (Auvray et al., 2016).

To reduce the intermediation chain and their related costs, another solution that we support the most is to create a Stakeholder Bank of Investment and Financing (SBIF). Such a European or national institution could then act as an intermediary[21] between institutional savings (those of pension funds and insurance companies) and granted loan to firms. It would select company investment projects and essentially finance them with savings collected from other institutional investors. The local subsidiaries of such a public financial intermediary could not only ensure a function of traditional loans, but also structure itself in venture capital activity, that is to say a jurisdiction of funding for innovative but risky activities in collaboration with local investors. Institutional investors, in return, would hold the securities issued by the SBIF, which could compensate the different segments of risk. To make them attractive, these securities could have less regulatory capital requirements for banks, insurers and pension funds and could be guaranteed by the European Central Bank (ECB).

A public financial intermediation and the explicit guarantee of the Central Bank are fully justified today. First of all, public authorities already provide a massive implicit subsidy of a systemic nature to banks, which, nevertheless, no longer carry out their role of financing the economy. This implicit subsidy takes place with a much less expensive debt capacity for these banks than for any other non-systemic bank. For banks in the euro zone, for example, it is estimated that this implicit subsidy would save them between 0.6% and 0.9% on the interest rate. In that context, there is no reason that the public authority does not give its explicit support to the development of a bond market by positioning itself as a central intermediary in such markets. An explicit return of the State in financing long-term investments would, moreover, only be the recognition of the reality of risk taking in innovation in the late twentieth and early twenty-first century. Indeed Mazzucato (2013) reminds us of just how much State funding in the United States and the United Kingdom, is the source of many radical innovations in the pharmaceutical and biotechnology industries, defence industry, computers or Internet industry, or even the nuclear industry.

Making reference to support by the Central Bank is all the more justified today in that Central Banks now act as key purchasers on private debt securities markets, so much so, that some call them last resort buyers (Mehrling, 2010). Most central banks, except the ECB, provide this intermediary function. A guarantee of the SBIF by the Central Bank would be sufficient to attract investors and make a liquid market from the shares of this partnership institution. Obviously the securities would then be risk-free, but necessarily less profitable, the fruits of innovation being shared between the public funder, the risk taker, and private savings. This is in fact the primary reason for remuneration of a financial intermediary, this function of assuming the risk of transforming short-term liability maturities into long-term assets, as previously seen in part 2. It seems today that insurers and pension funds that have long-term potential do not wish to assume this function, favouring the liquidity of their assets despite long-term

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

commitments to their liabilities. Since these financial intermediaries don't invest in the long term, it is possible to compel them to do so by making a delegation of asset management, the savings they collect being redirected to finance a SBIF that would take care to invest these savings. The public intermediary would then do what financial intermediaries are no longer doing spontaneously: finance productive investment and make long term commitments.

Here we see that the purpose of SBIF is not merely to stimulate an initial expenditure and generate overall income and private spending, upstream (private investment) and downstream (consumer spending). Its role is to redirect investment on the basis of a policy-making decision, i.e. to establish long-term planning, that of innovation time which amounts to decades. Ensuring this long-term funding consequently goes beyond the policy-making cycle and necessarily implies a multi-party governance including unions, majority and opposition, as is the case for example for the French Caisse des Dépots et Consignation. Such an institution could rely on asset managers with industrial skills. The governance of such a SBIF is quite clear: partnership composition, resources from the subscription of bonds by institutional investors, investment rules favouring the primary market, long-term holding, a moderate dividends policy, targeting of certain sectors such as energy transition, etc. The aim is to protect companies from financial market pressures by the increased power of long-term committed players and to compel institutional investors to be genuinely long-term investors through a forced loan. The SBIF could also give some leeway to public industrial policy (the strategist State), since its investments do not weigh on public deficit. Ultimately, it is only a question of re-slotting finance into the economy (to ensure that finance finances investments in the real economy) and in society (revert to political deliberation on projects to be financed).

## 5. CONCLUSION

This chapter deals with intermediaries in the financial sector such as banks and institutional investors. These actors are expected to play a central role in economic growth via the funding of investment because they are supposed to match creditors' desires (households) with borrowers' needs (firms) at a macroeconomic level. It aims to reassess the theoretical role of financial intermediation related to the allocation of savings in a context of a structural decline in overall investment for thirty years.

The analysis of the evolution of financial intermediaries' behaviours in their capacity to finance productive projects allows us to identify two main mechanisms leading to depress investment and employment. Corporate governance and the liquidity of the financial markets have become disciplining devices for managers. Indeed, listed companies are ruled from now on by shareholders who do not want to be immobilized in a stock and require high yield (dividends, interest). Consequently, corporations are pushed to overlook profitable investment opportunities in order to pursue shareholder value on financial markets organized for liquidity. The macroeconomic consequence of this shift in focus of companies at the expense of productive investment is a slowing of economic growth and rising unemployment.

This analysis raises the issue of guiding principles for new forms of financial intermediation dedicated to serving the economy. Such a reform implies an extension of financial commitment to support corporates' productive projects. Among the several paths of reform, there is a change in current corporate governance rules in order to reduce the primacy of shareholders on profit reallocation decisions to favour investment. Another complementary way would be to reconsider the self-regulation and impose a stricter regulation and supervision of financial intermediaries. At last, to reduce the intermediation chain and their related costs, another solution that we support the most is to create a Stakeholder Bank of Invest-

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

ment and Financing (SBIF). Such a European or national institution could then act as an intermediary between institutional savings (those of pension funds and insurance companies) and granted loan to firms. It should not be under the financial markets' pressure and would select company investment projects and essentially finance them with savings collected from other institutional investors.

## ENDNOTES

1 This budgetary constraint is temporarily lifted because it concerns a credit which should be repaid.

2 Within the meaning of formation of fixed capital formation. It is therefore a question of productive capital.

3 Funding for these pensions should mostly happen by capitalisation. Also, institutional investors will be expected to develop, notably through the creation of pension funds, by this potential accumulation of substantial amounts of mutual savings.

4 Since 2010, the euro zone is locked into austerity logic: the contraction of public budgets has affected the macroeconomic demand and hence investment. ; on the other hand, the United States and the United Kingdom have opened the floodgates of real estate credit and the wealth effect on financial markets, both engines allowing to support the demand, and therefore investment.

5 In the euro zone, it is South Europe which also suffers from a problem of supply of funding, in particular from the banks, with credit rationing.

6 Borrowers (lenders) will issue (purchase) shares.

7 This activity will generate an intermediation margin that depends on interest rates between lent funds and borrowed funds. Yet, these rates are not fixed but change with the macroeconomic conditions.

8 Perfect information, homogeneous goods, atomistic market, free entry and exit, free movement of factors of production.

9 Mutual funds are mere instruments than actors. Most often the time they are investment vehicles build by asset managers, insurance companies or banks.

10 There are of course many other reasons for the rise in public debt. Besides widespread tax competition that has stripped the states of their tax base, states have also experienced a significant rise in public spending to meet social demand for public services. States also had to bear a significant increase in real interest rates in the 1980s, following the change of monetary policy to fight inflation. Another reason is the slowdown in economic growth.

11 When a company buys back its own shares, it thus increases the share of income that will soon be distributed to them.

12 The ability to sell shares on financial markets becomes an ability to relocate corporations around the world, with offshoring also destroying jobs.

[13] Between 2002 and 2014, ROE of US and European industries ranged between 10% and 13% while that of universal banks was 10% and 20% from 2002 to 2005 and then fluctuated between 20% and 30% from 2004 to 2007 to decrease drastically after. The crisis showed the unsustainability of these levels of ROE (Villeroy de Galhau, 2015).

[14] The creation of a secondary market is necessary for the existence of the primary market to attract investors. However, it is important to remember that only the primary market really provides additional financing for the company.

[15] In the US, the phenomenon was identified by scholars during the first wave of hostile takeovers on the US stock markets in the eighties (Narayanan 1985; Miller et Rock, 1985; Stein, 1988, 1989). In France, since the late nineties, when US institutional shareholders bought share of Fench corporations, we note the work of Morin (1998), Baudru and Kechidi (1998), Orlean (1999) Baudru and Lavigne (2001), Lordon (2002), Aglietta and Rebérioux (2004).

# Chapter 89
# Trends of FDI and Production in Service Sectors:
## A Dynamic Panel Exercise with Indian Data

**Madhabendra Sinha**
*National Institute of Technology Durgapur, India*

**Partha Pratim Sengupta**
*National Institute of Technology Durgapur, India*

## ABSTRACT

*The chapter investigates the role of foreign direct investment (FDI) on performances of Indian services at sector level. Service sector is marked as one of the fastest growing sectors in India, contributing more than 65 percent of GDP. The maximum share of FDI inflows in India is also captured by service sectors. So FDI inflows can have significant impacts on services. We collect quarterly data of components of services from GDP estimates of Central Statistical Office (CSO) and monthly data of sector wise FDI inflows from DIPP over the period January 2009 to March 2016 in India. After matching the data series, we form a balanced panel for four basic service sectors as classified by CSO. The stochastic properties are looked into by carrying out LLC and IPS panel unit root tests. Empirical results from the estimate of Generalised Method of Moments (GMM) suggest that FDI Inflows enhance performances of Indian services.*

## INTRODUCTION

Service has been emerged as one of the largest and fastest growing sectors in the global economy, contributing more than 60 percent of global output, even larger share of employment in many countries (Hoekman & Mattoo, 2008) since last two and half decades. The growing share of services in global transactions has also accompanied the growth in service sectors. It is a fact that during the same time period trade in services has grown as fast as trade in goods is the cause of rise in international supply

of services. The ratio of global trade in services to goods has increased to 27 percent in 2010 from 20 percent in 1980 (WDI, 2011). Service sector has also attracted huge amount of inflow of foreign direct investment (FDI). Sector wise data of FDI stock provided by UNCTAD (2015) highlighted that the prominent role of services in global FDI. The services has accounted for 63 percent of global FDI stock, more than twice of the share of manufacturing, at 26 percent in 2012. There is a shift of ongoing sector level composition of FDI from manufacturing to services because the share of services in global FDI stock has gained 14 percent with a corresponding decrease in manufacturing to 26 percent from 41 percent since 1990.

Like global economy, India has also experienced a major improvement in services led economic growth since economic reform. Indian services sector assumed a central role in its remarkable growth story and grew at an average annual rate of 8 percent during 1990s. According to Economic Survey 2014-15 published by government of India, service sector is contributing nearly 65 percent to the overall economic growth since 2010. There has been satisfactory growth in Indian service sectors like Information Technology, Business Process Outsourcing and Knowledge Based Activities. Further, productivity growth in India, unlike other regions of the world, has been the strongest in services (IMF, 2006; Bosworth & Collins, 2007). A common phenomenon in economic growth theory is service-led growth (Kuznets, 1957; Chenery, 1960). Traditionally a major part of demand for services comes from the secondary phase of growth in manufacturing sector. But the growth of Indian service sector is having an altogether different story, largely independent of manufacturing sector.

Along with a large-scale expansion of output and employment in the services sector, India's trade in services has also been an outstanding during the post-reform period. Due to various measures of economic reform, India's service trade has been growing rapidly since the early 1990s. Banga (2005) and Dash and Parida (2011) found that high growth in Indian service sector in 1990s relates to higher growth of trade in services. India's services trade has registered a remarkable growth of 19.7 percent, which was fairly higher than the rate of growth of goods trade (13 percent) during 1990-2010. According to Handbook of Statistics on Indian Economy published by RBI, there has been a rapid growth of India's trade in services in the past two decades. It reached to US$ 240 billion in 2010 from US$ 6 billion in 1980s. India's service export has not only grown more rapidly than its merchandise export, but also it has grown faster than global service exports. Contribution of India's trade in services to total trade has increased from 20 percent in 1980s to 30.4 percent in 2010. A substantial part of the growth of service export (21.7 percent) was in the post-reform period. India was having a negative balance of trade in services in 1980s and 1990s, but from 2004 it has been positive. Share of India's trade in services to world has increased to more than 3 percent in 2010 from less than 1 percent in 1980, while the same in goods trade has remained constant at around 1 percent.

During the period of post liberalization, India has not witnessed only higher growth of aggregate FDI inflow but also the sector wise composition of FDI has changed considerably. Services sector has absorbed a very little portion of FDI during the first decade of post reform period. According to narrow definition of DIPP, government of India, only 7 percent of total FDI inflow came into this sector. But the broad definition of service sector, includes telecommunications, construction, computer software, trading, transports, information and broadcasting, hotel and tourism, consultancy services, health services and education, has described the share of total FDI inflows has gone up to 44 percent during this period. In the second decade of the period of post economic reforms this share increased even further to 60 percent. Financial, construction, communications, power, computer software and trade services have attracted larger part of FDI inflows as compared to other sectors within services.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

So India has experienced a remarkable contribution of services in it due to attracting larger share of FDI inflow since liberalization. The above discussion also argues that both services performance and FDI inflow have played important roles in remarkable economic growth during the post reforms period. In spite of the widening extensive FDI-services linkages, there is very few empirical works investigating the impact of FDI inflow in services on performances of services at sector level. On another side, the role of inflow of FDI on the production at aggregate level has been extensively documented in theoretical and empirical studies. Most of the studies relating to this paper have used annual data over an insignificant period. But we know FDI inflow in India has structurally changed from 2008-09. In this context our objective of the study is an attempt to investigate the role of FDI inflow specifically in service sectors on production of services by using data as available from 2009 to 2015, a remarkable period of post liberalization in India. We structure our chapter as follows. Existing theoretical and empirical evidences on inflow of FDI and production in services with Indian scenario have been documented in next section followed by the discussion of hypothesis and data source. After describing the methodology used in this study, we discuss our empirical findings. Final section concludes our chapter.

## FDI INFLOW AND SERVICE PRODUCTION: EXISTING EVIDENCES AND INDIAN SCENARIO

Nowadays the focus on the analysis of FDI inflow and its impact at aggregate level has been shifting towards the analysis at sector level. From different theoretical studies like Lipsey (2001), Mirodout (2006), Fernandes and Paunov (2008) etc., it can be argued that FDI in services can be benefitted to host countries in various ways like knowledge and technology spillovers, change in price, increase in varieties, improvement in quality and employment generation etc. Some studies showed that impact of FDI in manufacturing is higher than the impact of FDI in services (Alfaro 2003; Aykut and Sayek 2007). Inflows of FDI into different service sectors like financial, transport, communication and power, which are the key intermediate inputs of production of all sectors, enhance the overall productivity as well as economic growth in long run as observed by Francois (1990), Markusen (1989), Lipsey (2001), Fernandes and Paunov (2008).

Arguably the third mode of services is the most critical in facilitating inflow of FDI and also underpins many activities associated with other 'modes' (Fillat-Castejón et al., 2008; Francois & Hoekman, 2010). Different empirical evidence suggested that four modes service trade are complementary in nature (WTO, 2004; Lennon, 2008). That is why we expect that FDI inflow and trade in services are likely to be complementary to each other.

In the context Indian economy, a very few empirical studies have tried to investigate the linkage between trends and patters of FDI and production in service sectors. Banga (2005) found that high growth in services was related to higher growth trade in services in India. Agrawal (2005) and Pradhan (2002) failed to find any significant positive growth effects of FDI inflow. Sharma (2000) suggested that inflow of FDI has appeared to have insignificant impact on Indian export performances although its coefficient is having a positive sign. A unidirectional causality from FDI inflow to services export, which revealed that inflow of FDI inflows in services influence services export, has been observed by Bhattacharya and Bhattacharyya (2009). Dash and Parida (2011) has supported the India's services export-led growth during the post liberalization period. We have found the vast literature on FDI and economic growth unlike the lack of literature on services trade and economic growth in India and their results are mixed.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

We have also found that most of the existing studies have looked into the role of FDI inflow on aggregate growth of the economy. But Chakraborty and Nunnenkamp (2008) analysed the sector specific hypothesis and found only transitory effects of inflow of FDI on output in services sector. However the study emphasized that FDI in services may be growth promoting in the manufacturing through cross sector spillovers. There is a limitation of empirical literature on inflow of FDI and trade in services in general and particularly in India. Productivity improvement in certain sectors such as distribution of services is due to large inflow of FDI has been observed by Kim and Kim (2000) in case of Korean economy. The presence of short run unidirectional causality from FDI inflow to services export has been confirmed by Srivastava (2006). But Feng (2009) identified that FDI inflow is not having any significant impact on productivity and export of services in India.

We find that there has been significant inflow of FDI in India since the mid-1990s. The cumulative amount of inflow of FDI was Rs. 1,495,860 crore for the period of April, 2000 to March, 2016. Table 1 displays inflows of FDI into different sectors in India during the recent period. It is revealed that nearly 18 percent of total FDI inflow was captured by the services sector during 2015-16, while the construction sector got around 8 percent. Computer, software and hardware, telecommunications, and automobile industry sector have received around 7 percent, 6 percent and 5 percent respectively. Inflows of FDI to drugs and pharmaceuticals, chemicals (other than fertilizers), trading, power and Hotel and Tourism were near about 5 percent, 4 percent, 4 percent, 4 percent and 3 percent respectively. During the same period out these top ten sectors FDI inflows to rest of the sectors accounted for around thirty six percent.

The policy of economic reforms has facilitated the country to record a high growth in general as well as particularly in service sector in India. Emerging situation in India as a fastest growing country in the world since early 1990s is mainly due to rapid growth in service sector in a large extent. During the post

*Source:* Various issues of Handbook of Statistics on Indian Economy, RBI

reform period, output growth in Indian services has been much higher than the growth in agriculture and industry. Contribution of services to GDP in India during present period is more than 65 percent. Trends of sector wise production of services have been tabulated as following in details.

So the above discussions are suggesting that the theoretical as well as empirical literature do not underline any clear-cut conclusion on the relationship between FDI inflow and international service trade in terms of export. Against this background, our study is an attempt to examine specifically the causal linkage between specific inflow of FDI in services sector and export of services in Indian economy during the period of post reform.

## HYPOTHESIS AND DATA

The contributions within theoretical and literature show the ambiguity of the relationship between inward FDI specifically in the services sector and international trade in services. The conclusions of models have been shared between substitutability and complementarity. In this context the basic hypothesis to be examined for achieving the above mentioned objective of the study are categorized as following:

- Inflows of FDI in services do not have any impact on production of services.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

In this study we have used sector wise quarterly data of GDP in services provided by the Central Statistical Office (CSO), Government of India on monthly basis and monthly data on sector specific FDI inflows for services in India from DIPP, Govt. of India over the period January, 2009 to March, 2016. We have converted and compiled the sector wise monthly FDI data to quarterly data to match with data of sector wise GDP of services. DIPP provides the monthly cumulative data of FDI inflow for sixty three sectors in India, from which we have obtained the individual monthly data for each sector by subtracting the cumulative of last month from present. To structure a balance panel by using four basic sectors like (i) Construction; (ii) Trade, Hotels, Transport and Communication; (iii) Financing, Insurance, Real Estate and Business Services; and (iv) Community, Social and Personal Services of Indian services as classified by CSO we have accumulated the FDI data with corresponding to four basic service sectors. So we treat sector wise GDP of services and FDI inflow as the variables in our study.

## METHODOLOGY

The relationship between FDI inflow and service production in India is estimated by applying the Generalized Method of Moment (GMM) approach in a dynamic panel frame to control for endogeneity in our regression model. Use of panel data to estimate the common relationships across sectors is particularly appropriate because it allows the identification of sector-specific effects which control for unobserved or missing variables. Panel models make more information available due to more efficiency and degrees of freedom. The models also allow to control the individual heterogeneity and to identify the effects which cannot be identified in time series and cross section data.

Panel data unit root tests have become very popular recently for solving the problem of low power of the tests for a single time series. Panel unit root tests developed by Levin-Lin and Chu [LLC] in 2002 and Im-Pesaran-Shin [IPS] in 2003 are used to explore the panel time series properties of the variables. Panel unit root tests, although similar, are not identical to unit root tests carried out on a single series. In testing panel unit roots, the basic ADF specification is:

$$\Delta y_{it} = \rho y_{i,t-1} + \sum_{j=1}^{p_i} \eta_{ij} \Delta y_{i,t-1} + X'_{it}\delta + \varepsilon_{it} \qquad (1)$$

The LLC test allows the intercepts, the time trends, the variances of residual and the autocorrelation order to vary freely across the cross section units. But it will require the time series of independently generated with a common sample size and all individual AR(1) series have a common autocorrelation coefficient. The lag order $p_i$ is permitted to vary across individual states. The appropriate lag order is chosen by allowing the maximum lag order and then by using the t-statistics for $\eta_{ij}$. The estimate of the autocorrelation coefficient, $\rho$, is not obtained directly from the estimation of equation (1). By using proxies for $\Delta y_{it}$ and $y_{it}$ that are standardised and free of deterministic components and autocorrelations.

The most commonly used estimator for dynamic panels with fixed effects in the literature is the GMM estimator by Arellano and Bond (1991). In this approach, the fixed effects are first eliminated using first differences instead of actual level of variables and then an instrumental variable estimation of the differenced equation is performed. As the instruments for the lagged differences of the endogenous variable or other variables which are correlated with the error term in differenced term – all lagged levels of the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

variables in question are used, starting with lag two and potentially going back to the beginning of the sample. The overall validity of instruments can be checked by a Sargan test of over-identifying restrictions.

The simple model of dynamic panel, with one period lag can usually be expressed as:

$$y_{it} = \alpha_i + \theta_t + \beta y_{i,t-t} + x'_{it}\eta + \varepsilon_{it} \tag{2}$$

$\alpha_i$ represents fixed effect, $\theta_t$ is time dummy, $x_{it}$ is a (k-1)×1 vector of exogenous repressors and $\varepsilon_{it} \sim N(0, \sigma^2)$ is a random disturbance.

In our study, sector wise GDP of Indian Services as dependent variables and inflows of FDI in services at specific sector level compare to GDP Series as independent variable. A fixed effect model is more suitable than a random effect model in panel frame because macro panel contains most of the sectors under consideration and it is less likely to be a random sample.

The basic GMM panel estimators, $\delta = \left(z'x\right)^{-1} z'y$ , are based on moments of the form,

$$g\left(\delta\right) = \sum_{i=1}^{N} g_i\left(\delta\right) = \sum_{i=1}^{N} z'_i \varepsilon_i\left(\delta\right) \tag{3}$$

Where, $z_i$ is a $T_i$×p matrix of instruments for cross-section, *i*, and,

$$\varepsilon_i\left(\delta\right) = \left(y_i - f\left(x_{it}, \delta\right)\right) \tag{4}$$

GMM estimation minimizes the quadratic form:

$$S\left(\delta\right) = \left(\sum_{i=1}^{N} z'_i \varepsilon\left(\delta\right)\right)' H \left(\sum_{i=1}^{N} z'_i \varepsilon\left(\delta\right)\right) \tag{5}$$

with respect to δ for a suitable chosen weighting matrix H.

Thus the basics of GMM estimation involve to specify the instruments Z and to choose the weighting matrix H, and (3) determining an estimator.

## EMPIRICAL FINDINGS

Our panel data consists of sector wise monthly data for production in Indian service sectors for the period 2009 to 2016. In order to perform dynamic panel estimation of the impact of FDI inflow on level of production in service sectors, we have to verify the order of integration of all variables used in the analysis. We have carried out panel unit root tests by the methodology developed by Levin Lin and Chu (2002) and Im-Pesaran-Shin (2003). Test statistics of panel unit root are calculated for all underlying panels for all major service sectors in India. The lag lengths have been selected by following minimum AIC rule to estimate the test statistics. We have incorporated individual effects and individual linear

trends as exogenous variables in the estimated equations. The test statistics are shown in Table 3. We have failed to reject the null hypothesis that the series contains unit roots both in terms of LLC test, but IPS test suggests that the series are stationary. However, the first differences are stationary in terms of LLC statistics.

We have used the first difference GMM developed in Arellano and Bond (1991) to control the unobserved heterogeneity involved in the estimated relationship. The value of GDP of service sectors is used as the dependent variable and FDI as independent variable in dynamic equation. The presence of lagged dependent variable in the estimated equation captures the dynamics of service productivity in terms of index. This dynamics can account for the differences in the capability of investments in different service sectors. The Table 4 shows the estimated coefficients of the relationship between production of service sectors and inflow of FDI in India in a dynamic panel frame. Land based activities are dominating in the countryside. We have incorporated some relevant variables as instrument to capture their effects on the relationship between sector wise service production and FDI inflow.

The lower portion of Table 4 displays additional information about the specification of the model. Since the reported J-statistic is simply the Sargan statistic (value of the objective function of GMM at estimated parameters), and the instrument rank is greater than the number of estimated coefficients, we may use it to construct the Sargan test of over identifying restrictions. It is worth noting here that the difference in J-statistic as reported by a panel equation from that reported by an ordinary regression equation by a factor equal to the number of observations.

The effect of FDI inflow on service sectors' productivity is significantly positive. Thus the inflow of foreign capital enhances growth service sector in India by the process of integration of the domestic economy into the global economy with foreign capital and modern technology. We know if liberalisation

is reflected by the significant inflow of FDI, technological know-how and skilled management, openness is supposed to be growth enhancing through the improvement of service productivity in a competitive manner. However in India, foreign capital in the form of FDI flow has stimulated mainly the output of Trade, Hotels, Transport and Communication with slow progress in other service sectors as well as in industry as general with in imports in merchandise trade due to inflows of foreign financial capital, and higher proportional increase.

Our empirical results support the predictions put forward by the different theoretical models showing the relationship between FDI inflow and production performance of an open economy. The liberalization the Indian economy by allowing FDI in service sectors enjoying comparative advantage in labour intensive products in the world market has not been beneficial to labour engaged in the production of such goods but makes the demand for labour more elastic leading to employment enhancing and wage shocking arise from shocks to productivity or to output demand.

## CONCLUSION

The chapter empirically investigated the causality between rising capital inflow in the form of FDI and trade in services in terms of both export and import in India during 2009 to 2015. The broad area of our chapter is relating to international trade and economic development with special emphasis on inflow of foreign capital and its effectiveness on FDI attracting and fastest growing sectors in developing countries like India, where we get some traditional views suggesting some positive as well as negative impacts of FDI inflows in different situations. Our empirical findings highlight that the increase in both FDI inflow as well as its one period lag value are the significant factors of remarkable improvements of trade in services in terms of service export in India. The study also shows that the inflow of FDI is insignificant to promote Indian service import and FDI inflows are not influenced by Indian foreign trade in services.

Our findings may be explained by the way that present inflow of FDI is important but insufficiently and appropriately used in the export promoting service sectors as well as growth enhancing sectors in India. Thus, it may be imperative for the policy makers in India to make a policy for attracting more FDI in such a way that it could significantly enhance growth of service export. The liberal and competitive investment climates create the basis for FDI to enter and raise the potential for output growth in host economy, but improvements occur if the domestic service sectors are capable of responding to new incentives. The key policy measures are thus to improve the infrastructure and education so as to rise the absorptive capacity of the fruits of FDI domestically.

## KEY TERMS AND DEFINITIONS

**Dynamic Panel Model:** In the context of panel data, we usually must deal with unobserved heterogeneity by applying the within transformation, as in one-way fixed effects models, or by taking first differences if the second dimension of the panel is a proper time series.

**Economic Reform:** It is a major change in the structure of Indian economy initiated in the early nineties of the twentieth century.

**Foreign Direct Investment:** It is an investment made by any individual or a company in one country in business interests in another country, in the form of either establishing business operations or acquiring business assets in the other country.

**GMM Estimation:** In econometrics, the generalized method of moments is a generic method for estimating parameters in statistical models. It is a general estimation principle. Estimators are derived from so-called moment conditions.

**India:** It is the second largest populated country in the world after China situated in the South Asian zone.

**Panel Unit Root Test:** Individual unit root tests have limited power. The power of a test is the probability of rejecting the null when it is false and the null hypothesis is unit root. Sometimes, a mix of cross section and time series data are considered and then the unit root test of this panel is termed as panel data unit root test.

**Production of Services:** It is a sector of an economy that is responsible for maintaining different factors that are responsible for manufacturing and agricultural products.

# Chapter 90
# Rising Economic Powers among Economies in Transition:
## Is There Enough Space on the Global Market?

**Vasily Erokhin**
https://orcid.org/0000-0002-3745-5469
*Harbin Engineering University, China*

## ABSTRACT

*The chapter covers contemporary global developments, particularly international trade and economic integration, with involvement of the economies in transition, BRICS countries, and new rising powers of Latin America and Asia. The issues, addressed in the chapter, are related to the concept of globalization in general; specific challenges of globalization for the economies in transition, and application of those general challenges in selected countries (China, Russia, Brazil, etc.). Chapter is concluded with investigations of regional trade integration as a response to threats of globalization and expectations of a new global order with growing involvement of economies in transition (particularly, BRICS, the CIS, the EAEU, and other countries of Latin America and Asia).*

## INTRODUCTION

Economies in transition have their own way of development. Most of them are highly dependent on global market, particularly global demand on natural resources and primary products. In addition, most of the economies in transition are not very much diversified; they are not able to spread risks of lower global demand in particular industries on the entire domestic economy. The common challenge for the economies in transition is to broaden and diversify their growth base. In their efforts to do this, these countries need to improve market access through trade policies and accession to the World Trade Organization (WTO), to introduce active industrial and other production sector policies, to develop infrastructure and attract investment and new technologies.

"Economy in transition" is a rather general definition. It is commonly accepted, that it is associated with the countries of the Former Soviet Union (FSU) (currently consolidated into the Commonwealth of Independent States (CIS)) and some countries of the Central and Eastern Europe, which experienced the Soviet-type model of development and underwent large economic and political transitions in the early 1990s, from centrally-planned communist regimes to democratic market economies (Khandelwal & Roitman, 2013). According to the Department of Economic and Social Affairs of the United Nations Secretariat (UN/DESA) (2015), economies in transition are twelve countries of the FSU (Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Kyrgyzstan, Moldova, Russia, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan) and five countries of the South-Eastern Europe (Albania, Bosnia and Herzegovina, Macedonia, Montenegro, and Republic of Serbia). In the beginning of the 2000s, the International Monetary Fund (2000) also considered four Asian (Cambodia, China, Laos, and Vietnam) and seven Central European economies (Bulgaria, Czech Republic, Hungary, Poland, Romania, Slovak Republic, and Slovenia) as transition ones.

Another definition ("emerging economies") has been widely used in relation to such economies in transition, as China and Russia. Goldman Sachs report (Wilson & Purushothaman, 2003) forecast that the economies of China and Russia along with another two giants, India and Brazil (the so-called "BRIC" in the 2000s, and "BRICS" after 2010, when South Africa joined the group), could grow to be collectively larger than the top world economies (the EU, the USA, and Japan) before 2050.

All those economies in transition (or "emerging economies") have followed various pathways to economic growth, and have both common features and differences. Countries of the Central and Eastern Europe progressed into well-functioning market economies and have become members of the EU. Asian economies adopted gradual transition mode and even emerged into the key market players (China). For most of the CIS countries, including Russia, process of market reforms is still incomplete.

The chapter consists of three parts. First part is related to the investigation of globalization and contemporary challenges for economies in transition. Various approaches to understanding of globalization as economic and social phenomena are discussed. Combining various existing classifications of the economies in transition, it is decided to consider such to be the countries of the former Soviet Union, Central and Eastern Europe, and Asia, which experienced the Soviet-type model of development and underwent large economic and political transitions from centrally-planned regimes to democratic market economies. Second prt includes overview and comparison analysis of the major alliances of the economies in transition: the CIS, BRICS, and the Eurasian Economic Union (EAEU). Third part concludes the chapter with the detailed investigation of the existing strengths and weaknesses of each economy in transition in view of international competition.

## BACKGROUND

Opening of the economies in transition to the international market over the past two decades has fundamentally changed their economic and business environments (Khanna & Palepu, 2010). The term globalization has been used since the 1980s and especially increasingly since the 1990s, when transition processes started in many developing countries (post-Soviet area, Eastern Europe, and South-East Asia).

McGrew (1990) recognizes globalization as a multiplicity of linkages and interconnections that transcend the nation states (and by implication the societies) which make up the modern world system. Dawson (2003) defines globalization as the flow across national boundaries of goods and services,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

capital, people, technology, ideas, and culture. Scholte (2002) states that globalization stands out for a public spread across the world as one of the defining terms of late twentieth century social consciousness.

Apart from public issues and social linkages, there are other approaches to understanding of the driving forces of globalization, such as environmental changes, poverty, intercultural issues, etc. However, as of Fischer and Gelb (1991), in relation to the economies in transition, effective integration to a market economy is to be achieved through progress in liberalization of prices and trade. Their point of view is supported by Mrak (2000), who states, that there is no economic integration of the economies in transition to market economy without establishing participation of economic actors from these countries in the international markets of goods and services. The International Monetary Fund (2000) recognizes international trade and transactions as one of the four basic aspects of globalization (remaining three are capital and investment movements, migration and movement of people, and the dissemination of knowledge). Capello and Perucca (2013) agree that increasing international trade is a form of internationalization of production and markets, which give rise to the growing integration and interdependency of countries on the global market.

Globalization in terms of trade and capital inflows makes economies in transition more dependent on the world market (Tisdell, 1999). The Organization for Economic Co-operation and Development (1993) also understands globalization "as the phenomenon by which markets and production in different countries are becoming increasingly interdependent due to the dynamics of trade in goods and services and the flows of capital and technology" (p. 7). Bairoch and Kozul-Wright (1996) explain globalization as a "process in which the production and financial structures of countries are becoming interlinked by an increasing number of cross-border transactions to create an international division of labour in which national wealth creation comes, increasingly, to depend on economic agents in other countries, and the ultimate stage of economic integration where such dependence has reached its spatial limit" (p. 3).

Economic theory suggests that globalization should bring economic advantages to economies in transition, such as easier access to the global market as a result of liberalization of trade, enhanced economic growth as a result of better utilization of competitive advantages, and greater diversity of choice of commodities. Kolapo, Olufemi, and Olusola (2012) emphasize impacts and effects of globalization processes on the regional growth with particular reference to African countries. Gurgul and Lach (2014) found strong and robust evidence of stimulating effect of globalization processes on rise in international trade, growth of foreign investment, and reduction of import barriers in the economies in transition of Central and Eastern Europe. Wu (2006) recognizes increasing integration with the international community (including external trade, foreign direct investments, etc.) as one of the main drivers of rapid economic growth in China in the past decades.

However, there are many consequences of globalization, which have in many cases not been favourable so far for the economies in transition (Tisdell, 1999). Market niches are already heavily occupied. New entrants have to use all their competitive advantages in the most effective way to capture them. The common internal challenges for the economies in transition are diversification of their growth base and development of internal market institutions and policies. As of Khanna and Palepu (2010), emerging markets reflect those areas where buyers and sellers are not easily or efficiently able to come together. Ineffective market mechanisms and low integration of the most economies in transition into the global market create higher transaction costs and operating challenges. In their efforts to emerge effectively, economies in transition need to improve market access through trade policies, trade and economic alliances, to introduce active industrial and other production sector policies, to develop infrastructure and attract investment and new technologies.

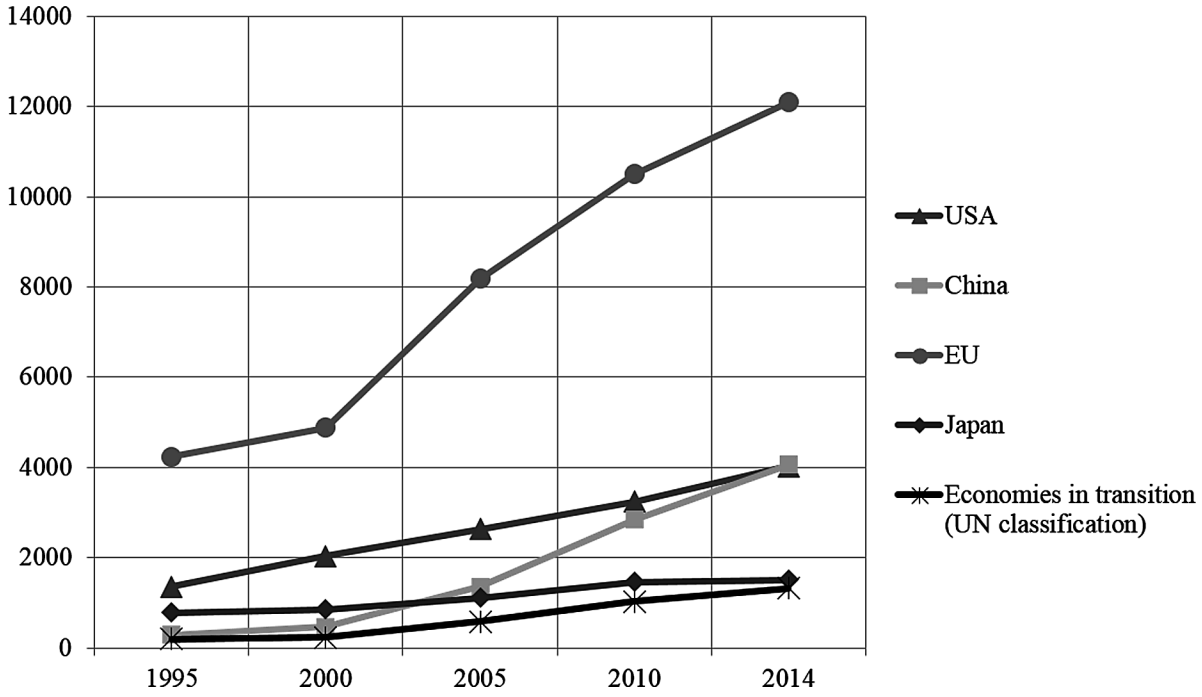
## MAIN FOCUS OF THE CHAPTER



### Globalization and Its Challenges for the Economies in Transition

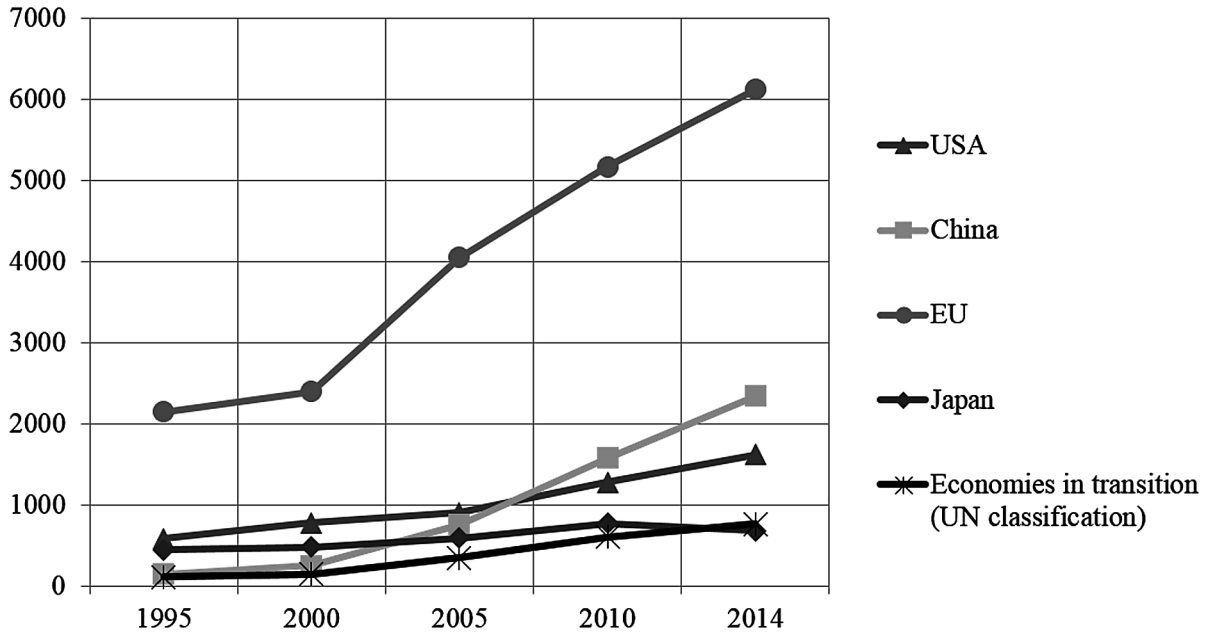
During past decades, countries have become interlinked. The dynamic growth of world merchandise exports and imports after the Second World War is one of the most important factors of global economic development. Such a growth was conditioned by quick restoration after the war, knowledge and technology transfer from military sectors into production, steady supply of energy resources, and growing economic integration. Liberalization of trade regimes gave a boost to international trade.

Bigger and more developed nations were more involved into international trade. The EU, the USA, Germany, and the UK are still among the top-ten countries of the world on foreign trade turnover. However, the major trend of international trade over past decades has been the increasing share of developing and newly industrialized countries. In 1960, the USA accounted for over 40% of world economic activity, in 2014 – for less than 11% of global foreign trade turnover (FTT). The USA together with the EU and Japan still accumulate a significant share of global exports, but new export powers are rising. They are China, South Korea, Hong Kong, Brazil, India, and other emerging economies.

Countries, which have been referred to as "economies in transition" since the early 1990s, have also progressed even though their aggregated foreign trade turnover (FTT) in 2014 amounted below Japan's FTT (Figure 1).

*Figure 1. Top countries by foreign trade turnover and economies in transition in 1995-2014, $ billion*
*Source: Author's development based on the United Nations Conference on Trade and Development (2015)*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use



Aggregated export of the economies in transition increased from $111 billion in 1995 to almost $770 billion in 2014 (Figure 2), which was half as many, as the export of the USA. Over 65% of total export of the economies in transition in 2014 accrued to Russia (in 1995 – over 70%; in 2000 – 71%). Thus, rapid growth of export after 2000 can be explained by oil price hike on the international market, since oil amounted 55-65% of total Russia's export during 2000-2014.

Aggregated import of the economies in transition increased too, up to $560 billion in 2014 from only $90 billion in 1995 (the peak was recorded in 2013 – $595 billion) (Figure 3). Again, Russia's share in total import prevailed – over 53% in 2014.

The economies in transition have come a long way in opening up their economies to the global market. After decline in the early 1990s, most of the economies recovered and found new pathways to economic growth. Most of them returned to pre-transition level of GDP (1991) only in the early 2000s, more than ten years after the start of market reforms. For many of the economies in transition the recovery has taken longer, for some of them the process continues. Such CIS countries as Georgia, Kyrgyzstan, Moldova, and Tajikistan reached the pre-transition levels of GDP only after 2005 (Table 1).

Annual rates of GDP growth in developed, developing and transition economies are different. Since the 1990s, developed countries have grown by 2-3% annually, except two crisis years of 2008 and 2009. The rates of GDP growth for emerging economies have been even higher – about 5-6% in average (above 10% for China). As for the economies in transition, the rates have been very fluctuant. This is the result of high dependence on the global market, particularly global demand on natural resources and primary products. In addition, most of the economies in transition are not very much diversified; they are not able to spread risks of lower global demand in particular industries on the entire domestic economy. In general, aggregated GDP of the economies in transition have increased almost fourfold since the beginning of transition period in 1991 (Figure 4), while GDPs of the leading economies (the USA and China)

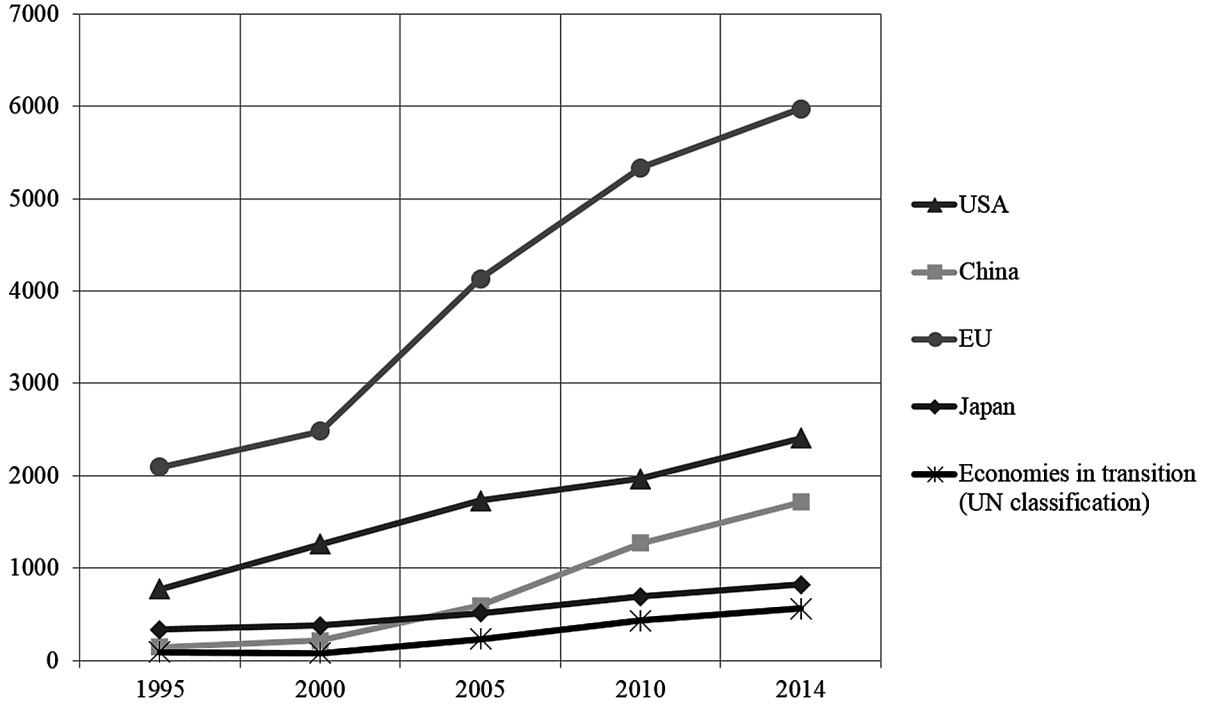


*Figure 2. World top exporters and economies in transition in 1995-2014, $ billion*

*Figure 3. World top importers and economies in transition in 1995-2014, $ billion*
*Source: Author's development based on the United Nations Conference on Trade and Development (2015)*

and alliances (the EU) have increased rapidly, especially in case of China – up to over $10 trillion in 2014 from $381 billion in 1991. It should be emphasized, that China's GDP in 1991 was only a half as big as the aggregated GDP of the economies in transition.

Despite certain progress, volumes of GDP and foreign trade of the economies in transition are well below then those of the developed countries and emerging economies. In order to increase their competitiveness on the global market most of the economies in transition are now actively seeking for strategic allies – between themselves and other emerging economies, through which they would like to strengthen geopolitical, economic and trade positions.

## Promising Alliances of the Economies in Transition and Emerging Economies

One of the alliances of the economies in transition, which was established during the breakup of the Soviet Union, is the Commonwealth of Independent States (CIS). As of 2015, CIS includes eleven FSU republics, now independent countries, which are considered as economies in transition by the Department of Economic and Social Affairs of the United Nations Secretariat (2015). Nine of them have ratified the CIS charter and are full CIS members (Armenia, Azerbaijan, Belarus, Moldova, Kazakhstan, Kyrgyzstan, Russia, Tajikistan, and Uzbekistan). Turkmenistan is an associate member. Ukraine is a founding and participating country, but legally not a member country. In March 2014, a bill was introduced to Ukraine's parliament to withdraw from the CIS following the Russia's actions in Crimea, but the country is still officially considered as the CIS member. Another country, Georgia, left the Commonwealth in 2009 because of political reasons and right after the military conflict with Russia in South Osetia.

Hereinafter for the purposes of the analysis, the author considers the CIS as the union of eleven post-Soviet states, i.e. economies in transition, due to their common political past and similar peculiarities of domestic markets and trade.

Most of the CIS countries passed through economic and social turbulences during the 1990s. Aggregated GDP of the bloc decreased almost twofold during the 1990s (Figure 5).

Nevertheless, after 2000 most of the CIS countries were able to recover. Growth of the aggregated GDP was to a high degree conditioned by Russia's recovery due to the growing oil prices. Russia has been the trendsetter of the bloc since the very beginning of the 1990s, having the biggest GDP among the CIS members. In 2010, Russia's GDP amounted 74.3% of the aggregated GDP of eleven CIS countries (Figure 6). Second biggest was Kazakhstan with 8.5%.

In spite of the collapse of the Soviet Union in 1991, traditional economic and trade ties between the newly established independent states remained tight. Naturally, those new states had aspiration to restore them; therefore a significant number of regional trade and economic agreements was signed in the 1990s.

The first one was Free Trade Zone of 1993, which was initiated by Russia and geographically covered Armenia, Belarus, Georgia, Moldova, Kazakhstan, Kyrgyzstan, Tajikistan, Ukraine, and Uzbekistan. However, this initiative did not exist long. Although it was initiated by Russia, the Russian Parliament did not ratify the Free Trade Agreement. The reason was that Russia insisted on exclusion of oil and gas from the free trade regime, which was unacceptable for its trade partners. The next agreement was

signed in 1995 when Russia, Belarus, and Kazakhstan established the Customs Union (CU). In 1997 and 1998, the CU was expanded by Kyrgyzstan and Tajikistan, and, finally, in 2001 was reorganized into the Eurasian Economic Community.

Despite such a growing integration within the bloc, the share of intra-CIS trade has been declining. During 2009-2010, it was negatively affected by the global financial crisis being only 8%, but in 2011-2013 there was a recovery back to 10%. Throughout the period of 1991-2014 the share of exports going to the EU was fluctuating around 40-50% with the peaks in 1992 and 2006.

Foreign trade of the CIS with the world is growing. During 1995-2014, aggregated foreign trade turnover of the bloc increased sixfold (Table 2). Russia prevailed in the aggregated FTT with 64.1% in 2014, followed by Kazakhstan (10.2%) and Ukraine (9.4%).

Foreign trade is an important source of income for the most of the CIS countries. Considering the bloc as a whole, top-five trading partners of the CIS in imports are the EU, China, the USA, Turkey, and South Korea. Top-five trading partners in exports are the EU, China, Turkey, Japan, and the USA. Aggregated share of the CIS bloc on the global market is rather small – 3.3% in 2014 (Table 3). Composed, largely, by Russia, it has decreased since 2011, when Russia's export to the world was the biggest due to the high oil prices.

Not every CIS country is export-oriented. For example, Armenia, Uzbekistan, and Turkmenistan are among the least exporting countries, which earn less than 17% of their GDPs with exports. Leading exporting CIS countries are Azerbaijan and Belarus with a share of exports over 40% of their GDPs.

Export flow from the CIS consists of capital-intensive goods. Most of the CIS countries, including Russia as the biggest exporter in the region, rely heavily on fuels and fuel product exports. CIS countries also specialize in export production that is intensive in the use of low-skilled workers (Zelenko, 2012). Such a low added-value export specialization limits market opportunities and makes economies in transition dependant on price fluctuation on specific markets (in particular, oil).

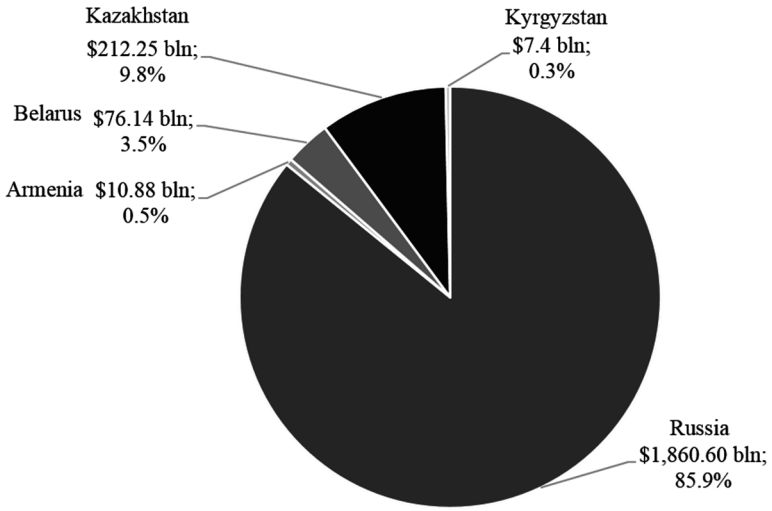
Source: Author's development based on World Economic Forum (2015)

According to the Global Competitiveness Report (2015), which ranks countries in overall competitiveness, the most competitive country among the CIS bloc is Azerbaijan (Table 4). Three CIS countries (Belarus, Turkmenistan, and Uzbekistan) were not included into the report.



Global competitiveness index includes 12 characteristics, including infrastructure, macroeconomic environment, market efficiency, market size, innovations, and others. Despite the certain improvements and growth of the aggregated average score up to 4.15 during 2012-2014, the overall competitiveness of the CIS countries on the global market remains low. Level of 4.15 is equivalent to the positions 65-79 of the Global Competitiveness Ranking in 2014, which means that the CIS countries are far behind most of the developed countries.

The leading economy of the bloc, Russia, was 53rd in 2014 with some improvements related to the efficiency of goods markets (in particular domestic competition) and business sophistication. Although these positive developments took place before the Ukraine conflict started (Schwab, 2014). Growing isolation from Western countries because of the recent Russia's actions in relation to Ukraine pushes the country into seeking even closer and more effective ties within the CIS alliance. There was the Eurasian Economic Community, which originated from the Commonwealth of Independent States in 2000 and was transformed into the Eurasian Economic Union (EAEU) in 2014. EAEU was established for effective promotion of free movement of goods, services, capital, and labor between participating countries (Armenia, Belarus, Kazakhstan, Kyrgyzstan, and Russia as of July 2015). Aggregated GDP of the union is $2.2 trillion in 2014, out of which Russia's share is 85.9% (Figure 7). Second is Kazakhstan with 9.8%, which totally makes 95.7%. Two countries control the union; provide its GDP and foreign trade turnover.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

*Figure 7. Percentage breakdown of the total GDP of the EAEU area by countries in 2014*
*Source: Author's development based on Trading Economics (2015)*

Size of this newly established block is comparable to the CIS ($2.2 trillion of the EAEU against $2.5 trillion of the CIS in 2014). Russia's intention is to make the union an alternative to rather inertial alliance of the CIS countries. Moreover, to make matters worse, such countries as Ukraine and Moldova do not consider the CIS as an effective integration mechanism, and would probably withdraw from it in the nearest future in pursuance of the integration with the EU. Another reason for Russia to develop the new EAEU initiative is its non-regional character. In the pursuit of increasing its economic and geopolitical power, Russia is actively looking for new strategic partners. Vietnam joined the free trade zone with the EAEU in 2015; two other countries (Syria and Thailand) expressed their interest in joining the union in the nearest future. The union is also open for those Central Asian states, which have not joined it by now (Tajikistan and Uzbekistan). Potentially, in the years ahead the EAEU may grow to be a certain alternative to the existing global powers: the EU, the USA, Japan, and China.

Nowadays the EAEU is still too small to grow into the regional power, comparable with the EU or any other alliance of developed nations. The vast majority of wealth comes from Russia, so it is not as if Russia is getting access to huge new markets by developing this union. One of the promising alliances for Russia (and for the entire global economy) is BRICS, which is an association of five major emerging national economies: Brazil, Russia, India, China, and South Africa. The BRICS members are countries, distinguished by their large, fast-growing economies and growing influence on regional and global affairs. As of 2014, five BRICS countries represent almost 3 billion people, which are 40% of the world population, with a combined nominal GDP of $17 trillion, which is 20% of the world GDP.

Growth in the BRICS area has increasingly diverged during the past years, especially after 2011 and in 2014. China and India continue to grow, although at slower paces, while Russia, Brazil, and South Africa shrink because of falling oil prices, geopolitical sanctions and policy uncertainty (Russia), decline in industrial production and investment and slowdown in household consumption (Brazil), energy shortages (South Africa) (Table 5).

Source: Author's development based on Trading Economics (2015)

Nota bene: notwithstanding that BRIC was established in 2006 and transformed into BRICS with entrance of South Africa in 2010, hereinafter the author considers separate member countries regardless their membership in the alliance, i.e. before 2006 (before 2010 in case of South Africa). The aim is to discover the retrospectives and current development tendencies of both the alliance and its members in order to assess their potentials on the global market.

Brazil, second largest BRICS economy, has been shrinking since 2012. The country suffers from water shortage, which prevents hydroelectric power stations from operating at full capacity and increases the cost of energy resources for industrial production, as well as from the slowdown in neighbor countries of Latin America (in particular, Argentina), which is the main foreign market for Brazil's export.

Russia has also been a bad performer since 2013. Western sanctions, imposed on Russia in 2014 in retaliation of its actions in relation to Ukraine (Crimea and South-Eastern regions of Ukraine) and Russia's counter-sanctions (food import ban) resulted in the rapid depreciation of the national currency (by almost 45% in 2014), high inflation (11% in 2014; 15% in the first quarter of 2015), capital flight (more than $150 billion in 2014), growing household debt and, consequently, shrinkage of domestic private consumption.

Economic growth in South Africa is held back by unstable electricity supplies, level of household debt, high rates of interest, and rather weak domestic demand.

China, despite the relative slowdown, is the largest economy of the bloc with 61.0% of its aggregated GDP (Figure 8).

Dominance of China is also observed in foreign trade of the bloc – 61.3% of the aggregated imports and 67.4% of the aggregated exports of BRICS in 2014. Russia is second in exports with 14.4% of the aggregated export in 2014, while India is second in imports (15.6%). As regards to foreign trade turnover, China is the ultimate leader with over $4 trillion in 2014, which is 64.7% of the aggregated BRICS's FTT (Table 6). Since 1995, it has increased thirteen-fold, which resulted in the rapid tenfold growth of the aggregated BRICS's FTT.

Growth in foreign trade turnover, rather high before 2011, stabilized in 2012 onwards. As of 2014, China is the only country among its BRICS associates, which FTT increased as compared to 2013 (by 3.1%). Russia along with Brazil experienced the deepest falls (by 6.4% and 6.0% correspondingly). Russia's export, largely dominated by oil and gas, was essentially constrained by the falling oil price, while import shrank due to the depreciation of the national currency. Brazil's FTT suffers from decreasing exports of industrial products to the markets of Latin America and depreciating national currency, which restricts imports.

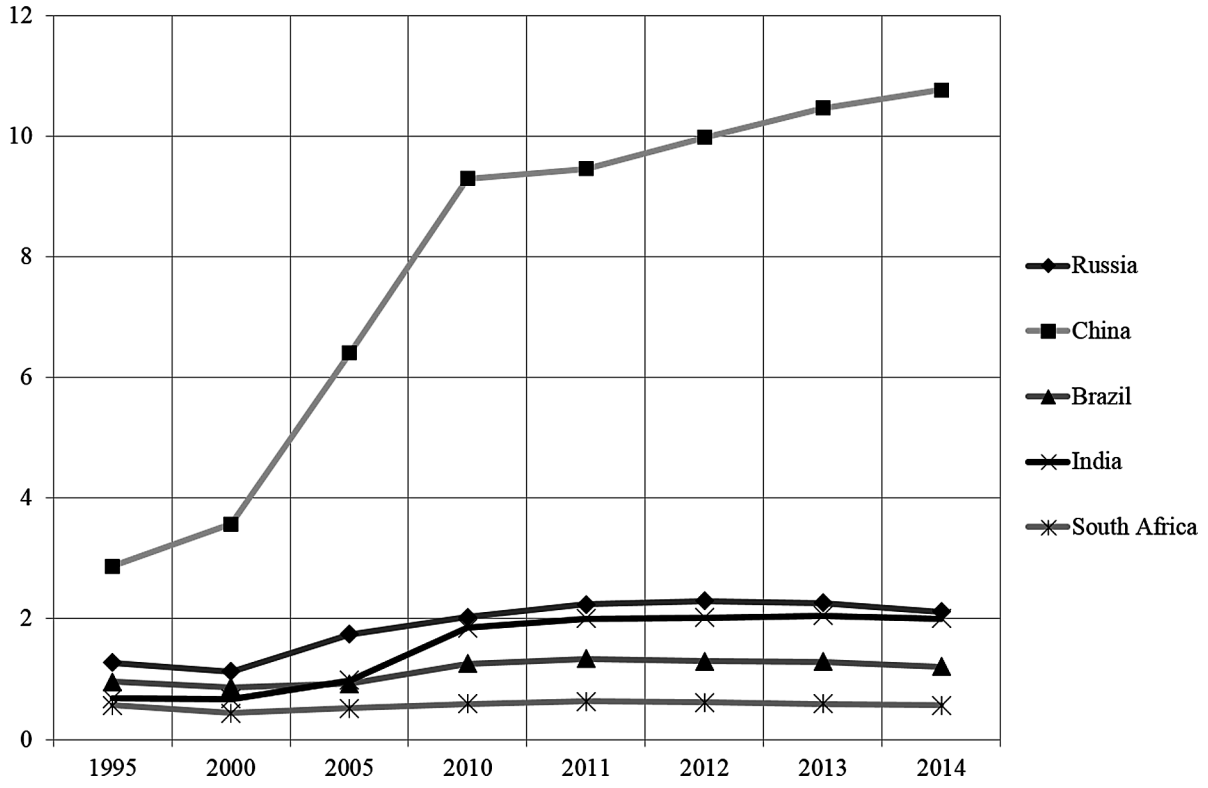
Source: Author's development based on the United Nations Conference on Trade and Development (2015)



Shares of the BRICS countries on the global market are rather small, except China, which occupied 10.8% in 2014. Russia's share decreased from the average 2.3% during 2011-2013 to 2.1% in 2014. Third biggest global market player among the BRICS countries was India with 2.0% of the global market in 2014 (Figure 9). Aggregated market share of five BRICS countries amounted 16.6% in 2014, the highest in 1995-2014.

In spite of the BRICS common core as an alliance of emerging economies, politically, economically and geographically BRICS countries have little in common. Member countries have unequal economic resources. As can be seen from GDP, FTT and market share breakdowns, China is the dominating economic force within BRICS. Its economy is bigger than those of all the other BRICS combined are. China may survive without BRICS, while BRICS would hardly survive without China. Brazil, India, and South Africa have the alternative organization, which is the IBSA Dialogue Forum. In case BRICS breaks up, these three countries still have a platform for integration.

*Figure 9. Shares of the BRICS countries on the global market in 1995-2014, %*
*Source: Author's development based on the United Nations Conference on Trade and Development (2015)*

It seems that Russia is the most interested party. Russia has an economy based on raw materials extraction as opposed to other BRICS members, which try to focus their economies on innovation and high-tech manufacturing. Russia needs those technologies for development, as well as BRICS common market for its exports. In view of escalating sanctions, growing trade, and financial isolation from Western countries, BRICS is becoming the only alternative for Russia. As soon as Western financial market is now limited for Russia because of the sanctions, BRICS becomes the largest potential source of investment. In 2015, the BRICS countries established the BRICS Development Bank worth over $100 billion (with Russia's share worth only $2 billion). This reserve pool is now accessible for Russia in case of escalating restrictions on Western financial market.

Indeed, participating countries, not only Russia, value its BRICS membership. There is a range of opportunities, which BRICS may bring to participating emerging economies. BRICS has a common core; it unites a group of emerging economies that grow fast, but until now had no chance to influence on global economic regulations. Recent Russia's and China's policies are aimed at the development of a multipolar world. BRICS is the very union, which may serve this goal through trade, investment, and political support. BRICS common market is considered by member countries as the extension of their domestic markets, which is ultimate for economic growth in the conditions of shrinking domestic demands.

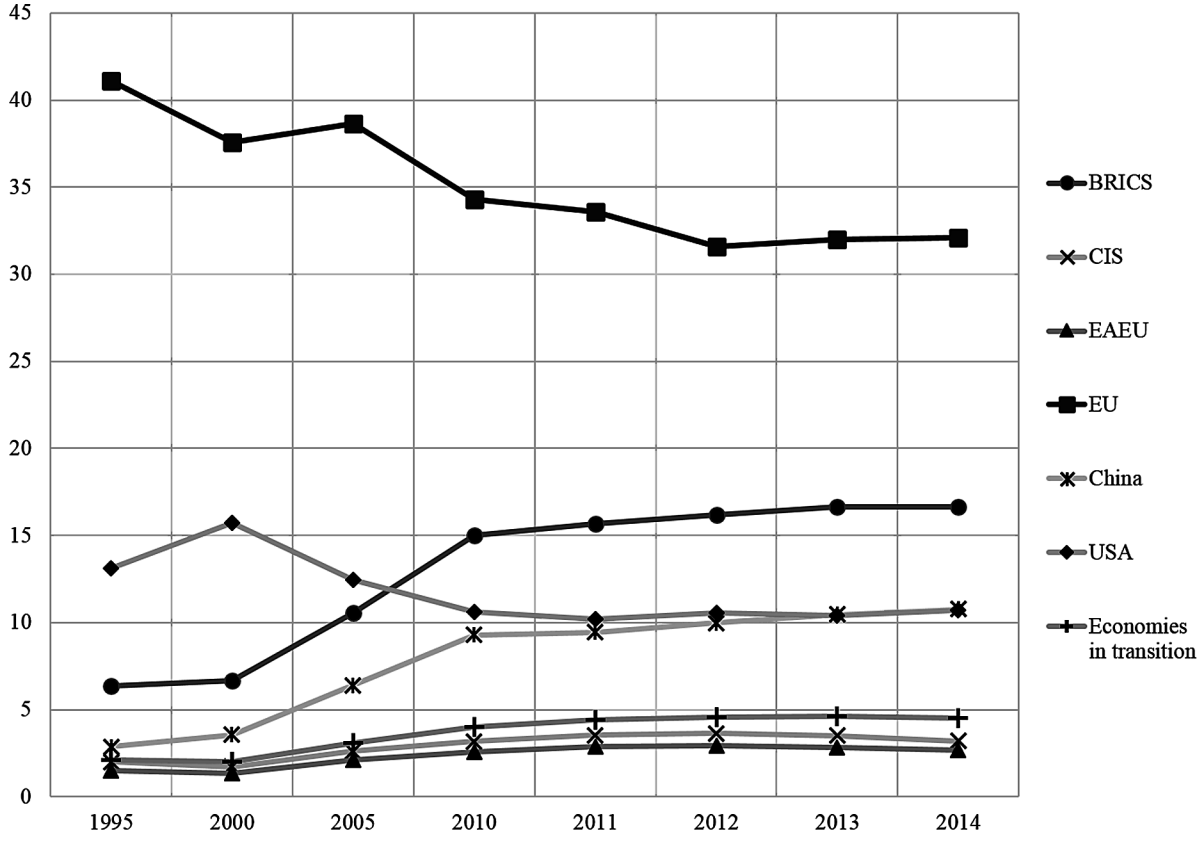
## Strengths and Weaknesses of the Economies in Transition on Their Way to the Global Market



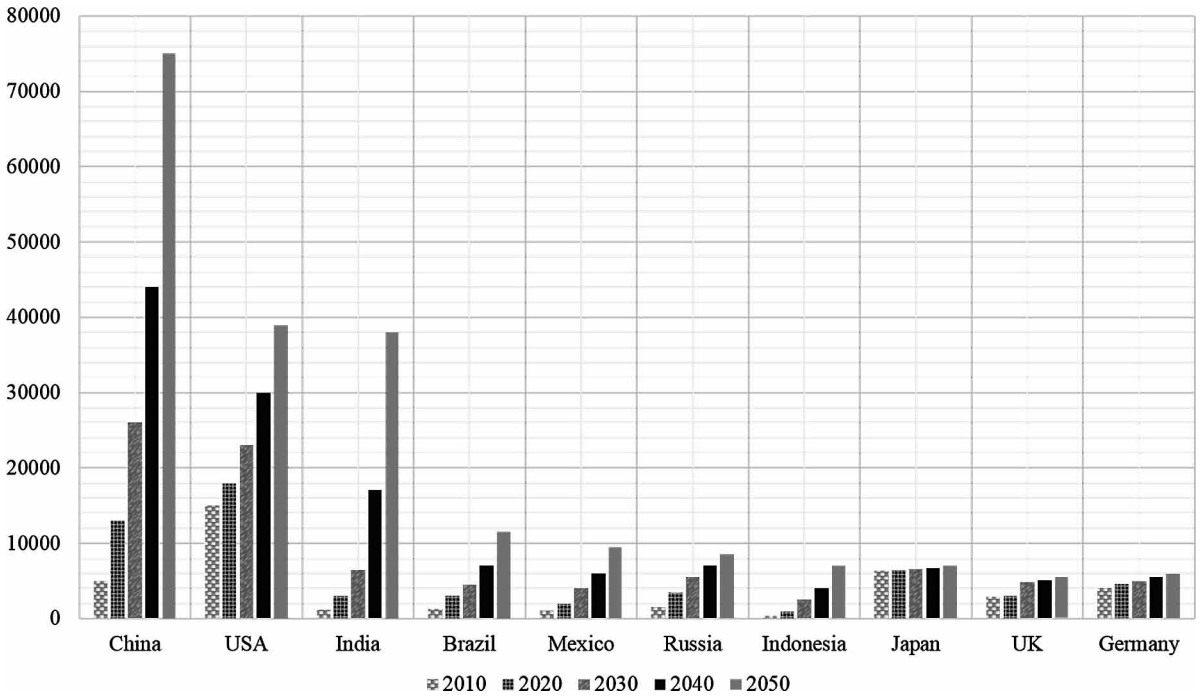
Current leading world producers and traders are the EU, the USA, China, and Japan. China has surpassed Japan as the world's second largest economy, after the United States, and now China is the only one convincing rival to the USA. Global market shares of China and the USA in 2014 are 10.8% and 10.7% correspondingly. Having approached each other in 2010-2011, since that time the market shares of those two major global powers have been fluctuating around 10% (Figure 10).

There is a distinctive tendency on the global market: "recognized" economic powers lose their market shares (minus 9.1 percentage points for the EU during 1995-2014; minus 2.4 percentage points for the USA), while emerging economies and their alliances rise. For the past two decades, China has made a pass from only 2.8% of the global market share in 1995 up to 10.8%. Although the deceleration in 2014 and, most probably, in 2015, China has certain advantages, which are expected to facilitate its economic growth in the future.

*Figure 10. Comparison of shares of the major world alliances and leading economies on the global market in 1995-2014, %*

*Source: Author's development based on the United Nations Conference on Trade and Development (2015)*

*Note: "Economies in transition" array includes twenty economies, recognized as transition ones by the UN and IMF (see Table 1), excluding China*



EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

BRICS alliance, where China dominates with 61.0% of the aggregated GDP and 64.7% of the aggregated FTT, has also spurred from 6.3% of the global market in 1995 up to 16.6% in 2014. As of Goldman Sachs (2007), by 2050 BRICS's economies are expected to become the major global economic powers (Figure 11). China and India will become the world's dominant suppliers of manufactured goods and services, while Brazil and Russia will become similarly dominant as suppliers of raw materials. Indonesia and Turkey have been mentioned as candidates for full membership in BRICS, while Argentina, Egypt, Iran, Nigeria, and Syria have expressed interest in joining BRICS. With inclusion of these economies, BRICS is expected to become the world largest economic alliance in the near future (Erokhin, 2015).

Is there a place for such players as economies in transition on the reshaping global market? For the purposes of the analysis, author excluded China and concentrated on such economies in transition, as the CIS and Eastern Europe. During 1995-2014, they have not been broken through on the global market (growth up to 4.5% of the global market share in 2014 from 2.1% in 1995). Non-CIS countries of Eastern Europe, recognized as the economies in transition by the United Nations (UN) (Albania, Bosnia and Herzegovina, Macedonia, Montenegro, and the Republic of Serbia), occupied only 0.2% of the global market in 2014. South-East Asian countries, recognized as the economies in transition by the International Monetary Fund (IMF) (Vietnam, Laos, and Cambodia) altogether reached 0.9% of the global market share in 2014.

What factors restrict economies in transition from a sustained growth of production and trade? What competitive advantages they have on the global market?

*Figure 11. Ten biggest economies in the world by 2050, measured in GDP, $ billion*

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The leading economy among those in transition is Russia (2.1% of the global market in 2014). Although Russia is forecasted to grow into the world's sixth economy by 2050 (Goldman Sachs, 2007), currently it is smaller than most of the developed countries. Being under Western sanctions, Russia has been the worst performer among the economies in transition since 2014. During the 2000s, lack of comprehensive structural reforms was masked by a growth fueled by sizeable oil revenues. Recent events around Russian-Ukrainian crisis clearly exposed economic weakness of such a growth model. In conditions of growing isolation from Western countries, BRICS may become an alternative for Russia, since it gives access to new export markets for Russia's oil and gas, and new sources for agricultural and merchandise imports. BRICS is larger than the EU, and is fitted up with all opportunities for development. Member countries are interested in each other, which is the fundamental background for integration. Another Russia's integration initiative, the EAEU, may have potential in case of its expanding. Currently, due to its overdependence on Russia, it cannot rival the wealth of a single EU country, Germany.

Second biggest economy in the region of the CIS is Kazakhstan. The country performed rather well during 1995-2014. As of 2014, it occupied 0.3% of the global market (0.1% in 1995). The country has a strategic position between Asia and Europe, diversified natural resources and actively attracts foreign investments. Its exports, however, essentially depend on oil prices. Deceleration of two Kazakhstan's major trade partners, Russia and China, will affect its economy in a negative way.

Ukraine, despite its current economic downturn due to political situation and military tensions, has certain potentials on the global market. The most competitive industries of Ukraine's economy are wheat and maize production. As most of the industrial export-oriented facilities (steel and coal) are concentrated in the regions of Donbass and Lugansk, Ukraine's export opportunities have been severely cut by temporary loss of those territories.

Fourth biggest economy in transition among the CIS countries is Belarus with $76 billion GDP and 0.2% of the global market in 2014. Competitive advantage of the country is diversified industrial sector, including rather competitive and profitable agricultural, machinery and chemical production. Belarus is very much dependent on Russia, which accounts for almost half of the total volume of Belarussian foreign trade in goods. Belarus is not rich with natural resources, and has to import them from Russia, exporting domestic agricultural and food products and machineries in return. Decelerating effective demand on Russia's market due to the fall of real incomes and inflation will decrease Belarussian export essentially.

Diversification of export destinations is becoming increasingly important for the economies in transition in view of ensurance of sustainable income from integration into the global market. The CIS country with the most undiversified export is Azerbaijan (92% of total export to the world is oil, gas, and mining products). Revenue from oil and gas exports is expected to suffer in the coming years because of falling prices, that is why the country needs to look for the ways to ensure sustainable income. Domestic non-oil and gas sector is currently suffering from a lack of investment, but as investment performance of oil industry decreases, non-oil sector might be attractive.

Uzbekistan, country in the Central Asia, resulted with the sixth GDP among the CIS countries and 0.07% of the global market share in 2014. Uzbekistan's exports are quite well diversified, but are still comprised mainly of natural resources and low value added goods including cotton, copper, fruits, and fertilizers. The national government has been rather effective in implementation of public investment programs directed towards modernizing energy production, hydrocarbon sector, and transport infrastructure. Uzbekistan's export to the world is very much dependent on raw materials prices and focused on the decelerating markets of Russia, China, and Kazakhstan.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The neighbor country of Uzbekistan, Turkmenistan, also heavily relies on export of oils and petroleum products to a small number of concentrated markets including China, Italy, and Turkey. Fuel and mining products provide over 80% of Turkmenistan's export to the world. Despite the fourth largest natural gas reserves in the world and diversified hydrocarbon export channels to China and Iran, such a weak economic diversification may bring serious threats to sustainability in the future.

Low level of product diversification and reliance upon export of natural resources is the common characteristic of the most economies in transition in the region of Central Asia. Another Central Asian state, Tajikistan, is also susceptible to volatile commodity prices with 60% of mining products, particularly aluminum, in national export to the world. It is worthwhile to note another, very specific item of Tajikistan's export, which is a workforce. About one million Tajiks, which is approximately a half of working-age population of the country, are working abroad, mostly in Russia. Their remittances account for almost 50% of national GDP, making Tajikistan the most remittance-dependent country in the world (World Bank Group, 2015, p. 12). Russia's economic downturn caused substantial decrease of remittances, which resulted in lowering of domestic consumption and decelerated economic growth.

High dependence on remittances from Russia is also specific to Kyrgyzstan (30% of national GDP). Kyrgyzstan is heavily dependent on export of gold, metals and minerals. Having vast hydroelectric potential, Kyrgyzstan nevertheless depends on energy and gas supplies from neighbour countries. The share of the country on the global market is one of the smallest among the CIS members (0.03% in 2014).

Two economies in transition in the region of Caucasus (Armenia and Georgia) have similar small contributions to the global trade turnover (0.01% and 0.03% respectively). Armenia's main export categories are manufactured goods chiefly classified by materials and natural resources, while Georgia export scrap metal, ores, wine, vehicles, mineral water and fruits and nuts. Georgia, as opposed to Armenia, is more oriented on Western markets, not Russia, due to the series of political and even military tensions with Russia during the 2000s. Whereas, Armenia's heavy dependence on trade with Russia and investments from this country is considered as Armenia's diversification weakness.

One of the smallest CIS countries ($7.9 billion GDP; 0.02% of global market in 2014) is Moldova. Moldova is the country, which may withdraw from the CIS in the near future. The country has the Partnership and Cooperation Agreement with the EU, and the European integration seems as an irreversible trend for Moldova. Moldova's target is to become an EU accession candidate country from 2017 and then a member in 2020. However, Moldova does not have substantial competitive advantages, except rather productive agriculture, in particular viniculture, while its domestic weaknesses are rather common to other economies in transition. The concluded free trade agreement with the EU (DCFTA – Deep and Comprehensive Free Trade Area) is expected to spur Moldova-EU trade flow, as it removes some import duties and provides Moldavian exporters with access to European markets.

There are countries among the economies in transition, which are well closer to the European integration, than Moldova. The UN recognizes five South-East European states (Albania, Bosnia and Herzegovina, Macedonia, Montenegro, and the Republic of Serbia) as economies in transition. Four of them, except Albania, used to be parts of Yugoslavia and became independent during the 1990-2000s. Aggregated GDP of the five countries is $91.5 billion; aggregated share on the global market is 0.2% (2014). The biggest economy in the region is the Republic of Serbia with $43.9 billion GDP. Originating from the single state, Bosnia and Herzegovina, Macedonia, Montenegro, and the Republic of Serbia have common features: poor export diversification, high unemployment, weak banking infrastructure, lack of investments, and social and ethnic fragmentation. There are certain advantages, which may increase the role of the region on the global market: energy (hydroelectric), agricultural and tourism potentials,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

friendly business environment, and close ties with the EU countries. Economies of South-East Europe are now actively focusing on the integration with the EU, considering the European market as strategic export destination.

The remaining three economies in transition, which have to be considered, are South-Asian states: Vietnam, Laos, and Cambodia. They are recognized as the economies in transition by the IMF due to their common past, related to the socialist modes of development and close ties with the Soviet Union. While the transition economic reforms in the former republics of the Soviet Union and Eastern European states were accompanied by the serious declines in GDP (see Figure 5), the South-Asian economies were rather successful in increase of their production and external trade. As of Shimomura et al. (1994), Vietnam, Laos, and Cambodia were able to take advantage of their geographical proximity to the emerging economies of East Asia (Japan, China, Singapore, Malaysia, etc.) and became integral parts of rapidly developing intra-regional trade networks.

Vietnam was a production and trade leader among the considered economies in transition with $186.2 billion GDP and 0.9% of the global trade turnover in 2014. The country has a strategic vision of its future economic development, which is built on diversification of domestic production and export, solid agricultural potential and natural resources, and skilled and low-cost labor. At the same time, Vietnam, Cambodia, and Laos have common shortcomings, originating from their past: underdeveloped infrastructure, high poverty levels, and incomplete economic and public sector reforms.

## SOLUTIONS AND RECOMMENDATIONS

Economies in transition, even representing one and the same geographical region, are considerably diverse from each other. Nevertheless, summarizing the overview of the major competitive advantages and existing weaknesses of the economies in transition in their integration into the global market, the most common features have to be emphasized (Table 7). Author divided the economies in transition into three groups: the CIS, Eastern European countries (the UN classification), and Asian countries (the IMF classification). Then the author distinguished the leading country in the regions (the biggest average GDP among groupmates in 1991-2014) and analyzed strengths and weaknesses separately for those three countries (Russia for the region of the CIS, Republic of Serbia for the region of Eastern Europe, and China for the region of Asia).

In order to breakthrough on the global market, economies in transition have to transform economic growth drivers, seize existing opportunities, reduce dependence on factors of production (investment and labour), and increase reliance on innovation and quality (Guoqiang, 2015). The major challenge would be development of a favourable external environment through establishment of effective ties with other countries and alliances. The process has already started for most of the economies in transition. The analysis demonstrated positive dynamics and potentials of such emerging markets, as BRICS. Participating countries need to make full use of those emerging markets and resources to expedite their economic transformations and improve their positions in increasingly globalized value chains.

*Table 7. Common strengths and weaknesses of the economies in transition in relation to international competition*

| Countries / Groups of Countries | Strengths | Weaknesses |
|---|---|---|
| CIS | • Abundant natural and labour resources.<br>• Agricultural potential.<br>• Traditional close economic, trade and social ties between the countries.<br>• Initiatives on inter-regional integration.<br>• Common language. | • Low diversification of output and export, dependence on fossil-fuel exports.<br>• Low value-added and innovation component in export.<br>• Weak infrastructures.<br>• Low effective demand on domestic markets, poverty.<br>• High degree of state involvement into market regulations.<br>• Corruption.<br>• Unfavorable and non-transparent investment regimes. |
| Russia | • Natural resources.<br>• Skilled labour force.<br>• Statue of regional and energy power. | • Growing dependence on fossil-fuel exports.<br>• Decreasing investment opportunities (restricted access to Western capital markets, foreign revenues shortfall).<br>• Low innovation component.<br>• Weak infrastructures.<br>• Declining demography (aging population, brain drain).<br>• Uncertainties and high political risks in domestic business environment and foreign policies. |
| Eastern Europe | • Energy (hydroelectric), agricultural and tourism potentials.<br>• Friendly business environment.<br>• Close ties with the EU countries. | • Poor export diversification.<br>• High unemployment.<br>• Weak banking infrastructure.<br>• Lack of investments.<br>• Social and ethnic fragmentation |
| Serbia | • Natural resources.<br>• Recreational potential.<br>• Prospected accession to the EU.<br>• Substantial foreign exchange reserves. | • Dependence on external funding.<br>• Weak infrastructures.<br>• Weak banking sector.<br>• High unemployment. |
| Asia | • Abundant natural and labour resources.<br>• Diversification of domestic production and export.<br>• Solid agricultural potential.<br>• Low-cost labor. | • Underdeveloped infrastructure.<br>• High poverty levels.<br>• Incomplete economic and public sector reforms. |
| China | • Industrial competitiveness.<br>• Output and export diversification.<br>• Infrastructure development.<br>• Gradual market reforms.<br>• Natural resources.<br>• Low-cost labor. | • Low share of consumption in GDP.<br>• Growing social and income inequality.<br>• Gradual drying up of the pool of low-cost labour.<br>• Environmental problems. |

## FUTURE RESEARCH DIRECTIONS

Author believes the major trend of research activities in relation to the economies in transition should be aimed at facing new global challenges. Until the present time, economies in transition have been focused on their domestic developments, but in order to be competitive on the global market they will have to face new global challenges. Integration gains momentum. Neither single country, even such giants as the USA or China, is able to compete. Investigations have to be directed on exploration of economic and trade cooperation of the economies in transition with the international community. China has recently proposed the "five connections" development plan (policy exchange, road network, trade talks,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

currency circulation, and people-to-people friendship), which encourages cooperation at practical and cultural levels (Guoqiang, 2015). Other economies in transition have to investigate implementation of such an approach in their domestic and foreign policies, as it encourages countries to share development opportunities in a mutually beneficial way.

## CONCLUSION

Regardless the region (former Soviet Union, Eastern Europe, or Asia), economies in transition originated from their common socialist-type model of economy, where the dominant state and collective ownership of the means of production minimized the role of natural competitive factors (Kolodko, 1998). Foreign trade was controlled by the state, which resulted in various distortions, low level of diversification, specialization of export destinations and import channels due to political preferences. During early stages of transition, most of the economies of that type experienced a decline in output and export, significant increase in inflation, and decrease in living standards of domestic population. Economic and trade liberalization in transition economies rapidly embedded them into the international market, however, being considerably non-competitive, they had to specialize on low value-added exports and high value-added technological imports. For at least two decades after the beginning of market reforms, most of the economies in transition have not been able to break the existing trade patterns.

Things are changing. Unimaginable growth of China, certain economic successes of Russia and Kazakhstan, and improvements in the region of the Eastern Europe demonstrated potentials of the economies in transition on the global market. By the 2010s, particular countries and their strengthening alliances had been rather effective in increasing their shares in the global output and trade. New economic powers have arose: China, Russia, Brazil, Eastern European and South-East Asian nations. The countries accelerated integration processes between themselves in order to aggregate existing competitive advantages and mitigate market risks. Most of the economies in transition are now involved in various inter-regional and international integration initiatives: the CIS, BRICS, the EAEU, and others.

Despite the evident achievements, transition process goes on and will persist in the near future. Unlike the past two-three decades of transition, coming years will manifest new factors: increasing competition between alliances; intensifying role of trade regulations (unification in the WTO framework and protectionism of particular domestic markets); growing tensions between major global powers as to shape a new multi-polar world order.

Is there a space on the reshaping market for such players, as economies in transition? The long-term outlook of such economies will depend on effective structural reforms, diversification and technical modernization of domestic production and exports, utilization of existing comparative advantages, and benefiting from integration: trade, economic, and financial. Mutually beneficial international trade and economic relations, predictable political situation, favourable regimes for investments, and respect to all foreign partners are key factors of success on the contemporary global market.

## KEY TERMS AND DEFINITIONS

**Economies in Transition:** The countries of the former Soviet Union, Central and Eastern Europe, and Asia, which experienced the Soviet-type model of development and underwent large economic and political transitions from centrally-planned regimes to democratic market economies.

**Emerging Economies:** The countries, progressing toward becoming advanced, but still lacking market efficiency and sustainable market mechanisms, having greater domestic and external risks due to political instability, infrastructure problems and currency volatility.

**Foreign Trade:** The system of international commodity-money relations composed of foreign trade activities of all countries worldwide.

**Global Market:** The system of relationships between buyers and sellers from different countries, who participate in the trade of goods and services.

**Globalization of Trade:** A process of development of an increasingly integrated international market by free trade and flow of capital between nations.

**Trade Liberalization:** A process of reduction or elimination of constraints in the sphere of international trade, including reduction or removal of custom tariffs, import quotas, abolishment of multiply exchange rates, and simplification of administrative requirements to import and export operations.

**Transition Period:** A period of time, when economy is changed to a new condition because of economic and administrative reforms.

## ABSTRACT

*New developments in the Information and Communications Technology industry have substantially increased the importance of the internet over the last decade. As a result, the finance sector has developed its technological capability to be able to compete in an online marketplace with other financial services providers and to be able to serve their customer. This chapter examines the use of technology in the financial industry and the various factors associated with it, as well as introducing the reader to the main types of project initiators-contributor business relations in online crowdfunding.*

## INTRODUCTION

E-Banking also written as electronic banking refers to the usage of computers in carrying out bank transactions. Examples of such transactions include withdrawal of money through cash dispensers or engaging in funds transfer through a point of sale. Electronic banking is also known as internet banking or online banking (Ainin, Lim & Wee, 2005). Therefore, this illustrates the complex nature of the concept of financial services as there is not a universal definition of E-banking. However, it is significant to note that internet or E-banking refers to the use of various electronic services that allow a financial account holder with a particular bank to access all his or her information through a computer. Therefore, in the context of this discussion E-banking will be defined as a self-service activity that permits bank account holder to get access to their accounts, as well as their updated general information on a financial institution's products and services. In addition, these users have the liberty of conducting financial transactions without time or geographical limitation by accessing the bank's website (Kallstrom, 2000, p. 20).

The technological advancement and the use of the Internet have raised a new platform for fundraising known as crowdfunding. Crowdfunding involves three parties: the project initiator or owner who needs funding, the contributor who is willing to give their money and the moderating organization that facilitates the engagement between the contributor and the initiator (Young, 2013, p. 33). Moderation can also be done through technology by the project initiator himself, using Web 2.0 and outside of platforms. The platform involves entrepreneurs or potential business owners asking for funding for their projects from the "crowd" or users from all over the world who may be interested in supporting their cause or business. Crowdfunding allow individuals the possibility to develop into their business ideas, even if it is only with a small amount of money. Governments encourage crowdfunding due to its positive impact on the economy as a whole, as it creates new jobs and fosters the economic growth of countries.

This chapter seeks to introduce the reader to e-banking services, online investments, and the main types of project initiators-contributor business relations in online crowdfunding.

## BACKGROUND

In the late 1970's home banking was the only way of offering financial products without the customer being present at the banking hall (Xu, Wikes, & Shah., 2006, p. 19). Financial institutions call this service home banking; however banks offer this service through phones.

Banking customers were able to transfer money, pay their invoices or check their account credit through touch-tone telephone while they were at home. New software was created that permitted connecting customer to the bank through a dial-up connection. Although in the late 1980s this service was not very popular for several reasons. First, home banking was only allowed for some services agreed by the bank. Second, this new service needed an important investment in technology, and only few financial institutions could afford this cost.

The use of computers was not common at the time in many households (Laopodis, 2013, p. 26). Among the financial institutions that offered home banking services are the leading banks like Citibank, Manufacturers Hanover and Chase Manhattan. All of them had its origin in America, thus showing the contribution of the United States to the e-banking industry. In the mid-1990's banks were starting to realize the need to move their financial services into the virtual realm. Apparently, e-banking was becoming an attractive concept as it helped banks diminish transaction costs; it was helpful in promoting easy integration of services as well as introduced interactive marketing capabilities. Additionally, online banking was instrumental towards boosting the bank's customer lists and profit margin faced by the businesses. Furthermore, internet banking allowed institutions to bundle their services into single packages; thus, attracting more customers at minimal overheads. The period of late 1990s saw the advent of the clicks and bricks euphoria; as a result, many banks realized that e-banking was a strategic and imperative innovation (Lassar, Woodford, & Moschovitis, 2005, p. 15). More so, during this period there were a lot of mergers and acquisitions within the financial industry that resulted in expanding customer base Therefore, financial firms viewed the World Wide Web as the only channel that would help in maintaining customers, as well as build loyalty. However, in the wake of the banks realizing the potential of e-banking a lot of customers across the globe remained hesitant to conduct their financial transaction over the internet. For example, there was the Y2K scare that was a disambiguation about a world crisis by the year 2000. In this connection, many customers feared online transactions because of

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

the fear that all computers would fail. Therefore, to avoid this problem a number of financial consumers were reluctant to move into the virtual world of financial service provision. Companies such as America Online, eBay and Amazon.com invested in marketing purchase of items through online platforms. For example, Bank of America took about 10 years to reach 2 million e-banking clients. In 2009 as per a report by Gartner Group, at least 47 percent of American adults were banking online.

Computational investing is another topic that provides insights on investing and stocks. It includes a collection of theories that have effectively been used as strategies for investing. For instance, John Bogle's passive investment approach recommends that entrepreneurs should allocate resources to assets that have minimum trading expenses. The reason for that is that active involvement in market-stock trade cannot match the returns of the market (Laopodis, 2013, p. 32). In other words, Bogle advocates for a long-term view approach to investing – one should pay attention to taxes and costs. Therefore, according to him, a well-diversified portfolio is an assortment of low-cost assets that have been in the market for a considerable number of years. That is, investors should adopt a buy-and-hold strategy.

Another theory of computation investing is value investing. According to Warren Buffet, who developed the idea, investors should exercise discipline, intelligence, and patience in relation to buying stock (Laopodis, 2013, p. 32). In other words, the entrepreneurs should purchase shares of reputable companies only.

## MAIN FOCUS OF THE CHAPTER

### 1. E-Banking

Internet banking allows access to financial information through accessing internet over a computer or by use of mobile phone that has Internet connection. Mobile banking is the latest revolution in virtual banking, it involves conducting financial transactions via a mobile device; for example, a mobile phone or tablet. The introduction of mobile banking led to new methods of payments by using a mobile phone to pay for commodities or services remotely. The first form of mobile banking was referred to as SMS banking. However, the invention of smart phones has overtaken SMS banking and now users of the internet-enabled mobile phones can use various applications based on the operating system to carry out financial transactions. There has been a remarkable growth in the number of households using virtual banking services. Population born between 1970 and 1990 also referred to as the generation Y embrace technology very fast once it comes to the market. Generation Y account for the highest number of users of online billing services to settle their account on student loans, credit cards and expenditures aimed at improving their lifestyle for example shopping online. Noteworthy, e-banking is highly entangled in every individual way of life without discriminating against age or those with disabilities (see Friedman (2000)).

Internet banking offers various services depending on the bank of choice for each customer:

#### Account Opening and Access Information

Banks that provide e-banking services allow their clients to open new accounts by accessing the bank's website. In order to complete this service, an individual logs in into the bank's website, fill an application online and submit the application. Afterwards, an account holder with online banking services

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

enjoys the opportunity of accessing financial information wherever they are with an Internet connection. Such information may include closing or opening accounts, checking updates as well as make inquiries captured in the account or even making payments.

## Electronic Check Conversion and Transfer of Funds

Electronic check conversion allows customers to convert their paper check to a new electronic payment. Essentially, the benefit of electronic payment is that the account holder with a bank can withdraw money from their account and wait until the other party receives the check. This service is faster as the normal check takes longer duration to process. Customers can also transfer funds across personal accounts and to different users as a way of covering the shortage in some accounts or make payments.

## Download Online Bank Statement

Clients can go through this document because it allows one to check even the previous year transactions so as to make sure accounts are in order (Lassar et al., 2005, p. 24). In the event of complaint, users can save their bank statement either as word or as PDF on their computer, tablets or smartphone for future evidence.

## Buy Financial Products

E-banking allows clients of the bank to buy financial products online. Examples of such products may include deposits, stocks, mutual funds and mortgages. The bank products vary across different financial institutions.

## Buy Good Online

Users of online banking benefit from the ability to login into their accounts and to buy goods online or make payment to their credit card. Nowadays, it is easy to buy goods online safely and quickly or simply make enquiries; therefore, saving on travel costs and time.

## Order for a Check Book

This is a booklet of blank checks that facilitates bank account holders to draw money from their account or deposit funds for the purpose of settling other company accounts or payment of bills (Lassar et al., 2005, p. 30). These checkbooks can be ordered online by e-banking service users, they receive the booklet through their mail.

## Make IRD Payments

IRD refers to the income that an individual is not entitled to receive during his or her lifetime. Such payments include IRA or other retirement schemes that an account holder cannot receive before death. The amount of IRD payments is not part of the final income tax return. This service is now available through internet banking, and it is easy to process all information an individual may need pertaining to IRD payments electronically.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

### Tax Information and Documents

Financial institutions assist their customers to complete several tasks such as offering tax documents online. Additionally, the banks help their clients to fill and submit the forms online. Overall, a financial firm helps in resolving tax related issues and usually this service is available to the customers free of charge.

### Alerts

An account holder with the access of internet banking can subscribe to receive alerts of every processed transaction by the financial institution. Consequently, the service will inform the customer about the existing bank account balance, and introduction of new products and transactions completed.

### The Importance of E-Banking

The main important characteristic of internet banking is significant time management, elimination of queues due to the automation of most financial services and availability of easy maintenance tools for managing one's money. E-banking offers cheaper costs of attaining banking services and increased comfort. With regard to the latter, customers are able to make financial transactions any time of the day, and without physical interactions with the bank.

Another characteristic of e-banking is rapid and uninterrupted access to information. For example, business firms can enjoy easier access to information by checking on multiple accounts at the tick of a button. In addition, internet banking allows for better management of cash by speeding up cash cycles and increasing efficiency of business transactions since numerous cash management tools are available on the World Wide Web. For instance, it is possible to manage a firm's short-term cash through internet banks in money market funds, in commercial papers, in over-night deposits, or in bonds and equities (Appei, 2009, p.7).

Furthermore, e-banking allows a customer to enjoy the convenience of carrying out financial transactions from the comfort of his or her office or home. The fact that e-banking allows a rapid response enables customers to wait until the end of a financial transaction without any fuss about it. Finally, internet banking allows for effective management of funds. Customers are allowed to download their account history and fund analyses on their computers or mobile phones before carrying out any actual transaction.

## 2. Benefits and Challenges of E-Banking

E-banking has transformed the provision of financial services around the world (Liao, Yuan, & Chen, 1999, p. 66). Financial institutions as well as customers obtain certain benefits from using e-banking as compared to the conventional method of banking.

Online banking allows account users to make payments across accounts to just about anyone. For example, client of the bank can choose anybody or any company whom he or she wants to make payments to and the bill pay service will facilitate this transaction.

Internet banking gives the account holder the liberty to control almost every aspect of his or her account. Besides this control over personal or business bank accounts, the customer can access other services within the financial industry (Liao et al., 1999). For example, buy or sell interest-earning assets,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

keep an update on stock market and money market. It is imperative to mention that accessing internet banking services on the bank's website is free, the only requirement is being an account holder with the entity and have access to the internet.

Customers enjoy the benefit of comparing best deals across banks and get access to the best special offers. Often individuals operate more than one bank account; therefore, it is easy using e-banking services to compare products offered by different banks. E-banking service allows bank account holders to access the financial institution on a 24 hours basis (Krantz, 2013, p. 19). Automated teller machines, and access to their bank account through the internet is convenient to the clients. Virtual banking is beneficial to customers because this system helps bank account holders to avoid queues common in banking facilities. Many of the customers who use online banking feel that this system saves time unlike when they spend time queuing in banks.

Internet banking contributes to a reduction of operational costs in the financial Institutions. In the long run commercial banks save on resources that would be paid to the tellers to manage the growing customer base in the bank. Therefore, it is relatively cheap to conduct financial services over the internet for the banks. Virtual banking has allowed banks to acquire a greater customer base through reaching new target markets (Liao et al., 1999). Precisely, the use of internet surmounts any geographical boundaries that would be difficult and expensive to break when using traditional banking systems. Interestingly, the banks use internet to reach the well-off households as internet penetrates highly in households that have a sustainable income. E- Banking reduces the costs affiliated to marketing especially with the introduction of internet marketing, helping to create a similar playing field for small and big banks. Therefore, the upcoming financial institutions can fight for survival through competing for customer base in the same market with the successful banks (Liao et al., 1999). Otherwise, it would be impossible for the small financial firms to compete with the leading companies through the traditional systems of marketing because of capital and market power challenges enjoyed by the big banks.

There has been a significant change in the level of efficiency in commercial banks after the introduction of e-banking. Use of internet in banking facilities allows the firms to operate in a paperless environment. For example, it is easy to keep records within a single file for a huge number of clients. The level of customer service and satisfaction continues to improve remarkably with e-banking systems. Principally, this improvement is attributed by the levels of efficiency in banks. In addition, internet banking offers the customers services that would be difficult to access through bank's branches (Liao et al., 1999). Online banking contributes to a reduction of the number of people visiting the facilities daily; therefore, improving on customer service both online and offline. Using e-banking services helps a financial entity to improve its public image by giving a good impression to existing and prospective customers. Noteworthy, an account holder may not be willing to use e-banking system, but by providing such services a bank helps in promoting a good reputation to the prospective and current customers.

Internet banking is beneficial to the stakeholders in the financial industry. Banks and customers enjoy extensive benefits by using this modern way of accessing financial information and products (Sarlak, & Astiani, 2011, p. 29). However, there are certain concerns or challenges that arise in the use of internet banking. Firstly, with the introduction of this new technology by the commercial banks there is a need to create a customer service support system that will provide support to the clients. Commercial banks face the challenge of maintaining a fast and reliable customer support system in a bid to protect their reputation as well as image in the market. Establishing such systems is costly but it is important towards getting the customers to trust internet banking as a way of undertaking financial transactions. Secondly, laws governing different countries present an interesting challenge to e-banking. Internet banking cannot

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

be limited within a geographical location or borders (Lassar et al., 2005, p. 45). However, each country or state has different laws that are distinct and are not applicable in territories beyond where the laws are enacted. Therefore, there is a need to harmonize some laws pertaining to electronic banking worldwide so as to ensure access to financial information and products is not restricted. Thirdly, the issue of security over the internet is another challenge that continues to affect online banking. In fact, this is one of the challenges for banks as customers inquire know the level of security or protection that virtual technology offers to them before they proceed to open online banking accounts. Internet technology attracts online cyber-crimes, and often bank customers become victims of fraud or theft especially with the use of ATM's (Lassar et al., 2005, p. 45). Hacking and phishing of financial information is an emerging trend and a challenge that banks deal with every financial year. Fourthly, internet banking creates regulatory challenges because of globalization of the financial industry. Internet allows provision of services from any location in the world posing a danger in regulation of financial intermediaries by the central bank. Inherently, commercial banks will find ways to avoid any supervision or regulation by the relevant authorities. For example, it is mandatory for every business to acquire a license from the government; similarly, financial institutions have to establish a licensed branch before they are granted permission to venture into virtual banking (Marina, 2009, p. 4). Fifthly, internet banking has led to increased activities of money laundering. Anonymity is one of the features evident with electronic banking. A client opens an account in a bank, but it is difficult for the financial entity to identify the type of business the nominal account holder is undertaking or even the location of the transactions. Presently, many governments have put up guidelines to combat money laundering. For example, it is mandatory for every individual opening a bank account to verify their identity and notify the bank of their residential address (Marina, 2009, p. 6). Finally, online banking poses serious macroeconomic challenges to the country's economy. For instance, the technological revolution in the finance industry particularly the advancement of banking practices makes it difficult for central bank to implement monetary policy. Consequently, it is always a challenge for the central bank trying to control economic activities and inflation especially with the globalization of financial services. In essence, expansion of electronic banking leads to a significant decline in financial transaction costs. Consequently, this leads to cheap credit in the economy hence eroding the effectiveness of monetary policy. Tobin tax is an example of a tool used by many governments towards controlling availability of credit in the economy especially it helps to increase costs of accessing financial products from the banks by the borrowers.

## 3. Investing Online

Some of the concepts discussed in Modern Investment Theory and computational investing are useful to stock brokers, especially when opening an online account. A stock broker is an individual or company that trades in shares on behalf of a client. If the interaction between the client and the broker is through a website, the broker is referred to as an online broker. The online service allows the investor to allocate some funds to the brokerage firm for the purchase and sell of stock. Normally, the transactions occur on order basis, that is, the client must request the broker to buy or sell profitable shares. Apart from trading in shares, a significant number of online brokers also provide other support services such as tax reporting, creation of financial statements, and so on. Optionally, an investor may decide to do the online trading independently. That means the entrepreneur will need to open an online stock brokerage account. To succeed in such a venture, the entrepreneur must consider several factors.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Firstly, the investor needs to acquire a portfolio tracking tool, which is a set of online tools that provide information on the trading of stock. Hence, the tool allows investors to keep a close eye on the performance of their stock while shopping for additional profitable investments. The portfolio tracking tool can be treated as an additional expense to the cost of opening an online brokerage. However, an effective method would be to treat portfolio tracking as a support service provided by an online broker (Hart, 2005, p. 36).

Secondly, transaction costs are incurred in operating the online brokerage account. Normally, the online broker that hosts the independent stockbrokerage account charges a specific amount for each transaction executed. In other words, an online broker may provide the portfolio tracking tool at a low cost, but charge the investor highly per transaction (Hart, 2005, p. 42).

Apart from that, some hosts charge for stop-sell order requests. Therefore, investors should take time to compare the charges of different hosts to ensure that they get value for their money.

Thirdly, the type of account matters. Often, investors have the option of opening either an individual retirement account (IRA) or retail account. Before opening an IRA, the entrepreneur should consult a tax advisor because some of the transactions done through the account are taxable. For instance, if a transfer of funds is done from the investor's IRA to an online broker's IRA, there are no tax penalties or consequences. However, taxes apply if the investor withdraws money from an online brokerage IRA. Conversely, transferring funds to a retail account has no tax implications. Similarly, the purchase of stock through the use of funds in the retail account has no tax implications. However, the income from the stocks sold through the account is taxable (Hart, 2005, p. 50).

Additionally, investors expect returns in form of dividends from companies in which they own shares. The dividends may be scrip dividends or dividend re-investment plans (DRIP). For the investors that subscribe to the scrip-dividend policy, the expected cash returns are automatically converted to new shares. Conversely, for those in DRIP, the cash dividends are first sent to a scheme administrator who then may use the funds to acquire the company's shares through the stock market or send the money to the stakeholders. Therefore, before opening an online account, the investor should consider the reinvestment service offered by the host (Hobson, 2012, p. 15).

Also, the investors need to determine the means through which they will fund their online brokerage accounts. Firstly, capital may be sourced from savings. In this case, keeping money in bank accounts yields low annual interest. Depositing the money into an online brokerage account will result in better cash benefits. Secondly, the IRA is also a source of funding. In this case, the funds can be transferred from an existing IRA to the online brokerage IRA mentioned earlier. Thirdly, the investors can opt to make direct deposits. In this regard, the cash-in-hand that they possess should be greater than or equal to the bare minimum required to open the online brokerage account. Given that the option will force the entrepreneurs to develop a working plan on how to make regular deposits into the account, discipline is required (Hart, 2005, p. 55). The investors can obtain additional hard cash from gifts, financial assets converted to money, extra income, refunds, and so on.

Therefore, before opening an online brokerage an account, one must consider several things. These include the type of account to be opened, transaction costs involved, and customer service. The investor should also take into account how the online brokerage shall be funded, the cost of the portfolio tracking tool, and the dividend re-investment policy provided. Once these queries have been addressed, the next step is to open an online brokerage account (Hart, 2005, p. 57). In reference to that, it is worth noting that managing a profitable stock investment portfolio requires thorough knowledge of ways of investing.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## 4. Trading Stocks and Options Online

Online stock trading is another important subtopic of investing and stocks. This type of trade is to some extent similar to regular transactions that involve one walking into a shop, picking the required items, paying for them, and leaving. That is, the online traders select the shares they prefer and electronically transfer the sum required for the purchase. Once the money is received, the sale is reflected. However, online trading has some complications because the prices of stocks are set in real time (Krantz, 2013, p. 129). Thus, the online investors have to use the following options in trading through the internet.

Firstly, customers can trade their stocks online through market orders. In this case, they have to instruct their stock brokers to sell their stock. Normally, the brokers are requested to sell the shares at the highest price that a willing customer is ready to pay. As a result, such orders are quickly executed (Krantz, 2013, p. 129). Given that it is easy to find such willing buyers, the online investors pay a small commission for the brokers' services.

Secondly, stocks can be traded online through limit orders. In this case, the online investors are allowed to set the prices at which they are willing to purchase or accept the sale of stock (Schwartz, 2010, p. 156). For instance, consider an entrepreneur who owns 40 shares, each valued at $100. Suppose the price of the stocks is declining and hence the investor estimates that soon the value of a share will plunge to $70. In this case, the online investor can sell the shares in two ways. The first option is through the market order, which was discussed above. However, that may not give the best returns since the buyers may momentarily offer lower prices than the projected minimum. Optionally, the online investor could set the lowest selling price at $85 to minimize losses. Thus, so long as the decline proceeds as expected, the limit order is the preferable alternative. When the shares' price falls to $85 per unit, the broker will sell all stocks if possible. Limit orders are not based on price alone. Some investors give a deadline within which to sell the stocks (Krantz, 2013, p. 129).

Sometimes, one may not obtain the returns expected after the sale of shares through the limit orders. This is because the shares' price may decline so rapidly that the seller is unable to place the stocks on sale at the agreed price. In this case, the broker may only sell a restricted number of stocks. The rest of the shares are kept in the investor's portfolio. Thus, the limit orders provide a false sense of security.

Online investors can also use stop market orders to trade online. This type of order is similar to a limit order in that a minimum buying or selling price is set. However, for the stop market orders, when shares' price reaches the designated value, the orders are converted into market orders (Krantz, 2013, p. 130). For instance, using the previous example, the broker may be instructed to execute a stop market order when the stocks' price reaches $85. In this case, if the value of shares suddenly plunges to $80 per unit, the online broker would still have to sell the shares at that price.

Fourthly, the shares can be traded through a stop limit order. This option is similar to a stop market order. However, once the defined price is exceeded, the stop limit order is converted into a limit order (Krantz, 2013, p. 130). Thus, the stop limit order prevents the sale of shares if the value of the stocks falls beneath the limit price. To elaborate further, still using the same example, suppose the activation price for selling stocks is $85 and the limit value is $75. When the shares' value falls below $85 per unit, the order becomes a limit order. Hence, when the price reaches $75, the broker is supposed to sell every available stock at that price (Krantz, 2013, p. 130). However, a further decline in price would result in no sale at all. That is, the remainder of stock is kept in the online investor's portfolio.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Lastly, the online stocks can be traded through a trailing stop. This type of order basically follows the market. For a favorable market, rising stock prices, the online investor instructs the broker to retain the shares until the value of the securities reaches a predetermined value. This order is referred to as a trailing sell stop. For a bearish market, the broker is expected to sell the shares as the stocks' price approaches a set minimum value (Pardo, 2008, p. 85). This order is known as an exit trailing stop. Thus, the online investors continuously search for positive yields during the stocks' transaction life.

Apart from stocks, options can also be traded online. An option is a financial instrument that gives one the right to sell or purchase a precise quantity of underlying stock at a prearranged price within a defined time period. The option seller is not legally obliged to carry out all the tasks stipulated in the contract when the financial instrument is handed over to a buyer. The online trading of options is done through screen-based or electronic methods. In the United States of America, there are several institutions – exchange companies – that specialize on options trading. They include the International Securities Exchange (ISE), Boston Options Exchange (BOX), and NASDAQ. The online trading of options has advantages as well as prerequisites that are worth discussing in details (Fontanills & Cawood, 2009, p.43). The online trading of options yields more benefits to the online investor than full-service or traditional brokerage. For example, for this type of trade, commission expenses are lower. That is, the traditional broker may charge $100 for a round turn, whereas an online brokerage charges only several dollars (Fontanills & Cawood, 2009, p. 45). In this case, a round turn refers to each deal or sale. Normally, a commission cost is charged on all orders. The charge applied varies depending on the service being offered. Also, the commission expenses decrease as the services offered to the investors increase. Another advantage of the online trading of options is that the online investors receive considerable support in terms of information as opposed to what happens in traditional brokerage.

## 5. Online Crowdfunding

A new startup needs some amount of funds in order to get the business started. In order to transform the entrepreneurial project into a reality, then it is necessary to have adequate cash to execute all such plans. Moreover, the fundraising will help the entrepreneur to develop the business model for the growth of the project and a successful business marketing plan (Damos, 2014, p. 32).

The technological advancement and the use of the Internet have raised a new platform for fundraising known as crowdfunding. Crowdfunding involves three parties: the project initiator or owner who needs funding, the contributor who is willing to give their money and the moderating organization that facilitates the engagement between the contributor and the initiator (Young, 2013, p. 33). Moderation can also be done through technology by the project initiator himself, using Web 2.0 and outside of platforms. The platform involves entrepreneurs or potential business owners asking for funding for their projects from the "crowd" or users from all over the world who may be interested in supporting their cause or business. Crowdfunding allow individuals the possibility to develop into their business ideas, even if it is only with a small amount of money. Governments encourage crowdfunding due to its positive impact on the economy as a whole, as it creates new jobs and fosters the economic growth of countries.

This chapter seeks to explain the main types of project initiators-contributor business relations in online crowdfunding.

The term crowdfunding is a relatively new concept to the market, however its origin comes from the construction of the Statue of Liberty's Pedestal. John Pulitzer, who was a popular publisher at the time, employed his newspaper to collect money for the construction of the pedestal. The initiative raised

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

100.000 dollars in only six months. Pullitzer promised to print the name of each donor, regardless of the amount of money donated. In August 1885, Pulitzer announced that he had collected the amount to $100.000 for the statue's pedestal. The Statue of Liberty, that had arrived from France packed in crates, was erected the next year. (See Young, (2013)). Nowadays, Crowdfunding is becoming is already very popular around the world and the Internet platforms are leading the rasing of funds.

In 2013, Crowdfunding raised over 5.1 billion dollars to help people in various projects all over the world and the figure is projected to increase in the future with the new platforms becoming more popular (See Crowdfunding Industry Report from Research firm Massolution). The new law of the Jumpstart Our Business Startups (JOBS) by President Obama in 2012 introduced a regulatory framework. Most of it still has to be translated into active regulatory elements to this date, protecting donors to crowdfunding projects and enabling businesses to use crowdfunding as a real source of funding. The Act enhanced the credibility of the platforms for crowdfunding while at the same time ensuring that the project owners or entrepreneurs had a viable and a good source of funding for their projects. Kickstarter and Indiegogo are some of the most popular platforms boasting of members in millions of all parts of the world, these websites have enough people to pool huge amounts of resources for the funding of their businesses.

There are different types of relations between project initiators and contributor in online crowdfunding:

## Reward-Based Crowdfunding

The reward-based form of crowdfunding is the most popular type with most contributors and initiators preferring this method due to the security of their funds under this method (See Crowdfunding Industry Report from Research firm Massolution, 2014). In reward-based crowdfunding, the target amount has to be established first for the completion of the project (Steinberg, 2012, p. 97). Then, the person or organization sets up donation amounts with an attached incentive that is proportional to the amount donated for the project. This method is hugely popular for artists, movie directors and other projects that have an aesthetic or prestigious value to the donor. For instance, if an artist was looking for a donation to help with a tour of Europe, he may offer signing autographs to people that will contribute $500 and backstage preparation with the cost to people contributing $1.000. These incentives ensure that the enthusiasts and the music lovers are motivated to donate to the cause (Young, 2013, p. 79). One of the unique characteristics with this method is that if the set platform allows for the project owner to get the amount only after the targeted amount is reached, he/she cannot be awarded the amount collected in case the donors do not raise all amounts. The donors can therefore get their money back and they have the confidence of recovery of the raised amount as a result (Agrawal, Catalini, & Goldfard (2015)).

One of the major benefits of reward-based crowdfunding is that it has low risks for the promoter or the company that is behind the campaign to raise funds or donated amounts. Once a company has raised the required amount for the project and they may have had the donations only with a special clause for the specific project they are able to avoid dealing with debts, credit implications or interest that is attached to the loans or government grants (Bruntje, & Gajda, 2016, p. 45). The reward-based crowdfunding method offers the chance to completely avoid all these problems and start their business or project without any possibility of future shortcomings due to any changes in the plans or the success of the project. The reward-based method also runs on low cost with the project owners being offered a chance to showcase their projects for only a small fee of their total collection and there are no high costs of managing the platform. As opposed to raising money through other conventional methods, where a person could end-up incurring a lot of costs for setting up the funds, crowdfunding sets this up at only a

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

small fee and the project is viewed and supported by millions from all over the world (Roebuck, 2011, p. 104). The reward-based method also offers the donors a chance to gain a personal connection with the project they have donated towards and the people they have funded.

## Equity-Based Crowdfunding

Equity-based crowdfunding is a form of crowdfunding where the contributors become part-owners of the company raising funds. Equity-based is not a popular form of crowdfunding since the majority of the projects are not huge companies that donors and people funding the projects can get a stake and own part of (Douw, 2012, p. 60). Most of the projects are by entrepreneurs who do not have shares that the investors can invest in. However, since the enactment of the Act in 2012 this form of crowdfunding has gained popularity with most people seeing it as an investment opportunity for the interested investors in lucrative projects that the investors deem to pick up and be beneficial in a near future. This is offered at very low rates as compared to the market rate since the project owners will need to make their proposal and project attractive to the potential investors through their competitive prices and growth potential in the future (Douw, 2012, p. 60).

Equity-based form of crowdfunding is slowly catching up with the other methods of crowdfunding. It is, however, a safe and viable method to raise money for the company and beneficial for the donor if the company makes profits in the future and they gain from the dividends or distribution. Equity-based crowdfunding can also be used to create a venture finance market. Equity crowdfunding does not only involve the shares as the only forms of securities, but also debt notes, convertible notes, and hybrid forms of equity and debt (see Freedman & Nutting, 2015, p. 5). In addition, there are some forms of partnerships that qualify as securities in equity-based crowdfunding. One of the main attributes of equity-based crowdfunding in creating venture-based market is its ability to connect startup business and the medium businesses to the larger investor community. Equity-based crowdfunding offers a platform to reach out to the companies through a single advertisement on the web. It ensures that the information reaches out to interested potential buyers and sells the business to the investors (Mollick, 2014). The venture space is therefore in ensuring that the investors and the business people meet. In addition, the venture space ensures that people with similar businesses and ideas can interact and advise each other on the best practices and the best ways to improve the businesses. The venture space is not only useful in raising the funds, but also ideas and plans on the best ways to improve the business given that there are other members of the crowd with the same ideas. It can also lead to mergers and amalgamation of two or more different venture businesses since the equity-based crowdfunding targets the business people who are interested in increasing their venture capital either through shares or other securities. The equity-based finance structure has a pool of professional small and large businesses that need a regular appraisal either through funding or through further investments (Steinberg, 2012, p. 113). Economic growth is also a factor that is hugely influenced by the success of the equity-based crowdfunding, since the growth of business companies contribute to the economic growth of the country. Most governments all over the world are taking up the new platforms and legislations have already been passed to ensure that crowdfunding for businesses and individual projects help the larger financial community that is the whole country. The venture finance marketplace has therefore transformed the equity-based crowdfunding concept to rally the support of the government and security legislations since it has been viewed as a milestone and a new trend in the financial sector.

## Reward-Based Crowdfunding

Credit-based crowdfunding is a method where the donors to a specific project loan out money to the person in the hope of future repayment of the amount owed. This is the safest method of crowdfunding for the donors since in case the project owner defaults in payment of the advanced loans the platform is liable for the payment of the loan to the donor (Tomczak & Brem, 2013, p. 341). Under this method the borrowers submit an amount that they wish to be loaned and the donors interested in the specific project advance the borrower the amount with a promise of repayment at a future date. The platform acts as the intermediary and or surety for the borrower and the donor to ensure that the donor gets the amount back and facilitate the pooling of funds for the borrower. The borrowers find crowdfunding attractive since it has very low or no interest rates for the borrowers and they only have to incur a fee to process the funds by the platform and agree on a flexible payment plan to refund the amount forwarded. In the event that there is any interest to be charged on the amount of money borrowed the borrower sets the interest to be charged that they are comfortable and can guarantee a refund within the stipulated time period (Mollick, 2014). This makes the method attractive for the borrowers since they are not required to pay a minimum or set interest rate that is predetermined and as a result they can guarantee payment. The lenders on the other hand have to evaluate the project for its risks or benefits and potential and establish if they are willing to lend money at the interest rate set by the borrower. The arrangement is similar to that of a bank loans with the main difference being the predetermined interest rates. Whereas in credit-based crowdfunding the borrower sets the interest rates, inviting donors to fund the project in a bank loan the borrower must agree to the terms set by the bank or the authorities involved (Althoff & Leskovec (2015)).

One of the main advantages is that the borrower does not have to give any form of collateral to the lender and they transact only in terms of good faith from the borrower and the donor of the project. The donor funds the borrower in the hope that they will repay the money not because they have a history of repaying or they have presented evidence to suggest that they are capable of repaying the money but only on faith they have on their project. This ensures that the platform eradicates many processes of loan funding and borrowing that would slow the timeline of acquiring a loan. Background checks run by the banks and also the examination of the presented information are a large part of the processing process making it tedious and time consuming. The process also rules out borrowing from poor and new business people that are looking for money to kick start their business and have no collateral or no history to guarantee payment of the amount that they have borrowed. Crowdfunding offers such people a chance to borrow even huge amounts of money without any form of guarantees and guarantors. Credit-based crowdfunding has been immense in eliminating the factors that hinder borrowing and lending since there are none in crowdfunding. The project and presentation of the ideas are the most important aspects of a project if one aims to be funded for a project accordingly. It is therefore advisable for one to lend both their time and resources in the presentation of the project to as many people as possible.

## Donation-Based Crowdfunding

Donation-based crowdfunding is the last method available for funding new initiatives. In this method, funds are raised for an initiative of public interest, although there is no economic benefit to the community financing the initiative. One of the greatest challenges of social entrepreneurs today is accessing startup

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

capital, that´s why donation-based crowdfunding makes this method an interesting financing solution. One example of donation-based crowdfunding is the 2008 election campaign of President Obama, the campaign team collected more than $137 million by this method.

One of the risks in a crowdfunding initiative is targeting and unrealistic financing initiative, as crowdfunding platforms charge a larger percentage fee if the target is not met, failing to deliver on the project's promise will negatively affect the project's reputation. Thus, it is very important to engage the potential community into the project and design the project according to their interests. That´s why advertising the campaign is an important part of the crowdfunding process, always keeping costs in mind, it is important to advertise the campaign through several channels and reaching the largest possible potential supporters. Most donations-based crowdfunding initiatives reward donors with something in exchange for their contribution. Typically this is some kind of perk, this is usually the most expensive part of the crowdfunding campaign. The most challenging part of the crowdfunding process is moving from the zero donation phase, as potential donors usually imitate what other supporters did, then a potential donor might be not willing to give funding to a project when no money has been raised yet. Encouraging close friends and contacts to contribute in the initial stages of the campaign will be helpful. The Regional Studies Association (RSA) explains that the most critical zone is when the 10%-50% of the initiative has been funded, as most unsuccessful campaigns fail somewhere in this range. Thus, in order to take the initiative to reality it is essential to push the campaign after the launch with advertising and showing previous donations. In initiatives involving social entrepreneurship like the ones involving this type of crowdfunding it is more important to have the certainty that it is a feasible project, as a poor crowdfunding campaign could harm the reputation of the company and affect future initiatives to get funding. Another important issue to consider is that the amount raised can be affected by declined funds later on coming from credit cards, wrong donations, or fraud.

## 6. Security in E-Banking and Finance

Some factors affect the safety of internet banking and online financial services. These include regulatory body supervisions, customer awareness, and internet infrastructure. On the other hand, according to Chavan (2013), increased use of the internet and mobile services as a new channel for distribution of banking services requires more thought towards security against sham activities. However, this responsibility should not be left to banks alone; Lee (2012) explains that customers and regulatory bodies also have a role in e-banking security. Furthermore, banks do not have any influence regarding the electronic devices and channels used by their customers to perform transactions.

The bank should create a procedure to increase security. Firstly, it is supposed to formulate a secure online banking infrastructure. Then it should ensure the implementation of an appropriate information security policy. Thirdly, the bank should provide a robust monitoring system for fraudulent activities and notify its account holders of any high-risk transactions through SMS. Fourthly, the bank is supposed to offer a two-factor authentication (TFA) protocol for its account holders. The first factor is something like a PIN number, which the customer knows, whereas the second factor is something that the customer will own such as a smart card with a chip authentication (Lee, 2012, p. 8). On the other hand, the customers' responsibility is to ensure that they have enough knowledge regarding the safety tips required in e-banking. For instance, a customer should always stay alert in safeguarding his or her identity as well as limiting public access to personal computers. According to Lee (2012), there are numerous tips for

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

safely logging on and off to a computer (Lee, 2012, p. 10). For example, a customer should never use a public computer to access his or her internet banking website. Customers should also close any open tabs and windows in a browser before logging on into e-banking. Moreover, after using the online service, the customer should always remember to log off. In safeguarding their identity, customers should use unique passwords that are difficult to guess. According to Lee (2012), a strong password should have at least six characters with a combination of numbers and letters. Furthermore, it is good for customers to often change their passwords and disable the 'Autocomplete' function in their browsers so that it does not remember previously input data.

Lee (2012) also advises that customers should never leave their TFA devices unattended (Lee, 2012, p.14). Other tips include disconnecting internet connections when not in use, backing up critical data on removable hard drives or Compact Discs, and installing internet security software for real-time detection of intrusions on a customer's computer. The roles of regulatory bodies in e-banking security are also several. According to Lee, regulatory bodies should develop adequate policies that promote customer protection and international cooperation among partners (Lee, 2012, p. 19).

## CONCLUSION

The e-banking revolution has quickly changed the global business of banking. As a result, banks all over the world have reoriented their business strategies in order to encompass the new opportunities offered by online banking. In other words, the banking sector has led global electronic trade in recent years. Internet banking has enabled banks to change strategic behavior, scale borders, and create new possibilities as a result. Furthermore, internet banking has changed banking services towards the neoclassical economic theories of market functioning. Due to this, the market has become transparent and clients can easily compare banking services from different banks. For example, while using the internet, the customer is only one-click away from competitors. Thus, if a client is not satisfied with the products or services offered by one bank, he or she is able to change to a preferred banking partner faster and more easily.

Online investing has tremendously reduced the physical costs of operations. As Williamson (2006) stated, technological advancements in information technology have reduced the costs of processing financial information, whereas use of the internet facilitates transmission of financial information. In fact, this is why online financial services have gained popularity in recent years. In the future, this will ensure that banking rates are friendly as well as encouraging to more innovations regarding the current products and services being offered by banking institutions. In addition, electronic delivery of financial services has enabled banks to meet their clients' expectations and create close customer relationships (Williamson, 2006). Hence, as discussed by Chavan (2013), online banking will eventually triumph over traditional banking in the coming years as more developing nations are now building their economies with specific focus on e-learning, e-commerce, and e-banking.

Online crowdfunding has funded many new companies and initiatives in their initial stages and is substituting the funding of organizations with more online platforms being created. The examination of the risk from both sides, the borrower and the donor, is essential before making an investment or borrowing to make sure that the business is finally successful. The legislation of the Act has enabled the platforms to conduct business better and have a larger crowd since the donors have the backing of the government and the law while engaging in the business.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Online Crowdfunding has introduced new funding new funding mechanism and rules for news businesses. Most of crowdfunding funds are collected through reward-based platforms, however equity crowdfunding is becoming more popular. It is expected that online crowdfunding will grow in popularity as many new crowdfunding opportunities become available. A new business that seeks funds through the online crowdfunding process comes out stronger as for the questions that has to answer and the scrutiny that it is put under, compared to convince a single angel investor. It is worth mentioning that because a startup does not obtain online crowdfunding does not necessarily mean that the business is not viable. It might be that investors may not be on that platform or perhaps is not the right time. One of the biggest challenges ahead will be communicating efficiently and engaging with investors after successful funding. Investors will possibly be interested in the big numbers and updates instead of the news from daily operations. Investors will be more likely to reinvest if they are kept engaged and the company is looking after them. Creating a mutual interest might foster that investors act as ongoing mentors in the business.

The importance of e-banking and online financial services can be summarized as significant time management, elimination of queues, cheaper costs. Customers are able to make financial transactions any time of the day, and without physical interactions with the bank. Another characteristic of e-banking is rapid and uninterrupted access to information. Furthermore, e-banking allows a customer to enjoy the convenience of carrying out financial transactions from the comfort of his or her office or home.

Security is an important issue in e-banking and finance. Banks have to create the organizational procedure for security. A secure online banking infrastructure is necessary, as well as the implementation of an appropriate information security policy, the bank should provide a robust monitoring system for fraudulent activities. Finally, the bank is supposed to offer a two-factor authentication (TFA) protocol for its account holders.

## KEY TERMS AND DEFINITIONS

**Angel Investor:** An investor who provides funding for small startups or entrepreneurs.

**Crowdfunding Platform:** Internet platforms which enable companies to advertise over the internet and obtain investments from registered users in return.

**E-Banking:** The performance of banking business through the internet. It is also known as "Internet banking" or "Online banking".

**Electronic Commerce:** A business model that enables to conduct business over the internet.

**Financial Institutions:** An institution that provides financial services to potential clients.

**Information Technology:** It is the use of any computers, storage, networking and other processes to create, store and exchange electronic data.

**Online Security:** Computer security related to the internet involving browsing and network security. It is designed to establish measures to use against attacks through internet.

**Online Trading:** Individual investors buy and sell stocks over an electronic network through a brokerage company.

# Chapter 92
# Nanotechnology, Long Waves, and Future of Manufacturing Industry:
## Comparative Analysis of European Union, East Asian Newly Industrialized Countries, and MENA Region

**Cem Okan Tuncel**
*Uludag University, Turkey*

**Ayda Polat**
*Uludag University, Turkey*

## ABSTRACT

*This study concerns the long wave theory of capitalist development with an aim to discuss and analyze the impact of nanotechnology on manufacturing industry. Long wave theory was asserted by Russian economist Kondratieff and it states the capitalist development with subsequent cycles which last 40 to 60 years each. The theory of Kondratieff was also contributed by other scholars as Schumpeter, Freeman, and Perez. Our research attempts to review how nanotechnology contributes economic growth, and how it changes the structure of manufacturing industry at the eve of the sixth Kondratieff wave. This structure was examined by using comparative case study of European Union, East Asian Newly Industrialized Countries and Middle East and North African (MENA) countries.*

## INTRODUCTION

The 2007-2008 crisis that went down in history as the first global crisis of the twenty first century and qualified as the “great depression”, brought together the debate about the economic growth and industry policies of many countries. Starting from 2008 the American mortgage crisis has transformed into a

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

global crisis and hit many national economies. While the world's growth slowed down, industrial production declined owing to both global and domestic demand collapse in many countries. It can be said that world economy has divided into two main economic sides since the late 1990's. One of the sides, the so called surplus economies, consists of national economies which have technology intensive industrial production base and competitive advantages in the engineering industry (automotive, machine, electronics, chemistry) such as Germany, South Korea, China, (albeit China's export depends on less technology intensive sectors); on the other side, the so called deficit economies, consisting of the USA, Southern parts of the European Union (Italy, Spain, Greece, Portugal), and Turkey. It is observed that behind the processes of their growth; are the fund flow and borrowing capacity of households through expanding credit, rather than relying on a successful technology-intensive industry capacity. This financial-based growth inevitability resulted in debt crises in many countries such as Italy, Greece, Portugal, and Iceland.

This debate that is ongoing in academic circles is related to how capitalism will get out from the ongoing stagnant conjecture and how a stable and sustainable economic growth would be ensured in the world's economy by reducing uncertainties after the crisis. While understanding the fact that the stagnancy caused by the crisis, which commenced in the global financial markets and dominated the real economy by expanding in a short period, would last for an extended period caused a questioning of the current industry policies, it accelerated the new industry policy searches that constitute an alternative for such policies as well. Countries are in search of a new industry policy for the revitalization of the industry and for recapturing permanent growth. In today's world where the demands for reindustrialization are increased, this priority is set to render the country's industry policies with the growth targets and base them on a sustainable growth strategy (OECD, 2013). The moving force of this new industrialization process will be the new generic technologies. In the OECD countries, share of the manufacture industry within the national production-added value and employment has been diminishing for the last thirty years. While the industry is losing its competitiveness, service sectors are growing more rapidly. The findings of UNIDO from the data that involve 90 countries in the 1950-2005 period, showed the proportion of the manufacturing industry within the GDP presents the fact that this proportion varied between 25 and 40 percent in the period subsequent to the Second World War in the early industrializing countries and exhibited a tendency toward a rapid decrease after 1980. The findings show that the regression in the proportion of the manufacturing industry in the GDP encountered since the 1980s are being experienced in developing countries (UNIDO, 2013).

It is clear that the crucial factor determining underlying competitiveness and economic growth is innovation. The growth of the GDP is positively related to the growth of the manufacturing sector and the productivity of the manufacturing sector is positively related to the growth of the manufacturing sector as well (Kaldor, 1967; Verdoorn, 1993).[1] Various studies in economic growth and development literature have shown that there is a robust and positive correlation between economic growth and technological capabilities of economy, export performance and industrial productivity (e.g. Stern et. al. 2000; Fagerberg & Verspagen, 2007; Fagerberg, 1987, 1996, 2005). It is important to understand that manufacturing industry is not only the main driving factor of economic growth but also the main source of technological development. After new technologies are firstly applied in manufacturing, they diffuse to other sectors such as services, construction, and agriculture (McKinsey, 2012). Hence surplus economies owing to their own industrial infrastructure have become more resistant against the crisis tides. For this reason, the European Commission recommended reinstalling industrialization plans to reverse the declining role of the manufacturing industry and increase its share of European Union GDP in 2011 as a preventative

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

measure to the crisis (European Commission, 2012). The future of European manufacturing industry debate has underlined the necessity and importance of supporting generic technology research areas such as nanotechnology, green technology, and biotechnology.

While growing literature on recent crises focuses on financial market failure, bad governance and wrong policy, few scholars have taken account of the structural roots of global crises (e.g. Šmihula, 2009; Gore, 2010; Devezas, 2010; Korotayev & Tsirel, 2010; Perez, 2009). Indeed; financial boom-bust cycles stemming from financial market failures or lack of sufficient regulations on the market is the conclusion of the crises rather than the cause. Actually, the structural roots of the recent crises should be searched for within long run development dynamics of capitalist economy. Long wave theory is the main way to explain this long run development dynamics. This approach was postulated by the seminal work of the Soviet economist Nikolai Kondratieff. He observed long-term economic fluctuations in cycles of 40 to 60 years (Kondratieff, 1935). This approach was transformed to an analytical and theoretical framework for understanding technological evolution and social change in historic times by Schumpeter and his followers. This study aims to analyze the impact of nanotechnology on the manufacturing industry. Advances in science and technology, especially in material science, microelectronics, information technology, biotechnology and nanotechnology will profoundly affect manufacturing. Our research tries to review how nanotechnology contributes to economic growth and changes the structure of the manufacturing industry on the eve of the sixth Kondratieff wave. This framework is investigated by using a comparative case study of European Union (EU), East Asian newly industrialized countries (NICs) and Middle East and North African (MENA) countries.

This paper will be organized as follows: In the first section, long wave theory from neo-Schumpeterian perspective will be examined. In the second section, the potential impact of nanotechnology on industry and its opportunity window will be drawn. In the third section, the role of nanotechnology research on industrialization strategy will be discussed via the comparative case study of the EU, the East Asian economies and MENA countries.

## LONG WAVES THEORY OF CAPITALIST DEVELOPMENT AND SCHUMPETER'S CONTRIBUTION

The theories that try to explain the capitalist development on the basis of long waves that are rising and falling into the stagnancy and crisis environment in connection with the termination of the postwar expansion period after the 1970s are gradually attracting the attentions of more and more economists. Different from the short term fluctuations referred to as the business cycles, development dynamics of the capitalist economy defined as long waves have become a rapidly growing field of research. According to the fundamental results reached by these different studies, economic development in capitalism forms as the consecutive big waves and the impacts and results of each of these waves expand within an entire period and leave its place in time for the subsequent waves of progress. The conjecture theories asserting that economy navigates with long termed fluctuations with ups and downs and that it has waves consisting of improvement, well-being, shrinkage, and crisis stages that have 40 to 50 years of life were presented for the first time in the article entitled "Long Waves in Economic Life" published by N. D. Kondratieff in 1919 (O'Hara, 1994). These long termed fluctuations can be considered to have consisted of four main periods which are improvement, well-being, shrinkage, and crisis. In 1939, Joseph Schumpeter suggested naming the cycles "Kondratieff waves (K-wave)" in his honor (Schumpeter, 1939).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Since the late 18th century, economists have empirically proven five Kondratieff waves. The fifth Kondratieff wave ended with the turn of this century, while a new long cycle, the sixth Kondratieff, has begun (Linstone & Devezas, 2012). The sixth wave will likely be focused on emerging research areas such biotechnology, "bioelectronics", nanotechnology and new material sciences (Perez, 2008; Klein, 2005).

Long wave theory was progressed by contribution of Joseph Schumpeter, one of the original social scientist of the twenty century (Fagerberg, 2003, p. 127). He developed an original approach focusing on the role of innovation and entrepreneur in economic life (Schumpeter, 1934). Economic development had to be seen as a process of qualitative change which is determined by innovation in Schumpeter's opinion. Innovation, in his view, as a new combination of existing resource was realized by entrepreneur. Schumpeter's dynamic theory used analyzing long run development of economy as well. According to his theory, K-wave begins with technological innovations, which then become the cornerstones of a prolonged economic upturn (McCraw, 2006). Innovations have clustered in certain industry and trigger new bursts of productivity throughout the entire economy. Productivity of whole economy began to decline because booster impact of innovations ran out. This periodic upward-downward motion of economic activities, so-called long wave, in world economy mainly has been determined by clustering innovation.

Schumpeter has scrutinized the capitalist system within the framework of the non-balance evolutionary process instead of the neoclassic stable fixed state balance approach. Innovation underlies the foundation of Schumpeter's this change dynamic, which is internal with its capitalist development. Innovation is defined as the presentation of the current resources as the new amalgamations (Schumpeter, 1934, p. 66). There are five basic innovation forms that are the source of an economic change.

1. New consumables: development of the new products qualified as the product innovation.
2. New production methods: use of the new techniques in the production qualified as the process innovation.
3. New markets: development of the new markets or new marketing possibilities.
4. New raw material resources: start of utilizing of new resources.
5. New industrial organizations: changes in the form of business conduct qualified as organizational innovation.

Those who realize innovations are the entrepreneurs. An entrepreneur is the person who pursues new products, who is in new searches in terms of the management of the firm, and who explores new markets. The role of an entrepreneur is to renew and remedy a production system by means of utilizing

*Table 1. The Kondratieff Waves*

| | Technological Revolution | Period of technological Revolution |
|---|---|---|

an invention or a technique that has never been used in general (Schumpeter, 1942, p. 202). Schumpeter's entrepreneurs do not come from a certain class; they constitute a talented minority (Heilbroner, 1999). This elite human type exhibit talent differences within itself. Differentiation of the agents, which ensure technological development, within themselves, constitutes the engine of the technological diversity and evolutionist development. The motive that activates an entrepreneur is profit. Profit is the gain of conducting innovation and obtained by entrepreneurs. In the appearance of innovation, bank loan plays a central role. In addition to the creative entrepreneur, risk-undertaking banker is the most significant element of an economic development (Hanusch & Pyka, 2007, p. 282). There is an inseparable union between the entrepreneur and the banker. According to Schumpeter, internal change dynamics of a capitalist economy is "innovation (reason)", "entrepreneur (subject)" and "bank loan (instrument)" (Gürkan, 2007, p. 254). Schumpeter defines capitalist economy as an unending "creative destruction" process. Every firm within the capitalist system try to increase its market share, and to have a dominant state by means of finding a new design, cost reducing endeavor, a new product, and new inputs as well as of developing new production methods. However, each innovation destroys the monopolist power preceding itself. This creative destruction waves constitute the basic dynamic of the long term development of the capitalist economy. Basic factor underlying the long fluctuations following a trend of decrease and increase in the capitalist development is that while new sectors where the profit shares and investment opportunities are extremely high depending on the innovation aggregations are appearing, the sectors based on the current matured technologies are disappearing in line with their loss of their profitability ratios. From this time, the topic of the causes of long waves remains central in the agenda of the neo-Schumpeterian tradition which is placed itself opposite to neoclassical economics, based on maximization behavior of rational economic agents. This analytical framework has been developed via contributions of neo-Schumpeterian scholars since the beginning of the 1980s.

## NEO-SCHUMPETERIAN TECHNO-ECONOMIC PARADIGM APPROACH

The Neo-Schumpeterian approach expounds the long waves of capitalist development within the framework of the scientific advancement model developed by Thomas Samuel Kuhn, an American physicist, historian, and philosopher of science. According to Kuhn, a stable period that is referred to as a normal scientific period is interrupted by a crisis period and this crisis period allows the inauguration of a new normal scientific period by causing the appearance of a scientific revolution (Kuhn, 1962). The current scientific paradigm defines the rules, standards, and scientific research methods shared by scientists, and create an ambiance of reconciliation for the continuation of the research tradition. Neo-Schumpeterian theory, or the technoeconomic paradigm approach, is a theory that combines Kondratieff's long waves theory with Schumpeter's economic development theory and that focuses within the capitalist development process on technological change (Taymaz, 1993, p. 14).

Techno-economic paradigm approach which focused on long run socioeconomic and institutional change dynamics of capitalistic economy by using K-wave framework was based on this neo-Schumpeterian tradition. Dosi (1982) defines technology paradigm as a "model and pattern of solution of selected technological problems based on selected principle from the natural science and on selected material technologies" (p. 150). This conceptual analysis provides framework to understand how technology change in specific direction, and why this direction transforms. The paradigm thus limits the possible directions technological development may take. According to this approach, institutional environment is

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

itself endogenous factor which is determined by technological development. Moreover techno-economic paradigm approach provides theoretical background for analyses long wave in economy and understanding the groundbreaking transformation in society. Changes in techno-economic paradigms may be said to redefine the trajectory not only of the technological and economic spheres but also of the social sphere (Perez, 2008). Each techno-economic paradigm requires a new infrastructure allowing the new technologies to be diffused throughout the economic system while the dominant characteristics of the production system are restructured to incorporate processes that allow new products to be created and distributed. For each paradigm, there are common denominators that influence the behavior of the relative costs, supply and diffusion of new technologies and the organization of production processes (Dosi, 1984). Thus the notions of trajectory or paradigm highlight the importance of incremental innovations in the growth path following each radical innovation. Though it is true that major innovations have a central role in determining new investment and economic growth, expansion depends on incremental innovation (Perez, 1983, 1985, 2002).

According to Schumpeter, every long wave is unique because of the technological newness differences in that period on one hand and of the difference of the historical events such as wars, discovery of gold mines, or famine on the other. However, in the explanation of this long term fluctuations, the most important factor is innovations, which is the engine of capitalist growth source of the profits of the entrepreneurs (Freeman & Soete, 1997). The expression of technoeconomic paradigm contains, as a meaning, the economical selection process among a range of innovations that can be technically realized. In reality, a new paradigm's becoming clear takes relatively a long time (a few decades); expansion of this within the entire system takes longer. This expansion contains an interaction process where, among the technological, economic, and political forces, corporate innovations (or corporate renewals) gain utmost importance (Freeman, 1989, p. 89). For understanding the technoeconomic paradigm change, basic analysis level is the innovations also highlighted by Schumpeter. Some changes stemming from the innovations in their technological systems are so long-ranged in terms of the results they create that they have a substantial impact on functioning of entire economy. These changes form the phenomenon that Schumpeter names as "creative gales of destruction" that constitutes the main axis of his "long cycles in the economic development." Basic power underlying such creative destruction gales is the innovations that intensify in a certain historical period. Innovations are analyzed under four headings (Freeman & Perez, 1988, pp. 45-47):

1. **Incremental Innovations:** They are the minor technological changes that are encountered in the industry and services, that take place in different rations among industries from country to country, and that provide very little continuation. They are the innovations that mainly take place not as a result of the R&D studies but depending on the learning-by-practicing processes and the improvement of the engineering activities taking part in the production process or through the impressions and recommendations of the users.
2. **Radical Innovations:** They are the important and effective technological changes that appear as a result of the R&D activities, that do not exhibit a continuous feature, and that take place unequal among sectors. Even though the radical innovations such as nylon create significant structural changes, their impacts on the generality of the economy are relatively small and local.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. **Technological System Changes:** Deep-rooted technological changes causing the formation of the new sectors that affect the different sectors in economy. It stems from the amalgamation of the radical and incremental innovations in the manner that it will cover the organizational innovations affecting one or multiple firms. Synthetic substance innovations, petro-chemistry innovations, and internal combustion motor innovations can be exemplified for such changes.
4. **Techno-Economic Paradigm Changes (Technological Revolutions):** Some technological system changes have substantial impacts on the entire behavior of economy. These types of changes take place by way of the aggregation of the radical and incremental innovations and joint appearance of numerous technological systems as a result of it. Characteristic feature of a technological revolution is not its widespread impact on every branches of economy, not only on some products, services or sectors.

Technological revolutions or creative destruction gales create significant changes on the social structure. In order for these changes to expand along the entire economy, fundamental transformations in the manner of organization of production must be realized. Such technological revolutions cause the occurrence of rapidly shifting production functions for both the old and the new products. The extent of savings to be obtained in the labor or capital cannot be initially estimated completely; but the general economic and technical benefit in the design of the products and production method by means of using new technology become visible well by increasing gradually and new practical rules are also developed gradually. Such shifts in the paradigm make it possible to make a significant spurt in the potential productivity but such spurt takes place initially only in a few leading sectors. These gains cannot generally take place without organizational and social changes in other sectors (Freeman, 1989, p. 90). In order for the new economic paradigm to be superior over the old paradigm, it has to have the factor that can be defined as a group of key inputs that are unique to the new paradigm. These factors must have the following conditions (Freeman & Perez, 1988, p. 48):

1. Low and rapidly decreasing production costs;
2. Possibilities of supply that seem to be endless in the long term;
3. In the entire economy, potential of use in many products and processes

After the new technoeconomic paradigm dominates, it develops beneath a new orbit. Even though technological diversity grows rapidly as a result of the technological revolution, the productivity increase that will appear among the sectors based on the newly emerging technologies has a limit. As long as the possibilities of the new technological paradigm are consumed, profits will fall one by one as the sectors will come down to the level of growth and productivity increase speed will slow down (Taymaz, 1993, p. 15). Loss of productivity by the current paradigm will push economy toward the search of a new paradigm and the system will transit to a new technological paradigm. According to the neo-Schumpeterian approach, capitalist development process consists of five Kondratieff waves that are consecutive to date. Paradigm transitions have impact on the developing countries' industrialization dynamics. In the period of which the current technoeconomic paradigm is stable, corporate constructs will contribute to the development of the system harmonious with the dominant technological structure.

Capitalist development's stagnation depending on the technology matured within the current techno-economic paradigm will cause that a long-wave will enter a regression path decreasing the profit ratios. In the regression stage of the long wave, financialization appears as a historical resort with the purpose

of getting rid of the tendency of stagnancy encountered in economy. In this financialization period, in order to overcome the structural stagnancy by means of financial speculation and indebtedness, partial demand expansions are created. These demand expansion waves bring about problems as it is unable to constitute a sustainable growth. These problems expand toward high unemployment, incomplete employment, frequently encountered recessions, collapse of the stock exchange, and deflation. Deepening of the crisis will ensure the transformation of a technological system for the commencement of new increase waves. With the 2008 crisis, the debates regarding the structural roots of the crisis bring the fact that whether we are in the beginning of a new Kondratieff wave into the agenda of the economic arguments. In this context, the impacts of the crisis, the future of the manufacture industry, and whether a re-growth trend based on new technologies exists or not have become an important subject of debate. Another matter of debate is about the countries that might make use of the opportunity windows that will be opened in such a technological paradigm transition period.

Hence, in the following section, the opportunity windows opened by the techno economic paradigm changes and the situation of the countries that made use of it in the transition period before the opportunity (microelectronic revolution) and that are referred to as the Asian Tigers (Taiwan, South Korea, Hong Kong, Singapore) will be briefly presented and their position within the current paradigm change process will be scrutinized in comparison with the EU countries and other developed countries.

## Technoeconomic Paradigm Changes and Opportunity Windows: Rise of Asian Tigers

Perez and Soete's (1988) argument that new technological revolutions and paradigm changes open windows of opportunity that allow developing economies to catch up. These authors propose that the early entry into new techno-economic paradigm is the crucial point for the process of catching up. Within the technoeconomic paradigms, there are the product cycles presented by Vernon that affect developing countries' industrial developments and that make it possible for them to catch up to the developed countries. Depending on the standardization of product technology, comparative superiority will develop for the benefit of the developing countries. In this process, current standard products will be started to be manufactured by the developing countries' industries and this industrial output will open opportunity windows for the countries whose increased potential is developing (Shin, 1996, p. 18). Perez and Soete (1988) assert that the actual opportunity windows that will be a solution for the developing countries' development problems will appear within the technoeconomic paradigm change period. According to the authors, being the one that enters first into the technoeconomic paradigm has critical importance for the developing countries in order to capture what is developed.

The crisis encountered in the 1970s caused the experience of a substantial shrinkage in the developed countries' manufacture industries. This shrinkage intensified especially within the heavy industry sectors. In the developed countries, this deindustrialization phenomenon caused the increase of these countries' export from the developing countries to increase especially in the labor-intense industries (Dicken, 2007; Piore & Sabel, 1984). The phenomenon of deindustrialization within these central countries created an impact toward the development of the industries of the developing countries. Impact of this phenomenon on the spatial distribution of the global production system took place differently. Developing countries exhibited a substantial spurt in these industries as a result of the loss of productivity in the labor intensive sectors within the central countries. While the economic depression within the central countries in general were affecting the developing countries negatively, the NICs of Eastern Asia (Asian Tigers)

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

found the opportunity to develop their own industries by gaining particular advantages in the world's market within the global shrinkage age. Depending on the regional integration of labor in Eastern Asia, Japan became the country that had the most dynamic and competitive economy in the 1970s among the developed countries. NICs of Asia were added to the economy centered from Japan and they gained significant advantages in terms of production and growth. On this phenomenon referred to as the "East Asian Exceptionalism", geopolitical features of the world's system in addition to these countries' industry and technology policies they applied were effective.

According to the East Asian Exceptionalism approach, economic slow-down and industrial increase on global regional, national level are differentiating. For example, the economies referred to as the Asian Tigers exhibited a substantial development in exports in the 1960-1988 period and export commodity compositions were transferred to the technology intense goods in the manner that it is not encountered in the other developing countries (Yoo, 1999, pp. 76-77). In this context, behind the process referred to as the East Asian exceptionalism, underlies the fact that they successfully applied corporate arrangements that will support the newly emerging microelectronic-based technologies by making use of the "opportunity windows" created by a Technoeconomic paradigm transition age (Perez, 1985). Especially, South Korea (hence after Korea) terminated the import substitution stage earlier and adopted an export-led development strategy in the 1970s and entered the process of a rapid industrialization with the technology, education, and economy policies managed by a developmental state. In this region, in addition to Korea, Taiwan and Singapore has adopted this strategy and created the miracle of the Asian Tigers. Within the industrialization process, learning is the result of the integration of an overt and covert knowledge. Learning is first stage copycat imitation within the firm. The basic products manufactured at this stage are the products such as textiles, toys, and household goods that are labor intensive but with low technology. This stage basically has four knowledge accumulating mechanisms. These are training, direct foreign capital investments, grand-scale firm constitutions, and experienced technical workforce. Korea started this stage in the 1960s. Second stage is the "creative imitation stage" and shows itself with the expansion of the knowledge-based production. At this stage, knowledge has five basic sources. Formal technology transfer, reverse brain drain, integrated R&D, and universities and public research institutions. Korea started this stage in the 1980s. Exports of consumer electronics, automotive, semiconductor technology products increased during these years. The final stage is "the innovation stage". In the previous stages, knowledge or technology can be used by transferring or purchasing. However, at this stage, creation of knowledge and technology are necessary. At this stage, creation of technology has five fundamental mechanisms. The basic researches at the universities and implementation of the programs for the target by the public research institutions have accelerated the learning process.

Between the years of 1980 and 2000, developing countries' industrial product export growth speed and added value's growth speed they obtained from the world manufacture industry navigated above the world's average. Developing countries' share in the manufacture industry added value, which was 13.3% in 1980, increased to 23.8% in 2000 (Lall, 2004, p. 8). The countries group that increased its share most is the Eastern Asian countries that are expressed to have created a development miracle.

The Asian countries that focused on the technoeconomic transition age on the establishment and development of microelectronic based industries did know how to make use of the opportunity windows created by the transition age. Hence, while their share they received from the world's manufacture industry production is increasing continually and the competitive power increased in the industries based on the information and communication technologies, especially in Korea and Taiwan. On the other hand, as presented in the Vernon product cycle theory, the Latin American countries and the countries like

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Turkey that applied the export of the products with matured technologies whose production was given up by the developed central countries by producing them through the advantages created by the low labor costs failed to make use of the opportunities created by this age of transition.

In order to make use of the opportunities to be created by the New Technoeconomic paradigm; the standards of judgment based on the old paradigm, research practices, and business conduct models are expected to be rendered harmonious with the requirements of the new paradigm. The countries that fulfill this requirements and having a scientific infrastructure focused on the production of technology will make use of the possible opportunity windows that will be opened in this paradigm transition process.

## SIXTH KONDRATIEFF DEBATES: NANOTECHNOLOGY AND FUTURE OF MANUFACTURE INDUSTRY

Nanotechnology, one of the generic technologies at the beginning of sixth Kondratieff, has great potential for economic growth. Some authors has suggested that the nanotechnologies will be part of the next technological revolution because they have the potential to create big changes in technologies, products and industries, with social and economical implications to long term (Perez, 2002). Few new technologies have been accompanied by such expansive promises of their potential to change the world as nanotechnology (Wonglimpiyarat, 2005). Nanotechnology has important implications for most sectors namely medicine, information, energy, materials, manufacturing, instrumentation, food, water, the environment and security as key areas (Kostoff *et al*. 2007). Nanotechnology presents a new revolutionist approach in the fundamental researches (Wonglimpiyarat, 2005; Nefidow, 2002). Investment on the technologies in nano-scale will drive the technological conventionalization defined in macro and micro levels toward the nano-systems. A new paradigm change will reveal the requirement that the old systems must be designed again as a whole. In order to create a sustainable and information-based industry system, it will be obligatory to create a nanoscience-based new research paradigm. Even though nanotechnology is principally similar with molecular manufacture, it is an applied science focusing on studying the innovations of the nano-dimensional matters resulting from the dimension-based phenomena (Roco, 2003). Nanotechnology is related to the real-life implementations of the findings of nanoscience Nanotechnology's impact is so widespread that an excessively absolute definition can be illustrated in the manner that its actual scope is not realistic. Nanotechnology is the total of multiple technologies, processes, and techniques rather than a specific field of science or engineering (Roure, 2013).

The fact that nanotechnology is an interdisciplinary science and its domination of the different areas brought together the cooperation of the scientists from different disciplines and has the potential to impact many areas fundamentally in view of its outcomes.[2] In the forthcoming years, indispensableness of nanotechnology for many fields will be understood better. The added value that will be obtained especially in health, defense, textiles, energy, electronics, and photonics will take part in the market of high products and are expected to pave the way for new sectors (Roco, 2005).

Countries' industries will rise on the technologies and products that are obtained as a result of the rapid nanotechnology researches. In the nanotechnology field, the largest investment in the world is made by the USA. In the USA, national nanotechnology investment was 710 million dollars for 2003, which was increased to 850 million dollars for the first half of 2005. The US is followed by Japan with 650 million dollars and the European Union (EU) with 400 million dollars. Nanotechnology has become a sector that is growing in the entire world like an avalanche. In this field, 20 thousand researchers are studying

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

worldwide at present. According to the estimations of the American National Science Academy, the number of the workers who will be working in the nanotechnology production sector in the forthcoming 15 years will be 2 million. The fact that nanotechnology is in the early stage creates substantial growth potential for the countries that will produce and develop this technology (Perez & Dominique, 2008).

Nanotechnology's evolution as a technologic system is presented in the Table 3. While the 2001-2010 period marks a period in which nanotechnology is used more indirectly, it is seen that its use for improving the current products and processes is widespread also in this period. In the period that started subsequent to 2011, we witness that nanotechnology has transcendent the improvement of current product process or industries and started to create new product processes and industries. In this period, the transformation impact of nanotechnology on the industry is gradually increasing (Roco, 2011, p. 433).

When the basic indicators are reviewed about nanotechnology in Table 4, it is seen that the US is the banner-bearer in terms of this technology. And a significant growth in every indicator appears to have been realized from the scrutiny of the basic indicators of the technology in the 2000-2008 periods. The biggest growth takes place in the R&D investments in this technology field and in the patents received (Roco, 2011, p. 429).

*Table 3. Transition between the Two Predominant Phases in Nanotechnology Development, 2000-2020*

| Interval | 2001-2010 ("Nano 1") | 2011-2020 ("Nano 2") |
|---|---|---|
| Measurements | Indirect, using time and volume averaging approaches | Direct, with atomic precision in the biological or engineering domains, and femtosecond resolution |
| Phenomena | Discovery of individual phenomena and nanostructures | Complex simultaneous phenomena; nanoscale integration |
| New R&D paradigms | Multidisciplinary discovery from the nanoscale | Focus on new performance; new domains of application; an increased focus on innovation |
| Synthesis and manufacturing processes | Empirical/semi-empirical; dominant: top-down miniaturization; nanoscale components; polymers and hard materials | Science-based design; increasing molecular bottom up assembly; nanoscale systems; increasingly biobased processes |
| Products | Improved existing products by using nanocomponents | Revolutionary new products enabled by creation of new systems; increasing bio-medical focus |
| Technology | From fragmented domains to cross-sector clusters | Toward emerging and converging technologies |
| Nanoscience and engineering penetration into new technologies | Advanced materials, electronics, chemicals, and pharmaceuticals | Increasing to: nanobiotechnology, energy resources, water resources, food and agriculture, forestry, simulation-based design methods; cognitive technologies |
| Education | From micro- to nanoscale based | Reversing the pyramid of learning by earlier learning of general nanotechnology concepts (Roco, 2003b) |
| Societal impact | Ethical and EHS issues | Mass application; expanding sustainability, productivity, and health; socio-economic effects |
| Governance | Establish new methods; science-centric ecosystem | User-centric ecosystem; increasingly participatory; techno-socio-economic approach |
| International | Form al S&T community; establish nomenclature, patent, and standards organizations | Global implications for economy, balance of forces, environment, sustainability |

In the evaluation of the countries' current statuses in terms of the nanotechnology, the superiority of the developed countries stands out. In the Table 5, Nanotechnology R&D expenditures in the business sector are presented. According to the data given in the table, the countries that spent most for R&D are the US, Germany, Japan, and Russia. Mexico and South Africa, which will be evaluated later on within the developing countries category, are the countries that make investment on nanotechnology as well. Belgium, Italy, Switzerland, and Czech Republic within the EU are also conducting R&D activities.

In the Table 6, the number of firms active in nanotechnology is presented. The countries where the nanotechnology firms are most intense are the US, Germany, France, Japan, and Switzerland. These countries are also spearheading in terms of the number of the dedicated nanotechnology firms. The USA and Germany, France, Switzerland, Italy Belgium, and Denmark in the EU and specifically Japan in Asia seem to be the countries that have succeeded to establish nanotechnology-based business sector.

In the Figure 1, share of the countries in nanotechnology patents filed under PCT are presented. When examined in terms of the countries and country groups, the USA is by far superior in regards to nanotechnology patents. In terms of the country groups, the EU is listed second. Within the EU, the leading country in terms of the nanotechnology patents is Germany. Within the Asian countries, Japan and Korea are the countries that stand out. The countries group referred to as the BRICS (Brazil, Russia, India, China, and South Africa) countries is rated five in terms of number of patents. Within the

*Table 6. Number of Firm Active in Nanotechnology, (2011 or latest available year)*

| Country | Nanotechnology firms* | Dedicated nanotechnology firms** | % dedicated |
|---|---|---|---|
| **United States** | 4.928 | 575 | 12% |

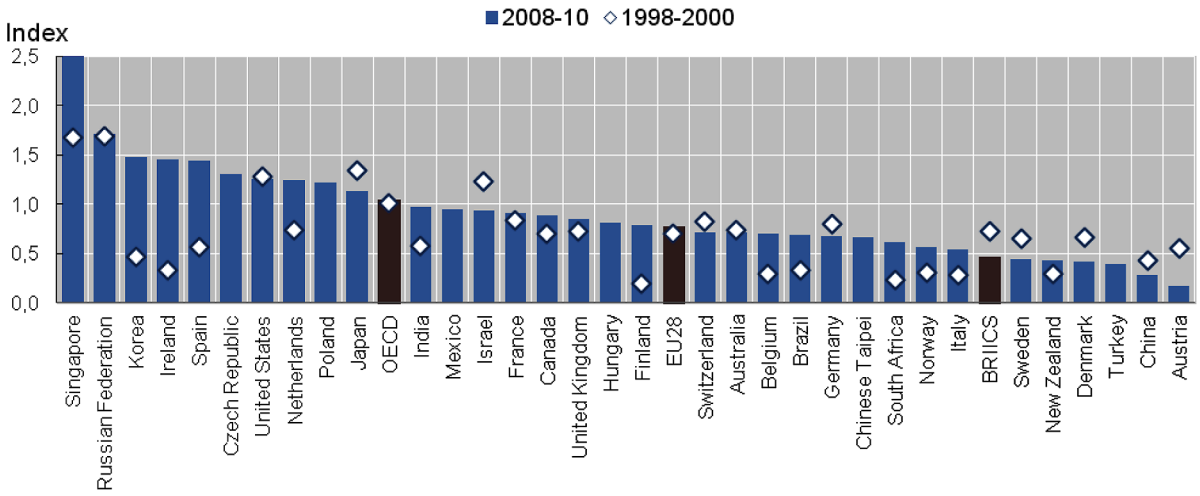
*Figure 1. Share of Countries in Nanotechnology Patents Filed Under PCT, (2008-10)*
**Source:** *OECD, Key Nanotechnology Indicators.*

EU, the countries producing technology in the field of nanotechnology after Germany are France, the United Kingdom (UK), and the Netherlands. Among the developing countries (DCs), China is the leading country in regards to the number of the nanotechnology patents.

In the Figure 2, "Revealed Technological Advantage" in nanotechnologies is presented. Thanks to an index, technological advantages of countries in nanotechnology and the relative change of these advantages are presented for the 1998-2000 and 2008-2010 periods. According to the results of this index, within the meaning of the country groups, OECD countries and the EU countries are protecting their nanotechnology advantage they obtained in 1998 to 2000. BRICS countries seem to have lost their advantage they had in the 1998-2000 period. On country level, the Asian countries like Singapore and Korea and the EU countries like Ireland, Spain, Norway, Italy, Finland, and the Netherlands increased their nanotechnology advantage, compared to the previous year. The countries like Japan, Israel, Denmark, and China seem to have lost their technological advantages compared to the 1998-2000 period. The USA, Germany, and Russia have protected their technology superiority in terms of nanotechnology. The countries exhibiting most development between the two sub-periods compared are the countries referred to as the Asian Tigers, such as Korea and Singapore, and Spain, Ireland, Belgium, and Finland. Being within the developing countries category, South Africa and Brazil have become the countries that are developing their technological advantage. The technological advantage of these countries that are among the BRICS countries has developed stems from the relative recession of the superiority of the BRICS countries as a whole and from the decrease of technology investments in China and India.



On the subject of nanotechnology, having a role of technological superiority depends on imposed national scale state policies on technology based development. Taking these national programs aimed for the nanotechnology area very dedicatedly starting with a budget is extremely important. There are national research programs in the countries that make technological effort on the topic of nanotechnology.

According to European Commission strategy document nanotechnology open up the possibility of important developments, trend breaks, for a sustainable European manufacturing future. For this reason nanotechnology is accepted as the key manufacturing technology by policy maker in the EU (European Commission, 2003). Over the last decade the EU has established a strong knowledge base in nanosci-

**Source:** *OECD, Key Nanotechnology Indicators,*

ences. Several EU countries have dedicated research programs from the mid to late 1990s. Despite the fact that some countries do not have specific nanotechnology initiatives, relevant R&D is often embedded within other programs such as the Framework Program (FP). Within the EU, however, Germany and France implement specific national programs aimed for nanotechnology based technological development. Numerous collaborative research projects and other initiatives have already been supported via the EU Framework Programs. While the fourth and fifth Framework Programs have already funded a good number of nanotechnology projects, only in the sixth one nanotechnology has been identified as

*Table 7. Accountability for Public Spending in Nanotechnology towards a Responsible R&D Scheme*

| Country | Funding Programs | Nano-Specific? | Value |
|---|---|---|---|
| **Brazil** | Ministry for Science & Technology | No | R$11.87 million (€4.9 million) |
| **China** | Medium & Long Term Development Plan | Yes | US$38.2 million (€29.1 million) |
| **European Union** | Framework Program | No | €3.5 billion |
| **France** | Nano 2012 Program | Yes | €500 million |
| **Germany** | Nano Initiative – Action Plan 2010 | Yes | €370 million |
| **India** | Nano Mission | Yes | Rs. 1000 crore (€144.8 million) |
| **Japan** | MEXT | No | €470 million |
| **Russia** | Development of nanotechnology infrastructure in the Russian Federation for 2008-2011 | Yes | €693.3 million |
| **UK** | Research Councils UK/Technology Strategy Board | No | €256 million |
| **USA** | National Nanotechnology Initiative | Yes | $2.1 billion (€1.6 billion) |

**Source:** Roure (2013, p. 16).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

one of the major priorities (European Commission, 2004, p. 8). USA is a pioneer country on this technology established a special program called 'National Nanotechnology Initiative'. Brazil and India as a 'developing countries' have special program for nanotechnology as well. R&D programs of several countries were presented in Table 7.

In the period when world industrial production has shifted from west to east in order to attain the objective of re-industrialization which has been proclaimed by European Commission in 2011, Europe should base their industrial infrastructure on the new technologies particularly on nanotechnology. Asian Tigers well evaluated opportunities opened by techno-economic paradigm's process of change in the end of 1970s, which is Fifth Kondratieff's period of rise. Nowadays industrialized Asian countries like Korea, Taiwan, Singapore and particularly Japan using their opportunity utilization experience value a lot investment in technology based researches. The research facilities of Asian countries in nanotechnology were summarized in Table 8.

*Table 8. Nanotechnology Research and Policies in Asian Countries*

| Country | Research policies and activities |
|---|---|
| **Thailand** | Research activities in the field of nanotechnology are intended to respond to scientific and technological needs of Thai government's policy. The National Nanotechnology (Nanotech) is set up with an aim to increase Thailand's competitiveness. The R&D areas of focus include advanced polymer, nanocarbon, nanoglass, nanometal, nanoparticles, nanocoating, nanosynthesis with applications to the industries of automotive, food, energy, environment, medicine and health. |
| **Malaysia** | The Malaysian government sets aside, under the eighth Malaysian Plan, USD 8 million for research in nanotechnology and precision engineering technology. The research projects in focus are nanophysics and nano-chemistry. Malaysia currently invests in high-cost laboratories to incubate and develop new technologies, in an attempt to shift from a traditional manufacturing and assembly base into nano-R&D. |
| **Singapore** | Singapore's government policy in nanotechnology promotion is focused on disk storage and biological fields. In 2002, the National University of Singapore Nanoscience and Nanotechnology Initiative (NUSNNI) was established as an interdisciplinary group to accelerate nanotechnology business. |
| **China** | The Chinese policy involved 'Climbing Project on Nanometer Science' (1990–1999). China has budgeted USD 240 million in less than five years from the central government and approximately USD 240–360 million from local governments for nanotechnology research. The areas of strength are development of nanoprobes and manufacturing processes using nanotubes. |
| **S. Korea** | The Korean government formulated the 'Comprehensive Plan for Nanotechnology Development' in 2001. It also launched a National Nanotechnology Program covering various fields whereby nanomaterials is one of the key research areas. The research projects are funded jointly by the government and the private sector. Major funding agencies are the Ministry of Science and Technology, the Ministry of commerce, Industry, and Energy. The research programs funded by the Ministry of Science and Technology are mostly basic nanotechnology while the Ministry of Commerce, Industry, and Energy supports the research programs close to commercialization. |
| **Taiwan** | Taiwan launched the National S&T Priority Program on Nanotechnology in Taiwan (NPNT) with a budget of USD 680 million for research in nanotechnology. The implementing mechanism of fund allocation is according to a 20C/60/20-rule, with (1) 20% of the funding to be targeted towards nanotechnology with short-term commercial potentials, particularly those help upgrade the competitiveness of the traditional industries, (2) 60% of the R&D resources to be invested in the fields that will impact future competitiveness of current Taiwan hi-tech industries, (3) 20% of the project to be concentrated on the exploratory studies for potential applications that will generate innovative and new technologies. |
| **Japan** | Nanotechnology is ranked as an important field in the Second Science and Technology Basic Plan of the Japanese government. In 2002, the Japanese government announced the promotion of the 'New Industry Development Strategy' to tie nanotechnology and material science with new industries. Japan views the development of nanotechnology as the key to restoring its economy. In addition to government sponsored R&D, large corporations—Hitachi, Sony, Toray, Mitsubishi, Fujitsu, and Mitsui have invested in nanotechnology research. |

On the other hand, as the last debt crisis in the EU revealed, based on industrial production between the northern industry decline and southern structural problems are seen as the biggest obstacles in front of the goal of re-industrialization. However, there is no particular united technology program for nanotechnology in the EU. Especially Germany and France, within the EU, promote research activities on the subject of nanotechnology. After these countries, Netherlands, Finland, Belgium, Spain are the countries that invest in nanotechnology.

## SIXTH KONDRATIEFF DEBATES AND OPPORTUNITIES FOR MENA COUNTRIES

MENA countries are included in the group of the oil exporting countries and other developing countries[3]. The basic development indicators for MENA region are presented in the Table 9.

They are upper-middle and lower middle countries except the oil-rich countries like Saudi Arabia, Qatar, Kuwait and Omman (Yousef, 2004, p. 92). The big stagnation of which the world economy has entered into following the 2008 crisis has put on the agenda the discussions about the assertion that the world was at the eve of a new technological revolution. In terms of share of GDP, manufacturing industry in MENA countries is generally quite low. Industrial production in the region has historically been focused on labour intensive and low-tech sectors such as textiles, oil production, food processing (O'Sullivan *et al.*, 2011). When we have a look at the economic situation of the MENA region from the perspective of techno-economic paradigm, we observe that the chances of the countries of this region to make use of windows of opportunities that would be opened up by the age of technological transformation is very low.

*Table 9. Basic Indicators for the MENA Region, 2013*

| Country | Population (millions) | Population Growth (Annual %) | GDP, US$ (billions) | GDP Per Capita (current US$) |
|---|---|---|---|---|
| **Algeria** | 39,2 | 1,9 | 210,183 | 5371 |
| **Egypt** | 82 | 1,6 | 271,972 | 3314 |
| **Iran** | 77 | 1,3 | 398,904 | 4763 |
| **Iraq** | 33 | 2,5 | 222,879 | 6670 |
| **Jordan** | 6,5 | 2,2 | 33,678 | 5214 |
| **Kuwait** | 3,3 | 3,6 | 183,219 | 56,367 |
| **Oman** | 3,6 | 9,2 | 80,570 | 22,181 |
| **Libya** | 6,2 | 0,8 | 75,456 | 12,167 |
| **Morocco** | 33 | 1,5 | 104,374 | 3109 |
| **Qatar** | 2,1 | 5,6 | 202,450 | 93,352 |
| **Tunisia** | 10,8 | 1 | 47,128 | 4329 |
| **Saudi Arabia** | 28,8 | 1,9 | 475,272 | 25,852 |
| **Yemen** | 24,4 | 2,3 | 35,956 | 1473 |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

MENA countries couldn't have reached a high rate of growth in the last 30 years. As presented in the Table 10, a significant part of the countries of the region have shrunken instead of growth (e.g. Algeria, Iraq and Qatar). In the recent years on the other hand, the countries of the region have failed to realize a good performance of growth as a result of the crisis conditions prevailing in the world due to the political ambiguity. Hakura (2004) has examined the growth performance of 16 MENA for the period 1980-2000 comparatively with other developing countries. The average rate of the growth of per capita real GNP of MENA countries during the said 20 years period has been zero %. While the oil exporting countries within that group has shrunken at the rate of -1.1% / year, the countries which are not oil exporter have realised an average annual growth of 1.4%. While the average annual growth rate of the East-Asian countries has been 4.1% during the same period, the growth rate of the DCs outside East-Asia has been 0.3%. When we have a look at the facts from the point of view of the performance of growth we may say that the countries of the region have remained far behind especially the East-Asian countries of which economies are based on the export of industrial goods. On the other hand, oil exporting countries have incurred the process which is called "the curse of natural resources"4 in the literature because they have an economy which is based on a single natural resource and has consequently showed a performance of growth which is lower than that of the group of countries which don't export oil. When the countries of the region are analysed among themselves we see that the MENA countries converge towards each other conditionally. An inquiry that covers 22 MENA countries during the 1970-2003 period shows that an absolute and conditional convergence has taken place but the speed of convergence was slow (Sameti et. al., 2010). However it seems quite difficult for the countries in the region which are in the middle-income group, to get rid out of the middle-income trap in which they have fallen. While the countries which have suffered economic crisis have experienced a slight process of recovery albeit below their real potential of growth in the aftermath of 2011, the rate of growth in the oil exporting countries has

*Table 10. Growth performance of MENA Region(GDP per capita-annual %)*

| Country | 1981-2010 | 2011 | 2012 | 2013 |
|---|---|---|---|---|
| Algeria | -1,4 | 2,8 | 3,3 | 2,7 |
| Egypt | 2,2 | 1,8 | 2,2 | 2,1 |
| Iran | 0,4 | 3 | 3 | -5,8 |
| Iraq | -2,8 | 9,7 | 7,2 | 4 |
| Jordan | -0,4 | 2,6 | 2,7 | 2,8 |
| Kuwait | -2,6 | 6,3 | 6,2 | n.a |
| Oman | 2,1 | 5,5 | 5 | 5,1 |

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

dropped as a result of the decreasing demand in the world economy. When considered from this point of view we see that macro-economic vulnerability increases not only in the crisis-ridden countries but also in the oil exporting countries in the region.

The countries of the region have been at the stage of a series of political changes especially in the aftermath of global crisis. In addition, The Arab Spring which has been triggered by factors such as the high rate of unemployment among the young generation, unfair distribution of income and political degeneration has deeply influenced not only the crisis-ridden countries but also the entire MENA. The Arab Spring has before all else led to the decrease of the rate of the economic growth in the region. Setbacks down to 40% have been observed in the industrial output especially in countries like Egypt and Tunisia. Factors such as political ambiguity and security problem has led to the decrease of the confidence of the investors and consumers and consequently restricted the possibilities of finance. The crisis makes it difficult to maintain the economic stability in the region and leads to the increase of structural problems more intensively. Three important fields of economic problems come to the fore when MENA countries are evaluated as a whole (World Economic Forum, 2013; IMF, 2014):

*a. High rate of unemployment:* Due to the high rate of unemployment of the young generation, increased rate of participation in the labor force is also important from the point of view of ensuring political stability. And for that purpose the rate of growth must be increased. To this end private sector investments must be encouraged since the capacity of the public sector to finance the necessary investments is quite limited. One of the most distinctive characteristics of MENA countries is the population increase. According to the data of World Development Indicators for the year 2014 prepared by the World Bank, MENA countries have the second highest population increase rate with an average annual rate of 1.72 for the period 2000-2012, following Sub-Saharan countries which scored 2.68%. Together with South Asian region MENA region is the second region in the world with the highest percentage of the population of the age group 0-14 in the world, surpassed only by Sub-Saharan region.

*b. Upset of fiscal balance:* Significant increases have been observed in the public spending due to the political ambiguity following the crisis. The increasing public deficit has also increased the need for public borrowing. Because of this situation the financing of the public deficit by the financial markets which are already weak brings about an effect of exclusion on the private sector of the country.

*c. The need for structural reforms:* Structural reforms like the introduction of the arrangements required for establishing a competitive an effective market system, ensuring transparency and effectiveness in the markets as well as increasing institutional quality and the quality of education, deepening the structure and increasing the quality of the financial markets has a vital importance from the point of view of ensuring the economic functioning of these countries gain a healthy structure in the long term.

As has been discussed within the framework of the techno-economic set of values, world economy is in the eve of an age of technological transformation. Only those countries, which have a sufficient technological accumulation, shall have the possibility of making use of the opportunities opened up by this age. Taking into consideration the fact that nanotechnology is one of the leading technologies of this age of transformation, the investments made in science and technology gain even more importance. While countries like USA, Germany, Japan and Korea are ready to enter this age of technology, many developing countries are faced with the risk of remaining behind from the technological point of view due to their lack of a sufficient infrastructure. When the situation of the MENA countries in this age of technological transformation is examined, we see that they are very backward from the point of view of the scientific and technological infrastructure. The basic scientific and technological indicators about MENA countries are presented in the Table 11.

**Source:** http://data.worldbank.org/indicator *2005 **2008 ***2009

Manufacturing industry is not developed in the oil exporting countries since their economy is based on a single natural resource. On the other hand North-African countries like Egypt, Tunisia and Morocco are in a backward state in terms of the indicators of scientific and technological development. Among MENA countries Iran is the most developed country in terms of the indicators of scientific and technological development. Despite being an oil producing country Iran is in a relatively developed state in comparison to other countries in the region in terms of technological accumulation thanks to the investments made especially in the field of nuclear energy and defence industry. When the region is evaluated as a whole we observe that the countries of the region have a weak technological infrastructure. Those countries have no accumulation at all in the field of generic technologies which are accepted as the carrier of sixth Kontradief wave. For that reason the risk for the countries in the region to remain even more behind the developed countries in terms of economic development is quite high since they have no possibility of making use of the windows of opportunities opened up in this period of the change of technoeconomic paradigms.

## CONCLUSION

It is observed that the world is in a global technological revolution process relying on the developments in biotechnology, nanotechnology, material and information technologies. New areas that will be brought about by these generic technologies can be exemplified as cheap solar energy, rural wireless communications, wearable computers, quantum cryptography, hybrid vehicles, improved diagnostic and surgical methods, and green manufacturing. These new technologies will change the production methods and manufactured products in many manufacturing industry fields. The countries that will benefit from a sustainable growth depending upon the manufacturing industry's production will be the countries with the skills of producing, utilizing, and adapting these new technologies. Within the scope of this study,

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

first the long wave theory for the capitalist development was scrutinized through a neo-Schumpeterian perspective and secondly, the phenomenon of technoeconomic paradigm change was discussed . Analyses regarding the fact that the phenomenon of big and deepening stagnancy experienced in the 2008 is the harbinger of the end of the current Kondratieff wave and the start of the sixth Kondratieff wave were presented and it was stated that the new growth waves will appear in connection with the generic technologies, specifically nanotechnology.

The change that will be created by the nanotechnology revolution in the near future of the humanity can only be estimated in its essentials. It seems that nanotechnology will leave its mark on civilization in the forthcoming decades and through such developments, divergence between the weak and the strong countries will increase. Nanoscience and nanotechnology are rapidly entering our lives in many different fields. This impact starts with informatics and communication and extends toward the defense industry, space and aircraft technologies, and even molecular biology and genetic engineering. Substantial and surprising outputs and new markets are expected from nanotechnology in the next 10 to 15 years. It is observed that hundreds of nanotechnology research centers and departments at universities are being established in Europe, the USA, and Japan. The expert staff is producing information and technology primarily for the national interests and then commercial interests in a competitive atmosphere in these centers. With nanotechnology, the gap between developed countries and undeveloped countries will grow bigger and bigger in such a manner that it will unlikely to be closed again and the countries that master nanotechnology will become stronger in terms of the level of wealth, national defense, and economy.

Within the scope of the study, the relative positions of enriching Asian countries and European Union countries in regards to nanotechnology were comparatively examined making use of the previous technoeconomic paradigm change (so called microelectronic revolution). A conclusion reached is that apart from these two country groups, the country that is the most ready in such a technological revolution appears to be the USA as it is highly advanced in every measure. Japan is the second country that has technological superiority in terms of nanotechnology. Within the EU, the spearheading country in nanotechnology is Germany. This is due to the fact that it is the production and export base of the EU with a very competitive manufacture industry. Other important European countries in terms of nanotechnology research and investment activities are France, the UK, Switzerland, the Netherlands, Belgium, Italy, Denmark, and Finland.

Korea, Taiwan, Singapore, which made use of the previous technoeconomic paradigm change successfully, appear to be preparing well within this technological revolution. The EU's re-industrialization program will be able to make the dream of a globally competitive Europe possible only if it is based on these new technologies. In the EU, Germany, the trailblazer of industrial production, is the leading country in terms of nanotechnology and the EU's southern countries (Spain, Italy, Portugal, and Greece) that experienced a debt crisis during the 2008 stagnation will have to create a nanotechnology-based industrial structure to reestablish their competitive power within their disempowered industries. If the EU fails to realize this transformation, it seems extremely difficult that it can maintain its competitive position against the Asian economies, primarily South Korea, Japan and China.

It seems difficult for the countries that were unable to catch the industrial and microelectronic revolution in a timely manner to make use of the opportunity window that will be opened within this technoeconomic paradigm transformation period. The ability to seize this opportunity will only be possible by nationally empowering the expert staff, by providing education, and by paving the way for the technological accumulation that will be transferred from one generation to other.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Among the developing countries, China is in the process of obtaining a significant technological capability for nanotechnology. Thailand and Malaysia, which are accepted as the second generation of newly industrializing Asian countries, are implementing different national projects in regards to nanotechnology. South Africa and Brazil are trying to make investments in this technology even though these investment capacities are limited. On the other hand, the MENA region has no accumulation at all in the field of generic technologies which are accepted as the carrier of the sixth Kondratieff wave. These countries have insufficient scientific and technological infrastructure for utilizing the development opportunities which have emerged from transformation phase of world economy. For that reason the risk for the MENA countries to remain further behind the developed countries in terms of economic development seems to be very high.

## KEY TERMS AND DEFINITIONS

**Kondratiev Wave:** Kondratiev wave is long termed fluctuations that can be considered to have consisted of four main periods as improvement, well-being, shrinkage, and crisis. It is claimed that the period of the wave ranges from forty to sixty years.

**Manufacturing Industry:** Manufacturing industry refers to those industries which involve in the manufacturing and processing of items and indulge in either creation of new commodities or in value addition.

**Nanotechnology:** Nanotechnology is the manipulation of matter on an atomic, molecular, and supramolecular scale.

**Technoeconomic Paradigm:** Techno-economic paradigm are at the core of general, innovation-based theory of economic and societal development as conceived by Chris Freeman and Carlota Perez. Neo-Schumpeterian theory, or technoeconomic paradigm approach, is a theory that combines Kondratieff's long waves theory with Schumpeter's economic development theory and that focuses within the capitalist development process on technological change.

## ENDNOTES

1 These relationships are also known as "Kaldor-Verdoorn's Law" in development economics literature.

2 The first name who attracts attentions in this regard is Richard Feynman who received Nobel Physics Award in 1965 thanks to his studies in the fields of quantum electrodynamics and the physics of the elementary particles. Richard Feynman says "There is plenty of room at the bottom" in his speech he gave in 1959 in California Institute of Technology, and calls attentions to atomic engineering.

3 MENA countries can be classified in three main groups: *Resource-rich, labor-abundant countries* are producers and exporters of oil and gas and have large native populations, which represent almost the totality of their residents. This group of countries includes Algeria, Iraq, Syria, and Yemen. *Resource-rich, labor-importing countries* are producers and exporters of oil and gas and have large shares of foreign or expatriate residents, who represent a significant percentage of the

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

total population, even the majority in some cases. This group of countries comprises the Gulf Co-operation Council (GCC) members (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates) and Libya. *Resource-poor countries* are small producers or importers of oil and gas. These countries include Egypt, Jordan, Lebanon, Mauritania, Morocco and Tunisia (World Bank, 2007).

[4] The curse of natural resource refers to the paradox that countries and regions with an abundance of natural resources, specifically point-source non-renewable resources like minerals and fuels, tend to have less economic growth and worse development outcomes than countries with fewer natural resources. This is hypothesized to happen for many different reasons, including a decline in the competitiveness of other economic sectors, volatility of revenues from the natural resource sector due to exposure to global commodity market swings, government mismanagement of resources or weak, ineffectual, unstable or corrupt institutions.

# Chapter 93
# Place-Based Subnational Development:
## Unpacking Some of the Key Conceptual Strands and Normative Dispositions

**Nick Gray**
*Northumbria University, UK*

**Lee Pugalis**
*University of Technology Sydney, Australia*

## ABSTRACT

*This chapter offers a critical theoretically informed and policy-relevant exploration of some of the most prevalent conceptual strands informing place-based development scholarship, discourse, and practice. In doing so, it examines the emphasis on co-operation, open governance, and the assumption that all places have the potential to grow and prosper. Further, it analyzes normative dispositions – namely that place-based modes of subnational development could represent a viable and progressive approach which reconciles pervasive tensions between economic growth and spatial equity. In the process, the chapter identifies four key conceptual strands that characterize place-based development theory and practice.*

## INTRODUCTION

*The starting point of a place-based development policy is the idea that most of the knowledge needed to fully exploit the growth potential of a place and to design tailor-made institutions and investments is not readily available—whether held by the state, large corporations, or local agents—and must be produced anew through a participatory and deliberative process involving all local and external actors. (Barca, McCann, & Rodríguez-Pose, 2012, p. 147)*

Place-based modes of subnational development are viewed by some as a significant emergent paradigm (OECD, 2011; Tomaney, 2010). Nevertheless, this purportedly "new" paradigm of regional development is in need of greater theoretical attention and conceptual clarification than hitherto (Pugalis & Bentley, 2014). Mendez (2012) credited Winnick (1966) with first employing the concept of place prosperity versus people prosperity to illustrate one of the core tensions in subnational development (including local and regional policy). Nevertheless, the term "place-based" is often used carelessly, such as when the same actors and institutions may adopt it in different settings to mean distinctly different things (Pugalis & Gray 2016). In some interpretations, for example, it is invoked to refer to decentralized or devolved funding and decision-making. In others, for example, place-based development is a codification of emergent practices concerned with bottom-up development, innovation, and multi-level governance. The codification of place-based development, exemplified in Barca (2009), represents a subtle case for investment in active subnational development policies intended to boost growth in highly competitive places as well as those less developed places, such as "lagging regions." In this respect, it is in part a response to "spatially-blind" policy responses, such as those advocated by the World Bank Development Report (2009) "reshaping economic geography" as well as political and other pressures.

Importantly, place-based development is not, as some have interpreted, simply another term for area-based interventions or policy that is in some way spatially targeted (Hildreth & Bailey, 2014). Neither does it posit a policy choice between focusing interventions on people or place (Barca, 2011). Indeed, its proponents argue that place-based development *is* a people focused policy, albeit one that intends to fully account for spatial factors (Garcilazo, Martins, & Tompson, 2010). Furthermore, the adoption of a place-based approach does not preclude the deployment of other, for example, "space neutral" interventions. Simply put, place-based approaches to subnational development, of which there are manifold varieties (Pugalis & Bentley, 2015), recognize that place matters.

With a focus on place-based subnational development, this chapter sets out to assist researchers and policymakers by providing a critical exploration of some of the key ideas and normative dispositions implicit within this increasingly influential approach (promoted by international organizations such as the OECD). The chapter hopes to help clarify some of the thinking lurking behind place-based policy epistemologies and philosophies through identifying four key conceptual strands that are pervasive in dominant notions of place-based development: decentralization, multi-level governance, knowledge and innovation, and institutions. Whilst collectively these strands provide only a starting point for a fuller theorization of place-based development, both individually and collectively they nevertheless offer a useful analytical device for disentangling, distinguishing, and analyzing distinct varieties of place-based development policy.

The approach for explicating foundational conceptual strands of place-based thinking recognizes that attempts to define the notion and practice of place-based development too tightly could limit its effectiveness, diluting the fundamental feature that context of place matters (Pugalis & Bentley, 2014). From this perspective, a primary dimension of place-based modes of local and regional development, and arguably one of its major strengths, is its flexibility. It is for this reason that the chapter seeks to unpack "conceptual strands" rather than a more prescriptive "framework" or "ideal type." Through an exposition of a dominant place-based narrative that has found favor in European discourse, the chapter demonstrates that it is implicitly progressive in its approach. Importantly, place-based development represents an attempt to reconcile policies intended to promote equity (within and between places) and economic efficiency (growth).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

The remainder of this chapter is organized into five sections. The first substantive sections seek to situate place-based development historically in the context of a shift from government to governance, the importance of more flexible or relational understanding of place, and the emergence of subnational development policy that seeks to promote growth over redistribution. Next, the chapter discusses some of the interrelated key conceptual strands of place-based development – decentralization, multi-level governance, knowledge and innovation, and institutions – before exploring the vital normative dispositions of the place-based narrative. The chapter closes with a discussion of some of the key conclusions and policy implications.

## BACKROUND

### From Government to Governance

Place-based development emphasizes flexible policy geographies, the involvement of multiple stakeholders, and multiple levels of governance, and as such can be conceptualized as embodying what is frequently termed "a shift from government to governance." In this sense, dominant discourse associated with place-based forms of development (Barca, 2009, 2011) does not necessarily present an entirely new approach, but rather codifies a number of economic and social development ideas and practices that have emerged over recent decades (Tomaney, 2010). In common with the social sciences more broadly, the theory and practice of development policy has witnessed the emergence of various transition theories of epochal and structural shift in the capitalist system, seen to begin around the mid- to late-1970s. Such a transformation has been theorized in a multitude of ways, often, although not always, complementary, including as a shift from a Fordist to post-Fordist regime of accumulation (Gertler, 1988) or from a Keynesian welfare state to a Schumpeterian workfare state (Jessop, 2002). A vital contention in the context of subnational development is that this shift has witnessed a transition from a system of government to one of governance, engendering state rescaling (Brenner, 2004; Goodwin, Jones, & Jones, 2012; Jessop, 2002). In respect of subnational development, this rescaling of the state has been broadly conceptualized as new regionalism or even new localism (Corry, Stoker, & New Local Government Network, 2002; Storper, 1997). Associated with the proliferation of partnership working and multi-actor collaboration has been the heightened attention afforded to "good" or "effective" governance (Hendriks, 2014), which is increasingly considered to be a decisive factor in subnational development policy, a trend that can be observed globally (Schindler, 2015; Storper, 2014).

The opening up of policy and decision-making to actors outside of the traditional formal apparatus of government has not necessarily diminished the role of the state. Rather, there has been a qualitative shift in state practice. Meta-governance describes the process by which the state in effect *lends* power to other agents while retaining a vital steering role, setting the rules by which governance institutions operate (Jessop, 2002). Meta-governance provides the background to broad changes in approaches to subnational development. This reallocation or lending state power from the center to different scales of government and dispersed actors is vital to an understanding of place-based thinking.

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

## From Redistribution to Growth-Oriented Subnational Development

The rescaling of the state and attendant new forms of governance is linked to another central element of place-based thinking – a widespread interest in the "contingent conditions of growth in particular regions" (Martin & Sunley, 1998, p. 202). That is, a growing interest in the locality attributes or spatial factors that influence the development and economic trajectories of particular places, such as cities and regions. Renewed attention and interest in the spatial makeup of particular places reflects a view that previous approaches to development, such as subsidies aimed at attracting foreign direct investment, have failed in their objective to spatially rebalance national economies. This "old" paradigm of subnational development, to invoke the language of the OCED (2009), has been extensively critiqued. One severe shortcoming of old-style development policies was their top-down nature, which tended to neglect or override place-based knowledges, competencies, and attributes in favor of "one-size-fits-all" models. Moreover, old-style development policies have also been lambasted for a preoccupation with "hard" physical infrastructure to the detriment of "soft" interventions, as well as strategies intended to attract (exogenous) mobile investment at the expense of developing endogenous capabilities and capacity. The deficiencies of the "old" paradigm of subnational development has prompted "new" approaches, witnessed for example through a growing interest in bottom-up forms of subnational development policies that are often focused on mobilizing endogenous resources, such as the harnessing of place-based "assets" (of both soft and hard nature). Indeed, the contemporary interpretation of the new economic geography (Krugman, 1998), which prioritizes promoting agglomeration, described by Tomaney (2014) as the "neo orthodoxy," concludes that traditional redistributive policies intended to reduce the concentration of economic activity may have reduced overall national economic efficiency (Gill, 2010). The contemporary agglomeration-driven approach holds agglomerations to be "natural," thus advocating that efforts to stem market-driven growth of agglomerations and promote growth in lagging places are inherently inefficient. A key insight from these debates is that there is necessarily an economic trade-off or compromise between policies that promote efficient economic growth and those that promote equity and inclusion (Martin, 2015).

# PLACE-BASED THINKING: THE INFLUENCE OF EVOLUTIONARY ECONOMIC GEOGRAPHY, INSTITUTIONALIST APPROACHES, AND INNOVATION

Place-based thinking emphasizes the importance of place in the sense of history and relationships with the wider social and economic system. Within this, it emphasizes the role of governance institutions and the value of local knowledge in maximizing endogenous potential. This section discusses some of the key theories informing place-based thinking, particularly ideas around evolutionary economic geography, institutions, and innovation. However, it is important to first unpack the notion of "place," as this is instrumental in shaping place-based thinking.

## Different Understandings of Place

Given its centrality, the concept of place is employed surprisingly loosely in much of the literature on place-based development. Indeed, Barca (2009, p. 4) deployed the notions of "place" and "territory" in an interchangeable manner. Many others researchers and practitioners have assumed that "place" is an

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

accepted concept: devoid of contradictions and contestation. Barca discussed relational understandings of geography and the notion of place is informed by a pragmatic, policy-led conception of place:

*In the context of a policy aimed at development, place must be defined as a social concept, a contiguous/continuous area within whose boundaries a set of conditions conducive to development apply more than they do across boundaries (i.e. relative to other places): natural and cultural circumstances and the preferences of people are more homogeneous or complementary, the knowledge of people is more synergetic, and positive externalities and formal and informal institutions are more likely to arise. The boundaries of places are thus independent of administrative boundaries, endogenous to the policy process and can change over time. (Barca, 2009, p. 5)*

From a relational geographical perspective this is potentially problematic. Painter (2010, p. 1094), for example, was critical of attempts to incorporate relational geography and networks into a "taken for granted notion of territory," going on to argue that territory is composed of diverse relations, such as socio-technical practices.

A full engagement with the notion of place calls for theories and practice to engage with global-local interplays (Massy, 2013). More prosaically, relational ideas are considered in conjunction with territorial geographies with the objective of facilitating a fine-grained interpretation of places. However, engaging with relational theories of place does not need to override territorial theories of place. Indeed, they can complement one another (Jones & Woods, 2013). In practical terms, for example, it has been observed that "… boundary setting is still evident and part of the language and practices of governance and institutions" (Pike & Tomaney, 2009, p. 30), even when relational perspectives of place are prominent. Place-based approaches emphasizing relational geographies often do so against a political backdrop of the need to define the territories of places for administrative purposes. It is in this respect that Pike and Tomaney (2009) contended that purely relational accounts risk downplaying the continued importance of territorial boundaries to subnational development.

In practice, pragmatic attempts to account for the relational dimensions of place often deploy the proxy notion of functional economic areas, which are derived from available socio-economic datasets, such as those representing travel-to-work flows or retail catchment areas. Nevertheless, the utility of functional economic area analyses in shaping place-based policy responses is not without significant limitations. Rees and Lord (2013), for example, found that while the bottom-up construction of Local Enterprise Partnership geographies in England was, in principle, based upon functional economic market areas, the boundaries were more likely to be politically negotiated and influenced by historical preferences and alliances. This is consistent with Pugalis and Townsend's (2013) observation on the continuity between these boundaries with that of a series of historical antecedents.

The notion of relational geography raises long-term practical questions of horizontal governance and relationships between subnational development entities working within overlapping geographies. Typically, institutional geographies based upon given definitions of relational and territorial geographies may overlap and even compete for public and private resources or devolved powers (Haughton & Allmendinger, 2008). This is likely to be an important issue to resolve if institutions are to successfully implement place-based strategies with an emphasis on co-operation *within* places. Different relational geographies could be competing or incompatible. For example, technical constructs based upon data, such as travel-to-work areas, will not necessarily correspond with lived experiences of place. Healey (2009) pointed to the problem of multiple interpretations of the "City Region" – not only functional

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

economic market or spatial planning areas but subjective interpretations based upon distinct histories, identities and cultural understandings.

In this sense, place-based thinking can be understood as an attempt to incorporate the philosophies and language of relational readings of place; nevertheless, in practice the importance of territorial readings of place often come to the fore. There is a prosaic aspect to this perspective; it is difficult to govern a place of relational flows that is in a continuous process of becoming and is experienced by different actors in different ways. Governance is a pragmatic exercise and is necessarily territorial (Pike & Tomaney, 2009). Furthermore, while economic activity is evidently not bounded to a particular territory, there is compelling evidence that economic activity, and capitalism in particular (Cox, 2013), is fundamentally spatial and has a spatial pull – powerfully illustrated, for example, in the work of Harvey (1989a, 1989b, 1996) and the focus of New Economic Geography on cities and agglomeration in economic activity (Krugman, 1991). In essence, place-based thinking attempts to incorporate a more relational understanding of place and territory into subnational governance and development, but it is fundamentally a territorial policy approach.

## Antecedents to Place-Based Thinking: The Influence of Different Approaches

Evolutionary thinking, the perspective that places develop according to an historical trajectory, is central to the new paradigm of subnational development. Such an approach, focusing on the way that history shapes the future development of places, according to some, is better able to explain the complexities of uneven development (Boschma & Martin, 2007). The idea of path dependency – a biological metaphor describing the way that a system is shaped by its history – continues to be influential with its emphasis on how the long-term development of spatial economies is influenced by proximity to natural resources, technological lock in, or social capital and culture (Martin & Sunley, 2006), and is a particularly influential theory in terms of shaping dominant interpretations of place-based thinking.

Institutionalist approaches also perform an influential role in contemporary subnational development theory and practice, particularly in the context of governance (Pike, Rodríguez-Pose, & Tomaney, 2006). These ideas seek to explain underlying differences in economic growth trajectories of places in terms of variations in the quality and configuration of place-specific institutions, expressed through notions such as "institutional thickness" (Amin & Thrift, 1995; Coulson & Ferrario, 2007). For example, institutions are perceived to influence a place's ability to innovate or adapt to new technology (Martin, 2008). Institutions in this sense can be formal and informal, encompassing routines and conventions as well as governance agencies, and are said to mediate social and economic processes in that they provide stability and predictability, and promote the confidence and trust between individuals that facilitates social and economic exchange (Farole, Rodríguez-Pose, & Storper, 2010). An institutional understanding of subnational development emphasizes the role of place-based institutions' particular ability to utilize local knowledge to develop place-specific and bottom-up development strategies, or to help places adapt to change. These institutional ideas run through the prevalent interpretations of place-based development although, as argued in this chapter, the dominant place-based narrative has an important normative dimension not necessarily shared by institutional approached more broadly.

Ideas around innovation-driven growth and endogenous growth theories also appear to be of central importance in respect of informing place-based thinking. Innovation is argued by many to be the key determinant of growth in a highly developed economy (Aghion & Howitt, 2006). This strain of thinking conceptualizes the building of places' ability to innovate and use knowledge through learning processes

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

as crucial to economic development (Barca, 2011). Closely associated ideas of "regional innovation systems" and "learning regions" developed in part as attempts to understand spatial disparities in innovation (Farole, Rodríguez-Pose, & Storper, 2010). There are different interpretations of these ideas but they share an interest in technological infrastructure, such as universities and business research and development facilities, and their mediation through formal and informal institutions. This emphasis on the vital role of knowledge and innovation is a core component of place-based thinking.

Institutional ideas and learning theories continue to be the subject of fervent debate – they are relatively heterodox and have been criticized for a conceptual and empirical vagueness (Pike, Rodríguez-Pose, & Tomaney, 2006). Endogenous growth theories share a focus on the importance of innovation, but develop the concept within the context of an orthodox economic model. Its emphasis on tapping into or releasing potential within all places contributed to the shift in focus in regional development policy away from the redistributive donor/recipient model (Pike, Rodríguez-Pose, & Tomaney, 2007) and towards growth-oriented approaches aimed at all places – successful as well as lagging (Scott & Storper, 2003). From this perspective, the purpose of subnational development policy is to raise the performance of *all places* (not only lagging places) rather than ameliorate disparities through redistribution – a principle that underpins place-based thinking.

## FOUR CONCEPTUAL STRANDS: A PRIMER FOR A FULLER THEORIZATION OF PLACE-BASED DEVELOPMENT POLICY

This section introduces four key conceptual strands that are pervasive in dominant notions of place-based development, and which can be used to disentangle and identify different varieties and interpretations of the approach. These strands have been extracted, formulated, and reformulated based upon a close reading of the dominant European place-based narrative (for example, Barca, 2009; OECD, 2009). Collectively, the four strands are not intended to provide a definitive place-based development conceptual schema. Indeed, it is hoped that they will perform a primer for a fuller theorization of place-based development policy. Moreover, the importance of each conceptual strand will be contingent on the characteristics of particular contexts. Hence, these strands are not prescriptive, but are intended as analytical devices to help inform theory development, empirical analysis, and policy crafting.

### Decentralization

The status of decentralization within a place-based approach to development and governance requires careful consideration. The dominant European place-based narrative was initially articulated as an agenda for implementing European Union (EU) regional development policy (Barca, 2009) and assumes a degree of decentralized decision-making reflecting existing governance structures within the EU. At the same time, the EU place-based narrative does not assume that decentralized decision-making is an ultimate goal or end in itself.

While the principle of decentralized policy development and decision-making is central to place-based thinking, the perspective is somewhat skeptical of the transformative power of decentralization or devolution. Central to this reasoning is the recognition that there can be weaknesses in a "localist" methodology – the most frequently cited being rent-seeking[1] local elites and inappropriate or weak local institutions (Barca, 2009; Barca, McCann, & Rodríguez-Pose, 2012; Hildreth & Bailey, 2014). By

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

definition, the approach also assumes/posits weakness in national governments' ability to implement policies for places (Hildreth & Bailey, 2014). One interpretation of this is a form of meta-governance, known as "conditional localism" (Hildreth, 2011), whereby the decentralization of policy responsibilities are contingent on centrally-imposed conditionalities. More positively, a place-based approach would involve partnership through multi-level governance in order to reach a democratic consensus. This might mean some form of deliberative democratic process. However, as Bentley, Pugalis and Shutt (2016) have argued, the national regime of meta-governance is vital – that is, attempting to implement a place-based approach in one place without the support of the central state is likely to prove challenging.

Despite the reservations discussed above, decentralization of governance capacity is often deemed to be a precondition of place-based approaches into order to provide the freedom, flexibility, and fiscal capacity required for a place-based development strategy. In the simplest sense, national governments are likely to lack the detailed and nuanced understanding of place, such as its history and economic potential (Hildreth & Baily, 2014). However, not all interpretations of a place-based approach see decentralization as a sufficient condition for success or an end goal of development that will axiomatically result in better development outcomes. From a place-based perspective, places require the institutional and financial capacity to govern, which would imply that the mere decentralization (or transferring) of responsibilities is insufficient, especially in the context of weak or dysfunctional institutional environments. As Deas (2013) found, when lobbying for greater devolution, local elites do not always prioritize increased democratic accountability as part of the process. In addition, evidence for the economically transformative effect of devolution and decentralization is unclear (Rodríguez-Pose & Gill, 2005). It does not necessarily follow that devolved leadership leads to the more nuanced elements of a place-based approach – for example, open co-operative governance institutions and policy that is rooted in a deep understanding of place, its potential, and path dependencies. Importantly in this context, the principle of subsidiarity holds that a decision should be taken as closely as possible to the people it effects. In practice this means a presumption that organizations should only perform those activities that cannot be performed more effectively at a lower level. In place-based development, the principle of subsidiarity applies to *tasks* rather than sectors. That is, functions of governance are not necessarily decentralized in their entirety; rather, different levels of government take on different tasks in a system of multi-level governance.

## Multi-Level Governance

Multi-level governance can be seen in the context of the shift to meta-governance where the central state "lends" powers to different levels and partnerships, including subnational governance institutions. National governments continue to play an active role, steering or setting the rules for other institutions and retains control of most macro-level policy. Subnational institutions, such as local development bodies or regional development agencies, are perceived as appropriately positioned to influence the supply side of the economy and facilitate structural change, and this is argued to become more important if the objective is to take a higher value, innovation-led path (Pike, Rodríguez-Pose, & Tomaney, 2007) to development, rather than one of low-cost flexible labor.

Conditionality, as discussed earlier, within a multi-level governance framework also remains an important aspect. Higher levels of government will continue to set the framework within which subnational institutions operate, and the characteristics of the framework or mode of national governance are likely to determine or constrain subnational governance institutions capability to act. Clearly, this

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

interpretation of the place-based approach is open to criticism from those who argue that successful development calls for greater devolution or, more straightforwardly, that democratic decentralization is desirable in its own right.

Multi-level governance is understood to be important as a means of addressing weaknesses at the local *and* national level (Hildreth & Bailey, 2014). Given the primacy that place-based thinking affords to knowledge, it is argued that national government is unlikely to possess the necessary deep understandings of places, such as their path dependencies, economic weaknesses, culture, politics, and endogenous potential. From a different perspective, there may be long-run weaknesses at subnational scales that prevent effective policy development – for example, inappropriately configured local institutions of policy capture by ineffective and/or rent-seeking local elites (Harvey, 1974; Stone, 1989). Indeed, given that it is predicated upon building on the knowledge and capabilities of its beneficiaries, a place-based approach brings with it the risk of institutional capture by coalitions of vested interests or of encouraging rent-seeking. This risk is explicitly acknowledged in the literature, and multi-level governance has been posited as a mitigation of this risk (Barca, 2009; OECD, 2009). More positively, multi-level co-operative governance with local and national actors working together is seen as essential in facilitating innovation and endogenous development (Barca, 2011).

In a more prosaic sense, subnational governance institutions are likely to be necessary if places are to have some influence over non-localized policies, such as education (Parkinson & Meegan, 2013). Alternatively, multi-level governance itself introduces the risk that exogenous institutions or actors – particularly central government – will dominate the decision-making processes. The implication is an extremely thin form of place-based development. For example, in examining the developing configuration of subnational economic growth partnerships in England, Peck, Connolly, Durnin, & Jackson (2013) found that Whitehall departments and national agencies continued to perceive place-based institutions as mechanisms for delivering national priorities. This tendency, taken together with the ability of central government to set the agenda, suggests that effective place-based strategies require positive intention on the part of the center to collaborate in implementing place-based governance and development strategies – that is, a mode of governance that is conducive to place-based development approaches (Bentley, Pugalis, & Shutt, 2016). Tomaney (2010) cited the success of a shift in governance structure and the introduction of strong accountable subnational institutions in promoting regional development in Sweden. The Västra Götaland region was created through merger of existing smaller territories and given a greater level of autonomy via an elected assembly. "Regional Growth Agreements" were introduced, aimed at bringing together regional knowledge bases with existing economic activity, for example through better university/industry knowledge transfer. While direct cause is always difficult to establish in economic development, by the mid-2000s performance in the region had improved and the rate of R&D investment was exceptionally high.

## Knowledge and Innovation

For Barca (2011), assumptions about the nature of knowledge provide the crucial distinguishing feature of a place-based approach. Endogenous growth models suggest that low levels of human capital and low innovation capacity are vital factors in limiting growth potential (Farole, Rodríguez-Pose, & Storper, 2011). The European place-based narrative assumes local knowledge to be vital for innovation and endogenous growth, and that the goal of public policy is to uncover or stimulate new knowledge via the interaction of local and external actors (including private and social sectors) through multi-level

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

governance institutions (Hildreth & Bailey, 2013). Importantly, place-based thinking observes that that this knowledge is essentially contingent and partial and not readily available to local or national actors, including central and local government, or private sector firms. The approach follows Hayek (1945) in the view that actors' access to knowledge is inevitably imperfect and that individuals and institutions will have only a fraction of the total knowledge available. It follows from an economic development perspective that no individual actor or agency, including state institutions, will necessarily "know best." Importantly, however, while the classic Hayekian critique of government builds on this understanding to argue that markets represent the most effective (or least inefficient) means of aggregating knowledge and preferences, the place-based approach posits a central role for all tiers of government institutions in facilitating the co-ordination of actors in a process of innovation.

Emphasis on locally produced knowledge leads to the closely related policy of smart specialization (Foray, 2015) – argued to be close to Rodrik's (2004) understanding of "industrial policy as a process of discovery requiring strategic collaboration between the private sector and state in unlocking growth opportunities" (Hildreth & Bailey, 2013, p. 242). Smart specialization involves strategies to invest in innovation that draws upon existing local (embedded) knowledge – the approach is distinctively place-based and emphasizes an awareness of local path dependencies (Marlow & Richardson, 2015). By way of example, Bailey, Hildreth & de Propris (2015) highlighted the value of local knowledge and local actors in promoting innovation and industrial clusters in the West Midlands region of the UK, where a "Niche Vehicles Network" facilitates collaboration around new technologies in small-scale automotive production. They argued that a central government department would lack the local knowledge and capacity to facilitate such locally tailored initiatives.

The primacy accorded to knowledge in place-based development leads the place-based approach to prioritize impact assessments of policy interventions. This is in part because the codified place-based approach was commissioned and formulated to underpin the 2015–2020 round of the European Structural and Investment Funds (ESIF). Critics have argued that development policy in Europe has suffered from a lack of serious and systematic evaluation of what works (Barca, 2009). These ideas raise a number of practical questions around the potential for place-based development strategies. The theoretical literature is not clear on the form and process through which places might stimulate and aggregate knowledge. Furthermore, it is not clear how, if at all, a place-based strategy might differ substantially from previous attempts to facilitate endogenous local innovation.

## Institutions

"Institution" as a concept has a particular and, sometimes, shifting meaning in subnational development literature. In the first instance, institutions are taken to be formal social arrangements and practices such as property right and the legal system, alongside informal social practices such as social norms and personal contacts (Rodríguez-Pose, 2013), in many ways the essential subject matter of sociology (Durkheim, 1964). In this sense, basic institutional weakness can hinder development. One example is hampering access to education or encouraging patronage in the distribution of public resources. This understanding of institutions as social norms and practices is crucial to place-based thinking, although there is limited agreement on how to increase institutional capacity in this sense (Rodríguez-Pose, 2013). At the same time, in practice, while some have argued that institutions cannot be equated with organizations (Storper, 1997), much of the literature on subnational governance and development tends to concentrate on institutions as formal governance organizations (see, for example, Tomaney, 2014).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Storper (1997) has argued that successful local economies are likely to be rooted in the local social and institutional fabric, whilst Farole, Rodríguez-Pose and Storper (2011) posited that the relationships between institutions and the wider community is vital in the pursuit of economic growth. This conception of institutions is at the core of place-based thinking. Tomaney, for one, argued that:

*…effective institutions make a significant contribution to the process of regional growth because of their key role in the interpretation and mediation of broader economic contexts and through their leading role in shaping and coordinating incentives for investment and enterprise. (Tomaney, 2014, p. 131)*

Place-based thinking emphasizes the role that "open" governance institutions can perform in marshalling diverse stakeholders, including individual and institutional actors in the public, private, and social sectors. Importantly, subnational institutions are vital to the task of stimulating, uncovering, and bringing together the knowledge and ideas understood to be necessary for innovation and endogenous development:

*There is … a need for public action to establish a process through which the knowledge and preferences of all those living in a place are elicited and aggregated and the decisions made and their effects submitted to scrutiny and public debate. (Barca, 2009, p. 23)*

The notion of open, democratic institutions at the heart of place-based governance, working to aggregate the preferences of all stakeholders, underscores the normative nature of the dominant place-based narrative. The approach draws upon and echoes ideas of deliberative democracy and participatory governance exemplified in Fung, Wright, and Abers (2003) and implicit in Habemas's (1984) theorization of communicative action.

The principle of open democracy appears to be paramount to the articulation of the dominant European place-based narrative, but is not a necessary element in all interpretations of place-based thinking. For example, Parkinson and Meegan (2013) used the term somewhat more broadly, retaining the emphasis on endogenous potential but within an interpretation of "placed-based" that is more about devolution and decentralized leadership and decision-making without the emphasis on the open democratic process to accompany it. This distinction is potentially significant, given that the principle of democratic inclusivity contrasts with discussions of some forms of place-based governance that have been described as "post political" (Zizek, 1999). For example, some such as Deas (2013) have argued that devolved decision-making (i.e., notionally closer to the population it most directly affects) does not necessarily engender decision-making that is more open or democratically accountable. Questions of democratic deficit and transparency are part of ongoing debates internationally concerning subnational development, meaning that the central role that the codified place-based narrative envisages for open, participatory institutions is a core characteristic of the approach.

The centrality of open governance and democratic accountability to the conception of placed-development set out here raises important practical questions around the institutional characteristics necessary to successfully facilitate such an approach. Governance institutions, particularly those concerned with local and regional development, have been characterized in terms of "hard" and "soft" spaces (Haughton & Allmendiger, 2008). Hard spaces of governance are the more visible institutions of govern*ment* and are more likely to hold statutory duties around, for example, service delivery, consultation, and equality legislation. In terms of subnational development, policymakers often perceive these hard spaces to

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

be "slow, bureaucratic and rigid" (Haughton & Allmendiger, 2008, p. 143). Next to this, soft spaces of governance represent "alternative administrative geographies" (Haughton & Allmendiger, 2008, p. 143), sometimes operating out of the public eye and addressing particular issues. In a positive sense, soft spaces can complement hard spaces, particularly in efforts to achieve "soft outcomes" such as building partnerships. In this respect such "spaces" could be an important part of a place-based approach. At the same time, the somewhat fuzzy lines of accountability raise some important questions associated with matters of democratic accountability, which sit uncomfortably with an approach built upon the principle of open democratic institutions.

Soft governance spaces are perceived to be agile; that is, they are in theory flexible to changing development contours. Hence, they can be more readily dissolved, adapted, or reformed to meet the needs of particular policy initiatives or places. However, Pugalis and Townsend (2013) found striking similarities between the territories of "new" spaces of soft governance and that of antecedents, which raises questions around the flexibility or newness of such arrangements. Yet Pugalis and Townsend (2013) suggested that this partial continuity could also be interpreted as evidence of the malleability of soft spaces.

The place-based emphasis on relational interactions (within and beyond defined territorial envelopes) raises further questions around the notion of hard and soft institutions and "appropriate" scales of governance. There are particular issues to resolve around whether notionally more accountable hard institutions would be sufficiently flexible to deal with the dynamics and multiplicity of "place" that a place-based development strategy would entail. This in turn relates to questions around multi-level governance and the national mode of governance. Under a governance system where the center continues to steer or set the rules of the game (Jessop, 2002), it follows that subnational governance institutions' ability to facilitate or impede place-based development strategies will be to a large extent constrained or steered by the national mode of governance (Bentley, Pugalis, & Shutt, 2016). That is, subnational governance institutions and their ability to act must be viewed in the context of the broader system of governance.

## THE NORMATIVE DISPOSITIONS OF THE PLACE-BASED META-NARRATIVE

Having identified and analyzed four conceptual strands informing the dominant place-based development narrative, this section begins to draw out some of the normative dispositions and tensions in place-based thinking. There is tension in the sense that place-based development represents and attempts to reconcile economic growth and spatial equity; the approach holds that all places have potential for economic growth, but is simultaneously presented as a way to stimulate growth in "lagging" places. In part, the place-based approach seeks to do this by framing the debate in terms of places' potential wherein a key cause of underdevelopment and, therefore, to some extent spatial disparities is the failure of particular places to make full use of their resources and economic potential (Farole, Rodríguez-Pose, & Storper, 2011). Therefore, place-based development policy should seek to facilitate places' ability to maximize their own endogenous economic potential. In this sense, a key normative disposition of the place-based meta-narrative is that the responsibility for the development trajectory of particular places, in part at least, rests with the actors and institutions coming together to produce that place. Thus, placed-based policies are open to capture by neoliberal agendas that seek to individualize responsibilities, which has witnessed an erosion of the welfare state in many countries and other trends, such as the "pushing down" of cuts to public sector budgets (Peck, 2013).

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

Place-based thinking can be understood in part as an attempt to address the problem of spatially uneven development (Pugalis & Bentley, 2014); indeed, within the European Union it informs European Union subnational development policy. In the simplest sense, place-based development, particularly in the dominant European narrative, aims to maximize a locality's endogenous economic potential via informal and formal democratic institutions. In this sense it builds on long-standing ideas around the importance of endogenous growth and the role of place-based actors in uncovering and mobilizing economic potential. This emphasis on the importance of local institutions in mediating outcomes in different places suggests improved outcomes are likely to be achieved in lagging or economically less successful places with policies designed to trigger and support institutional change. This leads to a policy focus on building institutional capacity.

The focus of place-based thinking on spatial disparities indicates a prominent normative dimension. Pike, Rodríguez-Pose, and Tomaney, (2007) have contended that development theory and practice is necessarily normative, in the sense that it cannot be a technical task to be separated from underpinning principles and values such as equity and democracy. This position differs markedly from much contemporary development theory and practice that interprets development and governance as a technocratic, even apolitical, exercise (Tomaney, 2014). The dominant place-based narrative is normative in the sense that its underpinning values are close to those discussed by Pike, Rodríguez-Pose and Tomaney (2007) when arguing for development that is holistic, progressive, and sustainable.

Reflecting Sen's (1999, p. 127) argument that development should follow an "integrated and multifaceted approach," the primary objective of holistic development is concerned with balancing economic growth with alternative outcomes – for example, social, environmental, and cultural. This reflects an emergent trend: from the 1960s onwards, elements of regional development practice began to take a more social or community-led approach that in contemporary theory and "dominant economic focus" has broadened further to encompass "social ecological and cultural concerns" (Pike, Rodríguez-Pose, & Tomaney, 2007, p. 1255). Progressive development is concerned with achieving social and spatial equity and is usually underpinned by critiques of neoliberal capitalism, advocating a central role for public institutions where "public discussion and social participation within a democratic framework are integral" (p. 1263). From this perspective, governance institutions are encouraged to intervene in markets for the common good, and development should avoid negative zero-sum strategies such as inter-territorial competition or "place wars." Importantly, development should be specific to place, sensitive to the "conditioned by cultural values, institutions, and prevailing modes of social and political mobilisation" (p. 1264). Sustainable development is concerned with equity in the sense that it is long-term in the way it considers natural resources – it also encourages the identifications of structural problems and where they fit with place specific assets and solutions.

Place-based thinking takes many of the principles and ideas sketched out in this chapter – institutional economics, theories of innovation and learning, endogenous growth – and aims to codify them into an implicitly progressive approach to subnational development. In this sense, the codification of and advocacy for a particular place-based approach could represent an attempt to claim or employ the concepts of place and decentralized governance for progressive ends. It attempts to do so by providing a framework for action, based upon the principle of open democratic institutions facilitating the mobilization of endogenous potential.

The codified and implicitly progressive place-based approach is distinguished by its fundamentally optimistic view of the role of governance – one that might be characterized as modernist in its underpinning values and philosophy. It advocates that subnational development outcomes can be improved by

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

active and deliberate intervention by government and governance institutions. This stands in contrast to market-first, minimal interventionist, or supply side strategies that have been said to characterize neoliberal approaches. Such approaches typically seek to "create the conditions" for growth or facilitate labor mobility via time-honored interventions such as infrastructure investment or theoretically space neutral measures around spatial planning and skills. Conversely, Tomaney (2014, p. 132) asserted that institutional/place-based thinking emphasizes the "constructive role of the state … in shaping patterns of development" – implicitly for progressive ends.

## CONCLUSION

Place is a contested concept in the social sciences and policy discourse. Yet it is often deployed in research and practice in a straightforward manner that neglects this contestation and, thus, richness. Guided by philosophies that assert that place matters in manifold ways that transcend social, economic, environmental, and cultural domains, a "new" paradigm of subnational development has been observed that is said to be informed by place-based thinking that seeks to account for the particularities of place. How places are understood, articulated, and thus produced matters, generating important policy implications. In the simplest sense it is important that subnational institutions identify policy "issues," derive policy "solutions," and make decisions in a manner that is cognizant of the matter at hand. In other words, there is no single, fixed scale or geography when pursuing a place-based methodology. Whilst the territory of the governance mechanism might be more or less fixed, this should not necessarily constrain the geographies and spaces of action and intervention.

Different approaches to development variously conflict or concur on the nature of the contemporary economy and the role of subnational governance institutions. However, while there are crucial differences in their interpretation, a core point of agreement is on the continued or growing importance of place in a globalized economy (Barca, 2011). A contemporary space-neutral approach sees a primary role for policy in facilitating natural economic agglomerations with predominantly supply side interventions, such as transport investment, education, and land use planning. Place-based approaches start from the position that subnational development policies, whether direct or indirect, are spatially sensitive, even though some forms of policy purport to be "space neutral"; spatial agglomeration always has policy as well as market causes. In this respect, place-based thinking echoes longstanding theorizations of the relationship between the economy and society (Polanyi, 1945), implicitly arguing that economic activity is necessarily embedded in society and for the impossibility of "natural" economic phenomenon free of political influence. A place-based approach can be distinguished by its "thinking" vis-à-vis place particularities, including the weight it accords to history (or path dependency) and, crucially, its normative concern with spatial disparity.

The chapter has situated place-based thinking historically as part of longer term trends – specifically a posited structural shift from government to governance and a concurrent and associated rescaling of the state. The chapter has also demonstrated that place-based approaches have recent antecedents in subnational development theory and practice, many of which it draws together or "codifies" (Tomaney, 2014). Informed by predominant theories guiding place-based thinking, four key conceptual strands have been identified, which help to realize the dominant articulation of place-based development policy.

The four conceptual strands are summarized as follows:

EBSCOhost - printed on 2/8/2023 11:07 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The process of decentralization can empower subnational actors and it is often considered to facilitate the scope for engendering "bottom-up" development strategies that are attuned to the "local" specificities of places. However, from a place-based perspective, decentralization is not in itself sufficient and there remains an important role for exogenous and distanciated actors, which could help to temper the risks of the "local trap," including parochial decision-making.
- Multi-level governance working is promoted as a means of enhancing vertical and horizontal co-ordination and policy integration. Multi-level governance also serves to facilitate effective oversight at the lower level – addressing weaknesses in local elites and the possibility of rent-seeking behavior. In this respect, the dominant place-based narrative is not a straightforward devolution policy, and conditionality remains important.
- Local knowledge is thought to play a central role in mobilizing endogenous potential and innovation. One high-profile practical policy manifestation of this principle is the closely related concept of smart specialization.
- Open, democratic institutions are considered to perform a vital role in bringing together local and national actors in an effort to access and aggregate this knowledge.

This chapter has argued that the dominant place-based narrative is normative, sharing many similarities with "progressive" modes of subnational development, such as those advocated by Pike, Rodríguez-Pose and Tomaney (2007). The dominant place-based approach can be viewed as an explicit attempt to reconcile tensions between equity and efficiency with the duel stated objectives to reduce "inefficiency" and "persistent social exclusion" (Barca, 2009, p. XI). It advocates achieving this through policies that build place-based institutional capacity to take advantage of or mobilize untapped endogenous potential. Equity and efficiency are often characterized as conflicting – some perceive a trade-off between policy that aims to improve the position of poor places and policy that is intended to boost economic growth (Martin, 2015), but from a place-based perspective the terms of the debate and the assumption of a trade-off are incorrect (Mendez, 2012). Equity and efficiency are reconciled by the pursuit of growth-oriented policies in lagging places with the key rationale being that national governments routinely underestimate the contribution that the least productive regions make to economic growth. Related to this is the contention that the fostering of major economic agglomerations should not be a primary growth strategy, and that agglomeration is "neither a necessary nor a sufficient condition for high growth" (Barca, 2009, p. 18).

From a practical policy perspective, place-based thinking holds that the objectives of subnational development policy are to facilitate places maximizing their resources and to promote social inclusion. The former should stimulate the latter, alongside social policies and space-neutral policies to boost skills, connectivity, and labor mobility. Hadjimichalis and Hudson (2014) have suggested the drift away from concern about uneven development is in part explained by an obsession with studying successful places, with a view to replicating their success elsewhere in the form of, for example, high-tech clusters or a large creative class. Martin (2015) has contended that less energy has been directed into understanding the path followed by less successful places. Rather than seek to replicate a successful policy, a place-based approach would begin with the aim to gain a deeper understanding of a place's history, including its relationship with other places and the wider economic system as a whole.

## ENDNOTES

[1] In economics, rent-seeking is behavior aimed at extracting value from assets rather than engaging in productive activity. For example, this might involve land owners seeking to increase the value of their property by lobbying/influencing governance institutions to implement particular policies, such as fiscal incentives to invest in a particular area or providing infrastructure that will increase the value of nearby property.
