- **AFO (Ankle-Foot Orthosis):** AFO devices are used to solve the major complicated issues associated with the foot slap during load response and toe-drag during swing. AFO can be designed with or without articulated joint with various motion control elements like springs, dampers, series elastic actuator and four-bar mechanism.
- **KAFO (Knee-Ankle-Foot Orthosis):** AFO plus knee control (locked or hinged). Locked KAFOs and KAFO with a posterior off-set knee joint are the different types available in the market.
- **HKAFO (Hip-Knee-Ankle-Foot Orthosis):** Extension of KAFO by adding a pelvic band.

Trunk Orthosis

The human body excluding the appendages is referred to as the trunk. When talks about orthosis are done, trunk orthosis is often neglected while concentrating on limb orthosis. The trunk holds all vital organs and this is necessary for functioning of the human system in the format it is designed for. Trunk orthosis comprises of orthosis application to the skull, neck and spinal portion, cervical, lumbosacral, thora columbo sacralare are the regions for which orthosis is prescribed. These regions are vital for posture and weight distribution on the lower limbs. Compared to orthosis advised for patients in other regions, orthosis in these regions are more rigid to restrict movement and maintain posture.

Exoskeleton

Skeleton is the support system of the human body. "Exo" means external and skeleton is the internal framework. Exoskeleton is an external framework which is often a robotic mechanical suit worn by human being. It is a type of advanced orthosis used in conditions where a patient cannot use his upper or lower extremities or both (Ali, 2014).It can be considered as a type of mobile machine which moves as the wearer moves. It provides additional strength and support to the wearer. Apart from its role as orthosis, a whole body exoskeleton is used in by people with dangerous or tiring jobs. Some examples exoskeletons are:

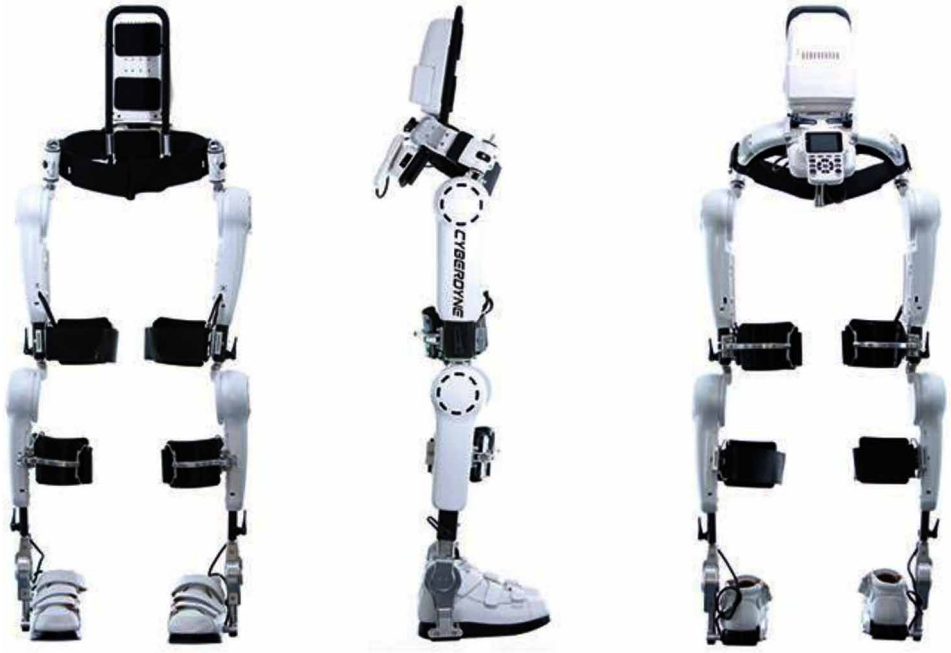
- **Rex:** It is self balancing, hands-free robotic device for rehabilitation. It will provide the power to move Rex and a user of up to 100Kg. The main benefit for patient is, he/she can get full range of movement in legs.
- **HAL 5:** Designed to help the disabled and elderly. It is used to support movement and to lift weights.
- **Ekso Suit:** Used by paralyzed patients for standing, walking and climbing stairs. I consist of pair of powered robotics legs. The users turn themselves into Ekso suit placing their feet on the foot-plates and securing straps around their legs, hips, and torso. The Ekso Suit transfers their weight to the ground, and they uses two arm braces to keep themselves from falling over.
- **Berkeley Lower Extremity Exoskeleton (BLEEX):** Lower extremity exoskeletons seek to supplement the intelligence and sensory systems of a human with significant strength and endurance of a pair of wearable robotic legs that supports a payload.

Figure 9. Hal 5
Source: http://cdn.walk-again.com/wp-content/uploads/hal_overview_700.jpg on 11th June 2017.



Components and Working of Exoskeleton

The basic components of an exoskeleton are: (i) the skeleton (made of light weight metals like aluminium, nickel, titanium and hard plastics); (ii) micro computers (for controlling movement of various motors for joint movement and signal relays; (iii) power supply (powered by an internal combustion engine, batteries or potentially fuel cells); (iv) multi-speed motors (for adjusting and performing as required); (v) control pad (enables the user to select various modes of movement); (vi) sensors (for sensing and recognizing movements such as grasping, holding, lifting etc. with precision)

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Ekso suit
Source: http://josefmicanekdesign.com/ekso-suit-helps-the-paralyzed-walk-again/ on 11th June 2017.

Exoskeleton functions like the musculoskeletal system involving the signals of brain for movement. When a person attempts to move, the signal from the muscles are picked up from the skin or beneath (implanted) by the bioelectric sensors. These signals are used to control and activate the motor suit for the movement of the exoskeleton along with the muscle movement of the wearer aiding the wearer to move and perform activities. This is called 'voluntary control system' that provides movement interpreting the wearer's intention from the bio signals in advance of the actual movement.

Applications of Exoskeleton

The use of exoskeleton is not only limited for use in conditions of mobility issues. Exoskeleton is used in fields of:

- **Medical:** Assist the disabled and elderly to move from one place to another and in their daily tasks. It can also be used to help paralytic patients to stand, walk and even climb stairs and to amplify muscle strength for people with muscular dystrophy and other neuromuscular disabilities.
- **Military:** It has potential use in the military as an aid to increase endurance, speed, and strength, particularly that of wounded soldiers that would otherwise be helpless. It can be used to protect soldiers from enemy fire by repelling bullets. This increases the efficiency of soldiers. It can be used for mission in places where vehicles can't access.
- **Rescue:** It can be used in any physically demanding job such as disaster rescue or construction, rescue operations in hazardous or hard-to-access environments.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. BLEEX
Source: http://bleex.me.berkeley.edu/research/exoskeleton/bleex/ on 11th June 2017.

- **Entertainment:** It is used in activities which demands extreme and dangerous performance while ensuring the safety of the performer such as performing superhuman stunts without risking the person's life and is used as a preventive measure in extreme sports.

Jaipur Foot

In 1968, Jaipur foot was first developed and carried forward by Bhagwan Mahaveer Viklang Sahayata Samiti, India for societal betterment in 1975. Jaipur Foot is a renowned one for its facilitation in changing lives of many physically challenged people worldwide. The development of the Jaipur Foot proved to be a remarkable triumph in the history of prosthetic foot (Coupland RM, 1991). It is an artificial limb which replaces the missing extremity. According to one research by Dr. Goutam Reddy from Massachusetts Institute of Technology it is low cost, durable, water proof and can be used without shoes.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Jaipur Foot, named after the place where it was designed, is flexible along multiple axes, which allows natural movement of the foot. The Jaipur Foot technology is based on traditional craft using small local production methods. It has already helped over 900,000 amputees in developing and landmine-affected countries (Sethi PK 1972). The limb is so efficient that a person can walk like a normal person and sit in a crossed leg position. It helps them to go back to their jobs and earn for their families. In a world where prosthetics is a complicated and expensive industry, there is an operation of impressive scope that offers hope to the some of the most impoverished citizens of India and maybe even the world. It offers these handicapped citizens a chance to return to their livelihoods and pursue their dreams.

Working Method of Jaipur Foot

The Jaipur foot was designed according to the socio-culture needs of handicapped people of India keeping in view cost factor, ease of use and product quality. Due to its unique property it permits squatting, sitting in crossed leg position, walking on uneven surface, even in wet muddy field. It has proved to be a 'universal design' and can interface with prosthetic technology used around the globe. It is distinguished from other prosthesis because it have central keel which permits mobility in all planes despite having non articulation.

Devices for Mobility

Overview of Robotic Aids for Mobility

Over the past few decades, technology has advanced immensely serving as a boon to rehabilitation and assistive technology. Not only has it helped in developing devices with sophisticated functionalities, but also enhancing its aesthetic value. This gives the user of assistive devices a positive mental attitude towards the use of the device thus aiding in the rehabilitation process.

Apart from the basic need of food, cloth and shelter, the other needs of an individual are independence in carrying out his/her own activities and independence in movement. However, owing to unfortunate

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

events, this independence may be compensated partially or totally. Engineering science and technology proves as a boon in such conditions. It has helped traditional techniques in rehabilitation become automatic and closely tailor-made as possible to suit a wide scale of patient conditions.

Basic everyday activities or often referred to as activities of daily living (ADL) include eating, cleaning, dressing, brushing, reading, etc. Performing such activities requires free movement of the body and its parts. In case of patient suffering from motor disabilities, such movements are often largely compensated. Often rehabilitation practices through occupational therapy and physical therapy serves as a helping hand in training for performing such activities. Additionally, assistive aids such as grabbers, feeders, wheelchair, etc., provide assistance in helping perform activities better.

From activities such as brushing to moving about in vicinity or beyond that, technology has come up with solutions to help people with motor disability to help them perform activities. Feeders and grabbers for people with compensated freedom of movement in the upper limb are available. This makes them hold things and transfer food without spilling or dropping all over and boosting their confidence to perform activities.

The generations of wheelchair has also advanced from manual wheelchairs to powered wheelchairs. Sophisticated features such as voice-controlled, EOG-controlled, EEG-controlled, joystick controlled wheelchairs are also available in market and research (Bourke, 2001). The design and materials used have also transformed to give best comfort and suit patient conditions. Motorized tricycle, scooters, modified licensed vehicles, walkers with brakes and many such innovative introductions are made for a better social involvement of person with challenges in mobility.

Manual and Attendant Propelled Wheelchair

Chair with wheels was invented in the 5th century. Since then, ithas undergone continuous modifications in design and technology associated with it. A basic manual wheelchair incorporates a seat, foot rests, four wheels (2 caster wheels at the front, 2 large wheels at the back).The two large wheels usually have hand rims (metal or plastic) to aid in propulsion by the patient. Push handles at the top of the back for manual propulsion by second person assisting the device user. A wheelchair acts as an assist to people for whom walking is difficult or impossible due to illness, injury or disability.

Traditional wheelchairs are manually propelled or attendant propelled. It requires physical effort for propulsion in both the cases. In case of manually propelled wheelchairs, the two hind wheels are made large enough to allow the user for proper biceps elevation and alignment for propulsion. This alignment is necessary to avoid any upper extremity problems, possibility of stroke and loading in the hand. In any wheelchair, the back-hip alignment, knee-foot alignment is always maintained at 90^{o} to maintain a proper posture in order to avoid additional problems. Cushions are fitted at seat to prevent pressure sores from long sitting hours and also at back for rest. In an attendant propelled wheelchair, included for safety. Push handle bracket are fitted at the top of the back of the wheelchair. This allows easy propulsion of the wheelchair.

There are different types of wheelchairs based on the utility, duration and patient conditions. For example, wheelchairs used in hospitals, brief outings, airports etc., are not quite comfortable but serves the purpose as it is used for a short duration of time. However, wheelchairs used at home or work (in few cases) are quite different from the above mentioned as they are ergonomically designed for longer use time and also to suit the comfort and work environment and conditions. All wheelchairs can be customized for user's need such as seat dimensions, height, seat angle, footrests, leg rests, front caster,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Types of wheelchair
Source: http://www.wheelchairsmanufacturers.com/ on 11th June 2017.

and backrests etc. Wheelchair designs are based on factors such as intended use, abilities of the user, resources available, existing products, durability, function, aesthetics and comfort.

Special Purpose Wheelchair

Moving forward from traditional wheelchairs, there are other types of wheelchair which are designed for special purposes (Gomi, 1998). There are wheelchairs for different types of sports, recreational activities, racing wheelchairs, wheelchairs for staircase ascend or descend with the introduction of Paralympics and growing interests in sport activities by people with motor disabilities, wheelchairs have undergone a drastic evolution to serve the purpose. However, such wheelchairs are for recreational use and not for use in daily life and long run.

Not all environments are made friendly for people on four wheels. There are steps and irregular terrain everywhere and also presence of slides is less common compared to flights. Therefore, there are wheelchairs modified for use for staircase to ascend and descend. However, these wheelchairs are costly and not commercially available but mostly on a trial stage.

There are other types of wheelchairs for staircase ascend and descend (Chaichanasiri, 2011). However, these are not specially designed for the purpose. Instead spokes are attached as appendage on the hind portion of the wheelchair between the hind wheels.

Automated and Powered Wheelchair

Manually and attendant propelled wheelchair which requires physical effort are tiresome for long duration use. Also, it may sometimes lead to other physical and functional problems both for the attendant and the user. To remove these difficulties, implementation of technologies for developing automated and powered wheelchair is available and research for improvements are taking place. This has transformed wheelchair into a “will-chair”.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

In automated and powered wheelchair, there is no manual physical effort involved. The rotation of the wheels which in turn is responsible for the movement of the wheelchair is done with the help of motors. The motor is the source for movement of the wheelchair. Power source for the functioning of the motor is provided using battery. The motor and power source assembly is such that it produces enough power to carry the load of the wheelchair and the user sitting on it and move carrying the total load. The direction and velocity for movement is controlled by an interface between the user and the wheelchair. Another important component of an automated wheelchair is the controller.

The basic components of an automated and powered wheelchair are as follows:

- **Input Device:** A joystick is the most standard way of controlling a powered wheelchair. It is mounted on either side of the wheelchair. Some alternative ways to control a motorized wheelchair are: (i) mini joystick: These are smaller than the normal joystick used in the wheelchairs and require less force to operate, a pressure as low as 18g; (ii) touchpad: It is similar to what you find in computer for controlling its cursor. The touchpad is based on touch but not pressure. Touchpad can be configured for the user such that touching a specific spot with respect to the centre will move in a configured direction or just dragging the finger on touchpad in the desired direction; (iii) sip and puff controls: These are controlled by sucking and blowing to a mouthpiece. The sip and puff can be programmed such that it will have mode to operate other controls. It requires some practice for the user to get good at driving the wheelchair. The system can also determine the strength of sip and puff besides just distinguishing them.
- **Controller:** The controller acts as the intermediate between the user and input device i.e. joystick or other forms of input device discussed above. It includes the electronics and software that is required to modify the signal from the input device, which is then converted to output and passed to the wheelchair for control. In other words the function of a controller is to translate various commands from the input and monitor performance and provide feedback to the user.
- **Power Controller:** Its function is control the electrical power delivered to the motors which controls the wheelchair speed.
- **Motor:** The basic function is to generate driving torque and to provide steering control for the wheelchair. The wheelchairs commonly make use of permanent magnet direct current motors with brushes. Most permanent magnet motors have conversion efficiency in the range of 60-80%.
- **Drive Trains:** They provide transmission of motor's torque for driving the wheel and to provide required speed versus torque reduction. The drive trains can convert high motor speed to low speed with increase in the torque. It's done with efficiency of 50-70%.
- **Battery:** The powered wheelchairs basically use rechargeable deep-cycle batteries rated 12-80 amperes-per-hour. The batteries can be wet-cell or dry-cell batteries. Majority of the manufactures use gel-cell based batteries over wet-cell due to its low maintenance and other environmental concerns.

Advantages of Wheelchair

Wheelchairs have given mobility life to people with motor disability. This has provided them with a feel for independence to a certain extent. Use of wheelchair gives them better performance in daily life. Movement in rough terrain happens at ease. Wheelchair provides benefit in most of the aspects of its utility except that it is costly.

Devices for Visually Impaired

Visual System

Visual system is the part of higher function of brain that is central nervous system (CNS). It gives ability to the organism to process the visual details. Visual system also detects and interprets information from visual light to build a representation of the surrounding environment. Visual system comprises (Hersh, 2008) of many parts such as eyes specially retina, optic nerve, optic chiasma, optic tract, genticulate body and visual cortex.

Function of Visual System

During the mechanism of work cornea and lens refract light into a small image and shine it on the retina. The retina transfers this image into rod and cone cell of the eyes. Optic nerve which is the part of cranial nerve carries these electric pluses through optic canal and reached to the optic chisma (Toh, 2008). The structure of eyes involve many parts such as eyes specially retina, optic nerve, optic chiasma, optic tract, genticulate body and visual cortex.

- **Eye:** It provide organisms vision, it have ability to process visual field as well as enabling many photo response function as that are dependent of vision. The main function of eye is to detect light. In eyes retina consists of a large number of photo receptor cells which contains particular protein molecules called opsins. In humans, two types of opsins are involved in conscious vision: rod opsins and cone opsins. It transmits a signal to the cell through a signal transduction pathway, resulting in hyper-polarization of the photoreceptor.
- **Optic Nerve:** It is a part of cranial nerve, it paired nerve that transmits visual information from the retina to the brain. It is derived from optic stalks during developmental period of life and composed of retinal ganglion cell axons and glial cell. In human body optic nerve extends from the optic disc to the optic chisma and continues as optic track (Vilensky, 2015, Selhorst, 2009). Optic nerve is the part of cranial nervous system because it derived from an out pouching of the diencephalon (Optic stalks) during embryonic development.
- **Optic Chiasma:** The optic nerve of both the eyes where meets and cross each other that point is called optic chisma (Turner, 2010). It situated at the base of hypothalamus of the brain.. At this point the information coming from both eyes is combined and then splits according to the visual field. The corresponding halves of the field of view (right and left) are sent to the left and right halves of the brain, respectively, to be processed(Nolte, 2002)
- **Optic Tract:** Optic tractis a part of the visual system in the brain. It is a continuation of the optic nerve that relays information from the optic chiasm to the ipsilateral lateral geniculate nucleus (LGN), pretectal nuclei, and superior colliculus (Britannica, 2011).
- **Visual Cortex:** It passes the visual information through the visual hierarchy, the complexity of the neural representation increases. It receives the impulses sent to it from the eye that contain what the image.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Types of Visual Impairment

Visual impairment is defined as decreased ability to see to a degree that causes problems not fixable by usual means, such as glasses. Some also include those who have a decreased ability to see because they do not have access to glasses or contact lenses. Visual impairment is often defined as a best corrected visual acuity of worse than either 20/40 or 20/60. According to world health organization the visual impairment (Sinha, 2015) or visual acuity can be defined as in many forms such as given below (Maberley, 2006).

- **Low Visual Acuity:** Vision between 20/70 and 20/400 with the best possible correction in visual field of 20 degree or less than 20 degree.
- **Mild Blindness:** Visual acuity worse than 20/400 with the best possible correction, or visual field of 20 degree or less.
- **Blindness:** Visual acuity of 20/200 or worse with best possible correction in visual field 20 degrees or less.

Causes of Visual Impairment

Types of impairment are different for different causes of visual impairment.

- **Visual Impairment in Glaucoma:** In glaucoma normal fluid pressure increases as compared to normal pressure inside the eye. In glaucoma peripheries seem to be normal.
- **Age Related Macular Degeneration (AMD):** In this type of visual impairment central area of the eye becomes woolly or cottony opacity obsures the central part of the vision. The peripheries may be normally seen. In usually blurs the sharp, central vision that is needed for closely viewed activities like reading sewing and driving. Patients have no pain in the visual impairment.
- **Cataract:** There is general clouding of the vision. In this condition whole eye lens is affected the blurring or vision may be diffuse until it is totally lost.
- **Diabetic Retinopathy:** Diabetes leads to damage of the smaller arties and blood vessels at the back of the eyes over the retina. Diabetic retinopathy is the most common diabetic eye disease and a leading cause of blindness in adults. Usually vision impairment in diabetics begins as black spots or floating shapes that appear in the field of vision. Slowly compete vision may be lost if left unchecked.
- **Near Sightedness:** Myopia or near sightedness or short sightedness means a person can see nearby objects clearly but distant objects appears blurred. High myopia may lead to vision impairment.
- **Retinitis Pigmentosa:** This is genetic condition which initially manifests as night blindness. As the disease progress there may be a tunneling of vision with loss of peripheral vision followed by the compete blindness.

Cortical and Retinal Implant

Cortical and retinal implants are used to enhance vision or substitute parts of organ system function. Cortical implant consists of a chip or cable implanted in the visual cortex in the brain and the useful vision is enabled through camera or glasses. In case of retinal implants, the chip containing about 3500 solar cells with its own stimulating electrodes in about 2mm in diameter is implanted. The cells convert

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

light energy into pulses to stimulate the remaining functioning part of the retina. There are two approaches for implant:

Epiretinal approach: In this, the electrode array is implanted on the surface of the retina to stimulate the overlying cells of the retina (ganglion cells).

Subretinal approach: In this, the implant is made behind the retina between the photoreceptor layer and the retinal pigment epithelium, directly stimulating retinal cells and relying on the normal processing of the inner and middle retinal layers.

Mobility Aids

Mobility for the visually impaired or blind has been a hindrance as most of the designs in the environments were not done taking such groups into consideration. Although designs are being implement in few places and transport system. However, it cannot ease up the movement problem faced by the group. Assistance acts as a boon in such cases. White cane is widely used by blind and visually impaired to aid them in mobility. An improvised version is use of ultrasound technology in white cane of the user to help them identify the presence of object on their route and traverse avoiding it.

Ultrasound is a sound wave ranging in the frequency of 15-20 kHz. Most objects in nature reflect ultrasound. This is used in developing the improvised white cane with ultrasound technology. In this, the hand held portion of the cane has control buttons that emits ultrasonic waves on a press. Around the tip of the cane, ultrasound transmitter and receiver are present. The transmitter transmits the sound waves which upon hitting an object (if any) reflect the waves and the user receives indication on object in the form of light vibrations. This has helped in making the group of users more independent with regards to movement.

Devices for Hearing Impaired

Auditory Pathway

Auditory system is a sensory system which is meant for sense of hearing. It includes both sensory and auditory parts of the sensory system.In auditory pathway cochlear nerve fibers synapse into the dorsal and ventral cochlear nuclei. Cochlear nuclei contain second order neurons so the auditory pathway is bilateral in nature (Harlow 1946). In auditory pathways fibers decussate remains ipsilateral that the pathway ascends in the lateral leminscus and then in the brachium of the caudal collicus from which neurons send their axons through the internal capsule to cerebral cortex surrounding the sylvian sulcus.

In auditory pathway cochlear nuclei receives input from the ipsilateral cochlear nerve. Similarly dorsal nucleus of trapezoid body receives input from right and left ears. Cochlear nucleus works as sound localization, for example it detecting phase and intensity different between the two ears. After detecting the sound location it sends the output to cranial nerves V and VII for reflex contraction of tensor tympani and stapedius muscle to dampen loud sound. In auditory pathway nucleus is the main source of efferent axons which tune the spinal organ for frequency discrimination.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Functional Hearing Assessment

A hearing test provides an evaluation of the sensitivity of a person's sense of hearing. The hearing test is performed by audiologist by using instrument called audiometer. It determines a person hearing sensitivity at different frequencies. Before hearing assessment ear examination is required prior to hearing test. In this examination the ear of the patient are usually examined with an otoscope to make sure they are free of wax that the eardrum is intact, ear are not infected and the middle ear is free of fluid (Johnson 1993). There are many genetic dis-order, ageing problems, exposure to noise, environmental pollution, birth complication and side effects of medication that results the hearing loss and hearing impartment.

Type of Hearing Tests

- **Pure Tone Audiometry:** It is the most oldest and common method of hearing testing. It measure the air and bone conduction thresholds for each ear in a set of eight standard frequency from 250Hz to 8000Hz (Yusuf Kemal Kemaloglu 2005). This test is performed in sound booth using a pair of headphones connected to an external audiometer and the result of this test is ploted in form of audiogram diagram form at the tested frequency.
- **Web and Rinne Test:** This test helps to determine the kind of hearing loss is present in the patient. In this examination of hearing test vibrating tuning fork is placed behind the ear near to the mastoid process. When patient can no longer feel/hear the vibration (Yueh, 2003) the tuning fork is held in front of the ear; the patient should once more be able to hear a ringing sound. If patient so not perform this test mean there is conductive hearing loss in the ear. In that condition patient is then asked if the sound is localized ion the centre of the head. If again there is conductive hearing loss it should be louder in the affected ear and if there is only sensor neural hearing loss it will be quieter in the affected ear.
- **Physiological Tests:** Auditory brainstem response testing, oto acoustic emission audiometry and tympanometry comes under the physiological test. These tests are mainly performed to describe neurological or mechanical functioning of the auditory system but these test do not involve person being tested.
- **Behaviour Test:** It required participation of the individual being tested. Most common behaviour test involve pure tones which generate sound by machine. These machine generated sounds are very controlled for their pitch and loudness. All natural sounds, especially speech, contain a combination of different frequencies (pitch) of varying intensity (loudness). During pure tone testing, audiologists are trying to find an individual's threshold at various frequencies. Threshold is the intensity level where a sound can just be detected. There is not an exact one-to-one correspondence between auditory thresholds and what an individual can do with her or his hearing, but pure tone testing is important to use as a starting point for predictions and to use as the basis for hearing aid fitting.

Auditory Augmentation and Substitution

Hearing impairment may be mild or profound. In case of mild impairment, auditory augmentation is provided for rehabilitation of the impairment while auditory substitution is required in case of profound impairment.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hearing aid is a type of auditory augmentation. A hearing aid is an electronic device which amplifies the incoming sound for perception. The different components that are assembled together form a hearing aid are described below.

- **Microphone:** A microphone serves the function of the external ear of receiving sound. The received sound is then converted into electrical impulses and sent to the amplifier.
- **Amplifier:** The amplifier increases the intensity of the electrical impulses generated by the microphone.
- **Receiver:** The receiver's role is to convert the amplified electrical signals to sound with greater intensity than the perceived sound. It then delivers the sound to the inner portion of the ear.
- **Battery:** Battery serves as a source of power for the operation of the device.

Hearing aids are available in different styles to suit the requirement and choice of an individual. The components are held in a small case making the hearing aid highly portable and hardly visible. The different styles indicate the location for placement of the hearing aid. Hearing aids are mostly digital or of programmable type.

- **Behind-the-Ear (BTE):** BTE hearing aids is placed behind the ear and has a hook shaped plastic moulded extension from the case which is used for fit in concha. The sound travels from the case and is delivered into the ear through the mold. It is used for mild to profound hearing loss and can used by all ages. However, BTE is visible and might be an embarrassment to the user. Hence, other styles are preferred in many cases.

Figure 14. BTE
Source: http://www.alimco.in/content/854_1_BehindTheEarHearingAidDigital.aspx on 11th June 2017.

- **In-the-Ear (ITE):** An ITE hearing aid completely fits in the orifice of the outer ear. The components are held in a hard plastic case for a proper casing. Due to its small size, the ITE has problems for fit and also damages can occur due to earwax or fluids. It is not worn by children as the casing needs to be replaced as the ear grows. It is used for mild to severe hearing loss.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 15. ITE
Source: http://www.alimco.in/content/854_1_BehindTheEarHearingAidDigital.aspx on 11th June 2017.

- **In-the-Canal (ITC):** It is a customized hearing aid in which the case is developed for perfect fit depending on the size and shape of the ear canal. It is used for mild to moderately severe hearing loss.

Figure 16. ITC
Source: http://www.alimco.in/content/854_1_BehindTheEarHearingAidDigital.aspx on 11th June 2017.

- **Completely-in-Canal (CIC):** CIC is another custom-fit hearing aid and concealed in the ear canal. It is smaller in size as compared to other hearing aids and is not comfortable for repeated removal and adjustment. It is also prone for damage by earwax and fluids.

Figure 17. BCI

When hearing impairment is profound, auditory augmentation is of vain. The subject needs to have auditory substitution i.e., an artificial auditory pathway is required. Cochlear implant is a form of auditory substitution. It consists of 4 main parts: microphone; speech processor; transmitter-receiver and implanted electrode array. The microphone is employed for collecting sound from the environment and feeding it to the speech processor. The speech processor has the necessary volume adjust. Its primary role is to convert the incoming sound into matching intensity of electrical signals. This signal is then sent to the parts present inner in the ear via the transmitter-receiver assembly. The transmitter-receiver as the name suggests does the function of transmitting the electrical signal from the external portion of the implant components to the internal portion. This can occur in two ways: transcutaneous or percutaneous. The electrode array is a wire consisting of multiple electrodes placed in the scala tympani. It stimulates the hair cells with the electrical signal received from the receiver.

Tactile Sensors

A tactile sensor is a device that measures information arising from physical interaction with its environment (A. S. Hsieh, 1995). Tactile sensors are generally modeled after the biological sense of cutaneous touch which is capable of detecting stimuli resulting from mechanical stimulation, temperature, and pain. Tactile sensors are used in robotics, computer hardware and security systems. A common application of tactile sensors is in touchscreen devices on mobile phones and computing. Tactile sensors may be of different types including piezo-resistive, piezoelectric, capacitive and elasto-resistive sensors (Cutkosky, M. R.1989).

Applications of Tactile Sensors

Tactile sensors are nowadays employed in everyday life having innumerable applications such as lighting lamps which dim or lighten up by touching the base or the elevator button. They have several applications in the field of rehabilitation and assistive devices for disabled. Sensors are quite small in appearance but they have high sensitivities which suit several medical applications. They are designed keeping in view having minor effect on what parameter is being measured; thereby making the sensor smaller that often improves their sensitivity and introduces other advantages (A. M. Wing 1993). Tactile sensors can be used to test the performance of all types of applications. For example, these sensors have been used in the manufacturing of automobiles (brakes, clutches, door seals, gasket), battery lamination, bolted joints, fuel cells etc. Nowadays tactile sensors are much familiar in field of rehabilitation such as soft silicone tactile sensor for measuring pressure while gait training in stroke or hemiparetic patients, alternative tactile sensors for perceptron neural networks by applying the contact evaluation according to the algorithm, pressure sensor for detecting normal force on human weight nearing joints and biological inspired tactile sensors for finger pressure measurements.

Computer Brain Interfacing (BCI)

Research on brain computer interfacing (BCIs) began in the 1970s at the University of California, Los Angeles (UCLA) under a grant from the National Science Foundation (Adjouadi M. A 2000). The papers published after this research also mark the first appearance of the expression brain–computer interface in scientific literature. Computer interfacing is a process of shared boundary across which two or more

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

separate components of computer system exchange information. The exchange can be between software, computer hardware, peripheral devices, humans and combinations of these. Some computer hardware devices, such as a touchscreen, can send and receive data through the interface, while others such as a mouse or microphone may only provide an interface to send data to a given system. A brain computer interface (BCI), sometimes called a mind-machine interface (MMI), direct neural interface (DNI), or brain–machine interface (BMI), is a direct communication pathway between an enhanced or wired brain and an external device (Evarts EV.1966). BCIs are often directed at researching, mapping, assisting, augmenting, or repairing human cognitive or sensory-motor functions.

The history of brain–computer interfaces (BCIs) starts with Hans Berger's discovery of the electrical activity of the human brain and the development of electroencephalography (EEG). In 1924, Berger was the first person to record human brain activity by means of EEG. Berger was able to identify oscillatory activity, such as Berger's wave or the alpha wave (8–13 Hz), by analysing EEG traces. It is a direct communication pathway between an enhanced or wired brain and an external device. BCIs are often directed at researching, mapping, assisting, augmenting, or repairing human cognitive or sensory-motor functions.

Cost Analysis of Affordable Devices for Rehabilitation

Cost-effectiveness and cost-benefit studies are conducted at a level that involves more than just a local program (such as an individual's state strengthening project). Sometimes they also involve following up over a long period of time, to look at the long-term impact of interventions. They are often used by policy analysts and legislators to make broad policy decisions, so they might look at a large federal program, or compare several smaller pilot programs that take different approaches to solving the same societal problems. People often use the terms interchangeably, but there are important differences between them.

Cost Effective Analysis Helps Us in Following Aspects

- Cost analyses can provide estimates of what a program's costs and benefits are likely to be, before it is implemented.
- Cost analyses may improve understanding of program operation, and tell what levels of intervention are most cost-effective.
- Cost analyses may reveal unexpected costs.
- Whether or not the outlined program is having a significant net effect on the desired outcomes.
- Whether the least expensive alternative is always the best alternative.

ADVANTAGES OF USING COST ANALYSES

- Promotes fiscal accountability in programs.
- Helps set priorities when resources are limited
- Can be extremely powerful and persuasive to legislators, policy makers, and other funders.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

DISADVANTAGES OF USING COST ANALYSES

- Requires a great deal of technical skill and knowledge
- Market costs (what people actually pay for something) don't always reflect "real" social costs
- Sometimes there are multiple competing goals, so we need to weight them or prioritize them in some way.
- Sometimes costs and monetary values are considered less important than other, more intangible values or program outcomes
- The best-known cost-benefit studies have looked at long-term outcomes, but most program evaluations don't have the time or resources to conduct long-term follow-up studies.

CONCLUSION

In this chapter, the importance of Rehabilitation Engineering was well explained in section – 1, based on the census data 2011 provided by the Government of India and World Health Organization. Section – 2 explains about the trends in development of prostatic and orthotic devices and how, the technology can be used to improve the current devices in the market. Devices for mobility and its development were explained in section – 3. Devices for visual impairment and hearing impairment and its uses are explained in section 4 and 5 respectively.

Chapter 31
Technology and Cognitive Empowerment for Healthy Elderly:
The Link between Cognitive Skills Acquisition and Well-Being

Silvia Serino
IRCCS Istituto Auxologico Italiano, Italy

Elisa Pedroli
Applied Technology for Neuro-Psychology Lab, IRCCS Istituto Auxologico Italiano, Italy

ABSTRACT

The progressive growth of the ageing population represents opportunities as well as challenges. Consistently, the identification of effective cognitive empowerment programs in elderly population is now a worldwide health policy priority, specially for their preventive effect. In this chapter, within the paradigm of Positive Technology, the main focus will be on the use advanced technologies as effective tools for a new class of applications aimed at improving the traditional cognitive empowerment in elderly. Specifically, the attention will be devoted on how advanced technologies may be used to support elderly in reaching engaging and self-actualizing experiences. On the basis of the most recent evidence in literature, it will be discussed the possible advantages in using such advanced technologies for improving well-being in frail elderly: coupled with an increase in cognitive skills acquisition, the advantages may range increased self-efficacy and decreased subjective weakness, with a consequent improvement in both physical and cognitive performance.

INTRODUCTION

The ageing population (aged 65 and over) is projected to increase to 1.2 billion by 2025. According to the most recent demographic projections, there are 87.31 million elderly people in Europe (Lagiewka, 2012). The progressive growth of the ageing population represents opportunities as well as challenges. On one side, because of the substantial increase in life expectancy, the onset and prevalence of neurodegenerative disease will dramatically increase. To date, for example, Alzheimer's disease (AD) is the most common type of dementia, and it is estimated that the number of people affected will reach 81.1 million by 2040 (Ferri et al., 2006). On the other side, although ageing is usually related to physical and cognitive decline, many elderly individuals want to remain physically and cognitively healthy. Consistently, the identification of effective cognitive empowerment programs for healthy elderly populations is now a worldwide health policy priority.

The potential benefits of cognitive empowerment programs for individuals suffering from cognitive impairment and/or dementia have been increasingly recognized (Belleville et al., 2006; Bier et al., 2015; Buschert, Bokde, & Hampel, 2010; Jean, Bergeron, Thivierge, & Simard, 2010; Thivierge, Jean, & Simard, 2014). Moreover, the potentiality of cognitive empowerment programs is now accepted in healthy elderly populations as well (i.e., older individuals without current diagnosable cognitive impairment), especially for their preventive effect (see for example, Chapman et al., 2015; Kelly et al., 2014; Rebok et al., 2014; Willis et al., 2006).

An interesting recent study carried out by Hudson and colleagues (Hudson, Day, & Oliver, 2015) helps us understand why the definition of effective cognitive empowerment programs for healthy elderly populations may be particularly important. Indeed, Hudson and colleagues (Hudson et al., 2015) enrolled six older sedentary individuals in an exercise programme and interviewed them about their attitudes towards physical activity and their physical self-perceptions and identity. Participants' stories highlighted that while older adults may perceive exercise positively, their existing narratives of age-related decline may be resistant to change. The results of this study highlighted that it may be essential for all elderly people, cognitively impaired or not, to participate in cognitive empowerment programs since these kinds of activities may positively stimulate the elderly to change their attitudes towards age-related decline by increasing their self-efficacy. Indeed, what is crucial for a successful change is the increase in their sense of control. Participants at the beginning of the exercise programme described some existential challenges as well as their resolution of these. From this perspective, the possibility to participate in effective cognitive empowerment programs may become a resource both to delay cognitive impairment associated with ageing and to stimulate crucial cognitive skills fundamental to cope with the decline associated with an ageing body. The idea that cognitive empowerment programs can delay cognitive decline and improve sense of control in healthy older adults has dramatic consequences for its potential application. Cognitive intervention may help older individuals because they retain the cognitive capabilities to learn and apply sets of new strategies to improve their well-being. If designed properly, cognitive interventions may improve the cognitive functioning of elderly individuals and alleviate their anxiety resulting from their cognitive and physical difficulties related to both normal ageing and age-related disease.

The question is how to design and implement effective cognitive empowerment programs. To understand the role of cognitive empowerment programs for the elderly, the different types of traditional approaches will be presented alongside their specific characteristics in the following paragraph.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

COGNITIVE EMPOWERMENT FOR THE ELDERLY

Cognitive empowerment programs for elderly people can be generally included in the broader definition of "non-pharmacological interventions:" they directly or indirectly stimulate the cognitive functioning, as opposed to other interventions for elderly people that focus on emotion regulation (i.e., depressive symptoms) or physical frailty (i.e., fall prevention or weight loss) (Bahar-Fuchs, Clare, & Woods, 2013). These interventions typically involve elders in different types of activities, ranging from specific cognitive training focused on a particular cognitive function to group-based intervention aimed at promoting the cognitive functioning in a variety of different social contexts that are relevant for daily life. The different types of cognitive empowerment programs may be complementary or not, and the choice of a particular training depends on the objectives and the cognitive profile of the individual.

To summarize and provide some useful guidelines, a recent Cochrane review (Bahar-Fuchs et al., 2013) classified the most used cognitive empowerment programs for the elderly into two main categories: "cognitive training" (or "retraining," or "brain training") and "cognitive rehabilitation." In the scientific literature, these definitions have often been used interchangeably, but in the aforementioned Cochrane review (Bahar-Fuchs et al., 2013), and in its previous version (Clare & Woods, 2003), it is possible to have an extensive description of these two related but distinct forms of cognitive empowerment programs.

The term "cognitive training" is used to describe the repeated practice of series of exercises in order to specifically stimulate targeted cognitive functions (e.g., attention, episodic memory, executive functions). Belleville (Belleville, 2008) defined cognitive training as "teaching theoretically motivated strategies and skills in order to optimize cognition functioning" (pg. 57). Cognitive training may be offered individually or in group sessions. During the training, the different exercises are specifically tailored according to individual performance and to the progress made. Another important assumption underlying these programs is that the cognitive abilities learnt during the training may be generalized to real-life situations. An interesting example was offered by Kaci Fairchild and Scogin (Kaci Fairchild & Scogin, 2010), who developed and tested a memory enhancement program for cognitively healthy elderly. In their study, 53 older adults were assigned to either a memory enhancement condition or a minimal social support condition. Results showed that participants who received the memory enhancement program had a significant improvement in their mnestic abilities, such as remembering names with faces, having fewer lapses in memory and not misplacing household objects, and feeling more confident about their memory.

On the other side, the term "cognitive rehabilitation," originally developed to indicate all programs used to help individuals with brain injuries achieve satisfactory social functioning within their daily context, is now used to refer to programs for people with cognitive impairments. Although the primary aim of cognitive rehabilitation is the development of new effective ways to restore/improve the cognitive functioning of individuals with cognitive impairment, this field has recognized the role of empowerment as a critical element of any treatment strategy. This implies a shift from a traditional medical perspective that focuses on illness, dependence and deficiency to a new integrated approach that focuses on supporting wellness, independence and competence. Indeed, the International Classification of Functioning Disability and Health (ICF) of the World Health Organization (WHO, 2003) defines disability as a "condition in which people are temporarily or definitively unable to perform an activity in the correct manner and/or at a level generally considered 'normal' for the human being." As underlined by Morganti and Riva (Morganti & Riva, 2004), this definition focuses not on deficits but on assets: a person is disabled when she/he is not able to fully exploit her/his relationship with everyday contexts. The emphasis in cognitive

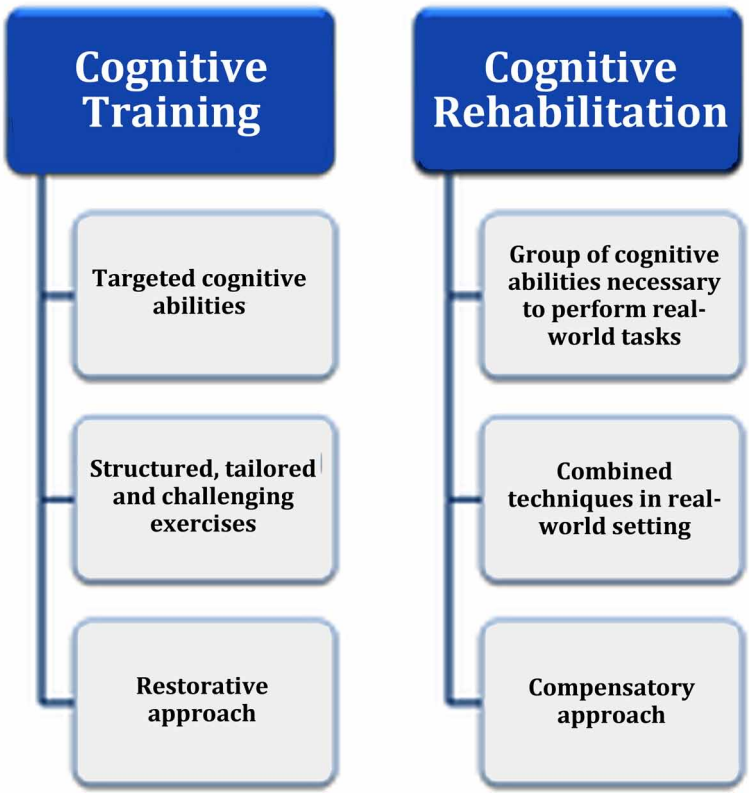
EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

rehabilitation is not on a specific exercise, but rather on improving cognitive and social functioning: it is generally implemented in real-life settings with the crucial support of caregivers. Clare and colleagues (Clare et al., 2010) offered an interesting example of "cognitive rehabilitation" for patients suffering from AD. In their study, 69 individuals in the early stages of AD were enrolled in eight weekly individual sessions of cognitive rehabilitation consisting of personalized interventions to address individually relevant goals supported by components addressing practical aids and strategies, techniques for learning new information, practice in maintaining attention and concentration and techniques for stress management. This combined approach showed significant improvement in ratings of goal performance and satisfaction.

These two approaches to cognitive empowerment programmes are based on two different conceptual frameworks: a restorative approach and a compensatory approach (Ylvisaker, Hanks, & Johnson-Greene, 2002). In cognitive training implemented following a restorative approach ("use it or lose it," the well-known principle of brain plasticity), repeated exercises of increasing difficulty specifically targeting a cognitive function may accelerate synaptic growth and repair (Draganski et al., 2006; Hertzog, Kramer, Wilson, & Lindenberger, 2008). On the other hand, cognitive rehabilitation implemented following a compensatory approach exploits residual cognitive abilities of people with impaired cognitive domains.

It is important to acknowledge that under the "umbrella term" of "cognitive empowerment programme," both approaches can be used. But it is crucial to know that they have a different clinical rationale from which derives different peculiar techniques.

Figure 1. The most peculiar features of the two most common approaches for cognitive empowerment programmes: cognitive training and cognitive rehabilitation



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

In Figure 1, the most peculiar features of the two most common approaches for developing an effective cognitive empowerment programme are summarized.

The Role of Advanced Technologies for Cognitive Empowerment: A Recent Trend

The dramatic development in the Information and Communication Technology (ICT) sector has resulted in incredible change in the way we interact and live. One of the newest fields that benefits from the advances in technology is that of cognitive assessment and rehabilitation (Bohil, Alicea, & Biocca, 2011; Gaggioli & Riva, 2014; Rose, Brooks, & Rizzo, 2005). In this context, indeed, an increasing trend is the use of advanced technologies, from computer-based application to more sophisticated virtual-based programmes, as functional tools for a new class of applications aimed to improve the traditional cognitive empowerment in the elderly (Barnes et al., 2009; Coyle, Traynor, & Solowij, 2014; García-Betances, Arredondo Waldmeyer, Fico, & Cabrera-Umpiérrez, 2015; García-Betances, Jiménez-Mixco, Arredondo, & Cabrera-Umpiérrez, 2015; Lampit, Hallock, & Valenzuela, 2014). What are the main advantages in using advanced technologies for supporting traditional cognitive empowerment? In general terms, the introduction of technology may offer a more flexible and personalized approach to traditional training programs.

First of all, computer-based cognitive empowerment programmes offer the chance to quantitatively measure behavior while maintaining strict control over stimulus delivery. Moreover, this kind of program allows cognitive exercises to be easily personalized to guarantee real-time performance feedback and an adjustment according to the user's ability level. Walinsky and colleagues (Wolinsky, Vander Weg, Howren, Jones, & Dotson, 2013) offered an interesting example of this great advantage by developing and testing a training programme for older adults focused on processing speed that could be easily delivered either in a clinical setting or at home using portable computers. In this programme, processing speed was improved by progressively reducing the time of exposure to stimuli for a correct identification. Interestingly, thanks to the use of technology, the training programme advanced automatically and in a controllable manner to a greater challenge when participants achieved a 75% success rate.

In the field of cognitive training and rehabilitation, Virtual Reality (VR) has been introduced to offer a completely new paradigm in which individuals (and, of course, patients) are no longer simply observers of stimuli appearing on a computer screen, but they are actively involved within ecologically valid virtual worlds (Riva, Mantovani, & Gaggioli, 2004). VR appears to be a suitable medium that offers several requirements for an effective cognitive empowerment program: repetitive practice, feedback about performance, multimodal stimulation and controlled and secure environments (Bohil et al., 2011; Riva et al., 2004; Schultheis & Rizzo, 2001). Peculiarly, it is possible to control and manipulate tailored exercises within meaningful, ecologically valid and engaging environments using virtual environments (Riva & Gaggioli, 2009).

It is interesting to report the words of McGee, who suggested that "older adults with impairments in memory and executive functioning could be presented with hierarchical rehabilitative challenges in a VE more efficiently and consistently than with traditional methods" (McGee et al., 2000). Indeed, one of the crucial features of the VR technology is the interactivity: immersive virtual environments incorporate a highly sensitive head and body tracking system. Interestingly, Optale and colleagues demonstrated how it is possible to exploit the interactivity of VR to stimulate the spatial functioning of older adults with cognitive impairment (Optale, Capodieci, Marin, Pastore, & Piron, 2007; Optale et al., 2001). They pro-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

posed and tested a cognitive rehabilitation memory training programme carried out on twelve patients suffering from mild cognitive impairments (Optale et al., 2007). This rehabilitation treatment consisted of three different listening experiences alternated with three different virtual experiences. The patients were invited to make an oral summary of their audio or VR experience to enhance their mnemonic abilities. During the immersive VR experience, patients were free to navigate in the environments. However, if the patients took a "wrong turn" and ended up at a dead-end, they were immediately transported back to that point along the path in the VR environment immediately before they took the "wrong turn."

After this brief overview of the potentiality of advanced technologies for integrating cognitive empowerment programmes for the elderly, the question is how to design and implement effective cognitive empowerment programmes exploiting the potentiality of new advanced technology.

New disciplines have been introduced, such as "gerontechnology", which refers to the "study of technology for ensuring good health, full social participation, and independent living throughout the entire life span" (Harrington & Harrington, 2000). However, continued technological advances, and progress in neuroscience and neurological research, require a new conceptual and practical framework. In this direction, a more comprehensive perspective is that of Positive Technology (Botella et al., 2012; Riva, Banos, Botella, Wiederhold, & Gaggioli, 2012; Riva & Gaggioli, 2015), which will be presented in the next section.

AN INTRODUCTION TO POSITIVE TECHNOLOGY

To specifically design and deliver cognitive empowerment programmes, from the design of a tool to its introduction into the clinical practice after scientific validation, it is crucial to adopt a comprehensive framework that can provide scientifically validated guidelines for technological development that meets the needs of an ageing society.

Within this direction, Positive Technology is an emerging field that could be defined as the scientific and applied approach that exploits the potentiality of advanced technology for improving the quality of our personal experience (Botella et al., 2012; Riva et al., 2012; Riva & Gaggioli, 2015). As recently suggested by Riva and colleagues (Riva et al., 2012), the dramatic advancement in the ICT sector has challenged technology developers, designers and psychologists to reflect on how to develop positive technologies to promote well-being. More recently, it has also been suggested that positive technologies may play an important role in dealing with age-related decline by improving well-being of the elderly (Riva et al., 2014).

Why it is possible to reflect about "positive technologies" for elderly? What is well-being, and why is this concept useful for designing effective cognitive empowerment programmes for the elderly? The emerging discipline of Positive Psychology provides a critical framework to both define well-being and to understand how to use technology to develop cognitive empowerment programmes for the elderly. Positive Psychology can be broadly defined as the scientific study of well-being to understand human strength and virtues and to promote them to allow individuals, communities and societies to flourish (Delle Fave, Massimini, & Bassi, 2011; Ryan & Deci, 2001; Seligman & Csikszentmihalyi, 2000; Snyder, 2010). Within this perspective, it appears to be a really promising framework to develop advanced technologies for health. According to Seligman (Seligman, 2002), who is considered the father of Positive Psychology, the definition of a "good life" consists of three different aspects of life, which correspond to different constituents of well-being:

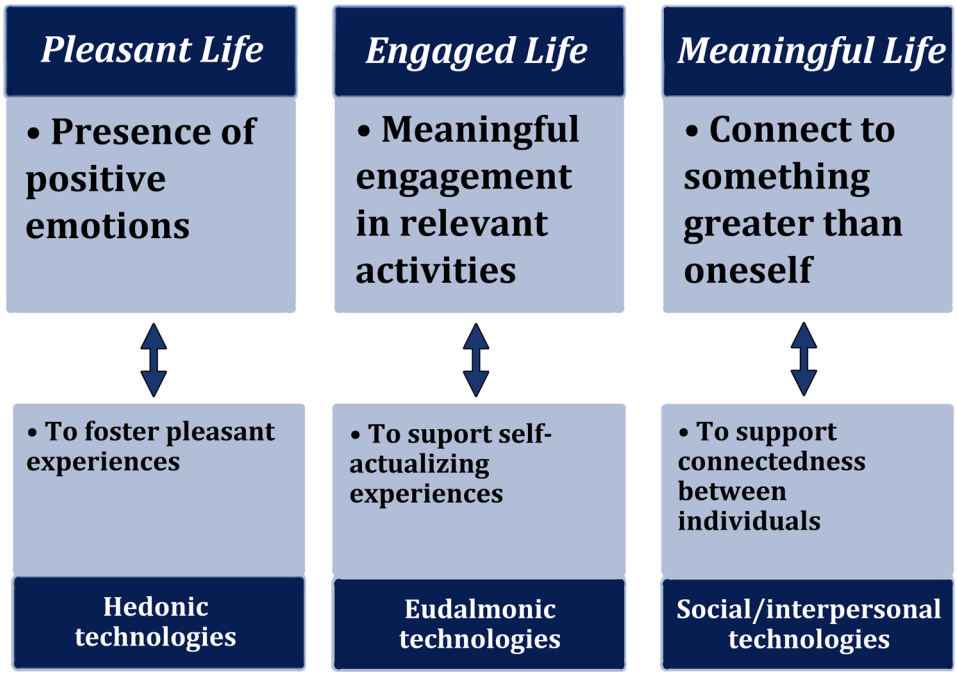
EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **The Pleasant Life:** Achieved through the presence of positive emotions;
2. **The Engaged Life:** Achieved through meaningful engagement in relevant activities that require the exploitation of individual strengths and virtues;
3. **The Meaningful Life:** Achieved through striving to connect to something greater than oneself.

Accordingly, it is possible to classify positive technologies according to their effects on these three aspects of well-being (see also Figure 2):

1. **Hedonic Positive Technologies:** Technologies used to foster positive emotions and pleasant experiences;
2. **Eudaimonic Positive Technologies:** Technologies used to support individuals in reaching engaging and self-actualizing experience;
3. **Social/Interpersonal Positive Technologies:** Technologies used to support and improve integration and connectedness between individuals and groups.

Figure 2. Positive technology: how to use technology to promote well-being



To further understand positive technologies and their role in improving well-being in the elderly, it is useful to introduce some relevant examples. A first crucial example of hedonic positive technology is the computer-based multi-media system recently developed and tested by Alm and colleagues (Alm et al., 2009). They started from the idea that interactive entertainment systems specifically designed for elderly individuals may engage them in activities that make life more enjoyable, thereby reducing depressive symptoms that may be associated with ageing and dementia. Their computer-based multimedia system was composed of three parts:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The entertainment system supplied engaging content in the form of interactive 3D games with simple, attractive and colorful interfaces;
2. The creative tool allowed a person to freely compose musical sounds independently of their musical skills;
3. The communication support system was designed to help the elderly communicate with their caregivers.

Within the Nostalgia Bits (NoBits) project, Gaggioli and colleagues gave us an example of social/interpersonal positive technology specially developed for the elderly. Indeed, the Nostalgia Bits (NoBits) project aimed at fostering social interaction between the elderly and children through collecting memories and increasing cross-sectional interactions and mentoring. They developed a web-based platform where tangible artifacts of an elderly person's life experience (e.g., photos, stories, personal documents) could be uploaded and thus become a meaningful resource to other generations and an "instrument" to connect elderly users with members of their own generation (Morganti, Riva, Bonfiglio, & Gaggioli, 2013). Findings collected from a user needs analysis conducted on 23 elderly and 310 children showed that both samples readily acceptedthe NoBits concept and that supporting collaborative reminiscing with social media is a promising approach to increase cross-generational interactions and mentoring.

Using the framework of Positive Technology (Botella et al., 2012; Riva et al., 2012; Riva & Gaggioli, 2015), in the following paragraph the attention will be specifically devoted to how advanced technologies that may be specifically used to support healthy elderly people in reaching engaging and self-actualizing experiences and how these experiences may be useful for improving traditional cognitive empowerment programmes.

The Potentiality for Eudaimonic Positive Technologies for Elderly

Although ageing is typically associated with a decline in physical and cognitive health, this decline can be delayed with effective interventions. In the previous paragraph, it was suggested how positive technologies can be specifically used to support positive emotions and promote connectedness for the elderly (Riva et al., 2014). The two relevant examples presented help us to understand how technology may play an important role in structuring successful pleasant experiences for improving the quality of life for the elderly and improving the strength of their relationships. An improvement in the quality of personal experience, in terms of subjective well-being, can delay age-related decline (Diener & Chan, 2011).

The theory of flow (Csikszentmihalyi, 1991) provides a useful framework to define an "engaging and self-actualizing experience," as well as how they can be used to enable a positive change (Inghilleri, Riva, & Riva, 2015). Flow, or optimal experience, is a state of full engagement, deep concentration and action awareness, occurring during an activity perceived as highly self-rewarding, characterized by clear goals, unambiguous and immediate feedback and an altered sense of time. Specifically, flow is a positive state characterized by a perceived balance between high environmental opportunities for action (challenges) and adequate personal resources in facing them (skills).

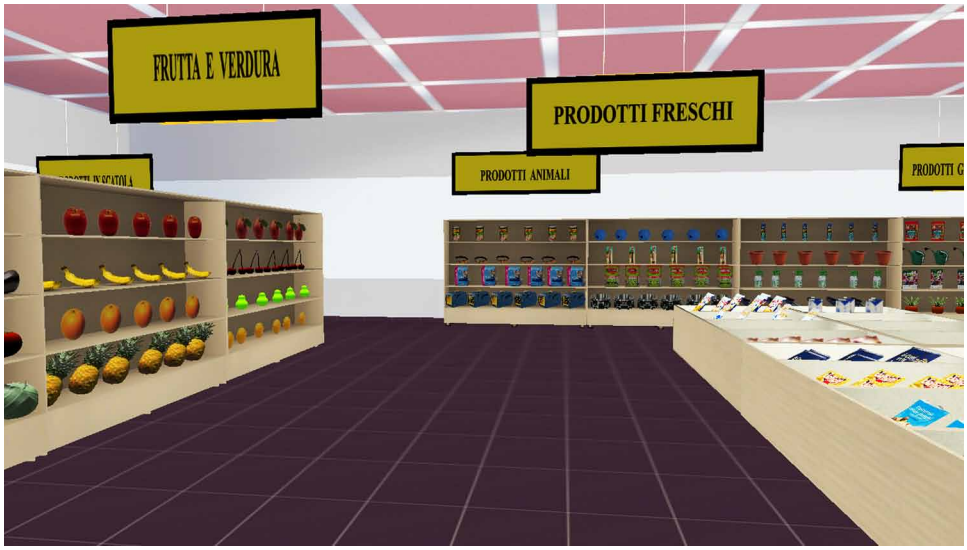
Thanks to some key characteristics, Riva and colleagues suggested that advanced technologies, and specifically VR, could be possible sources of flow (Riva & Gaggioli, 2009). First of all, immersive and interactive technologies offer incredible opportunities for action (goals and rules): users are no longer just observers, but active participants within a wide range of increasingly challenging situations and tasks. Second, immersive and interactive technologies offer the chance for giving timing, appropriate

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

and multimodal feedback to individuals based on their actions and behaviors. Within this perspective, Riva and colleagues introduced the strategy of "transformation of flow" (Riva & Gaggioli, 2009), suggesting the possibility to exploit the potentiality of using advanced technology for a new class of (positive) applications in mental health for the elderly. This strategy is based on the idea that, thanks to the continuous cognitive skills acquisition provided by an effective and interactive cognitive empowerment programme, an optimal experience (i.e., balance between skills and demands) is progressively reached and supported by the use of advanced technologies, and this state may be used to promote new and unexpected psychological resources.

Riva and colleagues (Riva et al., 2014) detailed the following steps for the development of eudaimonic positive technology applications for elderly that may integrate traditional cognitive programmes. The first suggested step is the development of an enriched environment containing functional real-world demands. An example was given by the Virtual Multiple Errands Test (VMET), a virtual version of the original Multiple Errands Test (Shallice & Burgess, 1991) developed for an ecological evaluation of executive functions. The test comprised a virtual supermarket where participants were instructed to select and buy various products presented on shelves and to complete tasks that abided by certain rules (see Figure 3). A recent study showed that VMET was more sensitive in the early detection of executive deficits in a sample of elderly participants suffering from Parkinson's disease (Cipresso et al., 2014). One interesting example of the same approach was tested in a pilot study by Kizony and colleagues (Kizony, Korman, Sinoff, Klinger, & Josman, 2012). They used a modified version of the VMET (i.e., a shopping task) for the rehabilitation of the executive functions in a sample of seven participants with non-amnestic or multi-domain mild cognitive impairment. Although preliminary, results showed the potentiality of this kind of ecological task as a potentially effective tool for training the executive functioning in elderly people suffering from mild cognitive impairment.

Figure 3. Screenshot of the virtual multiple errands test (VMET)
From Cipresso et al. (2014).



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The second step is the use of technology for developing interventions with tasks of increasing difficulty (challenges) that are matched to the cognitive level of the individual (skills). An example of a procedure showing increasing difficulty that is able to discriminate between the cognitive level of patients with mild cognitive impairment and patients with Alzheimer's disease has been recently proposed by Serino and colleagues (Serino, Morganti, Di Stefano, & Riva). Findings showed that patients with mild cognitive impairment performed significantly more poorly in the third trial of the first task, while patients with Alzheimer's disease performed significantly more poorly in the second task. A recent study by Kober and colleagues demonstrated the potentiality of VR in enhancing spatial abilities of neurological patients with focal brain lesions (Kober et al., 2013). They tested the efficacy of a verbally-guided passive navigation training in which participants were required to progressively learn the correct directions at each junction they had seen during the learning phase. Results showed that route-finding ability increased over the five VR sessions.

Finally, the third step is the cultivation of optimal experiences reached during the clinical session by linking the results obtained to the actual experience and skills during real life. The incredible development in mobile communications allows the diffusion of cognitive empowerment programmes via virtual environments implemented on mobile devices. This permits the extension of these immersive and interactive program at home to guarantee the continuity between virtual and real experience.

The expected benefit of this new class of eudaimonic positive technologies for the elderly is a functional reorganization of the brain produced by the broadening of the thought-action repertoire associated with an increase in self-efficacy.

FRAIL ELDERLY: WHY USE POSITIVE TECHNOLOGIES FOR COGNITIVE EMPOWERMENT

In the last 30 years, research has tried to identify the most salient and earliest cognitive symptoms characterizing the cognitive decline associated with neurodegenerative diseases (Aarsland, Brønnick, & Fladby, 2011; Albert, 2011; Bastin & Salmon, 2014; Breitve et al., 2014; Hu et al., 2014; Petersen, 2011). Specifically, several studies from both genetic at-risk cohorts and clinically normal individuals suggest that the pathophysiology cascade of neurodegenerative diseases begins years before the diagnosis of dementia (Aarsland et al., 2011; Hu et al., 2014; Sperling et al., 2011).

In this direction, mild cognitive impairment may represent a useful clinical entity for detecting subtle signs of early cognitive decline (Petersen, 2004, 2011). Indeed, mild cognitive impairment refers to a cognitive decline that does not significantly impair cognitive functioning, i.e., it is used when an older person does not meet the criteria for dementia either because they lack two deficits in two different cognitive domains or because their cognitive deficits do not significantly affect their usual activities (Peterson, 2011). Evaluation for capturing the first sign of cognitive decline is usually done using standard clinical tests, such as the Mini-Mental State Examination (Folstein, Folstein, & McHugh, 1975) or the Montreal Cognitive Assessment Test (Nasreddine et al., 2005). This prompt neuropsychological evaluation is absolutely needed because older individuals with mild cognitive impairment were progressing more frequently to Alzheimer's disease compared to healthy age-matched controls (for a review, see Mitchell & Shiri-Feshki, 2009).

Associated with mild cognitive impairment is frailty, a condition defined as a multifaceted syndrome generally marked by the progressive decreased ability of an elderly individual to respond to stressors (Fried

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2001). As described by Fried (Fried et al., 2001), from a clinical perspective, frail older persons are characterized by height and muscle loss, physical exhaustion and weakness, slow gait and lower levels of activity and functionality. It is crucial to highlight that cognitive decline in frailty is not as evident as cognitive impairment in other neurodegenerative disorders, but recent crucial evidence has reported that this syndrome increases the risk of future cognitive decline (Robertson, Savva, & Kenny, 2013).

In this direction, a recent consensus panel proposed the identification of the so-called "cognitive frailty" as a heterogeneous clinical manifestation characterized by the simultaneous presence of both physical frailty and cognitive impairment (Kelaiditi et al., 2013). According to the recent clinical guidelines developed by the aforementioned consensus group (Kelaiditi et al., 2013), the key factors defining cognitive frailty are as follows: the presence of physical frailty and cognitive impairment and the concurrent exclusion of concurrent ad dementia. Consequently, identifying and treating frail people may be an effective way to prevent or delay dementia. More specifically, some recent evidence has established a link between frailty and cognitive domains such as executive function, attention and processing speed (Boyle, Buchman, Wilson, Leurgans, & Bennett, 2010; Langlois et al., 2012; Macuco et al., 2012; Yassuda et al., 2012). However, today, a critical challenge has been to find new early innovative cognitive interventions to break the link between cognitive decline and frailty. To date, there are different traditional preventive approaches that may be considered for cognitively frail elderly people. These include promotion of physical activity, general cognitive stimulation, healthy dietary habits and good integrated lifestyles (i.e., smoking cessation, optimal daily sleep, promotion of positive emotions) (Desai, Grossberg, & Chibnall, 2010). Considering the suggested association between frailty and cognition, it is argued that positives technologies may play an important role in supporting the development of future cognitive empowerment programs for the elderly. On the basis of the most recent evidence in literature, in the following paragraph we will describe how eudaimonic positive technologies may integrate traditional cognitive training for frailty. Coupled with an increase in cognitive skills acquisition, the advantages may include improved mood, increased self-efficacy and decreased subjective weakness, with a consequent improvement in both physical and cognitive performance.

The Role of Advanced Technologies for Cognitive Empowerment: A Recent Trend

The application of advanced positive eudaimonic technologies may yield to more ecologically valid protocols focused on the specific needs of different individuals and specifically intended to promote well-being in terms of engaging and self-actualizing experiences within challenging everyday life scenarios (Riva et al., 2014).

This is particularly relevant for frail older individuals, for whom prompt cognitive interventions may delay cognitive decline. Considering their concurrent physical early impairment (Fried et al., 2001), there is a need to develop cognitive empowerment programmes that reflect ecological situations in order to prompt the restoration of functional ability in their daily lives. Moreover, as explained before, recent studies have demonstrated that there is some cognitive weakness in frail individuals in some areas, namely executive functioning and attention processing (Boyle et al., 2010; Langlois et al., 2012; Macuco et al., 2012; Yassuda et al., 2012). On the basis of this evidence, Goal Management Training (Robertson, 1996) appears to be a promising cognitive empowerment programme for the stimulation of executive functioning in frail older individuals. Robertson (Robertson, 1996) developed the Goal Management Training (Robertson, 1996) as a theoretically-based intervention aimed at helping individuals be more

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

and more effective at properly encoding intended goals by learning a mental checking system that enables them to maintain an active focus. Goal Management Training (GMT) is a structured cognitive training protocol based on Duncan's theory (Duncan, 1986, 1995; Duncan & Owen, 2000; Duncan et al., 2000) of disorganization of behavior following damage to the frontal lobes or to circuits that include frontal structures. In the "goal-neglect theory," Duncan argued that human behavior is goal-oriented since it is controlled by a list of goals or sub-goals. Individuals are able to formulate, store and check all these goals and sub-goals in order to effectively respond to environmental and/or internal demands. GMT can be generally defined as cognitive training for executive functions with two principal objectives: 1) improve awareness on behavior and its underlying goals; and 2) retain cognitive control when behavior becomes inconsistent with intended goals. The GMT trains individuals in five stages that characterise the most crucial elements for an effective rehabilitation of executive functions. In Stage 1, "STOP" participants are trained to ask themselves what they are doing at the moment and direct awareness towards relevant goals. In Stage 2, "DEFINE" participants are trained to define the main task and state the goals. In Stage 3, "LIST" participants are trained to list the steps necessary to achieve the main task. In Stage 4, "LEARN" participants are trained to encode and store goals and sub-goals. In Stage 5, "CHECK," the outcome of action is compared with the desired goal. Levine and colleagues (Levine et al., 2000) have demonstrated the clinical utility and efficacy of the GMT among patients with lesions in the frontal lobes.

GMT has been extensively developed, with different versions having been published ranging from a single session (Levine et al., 2000) to a 14-hour GMT training course for group rehabilitation in clinical settings (Levine et al., 2011). A very recent systematic review proposed by Krasny-Pacini and colleagues showed (Krasny-Pacini, Chevignard, & Evans, 2013) that comprehensive rehabilitation programs incorporating GMT, but also integrating other approaches, are effective in executive function rehabilitation following brain injury in adults.

However, as previously explained, the real challenge of cognitive training focusing on executive functions for frail older individuals is to improve the ability to participate in meaningful activities through transfer and generalization. For instance, if a cognitive rehabilitative intervention has been carried out at a rehabilitation center to improve executive abilities, it is important that the patient use these abilities in daily life activities such as preparation of a meal (generalization) at home (transfer). To address these needs, and to develop a programme that reflects ecological situations to prompt the restoration of functional ability in daily life, the use of advance virtual reality-based simulations has been proposed.

Following the guidelines of GMT, frail individuals with the use of VR may be composed of five stages: in Stages 1 and 2, frail people will be trained to direct awareness towards relevant goals and define the main task to achieve within virtual realistic environments. In Stage 3, people will be trained to list the steps necessary to achieve the main task, while in Stage 4 they will be trained to encode and store all the goals. In Stage 5, the outcome of action will be compared with the desired goal. To help frail people train their ability in formulating, storing and checking the goals necessary to perform a desired action, the VR-GMT protocol would be implemented in two virtual ecological environment real-life activities within ecological scenario (for example, purchasing an item or meal preparation). As suggested by Riva (Riva & Gaggioli, 2009; Riva et al., 2014), these enriched environments will contain functional real-world demands (for example, purchasing an item or meal preparation, including tasks of increasingly difficulty that will be progressively matched to the cognitive level of the individual). Then, as previously explained, it is crucial to cultivate the optimal experiences reached during the clinical session of GMT with VR by linking the results obtained to the actual experience and skills during real life. Within this perspective, the GMT with VR will be delivered on the following integrated devices: 1) a VR platform

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the clinical setting that allows the chance to deliver secure and engaging cognitive exercises, and 2) a smartphone that allows the chance to deliver virtual-based cognitive exercises during daily life.

With this integrated technological platform, this kind of cognitive empowerment programme based on the principle of GMT may be a eudaimonic positive technology specifically designed for frail older people. Beyond specific improvements in executive functioning, the adoption of a eudaimonic positive technology exploiting the strategy of "transformation of flow" (Riva & Gaggioli, 2009) may range from increased self-efficacy (thanks to the continuous skills acquisition provided by the challenging virtual experiences) to decreased subjective weakness (thanks to the habituation to real-life scenarios provided by ecologically valid virtual environments), with a consequent improvement in both physical and cognitive performance.

FUTURE RESEARCH DIRECTIONS

In the previous paragraphs, we argued that there is a "window of possibility" to develop a new class of applications that may enhance the traditional approaches used for cognitive empowerment in the elderly. In considering the future definition and testing of protocols using advanced technologies for improving well-being of the elderly, it is important to take into account the warnings of the above-mentioned recent Cochrane review about the efficacy of traditional cognitive programmes for patients suffering from mild AD and vascular dementia (Bahar-Fuchs et al., 2013). Conclusions about the efficacy of non-pharmacological interventions, especially about long-term effects, must still be viewed with caution due to the small number of randomized controlled trials. However, the findings available are promising and justify further studies in this direction.

Controlled studies testing the role of advanced positive technologies with a greater number of patients, appropriate control groups, a better definition of inclusion/exclusion criteria, standardized outcomes measures and follow-up measures are absolutely needed.

CONCLUSION

Recently, the World Health Organization (WHO, 2001) developed a new framework of human functioning and disability to underline the interactive relationship between health conditions and psychological and environmental factors. Disability is defined as a term representing a condition in which individuals are temporarily or definitively unable to perform an "activity" in the correct manner and/or at a level generally considered "normal" for the human being. The emphasis given to the "activity" highlights the dynamic interactions between person and environment. By consequence, it also emphasises the key concept of "participation" as an important outcome of well-being. This definition is focused not on deficits but on assets: a person is disabled when she/he is not able to fully exploit her/his relationship with everyday contexts. Participation reduction refers to the social, familial, educational or other role disadvantages associated with a disability (e.g., failure in school or loss of a job because of a communication impairment). This comprehensive framework permits a deeper understanding of why the introduction of the concept of "empowerment" as a key factor in any cognitive/physical training strategy is needed when considering dynamic interactions between older people (with and without impairment) and his/her environment.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Within the theoretical paradigm of Positive Technology (Botella et al., 2012; Riva et al., 2012; Riva & Gaggioli, 2015), in this chapter it has been detailed how advanced technologies may enhance the traditional approaches used for cognitive empowerment in the elderly. After a brief presentation on how different positive technologies may be differently classified according to their effect in promoting different constituents of well-being, the focus will be specifically devoted to how advanced technologies (and particularly VR) may be used to support healthy elderly people in reaching engaging and self-actualizing experiences. The theory of flow (Csikszentmihalyi, 1991) provides an useful framework by which to define what constitutes an "engaging and self-actualizing experience," as well as how they can be used to enable a positive change to improve well-being (Inghilleri et al., 2015).

Thanks to the continuous cognitive skills acquisition provided by an effective and interactive cognitive empowerment programme, an optimal experience (i.e., balance between skills and demands) may be progressively reached and supported by the use of advanced technologies, and this state may be used to promote new and unexpected psychological resources (Riva & Gaggioli, 2009). This strategy, known as "transformation of flow," opens new interesting possibilities for developing innovative cognitive training able to exploit the potentiality of positive technologies to stimulate cognitive functioning in elderly people. An example is offered in the last section: a possible use of positive technologies for integrating a standard theoretically-based cognitive empowerment program for executive functioning in frail elderly has been presented.

In sum, as positive technologies may have an important role in the design, development and testing of cognitive empowerment programs for the elderly, future studies and controlled trials will be needed to deeply explore the potentiality of advanced technologies to meets the need of ageing society.

KEY TERMS AND DEFINITIONS

Cognitive Rehabilitation: Originally developed to indicate all programs used to help individuals with brain injury to achieve a satisfactory social functioning within their daily context, it is now used to refer to programs for people with cognitive impairments.

Cognitive Training: Repeated practice of series of exercises in order to specifically stimulate targeted cognitive functions.

Empowerment: (within a rehabilitation perspective) A key factor in any cognitive/physical training strategy is needed when considering dynamic interactions between older persons (with and without impairment) and his/her environment.

Flow: A state of full engagement, deep concentration and action awareness that occurs during an activity perceived as highly self-rewarding, characterized by clear goals, unambiguous and immediate feedback and an altered sense of time.

Frailty: A condition that can be defined as a multifaceted syndrome generally marked by a progressive decreased ability of an elderly individual to respond to stressors.

Transformation of Flow: A strategy based on an idea that an optimal experience (i.e., balance between skills and demands) is progressively reached and supported by the use of advanced technologies, and that this state may be used to promote new and unexpected psychological resources.

ABSTRACT

This chapter outlines the current state of the art of Kinect sensor gait and activity authentication. It also focuses on emotional cues that could be observed from human body and posture. It presents a prototype of a system that combines recently developed behavioral gait and posture recognition methods for human emotion identification. A backbone of the system is Kinect sensor gait recognition, which explores the relationship between joint-relative angles and joint-relative distances through machine learning. The chapter then introduces a real-time gesture recognition system developed using Kinect sensor and trained with SVM classifier. Preliminary experimental results demonstrate accuracy and feasibility of using such systems in real-world scenarios. While gait and emotion from body movement has been researched in the context of standalone biometric security systems, they were never previously explored for physiotherapy rehabilitation and real-time patient feedback. The survey of recent progress and open problems in crucial areas of medical patient rehabilitation and rescue operations conclude this chapter.

INTRODUCTION

Rapid development of biometric technology has opened doors to a new class of fast and reliable identity management solution and has forever changed the research landscape (Jain et.al. 2008; Kisku et.al. 2013). Biometric relies on using observable unobtrusive traits (such as iris, fingerprint, face, voice or gait), to remotely authenticate a user. There has been a significant surge in the number of effective approaches to user authentication, discretionary access control to secure resources, and integration of biometric recognition algorithms with consumer products (such as cell phone with iris and/or fingerprint recognition, biometric door locks, industrial and military robots with voice recognition, self-driving cars with human silhouette identification, game consoles with gait recognition, etc.) (Jain et.al 2008; Kisku et.al 2013; Gavrilova & Monwar 2012). This chapter presents an overview of the most recent uses of Kinect sensor technology for biometric user identification and activity recognition, and presents an emerging methodology for emotion and intention recognition from body position and movement. The applications in real-world scenarios for medical diagnostics and search and rescue operations are discussed, along with numerous open problems in this domain.

Traditional definition of biometrics research scope usually includes recognizing someone's identity from the collected biometric data, which includes physiological, behavioural, soft, and social traits. Physiological features can be often collected visually (facial image, ear, iris etc.) or through some specialized devices, such as infrared sensors, remote temperature measuring devices, and so on. Behavioural characteristics include the way a person walks (gait), talks (voice) and writes (typing patterns, keystroke pressure). Soft biometrics include data which can be easily collected but not highly unique, such as age, gender, height or weight. One significant area where the development of biometric technologies can have a high tangible effect on society is emergency response and medicine. It is generating a lot of interest and getting traction in biometric research, as well as in related fields looking into human interaction, physiological studies, user profiling, pattern recognition, authorship identification and collective intelligence.

This book chapter outlines the current state of the art of Kinect sensor gait and activity authentication, while focusing on emotional cues that could be observed from human body and posture. It then presents a prototype of a new system which combines recently developed behavioral gait and posture recognition for human emotion identification. A backbone of the system is Kinect sensor gait recognition method, which explores the relationship between joint-relative angles and joint-relative distances through machine learning. The chapter then introduces a real-time gesture recognition system, developed using Kinect sensor and trained with SVM classifier, to recognize four emotions of the human body. Preliminary experimental results demonstrate accuracy and feasibility of using such systems in real-world scenarios. While gait and emotion from body movement has been researched in the context of standalone biometric security systems, they were never previously explored for physiotherapy rehabilitation and real-time patient feedback. Thus, the survey of recent progress and open problems in crucial areas of medical patient rehabilitation and rescue operations conclude this chapter.

BACKGROUND STUDY AND LITERATURE REVIEW

Rapid technological advancement has led to a new field of biometric security, in which emotional state of an individual can be predicted by analysing body movement patterns. Recognition of a person's emotional state and appropriate response is the foundation of all social interactions. As computing resources

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

become more sophisticated, it is reasonable to treat them as social agents. Organizations such as financial services, healthcare, telecommunication, e-commerce and e-education are developing new approaches to recognize and predict human behaviour to create more secure biometric systems. Automatic recognition of emotion has many potential applications including but not limited to smart home services, patient behaviour monitoring, passenger behaviour profiling and so forth (Adey, 2009; Fragopanagos & Taylor, 2005; Gavrilova & Monwar, 2012). We start with the brief overview of emotion recognition in biometrics, before proceeding onto the sensing devices, datasets and recent methodologies to detect emotion from biometric traits, focusing specifically on emotions from motion recognition.

Emotion Recognition in Biometrics

Traditionally, emotions have been recognized from facial expression (Fasel & Luettin, 2003). However, it is also possible to recognize emotions from speech (Koolagudi & Rao, 2012), gaze (He et al., 2018), or body movements (Molchanov et al., 2015). A combination of multiple biometric modalities have been used to create more robust systems (Bänziger et al., 2009). In this chapter, we focus our attention on recognizing emotions from body posture and body movements.

Motion-based recognition system follows a general pipeline which starts with detection of the human body and subtraction of background information from every frame. In Dalal et al. (2006), researchers utilized the Histogram of Oriented Gradient (HOG) features for human silhouette detection. Another important contribution was made in Felzenszwalb et al. (2008), where geometric information extracted from the body was sued to create a human body model - the Deformable Partial Model (DPM). In the second part of the pipeline, a human posture is detected and tracked to reduce any redundant information. Initially, researchers predominantly used model-based approaches for posture detection, however in Siddiqui et al. (2010) the combination of gradient space similarity with the Monte Carlo approach was used to estimate a human posture. The final step is to build an appropriate representation of the extracted data and to apply a learning technique to map a body movement to a specific emotion.

Observing specific sections of the body, such as hands, can provide important cues to recognize a person's emotional state. It provides critical body language information, which can help determine whether a person is honest or insincere by observing the position of the hands (Molchanov et al., 2015). The pace of nodding the head is another indicator of a person's patience level (Pease & Pease 2004). Other attempts to understand emotion from body gestures were conducted using Dynamic Time Warping (DTW) and Hidden Naïve Bayes (HNB) to classify dynamic body gestures into anger, joy, pleasure or sadness (Castellano et al., 2007). A recent work by Seneca et al. (2016) used Artificial Neural Networks (ANN) to visualize human emotion continuously during a theatre performance. Most recently, Ahmed et al. (2018) applied score and rank-level fusion techniques to recognize human emotions from a body posture.

Deep Learning for Emotion Recognition

Deep learning techniques have drawn a significant attention in object recognition and information security domains due to their inherent capability to perform well in a case where domain-specific knowledge is required for feature representation. To reduce the limitations of classical methodologies, deep learning techniques such as convolution neural network (CNN) (Li & Chan, 2014) and multi-stage CNN (Newell et al., 2016) have been proposed. An early application of deep learning was introduced by Kosti et al.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

(2017), who used two low-rank CNN to fuse background and movement information to recognize 26 emotions. Another approach was used in Fan et al. (2016) to recognize emotion from video sequences. A combination of Recurrent Neural Network (RNN) and Convolution Neural Network (CNN) was employed in this work to encode both structural and motion information for emotion recognition. Recently, researchers are focused on applying deep learning techniques for feature extraction of motion capture-based biometric systems. In Toshev and Szegedy (2014), a seven-layered Convolution Deep Neural Network to represent body joints from motion images were used. Similarly, Deep Neural Networks (DNN) were used to model large-scale movement of body parts such as the torso, hand, and leg (Neverova et al., 2013) with subsequent application of Recurrent Neural Network (RNN) and Long-short Term Memory (LSTM) for gesture recognition.

Overview of Motion Capture Devices

Existing motion capture technologies are centred around three main approaches: electromechanical, electromagnetic and optical tracking systems. Electromechanical systems require placing measuring devices at various points of the human body. This approach is restrictive in their weight and freedom of movement and thereby inhibiting the full range of movement. Electromagnetic sensors improve the range of motion to be captured, and are lighter and more comfortable than electromechanical devices. However, the wires attached to each sensor restrict the overall freedom of movement of the human subject. The least restrictive motion capture system is optical-based. Examples of optical-based motion capture systems are pre-calibrated multi-camera set-ups and depth camera-based image capturing devices. These devices allow full freedom of movement and the use of non-intrusive means for data acquisition. Microsoft Kinect is a low-cost depth-sensing camera technology that provides marker-less full-body tracking capability. It has been used for physical rehabilitation which requires accurate and appropriate tracking and feedback of performance. Such devices can be utilized to create an interactive game-based rehabilitation tool for balance training of adults with neurological injury (Lange & Chang 2011). They are also suitable for emotion recognition from a body posture or gait (Ahmed et al., 2018).

Datasets

With the advent of new motion-capturing devices, and the evolution of machine learning methods, there is a pressing need for high-quality datasets to test newly developed approaches to motion recognition. In 2018, a dataset named University of Idaho-Physical Rehabilitation Movement Data (UI-PRMD) (Vakanski et al., 2018), was created for the patients in physical rehabilitation programs. This publicly available dataset comprised of 10 healthy subjects who performed 10 repetitions of different physical therapy movements which were related to common exercises. The researchers then used Vicon Optical Tracker and Microsoft Kinect to capture a variety of motions. Majority of freely accessible datasets for emotion recognition contain acted expressions, but the most conventional way of collecting emotion data is to allow actors to immerse in a scene portraying an emotion. Although professionals are very good at mimicking various emotional states, they lack the spontaneity of a real-life emotion. Most of the authors predominantly focus only on a few basic emotions, such as sorrow, anger, or happiness. Fear, surprise, and disgust are other emotions that sometimes are more difficult to recognize. Some emotional states are named interchangeably, for example joy is often used instead of happiness.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

One of the first publicly available body language databases was created to recognize 10 emotions by using RGB camera sensors to produce 206 video samples of different emotions (Gunes & Piccardi, 2005). A subset of LIRIS-ACCEDE video database contained RGB video data from 64 subjects for six different emotions (Baveye et al., 2015). Another work involved creation of a dataset extracted from the Microsoft Kinect v2 sensor (Saha et al., 2014). It comprised stimulating 10 subjects to emotions namely anger, fear, happiness, sorrow and relaxed state, from which 3D skeleton gesture data was gathered. A more recent emoFBVP database was created to recognize multi-modal emotion recognition and contained video recordings of the subject's face, body gesture, voice and physiological signals (Ranganathan et al., 2016). IN that research, 23 different emotions using audiovisual information were studied from 10 professionals, with each recording repeated up to six times. Lastly, another dataset called UTD-MHAD which contains four temporarily synchronized data modalities of RGB videos, depth videos, Kinect Camera and a wearable inertial sensor for 27 human actions is available (Chen et al., 2015). Table 1 presents a summary of some datasets for gesture-based expression recognition.

Table 1. Summary of some of the publicly available datasets for gesture-based expression recognition

Reference	Name	Device	Body Parts	Modality	#Emotions	#Gestures	#Samples
[Gunes&Piccardi 2005]	FABO	Digital Camera	Face and Body	Visual	10	NA	206

[Fothergill et.al 2012]	MSRC-12	Kinect	Whole Body	Depth	NA	12	30

Research Challenges

As demonstrated by the recent research in this domain, gesture is an important and a versatile tool to communicate thoughts and emotions, but identification and detection of emotion-specific motion is a very challenging task. Specific motion cues are universally understood, for example nodding can be interpreted as a sign of confirmation. Turning away can be interpreted as a refusal and the expansion of nostrils can be a sign of an anger (Noroozi et al., 2018). But sometimes, interpretation of intent can also be subjective, and it may depend on the person making an observation. The emotion of a person may also depend on a person gender and/or culture (Pease & Pease, 2004). Research on automatic emotion recognition has mainly focused on face and voice as the primary source for emotion analysis. In fact, 95% of all the literature used the face as the only modality (De Gelder, 2009). Emotion analysis from posture and movement is still an unexplored domain with very high potential and numerous real-world applications.

METHODOLOGY FOR EMOTION RECOGNITION FROM BODY MOVEMENT

Research Domain Overview

Emotional expression can be transmitted through verbal or non-verbal (gait, signature or facial expression) cues. Studies indicate that a human observer can easily recognize emotions expressed through body movement. Body movement can be retrieved very efficiently using surveillance cameras and wearable sensors. Development of inexpensive sensor technologies such as the Microsoft Kinect, which is a marker-free infrared motion capture system, enables continuous monitoring of three-dimensional body movement patterns. Fig. 1 shows some examples of depth images extracted using Kinect V2 sensor. The images show 2D color, 2D grey-scale, skeleton and a color depth-map (from left to right). In addition to different data streams that can be obtained from Kinect (RGB, depth, audio, etc.), it can also construct a 3D virtual skeleton from the human body and track it in real-time. Although skeletal data tracked by Kinect sensor is noisier than the traditional MOCAP data, the computationally inexpensive tracking of real-time skeleton contributed to recent spike in the action recognition methods that rely on the Kinect (Xia et al., 2012; Yang & Tian, 2014). More recently, new features based on Joint Relative Angle (JRA) and Joint Relative Distance (JRD) were introduced and trained using three classifiers –SVM, Decision trees, and KNN (Ahmed et al., 2016a; Ahmed et al., 2016b). For this reason, Kinect is an excellent choice to record human movement features and automatic recognition of emotion in a non-intrusive way. However, none of these works considered emotion recognition from the human body. The main research objective is thus to develop an automatic emotion recognition system from the analysis of body motion features acquired using Kinect sensor.

Figure 1. Depth images of human gait captured using Kinect V2 sensor (Ahmed et al., 2015)

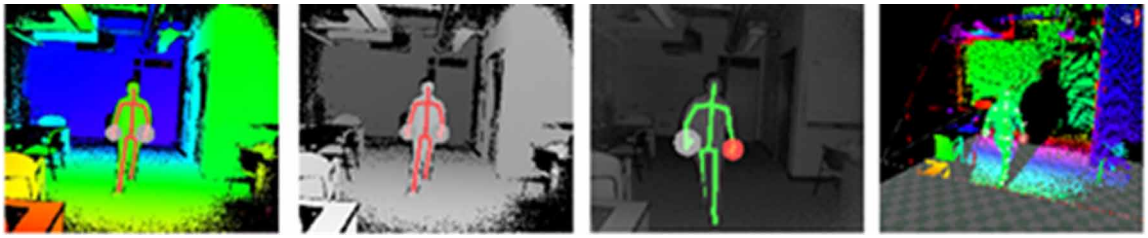

Figure 2 depicts the sequence of body skeleton joints, taken over the period of time, and corresponding to four distinct emotions: Happiness, Sadness, Anger and Fear. As it can be observed, while the body skeleton belongs to the same person in all the sequences, the body position at the corresponding time for different emotions is quite different (see, for example, body skeleton positions recorded at 10, 20 and 22 - the final image in the sequence). The question is how to determine which features characterize emotion expressed through body movements. In order to do it, we shall take a look at the various ways to discover knowledge about human perceptual and cognitive processes, responsible for emotional states (Kisku et al., 2013; Amir et al., 2016; Gavrilova et al., 2017). This acquired knowledge can be utilized to build a system for an automatic emotion recognition. This research attempts to answer the following essential questions:

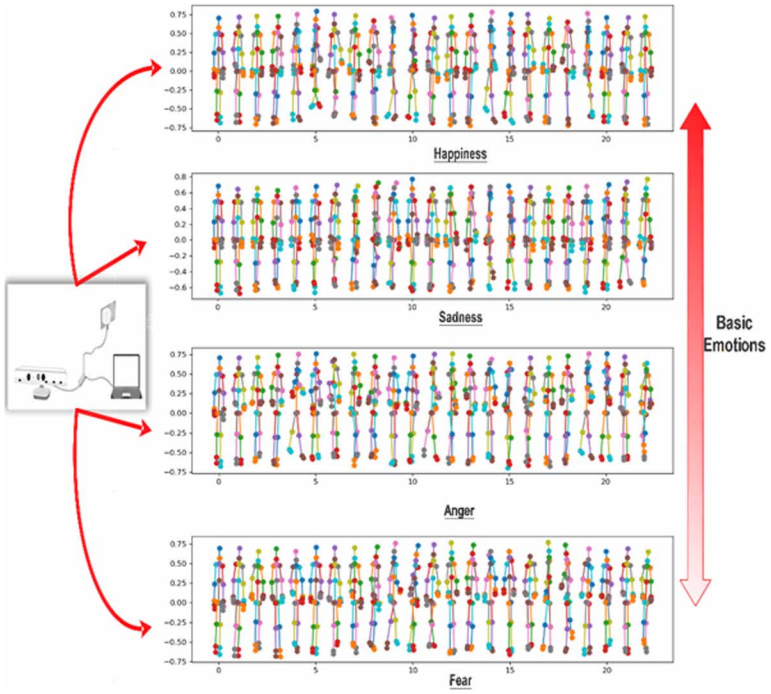
EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- What are the visual cues embedded in our daily movement that reflect specific emotional response?
- What is the extent of change in an individual's movement pattern with respect to a specific emotional response?
- How does one identify emotion specific spatially localized features and their individual impact for different emotional states?

Figure 2. 3D Skeleton data for different walking emotion extracted using Kinect V2 sensor



One way to respond to such questions is to extract emotion specific features from human gait data based on already established frameworks and further analyze the effectiveness of such features by comparing performances exhibited by various other machine learning methods. One should keep in mind that visual cues present in body movement are very subtle and require significant processing for identification. Information available about the exact nature of encoding of biological and psychological traits from the visual motion patterns is quite insufficient. The emotional states of individuals are expressed using a distinct group of general movement features which are difficult to detect and generalize. For example, moving backwards might be indicative of fear, shame, and surprise. However, a slow drop of head and folded arm position reduces the chance of fear and surprise. Such information is often very contextual, making it difficult to build a robust system.

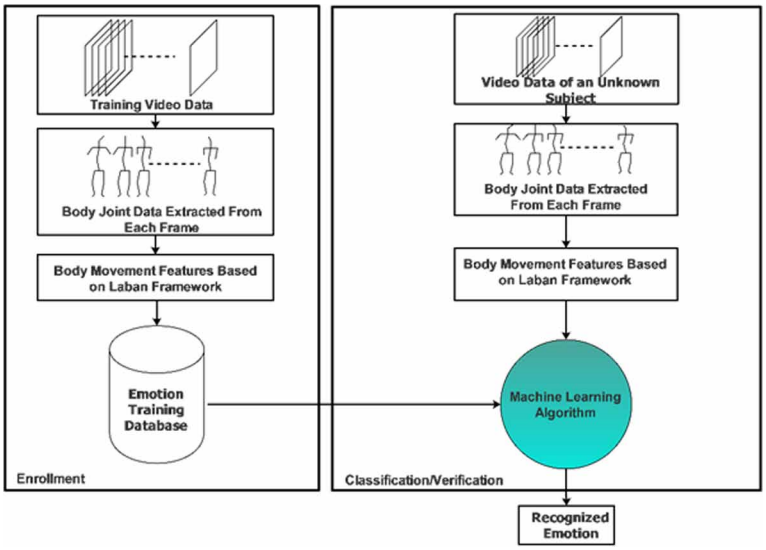
Emotion From Motion Recognition Systems

An emotion recognition system based on body movement can be modelled in a manner similar to an activity recognition system. However, the selected features must be consistent with physiological traits

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

exhibited during a specific emotion. A reasonable approach here is to extract features based on an already established framework. For example, Rudolph Laban theorized a framework known as LMA (Laban Movement Analysis) to extract motion qualities (Laban & Ulmann, 2011). This framework has been used successfully to classify emotions during theatre performance (Aristidou et al., 2015). It incorporated ideas from anatomy, kinesiology and psychology to describe the human movement. The LMA framework has four components, each describing a quality of motion. These components are body, shape, effort and space. The body component generally comprises of structural information like the head inclination and flex angle. The shape component accounts for the change in shape for different emotional stimuli. The average distance of the joints from the base joint data can be used for the shape component. The effort component describes the intention and the dynamic attributes of the movement like kinetic energy and velocity of different joints of the body. Lastly, the space component captures information about how an individual utilizes the space around the body. Contraction index of the upper and lower body is used to measure space utilization during motion analysis of the human body. Figure 3 shows a conceptual flowchart of an emotion recognition system.

Figure 3. Conceptual flowchart of an emotion recognition system

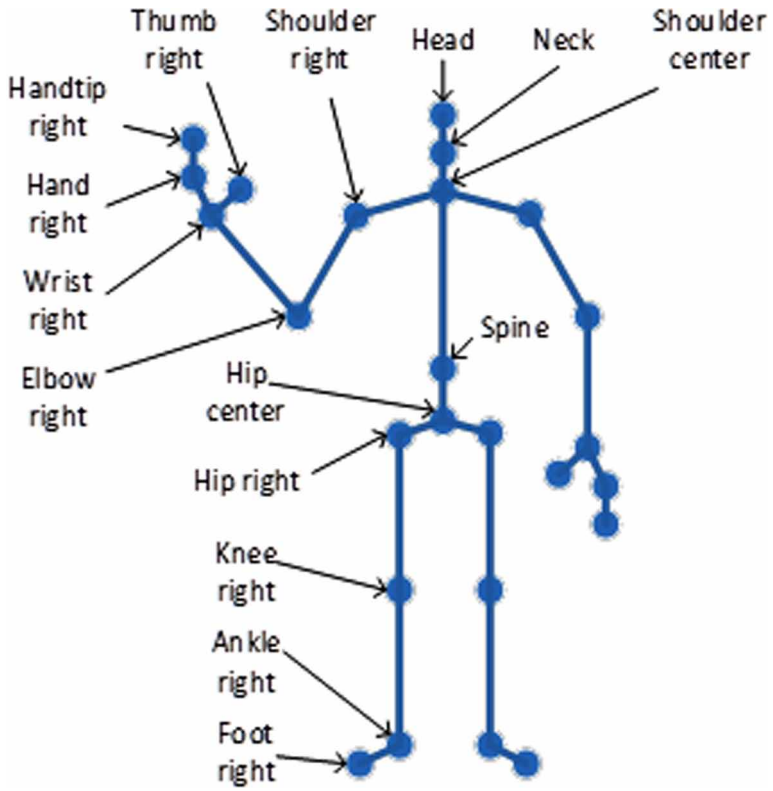


Once emotion specific geometric and kinematic features are extracted, these features are quantized to create a feature vector, which is subsequently used for training and testing purposes in classification task powered by the machine learning algorithms. Supervised machine learning algorithms such as Support Vector Machine (SVM), K-Nearest Neighbor (KNN), and Decision Trees (DTree) have already been used in similar applications for Kinect based action recognition (Ahmed et al., 2016), gait recognition (Ahmed et al., 2015), and in gender recognition from aesthetic preferences using an ensemble of classifiers trained by genetic algorithms (Azam & Gavrilova 2017a, 2017b). It is thus reasonable to assume that these classifiers would produce similar performance for emotion recognition. Multiple expert systems can be trained in conjunction to create a more robust emotion recognition system. Information fusion techniques can be used to combine the scores by varying the individual contribution of the expert systems.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The first work of its kind has been recently reported in Maret et al (2018a), where research on how emotions could be identified and recognized from Kinect recordings of body joints (see Figure 4) was conducted. Their article describes a system capable of recognizing emotions such as friendly, distress, annoyed and neutral, based on body movement. Features extracted from 3D skeleton using Kinect sensor are classified by five machine learning techniques: KNN, SVM, Decision tree, Neural Network and Naive Bayes. A genetic algorithm is then invoked to find the best system parameters to achieve the higher recognition rate. The system achieved 98.96% average accuracy on the small scale experimental dataset recorded under controlled environment. The system integration with embedded hardware for emotion recognition in real time in an emergency response scenario is currently underway (Maret et al., 2018b).

Figure 4. Kinect skeletal joints tracked for emotion recognition



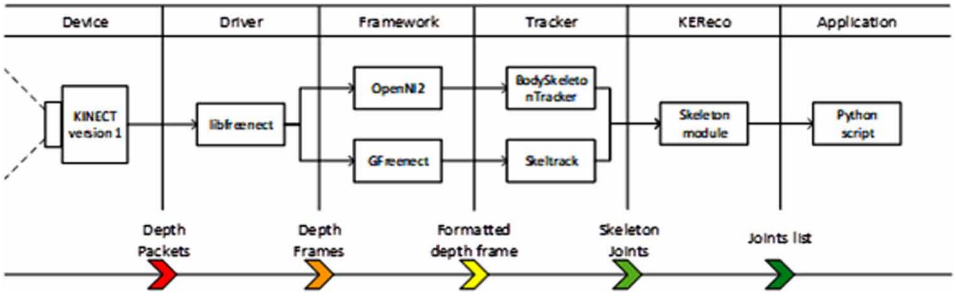
Real-Time Gesture Recognition Methodology

As it was shown in the above discussion, many activity recognition approaches rely on machine learning for feature classification tasks. However, almost no research looked into usage of Kinect in real-time for tasks beyond gait and activity recognition. While there has been a surge in the number of action recognition systems developed based on Kinect sensor technology, recognizing emotion or performing crowd observation from the body movements or gestures has been rarely considered. Very recently, the first embedded hardware device that monitors the number of people inside the confined space using Kinect

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

sensor was developed (Munier et al., 2017). This section outlines one of the first studies on the potential use of Kinect in situation awareness systems to provide additional cues in response to an emergency situation. It presents a new framework for using Kinect gait sensor to identify a person in distress, through observation of a person's upper body movement. The classification relies on a commonly used supervised machine learning method: SVM and a framework to integrate Kinect based gesture recognition method with a real-time embedded system.

Figure 5. Real-time gesture tracking system flowchart



The overview of the methodology for the first prototype of a real-time Kinect emotion recognition system is presented below. Figure 5 depicts the flowchart of the proposed method for gesture recognition based on Kinect sensor capturing upper body motion. The tracking library, Body Skeleton Tracker (BST) is proposed to be used with OpenNI2 framework, which provides structured frames. Then, the BST returns the body joints corresponding to hand, elbow, shoulder (left and right), head and shoulder center, as shown in Figure 6. This process is performed using C library and the KEReco library developed specifically as an add-on to a Python script.

Kinect uses infrared sensor and depth image to detect and track a 3D object. The SDK also provides twenty-five 3-dimensional coordinates of the joint locations of the human body. Figure 7 shows the names of the joint locations extracted using Kinect. The coordinate system is transformed to hip center to eliminate the variability of the distance between the Kinect sensor and the subject. The skeleton joint data was recorded for each frame during the entire gait cycle. From the skeleton joint location data of each subject, geometric and kinematic features were collected using a proposed method.

In order to match the data from the BST, the tracking reference point has to be changed. Mathematical transformation have to be made to adjust the view, they are a translation from the top right to the middle of the camera field of view and two symmetry transformations on XZ and YZ axis. Equation 1 shows all the transformations applied.

$$\left(f_2 \, o \, f_1\right)\left(x, y, z\right) = \left(\begin{pmatrix} x \\ y \\ z \end{pmatrix} + \vec{v}_1\right)\begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix} \tag{1}$$

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Extracted skeletal joints

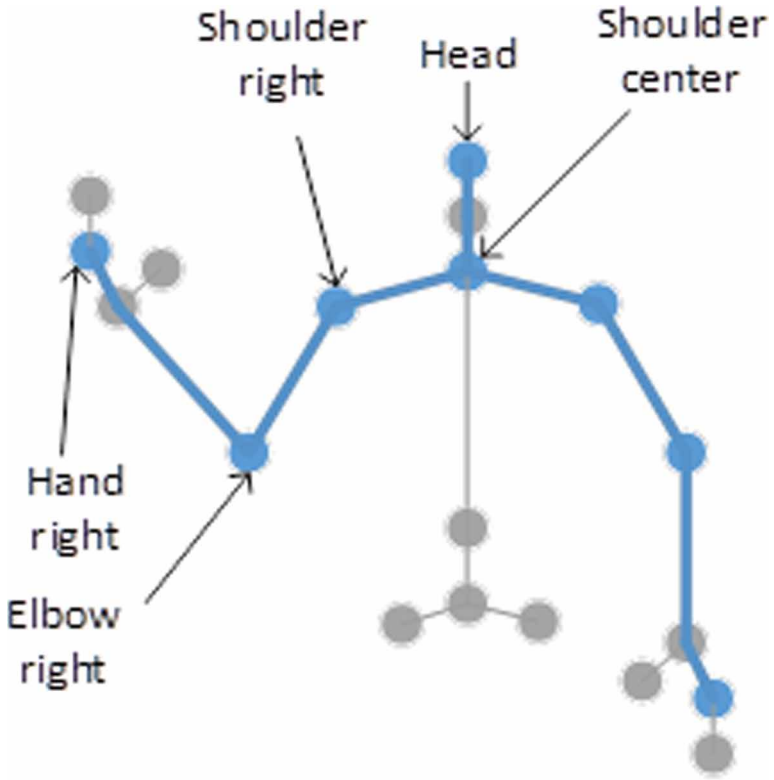


Figure 7. Extracted skeletal joints

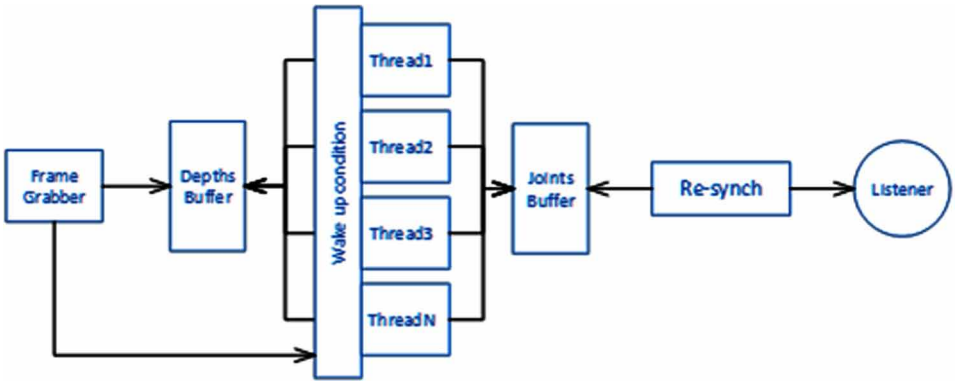
A conversion from pixels to meters also has to be performed in order to match the data origin. The grabber process obtains every depth frame from Kinect and stores them in a temporary buffer. When a new frame is saved in the first buffer, any decoding thread can pick a depth frame. Then this thread will decode the depth frame and will return tracked joints. These tracker joints are stored in the second buffer which will be resynchronized if a recent frame is decoded faster than an older (see Figure 8). This process is explained below. The main issue of running a gesture recognition method on the embedded hardware is the skeleton decode time. Running on a single core takes up to three seconds to process all the 30 frames per second (FPS). At most 10FPS can be processed on a single core. The skeleton algo-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

rithm library was optimized to be run in real time. The optimization was done by using more threads to decode the skeleton over multiple cores. The optimization was made by increasing the number of threads that tracks the skeleton from the depth frame. The Kinect grabber thread stores frames inside a buffer where every other decoder threads can pick one of them randomly with the corresponding frame position (FID). A wake up condition activates all threads when depth frames are available. Once the decoder process is finished, all threads store skeleton's joints in a buffer where the frame will be resynchronized. If a thread has the next following frame ID, this thread can notify the callback. If all frame IDs are not consecutive, the thread will continue decoding the next frame. If the next thread can reorder correctly all the frames, then it will flush the buffer to the callback. Note that buffers are thread safe, which means that only a single thread can access the buffer at a time. If a thread is still decoding a first frame and the buffer becomes overflowed, a re-synchronization will be made. Finally, after resynchronization, all joints are sent to the application with a callback. The feature computation is performed similarly to (Ahmed et al., 2016), which used JRD –Joint Relative Distance and JRA –Joint Relative Angle features. In order to recognize emotions based on arm gestures, Support Vector Machine (SVM) classifier was used. The best configuration to use within the SVM classifier was determined experimentally and used 75 features from 15 frames.

The frame buffer was used to hold at most 75 features before a new prediction was made by the classifier. After the classifier prediction, the buffer removed the oldest frame. The extracted features from the next frame would then be added to the buffer and a new prediction made.

Figure 8. Extraction joints optimization



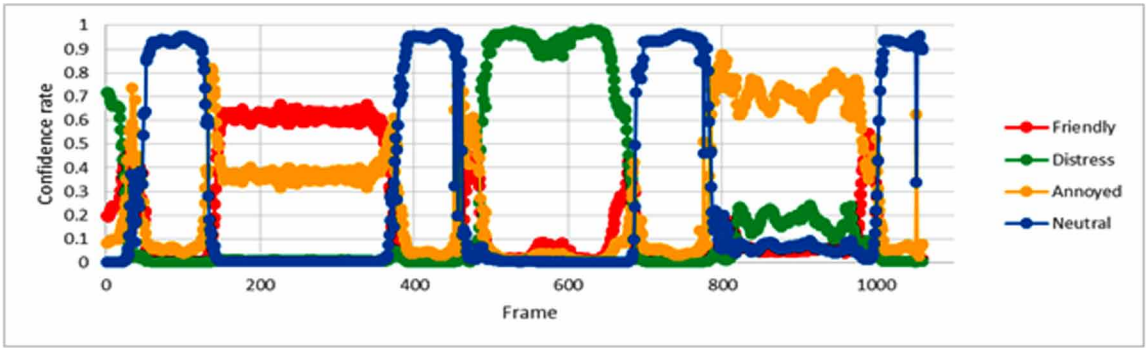
Experimental Results

Some preliminary results obtained on a small scale sample dataset demonstrate that gestures are correctly recognized in real-time. The dataset consisting of eight subjects with four gestures was collected using Kinect version 2. The training set contained four gestures recorded at two distances: one collected two meters away from the Kinect and a second collected four meters away.

The experiments were run using two-fold cross-validation. This dataset was used to train the SVM classifier in order to predict confidence rate in a given gesture over other gestures. The main experiment is based on recognizing emotions from gestures in real time. Emotions to be recognized were: friendly,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

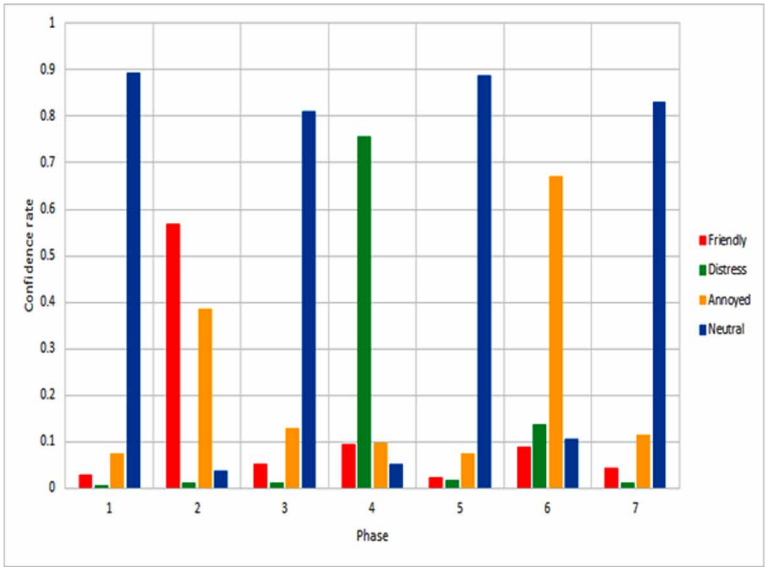
Figure 9. SVM continuoud gesture recognition on embedded system



neutral, distress, neutral, annoyed and neutral. The neutral state was held for 5 second while others emotions for 10 seconds. The experiment was made using the SVM classifier and the Kinect V2 sensor. The Microsoft Kinect SDK 2 tracked all skeleton joints. From these joints features were extracted and then predicted by a classifier with the obtained confidence rate presented in Figure 9. These preliminary results demonstrate that the methodology is suitable for real-time body gesture recognition and the subsequent rescue operations. In order to avoid the transition effect when gestures changed, a threshold for gesture to be stable for 30 frames was set, which mitigated the issue. Another observation is that friendliness and annoyance were the two closest gestures, while all the other gestures were easily distinguishable. SVM confidence was above 85% for each gesture, computed according to the distance from the hyperplane.

Figure 10 shows a sequence of emotions from gestures, accurately recognized in 100% of cases in real-time for each frame. Note that since the developed hardware prototype is the first system of its kind, no comparators exist that could identify the four gestures based on sensor based recorded arm movement

Figure 10. SVM real-time gesture recognition results



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

at the time. Thus, in order to validate our results, we extracted the AuC data for seven difference scenarios where the subject was asked to perform a sequence of arm gestures (Table 2 and Table 3) and the Confusion Matrix (Table 4 and Table 5). We performed experiments to compare method performance for PC (Personal Computer) and ES (Embedded System). The results demonstrated that both could predict the correct emotion with up to 97.7%. Note that the accuracy of the predicted class vs actual class was highest for PC for emotion of distress. This is the expected result, and very useful as the main intent of the system is to recognize a person who requires the assistance in emergency situations. The lowest recognition was for Friendly emotion (70.2% on PC, 61.7% on ES). The rest of the results were very high, with Distressed and Neutral emotions being recognized correctly in over 90% cases for both PC and ES, and Annoyance recognized with over 70% accuracy for ES and over 90% accuracy on PC. We conclude that for neutral emotion, the recognition rate is the same for PC and ES. For dynamic emotion recognition, the BodySkeletonTracker (BTS) performs slightly worse than the Microsoft SDK. We assume that this is due to the real-time tracking process implemented on the hardware. Further research is required to investigate this issue more comprehensively.

Table 2. Four emotions AUCurve for ES

		Area Under Curve			
		AUCFriendly	**AUCDistress**	**AUCAnnoyed**	**AUCNeutral**
Scenarios	1	0.479	0.216	5.564	89.74
	2	177.609	1.919	89.103	11.367
	3	1.128	0.728	6.258	116.884
	4	10.778	228.999	18.003	8.218
	5	0.975	0.89	6.275	110.858
	6	2.318	16.857	253.25	17.573
	7	1.432	1.251	6.751	119.564

Table 3. Four emotions AUCurve for ES

		Area Under Curve			
		AUCFriendly	**AUCDistress**	**AUCAnnoyed**	**AUCNeutral**
Scenarios	1	0.641	0.284	4.731	70.341

	5	0.794	0.479	6.706	86.019
	6	21.768	30.831	150.526	18.873
	7	0.401	0.291	3.658	43.648

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another observation is that the Microsoft skeleton is more stable when the same arm movement is of a certain duration, while the BST skeleton is less stable during transition. The BST system has to recalculate positions of joints during an arm movement and an emotion change. Despite that, the BST system provides a reliable real-time solution on an embedded board, which can be used in multiple real-world scenarios. The overall deviation of the embedded system prediction from the PC version is about 9%, which can be tolerated because the identified human emotion and the arm movement recognition still remains correct in all cases.

Table 4. Confusion matrix for Predicted Class for PC

		Predicted Class			
		Friendly	**Distress**	**Annoyed**	**Neutral**
Actual Class	Friendly	0.702	0.007	0.282	0.007
	Distress	0.004	0.977	0.008	0.009
	Annoyed	0.008	0.063	0.903	0.024
	Neutral	0.008	0.005	0.052	0.932

There are many application domains for the developed system. Emotion recognition systems can be used to enhance the decision-making capability of human operators. For security at an airport and surveillance systems, behavioural and other physiological traits can be monitored to capture true intention of a person [Adey 2009]. Assisted technologies can be developed to improve human-computer interactions. Intelligent avatars and other interactive dialog systems can improve user's experience while accessing smart communication devices (Faundez-Zanuy et al., 2013). Finally, emotion recognition system can also be used in rescue operations or in a patient observation scenario. Typically, an expert will observe emotions expressed through gestures or body movement to identify signature behaviour in the patients. An intelligent system capable of distinguishing emotional states of an individual can be useful for monitoring a patient and for making quick responses. The extension of this research will assist not only in establishment of new methodology in the domain of biometric security, but also in assisting new method integration in the health care domain, providing personalized healthcare targeting to specific patient needs.

Table 5. Confusion matrix for Predicted Class for ES

		Predicted Class			
		Friendly	**Distress**	**Annoyed**	**Neutral**

DEVELOPED METHODOLOGY IN DISASTER RESPONSE AND MEDICAL APPLICATIONS

While the previous section discussed in detail how biometric sensors can capture and process biometric information from body movement, and recognize gestures in real-time, this section gives emphasis on the extension of this emerging research to the fields of medical patient treatment and disaster response. The prototype system presented in the previous section can be used in one of many emergency scenarios, as well as in multiple medical applications.

Although the scale and the methods may vary, technology has always played a crucial role in ensuring public safety. Within the domains of rescue operations and natural disaster recovery, biometric technology offers a promising future for first responders and victims alike. In life threatening rescue operations, technology needs to be accurate, portable, reliable and inexpensive. Microsoft's Kinect lends itself thoroughly to this effort by offering compact sensors at a comparatively low cost (Zhang et al., 2013). Rescue operations often take place in harsh environments which can be described as uncertain, dynamic, hazardous and lacking in resources (Wong et al., 2017). This is especially true in a case of natural disasters, where communication may be limited and unstable. Due to the possible number of victims following every crisis, manual labor alone can prove impractical when the affected area is substantial. With these constraints in mind, research into autonomous systems combined with Kinect sensors have recently gained traction (Al-Kaff et al., 2017; Osman et al., 2017; Wang et al., 2017). While the application of the Kinect in real life scenarios can be limited due to occlusions, unfavorable lighting, noise and distance to a sensor, methodologies that seek to overcome those limitations are currently being actively developed. Some examples of such applications can be found below.

Natural Disasters

In the aftermath of a natural disaster, the natural environment can have noxious fumes, fires, exposed powerlines or unstable debris. Rescuer and victims' safety is a primary concern when navigating a disaster zone. Recent research has proposed the use of automatic approaches for providing aid and accessing the environment. By employing biometric identification algorithms, Kinect can be used to recognize and locate victims in distress. It was recently demonstrated that the Kinect RGB-D sensor can be used to construct a 3D model of an indoor environment, which may be too dangerous for humans to reach (Wang et al., 2017). Research has also been done to develop identification of persons and objects for Unmanned Aerial Vehicles (UAVs) during airborne rescue operations (Al-Kaff et al., 2017; Osman et al., 2017). These works are focused on decreasing human involvement in potentially dangerous situations, while remaining effective and robust in a limited environment. Usage of Kinect depth maps have been considered for disaster detection as well. Improved methodologies that handle occlusion of turbid waters for earthquake or tsunami detection have been tested in a lab setting, with experimental results outperforming current methods (Liu et al., 2017).

Refugee Camps

Large displacements of people are difficult to keep track of, particularly when the matter can evolve into a national security concern. It is very taxing for governments to deal with the maintenance of refugee camps or disaster centers, which often results in missing or unreported people. Biometric technology

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

can reduce confusion because it does not require paperwork and has multi-modal systems to ensure accuracy. Microsoft's Kinect can employ gait recognition in refugee scenarios due to its speed, low cost and unobtrusive nature. Previous research supports the use of multiple Kinect sensors within the same system to increase coverage without a loss in accuracy (Banerjee et al., 2013). This would result in decreased queue times, more organized registration and accurate records. The non-pervasive gait identification additionally makes data collection more acceptable compared to other biometrics, such as traditional fingerprints for example.

Hostage Situations

There are many constraints to operations when hostages are involved. Technology must be compact, covert and silent to ensure victims safety. The Kinect sensors excel in this field because of its small size and ability to produce both RGB images and depth maps. Gesture recognition could see much usage in hostage situations, as the rescue team could communicate with the technology while being at a distance and without a sound. Morse code, for example, can be deciphered by the Kinect with relevant algorithms (Li et al., 2017). Extensive research into hand and finger tracking using the Kinect exists, though optimal performance occurs only in certain circumstances (Smari et al., 2016). Additional research involves the incorporation of the Kinect into radar biometric detection by simulation of Micro-Doppler signatures. These signatures can deliver biometric details including heartbeats, blood vessels and breathing, with certain methods that can detect vital signals through walls (Amir et al., 2017).

Neurological Disease Treatment

As it was noted above, Kinect sensor is a light, a portable and a convenient device, which makes it useful not only for disaster and recovery, but also for medical providers and their patients (Roy et al., 2013; Stone & Skubic, 2013). In 2012, research team (Fernandez-Baena et al., 2012) compared the accuracy of optical motion capture professional system with reflective markers and Kinect motion capture in capturing joint angle data. They concluded that the precision of the Kinect is lower than that of an optical capture system, but its accuracy is sufficient for medical rehabilitation.

Some neurological diseases (such as stroke, Alzheimer's disease) and limb dysfunction caused by external trauma can seriously affect the patient's motor ability and quality of life. Intensive and repetitive training can help patients with physical rehabilitation and neural reorganization. Traditionally, physiotherapy and rehabilitation training is performed at a rehabilitation center of a hospital, and the patient needs to wear a tracking device. Several studies have evaluated the accuracy and feasibility of using Kinect for motion capture in rehabilitation systems. For example, in Chang et al (2011), researchers assessed the possibility of using Kinect-based system for rehabilitation of young adults with motor impairments. They used an A-B-A-B reversal replication design and reached a conclusion that Kinect-based systems enhance the therapeutic effect due to their interactive interface with audio and video feedback. However, the results were based on only two cases and more participants should to be used to validate the study. In Lange et al. (2011), researchers developed and evaluated an interactive game-based rehabilitation tool for balance training of adults with neurological injury. They demonstrated that the system was very well accepted by the patients.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Elderly Care and Rehabilitation

Elderly care and rehabilitation recently emerged as the two main directions in this field. In 2012, Stone and Skubic presented initial results of monitoring the gait of seven older adults continuously, using a Kinect sensor, along with a methodology for computing average gait parameters which may be predictive of future falls and adverse events in older adults (Stone & Skubic, 2012). In 2012, Zhang et al (2012) designed a method of extracting data from 2D images when a human subject was out of range of the Kinect's depth sensing, to enhance fall detection system capability. Soon after, researchers designed a Kinect-based system for in-home rehabilitation exercises monitoring and guidance (Zhao et al., 2014). The system implemented a set of correctness rules for each exercise and assessed the patient's movement in real-time to help the patient perform the exercise correctly. In addition, it provided an interactive feedback to patients for rehabilitation exercise monitoring applications.

Virtual and Augmented Reality for Medical Systems

Over the past decade, many researchers have focused on finding appropriate sensors and computing technology for motion capture to help develop ancillary medical systems (Chang et al., 2011; Fernandez-Baena et al., 2012). Virtual and augmented reality systems are being developed and tested to motivate patients. Use of such systems makes repetitive exercises more useful and interesting, and many of such systems are currently based on Kinect sensor. Kinect was intended as a game equipment, thus many studies combined its initial function with medical rehabilitation to design game-based rehabilitation system. In 2012, Gotsis and his team (Gotsis et al., 2012) designed an integrated hardware (consisting of a custom metal rig, six game tracks, a Microsoft Kinect, a laptop and a large screen) and software platform for rapid prototyping of virtual reality-based games for upper body exercise and rehabilitation. At the same time, Huang et al (2012) designed a smart glove for motion and finger angle extraction and integrating with Kinect for an upper extremities gaming application. However, such systems have to be more entertaining so that the patient could be better motivated. In 2013, a system known as "Kinect-o-Therapy" was developed, which incorporated serious games that process 3D input using the Microsoft Kinect motion sensor to build an effective rehabilitation system that gives feedback to the patient and the doctors (Roy et al., 2013). It used real-time motion capture data to animate characters in game, making rehabilitation more fun, engaging and rewarding. Since then, many researchers have focused on using Kinect in combination with motivating and fun recovery games, feedback systems with motion tracking, and medical systems for in-home use.

OPEN PROBLEMS AND FUTURE RESEARCH DIRECTIONS

As Kinect sensors emerged only recently as an active area of research with multiple applications, there are many problems and directions for the future work. Emotion recognition is an emerging area of research and has put forth several open-ended questions to the scientific community. One crucial question that needs to be answered is *whether body movement can be used as a standalone communication channel for emotional expression.* Research conducted up until now shows that it is beneficial to use body movement features in a multi-modal system alongside facial and voice features, as typically this results in a better performance for most practical applications (Gavrilova & Monwar, 2012). Biometric fusion can

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

also in the future automatically recognize in real time if a patient is experiencing distress, and to inform health care provider on patient-specific recommendation of exercises or treatment.

Many spatially localized features can be extracted from the analysis of body movement. Finding out *the right subset of features and their individual contribution to classify emotion* is still an open problem (Maret et al., 2018a). Algorithms such as particle swarm optimization (PSO) and genetic algorithm (GA) can be used to generate the right subset of features along with the correct weight distribution to measure the individual impact of such features in emotion recognition. Finally, testing those methods on large-scale datasets in real-time will assist in providing definite answers to the open problems posted above.

One of the key issues is optimizing methods for *actual application outside of testing environments*. The constraints of size, speed, cost and accuracy have always been a limiting factor (Lange et al., 2011). Much of the proposed future work includes expanding the conditions in which Kinect can acceptably function. Since real disaster scenarios will not have favorable conditions, research must be done to address the innate weaknesses of the sensors or methodologies. This can include work into occlusion correction, lighting tolerance and noise filtering. Once usage of the Kinect is more universally applicable, mass adoption into rescue processes seems most logical.

In order to integrate the Kinect sensor in core medical applications, *a critical validation step is needed*. This will provide proper evaluation of the accuracy and latency of the action capture data obtained from Kinect for special diagnostic scenarios. In 2015, gait analysis of patients with Parkinson's disease (Bigy et al., 2015) was studied using healthy actors in a laboratory environment. Next year, the accuracy, precision, resolution, various measurement distances and angles of both Kinect 1 and Kinect 2 were investigated (Pohlmann et al., 2016). However, more studies to evaluate patient benefit in a controlled and randomized fashion should be performed in the future.

Another challenge in medical applications based on the Kinect is that repurposing a technology initially intended for young and healthy people into a system for elderly patients *requires new design strategies for the physiological and the psychological considerations* (Adey, 2009). First of all, medical rehabilitation games based on Kinect should be designed with high standards of captivating and long-term enjoyment potential while maintaining seamless methodologies of adaptation and monitoring of players' needs. But overexertion injuries in both individual movements and length of play are not encouraged. Also, user-friendly interfaces should be applied and wearable system should not be bulky. Thus, making existing medical systems more ergonomic is another open problem.

As the Kinect is an inexpensive device, some factors may affect its performance which may make it inadequate for some medical applications that require a high-level of accuracy. *In a multi-modal and multi-sensor scenario*, this issue should be carefully investigated. Over recent years, a new approach that advocates the use of multiple Kinect sensors was introduced to improve the data capturing accuracy. For example, (Beyl et al., 2013) discovered that the use of multiple Kinect sensors and careful calibration in the challenging uncontrollable environment during surgery could provide a median accuracy of 19.8 mm; however, the maximum error was around 100 mm, which was still too high to be practical. In addition, other sensors and equipment can be fused with Kinect to enhance quality and accuracy in the future through multi-modal and multi-sensor systems. Finally, *issues of data privacy* in the context of medical, virtual reality or search and rescue operations should not be overlooked.

CHAPTER SUMMARY

This book chapter outlined the current state of the art of Kinect gait and activity authentication, while focusing on emotional cues that could be observed from human body and posture. It presented a prototype of a new system which combined recently developed behavioral gait and posture recognition for human emotion identification. It then presented an overview of the first real-time gesture recognition system which could be used in emergency response or situation awareness systems, together with preliminary experimental results. The survey of recent progress and open problems in the areas of medical patient rehabilitation and rescue operations as linked to sensor based body movement concluded this chapter.

The chapter outlined some of the future directions of sensor based motion tracking research for a variety of application. The key open problems that should be addressed in the future research were also identified. They include introduction of new multi-Kinect and multi-sensor approaches for medical scenarios; development of the occlusion correction, lighting tolerance and a noise filtering methods; integration and testing of developed methodologies in real-time; careful assessment of the use of sensors for patient rehabilitation on a larger population sample and on different types of skeletomuscular conditions. In addition, it was pointed out that the multi-disciplinary team of experts should be involved in deploying new technology-enabled methodologies, and a special care and consideration should be given to privacy aspects of collecting and processing sensitive data.

ACKNOWLEDGMENT

Authors would like to thank NSERC DG program grant RT731064 and NSERC ENGAGE grant EGP522291 for partial support of this project, as well as all members of the Biometric Technologies laboratory at the University of Calgary and all collaborators for their valuable discussions during this chapter preparation.

Chapter 33
Stroke Rehabilitation and Parkinson's Disease Tremor Reduction Using BCIs Combined With FES

Sophie V. Adama
Leipzig University, Leipzig, Germany

Martin Bogdan
Leipzig University, Leipzig, Germany

ABSTRACT

This article describes how Stroke and Parkinson's disease are two illnesses that particularly affect motor functions. With the advancements in technology, there is a lot of research focusing on finding solutions: to contribute to neuroplasticity in the first case, and to reduce symptoms in the second case. This manuscript describes the design of a brain-computer interface system (BCI) system paired with an electrical muscle stimulation suit for stroke rehabilitation and the reduction of tremors caused by Parkinson's disease. The idea is to strengthen the sensory-motor feedback loop, which will allow a more stabilized control of the affected extremities by taking into account the patient's motivation. To do so, his brain signals are measured to detect his intention to attempt to execute a movement, in contrast to the classical approach where the movement executions are imposed. A first feasibility study was completed. The author's next step is planning to test the system first with healthy subjects and finally with patients.

INTRODUCTION

This manuscript describes the design of a non-invasive EEG-based Brain-Computer Interface (BCI) system for motor recovery of stroke patients and for tremor reduction in patients with Parkinson's disease. Patients suffering from these diseases present motor impairments that prevent them to fully live

their daily lives. In the case of stroke, some motor functions can be recovered some time after the stroke given a suitable rehabilitation therapy. Parkinson's disease symptoms on the other hand tend to worsen as time passes.

Several rehabilitation methods, such as Robot-assisted arms, Functional Electrical Stimulation (FES) and BCI combined with exoskeleton are examples of technology-based rehabilitation therapies (Ramos-Murguialday et al., 2012) being used, some with more success than others are. Nevertheless, in the end, the most important factor in the success of a rehabilitation therapy is the patient himself. Indeed, most of these therapies require the patient to perform the same movement multiple times. In the long term, the patient will lose interest since he gets bored by repeating the same exercise several times. This increasing boredom will consequently affect his motivation. Bhagat et al. (2014) demonstrated that a lack of the latter would limit the effectiveness of the rehabilitation process.

Lew et al. (2012) successfully extracted brain signals signatures indicating volitional upper limb movement intention from healthy persons, and detected the intention as early as 1500 ms before the movement onset. Bhagat et al. (2014), Ramos-Murguialday et al. (2015) and Yilmaz, (2015) performed similar experiments with stroke patients. Those studies suggest that it is possible to develop closed-loop brain-machines interfaces driven by the user's voluntary movement intention (Spüler et al., 2014). Plus, FES-based therapy has proven to be very promising for motor recovery during stroke rehabilitation (Noma et al., 2014).

Here, a system that combines BCI with a VisionBody suit that provides Electrical Muscle Stimulation (EMS) is proposed. The VisionBody suit is chosen to facilitate real-world applications. This suit, originally used in fitness and sports, provides Electrical Muscle Stimulation through electrode pads - located in the arms, legs, breast, etc. - directly to the skin in direct proximity to the muscles to be stimulated. The impulses delivered by these electrodes mimic the action potential coming from the Central Nervous System, causing the muscles to contract.

Our aim is to overcome patients' boredom and lack of engagement to the rehabilitation tasks by allowing them to execute voluntarily the required movements and detecting those intentions using their brain signals. As soon as an intent to move is being detected, the VisionBody suit will be used to deliver the electrical stimulation to the patient's muscles to assist him in the movement production in the case of stroke, and to suppress tremors that may occur while executing a movement in the case of Parkinson's disease. Otherwise, if no intention to move is detected, no support for the movement via Functional Electrical Stimulation (FES) will be provided. By doing so, it is intended to strengthen the sensorimotor feedback loop in order to stabilize the control of the affected extremities. A more positive engagement is then expected from the patients. This has the potential to increase the functionality of the affected limbs, and reduce fatigue by minimizing the energy consumption, the ultimate goal being the improvement of the daily lives of the patients.

The manuscript is organized as follows: first, an overview of stroke and Parkinson's disease is presented, followed by some rehabilitation techniques and treatments used for the two illnesses; then, the tools and methods used for the experiment were presented along with some results.

BACKGROUND

Stroke

One of our target groups is stroke survivors. Stroke is among the leading causes of adult disability in the so-called developed countries.

Causes

It is caused by blocked or burst blood vessels in an area of the brain, which cause the blood flow in this area to be cut-off. The lack of oxygen will cause the brain cells to die and the abilities controlled by these areas, such as motor function or memory, will be lost (Bornstein, 2009).

Treatments and Rehabilitation Techniques

9 out of 10 stroke survivors have some degree of paralysis immediately after the stroke. They will then need to relearn those lost skills by the means of rehabilitation therapies, which may involve regular physical therapies or therapies that involve the use of technology, in order for them regain some independence and improve their daily lives (Kwakkel et al., 1999). Continuous rehabilitation and therapy can help stroke survivors regain voluntary movement even years following their stroke. For the moment, several methods are used to help movement recovery in stroke patients.

Functional Electrical Stimulation

Functional Electrical Stimulation uses electricity to stimulate weakened muscles and to cause them to contract. It has been successfully used to improve motor control in chronic stroke patients (Noma et al., 2014). Qu et al. (2016) built a network-based multichannel neuromuscular electrical stimulation system for people with paretic stroke to assist them with multi-joint movements. The system was tested both with nondisabled subjects and with subjects with stroke. Moreover, results showed that the patients improved their performance in executing these multi-joint movements.

The methods mentioned above require the patient to perform the same cue-based movement multiple times during a session. Over time, he may lose interest and this will affect his motivation. Which in turn, will reduce the effectiveness of the rehabilitation therapy. Engaging the patient in the therapy, by encouraging him to attempt to move on his own and at his pace, may overcome that. For stroke patients with some residual muscle activity, for example, EMG can be used to trigger FES. This allows the detection of voluntary movement even from the smallest electrical EMG signal. Which, in turn will be used to initiate the stimulation of these muscles and help produce an actual movement (Gabr, 2005).

EEG-Based Brain-Computer Interfaces

The first tool used in this study is the brain-computer interface (BCI). A BCI allows interfacing the brain and a computer by translating the electrical signal of the brain into control signals for external devices such as a robotic arm, a virtual keyboard or a virtual mouse. To do so, special electronic sensors are attached to the head and hooked to a computer where the electroencephalogram (EEG) is recorded. These

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

sensors can be invasive or non-invasive. A typical BCI system consists of a signal acquisition module, a signal processing module, a module for features extraction and classification that translates the results of the features classification into a feedback or a device command.

Brain signals recorded from invasive electrodes have very good signal to noise ratio, as opposed to non-invasive electrodes. But invasiveness requires the electrodes to be implanted surgically. Anyhow, invasive-BCI has been widely used to restore mobility on paralyzed patients, especially those with spinal cord injury (Bouton, 2016; Leuthardt, 2004). The brain delivers information about a movement. It controls the corresponding muscles and triggers the movement. In case of spinal cord injury, the pathway from the brain to the extremities is compromised, resulting in the incapacity to perform voluntary movements. BCI can then be used as an alternative pathway to control the limbs. In other words, it is used as an artificial connection between the brain and the limbs, to bypass to some extent the lost connection. Brain-Computer Interfaces come into play by detecting the intention to move from the acquired brain signals, and by translating them into command to an external device, such as a robotic arm or to trigger an electrical stimulation to the muscles to produce the desired movement (Ethier, 2012).

A similar experiment has been conducted with non-invasive BCI, for the first time in 2003 in a patient suffering from tetraplegia (Pfurtschellera, 2003). The author wanted to prove the feasibility of controlling a FES using three pairs of surface electrodes by a patient with spinal cord injury with complete motor and sensory lesion. After 10 months of training, the patient was able to grasp a cylinder with the paralyzed hand.

As opposed to spinal cord injury where there is no brain damage, the messaging between the brain and muscles may not work properly when parts of the brain are damaged after a stroke. It usually concerns the side of the body opposite the side of the damaged brain, the arms or the legs most of the time. And this raises the question whether it is possible to use EEG signals from the damaged contralateral hemisphere to detect the patient's intention to move. Recent research on BCI for stroke rehabilitation shows that it can work as assistive BCI to support the patient in his daily life, but also as rehabilitation BCI to facilitate neuroplasticity (Soekadar et al., 2015). Earlier researches show that following a stroke, the hemisphere responsible for organizing a movement of the impaired limb depends on the patient's progress. For those who did not make a good functional recovery, the ipsilateral hemisphere plays the role. For those who made a nearly complete recovery, it is the contralateral hemisphere (Serrien, 2004). Antelis et al. (2015) were able to decode movement intentions from six severely affected stroke patients attempting to move their paretic arm by means of brain activity of the healthy contralesional motor cortex. Yilmaz et al. (2015) discovered that Movement-related slow cortical potentials (SCPs) amplitudes can be observed and are larger over the midline areas for paretic hand movement in severely paralyzed stroke patients. They are larger than in the contralateral and midline area compared to the ipsilateral area for healthy hand movement.

Thus, it is possible to detect movement intention from the brain activity of stroke patients. However, most research only focuses on the control of robotic devices and rehabilitation therapies consisting of repetitive cue-based movements. Furthermore, the devices used for rehabilitation, whether they are EEG-based or not, not only help the patient performing the movement but also completed it. The patient does not need then to make the effort to finish the movement; he just needs to start it. This lack of engagement from the patient will then result in an unsatisfying outcome of the training (Bhagat, et al. 2014). On the other hand, Soekadar et al. (2015) noticed remarkable improvements of motor and cognitive capacities in patients training with a goal-oriented behavioural therapy. This suggests that the patient's motivation and engagement play an important role in the rehabilitation process.

Parkinson's Disease

The other target group of this research is Parkinson's disease patients. It affects the motor system and typically appears between the ages of 50 and 69, with symptoms worsening with time. At the beginning of the disease, the most obvious symptoms are shaking, rigidity, slowness of movement, and difficulty with walking. These symptoms are the result of the death of cells in the *subtantia nigra* that produce dopamine (Janvkovic & Tolosa, 2007).

Causes

It is known that secondary Parkinson's disease is caused by toxins, but there is no known cause for primary Parkinson's disease. There is no cure for the condition at the moment. However, the symptoms can be reduced or inhibited with medication and surgical procedures.

Treatments for Tremors

There are several types of tremor. Rest tremor is a well-known symptom of the condition. It appears mostly during rest and affects the patient in his everyday tasks. It affects mostly the hands and the head, and is an approximately rhythmic and roughly sinusoidal involuntary shaking at a frequency of 3 to 6 Hz (Grimaldi et al., 2010; Janvkovic et al., 2007; Manto et al., 2003). In contrast, action tremor appears when the patient is performing every day's task such as holding a magazine or drinking from a cup.

Tremors have been treated with medication, but with not much success and a lot of side effects. However, they have been well controlled by Deep Brain Stimulation (DBS) (Benabid, 2003; Limousin et al., 2008).

Deep Brain Stimulation

Deep Brain Stimulation (DBS) is a surgical procedure that place electrodes into parts of the brain such as the subthalamic nucleus, the globus pallidus interna or the thalamus. These electrodes produce electrical impulses to stimulate the target area. This will affect movement by altering the activity in that area of the brain. In case of tremor caused by Parkinson's disease, the electrodes are usually placed on the thalamus (Munhoz, 2016). Benabid et al. (1987) were able to relieve tremors from patients who were resistant to drug therapy by combining thalamotomy and stimulation to their brain. Like every other surgery, DBS surgery is a very risky procedure. Moreover, the patient selection process is also very competitive; not every subject who wants to undergo the procedure will be granted his wishes (Munhoz et al., 2016).

Other Methods

In their research, Manto et al. (2003) were able to successfully reduce tremors from patients. To do so, they extracted characteristics such as force, position, velocity and acceleration of the pathological tremor, and used them to define the loads or forces' parameters required to be able to counteract its action.

Zhang (2016) from Microsoft Research Cambridge built a tremor-reducing wearable device to counter the effects of tremors in a 33 years old woman diagnosed with Parkinson's disease, allowing her to write and draw more precisely than before.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

MOTIVATIONS

Previous researches have shown that despite the brain injury after stroke, it is possible to detect patients' movement intention. In addition, the importance of patients' motivation and engagement during rehabilitation has been demonstrated. Rehabilitation methods using robot-assisted arms or neuromuscular electrical stimulation require the patient to repeatedly perform a given movement. Over time, the monotony of these methods affects the patient's interest and decreases his motivation. This lack of motivation limits the effectiveness of the rehabilitation process. The proposed system aims at taking into account the patient's motivation and increasing his engagement in order to improve the outcomes of the therapies and the treatments. The hypothesis used in this approach is that due to the connection of the patient's intent with the supporting stimulation, the sensory-motor feedback loop will be to strengthen resp. re-established and this will allow future movements to be performed without engaging the system.

On the other hand, tremor has been quite unsuccessfully treated with medication, but has been well controlled by Deep Brain Stimulation (DBS). DBS is very invasive and the process to choose patients for the surgery is very selective. Electrical stimulation has the potential to counter the effect of tremors, with the advantage of being non-invasive. In this case, BCI will be used to detect the patient's intention to move and in addition, Electromyography will be recorded. The latter will then be used to define the electrical stimulation parameters necessary to counter the effect of the tremors. This has the potential to improve the daily lives of Parkinson's Disease patients by reducing fatigue for instance.

In both case, a VisionBody suit will be used to facilitate the application of the system in real life environment.

PROPOSED TOOLS AND METHODS

System Design

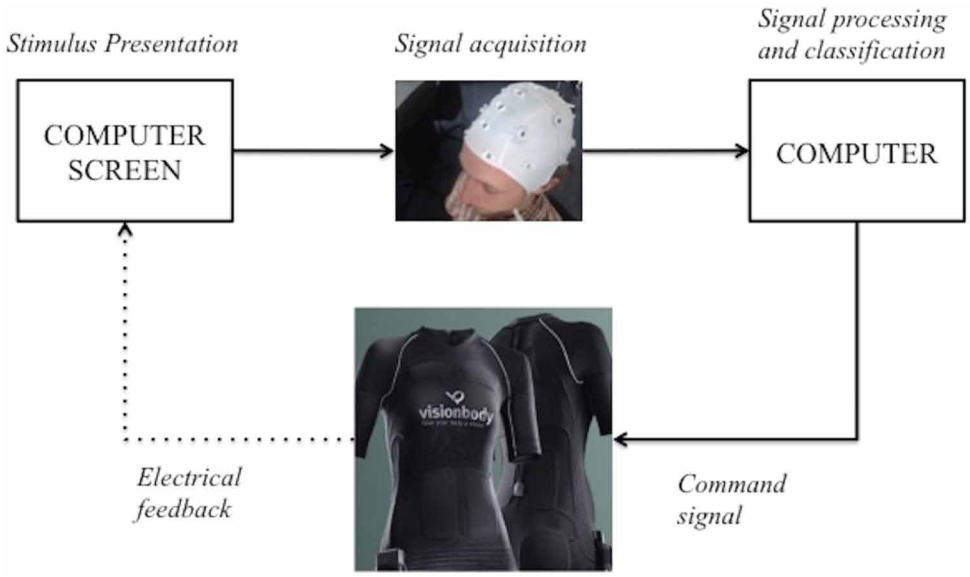
The overall system design is shown in Figure 1. The system consists of:

- **A computer screen:** This screen is mainly used to display the cues to the subjects during the experiment. The stimulus presentation was programmed using BCI2000;
- **A 16-channel g.USBamp acquisition device from g.tec (Austria) connected to a laptop on which BCI2000 is installed:** Brain signals are acquired using the g.tec amplifier. BCI2000 and self-written signal processing (see Figure 1) are used to process and classify the obtained raw signal. The laptop is also used to store the raw data;
- **A VisionBody exosuit:** Once the system detects patterns that indicate an intention to move, the computer sends a control signal to the VisionBody suit. That will then activate the electrical stimulation to the muscles. The communication between the computer and the suit is established via Bluetooth.

An experiment comprises two sessions, a calibration session and a training session. The calibration session is used to train the classifier for each and every subject. Figure 2 shows the course of a calibration session. Each session is composed of a number of trials and each trial starts with a preparation period of 1s. The EEG signals obtained during this period are used to establish a baseline. A second cue

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. System design: The BCI system is composed of a computer for stimulus presentation and data analysis, a signal acquisition tool using a 16-channel g.USBamp from g.tec. The feedback loop is executed using a VisionBody suit that is triggered when the system detects the subject's voluntary movement intention.

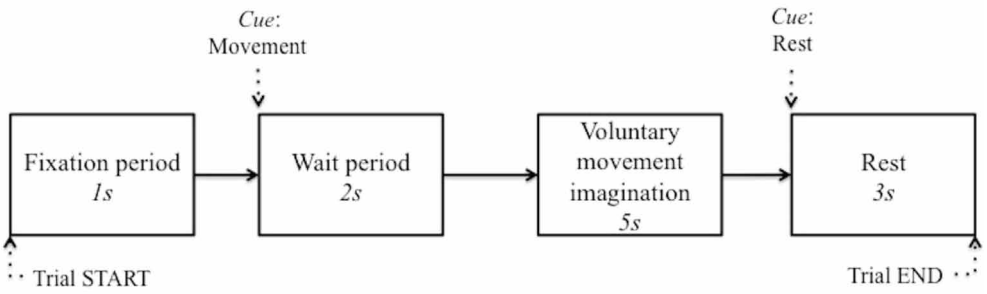


informs the participant of the type of movement to be performed. Prior to the start of the experiment, the participant is instructed to let at least 2s pass before executing or imagining the requested movement. The time frame available to execute the task is 5s. The patient's brain signals are continuously recorded, and movement related features are extracted. These features will be used as input to train the classifier.

This trained classifier is then used to detect voluntary movement intention during the 5s time window throughout the training session. The training session follows the same course as the calibration session, they differ only due to the fact that electrical stimulation is also activated in the meantime.

The detection of a movement intention triggers electrical stimulation to the muscles, and the stimulation is delivered until the target is reached. A trial will be considered successful when the movement is successfully executed during the allocated time. Each trial ends with a 3s rest period.

Figure 2. Experimental setup for the calibration session



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Participants in Prior Study

Two healthy, right-handed subjects participated in this preliminary study. All participants were informed of the purpose of the study.

Experimental Setup

Data Acquisition

Brain signal activity was measured with the g.USBamp amplifier at a sampling rate of 256 Hz. The electrodes were located at the International 10-20 system locations Fp1, Fp2, F3, F4, C3, C4, P3, P4, Fz, Cz, and Pz. The electrode FCz and AFz were used as reference and ground, respectively (Yilmaz, et al. 2015). These locations were chosen so that they are adequate for all subjects. The amplifier was set to filter the signal between 0.1 and 60 Hz, and an additional 50 Hz notch filter was used to remove noise introduced by the electric power. The EEG signals were then transferred to BCI2000 software (Schalk et al., 2004) for analysis and offline storage.

Electromyographic (EMG) data were also recorded at a 250 Hz sampling rate from one subject using medical grade stainless EMG sensors from a Myo armband (Myo TM) placed on the forearm for the tremor reduction task. This EMG will be used to predict the parameters needed during the tremor reduction process.

Task

The participants are seated in a chair, with hands resting on a desk in front of them. They were asked to imagine or execute hand opening or closing of the left or the right hand, depending on the cues presented on the screen using BCI2000. They were also instructed to avoid head or shoulder movements to reduce muscle artefacts.

Each experiment consisted of 40 runs; each run consisted of 8 trials. Trials started with a preparation phase of 1s, followed by a 7s movement imagination phase and a 3s rest phase (Figure 2). Preparation and imagination phases were initiated by visual clues presented on the screen.

Participants were also instructed to wait at least 2s after the cue before executing or imagining a movement. This is done to avoid the presence of an Event-Related Potential (ERP) called Contingent Negative Variation (CNV) that peaks 260 to 470 ms after a warning stimulus that requires a physical or mental response (Lew et al. 2012). It can be measured over the vertex with maximal amplitude of 20 μV (Nagai et al., 2004; Walter et al., 1964).

In addition, one subject was asked to simulate Parkinson's disease tremor. The simulated tremor will later be added to the recorded EMG to simulate tremor-contaminated EMG signal corresponding to a movement.

Data Analysis

The EEG signals were re-referenced using a common average reference (Ibanez et al., 2013; Schalk & Mellinger, 2010; Song, 2013). EEG signals are very susceptible to external artefacts such as eyes and muscles movements or other external sources. So, before this experiment, the authors performed another

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

preliminary experiment in order to study how the electrical stimulation produced by the VisionBody suit was affecting the recorded EEG signals. One participant took part in this preliminary study, wearing the VisionBody suit while his brain signals were continuously recorded. The electrical stimulation is adjustable from 0 to 100% of the maximal intensity defined by the VisionBody suit. In this study, stimulation ranging from 0 to 35%, with an increment of 5% in each trial, was used since higher values of intensity were painful for the participant. Visual inspection of the recorded brain signals showed that, starting at 20% of electrical stimulation, rectangular signal bursts are visible, and their amplitudes increase with an increase of the level of stimulation (Adama et al., 2016). These artefacts were rejected after filtering and applying Independent Component Analysis (ICA) from the EEGLAB toolbox (Delorme et al., 2004). After filtering and artefacts removal, movement related features would be extracted from the collected brain signals.

Features Extraction and Classification

Movement related potentials and Event-Related Synchronization of beta and Event-Desynchronization of alpha waves to assess pre-movement cortical activity were used. Here a feature extraction procedure similar to the ones described by Antelis (2017) and Bhagat (2014) was followed.

First, the signals were segmented into trial epochs of duration -2 to +2s, according to the movement execution. To extract the movement related potentials, EEG data were band-pass filtered with a zero-phase shift second order Butterworth filter at 0.1 - 1Hz and down sampled to 20 Hz. The amplitudes of the signal in that frequency band constitute the MRCP features. In addition, the power values are estimated using Welch method, with a Hamming window of 1s and a 50% overlapping. The features extracted are the logarithmic power of the signals in the alpha (8-13 Hz) and beta bands (13-30 Hz).

For both processes, the features were extracted with a one second sliding window in steps of 125 ms. Features obtained previous to -1.5s were labeled 'rest' and those following -1.5s were labeled 'pre-movement'. These features are used to train a classifier. The movement intentions are detected using a trained classifier.

Movement Intention Detection

Movement production is an elaborate process. In order to produce a movement, the brain sends messages to the limbs. For self-paced hand and foot movements for instance, a slowly increasing surface-negative cortical potential called Readiness Potential (RP) can be measured 1.5 to 1s before the movement onset. This component, also known as Bereitschaftspotential (BP), presents a steeper decay 400 ms before the movement starts and can be measured over the primary motor cortex M1 (Jahanshah & Hallett, 2003). Its amplitude is maximal over the frontal rather than the occipital area, ranging from 10 to 15 μV. BP amplitude increases with intentional engagement and reduced by mental indifference of the subject. Yilmaz et al. (2015) were able to extract these slow cortical potentials from severe chronic stroke patients with no residual paretic hand movement. Their results showed that the SCPs appeared and peaked earlier during paretic hand movement compared to healthy hand movement. Paretic hand movement also elicited larger amplitude over the midline brain while for healthy hand movement, contralateral and midline amplitudes are much larger than ipsilateral activity. Which make them an interesting feature to use for our system.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Event-Related Synchronization/Event-Related Desynchronization is another useful feature. Largely used in motor imagery, it has also been used to detect the intention to move a limb, which is characterized by a decrease of power in the alpha bands (8 - 15 Hz) and an increase of power in the beta bands (16 - 31 Hz) (Bhagat et al., 2014; Kornhuber & Deecke, 1965; Shakeel et al., 2015; Shibasaki & Hallett, 2006).

One important part of a BCI system is the EEG classifier. Several have been used in Brain-Computer Interfaces, and in particular to predict movement onset. Several classification methods have been used to classify and detect movement intention, such as Support Vector Machines, Linear Discriminant Analysis, k-nearest Neighbours or naïve Bayes (Planelles, 2013).

In this study, Radial Basis Function (RBF) kernel Support Vector Machine (SVM) was used for classification. The features used were the movement-related cortical potentials and the power spectra of the EEG signals. The classification accuracy is computed as the ratio of the number of the correctly predicted trials to the total number of trials.

Parkinson's Disease Tremor Onset Detection and Suppression Algorithm

Tremors affected the way patients execute simple tasks in their every day's life. In the case of Parkinson's disease, they can be predicted from EMG signal as demonstrated by Wu et al. (2010), using Radial Basis Function Neural Networks who found that the tremor onset signal is between 1 and 10 Hz and that the pre-tremor signal contains a large amount of activity between 10 and 30 Hz. Apart from muscle activity, tremors can also be predicted using parameters like Event-Related Synchronization / Event-Related Desynchronization (ERS/ERD) and Movement Related Cortical Potentials (Grimaldi et al., 2010).

Pathological tremors generally appear at frequencies between 3 to 12 Hz while voluntary movements are combination of lower frequencies from 1 to 4 Hz. In particular, tremors caused by Parkinson's disease lay between 3.5 to 6 Hz (Manto et al., 2003; Rocon et al., 2010). The most popular method to counter the effect of pathological tremors on patients has been to estimate parameters such as amplitude and frequency of the tremor, and used these to calibrate a loading force to suppress it. Even though there are several sensors that can be used to measure the electromyographic signals, most of these researchers used gyroscope (Grimaldi et al., 2010; Manto et al., 2003; Rocon et al., 2010). The frequency and amplitude of the tremor are then estimated using methods based on Fast Fourier transform (Adhikri et al., 2015; Wang et al., 2016).

In this study, these parameters are estimated using the recorded EMG data and used afterwards to determine the characteristics of the electrical stimulation needed to counteract the tremor from Vision-Body suit. Before applying the tremor estimation algorithm, the EMG data is filtered using a 5th order Butterworth pass band filter between the frequencies 5 to 20 Hz to remove unwanted low frequency drifts.

Note that this procedure was not applied on patients yet but performed to test the capability of the proposed signal processing for future use with patients. To the recorded EMG signal was added simulated tremor signal. This signal was created as a combination of 5 and 7 Hz sinusoidal waves with amplitudes of 1 and 0.5 respectively. The predicted tremor signal was estimated from the added signals using a Weighted Fourier Linear Combiner (WFLC) algorithm, as described by Adhikari and al. (2015). The WFLC algorithm is based on the Least Mean Square (LMS) algorithm and is widely used to reduce tremors and stabilize surgeons' hand during surgery.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Electrical Stimulation Delivery

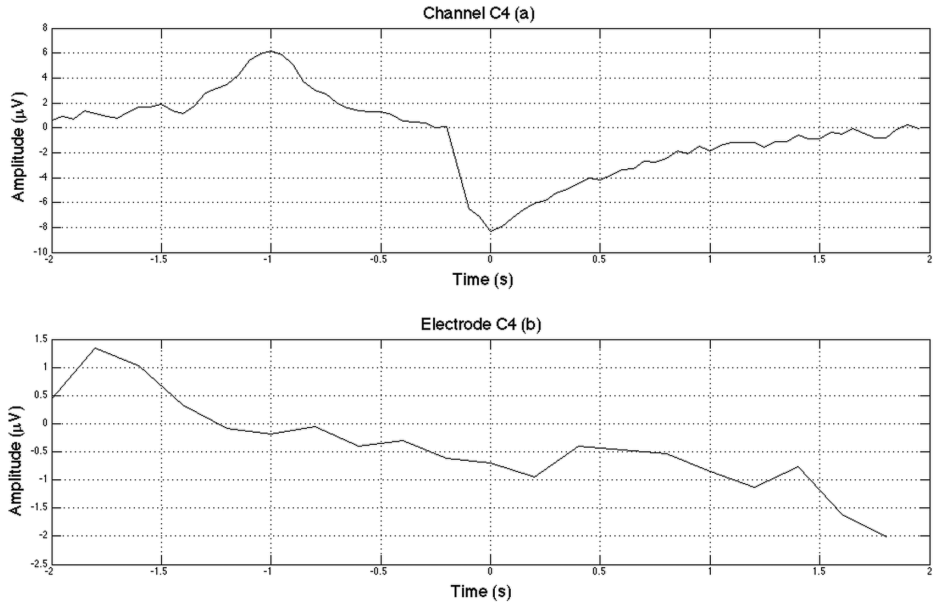
The feedback loop is executed using a VisionBody exosuit that is triggered when the system detects the subject's voluntary movement intention. The suit then delivers an electrical stimulation through the pad electrodes with an amplitude chosen between 0 and 50 mA, and a frequency of 20 to 50 Hz. Stimulation is sent by pulses of 0 to 0.5 ms and inter-pulses delays between 10 and 100 μs (Lee et al., 2015; Ono et al., 2013; Qu et al., 2016). For stroke patients, the exact values of the amplitude and the frequency of the electrical stimulation signals depend on the level of impairment of each patient individually. In the case of Parkinson's disease, these parameters are obtained after applying the WFLC algorithm to the contaminated EMG signal. Once the patient reaches the end of the movement, the electrical stimulation is turned off.

RESULTS

This study aims at designing an EEG-based brain-computer interface system combined with a VisionBody suit that provides electrical stimulation, for stroke rehabilitation and Parkinson's disease tremor reduction. Movement-related cortical potentials and power spectra of the alpha and beta waves were extracted from brain signals recorded from 11 electrodes as described above. In addition, EMG data were also recorded and used to determine the electrical stimulation parameters for the tremor reduction task.

Figure 3 shows an example of EEG signal recorded at electrode C4 when the participant is imagining opening his left hand (a), and during rest (b). The movement onset occurred at t=0s. Movement intentions were detected 1.25 to 0.9s prior to the movement onset. Literature shows that the typical values are between 1.5 and 1s prior to the movement onset (Jahanshani & Hallett, 2003).

Figure 3. Example of training data recorded at electrode C4: (a) When imagining a movement; and (b) During rest. The onset of the movement is at t = 0s.

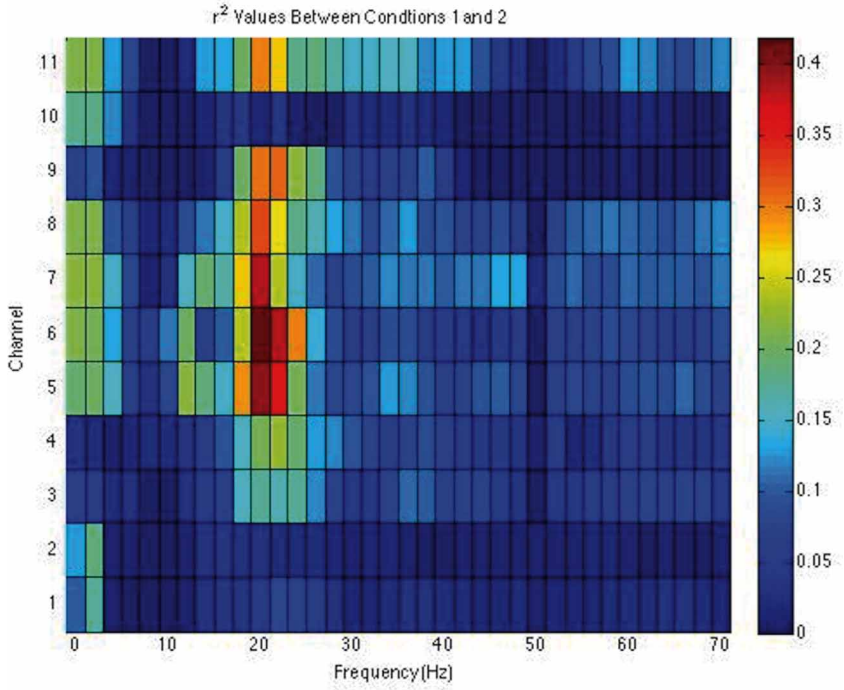


EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

For each participant, only channels with the higher r-squared values between 'rest' phase and 'movement' phase will be selected to implement the online system (training session) in order to reduce computation time. The channels with the higher r-squared values were located in the central and parietal areas (C3, C4 and P3) for Subject 1, and in the central and frontal areas (C3, C4, and Fz) for Subject 2 during both motor execution and motor imagination. Figure 4 is a feature map that represents the average channel/frequency matrices for a left hand movement execution of the first participant. The horizontal axis corresponds to the frequencies and the vertical axis corresponds to the channels. Condition 1 represents Rest while Condition 2 represents a left movement execution. The measured r-squared between the two conditions are represented in colour codes, and in this particular case, its values are the largest for channel 5 (C3), 6 (C4) and 7 (P3) with 0.3964, 0.3799 and 0.3416 respectively at 19 Hz.

The mean classification of the classifier is represented in Figure 5 for both subjects. It is calculated as the ratio of the number of true detections to the total number of attempts. The results show that the classification accuracy is higher during movement execution compared to movement imagination. Furthermore, it is higher while performing the task with the dominant hand. Left hand movement imagination classifications were the less reliable with less than 75% accuracy for both subjects. Overall, these results align to other similar research on movement imagination and execution researches with accuracies ranging from 64.5 to 87% for movement imagination, and from 69 to 99% for movement execution (Shakeel et al., 2015).

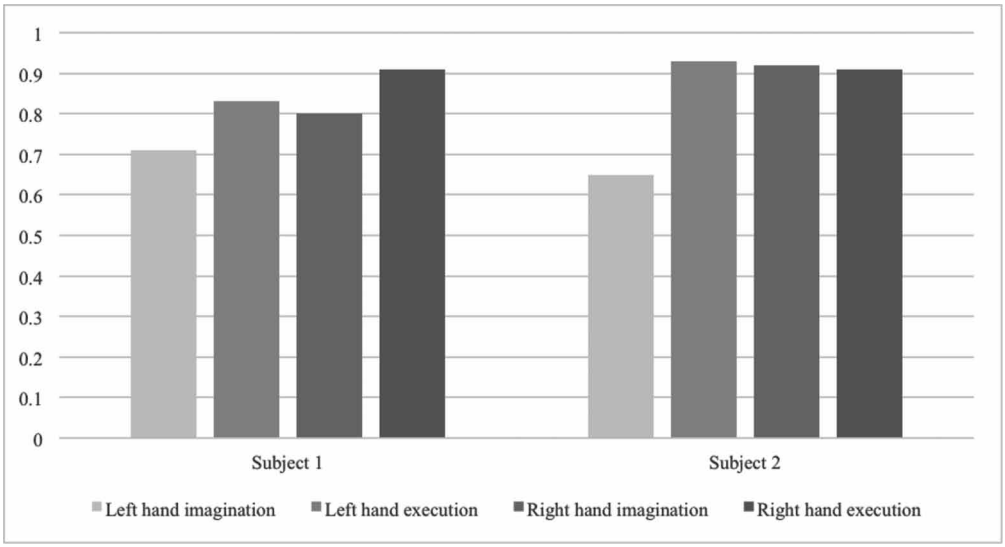
Figure 4. Selected features for the first participant where Condition 1: Rest and Condition 2: Left movement execution. The figure is a feature map in which the horizontal axis corresponds to frequencies and the vertical axis corresponds to the channels. The measured r-squared between 'rest' and 'left hand movement execution' are represented in colour codes. In this particular case, r-squared values are the largest for channels 5 (C3), 6 (C4), and 7 (P3) with 0.3964, 0.3799, and 0.3416 respectively, at 19 Hz.



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The tremor reduction task was tested with real EMG data to which simulated tremor data was added. A natural upper limb movement is composed of movements, which frequencies lay between 1 and 4 Hz. The signal was acquired at a 250 Hz sampling rate. Figure 6 shows a portion of the EMG signal used for this experiment and its periodogram. The latter shows that the dominant frequencies are effectively between 0.5 and 4 Hz, which correspond to the frequencies of a voluntary movement. Amplitudes are expressed in mV. A tremor signal was then generated as a combination of 5 and 7 Hz sinusoidal waves, with amplitudes of 1 and 0.5 respectively, to simulate Parkinson's disease tremor (cf. Figure 7). The predicted tremor signal and the residual tremor are presented in Figure 8. After applying the tremor reduction algorithm, the amplitude of the tremor is significantly reduced from 1.5 to less than 0.1 mV. The same conclusion can be deduced in Figure 9, which represents the periodogram of both signals. It shows a significant decrease in the signal power. A spectral coherence between the simulated tremor signal and the predicted tremor confirms that both signals have two correlated components around 5 and 7 Hz.

Figure 5. Average detection accuracy of the classifier, corresponding with the four tasks. The vertical axis represents the percentage of true positives, 1 equals 100%.



DISCUSSION AND CONCLUSION

This manuscript describes and proposes the design of an EEG-based Brain-Computer Interface combined with electrical stimulation intended for the rehabilitation of stroke and for tremor reduction in patients diagnosed with Parkinson's disease. The idea is to improve the outcomes of the rehabilitation therapy for stroke patients, in one hand, by engaging and motivating them in order to speed motor recovery. On the other hand, the system is expected to minimize the energy consumption of the arm with the patients experiencing tremors, thus reducing fatigue and possibly increasing its functionality. The VisionBody suit was chosen to deliver the electrical stimulation so that it can facilitate real-life application of the system.

Figure 6. Recorded EMG signal. The image at the top shows the recorded EMG signal from one participant. The sampling rate is 250 Hz. The amplitude of the signal is expressed in mV. The image at the bottom shows the periodogram of the same EMG signal. Signal frequencies lie between 0.5 to 4 Hz, which correspond to the frequency of voluntary movements.

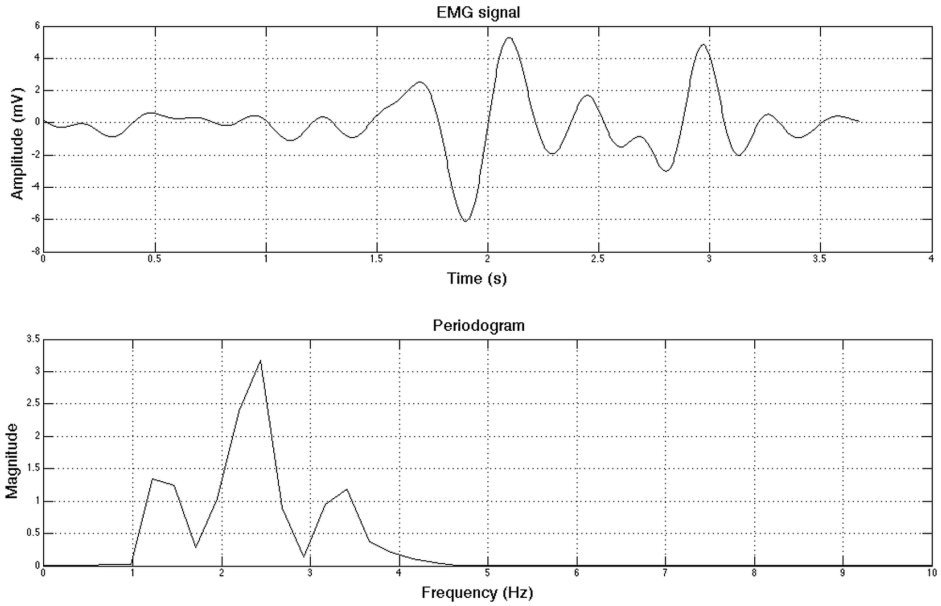

Figure 7. Simulated tremor signal. The tremor signal was created as a combination of 5 and 7Hz sinusoidal waves with amplitudes of 1 and 0.5 respectively, to simulate the Parkinson's disease tremor.

Figure 8. Predicted tremor signal and residual tremor after tremor suppression. The predicted tremor signal is obtained from the tremor suppression algorithm and will be used to calibrate the electrical stimulation. The remaining tremor is shown in the figure on the bottom. The amplitude of the original tremor signal was 1.5 mV and the remaining amplitude after the suppression algorithm is less than 0.1 mV.

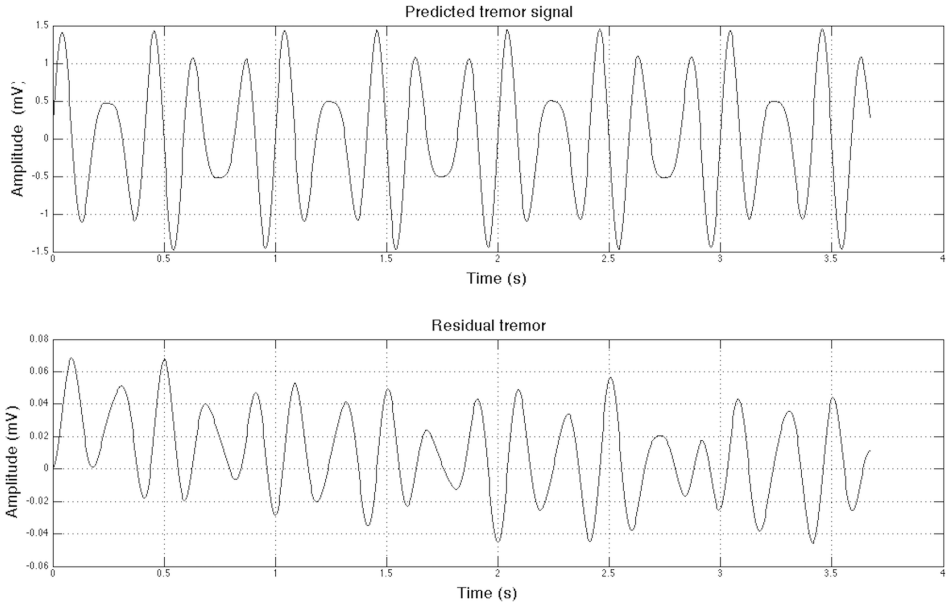

Figure 9. Periodogram of the original tremor (top) and the residual tremor (bottom). The power of the residual tremor is 1,2.10^6 times smaller than that of the original tremor, showing that the tremor is effectively reduced after applying the tremor suppression algorithm.

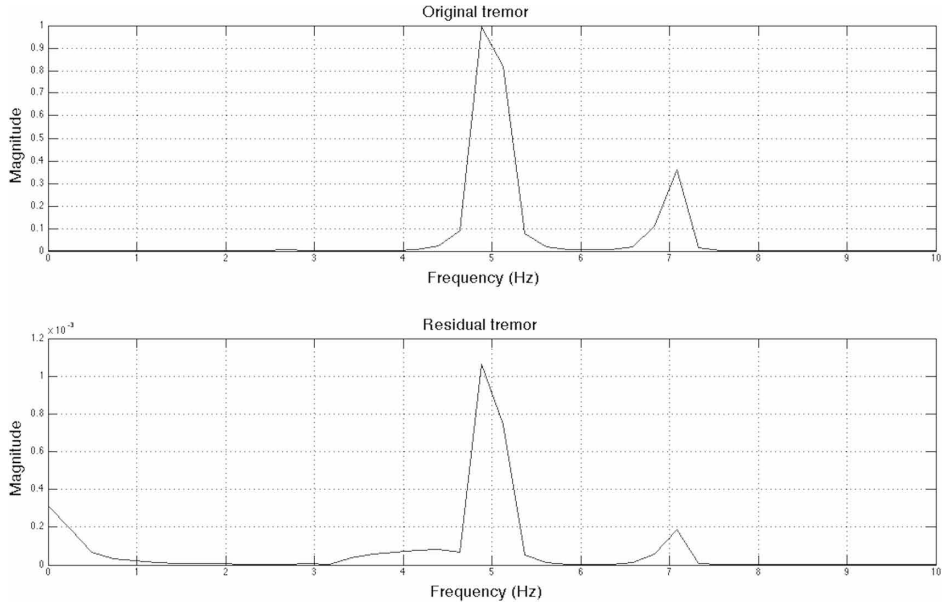

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bereitschaftspotential and the power values of alpha and beta waves were extracted from the EEG signal to detect movement intention. These features were then used as input to a Radial Basis Function kernel Support Vector Machine classifier in order to implement the online rehabilitation session. Overall, the detection accuracy is satisfactory and aligns with the results of previous researches. However, it appears that this accuracy was lower for movement imagination and execution of the non-dominant hand. Moreover, the algorithm used to counter the effect of the tremor was able to reduce the original tremor signal by 150% in our simulation, which is very promising. However, the study needs to be extended to more healthy participants to obtain deeper and more reliable results.

Thus, the authors have shown that the approach is promising and feasible from a technical point of view and might be followed up with patients. With the rise of mobile non-invasive BCI, the feasibility of this project would mean a facilitated real-life application, for instance in home care to improve patients' life. Future steps would be to incorporate the closed loop BCI/FES/EMG approach and to perform experiments in real-time still with healthy subjects. Once those have been done successfully, the approach will finally be extended to patients, preferably with some residual limb movement. Some of the challenges will be to obtain good classification results with less training data, to avoid patient fatigue and to correctly calibrate the parameters of the electrical stimulation depending on the level of impairment of each patient.

Chapter 34
Modes of Delivering Psychotherapy: Investigating Technology

Ebrahim Oshni Alvandi

Mark Symmons
Monash University, Melbourne, Australia

ABSTRACT

The ubiquity of telecommunications technologies and the internet facilitates offering different mental health services to the public, and the ongoing advancement in technologies introduces new venues to a range of psychotherapeutic services. It is critical to all clinicians and professionals in information and communications technology to have a clear understanding of the opportunities and challenges of these technologies. This article outlines the technologies that are currently used as part of psychotherapy. In particular, the paper discusses some of the current state of clinical research, advantageous and disadvantageous that relate to the use of these technologies.

INTRODUCTION: HISTORICAL BACKGROUND AND TELEPHONY-BASED APPLICATIONS

Counselling services traditionally offer 'treatment' in a private, face-to-face setting (e.g., an office or clinic). Technology-based counselling services, however, have surfaced as an alternative means of therapy where patients do not have access to in-person services. These services have been available for several decades. For example, the Australian Royal Flying Doctor Service (RFDS) used the Morse Code,

a coding system to transmit messages via the electromagnetic telegraph, was used in 1928-1929 by the Royal Flying Doctor Service (RFDS) in Australia to provide telehealth to remote areas (Margolis & Ypinazar, 2008; Persson, 2010). It was in the 1930s that the service called 'Voice Radio Therapy' was introduced and serviced remote areas of Australia by telephone. The use of telephone technology in psychotherapy continued in later years. For example, in an attempt to prevent suicides, the Samaritans[1] began the first telephone counselling service (called Lifeline) in London in 1953 (Hornblow, 1986) and four years later in 1957, three telephone counselling providers were established in the United States of America (Hornblow, 1986). In Australia, the first Lifeline service was officially introduced in 1963 (Coman, Burrows, & Evans, 2001), but it was during the 1970s that telephone technology services have provided psychotherapy services (see Lester, 1974 and Regan, 1997).

Since the 1980s, telephone psychotherapy has been recognised as a valued alternative to traditional face-to-face therapy and has been used to deliver various mental health services (Reese, Conoley, & Brossart, 2006; Robinson, 2009b), for instance, to provide care for obsessive-compulsive disorder (OCD) and depression (Lam, Lutz, Preece, Cayley, & Walker, 2011; Lerman et al., 1992; Marcus et al., 1993; Turner et al., 2014). Telephone counselling has also been effective in helping clients with the psychological issues associated with cancer (Badger, Segrin, Pasvogel, & Lopez, 2013; Bastian et al., 2013), with disability as an adult (Evans, Halar, & Smith, 1985), with smoking cessation (Bastian et al., 2013; Stead, Hartmann-Boyce, Perera, & Lancaster, 2013; Zhu et al., 1996), and with HIV infection (Velthoven, Brusamento, Majeed, & Car, 2013).

Given the success of telephone counselling, it is not surprising that the usefulness and appropriateness of other technologies for therapeutic purposes has been assessed. Several studies have identified the benefits or disadvantageous of those services, ethical and organizational issues, and the therapeutic outcomes achieved using differing technologies (see Haberstroh, Parr, Bradley, Morgan-Fleming, & Gee, 2008; Lovejoy, Demireva, Grayson, & McNamara, 2009; Richards & Viganó, 2013a; Schultze, 2006). For example, instant messaging, chatting, and video conferencing facilitate a person's ability to access services in spite of one's geographical distance from the service. These telecommunication systems open up new possibilities for communication between therapists and clients. This was the reason the current article outlines the story of use of technology in psychotherapy. The review will classify the technologies that have been used in psychotherapy and will also discuss some of the advantageous and disadvantageous that relate to the use of these technologies.

As a basis for this literature review, technologies have been categorised into four categories. Firstly, Internet-based technologies are covered with attention to the advantageous and disadvantageous of these technologies as a common medium of therapeutic delivery. Secondly, stand-alone platforms including mobile applications and technologies designed for automated self-help services are reviewed elucidating some of the challenges in using such automated systems in psychotherapy. The third category covers the use of 3D, and Virtual Reality (VR) therapeutic technology tools and the final category focuses in assistant therapists.

The material for this study was mainly drawn from the peer-reviewed literature in which the terms "computer-mediated therapy," "tele-counselling," "e-health," "internet-online counselling," "videoconferencing," "asynchronous therapy," "synchronous therapy," "Virtual Reality" were used. These terms were also used in a search of the databases EMBASE, PubMed, PsychINFO, and Google Scholar to gather articles on technology-based therapies, but no specific method was used to filter the clinical or experimental content of the papers reviewed.

INTERNET-BASED TECHNOLOGIES

In addition to telephone technology, the advancement in telecommunication technologies including internet facilities has introduced new modes of providing a range of psychotherapeutic services to the public. Three forms of internet-based technology in particular have been identified as potential tools for remote forms of psychotherapy: Blogs and forums, social media and interactive technologies.

Blogging and Forums

Blogging and forums are the first routes that are not, necessarily, aimed at generating therapeutic outcomes for the user. These technologies are generally used to deliver a tutorial on potential psychological treatments (Bennett-Levy, Thwaites, Chaddock, & Davis, 2009; Farrand, Perry, & Linsley, 2010). Although not be considered psychotherapy and counselling per se, the information shared on blogs or forums shares many features with group therapy and can, potentially, be integrated into more traditional forms of psychotherapy. Specifically, blogging can provide self-help support to groups (Nagel & Anthony, 2009) and provides an opportunity for peer support (Jorm, Morgan, & Malhi, 2013). Also, blogging provides users with an opportunity to share their personal knowledge about health (Swain, 2007), while simultaneously connecting geographically disparate groups. There, however, could comment on the threats of using community-based platforms such as blogs and forums for psychotherapeutic applications. It is expected that without proper clinical supervision by professional psychotherapists, rude or imprudent posts by other users could cause severe damage to a person who already seeks help for his/her unstable psychological state.

Social Media

There is also a growing interest in using social media, such as Facebook and Twitter, as an alternative to face-to-face therapy (Moorhead et al., 2013; Syred, Naidoo, Woodhall, & Baraitser, 2014). Similar to forums and blogs, social media can provide psychotherapeutic information, but in contrast to blogs and forums, social media allows dynamic and interactive communication between people (e.g., client and clinician) (Laranjo et al., 2014; Parikh & Huniewicz, 2015). For instance, users can communicate their concerns and seek help or advice from their 'friends' who interact with each other and who can share their responses or ideas via integrated digital media such as combinations of electronic text, graphics, moving images, and sound. Multimedia is a distinguished capability of social media which is seen rarely in forums or blogs.

Numerous free Facebook pages aim to raise awareness of, and prevention of, psychological disorders such as Depression and diseases such as Human Immunodeficiency Virus (HIV). These services are free, apart from the cost of an internet connection, and users are provided with access to the most up-to-date research and educational materials. These sites also provide psychotherapists with the opportunity to recommend their services. In short, interactivity, social and peer support, advertised services and access to inexpensive or free sources of information relating to specific mental health issues make social media appealing to potential clients (Moorhead et al., 2013). However, similar to forums the users' comments should be supervised by therapists to avoid negative impacts of improper statements or expressions on the others' psychological states.

Interactive Technologies

The new telecommunication systems have varying degrees of interactivity that enable talking backing to the user. For example, technologies which enable synchronous communication, such as Short Message Services (SMS) such as ReachOut[2] or SANE[3], video conferencing, podcasts, audio chatting, and instant text messaging (e.g., Yahoo Messenger) can also be used for instantaneous communication between a client and a clinician. Richards and Vigano (2013) suggest that clinicians and patients use these technologies because they are accessible from both desktop computers and portable devices, and thus help can be accessed easily if needed. Further, and from the client's perspective, can be accessed from almost anywhere (e.g., remote settings), and the costs are competitive relative to traditional, face-to-face sessions particularly when time and transportation expenses are considered (Chung, 2013; Griffiths, 2001; Maples & Han, 2008).

Text-based communication between the client and therapist can be conducted through e-mails, instant messages and chats. Email is amongst the most commonly used asynchronous technologies for internet-based therapy (Bellafiore, Colón, & Rosenberg, 2004). With asynchronous text-based psychotherapy (e.g., email), patients and the psychotherapists have time to consider their responses and the next steps in addressing the problem (Suler, 1997, 2000). When the synchronous text-based communication (e.g., chat mode) is employed, counselling pairs can be both sure that they are online and communicate simultaneously. (Mallen, Jenkins, Vogel, & Day, 2010; Satalkar, Shrivastava, & De Sousa, 2015). Although there is a need for appointments fixed in advance, the real-time text-based communication can provide opportunities to minimize or correct misunderstandings and have instant and supportive responses. Client anonymity is also listed as an advantage of text-based and, parenthetically, audio-based psychotherapy. This has a positive effect on therapeutic outcomes by allowing the client to be less inhibited (Suler, 2004; Tanis & Postmes, 2007).

Audio chat via standard telephone lines or sophisticated Internet-based technologies such as smartphones is found in the literature most adequate, achievable and effective method of distance mental health support (Day & Schneider, 2002; Kraus, Stricker, & Speyer, 2010; Mundt, Snyder, Cannizzaro, Chappie, & Geralts, 2007). While voice chat overcomes geographical barriers, different groups of people with various mental health issues can use this technology in a single or group psychotherapy. For example, Wiener, Spencer, Davidson, and Fair (1993) reported the effectivity of the audio-based psychosocial support for HIV-infected children and their families. Likewise, Gettings, Franco, and Santosh (2015) demonstrated that audio-conferencing was an effective method to support siblings of children with neurodevelopmental disorders. Furthermore, users of audio-based counselling services (e.g., telephone services such as Lifeline) rate the therapeutic attachment as stronger than other Internet-based counselling technologies such as text messaging (King, Bambling, Reid, & Thomas, 2006), and these services have had positive outcomes for several disorders (Choi et al., 2012; Chong & Moreno, 2012; Jang et al., 2013; Moreno, Chong, Dumbauld, Humke, & Byreddy, 2012).

When it comes to videoconferencing technologies, it is similar in many ways to face-to-face interactions. Videoconferencing sessions are a hybrid of networking, video, audio, and more that allow real-time visual and audio communication while overcoming potential issues such as travel costs, mobility challenges, socioeconomic status, and patient engagement (Casey, Joy, & Clough, 2013; Phillips, Vesmarovich, Hauber, Wiggers, & Egner, 2001). Specifically, this mode of delivery is thought to be the most credible substitute for face-to-face therapy in areas where face-to-face therapy is unlikely to be feasible, e.g., remote locations (Dongier, Tempier, Lalinec-Michaud, & Meunier, 1986; Ertelt et al., 2011).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Given the apparent benefits of using technology, it is not surprising that the usefulness and appropriateness of videoconferencing technologies for therapeutic purposes has been assessed (see Bee et al., 2008; Haberstroh, Parr, Bradley, Morgan-Fleming, & Gee, 2008; Lovejoy, Demireva, Grayson, & McNamara, 2009; Richards & Vigano, 2013; Schultze, 2006; Yuen, Goetter, Herbert, & Forman, 2012). Videoconferencing has been found to be an effective mode particularly in treating Obsessive Compulsive Disorders (Fitt & Rees, 2012), Anxiety Disorders (Rees & Maclaine, 2015), and Posttraumatic Stress Disorders (PSTD; Pelton, Wangelin, & Tuerk, 2015); the studies reported that participants experienced clinically significant reductions in their symptoms and an improved quality of life. The evidence to date is also highly suggestive that videoconferencing is comparable to face-to-face mental health care (Chakrabarti, 2015). For example, King et al. (2014) compared videoconferencing psychotherapy sessions with face-to-face counselling sessions and found that opioid-dependent individuals had responded well to treatments over the 12-week study and the two modes were equivalently effective. Further, the individuals in the videoconferencing group had high ratings of treatment satisfaction and therapeutic alliance.

In spite of positive outcomes, many practitioners and a significant research has suggested caution about the credibility and reliability of the online provision of psychotherapy (Alleman, 2002; Callahan & Inckle, 2012; Glasheen & Campbell, 2009; Lester, 2006; Robinson, 2009a; Skinner & Latchford, 2006; Wells, Mitchell, Finkelhor, & Becker-Blease, 2007). Some scholars believe it too early to be making claims regarding the long-term efficacy of online counselling for complex disorders such as depression (Dorstyn, Saniotis, & Sobhanian, 2013). These arguments are based on the belief that therapy via technology is not fully equivalent to face-to-face sessions (Barnett, 2005; DeLucia, Harold, & Tang, 2013). The main concerns address the interactivity of the session and "absence" of the counselling parties during computer-mediated psychotherapy (CMP). Taking the perspective of the clinician, therapeutic presence is the essential factor of therapeutic effectiveness (Schneider, 2015). This presence is referred as being in the moment with the client on not only physical interaction but also emotional and cognitive levels of communication (Geller & Greenberg, 2012), which the degree of such presence offered by communications media might be different than face-to-face sessions (Brahnam, 2014).

Another major area of concern is the usability of technology (McCarthy & Wright, 2004). The term usability denotes the ease with which the user can work with the technology or computerized system. Usability is the efficiency, effectiveness, and satisfaction by which users can achieve their goals with the technology (Bevan, 2001). Thus, if the user's experience includes a lack of functionality, whether a design or human factor this will impact on the communication particularly in online counselling environments (Manhal-Baugus, 2001). For example, looking at screens, or tablet or smartphone displays for extended periods of time can cause eye fatigue and may impede engagement between users during CMP sessions (Abbott, Klein, & Ciechomski, 2008). As such, Ertelt et al. (2011) have suggested studying the impact of the size of videoconferencing devices on the therapy, therapeutic relationships, and the engagement of the client. Other limits of usability in videoconferencing, may be insufficient image quality, low framing rate, flickering, and delays that make psychotherapy process unpleasant for clients and psychotherapists (Castelnuovo, Gaggioli, Mantovani, & Riva, 2003). Moreover, the angle of a webcam and the participant's distance from the video camera might also affect the relationship between psychotherapist and client. These factors can disturb eye-contact between the individuals (Manstead, Lea, & Goh, 2011).

There are also several technical issues apparent in Internet-based technologies that can impact this provision of psychotherapy negatively. Technical considerations for online providers, clinics or "lifelines" require IT support personnel and a secure web portal[4] to deliver efficient services. Difficulties with navigation and interaction due to poor quality software can also decrease the success of therapeutic

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

communication (DeLucia et al., 2013). For example, technical glitches such as software bugs may lead to a failure or fault in the used computer program and thus can affect the efficacy of online psychotherapy (Griffiths, 2001; Mishna, Bogo, & Sawyer, 2013).

Problems with hardware are other issues which negatively impact on the effectiveness of online counselling interventions (Manhal-Baugus, 2001). The patients may be ill-equipped for interaction via Web devices, or connectivity may be poor causing delays in information transfer. Such technical barriers can be detrimental to developing a strong therapeutic alliance (Sucala, Schnur, Brackman, Constantino, & Montgomery, 2013). Fortney, Burgess, Bosworth, Booth, and Kaboli (2011) note further that data quality may impede effective counselling. For example, a low bandwidth network will provide low fidelity video and audio information and slow upload and download (Bennett & Glasgow, 2009; Meropol et al., 2011; Smith, Bensink, Armfield, Stillman, & Cattery, 2005). Similarly, low-resolution images can impede eye contact between the client and psychotherapist (Abbott et al., 2008). Abbott and colleagues (2008) also note that colour distortions can have a negative impact on videoconferencing sessions (Abbott et al., 2008). Parenthetically, the restrictive storage/memory and processing speeds of many smartphones could distort video images which can also interfere with the therapeutic alliance (Boulos, Wheeler, Tavares, & Jones, 2011).

A further issue is the lack of familiarity with technologies. Clients with little or no knowledge of computers may reject online psychotherapy out of a fear of the unknown, or they might be confused by the process (Mallen, Day, & Green, 2003). Therefore, cybertherapists must be able to help clients in solving software and technology questions. However, psychotherapists may also have low levels of computer literacy and therefore be less confident and, possibly, less effective in an online environment (Popoola & Adebowale, 2012). In text-based therapy, for instance, both parties need to be competent in conveying mental health problems and emotional states, and potentially applying emoticons (e.g., ☺) appropriately to enhance emotional engagement (Abbott et al., 2008).

Ethical and legal issues should also be included in the list of potential challenges facing online therapy (Brenes, Ingram, & Danhauer, 2011; Gamble, Boyle, & Morris, 2015; Luxton, Pruitt, & Osenbach, 2014). These include privacy and security issues. A major ethical issue is that of confirming the identity of the client, particularly when it comes to text-based communication. Clinics or 'lifelines' require IT support personnel and a secure web portal to deliver efficient services by encrypting high-risk personal data of clients and preventing them from being hacked (i.e., avoiding the ability of third parties to access the client's information). Other, related, issues include providing consent in the CMP context (Jorm et al., 2013; Manhal-Baugus, 2001; Zack, Kraus, Stricker, & Speyer, 2010). Some argue that the identity of the therapist and client, their locations, and contact details for emergency purposes should be described in that consent form (Gamble et al., 2015). Further, some scholars maintain that it will be difficult to police practitioners' competence in computer-mediated environments (Reamer, 2013) and that accrediting bodies will have difficulty ensuring that psychotherapists are competent in delivering psychotherapy online (Chester & Glass, 2006). Therefore, the details of services provided and qualification of therapists have to be mentioned in the consent form and signed electronically or in conjunction with a hard copy. Similarly, fee arrangements to charge clients' for providing online healthcare and the health care coverage by health insurance companies should be discussed by authorities. In addition, a cybertherapist should be aware of cyber law to protect the clients' privacy and confidentiality. Given the number of potential ethical concerns, clear guidelines should be developed (Gholami-Kordkheili, Wild, & Strech, 2013; Grajales III, Sheps, Ho, Novak-Lauscher, & Eysenbach, 2014; Kramer, Mishkind, Luxton, & Shore,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

2013). Table 1 outlines the general advantages and disadvantages in psychotherapy via technology. The primary content of this table is adapted from Robinson (2009a), Shiller (2009) and Centore (2006).

STAND-ALONE PLATFORMS

Stand-alone platforms are alternatives that can provide simultaneous, automated counselling. These tools aim to provide clients with the ability to identify their problematic thoughts, emotions, and behaviours without the help of a psychotherapist. In other words, they are online, open-access programs that have been designed to provide an individual with the ability to self-diagnose.

Table 1. A comprehensive outlook of advantages and disadvantages of cybertherapy

Advantages of Virtual Counselling	Disadvantages of Virtual Counselling
Privacy	Feeling of being rushed
Anonymity from family, friends and coworkers	Time gap in response between client and psychotherapist during e-mail therapy
Emotionally safe environment	Feeling of not being valued
Empowerment; equal relationship with clinician	Difficulty in expressing emotions through text-based communication
Protection from negative counsellor emotions, such as boredom or criticism	Lack of emotional connection, rapport, and empathy
Convenience/Access	Experiencing a reduction of intimacy, trust, and commitment
Cost effectiveness / Affordability	Lack of privacy
Controllability of relationship and therapy	Lack of security and confidentiality
Greater ease with self-disclosing; less awkward and intimidating than face-to-face counselling	Stigma; Concerns about being caught by spouse or employer
Disinhibition/freedom to express themselves without embarrassment or fear of judgment from clinicians	Problems with the technology (malfunctions, glitches, and hardware failures)
Ability to be completely honest and open	Sense of loss from not having nonverbal cues or the personal warmth received from face-to-face contact
Responsiveness to clients needs during all clinical interaction	Absence of verbal and nonverbal cues (facial expressions, vocal signals or body language)
Various ways to communicate (e.g., telephone or email)	Lack of effectiveness/ clinical efficacy
Avoiding social stigma	Inaccessibility of ICT resources and knowledge; technical abilities of the participants
Accessibility	Clinicians' Credibility
Flexibility	Clinicians' lack of training
Time delay for review, evaluation and decision making of therapeutic communication	Legal and Ethical issues
Fewer unnecessary transfers and relocation of one or both counselling parties	
Re-readability of materials	
Services to remote area

In Australia, MoodGYM[5] and E-Couch[6] are the most well-known of these technologies (Klein & Cook, 2010; Klein et al., 2014). They have been developed by the Centre for Mental Health Research at the Australian National University. Addressing the question of design, the current technologies are self-tailored treatment programs based on computational models of psychotherapy. MoodGYM, for example, was coded to provide a computer-based version of Cognitive Behaviour Therapy (CBT) with five modules including an interactive game, anxiety and depression assessments, downloadable audio-based relaxation files, a workbook, and feedback based on the assessments, each of which is thought to assist the client in the self-treatment of their issue. Similarly, E-Couch is an internet-delivered, psychotherapy platform. It provides therapy for depression, generalised anxiety, social anxiety, relationship breakdowns, and loss and grief based on a CBT method. Outside Australia, PAXonline[7] was introduced in 2010 as a web-based platform to prevent and treat anxiety disorders in the Romanian population (Miclea, Miclea, Ciuca, & Budau, 2010). Other notable platforms available globally are Beating the Blue, Down Your Drink or Fear Fighter, Living Life To the Full, Beating Bipolar, Blues Begone, Mood Control, Coping-Tutor, Good Days Ahead, and ODIN[8].

Along with the increase in number of stand-alone therapies, the issue relating to their applicability is an ongoing debate in psychotherapy research. On the positive side, there are suggestions that the consistent positive outcomes of these therapies might, one day, lead to the replacement of human therapists (Foroushani, Schneider, & Assareh, 2011; Green & Iverson, 2009; Kaltenthaler, Parry, Beverley, & Ferriter, 2008). Other are more modest and claim that current stand-alone platforms are 'acceptable' in treating clients' mental disorders (Cavanagh & Shapiro, 2004; Marks, Cavanagh, & Gega, 2007) and have the benefit of cost effectiveness and accessibility to clients. Others have argued that the algorithm-based responses to psychological problems of stand-alone platforms are questionable (Christensen, Griffiths, & Farrer, 2009; Tantam, 2006). This has been supported by the dropout rates for computerized self-counselling services (Marks et al., 2007). For example, a recent study showed that a large proportion of clients (74%) assigned to MoodGYM psychotherapy dropped out (Donker et al., 2013). The same study reported that only 31.8% of participants finished half or more of the MoodGYM program. This rate is similar to that reported in earlier studies (Cavanagh & Shapiro, 2004; Clarke et al., 2005; Clarke et al., 2002; O'Kearney, Kang, Christensen, & Griffiths, 2009; Proudfoot et al., 2004), and hint at the possibility that people become frustrated or disenfranchised by stand-alone platforms.

Other, seemingly, important issues include the fact the stand-alone platforms cannot offer an effective therapeutic alliance between the clinician and client (Peck, 2010). Algorithmic programs are limited to one-way communication, although multimedia may add some human-like interactions. Further, these programs have a mechanistic design that impedes engagement between the user and the program. Besides the 'click and read' style of interaction, the programs incorporate only procedural and solid therapeutic interventions. They provide programmed therapeutic tasks for the clients to run in a predetermined order, which might not be followed or might become monotonous causing the client to quit the therapy. Therefore, although the effectiveness of these platforms seems strong and promising, therapist-client relationships should be considered in evaluation because that relationship is an important factor in transmitting therapeutic activities (Peck, 2010). This online transmission might be improved by investigating how psychotherapists act and develop reliable and valid therapeutic factors (Bachelor & Horvath, 1999).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Mobile Applications

Mobile software applications (called apps) are another group of emerging technologies. They are programs designed to run operations for various purposes on a mobile device such as smartphones or tablets. Although they are in the early stages of production, an increasing number of these apps come from to health sector (Handel, 2011; Ventola, 2014). Specifically, psychotherapy-centred apps available for what are considered to be the primary emotions (e.g., sadness; Hogan & Kerin, 2012; Marks, 2013). The main goal of these apps is to allow users to explore their moods/emotions. 'Emotion Sense', for example, records the moods of the users by means of their voice patterns or collects emotional data from text messages (Fox & Duggan, 2012; Sciences, 2013). This enables people to get an insight into their moods over a certain period of time.

However, these apps are not limited to recording and collecting data about people's emotional states. They contain a variety of strategies to assist individuals with therapy. These tools not only improve the accessibility of mental health care services beyond the clinic, but also enhance the efficiency of traditional care by providing coaching or self-help services (e.g., behaviour change management). FOCUS, for example, is a smartphone app that was developed to assist people with schizophrenia by helping them to self-manage their condition; interestingly, FOCUS has a high rate of acceptability and efficacy (Ben-Zeev et al., 2014). Other apps are based on psychological treatment methods such as Cognitive Behavioural Therapy (CBT) (e.g., eCBT, Calm[9]) or Dialectical Behaviour Therapy (DBT) (e.g., DBT Diary Card, Skills Coach[10]). These apps are designed to help people with anxiety, stress, depression and bipolar disorders.

Some mental health mobile apps attempt to conduct part of the therapeutic process. They collect statistics for the psychometric and diagnostic analyses of individuals, and have been designed for educational purposes (East & Havard, 2015). They aim to assess the wellbeing of clients and suggest possible therapeutic interventions. These technologies also enable clients to share relevant data with counsellors so that the health care professional can monitor the client's progress. NeuroAssess[11], launched in July 2013, is an example of this type of app. NeuroAssess captures information about a client's psychopathology and, using an automatic algorithm, measures the suicidal ideation of the client.

Psychology-centred applications are very useful portable programs, but they have limitations. They are similar to stand-alone platforms in that they are basically designed for one-way interaction, although there are some exceptions (see Luxton, McCann, Bush, Mishkind, and Reger (2011, p. 506). More importantly, their adequacy as therapeutic tools for serious psychological disorders is questionable. These apps generally assess, monitor, and track the intensity levels of factors (e.g., heart rate) associated with a small number of disorders (e.g., stress, anxiety, and sleep disorders) – 'Depressioncheck', for example, is an iPhone-based app of this range.

It is evident, therefore, that these tools do not provide clients with care as complex and complete as that received in face-to-face sessions. This has been noted by de Alva, Wadley, and Lederman (2015) who report dissatisfaction with applications when compared with face-to-face interventions. The participants in this study revealed that app-oriented health-tasks such as working and studying provided less support for them to deal with their life situations and reduce anxiety. It was also reported that the apps did not assist users in understanding, dealing with, or managing the real life activities of a person with mental problems.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another limitation is associated with the recording of online and offline information relating to clients'/users' behaviours. Although the recorded/stored data enables mental health practitioners to track a user's mood and mental state, the recorded information may not be reliable due to the calibration of the sensors or devices. Similarly, problems might arise if the apps interpret this data in place of a clinician. They might generate a generic interpretation without considering the subtleties that a clinician might deem important.

Additionally, and much like stand-alone platforms, there is the problem of protecting personal data (Luxton et al., 2011). The apps might not have been created by ethical and creditable organisations and it is possible that many non-accredited or open source apps may not have the client's best interests at heart. Not all apps are developed by authorized centres, such as 'PTSD Coach' developed by the USA's Department of Veterans' Affairs which is dependable in terms of privacy, safety, and accuracy of functioning.

Automated Self-Help Services

Other programs at the intersection of technology and mental health care are the fully automated self-help systems. Historically, debates concerning the automatized therapy date back to the 1960s with the development of 'ELIZA' (see Weizenbaum (1966)), and 'PlatoDoc' and 'MORTAN' which went live as automated therapy programs in the 1980s, or 'Dear Uncle Ezra' created in 1986 as the first web-based help service advising students at Cornell University. Based on the principles of cognitive therapy, these systems were designed to help people make decisions regarding their mental health; they were specifically designed to help clients' moderate the symptoms of depression (Granello, 2000; Selmi, Klein, Greist, Johnson, & Harris, 1982; Wagman & Kerber, 1984). It was expected at this time that artificial intelligence (AI) would replace human-to-human therapeutic interaction with a human-independent computerized environment. However, the developed programs were not successful.

With respect to technical and treatment history, debate regarding the possibility of automated psychotherapy can be generally placed at one (or the other) end of a spectrum. On one end is the full automatization of therapy. This is justified with the progress in technology and high level artificial intelligence becoming more like face-to-face therapy (Block, 2009; Newell & Simon, 1963; Turing, 1950). With this scenario, the computer becomes the psychotherapist with full treatment strategies. That said, automated therapists will require extensive databases of therapeutic and clinical knowledge, natural language processing, affective computing ability to calculate mental states via machine learning algorithms (Luxton, 2015). With current data-driven methods that are capable of mimicking, understanding and assisting animated and artificial information processing, proponents of this strong position cite successes in areas such as automated agents and avatars in virtual environments where it is claimed that disorders such as PTSD have been successfully treated (Reger, Rizzo, & Gahm, 2015).

At the other end of the spectrum is the idea that the best we can hope for are technologies that enhance communication between individuals. This weak view argues against fully automated therapy because of moral and ethical issues and technical and physical limitations such as memory capacity, low-level sensorimotor skills, and limited ability in affective and language processing (Dreyfus & Dreyfus, 2000; Dreyfus, 1992; Searle, 1992). Proponents of this view believe that automated therapists have failed in the past and will continue to fail because they cannot match a human therapist's capabilities, and have not passed the Turing test [12] (Luxton, 2015; Saygin, Cicekli, & Akman, 2003). It was also the view of the designer of ELIZA that important decisions cannot and should not be expected by computerized systems because these technologies equipped with AI techniques lack the human's cognitive qualities

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

such as empathy and perception (Weizenbaum, 1966). In other words, because theory of mind is an essential component of humans' interactions with one another, automated psychotherapy is unlikely to succeed until artificial agents become self-aware (Vardi, 2014). If this proves to be the case, should intelligent telecommunication applications and the intelligent technologies be put aside or can they be consolidated into new premises?

VIRTUAL REALITY

The 2D space of video-based technologies is fundamentally different from the usual, three-dimensional experience of in-person therapy (Manstead et al., 2011). Some of the drawbacks of 2D spaces are that the movements of therapy pairs (consultant and consultee) are limited relative to one another. Thus, Second Life technologies and other online virtual realities (VR)[13] have been introduced as ways of overcoming the negative influences of limited movement in 2D space.

There are different motivations that drive the widespread adoption of VR in psychotherapy. One has been the need for the collection of better information at the point of mental health servicing. To enable this, counsellors can provide stimuli to clients in virtual environments (VEs) that are similar to those in the real world (Clough & Casey, 2011). Threatening situations can be introduced safely on role-plays in VR using simulated avatars, easing the therapeutic process (Carey, 2010). That is, dangerous situations can be avoided as during the treatment of some phobias, allowing the fear to be attenuated (Riva, 2005). Virtual environments also simulate the triggers of social anxiety and provide opportunities to practise social interactions safely (Gaggioli, Gorini, & Riva, 2007) and, be observed unobtrusively by the clinician (Nagel & Anthony, 2011). The client and clinician can both use avatars to express mental problems verbally and mimic behavioural cues, while allowing the client to remain anonymous and reducing the stigma associated with psychological concerns (Quackenbush & Krasner, 2012). Virtual Reality also offers a rich medium for training and helping counsellors (Székely & Satava, 1999). Cybertherapists can practise and improve their skills by way of virtualized scenarios, clients, and clinical settings (Bennett-Levy & Perry, 2009; Kenny, Parsons, Gratch, Leuski, & Rizzo, 2007; Parsons, Buckwalter, Lange, & Kenny, 2014; Rizzo, D.Parsons, Kenny, & Buckwalter, 2012).

In light of these advantages, it is no surprise that VR is becoming increasing prevalent in therapy and is being employed by some psychotherapists (Gaggioli & Riva, 2007; Good, Gnanayutham, Sambhanthan, & Panjganj, 2013; Gregg & Tarrier, 2007; Riva, 2003; Riva, Wiederhold, & Molinari, 1998; Russ, 2012; Välimäki et al., 2012). For example, video games are being trialled as therapeutic tools in the treatment of autistic children (Fernández-Aranda et al., 2012). 'PlayMancer' is an example of a collaborative VE developed for the treatment of specific mental health issues (e.g., eating disorders) and pain rehabilitation[14] (Jiménez-Murcia et al., 2009). The authors of the game have found that patients with Impulse Control Disorder (ICD) felt comfortable using such a video game; participants' physiological and emotional reactions were attenuated by means of the reduction in their stress level. PlayMancer had also helped people with eating disorders and pain rehabilitation (Jiménez-Murcia et al., 2009). The game Pico's Adventures is another Kinect-based game which was employed to promote social initiation in children with Autism Spectrum Disorder (ASD; Malinverni et al., 2016). The early findings from field observations and video analysis have shown that children with ASD accepted the game positively and developed their social behaviours.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

'Pesky Nates!!!' is a similar program that uses gaming technology. It is based on CBT and is aimed at helping children with anxiety and depression[15]. Other developments including 'SimCoach', 'Virtual Justina', 'Bravemind', and 'STRIVE' are virtual reality platforms that create life-like characters and realistic environments to provide therapeutic help. 'SimCoach', for instance, has been developed to assist military personnel and their families to alleviate mental health issues, trauma, and addiction issues (Rizzo, Forbell, et al., 2012). This prototype also assists with other issues such as the welfare of, and the economic stress on, military families. 'Virtual Justina' is another prototype designed for patients with Post Traumatic Stress Disorder (PTSD) (Kenny, Parsons, Gratch, & Rizzo, 2008). Here, real dialogue (between a patient and a clinician) is conducted between avatars (Rizzo, D.Parsons, et al., 2012). 'Virtual Justina' is also being used as a virtual medium to train psychotherapists. The trainee can either communicate with real clients via virtual mediums or apply therapeutic principles to virtual patients (Kenny, Parsons, Pataki, et al., 2008; Kenny et al., 2007).

Although virtual environments hold substantial promise, there are some challenges facing psychotherapy using VR. Complex input and output devices and the graphics and animations of VEs need to be more sophisticated to more closely simulate real clinical spaces. Also, virtual worlds need to be realistic for treating disorders such phobias (Kenny et al., 2007). These design challenges continue in spite of considerable advances in simulation. For example, avatars used in VR clinics or hospitals need to simulate more than the human body. Avatars need to be equipped with human-like facial expressions and behavioural mannerisms which are taken for granted in face-to-face therapy sessions. Parenthetically, there is also the issue of the 'uncanny valley' whereby virtual people too closely mimic 'real' people causing disquiet or revulsion among users (see, for example, Mori, MacDorman, & Kageki, 2012; Morie, 2008; Nowak, 2015). Currently, some pilot studies have employed virtual reality equipment in treating mental disorders such as Complex Regional Pain Syndrome (CRPS) (Won et al., 2015) and social phobia (Gebara, Barros-Neto, Gertsenchtein, & Lotufo-Neto, 2016). From a clinical viewpoint, although the technologies have had positive impacts on the participants' psychological states, the virtual experience of objects, movements such as body language of others and the perception of clients' presence is not still satisfiable. It is expected that the development of virtual reality headsets and glasses such as Oculus Rift[16] may help to solve these issues (see Chang, Liu, Kang, Kao, & Chang, 2016). It is also expected that holographic telepresence be employed in psychotherapy as it can provide a live full-motion of remote users by three-dimensional (3D) videoconferencing (Hu, Baldwin, Niederberger, & Fattal, 2015). The technology will enable counselling pairs to communicate as natural as face-to-face by reconstructing, compressing and transmitting their models anywhere in the world in real time.

ASSISTANT PSYCHOTHERAPISTS

Although "immersive virtual environment(s) offer new possibilities for therapy, for example by providing realistic but not actual exposure" (Tantam, 2006, p. 419), fully automated psychotherapy is not currently possible. A significant part of this difficulty is replication of the relationship that clients form with their therapists (Duggan, 2016). Consequently, several researchers have suggested that automated psychotherapeutic systems might be better suited to acting as 'illusory therapist[s]' (Helgadóttir, Menzies, Onslow, Packman, & O'Brian, 2009a, p. 251), 'Virtual Consumer Consultant[s]' (Griffiths, 2013) or assistant therapists who enhance interactions between counselling pairs. That is, the assistant therapist acts as a coach (rather a therapist) and is equipped with self-management programs to help organise, process and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

progress treatment. It is proposed that assistant therapists might increase a cybertherapist's understanding of a client's mental health issues, reduce recovery time, and improve the quality of treatment (Bauer & Moessner, 2012; Howell & Muller, 2000). Assistant therapist programs can also be equipped with the technology to gather bio-sensory, behavioural, speech and/or neural data from clients to assist with correct diagnosis and therapeutic intervention (Griffiths, 2013).

There have been several assistant therapists developed that have achieved some level of success in regulating moods and attenuating depression (Both & Hoogendoorn, 2011; Both, Hoogendoorn, Klein, & Treur, 2010; Helgadóttir, Menzies, Onslow, Packman, & O'Brian, 2009b). However, and consistent with other cybertherapy tools, there are some concerns associated with assistant therapist technologies. Firstly, these technologies must be user-friendly and secure with any data kept confidential (Green & Iverson, 2009). Secondly, evidence of the validity and efficacy of the data collected is currently lacking. Further, assistant therapist technologies cannot provide corrective feedback to clients' responses (Helgadóttir et al., 2009a) and, as such, this may contribute to program dropout. To overcome this limitation, Helgadóttir et al. (2009a) suggest that client engagement should be increased in some way. They suggest providing a reminder service (e.g., reminder emails) to users, or designing task-relevant deadlines. Interestingly, the latter approach received positive feedback from clients in a study by Klein and Richards (2001). They specified time-limited access for clients in their online treatment program, and only one person in their trial dropped out.

While there is positive evidence for automated therapy (see, for example, Helgadóttir, Menzies, Onslow, Packman, & O'Brian, 2014), none of the current online 'assistant therapist' platforms adequately address all of the criteria necessary for successful online psychotherapy. Similar to stand-alone and automated therapists, it seems that the therapeutic alliance generated via online assistant therapists still lacks the productive personal connection between the clinician and client. Specifically, the emotional engagement present in face-to-face therapy is impaired via computerized systems (Reynolds, Stiles, Bailer, & Hughes, 2013; Reynolds JR, Stiles, & Grohol, 2006). Furthermore, diagnosing disorders becomes difficult because of the lack of non-verbal and/or behavioural cues (Li, Jaladin, & Abdullah, 2013). Moreover, Bambling (2008) claims that the lack of non-verbal cues reduces the emotional proximity and cognitive interaction between the clinician and client in online platforms and, consequently, client issues were often assessed inaccurately. Currently, with this technology, it is uncertain whether it is the client who has difficulty expressing their concerns or the psychotherapist who has difficulty identifying these concerns. It also remains unclear what impact technologies have on the clinician's ability to empathise and on the eventual diagnosis. These questions point to the necessity for detailed investigations in this area.

CONCLUSION

Psychotherapy has used telecommunications technologies to deliver remote therapy for many years. In this review article, several forms of telecommunications technologies have been outlined. Initially, a short history of the telephone used in psychotherapy was provided. Then, it was demonstrated that later advancements including the Internet, text-messaging services, and videoconferencing systems created new possibilities for remote therapy. While a large number of services via these technologies have demonstrated positive outcomes, the therapeutic experience itself remains of concern. The therapeutic relationship during technology-based sessions might be influenced due to compromised clinical, technical and ethical factors.

The article also described the expanding area of computerized systems employed in psychotherapy. It was revealed that some of the mental health issues (e.g., phobias, bulimia) had been treated effectively by using virtual therapy programs. However, although several stand-alone platforms and computerized therapists appear promising, it has been argued that the most promising use of online and virtual therapy programs is data gathering to compliment treatments of a 'real' psychotherapist. The suggestion is not that computerized systems are less effective, but that they should not be dismissed by providers and designers of online healthcare programs. The validating and evaluating of human-like relationships, and particularly those between counsellors and clients, is needed to ensure best-practice in simulated environments.

The future of the profession, particularly with reference to technological advancements which have shown substantial growth concerned with the video streaming quality, will be affected by the use of videoconferencing systems. It was discussed that these systems are most promising as they can allow the therapist and client to feel as if they were present in the clinic. Virtual reality can also be used as an alternative to a great extent by enhanced graphics and design of environments and devices. There is also an exciting voyage to the cutting edge of upcoming technologies such as mobile holographical telepresence that can offer clinicians, psychotherapists, and their clients a bit of different language. These people can experience psychotherapy session, as natural as face-to-face communication. However, other than the applicability and ethical frameworks, the main question that remains to be addressed is how this possibility will be provided to the community on a large scale and affordable.

Chapter 35
Hybrid Exoskeletons for Upper Limb Stroke Rehabilitation

ABSTRACT

Hybrid exoskeletons are a recent development, combining electrically controlled actuation with functional electrical stimulation, which potentially offers great benefits for muscular rehabilitation. This chapter presents a review on the state of the art of upper-limb hybrid exoskeletons with a particular focus on stroke rehabilitation. The current needs of the stroke rehabilitation field are discussed and the ability of hybrid exoskeletons to provide a solution to some of the gaps in this field is explored. Due to the early stage of development which most hybrid exoskeletons are in, little research has yet been done in control methods used for them. In particular, more investigation is needed with regards to the potential benefit of hybrid exoskeletons as a patient-monitoring and rehabilitation assist-as-need tool.

INTRODUCTION

Stroke is the second largest cause of disability worldwide after dementia (World Heart Federation, 2015). Each year the costs of stroke on society are considerable, both financially and with regards to the wellbeing of the affected individual, their families, and their friends. Approximately 1 in 6 people will suffer a stroke during their lives and these numbers are only likely to increase as the number of elderly

increase (World Stroke Campaign, 2015). Effective rehabilitation after a stroke is important if the costs of stroke on society are to be minimised.

A stroke can cause many impairments which interfere with a person's ability to perform tasks with their affected limbs. These will be described in the next few paragraphs. Temporary hemiparesis is common among stroke survivors. Regaining strength and movement in the affected side takes time and can be improved with the use of rehabilitation therapy involving repetitive and function-specific tasks (Senelick, 2010). Patients who undergo stroke rehabilitation generally have a few sessions a week with a physiotherapist where they undertake various exercises. Many patients, particularly the external patients, will also be assigned exercises to complete outside of their regular sessions with the physiotherapist.

The abilities of stroke patients can vary quite considerably. While it is more common for a patient to regain strength in their shoulder before the elbow and fingers respectively there are also many exceptions. The rate at which patients improve and the joints with which they struggle with can vary significantly from patient to patient. Muscle atrophy is one of the most common issues that occurs after a stroke. Muscle atrophy is the wasting away of the muscles which leads to a loss in the size and strength of the muscle. For each day a patient is in hospital lying in bed with minimal activity approximately 13% of muscular strength is lost (Ellis, Jackson, Liu, Molloy, & Paterson, 2013). Regaining muscle strength and motor control are very important if a patient is to regain independence in their day to day life. Muscle atrophy can only be prevented by physically working the muscles either through the patient's own volition or the use of Functional Electrical Stimulation (FES).

Problems that patients have after a stroke are not just limited to lack of strength in the affected limbs. Some patients can be very capable of movement but lack sensation. This makes it difficult for a patient to know how much force to apply when manipulating objects such as holding a glass of water. It can also make it difficult for a patient to perform movements with their limb without observing where the limb is. This increases the mental energy required to undertake everyday tasks and can even pose a danger to the patient's limb as they are not always aware of where it is. Other problems include muscle spasticity. Pharmacological and non-pharmacological treatments can combat spasticity.

A lack of control or strength in one joint may affect the ability of a patient to perform movements with another joint. For example, lack of control or strength at the wrist may make performing exercises with the hand difficult as the forearm may not be in the ideal positioned to allow a strong grip. Some patients may adopt compensatory patterns of movement due to their impairments. Over a longer period, these compensatory patterns can lead to long term issues such as pain. Some patients experience involuntary movements where the limb will move unpredictably without the patient intending it to. This can cause damage to the limb and may be embarrassing for some people. In addition, patients can often also suffer from reduced mental cognition and increased mental fatigue.

There are many different types of training strategies and devices which can be employed as tools to help combat the problems which stroke patients face. Despite all the interventions available however, there remain several gaps in the field of stroke rehabilitation. The current tools and rehabilitation methods used, as well as the gaps in the stroke rehabilitation field, will be described in the background section of this chapter. Following on from this the potential of hybrid exoskeletons to help fill some of these gaps will be discussed, an evaluation of the state of research with regards to upper limb hybrid exoskeletons will be undertaken, and future directions suggested.

BACKGROUND

Modern Stroke Technologies and Rehabilitation Methods

Devices used to aid stroke patients may be divided into passive devices and active devices. Passive devices, sometimes involving lockable and unlockable brakes or springs, can be used to limit a patient's movement either by locking a joint in place or by preventing a joint from moving too far in a direction. This can prevent a patient from hyper-extending or hyper-flexing or alternatively may be used to allow a patient to focus on a specific movement in isolation. Sometimes simple strapping tape may be used to remind a patient not to hyper-extend or hyper-flex. Passive devices can also be used to manage tremor or provide an elastic force for resistive training (Rocon et al., 2007).Active devices are devices which can move a patient's limbs on their own without help from the patient. Active devices are used to assist patients with movements that they may not be able to perform themselves or to provide resistive forces. Active devices may involve the use of functional electrical stimulation (FES), or an actuator, such as an electric motor, or pneumatic artificial muscle. Active devices are often heavier than passive devices due to the weight of the actuators however, they tend to be more useful for patients in the early stages of rehabilitation who have limited movement.

The training which a stroke patient will undergo can be either resistive or assistive. Resistive training involves the use of passive or active devices to provide a force against the movement of the patient. Coloured elastic bands are a common way of performing resistive training where one end will be tied to a static point and the patient will perform movements that stretch the rubber band requiring the patient to work harder to perform the movement. Alternatively resistive devices such as robots or exoskeletons may provide either a passive elastic force or an active (motorised/pneumatic/hydraulic) force in the opposite direction to which the patient wants to move (Carpi, Mannini, & De-Rossi, 2008). Resistive training is a good way for a patient with some movement already to build more muscular strength.

Assistive training involves the use of primarily active devices to provide an aiding force in the same direction as the movement of the patient. Assistive training can also include passive gravity balancing devices which reduce opposing forces for movement of limbs away from Earth (Gijbels et al., 2011). Assistive devices may be purely for rehabilitative training, for help with activities of daily living (ADL) and specific tasks, or a combination of the two. Assistive training may involve a physiotherapist providing the assistive forces, the use of functional electrical stimulation (FES), or an actuated robotic device.

Robotic devices have the potential to offer significant benefit to stroke rehabilitation when used in conjunction with physicians (Loureiro, Harwin, Nagai, & Johnson, 2011). They are capable of providing a higher frequency of training and allow for a safer way for a patient to practice movement without having to be directly supervised by a health professional (Loureiro et al., 2011; Maciejasz, Eschweiler, Gerlach-Hahn, Jansen-Troy, & Leonhardt, 2014). Robotic devices may include end-effector devices or exoskeletons. End-effector devices are located distally to the patient's limb. They are often simpler in design however as the movement of end effector devices increases in variety and range, the control becomes much more complex if injuries and redundant configurations are to be avoided. The general design of end-effector devices lends itself to be much less susceptible to portability than that of exoskeleton devices. Therefore, end-effectors are predominately used for rehabilitation purposes as opposed to assistance with ADL (Vaca Benitez et al., 2013). Exoskeletons are fitted more closely to the patient's body and closely mimic natural human movement. They are more complicated in structure but allow for independent control of different joints and much more precise control over a patient's limb (Maciejasz

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2014). However, many exoskeleton devices are also often limited in portability due to energy requirements and actuator weight.

The use of electromyography (EMG) to control and/or initiate movement can be used in conjunction with either active robotic devices or Functional electrical stimulation (FES). For a healthy person, and for many stroke patients, an attempt to move their limb will result in the production of muscle action potentials (MUAPs) at the site of the related muscle. These action potentials, measured in volts, and often in the range of 0-10mV peak, can be read using electrodes and signal processing and offer an indication of the subject's intended movement (De Luca, 2002). Despite the presence of the signals, the patient often lacks the strength to perform the movement. The EMG signals appear shortly before movement actually takes place thus it is possible to use EMG to initiate and control a device which can help the individual perform their intended movement in real-time (Chandrapal, 2012). This can allow for a larger variety of different movements to be produced by assistive devices rather than pre-programming in only specific movements and leaves the user free to use both their hands as they do not need to press a button or move a joystick to operate the device. Stroke rehabilitation training with EMG initiated and controlled devices also offer advantages in terms of patient improvement as when the patient observes the intended movement occurring it mentally reinforces and establishes the correct neural pathways required for self-production of the movement (Hara, 2013; Vaca Benitez et al., 2013). For patients who lack the production of action potentials at the muscle site electroencephalography (EEG) can be used instead, although this typically means a longer set up time.

Functional electrical stimulation (FES) is the application of high frequency electrical pulses to the nerves in order to elicit contractions in the muscle. There are many commercially available FES devices which are used for stroke rehabilitation. FES may be used to provide assistive training where the FES is initiated in response to a patient pushing a button or by some other intention estimation method (e.g EMG) with the goal being to practice performing a specific movement. Alternatively, it may be used at a lower dose with the main aim being not to produce significant movement of the limb but rather to strengthen the muscle through small cyclically induced muscle contractions. For stroke patients cyclically induced FES is often used to prevent subluxation of the shoulder muscle (Chae, Sheffler, & Knutson, 2008). FES devices also often have preprogramed sessions available which can be initiated with the single press of a button and which allow the patient to take the device home to use without worrying that they might alter the settings accidently. FES can help reduce muscle atrophy and increase muscle strength but it is less useful for aid with ADL on its own, as FES is difficult to control precisely, and quickly results in muscle fatigue (Doucet, Lam, & Griffin, 2012; Maciejasz et al., 2014). More recently FES has been combined with passive orthoses and robotic devices (Bioness Inc, 2015; Loureiro et al., 2011).

Requirements and Current State of Stroke Rehabilitation Robotics

Despite the expected increase in demand for at-home rehabilitation systems and ADL supporting devices many currently available rehabilitation robotic devices are lacking in portability, complex to use, and extremely expensive. Therefore, they are only suitable to use in clinics under the direct supervision of physicians (Lu et al., 2011; Maciejasz et al., 2014). If a patient's access to at home rehabilitation devices increases then this should also lead to an increase in the frequency of their training (Lu et al., 2011). It has been shown repeatedly that an increased dosage of training is highly positively correlated with patient improvement. Thus a higher uptake of at-home rehabilitation devices should result in increases in patient improvement (Vaca Benitez et al., 2013). To encourage a higher uptake of at-home rehabilitation

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

devices there needs to be a focus on designing rehabilitation devices, especially exoskeletons, which are cheap, portable, and easy to use.

A study (Biddiss & Chau, 2008) which surveyed a range of prosthetic hand users indicated that the most important requirement as defined by the users was a reduction in the weight of the device. A low-cost prosthetic was ranked as the third most important feature. Both cost and weight were considered more important than precise movement of the device. While this study was of prosthetic hand users and not exoskeleton users it is quite likely that a similar trend will occur for exoskeleton users. Patients are not likely to be tolerant of rehabilitation devices which must be constantly removed and re-attached, especially if the devices are time-consuming to attach or noticeable (heavy or bulky) when worn. It is therefore important that an exoskeleton designed for rehabilitation purposes must be lightweight as well as quick and easy to attach. A well-working exoskeleton is useless if patients will not use it.

Assessment tools currently used by physicians to monitor patient progress tend to be time-consuming, subjective, and lacking in sensitivity (Loureiro et al., 2011). Some of the more commonly used scales are only moderately reliable when patient improvements are small (Patton, Small, & Zev Rymer, 2008). Robotic devices offer new, more sensitive, and consistent options for monitoring of patient improvement but they need to be able to provide measures that can be easily understood by physicians and related to current methods. There is little consensus how to best evaluate the effect of robotic systems on patient progress and a wide variety of measures have been used throughout current research (Del-Ama et al., 2012; Lu et al., 2011; Maciejasz et al., 2014; Sivan, O'Connor, Makower, Levesley, & Bhakta, 2011). There is also a lack of wide-scale assessments of robotic devices. This can likely be contributed to the high cost to produce the devices (Loureiro et al., 2011). Some attempt has been made to assess and compare the pros and cons of current rehabilitation measures and create a standard for assessing the effect of robotic devices on patient improvement (Sivan et al., 2011). One of the more widely used scales in literature related to rehabilitation robots is the Fugl-Meyer scale (Sivan et al., 2011).

It is highly desirable in stroke rehabilitation robotics that a robot or exoskeleton be capable of performing assistance-as-needed. This way the patient is encouraged to make the effort to achieve movement rather than learning to rely on the robot to perform the movement (Jarrassé et al., 2014; Lu et al., 2011; Maciejasz et al., 2014). Appropriately timed action is more important than strength for functional gains, however repetitive practice which builds strength without specific functional application can still help to diminish impairment (Patton et al., 2008). The ability of rehabilitation robots to adapt to different users and even to the same user on different days or throughout the same session is also highly important with regards to minimising set-up time and cost of rehabilitation (Maciejasz et al., 2014). Compliance of assistive robots is another important factor to consider as the robot should aid and encourage but not limit the movement of the patient (Loureiro et al., 2011; Maciejasz et al., 2014). This is important for safety as well. The exception to this is robots which are deliberately used to temporarily constrain certain joints or for resistive training. However, consideration of the robot's interaction with the user in a safe manner is still the most important feature. Above all else the robot should pose no harm to the user or nearby individuals.

REVIEW OF UPPER LIMB HYBRID EXOSKELETONS

The Potential Benefits

In future, we may find that a hybrid of FES and robotics may be the most efficient for providing continuous locomotion or performance of vital activities of daily living in individuals with paralysis. (Doucet et al., 2012)

Electrically controllable actuated exoskeletons offer huge advantages in their ability to repetitively and precisely provide assistance or resistance to a user. However electrically controlled actuators which provide the required forces are often heavy in weight and have high power requirements which limits portability. In addition, external movement of a patient's limb without effort from the patient does nothing to combat muscle atrophy. Thus exoskeleton devices are more useful to patients who already have some ability to move their limb (Hara, 2013).

Functional Electrical Stimulation (FES) allows for a much lighter device which is also better suited to reducing muscle atrophy in patients with no, or extremely limited, movement. However, precise control of FES is extremely difficult and producing the specific, repetitive, and functional movement desired for effective stroke rehabilitation is not easily accomplished. Furthermore extended use of FES is limited by the introduction of muscle fatigue caused by the unnatural motor unit recruitment order (Doucet et al., 2012). The forces required for large movements, such as shoulder abduction, are often too great to be provided by the use of FES which is much better suited to smaller movements such as finger extension (Pylatiuk et al., 2009; Schill et al., 2011). Some patients also find the use of FES painful.

Combining the use of FES and an electrically controlled actuator within an exoskeleton can potentially result in a device which is overall lighter (and thus more portable) than a non-hybrid exoskeleton and which can produce greater forces and more precise control than FES on its' own. Using FES to provide some of the required forces allows the use of smaller actuators and a reduction in the energy requirements of the device. Likewise, as some of the forces are provided by the actuator the FES does not need to be as intense to produce the same movement thus reducing the amount of pain at the electrode sites and delaying muscle fatigue.

The combination of devices potentially offers a greater ability to precisely monitor patient progress. FES in combination with electromyography (EMG) can provide information on the muscle fatigue of the patient which, when combined with the consistency in movement provided by the electrically controlled actuators, could be useful for tracking patient progress across several sessions. With these features, hybrid exoskeletons have potentially great benefits for upper-limb stroke rehabilitation. However, there is little literature reporting the use of such devices. This chapter reviews the state of the field and proposes that there is a need for a portable, hybrid, assist-as-need exoskeleton for upper-limb stroke rehabilitation.

A review has previously been conducted on hybrid exoskeletons for lower limb rehabilitation of spinal injury patients (Del-Ama et al., 2012) and readers may refer to this if they wish to learn more about lower limb hybrid exoskeletons. It should be noted that in stroke rehabilitation "often, more severe impairments are found in the upper limb" (Lu et al., 2011) yet rehabilitation research focus is largely placed on recovery of function in the lower limb. All further discussion within this chapter will be with regards to the upper-limb and focus will mainly be from a stroke rehabilitation perspective.

A recent review was conducted on hybrid robotic systems for upper limb stroke rehabilitation (Resquín et al., 2016) however it predominately covered passive devices and actively actuated end-effector devices.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

No actively actuated hybrid exoskeletons were reviewed. The main focus of this chapter will be on upper-limb hybrid exoskeletons which use an electrically controlled actuator in combination with functional electrical stimulation to provide active assistance or resistance to the user. The FES and actuator do not necessarily need to be operating on the same joint and the goal of the hybrid exoskeleton may be purely rehabilitative or it may be designed to aid with ADL during rehabilitation.

A search was conducted in the IEEE, PubMed, ScienceDirect, and Google Scholar databases for relevant papers added prior to October 2016. A total of 12 different exoskeletons were found which combine an electrically controlled actuator with FES to provide active assistance or resistance to the user. Table 1 on page 7 presents a summary of these 12 reviewed upper limb hybrid exoskeletons.

The results are discussed in five subsections based on the key features of exoskeletons in stroke rehabilitation. The subsections are as follows: Firstly, the suitability of hybrid exoskeletons to aid movement in the different joints is discussed. The second subsection discusses ability of hybrid exoskeletons to provide a portable aid and the impact of actuator selection. The third subsection addresses hybrid exoskeletons as a patient monitoring tool. The fourth subsection discusses the various control schemes used as well as intention estimation methods. The final subsection presents an evaluation of the usability of the current upper-limb hybrid exoskeletons and the clinical evidence regarding the benefits and costs of hybrid exoskeletons. Future directions are then discussed and several concluding remarks summarizing the chapter are made.

Supported Movements

Presently when FES is used on the upper-limb for stroke rehabilitation it is either used to prevent subluxation of the shoulder or to aid with grasping movements in the hand. Rarely, if ever, is FES used to actuate the shoulder or elbow joints. There are several reasons for this. FES induced fatigue is considerably less pronounced for movement of smaller limbs, such as the fingers. In addition, for some patients FES is only capable of producing limited forces and so is much less suited to larger movements. There is also greater difficulty in controlling FES-induced movements when they are very large. It is much easier for a patient to practice only opening and closing of the hand than it is for a patient to practice only shoulder or elbow movement. Any movement of the shoulder and elbow will also result in movement of the hand. When FES is used to help actuate shoulder or elbow movements a physiotherapist or other helper is generally required to hold the lower part of the patients' arm to keep it from flopping about uncontrollably.

The joints which electrically controllable actuated exoskeletons are used for in stroke rehabilitation depend greatly on where the weight distribution of the exoskeleton is predominately located. Exoskeletons and end-effectors which place weight through some medium other than the patient themselves (e.g. the floor, a table, a chair, a lower limb exoskeleton) also often tend to be used more for fingers and wrist movement. As mentioned previously, functional gains are predominately related to regaining movement in these joints and most patients tend to regain movement in the shoulder and elbow first so it is no surprise that the fingers and wrist joints receive so much attention. However, the movement of the arm as a whole should not be ignored. Many functional tasks require control of all of the joints in the upper-limb. The ability to reach out, grasp a cup, bring it to the mouth, take a drink, and return it to the table, is an example of a key functional movement that utilises all of the main joints in the arm. Evidence strongly indicates that rehabilitation which practices movement of the arm as a whole produces better clinical outcomes than rehabilitation which focuses only on one or two joints (Resquín et al., 2016).

Table 1. Reviewed upper limb hybrid exoskeletons

System	Supported Movements	Portable	Stage of Development	FES	Actuator	Main Control Input	Control Methods	Feedback	Advantages	Possible Improvements
Orthojacket (Schill et al., 2011)	Shoulder, elbow (actuator only). Wrist and fingers (FES only).	Fixed to wheelchair. Elbow and wrist sections of the device can be made portable.	Investigative study on 3 healthy subjects (elbow only). Investigative study on 1 SCI subject (elbow only).	Motionstim 8 (wrist, fingers)	Stepper Motors (Shoulder). Fluidic actuators (elbow).	sEMG and/or joystick	sEMG proportional control.	Speed, position	Modularity.FES electrode array. Can be worn under clothing.	Full device has not yet been tested. Only testing of the modules have been done.No fatigue monitoring.
Haptic Robotic Glove (Hartopanu, Poboroniuc, Serea, Irimia, & Livint, 2015)	Fingers, thumb	No	Prototype	Motionstim 8	Firgelli linear actuators	Key/button press	Button proportional control.	Position	Allows independent control of fingers.	No fatigue monitoring. Response time is slow.
FES/Robot Hand (Wei Rong, Tong, Hu, & Ho, 2013)	Fingers	No	Pilot clinical study on 4 stroke subjects over 20 sessions.	2 channel stimulator	Firgelli linear actuators	sEMG	Model based. Open loop.	Position – for display only.	Shown to improve movement accuracy as well as voluntary effort and subject focus.	Some patients had trouble with the weight of the device.No fatigue monitoring.
Wearable Rehabilitation Robot (Tu, Huang, Yu, Xu, & He, 2012)	Shoulder, fingers	No	Prototype	Beurer EM41	Pneumatic muscles	Key/button press	PID control of a predefined trajectory.	Position	Demonstrates that hybrid exoskeletons can reduce the weight of the device with no performance loss.	Predefined trajectory. No fatigue monitoring.
EXOSLIM (Serea, Poboroniuc, Hartopanu, & Irimia, 2015)	Shoulder, elbow	No	Prototype	Motionstim 8	DC motors	Key/button press	Model based. Button proportional control.	Position, acceleration		No fatigue monitoring.
BCI-Controlled Exoskeleton (Elnady et al., 2015)	Elbow, wrist (actuator only). Fingers (FES only).	Yes	Investigative study on 9 stroke subjects over 2 sessions 7 days apart.	RehaStim 1 (fingers)	BLDC motor (elbow). Brushed DC motor (wrist).	EEG (Emotiv EPOC neuroheadset)	State machine with proportional control of predefined trajectories.	Position	Easy to put on (<30 s with help).	Predefined trajectory. No fatigue monitoring.

Table 1. Continued

System	Supported Movements	Portable	Stage of Development	FES	Actuator	Main Control Input	Control Methods	Feedback	Advantages	Possible Improvements
MUNDUS (Ambrosini et al., 2009; CROSTA, 2012; Pedrocchi et al., 2013)	Shoulder, elbow (FES only). Fingers (actuator only or FES only, not both)	No. Fixed to wheelchair. Restricted to table.	Investigative study on 1 SCI subject for the hybrid part. Test was unsuccessful.	RehaStim 1 (shoulder, elbow)	DC motors (fingers)	EEG (other control options available as well, e.g. sEMG or head/ eye movement).	Intergral control, or Biomimetic feedforward control, or Adaptive feedforward control.	Position, force, object location	RFID tags for object recognization. FES electrode array. Modularity.	Trial was unsuccessful for the hybrid part.Takes 35-40 minutes to set up and calibrate.
BCI-Controlled Wearable Robot (Looned, Webb, Xiao, & Menon, 2014)	Elbow, wrist (actuator only). Fingers (FES only).	Yes	Investigative study on 5 healthy subjects.	EMPI300 (fingers)	BLDC motor (elbow, wrist)	EEG	State machine with proportional control of predefined trajectories.	Position, acceleration	Easy to put on (<30 s with help).	Predefined trajectory. Not backdrivable. No fatigue monitoring.
RUPERT (Tu et al., 2014)	Shoulder (actuator only). Elbow. Fingers (FES only)	Unknown (tethered?)	Investigative study on 3 healthy subjects.	RehaStim 2	Pneumatic muscles	sEMG	sEMG PID control.	Position, pressure, Kinect		No fatigue monitoring.
THINK2GRASP (Rohm, Schneiders, Kreilinger, Müller-Putz, & Rupp, 2012; Rohm et al., 2013; Rupp et al., 2013)	Elbow (actuator only and not all users). Fingers (FES only).	No	An investigative study was done on hybrid portion of the device with 2 SCI subjects.	Motionstim 8 (fingers)	Electric motor (elbow)	EEG + shoulder position sensors	State machine for type of movement (EEG). Shoulder position sensors control degree of movement. Open loop.	System state, and joystick angle – for display only	Neoprene sleeve with Velcro attached electrodes.Provides visual feedback to the patient.Modular.	Subject required trunk restraint in order to produce normal correct movement. Takes at least an hour to set up and the device caused mental fatigue due to complex control. Control is switched between elbow and hand.
Early Hybrid Exoskeleton (Varoto, Barbarini, & Cliquet Jr, 2008)	Elbow (actuator only). Fingers (FES only).	Fixed to wheelchair.	Investigative study on 5 quadriplegic subjects.	2 channel stimulator	Electric motor (elbow)	Voice	Neural network processes pretrained voice commands.	Force, position, 3D visual motion capture.	Force feedback is provided to users.	Requires movement in the shoulder.
ALEx (Crema et al., 2015)	Shoulder, elbow (actuator only). Fingers (FES only).	No	Investigative study on 1 healthy patient of the elbow and shoulder modules.	Rehastim	Electric motor (shoulder, elbow)	GUI - key press	Impedance control.	Position, impedance	Back-drivable. Adjustable assistance/resistance.	No fatigue monitoring. Possible misalignments with the shoulder of the subject and not adaptable to different sized patients.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

For electrically controllable actuated exoskeletons which distribute their weight predominantly through the user, focus is typically on the more proximal joints. Actuator weight is a much bigger issue the further one gets from the body, especially when one considers that stroke patients are even less capable than healthy individuals of supporting added weight on the end of their arm. Even when placed close to the body's centre of gravity actuator weight can still be an issue.

Of the twelve upper-limb hybrid exoskeletons in Table 1 only five use FES and an electrically controlled actuator for the same joint. With one exception, in cases where FES and an electrically controlled actuator are used for different joints the FES is used for the fingers and the electrically controlled actuator is used for the elbow and shoulder. All of the exoskeletons with the exception of one, attempt to aid with movement of the fingers. In contrast, only a little over half of the exoskeletons attempt to aid with movement of the shoulder joint. The distribution of actuation type used in these exoskeletons is displayed in Table 2 and may be further divided up as shown in Table 3.

When grasping an object like a cup the fingers must first extend then flex while the wrist remains extended. Generally, using FES to flex the fingers will also result in flexion of the wrist. Some devices which aid with grasping hold the wrist in a constant position while FES is used to close the fingers. The hybrid exoskeletons which use FES only for grasping and an actuator only for shoulder/elbow movements vary in their treatment of the wrist joint. The wrist joint may be fixed, actuated, or neither. Despite the differences in wrist support, all four exoskeletons which report results on reach and grasp performance using this combination, enabled the users to achieve successful reach and hand-opening movements or reaching and grasping of objects such as a cup or pretzel (Elnady et al., 2015; Looned et al., 2014; Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013; Varoto et al., 2008).

Table 2. Distribution of actuation type by joint location

	Number
Fingers/wrist – Electrically controlled actuator + FES	2
Shoulder/elbow – Electrically controlled actuator + FES	2
Shoulder/elbow and fingers/wrist – Electrically controlled actuator + FES	1
Fingers/wrist – FES, shoulder/elbow – Electrically controlled actuator	6
Fingers/wrist – EC actuator, shoulder/elbow – FES	1
Total	12

Table 3. Distribution of actuation type by joint

	Fingers	**Wrist**	**Elbow**	**Shoulder**
Electrically controlled actuator and FES	3	0	2	2
Electrically controlled actuator only	1	2	6	3
FES only	7	1	2	1

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the more proximal joints fatigue from FES is a much bigger issue, as is the case with actuator weight on more distal joints. MUNDUS (Ambrosini et al., 2009; CROSTA, 2012; Pedrocchi et al., 2013) is unique in its use of FES only for actuation of the shoulder and elbow joints in combination with use of an actuator only for finger movements. It is important to note that FES for the shoulder and elbow is not used entirely on its own for this exoskeleton but is done in combination with passive elements (springs and elastic wires) or electric lockable/unlockable breaks which provide support against gravity. The use of FES in combination with passive components for the elbow and shoulder was shown to result in a reduction in the energy required from the patient to perform tasks. The testing of the grasping component of this exoskeleton however, was not successful due to the weight of the actuators.

The size and weight of the actuators was also found to be an issue for two out of three of the exoskeletons using hybrid actuation for the fingers; the Haptic Robotic Glove and the FES/Robot Hand (Hartopanu, Poboroniuc, Serea, Irimia, & Livint, 2013; Hartopanu, Poboroniuc, Serea, & Livint, 2014; W Rong, Tong, Hu, & Ho, 2012; Wei Rong et al., 2013). Despite its' issues with actuator weight, the FES/Robot Hand was able to demonstrate a decrease in the muscular effort required to perform tasks and a decrease in unnecessary muscular activity. Artificial tendons proved to be a solution to the actuator weight issues for the Haptic Robotic Glove (Hartopanu et al., 2015) as they allowed placement of the actuators to be situated closer to the centre of mass of the patients' body. Initial validation of the Haptic Robotic Glove appears to have been successful with regards to performing the desired movement however the device was limited by its slow response time.

The Wearable Rehabilitation Robot (Tu et al., 2012) successfully demonstrated the ability of hybrid exoskeletons to improve the accuracy, and reduce the weight and energy requirements, when compared respectively to an electrically controlled actuator or FES alone for both grasping and shoulder movement. Actual weight reduction of the exoskeleton has yet to be done however. The other two exoskeletons which use hybrid actuation for the shoulder and/or elbow have only been developed very recently. The EXOSLIM and RUPERT use hybrid actuation for the shoulder and elbow, and the elbow respectively (Serea et al., 2015; Serea, Poboroniuc, Hartopanu, & Olaru, 2014; Serea, Poboroniuc, Irimia, Hartopanu, & Olaru, 2013; Tu et al., 2014). So far only limited testing has been conducted of these two exoskeletons but initial results are promising.

Actuator Selection and Portability

Actuator selection for an exoskeleton greatly influences several key features of resulting device and in many cases selection of one type of actuator results in a trade-off somewhere. An ideal actuator is lightweight, powerful, fast, easy-to-control, durable, portable, cheap, and compliant. Portability of an exoskeleton may be divided into three key areas; ease of relocating the device, portability with a wheelchair, and full portability. Even if the device must be plugged into a wall or computer the ability to take it home enables the patient to perform rehabilitation away from the hospital, reducing travel costs, and increasing the frequency and repetitiveness of training. Most of these exoskeletons, with a few exceptions could likely be easily relocated to a different location. There are a couple of exceptions, the Wearable Rehabilitation Robot and RUPERT (Tu et al., 2014; Tu et al., 2012), which are quite bulky and require large air supplies.

Various types of pneumatic actuators are used by three hybrid exoskeletons in this review; the Wearable Rehabilitation Robot, RUPERT, and the OrthoJacket (Pylatiuk et al., 2009; Schill, Rupp, & Reischl, 2009; Schill et al., 2011; Schulz et al., 2009; Schulz, Schmitz, Wiegand, Pylatiuk, & Reischl, 2011; Tu et

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2014; Tu et al., 2012; Wiegand, Schmitz, Pylatiuk, & Schulz, 2011). Pneumatics can be light weight and are very compliant. However, they are difficult to control due to a non-linear performance, they can be slow to operate, and are they only capable of forces in one direction so must work in pairs. Perhaps the greatest barrier to the use of pneumatics is that they require a nearby air supply which can be difficult to make fully portable without adding significant weight. While the pneumatics used for the Wearable Rehabilitation Robot and RUPERT are quite bulky and pose as a barrier to portability, the OrthoJacket offers a much more compact solution.

The OrthoJacket is unique in its use of flexible fluidic actuators which may be actuated either by air or by liquid. These are lightweight and compliant and when pneumatic operation is used the supply easily fits under the wheelchair seat such that the OrthoJacket is portable with the use of the wheelchair. Typically hydraulic actuation sees more use in military lower-limb performance enhancement exoskeletons, such Raytheon XOS 2 (Army Technology, 2015), due to its' ability to produce large forces. However hydraulic actuation is usually very heavy and very expensive. Thus it is generally not well suited to medical rehabilitation applications, especially for the upper limb. Once again however, the OrthoJacket offers a unique solution, and when hydraulic operation of its's actuators is used the exoskeleton is capable of being made fully portable for the elbow and wrist sections (Pylatiuk et al., 2009). For the shoulder section, which uses an electric motor for actuation, the OrthoJacket is portable with the use of a wheelchair (Schill et al., 2011).

It should be mentioned here that only about half of the reviewed exoskeletons are aimed at stroke patients. The rest are aimed primarily at spinal cord injury (SCI) patients with some accounting for other neuromuscular and neurodegenerative dieses as well. Portability for SCI patients beyond the attachment to the patient's wheelchair is not often considered a high priority, as without a second exoskeleton for the legs the patient is not able to locomote independently anyway. On the other hand, stroke patients, who may have sufficient lower limb function but be lacking in upper limb function, can desire assistance with activities of daily living (ADL) which demand a higher level of portability.

Of the reviewed hybrid exoskeletons only the BCI-controlled Exoskeleton and the BCI-controlled Wearable Robot are fully portable for all of their joints (Elnady et al., 2015; Looned et al., 2014). In addition to the OrthoJacket, MUNDUS and the Early Hybrid Exoskeleton are also portable with the use of a wheelchair (Ambrosini et al., 2009; CROSTA, 2012; Pedrocchi et al., 2013; Varoto et al., 2008). Many of these exoskeletons are not fully portable because they are tethered to either a power/air supply or to a computer. For most of these exoskeletons, it would be possible to improve portability with wireless communications or a battery pack fixed on the user/wheelchair and in many cases future developments are planned to do so.

Electric motors are the most commonly used electrically controlled actuator among the reviewed hybrid exoskeletons and among upper-limb exoskeletons in general (Lo & Xie, 2012; Maciejasz et al., 2014), especially for movement of wrist, elbow, and shoulder joints. They are cheap, easy to control, compact, and powerful. The greatest limitations of electric motors are their weight and lack of compliance. Combining an electric motor with FES in an exoskeleton should reduce the amount of force needed and thus also the weight of the required electric motor. It is possible compliance could be improved by using methods such as Series Elastic Actuators (SEAs) (Veneman, Ekkelenkamp, Kruidhof, van der Helm, & van der Kooij, 2006). Electric motors have had most success on the proximal joints and are the actuators of choice in both reviewed exoskeletons which achieved full portability.

Two hybrid exoskeleton, the Haptic Robotic Glove and MUNDUS, attempted to use electric motors for finger actuation and neither was successful (Ambrosini et al., 2009; CROSTA, 2012; Hartopanu et

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2013; Hartopanu et al., 2014; Pedrocchi et al., 2013). Linear actuators were then used as a replacement in the Haptic Robotic Glove. They were also used by the FES/Robot Hand (W Rong et al., 2012; Wei Rong et al., 2013). Linear actuators are slightly more suited for actuation of the fingers, however even these can be too heavy as was seen with the FES/Robot Hand. As mentioned earlier one solution to this may be the use of artificial tendons as used by the Haptic Robotic Glove. Linear actuators can potentially offer more compliance and reduced weight than electric motors, however they can quickly become very bulky if used for larger movements.

Patient Monitoring and Feedback

The vast majority of these hybrid exoskeletons are aimed purely at ADL assistance, or a combination of ADL assistance and rehabilitation, rather than rehabilitation alone. Thus, for these hybrid exoskeletons, more focus has been placed on achieving functional movement and reducing energy requirements, rather than on patient monitoring and feedback. Many of the assessment measures currently used in stroke rehabilitation consist of the physiotherapist evaluating the ability of a patient to perform a movement and assigning a course grading to this. In the case of the commonly used Fugl-Meyer Assessment, movements are assessed as; can perform, can partially perform, or cannot perform. Obviously, each of these measures, especially 'can partially perform', covers a very large range of abilities, and small improvements are impossible to distinguish. Use of an exoskeleton which can measure position, speed, and/or the amount of assistance needed to help a patient achieve a movement greatly increases the precision and range which a patient ability can be measured across and removes the subjectivity of the measurement.

Among these reviewed hybrid exoskeletons, in cases where the speed of the patient is monitored, such as the BCI-controlled Exoskeleton and the BCI-controlled Wearable Robot, the timing is not done by the exoskeleton itself but rather by the observer (Elnady et al., 2015; Looned et al., 2014). Often where error measurement is done for tracking it is not fed back to the user but is rather used simply for testing of the exoskeleton. Only in two cases, The FES/Robot Hand and ALEx, is the tracking task feedback an inbuilt function designed to be presented to the patient and/or therapist as a means of patient monitoring (Crema et al., 2015; W Rong et al., 2012; Wei Rong et al., 2013). In the case of ALEx, the impedance of the exoskeleton can also be adjusted and monitored, which when compared with the tracking error feedback, can help the physiotherapist to assess and adjust the difficulty of the tasks. Currently, this assistance adjustment is done manually.

Using sEMG to simply show the user and physiotherapist when an attempt to move is made, can also be very useful. The THINK2GRASP allows the patient to see the activation level and current state of the exoskeleton which can improve their ability to control the exoskeleton (Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013). The FES/Robot Hand also monitors muscle activation levels however it is not known as to whether this is just for testing purposes of the exoskeleton or if it is intended to provide patient monitoring in a clinical setting. Other types of feedback can also be very useful when combined with exoskeleton rehabilitation. The Early Hybrid Exoskeleton provides haptic force feedback to the user which helps them relearn the force required to pick up objects and can especially aid patients who lack proprioception (Varoto et al., 2008).

At present, measurements of patient ability are largely limited to a combination of strength, precision, and speed. The ability of fatigue monitoring to be performed in combination with tracking and control of patient movements offers many advantages if fed back to the physiotherapist and could be extremely useful when selecting training programs. In addition, an exoskeleton could also be designed to auto-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

matically adjust its assistance in response to a combination of patient performance and physiotherapist commands. Little focus has been placed on muscular fatigue monitoring so far, let alone incorporating it into the feedback and control of the exoskeleton. Two of the exoskeletons, MUNDUS and THINK-2GRASP, monitor the muscular fatigue of the subject in order to test the performance of the exoskeleton (Ambrosini et al., 2009; CROSTA, 2012; Pedrocchi et al., 2013; Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013) but none incorporate fatigue monitoring feedback in the control or user interface of the exoskeleton. While some of the exoskeletons are modular and can be adapted to the different patients, none are capable of automatically adjusting their assistance in response to muscle fatigue. Much more research is required in the area of muscle fatigue monitoring. Indeed, much improvement is needed in the area of patient monitoring in general.

Intention Estimation and Control

Compatible control of both the electrically controlled actuator and the electrical stimulation is one of biggest challenges facing hybrid exoskeletons. Control of exoskeletons is typically focused mainly on achieving the correct the movement of the exoskeleton however in the case of hybrid exoskeletons and any device using FES, control of muscle fatigue is also an important consideration.

Prior to achieving any type of control however, the desired movement must first be specified. Typically, the initialisation of movement is always specified by the user in some way, and the actual movement itself can be either user-controlled or user-initialised. If the movement is user-initialised then a predefined trajectory is used and the user has limited control once the movement has begun. If the movement is user-controlled, then the exoskeleton will produce a movement which is continuously proportional to the user's intent. This should not be confused with a proportional controller, which is a type of controller with a feedback loop, where the control signal is proportional to the size of the error between desired output and measured output (Figure 1).

User-controlled movement is used in most of these exoskeletons and is preferable for two reasons. Firstly, it is more useful for the patient with regards to helping them with ADL, and secondly a movement which accurately reflects that which the patient is attempting to perform has been shown to better help with the formation and reestablishment of neural pathways (Maffiuletti, Minetto, Farina, & Bottinelli, 2011). This can speed up the recovery of the patient and help them to relearn self-movement. It is however, much more complex to implement than user-initialised movement.

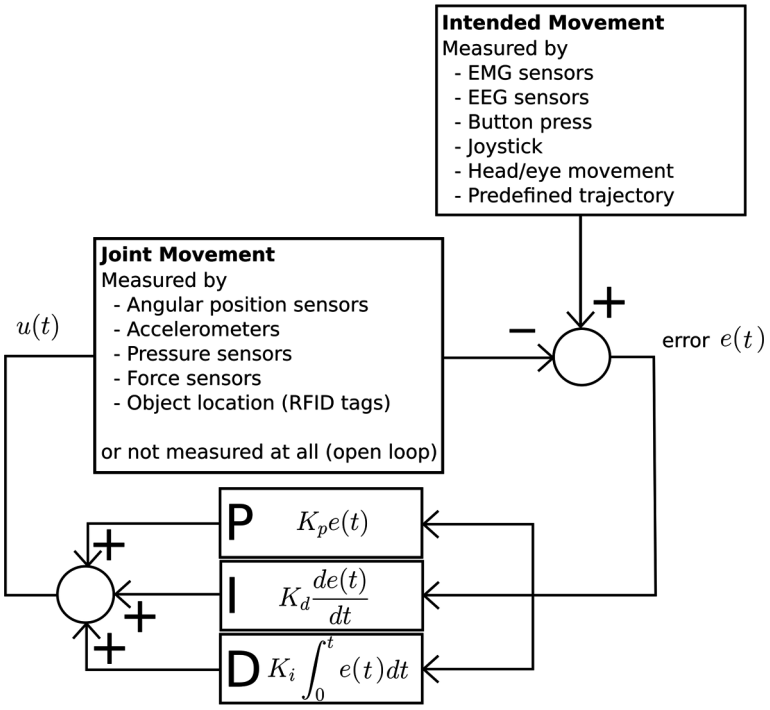
As described earlier, the simplest methods used to estimate the intention of the user is the use of key/button presses or a joystick. These methods are used in a few of these hybrid exoskeletons both as the sole method of intention estimation and in combination with other methods. The downside to using key/button presses or a joystick is that often then the patient's movement is limited in some way. Other methods for obtaining user intention include the monitoring of speech or eye movement. One exoskeleton, the Early Hybrid Exoskeleton, used voice recognition as its method of intention estimation. This method was correct in recognizing a particular command 92% of the time (Varoto et al., 2008). However, it should be noted that often speech can be impaired following a stroke so this method may not be suitable to all users. The exoskeleton, MUNDUS, which monitors eye movement was also successful in obtaining correct user intention. However, the eye-tracking unit used is mounted to a table and this method is thus limited in its portability (Ambrosini et al., 2009; CROSTA, 2012; Pedrocchi et al., 2013).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The use of EMG or EEG is much more portable and poses no limitations on movement. EEG was used by three of the reviewed exoskeletons, the BCI-Controlled Exoskeleton, the BCI-Controlled Wearable Robot, and THINK2GRASP. In all three of these exoskeletons EEG was used primarily to initialise movement which was either simply user-initialised or, in user-controlled exoskeletons, where the continuous control of the exoskeleton was done using a different method (Ambrosini et al., 2009; CROSTA, 2012; Elnady et al., 2015; Pedrocchi et al., 2013; Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013). As described earlier, when EMG signals are present in a stroke patient, measurement of these is preferable over the use of EEG, as EMG is particularly useful for fatigue monitoring and does not require the training that EEG does. Three exoskeletons use EMG for user intention estimation, the OrthoJacket, the FESFES/Robot Hand, and RUPERT (Wei Rong et al., 2013; Schill et al., 2011; Tu et al., 2014).

Control of the reviewed exoskeletons is either open loop, or more predominately, proportional or a variation of proportional-integral-derivative (PID) control (Figure 1). Two exceptions are The Early Hybrid Exoskeleton, which uses a neural network to recognize and respond to predefined voice commands (Varoto et al., 2008), and ALEx, which uses impedance control to follow a predefined trajectory (Crema et al., 2015). In exoskeletons which are capable of multiple different movements state machines are often used to select which movement to perform. For example, THINK2GRASP uses a state machine based on EEG readings to select the type of movement and position sensors at the shoulder to control the degree of movement (Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013).

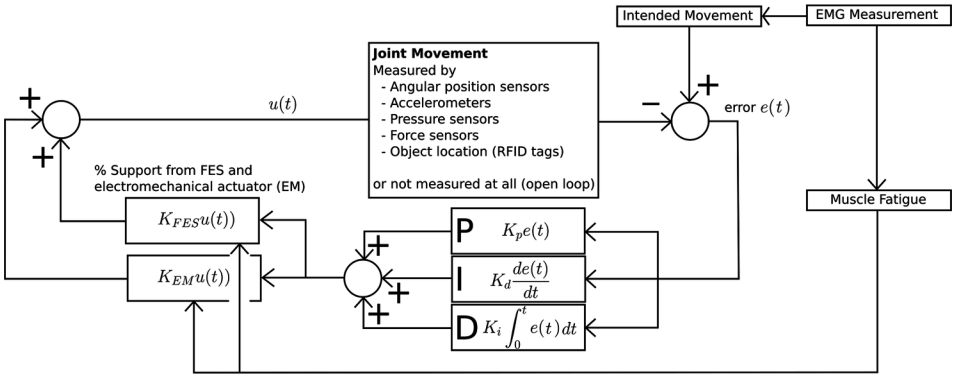
Figure 1. An example of closed loop PID exoskeleton control



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The parameters typically used for FES vary depending on the specific muscle, patient, and other factors, and have been discussed elsewhere (Doucet et al., 2012). Little feedback control of FES parameters has been performed in these hybrid exoskeletons. Parameters are often adjusted until desired movement is achieved and then fixed at a set level. The FES/Robot Hand compared different combinations of FES and electrically controlled actuator support with the aim of reducing tracking error. They found the optimal combination was to provide equally balanced support from each (W Rong et al., 2012; Wei Rong et al., 2013). It is important to note that the FES/Robot Hand did not use feedback in the control of the exoskeleton however, and thus these results are specific only to open loop control. With feedback, different combinations of FES and electrically controlled actuator support may produce different results. An example of what the PID control loop of an exoskeleton may look like with feedback of muscle fatigue added is displayed in Figure 2.

Figure 2. An example of closed loop PID exoskeleton control with fatigue feedback



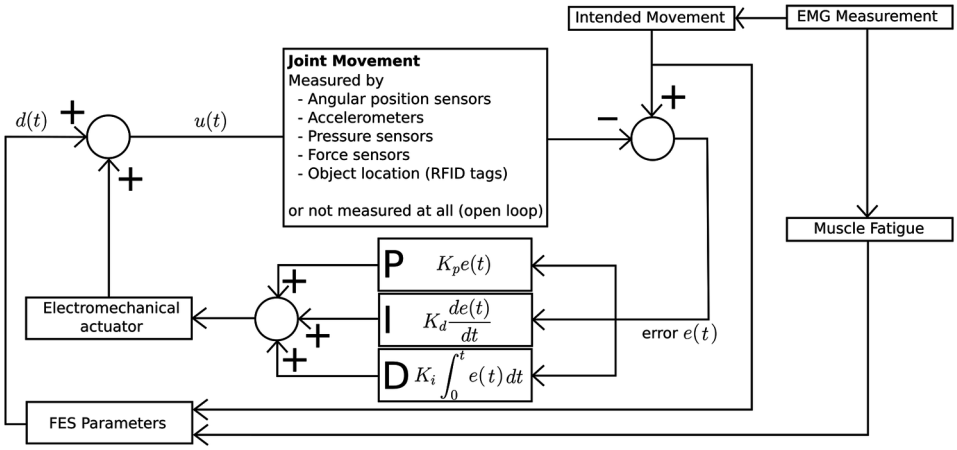
Cycling pulses on and off has been shown to improve muscle recovery, reduce fatigue, and increase patient comfort (Doucet et al., 2012). It was noted earlier however, that minimal fatigue monitoring has been performed among hybrid exoskeletons so far and as such no automatic control or management of muscle fatigue has been done. In some hybrid exoskeletons, like THINK2GRASP, when muscle fatigue is noticed by the researcher the stimulation intensity is simply increased to compensate (Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013). FES parameters such as frequency, pulse-width, ramp-time, and duty-cycle, can all affect onset of muscle fatigue. With the ability of the electrically controlled actuator to provide variable support the resulting movement of the hybrid exoskeleton need not alter with a variation in FES parameters. In such a case where multiple parameters of FES are varied it may be preferable to treat the muscle response from the FES as a disturbance and have the electrically controlled actuator compensate for the resulting output variation (Figure 3).

Usability and Trials

Usability is a key component in the ability of hybrid exoskeletons to improve patient outcomes. If patients and physiotherapist do not want to use the exoskeleton due to difficulties in using it or issues with comfort, then it does not matter how capable the exoskeleton is in improving patient outcomes.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Closed loop PID exoskeleton control with fatigue modelled as a disturbance



The preparation time of the hybrid exoskeletons reviewed ranges from the very quick (<30 s with help) as seen with the BCI-controlled Exoskeleton and BCI-controlled Wearable Robot (Elnady et al., 2015; Looned et al., 2014), to the excessive (up to 1 hour) for the THINK2GRASP exoskeleton (Rohm et al., 2012; Rohm et al., 2013; Rupp et al., 2013). However, many of these exoskeletons do not detail the preparation time so it is difficult to fully evaluate the status of this area. A typical patient session is about an hour long and will sometimes be divided into one section for the upper-limb and one section for the lower-limb. For a hybrid exoskeleton to be useful it should not take up a significant portion of this time to achieve a ready-to-use state. In addition, if the patient is to use the device at home then they need to be able to attach it without help.

Some exoskeletons were difficult to use, caused mental fatigue, and/or required several training sessions prior to their use, as was the case with THINK2GRASP. In certain cases, like the Early Hybrid Exoskeleton, patients did not have sufficient limb movement to use the device (Varoto et al., 2008), or in the case of THINK2GRASP, were not sufficiently able to use the control interface. ALEx was only capable of fitting patients of a smaller and thinner stature and suffered from possible joint misalignment at the shoulder (Crema et al., 2015). On a more positive note some exoskeletons proved useful even for patients with proprioception problems (Hartopanu et al., 2014), and others, such as the FES/Robot Hand, reduced the energy required of the user for a particular task (W Rong et al., 2012; Wei Rong et al., 2013). Some exoskeletons, such as the OrthoJacket, consisted of modular components and were capable of being adjusted to suit patients with different abilities.

The user interface of the hybrid exoskeleton needs to be very simple and intuitive to interact with, as cognitive ability and focus of a patient can be considerably impaired following a stroke. It is desirable that a patient have some control over the device without the need for direct observation. Control which a physiotherapist has over the exoskeleton should also be distinctively separate to the control which the patient has, much like the commercial FES devices which can have their parameters pre-set and then locked so the patient has no concerns about accidently changing physiotherapist settings. Modularity of an exoskeleton and the ability to fit different-sized or different-skilled patients is highly useful and desirable if adjustments are not overly time-consuming or complicated.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hybrid exoskeletons are a very recent development and thus only limited testing has been done to date. In some cases, the entire exoskeleton has not even been tested as a whole, such as can be seen with the OrthoJacket, the Haptic Robotic Glove, and ALEx (Crema et al., 2015; Hartopanu et al., 2013; Hartopanu et al., 2014; Pylatiuk et al., 2009; Schill et al., 2009; Schill et al., 2011; Schulz et al., 2009; Schulz et al., 2011; Wiegand et al., 2011). In many cases the exoskeleton has only been tested on the designer themselves or a couple of healthy subjects. None of these exoskeletons have been tested on more than 10 subjects or over more than 20 sessions, and only one hybrid exoskeleton, the FES/Robot Hand, has been tested where established clinical measures (such as the Fugl-Meyer scale) have been performed on patients as an evaluative measure of the exoskeleton's ability to improve rehabilitation (W Rong et al., 2012; Wei Rong et al., 2013). In most cases only functional testing has been performed.

FUTURE RESEARCH DIRECTIONS

Overall most success towards achieving functional movement, such as a reach and grasp of an object, has been had with hybrid exoskeletons which do not utilize the combination of FES and electrically controlled actuation at the same joint, or which use a passive component in place of an active actuator. Indeed, both setups also result in a simplification of the control of the exoskeleton. The use of FES on its' own for grasping has also proven successful for allowing patients to achieve functional movement with sufficient precision. There is room for improvement with regards to increasing precision, however actuator weight is likely to remain a significant barrier towards achieving this using full hybrid actuation, as has been seen in the results of the hybrid exoskeletons which use full hybrid actuation for grasping. Other methods may be more useful here, such as electrode arrays which have previously demonstrated a significant increase in the precision of grasping movements (Malešević et al., 2012).

With regards to the shoulder and elbow joints there remains the issue that unless the patient has some movement in these joints already, using only electrically controlled actuation for these two joints can only help with neural repair but not with reducing muscle atrophy. This is especially true for patients early on in recovery who have very limited movement. It may be that exoskeletons with passive components are sufficiently suited in some cases to reducing exoskeleton weight, reducing muscle fatigue, and producing functional movement, however these exoskeletons still rely on the use of FES on its' own to produce the entire movement. In many cases forces produced from FES are insufficient even with the help of a passive component (Resquín et al., 2016). Precise control is also easier to achieve with the use of an active actuator. Hybrid exoskeleton development in this area is especially new. Initial results do indicate that hybrid exoskeletons may prove useful for helping to achieve functional movement and to improve clinical outcomes, especially for patients with limited movement, in these more proximal joints. Electric motors have had the most success so far although there is plenty of opportunity for research into novel methods of actuation. While hybrid exoskeletons have been shown capable of reducing the energy requirements of the exoskeleton, actuator weight remains a common issue. Placement of the actuator is an important consideration and cable-actuated exoskeletons offer a lot of flexibility here.

Hybrid exoskeletons present a unique opportunity to further investigate the effects of FES parameters on muscle fatigue and potentially to delay muscle fatigue onset. In all cases where the FES device has been specified a commercial device has been used instead of one being designed specifically for use in the hybrid exoskeleton. This makes it easier to incorporate hybrid exoskeletons into a clinical setting as most rehabilitation clinics already use FES, however, depending on the device used, it may limit the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

flexibility and controllability of the hybrid exoskeleton possibly reducing their potential advantages. While proportional, PID, impedance, and admittance control are simple to implement it may be that more robust control schemes, such as artificial neural networks (ANNs) or other types, are be better suited to take full advantage of the hybrid combination and to perform fatigue management, patient improvement monitoring, or assist-as-need.

There are currently no commercially available upper-limb hybrid exoskeletons and predicted prices for exoskeletons which do have a long term view of commercialization are not expected to be cheap (Pedrocchi et al., 2013). Due to cost of hybrid exoskeletons and indeed exoskeletons in general wide scale evaluation is difficult (Loureiro et al., 2011). Devices which can prove beneficial to a wider range of subjects will likely be easier to commercialize. Modularity, which has been attempted in some of these exoskeletons, may help to lessen the barriers to commercialization, however it is important that usability and comfort are not sacrificed.

CONCLUSION

At this stage, success has been most prominent among hybrid exoskeletons which are focused on the more proximal joints. Indeed, hybrid exoskeletons may be more useful for the shoulder and elbow joints while FES alone may be successfully used for grasping. Many of the reviewed hybrid exoskeletons are only in the initial stages of development with limited trials conducted thus far and the potential benefits of hybrid exoskeletons have yet to be fully taken advantage of. The control schemes used are typically simple in nature and none perform involved fatigue management. The assist-as-need paradigm has yet to be implemented in any hybrid exoskeleton. The usability of current upper-limb hybrid exoskeletons is mixed with many exoskeletons performing quite well in some areas but lacking in others. Additionally, predicted commercial prices are not expected to be cheap. Despite this, preliminary results are promising and the ability of hybrid exoskeletons to improve the energy efficiency of exoskeletons has been successfully demonstrated in prototypes.

KEY TERMS AND DEFINITIONS

Activities of Daily Living (ADL): Activities conducted routinely during everyday life which most people can perform without assistance, for example, eating, bathing, dressing, toileting, transferring (walking), and continence.

Electroencephalography: The recording of the electrical activity in the brain.

Electromyography: The recording of electrical activity in muscle tissue.

Fugl-Meyer Scale: An index used to assess the sensorimotor impairment of people who have had a stroke.

Functional Electrical Stimulation (FES): Electrical stimulation applied to a muscle which results in functional movement.

Muscle Atrophy: A reduction in the mass of a muscle.

Muscle Fatigue: A reduction in the ability of a muscle to generate force.

Proprioception: The ability to sense the position and movement of the parts of one's own body.

Stroke: A stroke occurs when the blood supply to a section of the brain is blocked or reduced significantly, resulting in the deprivation of oxygen and nutrients.

Chapter 36
A SWOT Analysis of Virtual Reality for Seniors

Pooya Soltani
Aix Marseille University, France

ABSTRACT

The population of older people is increasing. In this book chapter, the author reviewed some of the applications of virtual reality (VR) for seniors in form of a strengths, weaknesses, opportunities, and threats (SWOT) analysis. This approach is commonly used to assess and guide internal and external parameters to accomplish a mission. Some of the challenges that the elderly are facing were reviewed and the way VR can help in overcoming those challenges were discussed. A comparison of VR technologies was also presented. The results show that VR's feasibility and concept are linked to existing technologies and the characteristics of each system control immersion, interaction, and stimulation. VR interventions might have the potential to be used as ecologically valid e-health screening systems. Systems should be specifically designed and adapted for seniors and usability issues should be addressed. Ideally, VR interventions work best in addition to traditional methods. Future studies should use more subjects to ensure the efficacy of such interventions for seniors.

INTRODUCTION

Human life expectancy and the population of elderly people over 60 years old are increasing. People might be less available to properly support older family members. Costs of hospitalization and nursery homes, as well as physical barriers, loneliness, and isolation, are among challenges that elderly are facing (Marcelino et al., 2018). Research has shown that regular physical activity (PA) is important for good health. It could also prevent various diseases and lower the risk of fall (Ofstedal, Zimmer, & Lin, 1999). Additionally, PA could improve memory and executive functions in the short and long term. However, aging is usually accompanied by deterioration of muscular strength, sensory sensitivity, and functional capacities (Park & Yim, 2016). These physiological changes affect the seniors' willingness to participate in regular PA (Lin et al., 2018). The physical decline also affects the elderly's quality

of life, falls, admission to the healthcare centers, and mortality. Cognitive impairments also affect the elderly's functional autonomy and result in a decline in physical performance and unsafe decisions and behaviors (Dommès et al., 2015).

By means of computers interfaces, virtual reality (VR) allows users to enter a virtual world. It uses various audiovisual technologies to provide high interaction leading to a feeling of immersion (Lin, Jeng, and Yeh, 2018). VR simulates environments and activities by using real-time stimulation of one or more sensory channels. Its feasibility and concept have been linked to the existing technologies for simulation and interaction. VR settings provide immediate feedback that could be necessary for all forms of learning (Manera et al., 2016). They also offer personalized environments according to the needs of the different participants.

Although seniors shape a considerable portion of our population, they are often overlooked when it comes to newly introduced technologies. They may not always be willing to accept new technologies, in fear of not being able to use them (Lin et al., 2018). Despite the functional loss, seniors still have the abilities to acquire and re-learn performance skills (Skjæret et al., 2016). Technology might be used to promote better performance for them. Jeng, Pai, and Yeh (2017) suggested that to encourage the elderly to use technology, psychological barriers should be broken. Teaching and providing hands-on experience and assistance, increase their willingness to experience new things. VR may have the advantage to control the type and amount of experience each patient receives and may boost learning transfer to the identified targets (Maillot et al., 2017). VR also has the ability to change the existing scenarios by modifying physics and other aspects of reality. Virtual tasks might be designed according to the elderly's needs for acquiring and practicing new skills repeatedly. The immersive nature of these interventions may also offer implicit learning processes without the patient's awareness (Rand et al., 2017).

Telerehabilitation uses information and communication technology and offers accessible and affordable services to people in their homes (Kizony et al., 2017). The use of VR and serious games for older adults are generally categorized in improving upper and lower limbs movements, balance, mobility training, daily living, neglect, and cognition (cf. Deutsch and Westcott, 2017). The challenge is to provide enough amount and intensity and therefore, various technological approaches have been proposed. VR could also be used as an add-on to robotic devices for execution of movement or to be used as standalone systems using visual stimulation and interaction (Hoermann et al., 2017; Cameirão, Bermudez, & Verschure, 2008).

Considering these issues, this book chapter will present a SWOT analysis of using VR for seniors. SWOT stands for strengths, weaknesses, opportunities, and threats, and is usually used in business to analyze the parameters that affect the company's competitive position in the market. A strength is a positive capacity that allows an entity reaching to its defined goals. A weakness is a limitation that slows the progress towards the defined goals. An opportunity is an internal or external force in favor of that entity. A threat is an unfavorable situation that could present a barrier or limitation in achieving goals. SWOT analysis is done to reveal the optimal match between strengths, weaknesses, opportunities, and threats that the company is facing. SWOT framework could also be applied outside of the business domain (Rizzo & Kim, 2005). Based on a SWOT analysis, strategies could take advantage of opportunities by using their strengths and by actively addressing threats by correcting the weaknesses.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

In this part, some of the challenges that elderly people might face are explained:

Falls affect approximately one-third of older adults per year and could significantly reduce their independent functionality (Talamo et al., 2017). Injuries and fall-related costs are high and their prevention are important public health challenges. Fall risks can be attributed to both motor and cognitive deficits. Multimodal interventions that target both motor and cognitive functions may contribute to fall reduction (Mirelman et al., 2013). Surveys and physical tests are used to measure both intrinsic and extrinsic risk factors. Physical tests are easy to administer but they lack ecological validity or the degree of similarity between the training environment and the real-world. Moreover, traditional tests may not have the ability to isolate specific sensory defects (Saldana et al., 2017). This is important as ecologically valid tests add value for predicting improvements in everyday functioning.

Static and dynamic balance training are usually prescribed to overcome day to day tasks in the older population. Biofeedback systems could also be beneficial for building new motor skills. They allow motor-cognitive systems integration and self-perception of treatment effectiveness (Montero-Alia et al., 2016). However, these systems are expensive, are not highly accessible, and require an expert to operate them. Other existing proactive interventions for fall prevention may also produce mixed success results because these exercises do not specifically target the neuromuscular skills required for fall prevention (Parijat et al., 2015).

Stroke is the main cause of long-term disability, and the majority of stroke patients are over 65. It creates many problems such as difficulties in completing daily living activities. Neuroplasticity and recovery after strokes are improved by repetitive, task-oriented, and intensive training. However, general barriers of cost, transport, information (on how and where to exercise), and time exist. Moreover, it seems that motivation is a major challenge for rehabilitation adherence (Paquin et al., 2016). Other parameters such as the number of exercises, their effectiveness, and their complexities might also contribute to the adherence (Pallazo et al., 2016). Stroke patients may also experience visual neglect as a result of brain dysfunction. In clinical practice, these patients are often observed for far and near space sight check.

Personally lived events are called episodic memories and they shape our identity and connect us the past and future. Changes in this type of memory (e.g. due to age) could predict the evolution towards neurodegenerative disorders (Abichou, La Corte, & Piolino, 2017). Alzheimer's disease (AD) is a common form of dementia and results in a decline in cognition and daily living activities. Mild cognitive impairment (MCI) is the limited declination of cognitive abilities in the AD. Patients with MCI have problems remembering the relationship between objects or between objects and their contexts. Spatial disorientation is another early manifestation of AD and MCI in which patients have problems in unfamiliar places.

Cognitive and functional tools are usually used to detect early manifestation of the disease. Assessing instrumental activities of daily living (e.g. using a bus or a telephone) is important for choosing better interventions for AD patients. Traditional neuropsychological tools use simple situations and are able to partially measure the characteristics of episodic memory. Ecological tasks might be more beneficial compared to subjective questionnaire-based assessments (Vallejo et al., 2017). Novel screening tests use new technologies and game principles and focus on the immersion of the users in various scenarios to mislead and deceive patients' minds (Fernandez & Argyriou, 2017). Assessing patients with VR application seems legitimate because they could recreate conditions similar to that of the real world. In the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

next section, the differences between different forms of VR are discussed and after, a SWOT analysis of how VR could address the mentioned challenges is presented.

MAIN FOCUS OF THE CHAPTER

Differences Between Exergames and the VR

Early studies have characterized active video games (exergames) as forms of VR. In fact, these two terms are usually used interchangeably. We have heard research findings like these: Elderly may have higher interests in participation in exergame sport activities than real-world activities (Wollersheim et al., 2010); When exergames are used for rehabilitation, elderly are more motivated and rarely drop out (Pigford & Andrews, 2010). There are also demented pieces of evidence on better control over posture stability and balance when using exergames (Chiang et al., 2011). So, what are the differences between exergames and VR?

For a system to create the illusion of interacting with a virtual world, it should offer presence, immersion, and flow. The presence or the realness of the world is partly created by the system's ability to deliver an illusion or degree of immersion. This is where the differences of exergames and other types of hardware is more visible. Exergame platforms detect your movements with their sensors and transfer them to computerized avatars inside the games. Nintendo Wii also comes with a balance board, a small portable force platform that could be coupled with various Wii Fit games. It adds enhanced immersion by monitoring center of gravity while the participants interact with the on-screen characters (Rendon et al., 2012). More immersive virtual environments include cave automatic virtual environments (CAVE) which are basically a video theater within a room. The walls of the cave are made up of rear-projection screens. Users enter the cave while wearing 3D glasses and their movements are monitored to continuously adjust viewers' perspective. Newer technologies such as head-mounted displays (HMD) use participant-centric perspective. They have a larger field of view (FOV) and stereoscopic visual fields that are constantly modified by head position and rotation. The recent HMDs have higher FOV, display resolution, and tracking latency resulting in a better creation of the visual illusion of real objects and scenarios.

One reason to consider exergames as VR might be that exergame platforms provide immediate feedback to players' movements, offering immersive feelings. Therefore, VR's feasibility and concept are linked to the existing technologies for immersion, interaction, and stimulation. The characteristics of each concept are responsible for delivering an illusion of reality (immersion). These characteristics later affect presence or the sense of being in the VR (Borrego et al., 2018). For example, one might argue that HMDs and CAVEs are more immersive than exergames because they provide higher visual stimulation. However, this degree of immersion is not necessarily related to the effectiveness of the system (Deutsch & Westcott, 2017), and both VR and video games create a state of flow, the optimal performance zone of the players.

Lee, Chen, and Chang (2016) argued that tasks presented on LCD displays are in fact presented in 2D. In a 2D virtual environment, there is no stereo vision and subjects see one planar view. Other cognitive and sensory cues may be used to indicate depth; for example, an avatar walking in a jungle. As patients need to imagine 3D patterns, a huge cognitive load is created when the information is presented in a 2D format (Sweller et al., 1998). It has been suggested that augmented reality (AR) provides better 3D stimuli and manual spatial manipulation (Sweller et al., 1998). On the other hand, by using

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

AR, users might change their behavior when they are aware of being observed (Sweller et al., 1998). Liebermann et al. (2012) also compared arm reaching movements made in 2D video VR environment with the real-world environment. They showed that movements patterns were affected by viewing angle and were slower, shorter, and less accurate compared to the real condition. They also suggested that a 2D VR environment may be perceptually and cognitively challenging for the participants because the intended 3D illusion presented by their VR was likely based on previous memories and experiences. They concluded that caution needs to be taken when using these environments for improving the quality of movement for rehabilitation of upper limb.

Another issue to consider is that visual systems contribute to balance and visual perturbation cause instability. Exergames do not completely encompass the viewer's FOV, and visual information from surroundings of the VR environment (e.g. TV or screen) can still provide stability cues (Menzies et al., 2016). HMDs obscure unwanted additional visual cues and add ecological validity through the addition of depth perception (Saldana et al., 2017). However, it may cause simulator sickness and if not properly designed or performed without supervision, may lead to falls.

Strength

Riva et al. (2004) used a VR-based multidimensional approach to treat body image (perception of the aesthetics or sexual attractiveness of one's body) attitudes. Their results showed positive short-term results in improving the overall psychological state of the participants compared to the traditional cognitive-behavioral training. Chang et al. (2014) compared the effects of a VR gaming system on sleep quality of elderly people with a disability. They showed that regular VR exercise significantly reduces stress among the older patients, confirming that it can improve their sleep quality. In his meta-analysis, Cardinale (2018) suggested that VR balance training using Nintendo Wii improves Borg balance scale score compared to no balance training, and helps people to multi-task during balance training. Parijat et al. (2015) used VR as a perturbation-based training tool for older adults. They found that their VR environment could induce perturbations similar to a slip. It could also reduce the incidence of balance loss during the actual experiment on a slippery surface. Mirelman et al. (2016) targeted the interplay between cognitive and mobility deficits and combined non-immersive VR gaming with treadmill training. After 6 months of training, those who trained on the treadmill using VR had a significantly lower fall incident rate compared to the treadmill only group.

Yasuda et al. (2017) examined the immediate effects of an immersive VR rehabilitation program (a reaching task and a visual searching task) using HMD. They concluded that this program might be beneficial for the visual searching task in far spatial neglect. Self-training compliance using video games for post-stroke rehabilitation is shown to be higher compared to traditional methods in elderly patients (Rand et al., 2017). Parsons and Barnett (2017) developed a VR measure of memory and validated it with traditional methods in older adults. Not only the VR measure was similar to traditional methods for memory measures, it provided objective measurements of individual memory components. Their subjects also preferred the VR task over the pen-and-paper measures. Vallejo et al. (2017) developed a VR serious game to assess cognitive function in healthy and AD patients using an ecological approach of daily living activities. Differences were expected between healthy and AD patients in terms of percentage of achievements and the time needed to achieve those tasks. However, the additional qualitative information regarding the errors in the achievement of the tasks provided information about cognitive functions.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Nir-Hadad et al. (2017) also validate their VR shopping task for the assessment of executive function in stroke elderly population. Maillot et al. (2017) developed an affordable and transportable VR system to help older pedestrians make safer street crossing decisions. They also measured whether training with the small-scale simulator transfers to a full-size simulator where they could actually walk. They showed that the small-scale simulator triggers more unsafe decisions compared to full-scale. It also allowed learning new skills and modify behavior to use in the large-scale simulator (learning transfer).

Weakness

Manera et al. (2016) argued that their VR task needs to be improved to fix usability issues. They attributed the lower performance of elderly in VR to the difficulties elderly have with using the mouse and possibly to eye strain from wearing the 3D glasses. In general, the senior population suffers from technological illiteracy. For maximum efficacy, VR systems should promote a user-centered design and their primary focus should be on inclusive design, usability, and accessibility. Different sensors might demand higher body performances. For example, to use Kinect, it is necessary to move the whole body. Some sensors might require players to have better coordination and in elderly it might cause lower levels of performance. Other technologies like touch screens may not require high levels of body movement but may demand higher mental agility (Palacio et al., 2017).

Bezerra et al. (2018) showed that VR environments provide improvements of performance in healthy older adults. However, there is no transfer of performance from VR to the real task and vice versa. Rand et al. (2017) compared video game and traditional self-training for upper limb rehabilitation in older adults after a stroke. Although improvements were observed in the two methods, they showed that the differences were not significant. Zygouris et al. (2015) used a virtual supermarket task for MCI screening. Although the task displayed a high correct classification rate between MCI and healthy elderly, it was unable to differentiate between MCI subtypes. Dommes et al. (2012) assessed the effectiveness of a VR training program for elderly on the street crossing decision making. Although they showed that immediately after the training, the intervention group and the control group differed significantly, these differences were not significant after 6 months. However, a clear shift to making more safe decisions was observed for all participants. In general, due to the lower number of subjects in different studies, the generalization of the results are somewhat restricted (Yeşilyaprak et al., 2016).

Opportunities

Mattan et al. (2017) discussed that age is associated with reduced perspective-taking capacity. They showed that compared to younger adults, older people are relatively more egocentric and more accurate when they are in the first person perspective compared to the third person perspective. Mohammadi et al. (2018) also used two VR navigation tasks (allocentric and egocentric virtual neighborhoods) in different AD patients. They showed that patients needed more time to find the goal in egocentric tasks. It might be possible to properly distinguish specific types of AD patients from others. Sobral Monteiro-Junior et al. (2017) showed that exergaming could offer improvements in short-term memory, working memory, and semantic memory/executive function over time. Valladares-Rodriguez et al. (2017) used a digital game to assess episodic memory, which is used to evaluate potential cognitive impairments in the elderly. Using the new ecological, non-intrusive, and better administrable tool, they conducted the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

test in a shorter time. They could also introduce scenarios that are closer to real life while being more engaging and highly acceptable compared to the classical pen-and-paper based method.

Fernandes and Argyriou (2017) used VR as an affordable approach for creating e-health screening AD diagnostic systems. They proposed VR tests that could evaluate memory loss related to common objects, recent events, expressing and understanding languages, and the ability to recognize abnormalities accurately and similarly for the presence of AD. From their research, Plancher et al. (2012) concluded that VR is better adapted for early diagnosis of AD compared to traditional verbal memory tools. Manera et al. (2016) tested the feasibility of an image-based VR system in MCI and dementia. Their patients reported high feelings of security and low discomfort, anxiety, and fatigue. Although the VR task was more difficult, they were also more satisfied with the VR condition and preferred it to the paper condition.

Lin et al. (2018) used means-end chain techniques to examine elderly's awareness and personal values regarding VR activities. Elderly population mentioned leisure VR activities to be fun, safe, easy, and physically and mentally healthy. While playing with VR, they were also seeking enjoyment, improved quality of life, and a sense of belonging. Goršič et al. (2017) explored the role of competition while using VR. They concluded that stroke patients (including elderly) who exercise with a peer in an unsupervised situation (e.g. home) exhibit higher enjoyment and exercise intensity compared to those who exercise alone. Brunner et al. (2017) explored the effectiveness of their upper extremity VR rehabilitation system and showed that the improvements were similar to the conventional therapy. They also suggested that the motivating nature of VR could be a supplement to standard rehabilitation.

Saldana et al. (2017) used HMD in VR to objectively assess balance by using visual-vestibular conflict and by comparing the results of postural sway with a force plate. Their preliminary results showed that the HMD is a valid, reliable, and comparable to traditional mechanical perturbation approaches for measuring balance. Popular HMDs allow easy navigation in life-size virtual environments and provide required spatial requirements of non-immersive serious games, exergames, and motor rehabilitation applications (Borrego et al., 2018). Such interaction allows natural navigation and exploration and therefore, the improved ecological validity of the task while facilitating skill transfer. Albiol-Pérez et al. (2017) designed a low-cost active balance rehabilitation system and measured the performance of balance control during 15 sessions of virtual rehabilitation. Although there were no statistically significant differences between the left, central, and right positions, their results indicated a trend of improvement, especially in the left and right sway which are important in avoiding risks of falls. Tsang and Fu (2016) compared the efficacy of their VR balance system with traditional balance training. They attributed the improvements in VR system to the real-time performance feedback and cuing stimuli that supports error-free learning.

Paquin et al. (2016) used a VR rehabilitation program for fine motor recovery of stroke patients. All of their subjects experienced a perceived increase in hand function and that they would recommend the program to other stroke survivors. McDonald et al. (2013) used a VR pain coach for the effects on the communication of pain by older adults. They measured pain and depressive symptoms before and one month after the intervention. Older adults shared a significant amount of clinically important pain information with the pain coach than the pain communication-only group. Pain intensity and depressive symptoms reduction showed a non-significant trend one month after the intervention. The VR pain coach shows a possible strategy for pain management discussions between practitioners and older adults.

Threats

Previous research has suggested side effects of display characteristics, obstacles, cost/benefit of the technology as weaknesses for the adoption of VR in rehabilitation (Rizo & Kim, 2005). Dizziness and imbalance might occur after using VR applications. Chairovano et al. (2018) perturbed visual inputs and measured their effects on self-report (complaint) vs. balance measurement (posturography). As they found no correlation between these two methods, it is important not to only rely on subjective measurement of dizziness, but also to objectively measure the imbalance; especially because questionnaires could be influenced by age, sex, motivation, and cognitive and emotional parameters (Yardley & Redfern, 2001). Eggenberger et al. (2015) also compared long-term multi-component cognitive-physical tasks: one was treadmill walking with simultaneous verbal memory training and the other VR video game dancing. Both types of training resulted in significant advantages in improving gait parameters compared to physical training only. However, these two interventions resulted in different training-specific adaptations in the gait. Cardinale (2018) suggests that VR balance training should be used in supplement with other interventions. With multi-component processes such as balance, there might be the possibility of errors leading to falls. The lower number of patients, especially in different types of AD might limit the generalization of the results (Mohammadi et al., 2018).

SOLUTIONS AND RECOMMENDATIONS

Technology is constantly evolving, and it has the potential to be applied to various domains. However, it needs to be adapted to meet the seniors' needs. Lee et al. (2016) designed a VR based rehabilitation and explored patients' perceived difficulty and enjoyment. They suggested that the level of enjoyment could be an indicator of the appropriateness of the difficulty levels. They identified five parameters that could affect this relationship: ease of following the directions, the experience of pain, achieved scores, novelty and immediate feedback, and self-perceived effectiveness. Participants' physical, cognitive, proprioceptive differences should also be considered while tailoring the VR systems. As mentioned by Lin et al. (2018), elderly people's decision-making processes are restricted to certain leisure activities. Different platforms should identify their feature and consider elderly's physiological functions to establish a marketing focus.

From their systematic review, Molina et al. (2014) concluded that most of the studies on the efficacy of inclusion of exergames for elderly have methodological problems. The duration of gameplay varies widely and therefore, it is hard to be conclusive about the physical benefits. Miller et al. (2014) also mentioned that although VR/gaming systems are effective and feasible, there is a high risk of bias for addressing impairments and participation. Booth et al. (2014) also systematically reviewed 251 articles on the effects of VR gaming systems on improving balance in older adults. The pooled results showed no significant differences. What is important is that video games for older people could help them to be more socially active. However, several parameters such as simplicity, social enjoyability, and entertaining new games should be considered. Video game controller should allow adequate time for the elderly to make decisions in order to achieve the games' objectives (Palacio et al., 2017).

FUTURE RESEARCH DIRECTIONS

As mentioned before, most of the studies lack an adequate number of participants which makes it hard to generalize the efficacy of results. Future studies should use a larger sample size and consider culture and gender-oriented tasks (Vallejo et al., 2017; Yeşilyaprak et al., 2016). Future studies should also have appropriate dosages of use to improve the validity of treatment prescription and safe functioning levels of the seniors (Cardinale, 2018). Follow-up and longitudinal studies with normalized baseline levels are required to identify the consistency of the beneficial effects of VR (Maillot et al., 2017; Nawaz et al., 2016; Mirelman et al., 2016). Feasibility studies are important in enhancing performance and other cognitive tasks in the target population. However, randomized controlled trial (RCT) efficacy studies should be conducted with control groups of healthy elderly participants, while creating more complex versions of the task (Kizony et al., 2017; Marena et al., 2016). Control groups and blinding participants and the tests also help in avoiding bias and learning effects (Yasuda et al., 2017). Similar VR and real tasks could also help in better understanding the transferability of the intervention (Bezerra et al., 2018). It is also important to assess psychosocial and cognitive emotion improvements after VR interventions (Cardinale, 2018). As suggested before, it is also important to consider the VR training as part of a holistic platform and not the sole effects (Cardinale, 2018).

CONCLUSION

VR is a rapidly developing subject and in this book chapter, the author discussed how VR could help in overcoming various struggles of the seniors. Both exergames and newer VR technologies have the ability to immerse players and their effectiveness may not be related to the levels of immersion they offer. However, each technology might address specific needs. As shown in Table 1, it seems that VR interventions have the potential to offer ecologically valid scenarios for screening various diseases. It is suggested that these interventions are used in addition to traditional interventions. More subjects and longer duration of use are needed to validate the efficacy of VR for seniors.

Table 1. Summary of SWOT analysis of using VR for seniors

Strengths	Weaknesses
1. Short term overall psychosocial state improvements 2. Improved balance and decreased risks of falls 3. Improved visual searching 4. Higher compliance to self-training 5. Similar validity to traditional memory tests 6. Enhanced ecological validity	1. Adaptation issues (usability, display technologies, platforms) 2. Limitations in skill transfer 3. Limitation is differentiating between subtypes of cognitive tests 4. Short lasting results 5. Restricted generalization of the results
Opportunities	**Threats**
1. Ability to modify physics and scenarios according to the needs 2. Efficiency 3. Affordable 4. Possible similar results to traditional interventions	1. Mixed positive and negative results 2. Low number of subjects 3. Little cost/benefit proofs for VR adoption

KEY TERMS AND DEFINITIONS

Alzheimer's Disease: Is a neurodegenerative disease that involves short-term memory loss, language disorientation, and other behavioral issues.

Ecological Validity: Refers to the extent to which the results of a research could be generalized to the real-life settings.

Exergame: A combination of exercise and gaming, exergame are video games that are also a form of exercise.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Mild Cognitive Impairment: Is a neurological disorder that happens in older adults and involves cognitive and instrumental activities of daily living impairments.

Serious Game: A game that is designed for a primary purpose other than pure entertainment. The serious adjective refers to issues such as defense, education, health care, engineering, and politics.

Skill Transfer: Is the concept of exploring how individuals would transfer learning in one context to another one.

Virtual Reality: An interactive computer generate experience within a simulate environment and involves different types of sensory feedbacks.

Chapter 37
Neurotechnology in the Development of Cyber-Psychotherapy Systems for Inducing and Measuring Altered States of Consciousness in Transpersonal Psychotherapy

Raul Valverde
Concordia University, USA

ABSTRACT

Transpersonal psychotherapy is based on transpersonal psychology and considers that the psyche is multidimensional and that there are several "levels of consciousness" and each has different characteristics and is governed by different laws. Transpersonal psychology is the study of human nature and proceeds on the assumption that human beings possess potentials that exceed the limits of their ego and integrate the spiritual experience within a broader understanding of the human psyche and consciousness. Altered states of consciousness have been used as psychotherapy in transpersonal psychology for decades. Although there are very well known techniques to induce altered state of consciousness as holotropic breathwork, Neurotechnology offers an alternative way not only to induce these states for transpersonal therapy but also to measure the level of a state of consciousness. The objective of this chapter is to provide a review of the main concepts of Neurotechnology and the main technologies that can be used to induce and measure altered state of consciousness for transpersonal psychotherapy and propose an architecture for a Cyber psychotherapy system that uses these technologies.

INTRODUCTION

Cyber therapy is an Internet based computer-mediated system used to facilitate psychotherapy (Botella et al. 2009). This includes new applications of technology within psychology and healthcare, which utilize augmented and virtual reality components in order to facilitate psychotherapy (Botella et al 2009). Interest in Neurotechnological devices has grown strongly since the release of 1986's classic text of Michael Hutchison "Megabrain" (1986). Besides Neurotechnological machines, the industry has developed a range of related devices including peripherals-tapes, subliminal tapes, Hypno-peripheral processing, sound meditation devices and altered state induction software programs for personal computers, etc. It seems like Neurotechnology combined with contemporary psychology may seem to be revolutionary but its roots are much older as humanity has made many attempts in the past to involve consciousness with technology. The flashing LEDs in a light and sound machine can be traced back to the old practice of starting a fire in order to induce trance. Sound recordings of brain entrainment undoubtedly have their roots in the ritual singing and shamanic use of wind instruments.

This current era of Neurotechnology was born from the experiments made in biofeedback that resulted in the work of some researchers of consciousness as Masters and Houston (1966) that created the AVE (an abbreviation of Audio Visual Environment) that is one of the first electronic brain entrainment devices. The AVE was the first device to use visual and auditory stimuli as a means of altering consciousness. Not much different that many of audiovisual devices of today, the AVE consisted of a wrap-around screen and headphones to bomb the sense in these two stimuli.

These signals generated by AVE devices and detectable by electroencephalogram (EEG) tests at specific frequency ranges; seem to vary from one state of consciousness to another for their users. The products of Neurotechnology appear to make possible to "tune" the brain to these different alternating frequencies, and in turn achieve new psychological states.

When you "tune" into these frequencies at a slower pace, our thought processes and central nervous system are altered, causing the brain to fall into a deep level of activity. In addition, when one is tuned to a frequency faster and a higher range, the wave activity can have a highly stimulating effect on the brain.

Altered states of consciousness have been used as a therapy for modern psychological paradigms as transpersonal psychology (Valverde 2015). Although there are several techniques such as holotropic breathing used to induce these altered states of consciousness, Neurotechnology offers a more easy to control alternative to the transpersonal therapies.

In order to understand Neurotechnology, this review begins with an introduction to the technologies that made possible the modern Neurotechnology including biofeedback, quantum physics, quantum biofeedback, theory of consciousness, principles and applications of Neurotechnology for inducing altered states of consciousness in transpersonal therapies. Finally, the chapter proposes an architecture to conduct transpersonal therapy over the internet with the use of Neurotechnology in order to induce and measure altered states of consciousness.

BIOFEEDBACK

Biofeedback literally means, "responding to life". The work of Miller opened the doors to research processes in biofeedback. Miller (1978) constructed an apparatus equipped with sensitive electrodes connected to a monitor on which the patient could see how the skin temperature behaved, teaching

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

patients to relax and concentrate to get it to relax the smooth vasculature of vessels peripheral blood in order to descend skin temperature.

Biofeedback is the process by which a person learns to influence involuntary body processes to receive physiological data from an electronic device that continuously monitors certain physiological parameters. It is a way of measuring the response to the physical, emotional, mental and spiritual stresses of life. Bodies under high stress are more prone to physical discomfort and even illness. The biofeedback response occurs when the body receives new information about their status (e.g. get 'feedback') and make healthy adjustments to reduce stress and tension. The result is a reduction of the nervous activity and increased vitality. Users of the feedback report a greater sense of well-being and joy.

Biofeedback Neurotechnology instruments measure muscle activity, skin temperature, electro-dermal activity (sweat gland activity), respiration, heart rate, heart rate variability, blood pressure, brain electrical activity and blood flow. These technologies are able to capture analog electrical signals from the body and translate those signals into meaningful information through complex algorithmic software that a technician can then decipher. Research shows that biofeedback, alone and in combination with other therapies is effective for treating a variety of medical and psychological disorders. Doctors, nurses, psychologists, counsellors, physical therapists, occupational therapists and other professionals currently use biofeedback. Computer scientists also use biofeedback in order to build human computer interactions (Valverde 2011).

Studies by Jonas and Levin (1999) show that biofeedback is ideal for patients that are looking for therapies that are softer, less toxic and less invasive. The biofeedback technique is applied in the field of psychology for treating phobias, neurosis, anxiety, depression and insomnia.

Quantum Physics

What we are able to perceive with our five senses is not reality. Quantum physics has shown that space and time are illusions of perception. Our body cannot really be a reality if it does not occupy most of the space it seems to occupy; an experiment made at the University of Manchester revealed the shape of the interior of an atom is almost entirely empty space. The question then became how we could possibly make the world around us see us if this is the case (Russell et al 1993).

Our true consciousness does not exist in our brains or in our bodies, but this illusion of our individual bodies along with the misinformation of our true origins has manifested the idea that we all think independently from one another. With this understanding, it seems possible to scientifically explain telepathy, clairvoyance, spiritual mediums related to the transfer of information between sources without physical means of communication phenomena. But when we understand that there is a common spiritual bond between all things in the universe and that we are all part of a divine intelligence, this simple understanding fills all the holes in modern religions and predictions about the future and literally every occurrence of events (Russell et al 1993).

According to quantum physics, the physical world and its reality, it's just a recreation of the observed. We created the body and reality, as we create the experience of our world in its different manifestations dimensional. In its essential state (atomic or cosmic sub quantum micro), the body is made of energy and information, not solid matter, this is only a meager level of perception. According to Tornell (2001), this is energy and information arising from the endless fields of energy and information spanning the entire universal creation. The quantum school explains consciousness by applying quantum theories and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

explains that consciousness has a quantum origin, is non local and creates our perceived reality from vibrating entities that can have multiple versions based on the observer's perception (Valverde 2016).

When looking at the electronic microscope, we are looking at our microcosm, we then can see how the quantum particles manifest virtually as a symphony and intelligent orchestration at speeds much higher than the visible light, this quantum view also represents the immutability of our macrocosm. In this reality, each individual inhabits a reality that is beyond all change, as more deep within us without the knowledge of our three-dimensional or physical outer senses. There is a core of being, an energy field that creates immortality in nature, and manifests as the physical body. This core is the essential being or soul, primordial seed, which is contained in an atom called seed. We are seeds of eternal essence at this stage of quantum eternity.

This is the seed based on new paradigms posed by Max Planck, J. Clark Maxwell, Faraday, Heisenberg, Schrodinger, Bohr, Einstein, S. Hawking, among many other pioneers of quantum mechanics. They understood that the way to see the world in their time was very wrong. Within the quantum paradigm, we are more than our physical body; our true self and personality are governed by the rules of the principle of cause and effect and are embedded into a body for the duration of human life. The field of human life is open and unlimited in its deeper quantum level, this means that we are immortal and timeless. Once we identify with the eternal reality that is consistent with quantum vision of the universe, we will enter the new paradigms of quantum consciousness. Everything that exists has a natural vibration to its atoms all the way up to the immensity of the universe to show a simple connection between land and our bodies.

Consciousness

Being aware is to realize everything that happens around you. It is as if in the previous moment you take an action, before acting you asking yourself: Is it right what I do? And someone who "is not you" answers only "yes" or "no" (Hawnser, 1997). Our mind before ordering an action to the physical body, studies the elements it has to do with the action: knowledge, physical strength, skill, etc. Consider the risks, the consequences, the material benefits that give us the results of the act, also any loss and damage and / or suffering that the action may bring to our selves or third parties (Hawnse, 1997).

Edelman and Tonomi (2000) think that the whole universe is actually one living organism with full conscious awareness of self. The consciousness of our universe is responsible for the form and purpose that all matter assumes. Carl Jung (1981) found that there is a collective unconscious connected to all humans. This means that all humanity shares a single mind with one another. This is evident in the world through accounts of shared mythology and symbols. This collectivity is a global example of the unconscious mind of the human body in which billions of cells share a similar signal. Human consciousness is an electromagnetic energy field; this could explain many paranormal phenomena such as telepathy and clairvoyance that seem to probe this.

Most Western scientists assume that consciousness is produced in some form by the brain. There is of course some evidence for that position. There is evidence of common sense in our daily lives. When we drink too much alcohol or takes a hard hit to the head, we do not think clearly. We also have more sophisticated tests of the relationship between the brain and consciousness. In fact all the theories of consciousness during the last century has been supported by psychologists who have been moving towards the materialism that characterized the nineteenth-century physics based on Newton's classical mechanics. These have been trying to show that consciousness is only the functioning of the physical brain. This materialistic psychology was supported by John Watson (1916), who wrote that psychol-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

ogy is a purely objective experimental branch of science that needs no consciousness in the same way that science does not need chemistry and physics. It is ironic that while Watson links psychology to the classical physical knowledge of Newtonian physics, there is overwhelming experimental evidence that the universe is related to quantum physics that could not be made without reference to consciousness.

John Lorber (1978) specialized in children with hydrocephalus, or water on the brain is a British neurologist. Children with this condition have an abnormal amount of cerebral spinal fluid accumulation in the cavities inside their brain compressing brain tissue that usually leads to mental retardation seizures, paralysis and blindness and if not treated to death. However, Lorber describes dozens of children and some adults with severe hydrocephalus but live normal lives. Indeed, in a sample of children with their cerebral space filled with ninety-five percent of spinal fluid in their skull leaving virtually no room for any brain tissue, half of them had a higher IQ than one hundred and thirty.

Some of the best evidence that consciousness can function independently of the brain come from near death experiences, profound experiences that some people report when they have been on the threshold of death. The near-death experiences are very short stories of people who have been clinically dead and then are resurrected or revived spontaneously after a brief interval with the memory of what they experienced during that period. According to Greyson (2010), many people with near death experiences reported vivid mental clarity exceptional sensory imagery and a clear memory of the experience and an experience that is more real, then in their daily lives.

Quantum Biofeedback

As the traditional biofeedback, uses sensors to monitor physiological relaxation indicators as the temperature of the skin and muscle tension, quantum biofeedback expands classical biofeedback by using galvanic skin response (GSR) and other similar devices together with modern computer technology to detect and measure the response of the built-mind-spirit body (sometimes called the super-conscious) to a large array of stress indicators. Quantum Biofeedback is a sophisticated biofeedback technique based on advanced scientific principles that promote a deeper understanding of health and healing. By seeing the body as a complex electrical circuit and by applying the principles of electrical engineering, wearable to analyze and balance the electric body. We usually think of the body as just anatomy and physiology; however, one of the easiest way to learn about the state of health of the body is by measuring electrical properties of the electric body.

Super-conscious makes adjustments to biological speeds to reduce internal tensions and sends 'back feedback' that allows the practitioner to focus the session on the parts of the body-mind-spirit more in need of relaxation. The result is a smooth passive relaxation session, still focused on those areas most in need of attention. When the body becomes so relaxed, the therapist can start the natural healing process. Many long-term stress cases can be reduced with biofeedback sessions. Quantum Biofeedback interacts with all cellular matrix of the body, which allows communication with the conscious and unconscious reactions of the body. This is accomplished by establishing electrical communication using 12 electrodes that are attached to the head, wrists, and ankles of the client. Classic Biofeedback is based on electrical measurements taken from the front (frontal cortex). This information is presented to the users who then try to consciously change his or her internal reactions to modify electrical results. Quantum Biofeedback uses people's link to all body cell matrix interface, not only the conscious aspects, but also with the unconscious, this provides greater gain in the understanding of health.

Users of this technology experience increases in physical health, strength and stamina, they can also display more confidence, they may find it easier to sleep, which can be more relaxed, and they may experience more happiness and satisfaction in a day-to-day basis (Health and Public Policy Committee 1985). Today, thousands of doctors and medical researchers worldwide are investigating electro medicine and biofeedback Neurotechnology devices as effective traditional methods of treatment alternatives. These pathways are new possibilities for the treatment of conditions such as spinal cord injury, muscular restoration, nerve regeneration, brain stimulation, bladder disorders, tumors, heart disease and other chronic diseases and disorders.

Transpersonal Psychology.

Transpersonal Psychology considers that the psyche is multidimensional. There are several "levels of consciousness" and each has different characteristics and is governed by different laws. Transpersonal psychology does not deny other schools of thought, as psychoanalysis does not arise as opposed; the right thing would be to say that attempts to go further. For transpersonal vision, Freud developments have been of fundamental value in the development of psychological science to include the idea of the unconscious in a discipline that was tied to the positivist rationalism. Certainly, psychoanalysis opened the possibilities of understanding the human psyche. Transpersonal psychology integrates the spiritual experience within a broader understanding of the human psyche. It is with the study of states of consciousness and the full potential of man, that transpersonal psychology assumes that humans can achieve harmony and transcend through spiritual development. Transpersonal is something that exceeds the range of human's own experience or personal history. Transpersonal refers to that which is beyond of the person who is the essential being.

Much of its discoveries and contributions come from the study of Eastern religions, and Christian mysticism. Transpersonal psychology is interested in the different forms of Buddhism, for meditation, for yoga, for mystical experiences, psychophysiological effects that all these phenomena, the limits of consciousness, etc. The ultimate goal of all this is to try to achieve an awakening that is the greater awareness that would raise the level of "being" that integrates psychology and spirituality.

Transpersonal psychotherapist Anthony Sutich (founder and first editor of the Journal of Transpersonal Psychology) provides one of the first formal definitions of transpersonal psychology in 1969 at the inaugural edition of the Journal of Transpersonal Psychology (Vol. 1, No. 1, Spring 1969). "The emerging Transpersonal Psychology refers specifically to the empirical, scientific study, and the responsible application of relevant results, becoming meta-needs individual and species-wide, the final values, conscience unitive, peak experiences, values, ecstasy, mystical, amazing experience, being, self, essence, joy, wonder, ultimate meaning, transcendence of self, the spirit, unity, cosmic consciousness, synergy of individual and species level, maximum interpersonal encounter, sacralisation of everyday life, transcendental phenomena, self-cosmic humor and joy maximum sensory awareness, responsiveness and expression; and concepts, experiences and activities " (Sutich, 1969).

Stanislav Grof, co-founder of transpersonal psychology with Abraham Maslow, defines transpersonal psychology as "The psychology that respects the entire spectrum of human experience, including holotropic states, and all domains of the psyche. - Biographical, perinatal and transpersonal "(Grof, 2000). Transpersonal psychology covers a multitude of experiences and behaviors produced by spontaneous or altered states of consciousness, impulses into higher states of being, and extraordinary spiritual practices induced. Transpersonal phenomena include the meditative experiences, dreaming, drug-induced

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

psychedelia, peak experiences, cosmic consciousness, enlightenment, mysticism, out of body experiences, channeling trance, near death experiences, memories reincarnations, extrasensory awareness, archetypal phenomena, accelerated learning, exceptional state of health and well-being, the mind-body healing and miraculous cures. Parapsychological phenomena are important for the reduction of science and spirit implications.

Altered States of Consciousness and Transpersonal Psychology

Ludwig (1972) defines an "altered state of consciousness" as any mental state (s) for various manoeuvres of physiological, psychological or pharmacological agents, which can be recognized subjectively by the same (or an objective observer of the individual person induced) as representing a sufficient deviation in the subjective experience or psychological functioning of certain general rules for that individual during alert awareness. This deviation can be sufficiently represented by a greater concern than usual with internal sensations or mental processes, changes in the formal characteristics of thought, and the deterioration of the test of reality to varying degrees. The cognitive approach to altered states of consciousness has revealed that similar features that are characteristic of many altered states of consciousness including "alterations in thinking", "sense of disturbed weather", "loss of control", "change in emotional expression "," change of body image, "" perceptual distortions "," change in the meaning or importance "," sense of the ineffable," and " feelings of rejuvenation "(Ludwig, 1972).

By applying the disruptive force requirement for the basic state of consciousness (either through some physiological action, such as drugs or deployment of attention and meditation), the current organization of cognitive subsystems is destabilized until a new force patterns (such as mental set, setting, expectations, drug effects) is applied to shape the subsystems in a whole new system, the production of a new discrete state of consciousness with its own stabilization processes.

Cognitive awareness approach has helped differentiate transpersonal psychologists' grades waking state of consciousness. Awareness, for example, is not one homogenous thing, but varies and changes as the colors of the rainbow. It is possible to stratify and states order to raise awareness of alert and focused relaxed concentration and spread the cosmic consciousness. A range of altered states of consciousness has been identified as drug-induced states, hypnosis, biofeedback, daydreaming, night dreaming, sensory deprivation, and paranormal experiences. With each state consisting of many levels and functions, in each region or area of consciousness, individuals are able to process different types of information at different levels of control (Goleman & Davidson, 1979; Ornstein, 1972).

Transpersonal psychologists tend to see the experiences of "mystical union", "enlightenment", "nirvana", and related experiences as natural and beneficial non-ordinary states of consciousness that may be subject to effects of state-dependent learning. The idea that the experience of the sacred can be interpreted as altered states of consciousness arose from the observation of twice that (a) psychedelic drugs have been used through the centuries and cultures to induce religious experiences and (b) reports from some drug experiences are phenomenologically (descriptively or experiential) indistinguishable from accounts of natural mystical experiences (Doblin, 1991; Grinspoon & Bakalar, 1997; Smith, 1964).

Transpersonal psychologist Charles T. Tart has examined the altered states of consciousness from a cognitive perspective in terms of changes in the configuration and operation of the underlying mental processes (Tart, 1971, 1976, 1983, 1992). A state of consciousness involves cognitive functioning following subsystems: exteroceptors (receives sensory information), interoceptors (kinesthetic receives input), input processing (working memory), the subconscious processes, sense of identity, evaluation

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

and decision making, emotions, space / time sense, long term memory, the motor output (behavior) plus latent functions. These 10 subsystems (more possible latent functions) define any discrete state of consciousness. The particular configuration of the subsystems in a given time is shaped and limited by the deployment of attention, the body's energies, characteristics of the structures themselves and the particular social and cultural environments in which they operate.

Grof (1988) suggested that the term "altered states of consciousness" cover transpersonal experiences; however, there are certain types of altered states of consciousness that do not meet the criteria for being transpersonal (involving an expansion or extension of consciousness beyond the limits of the usual and limitations time and space). For example, a living and complex childhood memory occurs in an altered state of consciousness (e.g. hypnosis or psychedelic sessions), but do not meet the criteria for being transpersonal. The cultural context of the 1960s and 1970s provided fertile ground for the emergence of transpersonal studies as an independent field of study in psychology. The infusion of ideas Eastern contemplative traditions of Zen, Advaita, Vedanta and Taoism, along with the institutionalization of the humanist revolution in academic psychology, and the growing interest in consciousness and altered states of consciousness that are triggered by the widespread use of psychedelics, paved the way for the birth of transpersonal psychology movement in California in the late 1960s (Ferrer, 2002).

Since the 1970s, transpersonal psychology, as the humanist movement that preceded it, has been divided into three different groups; the first group represented by the ideas of Grof (1988) that believes that transcendence can only occur in the presence of a altered state of consciousness. This group produces conceptual models of non-ordinary states of consciousness. The second group, led by Wilber (1980), include those trying to assign internal states of consciousness and identify with the monistic and perennial philosophy of Aldous Huxley. Wilber believes that all expressions of the highest state of consciousness in each tradition are the same as the psychopathic conditions occurring at the bottom, the normal waking reality in the middle and meditative states of higher consciousness in the top. The third and by far the largest segment of the transpersonal movement has no identifiable bearer, it sees the self as getting up and go to work in the morning, the higher consciousness is sweeping the floor, washing dishes, and raking leaves. The lighting is doing everything we are supposed to be doing at this minute. There is a preconceived thing; is not an altered state of consciousness, it is simply the deep philosophy, which is to be found most clearly in the mundane (Taylor, 1999).

Altered states of consciousness answer the question "who we really are?" The answer to this question is that we are a part of God and that humans are spiritual beings having human experiences that somehow reveal the direction of our full identity of our cosmic status (Valverde 2015).

Brain Waves

Our brain works primarily with bioelectrical energy. Although the power of electricity that handle our neurons is low (measured in mill volts), this power processes, manage, distribute and use vast amounts of information and generates multiple answers (almost infinite in possibilities). So by using micro electricity, we can conclude that the brain is a machine of low frequencies. Our brain, in addition to process information that comes by the senses, is capable of emitting extra-sensory information received via similar "electromagnetic waves", but with lower intensity similar to the frequencies of a radio transmitter-receiver. Our brain can act as a radio station, similar to numerous species of birds that in their migrations are guided by a genuine receiver of terrestrial magnetism located in the pituitary gland. With this receiver,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

they know where they have to fly and in what direction. It's like having a real compass incorporated into the brain. The mind could be defined as the "sense" of the brain (like sight is the sense of the eye).

A German psychiatrist, professor at the University of Vienna named Hans Berger (1.843-1941), demonstrated that a device "amplifier" that was called later electroencephalograph could capture electrical potential (voltage fluctuations) in the human brain. Before him, the English physician Richard Caton (1842-1926) showed similar potential in dogs. The first types of brain frequencies that were discovered were the "alpha" and "theta".

Later, these findings were complemented by research in the range frequencies captured by the electroencephalograph. Each type of wave results in a different neuropsychological state. That is, our mind, our body and our physical and physiological activity are completely different in each of these states or frequencies. The type of neuro-chemicals and hormones substances discharged into the blood flow varies depending on frequency and as much as the presence and quantity of such substances as the mood we have, interact to produce a physiological-mental-physical-end that involves a mental state. A level of consciousness is conscious thought that is always thinking even in moments of apparent inactivity, but trivial ideas continually pass by consciousness. Most of the thoughts are accompanied by reactions in behavior, and small involuntary movements. When you're not actively thinking then you're probably dreaming, according Signer and Streiner (1966) a person has throughout the day about 200 daydreams. Therefore, consciousness is the sum of all the different perceptions. The most common consciousness are wakefulness and sleep; however, changes in expressing both cerebral and psycho states change according to conscious or subconscious feelings of each person are distinguished. These changes are directly related to the electrical activity of the brain. This activity can be measured by the number of oscillations per second (Hz) that are linked to different states of consciousness in the brain: our brain only perceives a limited range of frequencies indispensable to operate with ease in this three-dimensional medium. 20 to 20,000 vibrations per second are perceptible by our ears, the colors perceived by our eyes range from red to violet (although extending beyond, up and down), all possible smells and tastes (which are also vibrations) and the endless textures that we can distinguish with our skin. But the brain is not only receiver but also is sends vibrations. It has been proven thanks to the EEG that the brain emits waves of varying intensity and frequency depending on the mental state of the person being observed. These waves are classified into:

The alpha state is when, if we would connect to an electro encephalogram, our brains would work between 7.5 to 14 cycles per second. When "operate" in this state, we rank among the border of the conscious and the unconscious. Is the gate between both states of consciousness and this makes "Alpha state" therefore a special status because it allows us, on the one hand, still have a conscious activity of our mind and body, that is, we realize what we think and happening around us. On the other hand, since the "lift" of consciousness in the "lower floors" of the mind, gives us access to information and own subconscious states, can use all the wealth of the 90% of "power" mental residing in the subconscious. This state is a "being comfortable" in inner peace and happiness, in deep relaxation. Greatly increases the power of suggestion and autosuggestion, that is, anything that we suggest alpha, will be more easily accepted and less "filters" by our conscious rationality.

Music is a very effective instrument of suggestion and production of alpha state made many instruments produce vibrations at that frequency. Hence, with relative ease, many people stay asleep at concerts or simply feel "moved" by the music to another dimension. If we put them to an electroencephalograph, most of those attending a concert in an auditorium would be running on alpha. The contemplation of the sea, the rolling waves and the sound they produce is a good inducer of alpha state. The tone of in-

Table 1. Type of brainwaves

Types of Brain Waves	States of Consciousness
BETA WAVES: 14 Hz to 30 Hz	This type of waves are recorded when the person is awake in a state of normal activity. Correspond to states of conscious attention, anxiety, surprise, fear, stress.
GAMMA WAVES: 25 and 100 Hz	They express pathological conditions of maximum tension, excitement and the individual enters a state of STRESS in which the coordination of ideas and normal physical activity are seriously altered.
ALPHA WAVES: 8 Hz to 13 Hz	Relaxation and rest, calm, reflective state. Reduction of bodily sensations. The subconscious begins to emerge: Abstraction, suggestibility. Assimilation of the study. Ease of visualization of mental images.
THETA WAVES: 3.5 Hz to 7 Hz	During sleep or in deep meditation, autogenous training, hypnosis, yoga (whenever the formations of the subconscious act). The state stimulates creative inspiration. Considered a state for maximum capacity of learning. Fantasy, imagination. Hypnagogic images.
DELTA WAVES: 1 Hz to 3 Hz	It arises mainly in the states of deep sleep and unconsciousness. Very rarely can be experienced being awake unless with a very hard training (Yoga, Meditation, Zen, Hypnosis, Self hypnosis) or with a synchronizer of hemispheres. It corresponds to deep sleep, hypnotic trance, REM sleep. It corresponds to sleep without dream, trance, deep hypnosis. Delta waves are very important in the healing process and strengthening the immune system.

dividuals things like music, prayer, smells, certain types of images (especially of nature, certain types of painting, Tibetan mandalas symbols or own) can be used to put ourselves in this special state of the mind, that makes us touch our innermost and reach the "spiritual zone" of human beings. Therefore, as we see, there are many things that can induce this state.

Magnus & Van der Holst (1987) speak of frequencies whose frequency ranges from 3.5 to 7.5 cycles per second. They are associated with the states of creative and decisive hallucination. During its broadcast, the person can discover events deeply hidden in the recesses of your subconscious, as well as conflicts and personality in particular. Is the wave of imagination and dynamic contact with other possible "dimensions psi" offering you the opportunity to research our personality and deep in our psychology?

Neurotechnology Principles

Robert Monroe (1982), one of the most prominent people in Neurotechnology in particular in the field of sound with neurological efficiency, devised the method HEMI-SYNC: (Synchronization of the cerebral hemispheres by means of sounds). Like a glass that resonates when a pure tone is emitted, the brain resonates when receives certain frequencies of waves, being synchronized with these, this effect is known as FFR Frequency Following Response (FFR).

Machines created based on FFR began to be popular in the 80s, the typical machine based on the principle of Monroe used stereo headphones that are used to send sound signals to each ear, for example 2 signs of 300 and 304 Hz. One ear will hear only 300 Hz signal and the other only 304, but since the sounds are combined in the brain, this will hear a third signal of 4 Hz, which is the difference between the two sound impulses. This third signal is not an audible sound, but an electrical signal that can only be created by the cerebral hemispheres acting in unison, and may go unnoticed, producing as a result, the two hemispheres are focused simultaneously on the same state of consciousness, increasing the brainpower.

The Monroe Institute was created based on the principles of Monroe. The Neurotechnology of the Monroe Institute is a system that mixes and sequences sound patterns designed to evoke beneficial

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

brainwave states for different human activities. Robert A. Monroe, who began studying the effects of sound on accelerated learning in the 50s, founded this institute. The work is the result of thousands of hours of laboratory sessions. Participants in these sessions listen to specific combinations and sequences of sound patterns and simultaneously report their experiences while electronic instruments measure the effects on the activity of their brain waves.

Walter (1964) while conducting experiments in which strobe devices used to send rhythmic flashes of light in the eyes, watched amazed that the flickering light could alter the activity of the entire cerebral cortex, rather than exclusively associated areas with vision. The subjective experiences of those who received the flashes were even more curious reported seeing "lights like comets, ultra fantastic colors, color mental". Moreover, Walter discovered that certain visual stimuli of a certain frequency could cause the brain to respond quickly adjusted to the same frequency of the stimulus it received. In 1982 a psychiatrist Denis Gorges created a machine called brain wave synchro-energizer, which applies the latest technology in the first device designed optical-acoustic stimulation. This is able to promote as its inventor claimed "an increase in the capabilities and functions of the human mind", this unleashed a wave of unprecedented research and experimentation, catalyzed by M. Hutchinson (1986) through his famous book Megabrain.

Our scheme of thought is influenced by the predominance of left hemisphere, logical and analytical thinking. Right hemisphere, creative thinking, visualization, and which carries out a holistic synthesis. On the back of the brain is where the intuitive thought takes place. Obviously use one of the two hemispheres or either of the brain regions severely limits our abilities. The optimal functioning of our brain, is given by the synchronization of the two hemispheres: by left-right and front-back alternating stimulation occurs almost simultaneously, an issue of brain wave of an identical amplitude and frequency. Neurotechnology is typically used for process brainwave entrainment to tune brainwaves. With these machines, we may experience theta waves, alpha, delta or including combinations of ranges using frequencies layered that mix several brainwave ranges in a synergistic pattern.

Hemi-Sync is a patented process sound that pulses to create the same electric waves in frequency and amplitude simultaneously in both hemispheres of the brain for specific purposes. Our brains have a hemisphere left and right. The left-brain is linear, logical, practical, and time -oriented. The right hemisphere seems to be much more nonlinear, abstract, creative, holistic, and not logic. We tend to use one hemisphere at a time, or better said, will favor hemispheres particular in terms of what we're doing. An accountant probably uses less of his right hemisphere than an artist would during the course of his workday. If the person were doing math, the staff would be using more of your left side. If the person were going to paint a masterpiece of art, the person would have the activity hemispheric more in the right. Both hemispheres are constantly interacting and both can be used simultaneously.

By merging both hemispheres we can make them to work together and with this we can increase our ability mental and improve our performance cognitive in general. Basically, it's like having a computer processor faster able to work at faster speeds. The greater integration creates better performance.

The mind machines that help the brain synchronizes naturally to balance hemispheric activity and adjusts the activity of brain waves to match the carrier frequencies embedded brainwaves. This hemispheric coherence induced audio produces an optimal state of comprehensive synergy of the entire brain. These hemispheres are connected by the corpus callosum that it serves as a conduit or a bridge between both sides. This bridge literally be exercised and strengthened until it is physically larger and more capable of transmitting data, ideas and feedback between the hemispheres.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The advance occurs when you use this principle to synchronize our brain wave frequencies chosen with the help of specific mental machines. We can do this easily by using technology of binaural beat audio and monophonic ringtones. This phenomenon is called trailing phenomenon.

The scientific principle of drag can be used to resonate, or synchronize our brain to tune specific frequencies. The drive is quite simple. If we have two tuning forks of the same pitch, if we strike one and hold it near the other both resonate at the same frequency. Given the fact that our brains function as a resonating chamber, oscillating pulses and patterns of neural excitation ripple through our brains like endless waves on a pond of a subtle dynamic electric field.

The creation process of frequency binaural beat is very simple to explain. First, we create two audio tones with two frequencies slightly different (i.e. 100 Hz and 107 Hz). When playing a tone in the ear left and the other tone in his right ear, the brain reacts to the stimulus audio by resonance brain activity to the difference between these two tones. Our brain waves adjust to match this frequency differential. For example, if we play a frequency of 100 Hz in the ear and left 107 Hz in the right ear, our brain tune the 7 Hz differential (107 Hz - 100 Hz = 7 Hz). This frequency tracking response makes our brain to resonate at 7 Hz frequencies and this falls within the range of theta brainwaves. This psychoacoustics state can create phenomenal results.

The electrical activity of neurons is changing patterns of electrical potential through all cell membranes. Each cell generates in the membrane potential that can be detected in about one micrometer of the cell and in large sets of brain cells that can work in harmony to generate potential of few micro volts, this can be detected through the skull and scalp by using electrodes. The variation of the electrical potential around the scalp is the basis of operation of the electroencephalogram (EEG). This method of recording the electrical activity of the brain, digitized maps produces the electrical activity of brain. The state in which the two hemispheres are synchronized by showing similar activity in both hemispheres, is sometimes known as “whole brain” and occurs randomly for short periods. Stimulation through the differential tone makes it possible to sustain this state for longer periods.

The Hemi-Sync process has already been tested and implemented in many ways for:

- Sleep better
- Reduce tension or stress
- Control pain
- Accelerate learning
- Study and concentration
- Enhance creativity
- Find solutions to problems

The Induction and Measurement of Altered States of Consciousness by Using Neurotechnology in Transpersonal Psychotherapy

The most frequently heard of studies of altered states of consciousness criticism is that they are hoaxes, some form of mental delusion. A good example is the case of Eastern yogis who for years claimed to be able to control parts of the nervous system and the body such as heart rate, blood pressure, hormone secretion, etc. Western scientists considered these claims impossible whose theories and personal experience denied this possibility.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Biofeedback research shows that many of the claims made by physicists yogis, changing the sound pattern proved to be true can change particularly the state of consciousness at will. EEG measurements have been based on the research and theories developed from the early work of Adrian and Matthews (1934) that discovered that the brain could go to certain frequencies with electronic brain stimulation, this work led to the discovery that various frequencies were linked to certain psychological states (Kamiya, 1968), and ultimately the work of Green et al. (1977) demonstrated the ability to control these states and frequencies. You could say that these tests were the first to show how the brain can boot, such as a computer with the right input frequency.

What exactly happens neurologically when we walked into alternate states of consciousness is still far from being understood. This gap in our knowledge of these kingdoms is largely due to deficiencies in both research tools and philosophies employed by scientific research, and our general reluctance of society to accept such states as real. Within the traditional scientific practice is important to understand how our brains create the bridge to stimulate altered states of consciousness, but understanding it tells us little or nothing about the correlation with psychological phenomena with which we are able to interpret altered states of consciousness. It is this inner cosmological view or its representation of our quantum reality.

Once we accept this premise as our fundamental metaphor for altered states of consciousness, then it is possible to postulate that our brainwave frequencies are measurement indicators of our psychological states and correspond to the various ways in which we produce. That is, these frequencies are the units of our quantum reality. This is how we create, outside the sphere of influence of the Heisenberg principle that says that our fields are a unified experience. Cade et al (1979) conducted EEG tests in 70 subjects and measure the ESR (electrical resistance of the skin) and with the application of its results to the work of Lesh (1970) was able to build in the table below that represents the objective and subjective correlates of these states.

Table 2. states of consciousness and frequency measurements

Consciousness	Measured Frequency	Types of Waves
Just he is beginning to relax with difficulty quieting the mind.	25-20	alpha and beta
Not very clear conscience or sense of anesthesia	20-16	Guests beta alpha continuous
Calm and relaxed with memories	16-13	Alpha continues without beta theta intermittent
State definite feeling of floating with increased imagination and more concentration sustained	13-10	Alfa falling Continuous theta
Living consciousness the body modification between awareness internal and external	10-8	alpha continuous theta falling Frequency
Awareness with satisfaction and deep intense alertness and calmness and detachment	8-5	Theta continuous alpha close to theta
New way of feeling by intuitive vision synthesis of opposites in a higher unity	below 4	Delta occasionally

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

One of the determinants of the results of the induction of altered states of consciousness in psychotherapy comes from Penfield and Perot (1963) who developed a study where a series of what was called in those days outside the body psychic visions were caused a that emerged not only for his epileptic patients but also in patients who had at the operating table for which they stimulated the surface of their brain. In one case study, one of his epileptic patients actually had visions of God descending from heaven.

An important factor in the development of Neurotechnology step was carried out by Persinger (1983). Persinger is the director of the neuroscience program at Laurentian University. Persinger (1983) is able to induce visions of God and other religious and mystical experiences in the laboratory by using a computer and what he calls the koran helmet was also given the nickname God helmet. His most important contribution to the induction of altered states of consciousness came when he had a vision as to the origins of spirituality in human evolution. He found that the temporal lobes of the brain are the source of most spiritual and mystical experiences= of the scientific literature.

The God helmet is a device used to induce altered states of consciousness using weak magnetic signals to direct brain activity. This can induce spiritual experiences and helps auto wing transpersonal exploration and transformation of many people. Persinger (1983) investigated some common perceptions of the inner mind by taking electromagnetic brain patterns seen in people who have near-death experiences. Persinger (1983) found that it can simulate that by applying complex significant magnetic fields in the brain that can also induce altered state of consciousness such as near-death experiences. Persinger et al (2000) conducted an experiment that tested the idea that mystical perception and stimulating the nerve activity in the brain can trigger paranormal experiences. In the experiment, volunteers were blindfolded in a soundproof chamber, this sensory deprivation allowed the mind to concentrate on electromagnetic patterns sent through the brain via a modified helmet. In the experiment, they were able to simulate the exact brain patterns that occur in near-death experiences.

Dr. Persinger (2000) suggests that his research will benefit psychotherapy by producing altered states of consciousness including near death experience, hearing voices and the sense of a presence as patients will able to deal with things like psychological depression by experiencing these altered states. Persinger (2000) suggests that these experiences are so strong that they are completely real to the person who has them. As a tool of science, the God helmet technology can bring us valuable new insight into the dark depths of the human mind. Persinger (1983) conducted experiments of the type of stimulation of the low level temporal lobes of the brain, in order to induce altered states in the subject in the experiment. After an initial feeling of floating in the air, the individual was feeling 'out of body'. Then the experiments used different subjects but whose constant is to describe their feelings with cosmic and spiritual meanings. Persinger mentions "Often intense listening experiences in which the person feels that some messages are communicated to him occurs". This transmission is perceived by the individual through a kind of feeling of "knowing what happens" without being able to necessarily say that hears a voice ". Persinger suggests that people with epilepsy, (temporal lobe dysfunction), are more likely to experiment altered states.

With the aid of Neurotechnology, people can discover hidden deep subconscious events as well as conflicts of personality offering the opportunity to research our personality and discover the depths of our psychology. Green, et al. (1970) mentioned, "every change in mental-emotional state, conscious or unconscious, is accompanied by an appropriate change in the physiological state." Our travels along with the continuous-consciousness is manifested by a wide range of psychological and physiological changes, inducing altered states of consciousness take our mental functions to places normally out of reach of our everyday consciousness, these areas are usually reserved for religion, mysticism and inges-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion of psychoactive substances. The experiences one is on a journey through the fall of consciousness into the realm of psychological experience known as the transpersonal, these transpersonal experiences are such that exceed normal limits of our existence and leave the empirical way of knowing, initiating human consciousness in a meeting with those areas of consciousness that are, in normal conditions, being largely inaccessible to us. This process of leaving the empirical normal physical limits of our existence seems to serve as further proof of what was described in this chapter before that religious, mystical and philosophical thought are related to quantum physics.

When individuals use Neurotechnology using the phenomenon of entrainment in the brain for days or weeks in a row, the out of body experience seems to be more the rule than the exception. Normally these experiences manifest as spontaneous feelings flying above a landscape. It is nothing strange that the same feeling out of the body that occurs in many different practices aimed access to altered states of consciousness as well as show as the main subject of near-death experiences. The timing and the subsequent stimulation of the two hemispheres of the brain entrainment can result with the use of Neurotechnology as Fischer and d'Aquili (1986) suggest. Much of what appears to take place within the transcendental experience of parapsychology seems to be what many of us commonly called the synchronicity. The synchronicity can be defined as a causal connecting principle of coincidence of events in space / time. Carl Jung, who is the first to describe the concept of synchronicity, saw that this state could be related to many transcendental experiences. These synchronistic events can be linked dreams, visions, meditative states and other inner experiences with tangible events in the life of the subject.

A growing number of professional researchers postulated that ESP could be linked to the alpha state (Lawrence, 1972). Dr. Edward Bokert of the American Society for Psychical Research analyzed mental states and has concluded that they are, at least in its early stages, "characterized by a highly aroused autonomic nervous system" (Lawrence, 1972) precisely what one finds in the ergotropic excitement associated with the brain and the use of neuro technologies. Dr. Charles Honorton of the Maimonides Medical Center has also found that the ESP seems to be associated with "relaxation, mild dissociation, passivity, and reduced visual imagery" (Honorton, 1970), which is commonly found when waves alpha occur with brain entrainment technologies. Indeed, Honorton found that the higher alpha production, the higher the score obtained in the individual tests ESP. It seems as if many of the psychic states that identified Grof as part of the "Experiential Extension Beyond the consensus reality and space-time" may be associated with changes in one level of consciousness to another.

Proposed Cyber-Psychotherapy System with the Use of Neurotechnology

The state of consciousness of someone can be measured by using physiological changes. Some physiological changes are typically associated with altered state of consciousness so measuring these physiological changes may provide evidence to more accurately determine the state of consciousness someone is in. Cade and Coxhead (1979) was able to map altered state of consciousness with alpha brain waves between 10 to 8 cycles.

The proposed Cyber-psychotherapy system uses EEG to show the ephemeral patterns of the electrical signals from the two hemispheres of the cortex as they are happening (Cade & Coxhead 1979). The EEG captures the users' brainwave signals. After being converted to digital form, the brainwaves are processed, and the results are wirelessly transmitted to the USB receiver. A brain mapping software interprets these signals to displays mental activity in real time. The software displays brain activity in four significant brainwave frequency bands (Delta, Theta, Alpha, Beta) and uses the headset to read data.

An application of quantum physics (Neurotechnology) in the altered states of consciousness was carried out by Persinger (1983). Persinger (1983) was able to induce visions of God and other religious and mystical experiences in the laboratory by using a computer and with what he called the Koran helmet that has also the nickname of the God helmet. He found that the temporal lobes of the brain are the source of the most spiritual experiences and other alternate state of consciousness.

This God helmet is a device to induce altered states of consciousness using weak magnetic signals to direct brain activity that can induce spiritual experiences that helps with transpersonal exploration and transformation of many people that is able to heal because of these transpersonal experiences (Persinger, 2000). It is suggested that altered states of consciousness such as sensed presence and out-of-body experience whether they are produced by magnetic, electric or other stimulations or circumstances can be most effectively explained as the changes of the relative contents and/or intensities of the test subjects' neural quantum entanglement with their surroundings including possibly spiritual environments or information (Hu & Wu, 2012).

The proposed Cyber-psychotherapy system uses the Koran helmet of Persinger (1983). The koran helmet software produces EEG signals. These are applied to the brain using modified commonly available magnetic coils. The magnetic signals are applied to the head at very low strength. The signals are short bursts, followed by intervals of silence. Each signal speaks a language that only one brain structure understands and responds. The brain has two hippocampus and two amygdalas, one on each side. When these structures respond, they can put the person in a positive altered state of consciousness.

The proposed architecture of the Cyber-psychotherapy is depicted in Figure 1. The therapist computer has installed Brain activity map software and Skype. Skype is a telecommunications software that allows verbal and text communications with the patient, the Brain activity map software allows the therapist to visualize the states of consciousness of the patient by detecting the frequency band with the highest level of activity. The therapist is able to access the EEG signals collected by the EEG headset wore by the patient. These digital signals are transmitted over the internet by using a cloud based hub such as Flexihub software (Flexihub 2016), FlexiHub is a USB over IP software solution, it enables sharing access to USB devices over Internet. The EEG headset is connected to the USB of the patient's computer via a USB wireless adaptor. The koran helmet is wore by the patient and is meant to induce altered states of consciousness by receiving modulated signals to both temporal lobes from a signal generator installed in the patient's computer.

CONCLUSION

Our present understanding of "brain entrainment technology" is still in its infancy, however, this chapter intends to open the eyes of the reader that this technology has great potential particularly for transpersonal therapies.

This chapter introduced Neurotechnology based technologies including quantum biofeedback; the latter has proven curative value for particular diseases that seem to be psychosomatic and also has been proven to help to measure state of consciousness of individuals. Transpersonal psychology was presented as a paradigm that recognizes the immortality of consciousness and relies on spiritual concepts that have roots in mystic religions as reincarnation and survival of consciousness after the brain death. The immortality of consciousness is based largely on the quantum theory explaining the origin of consciousness and its connection to the universe.

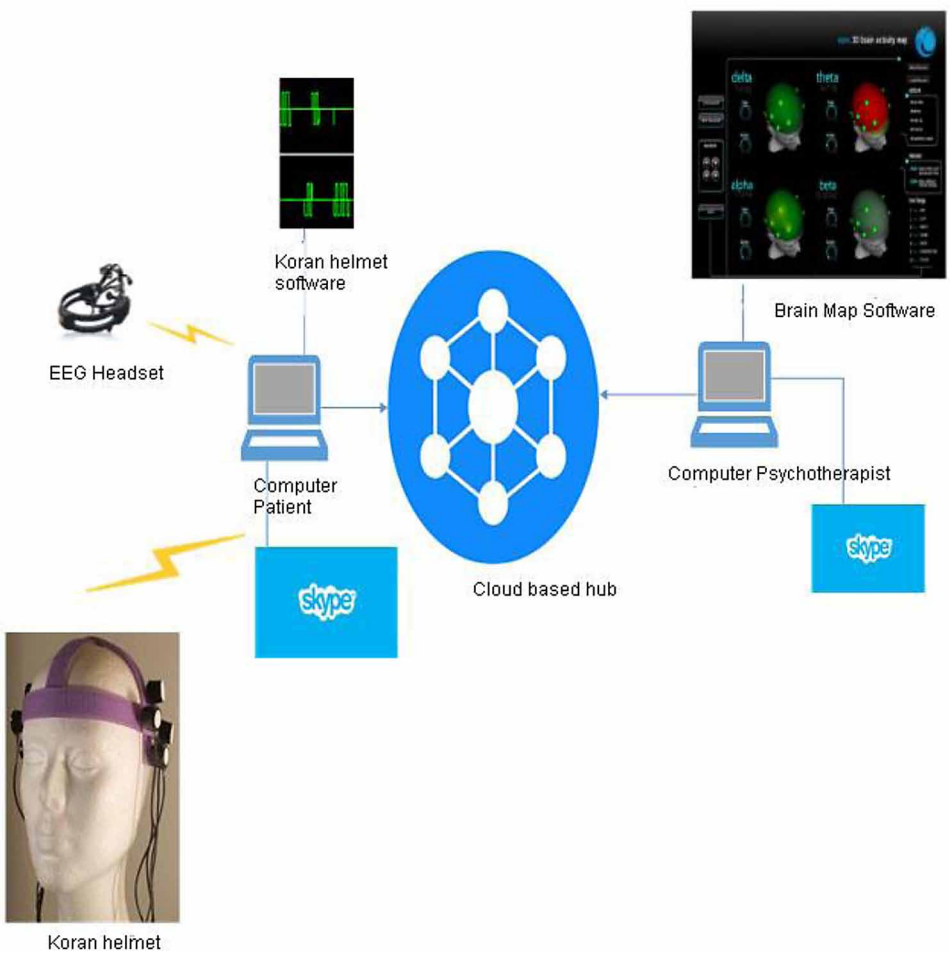
Figure 1. Proposed cyber-psychotherapy system



Neurotechnology explores the use of technologies of sound, light and radiofrequency to control the frequency of brain waves with the reason to induce altered states of consciousness. Altered states of consciousness have been proposed as therapies for healing in transpersonal psychology, these therapies recognize the spiritual essence of the individual and are based on the concept that psychological illnesses are rooted in the spirit and not in the brain. Once the patient knows the root of his or her problems, seems to find the answer to his or her anxieties and can self heal with these transpersonal experiences.

Inducing altered states of consciousness with Neurotechnology is a relatively new concept and although there are serious studies, they are not incorporated into traditional medicine more than anything by a lack of understanding of this technology in traditional medicine. The aim of this chapter is to open the eyes of the therapists about the potential of these technologies in the use of transpersonal therapies.

In this chapter a Cyber-psychotherapy system is proposed to support transpersonal psychotherapy. The system can be used to induce non-ordinary state of consciousness that can be used by transpersonal psychologists as a healing tool to cure his patients with psychological problems such as psychosis at a distance location with the help of Internet technologies. The proposed cyber psychotherapy system uses quantum signal generator for the induction of altered states of consciousness and has integrated an

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

EEG that serves as a biofeedback device in order to assess if the patient has reached the desired level of consciousness and can be used it to adjust the frequencies of the signal generator in order to improve the psychotherapy experience of the patient if necessary.

Chapter 38
Positive Technology for Helping People Cope with Stress

ABSTRACT

The emerging convergence of new technologies and health care is offering a new approach to support effective interventions. This chapter aims to describe how Positive Technology can help people cope with stress in several contexts. On the one hand, the potential capacity of sensor technologies to offer individuals the technology with which to monitor certain biological signals known to be associated with stress might serve to promote engagement with a mediated experience for stress management. On the other hand, the chapter focuses on the hedonic and eudaimonic experiences supported by technology in terms of inducing positive affective states and supporting personal growth by teaching strategies to reduce stress and enhance well-being. To further connect mediated experiences with real ones, the Interreality approach (IR) allows for the combination of assessment and intervention as inseparable parts of the general process of coping with stress.

INTRODUCTION

Stress is currently a growing problem that affects many people and significantly worsens their quality of life (Cohen, Janicki-Deverts, & Miller, 2007). Stress has various definitions that all converge upon the notion of "strain" or "the nonspecific response of the body to any demand placed upon it" (Selye, 1956).

According to Cohen et al. (Cohen et al., 2007), psychological stress occurs when people perceive that environmental demands tax or exceed their adaptive capacity. Thus, stressful experiences are conceptualized as person-environment transactions whose result is dependent on the impact of the external stimulus at three levels:

1. **Primary Appraisal:** i.e., A person's judgment about the significance of a stimulus as stressful, positive, controllable, challenging or irrelevant;
2. **Secondary Appraisal:** Which address what one can do about the situation;
3. **Problem Management Phase:** Which is aimed at regulation of the external stimulus.

According to these levels, it's evident that there is no ''best'' stress response: an optimal adaptation to environmental demands requires the ability to flexibly use coping strategies depending on the particular context and the specific stressors. In order to effectively manage stress, it is crucial to help people change the way they see the events and to learn to use coping skills.

While the mind and body's responses to stress can be helpful and adaptive in the short-term (McEwen, 1998), repeated or long-term activation of the stress response can damage the body over time (McEwen & Stellar, 1993; Seeman, Singer, Rowe, Horwitz, & McEwen, 1997), and the effects of chronic stress are common and costly (Kalia, 2002). Indeed, chronic stress is associated with lowered immune functioning, impaired memory, chronic headaches, cardiac disease and premature aging of genes, among others (Hammen, 2005; Kiecolt-Glaser, McGuire, Robles, & Glaser, 2002; Leserman et al., 2002; McEwen, 2006; Rozanski, Blumenthal, & Kaplan, 1999). Psychological stress has been linked empirically with dysregulation of facets of the human immune system. A recent review that focused on the effects of stress on inflammation in clinical populations has demonstrated that stress exposure can increase the likelihood of developing disease, as well as exacerbate pre-existing conditions (Morey, Boggero, Scott, & Segerstrom, 2015). For example, in persons with a particular genetic disposition, as well as high level of trait anxiety, repeated and early exposure to stress may result in a decreased threshold for developing anxiety (Jackson, Knight, & Rafferty, 2010; Lupien, McEwen, Gunnar, & Heim, 2009). Stressful events influence the pathogenesis of physical diseases by causing continuous negative affective states (potentially leading to feelings of anxiety and depression), which in turn may induce changes in the emotional circuitry of the brain that can contribute to stress-related psychopathology (Davidson, Jackson, & Kalin, 2000).

The range of considerable problems related to stress highlights the importance of successfully managing stress.

Is it possible to live and live well under stress? To answer this question Antonovsky proposed the salutogenesis model (Antonovsky, 1987, 1996), which deals with the issue of stress from a whole different perspective. According to Antonovsky, daily life is constantly subject to the micro- and macro-stressors that prevent a person from achieving a state of homeostasis. However, the vast majority of people are able to maintain a balanced relationship with the environment. In some cases, even under the most challenging circumstances, people succeed in developing, growing and achieving increasingly intense levels of well-being.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pathogenesis and salutogenesis are seen as complementary approaches. On the one hand, pathogenesis focuses on discovering the causes and precursors of disease and identifying disease risk factors. On the other hand, salutogenesis represents a model or framework focused on discovering the causes and origins of health and wellness (Latin *salus* = "health;" Greek *genesis* = "origins") (Antonovsky, 1979) and looks prospectively at how to create, enhance and improve physical, mental and social well-being. This paradigm focuses on locating and developing personal and social resources and adaptive tendencies, which result in effective coping behaviour and growth. Strümpfer (Strümpfer, 1995) suggested that there are six significant salutogenic strengths: the sense of coherence, hardiness, learned resourcefulness, potency, internal locus of control and self-efficacy. The salutogenic paradigm and its constructs developed from various personality theories emphasising personality growth, wellness and optimal psychological functioning (Antonovsky, 1987; Strümpfer, 1995).The work started by Antonovsky has been further developed within Positive Psychology, an emerging field that is defined as the scientific study of ordinary, positive and subjective human strengths, virtues, experiences and functioning (Seligman & Csikszentmihalyi, 2000; Sheldon & King, 2001).The progressive convergence between the objectives of Positive Psychology and the impressive advances of Information and Communication Technologies (ICTs) has led toward a new paradigm that has been named Positive Technology. This is a scientific and applied approach to the use of advanced technology for improving the quality of our personal experience (Botella et al., 2012; Riva, Banos, Botella, Wiederhold, & Gaggioli, 2012).Within this framework, this chapter aims to describe how interactive technologies can be effectively used in the assessment of stress and to support interventions for stress management. Proposals about how to combine assessment and interventions and integrate technology in these processes (Pallavicini, Gaggioli, et al., 2013; Riva, 2009a; Riva, Banos, et al., 2012) will be described at the end of the chapter.

PSYCHOLOGICAL ASSESSMENT OF STRESS SUPPORTED BY NEW TECHNOLOGIES

Typically, two main approaches are used to assess psychological stress in naturalistic conditions: the first is based on self-reporting of participants' subjective experiences and perception of stressful events; the second approach is based on sensing physiological signals associated with the stress response.

The first approach includes self-report questionnaires, such as the psychological stress measure (PSM) (Di Nuovo, Rispoli, & Genta, 2000; Lemyre & Tessier, 1988) or the perceived stress scale (PSS) (Cohen, 1986), the experience sampling method and the day reconstruction method.

The experience sampling method (ESM), also known as ecological momentary assessment (EMA), is a naturalistic observation technique that allows the capturing of participants' thoughts, feelings and behaviours at multiple times across a range of situations as they occur in the natural environment (Csikszentmihalyi & Larson, 1987). In a typical ESM study, participants are asked to fill out a form when prompted by an acoustic signal. Thanks to repeated sampling, a number of surveys are collected from each participant throughout the day, thus providing an ecologically valid and highly detailed description of the subjective quality of experience. ESM has been applied to study a wide range of behaviours and experiences, including daily stress (Serino et al., 2012). However, this procedure has high costs and places a significant burden on the participant (Scollon et al. 2003), thus limiting its practical applicability as a stress monitoring technique.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

A less expensive and time-consuming approach for assessing experience and affect in everyday life is the day reconstruction method (DRM), developed by Kahneman and colleagues (Kahneman, Krueger, Schkade, Schwarz, & Stone, 2004). It involves the retrospective recall of the study period as a continuous sequence of episodes, which are rated on a series of affect scales. DRM reports have been validated against experience sampling data, showing that this technique allows the identification of changes in affect over the course of the day with almost the same accuracy as ESM (Kahneman et al., 2004; A. A. Stone et al., 2006). However, since DRM respondents are asked to reconstruct the previous day by completing a structured self-administered questionnaire, this method is potentially susceptible to recall biases. Furthermore, it has been suggested that using retrospective measures as proxies for actual experience may result in weaker or inconsistent results, particularly when tested in connection to biologic pathways (Conner & Barrett, 2012).

The second strategy to assess stress in everyday situations is based on the analysis of physiological correlates of this experience. Psychological stressors are linked with the activation of two main neuro-physiological pathways that are involved in the maintenance of homeostasis: the hypothalamic-pituitary-adrenocortical (HPA) axis and the sympathetic-adrenal medullary system (SAM). One of the most investigated biomarker in the first system is salivary cortisol, which, together with catecholamines, is one of the end products of HPA activation (Kirschbaum & Hellhammer, 1989; G. E. Miller, Chen, & Zhou, 2007). However, due to significant between- and within-individual variation in the diurnal secretion of cortisol, the measurement of the magnitude of cortisol response is a difficult procedure that requires the application of advanced statistical approaches such as multilevel models (Hruschka, Kohrt, & Worthman, 2005; Ice, Katz-Stein, Himes, & Kane, 2004). With respect to the SAM system, heart rate variability (HRV), defined as the variation over time of the period between consecutive heartbeats, is increasingly regarded as a potentially convenient and non-invasive marker of autonomic activation associated with psychological stressors (Orsila et al., 2008). The normal variability in heart rate (HR) is controlled by the balancing activation of the (acceleratory) sympathetic and of the (deceleratory) parasympathetic branches of the autonomic nervous system. However, in stressful events or contexts, there is a trend towards increased sympathetic control and reduced vagal tone, which is associated with decreased HRV (Berntson & Cacioppo, 2004).

Higher HRV has been also associated with the availability of context- and goal-based control of emotions (Thayer, Ahs, Fredrikson, Sollers, & Wager, 2012). Based on this preliminary evidence, several authors have been experimenting with wearable heart monitors for the identification of stress levels from HRV, in both healthy and clinical populations. For example, Kim and colleagues (Kim, Seo, Cho, & Cho, 2008) used HRV patterns to discriminate between subjects reporting high and low levels of stress during the day, with an overall accuracy of 66.1%. In a similar study, Melillo et al. (Melillo, Bracale, & Pecchia, 2011) compared within-subject variations of short-term HRV measures using short-term ECG recordings in students undergoing university examination. By applying Linear Discriminant Analysis on nonlinear features of HRV for automatic stress detection, these authors were able to obtain a total classification accuracy of 90%. Kimhy and colleagues (Kimhy et al., 2009) investigated the relationship between stress and cardiac autonomic regulation in a sample of psychotic patients, using experience sampling in combination with cardiac monitoring. They found that momentary increases in stress were significantly associated with an increase in sympathovagal balance and parasympathetic withdrawal. In addition to studies that have examined the association between HRV and stress during waking hours, other recent research has proposed the use of HRV patterns during sleep as a supplement to the analy-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

sis of subjective assessments and voice messages collected during the workday (Muaremi, Arnrich, & Tröster, 2013). Results, though preliminary, have been encouraging.

As previously discussed, a fundamental issue in the measurement of stress in everyday life is that this response is idiosyncratic because it depends on an individual's perception of challenges and the skills that he/she can use to face those challenges. As a consequence, any approach aimed at inferring stress levels from "honest" physiological signals should take care not to overlook the role played by the subjective appraisal of the situation. Furthermore, since HRV values are characterized by high interindividual variability, it is important that the system be tailored to individual characteristics (Cinaz, Arnrich, La Marca, & Tröster, 2013; Morris et al., 2010).

One possible approach to developing adaptative systems for stress recognition has been suggested by Morris and Guilak (Morris et al., 2010). The strategy proposed by these authors involves identifying a subject's baseline and stress threshold in the lab by elicitation of sympathetic and parasympathetic responses, and then using this information to differentiate between stress and nonstress in daily life. A first attempt to implement this approach was performed by Cinaz and colleagues (Cinaz et al., 2013). These authors measured participants' sympathetic and parasympathetic responses during three different levels of mental workload (low, medium and high) in a controlled laboratory setting. Then they investigated whether the data collected in this calibration session were appropriate to discriminate between the corresponding workload levels that occurred during office work. To this end, individual HRV responses of each workload level were used to train the models and test the trained models on the data collected while the subjects performed normal office work, using a mobile ECG logger. Afterward, a multiple regression analysis was applied to model the relationship between relevant HRV features and the subjective ratings of perceived workload; resulting predictions were correct for six out of the seven subjects.

A possible integration between the above presented approaches is PsychLog (Gaggioli et al., 2013), a mobile experience sampling platform designed for research in mental health, which allows simultaneous collection of psychological, physiological (ECG) and motion activity data. PsychLog proposed the Italian adaptation of the ESM questionnaire applied by Jacobs and colleagues (Jacobs et al., 2007) for studying the immediate effects of stressors on mood. Specifically, psychological data are collected from surveys that can be simply customized by the experimenter by including open-ended and closed-ended questions investigating thoughts, current context (activity, persons present and location), appraisals of the current situation and mood. HR and activity data are acquired from a wireless electrocardiogram (Shimmer Research™) equipped with a three-axial accelerometer. The wearable sensor platform includes a board that allows the transduction, amplification and pre-processing of raw sensor signals, and a Bluetooth transmitter to wirelessly send the processed data. The unit is mounted on a soft-textile chest strap designed to seamlessly adapt to the user's body shape, allowing full freedom of movement. Sensed data are transmitted to the mobile phone's Bluetooth receiver and gathered by the PsychLog computing module, which stores and processes the signals for the extraction of relevant features.

Serino and colleagues (Serino et al., 2013) tested the use of PsychLog to investigate the fluctuation of individuals' experience and to detect, on the basis of psychophysiological real-time assessment, stressful events that normally occur during daily activities and situations. Promising results led the authors to consider PsychLog a valid tool to detect and offer real-time and effective interventions.

POSITIVE TECHNOLOGY INTERVENTIONS FOR STRESS MANAGEMENT

The emerging convergence of technology and health care is offering new methods and tools not only to assess but also to cope with stress. According to Botella and colleagues (Botella et al., 2012), the potentiality of technologies for psychological interventions has been demonstrated in several technological domains, including computer-assisted therapy (e.g., (Carr, Ghosh, & Marks, 1988; Proudfoot et al., 2004), virtual reality applications (e.g., (Glanz, Rizzo, & Graap, 2003; Riva, 2009b), the Internet and its evolution—Web 2.0 (e.g., Andersson, 2009; Gorini, Gaggioli, Vigna, & Riva, 2008) and mobile devices (e.g., Free et al., 2013; Phillips, Felix, Galli, Patel, & Edwards, 2010).

Specifically, there is growing empirical support for the use of these technologies for stress management training (Gorini et al., 2008; Preziosa, Grassi, Gaggioli, & Riva, 2009; Riva, 2009a).

If Positive Psychology identifies three constituents of well-being—namely positive emotions/pleasure, engagement/actualization and meaning/connectedness—positive technologies could be classified according to their effect in promoting these three features (Riva, Banos, et al., 2012):

1. **Hedonic Level:** Technologies used to induce and/or enhance positive and pleasant experiences;
2. **Eudaimonic Level:** Technologies used to support individuals in reaching engaging and self-actualizing experiences;
3. **Social and Interpersonal Level:** Technologies used to support and improve social integration and/or connectedness between individuals and groups.

These levels led to the manipulation of crucial features aimed to help people manage their stress through different positive technologies. Specifically, within this chapter we will focus on the hedonic and eudaimonic experiences supported by technologies in terms of inducing positive affective states and supporting personal growth by teaching strategies to reduce stress and enhance well-being.

Using Technologies to Foster Positive Emotional States

The first level of Positive Technology concerns how to use technology to foster positive emotional states.

Emotions occur at many levels of user experience, and positive emotions have the potential to trigger an upward spiral of flourishing (Fredrickson & Losada, 2005). According to Fredrickson (Frederickson, 2009), even though a positive emotional state is only momentary, its benefits can last in the form of traits, social bonds and abilities that endure well into the future.

The first step is to clarify the construct we are dealing with because it is essentially diffuse and conceptually difficult to define. Specifically, we want to delineate how we are using the term "emotions" and how we see it relative to related constructs such as mood and affect, according to many theorists and researchers (Batson, Shaw, & Oleson, 1992). Emotions are usually described as intense, short-lived affective states in response to particular stimuli. Moods, by contrast, are more diffuse and longer lasting, and it is often more difficult for an individual to describe the particular cause of his or her mood. The terms "affect" and "affective state" are broader and more inclusive, encompassing emotions, mood and some aspects of motivational processes.

Here we talk about positive emotions with a focus on relaxation as a positive psychological state. To induce positive emotional states in mediated experience, a typical approach is based on the exposure of emotion-eliciting materials, such as pictures, music or films (Codispoti, Bradley, & Lang, 2001; Eich,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ng, Macaulay, Percy, & Grebneva, 2007; Gross & Levenson, 1995; Philippot, 1993). A more recent approach is related to the use of Virtual Reality (VR) in inducing positive affective states. In order to develop virtual environments aimed to help people feel relaxed, one of the first aspects to consider is related to the virtual scenario in which participants can live a positive experience. Typically, virtual environments for stress management depict natural settings.

The theory at the base of the use of natural virtual environments is that restoration from stress and from mental fatigue relates to exposure to nature (Hartig, Evans, Jamner, Davis, & Gärling, 2003). Natural environments protect people against the impact of environmental stressors and offer physiological, emotional and attention restoration. Restorative environments are natural places that allow a shift towards more positively-toned emotional states and positive changes in physiological activity levels, behavior and cognitive functioning (Kaplan, 1995). In particular, immersion in a virtual computer-generated nature setting has been found to be a valid therapeutic aid in the treatment of anxiety disorders, as well as an effective tool in stress management and relaxation (Kahn, Severson, & Ruckert, 2009; Villani, Riva, & Riva, 2007). Plante and colleagues (Plante et al., 2003; Plante, Cage, Clements, & Stover, 2006) reported that individuals who interacted in a mediated environment enriched with a variety of positive visual and auditory stimulation reported greater improvement in self-efficacy and mood. Recently, computer-generated nature of VR has been demonstrated to promote restorative effects (Valtchanov, Barton, & Ellard, 2010).

Riva and Colleagues tested the potentiality of VR in inducing specific emotional responses, including positive moods (Riva et al., 2007). Results suggested the efficacy of VR as an affective medium: the relaxing virtual environments induced relaxation. Within the EMMA Project (Engaging Media for Mental Health Applications), some VR environments (Emotional Parks) were developed to induce positive states (Rosa María Baños et al., 2004; Rosa M Baños et al., 2008; Rosa María Baños et al., 2006). The strategies used to induce positive affective states within the experience in the virtual Emotional Parks combined Velten's self-statement (Velten, 1968), affective images from IAPS (Lang, Bradley, & Cuthbert, 1997) and music. The VR scenario experience was vivid and real and induced a high sense of presence that affected relaxation and the emotional response (Riva et al., 2007).

Villani and colleagues compared the efficacy of structured experiences provided through different technologies (video, audio and VR) for inducing relaxing states (Villani et al., 2007). Results of this experiment showed a significant reduction in anxiety and a significant improvement in positive emotional states, measured through self-report questionnaires and physiological parameters, but there was no difference among the media conditions. However, these results suggested two applied directions: when the goal is to produce a positive experience inducing positive emotions, the context (media form) plays the critical role; when the goal is to use the virtual experience to influence the affect, for example helping participants to cope with a problem, the content (media content) plays the critical role. This means that the virtual scenario and the technological devices can be helpful in affecting short-term psychological states, while the content of the experience plays a critical role in supporting the development of psychological skills useful to cope with real stressful situations. Participants may feel more engaged if they consider the experience to be crucial to their needs and goals (Scherer, 2001), and this is also true for mediated experiences (Villani, Repetto, Cipresso, & Riva, 2012; Villani et al., 2007; Villani & Riva, 2012). Thus, it is important to select people that recognize the importance of the proposed intervention for their well-being.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Using Technologies to Learn Strategies to Reduce Stress and Enhance Well-Being

As decribed before, the acquisition of specific skills of stress management during the mediated experience can promote a sense of personal self-efficacy and prepare people to cope with real stressful situations. According to Bandura's (Bandura, 1977) theory, once established, self-efficacy tends to generalize to other situations. Indeed, once acquired, these competencies assigned to internal factors become a means to the management of stressful situations, and they can be transferred and applied to other contexts.

According to this view, three approaches aimed to enhance well-being and strengthen specific mental abilities to cope with stress have attracted some interest: relaxation practices, meditation and stress management training.

Guided Relaxation Practices

The use of positive mediated interactive experiences to help people manage stress represents an innovative perspective. In this view, several studies have been carried out in the last ten years to verify the effectiveness of relaxation protocol supported by new technologies.

In a pilot study, Villani et al. (Villani et al., 2007) found that, after a brief protocol of two sessions where the virtual experience was accompanied by a relaxing narrative, people could learn relaxation strategies. These results led the authors to develop an extended stress management protocol (six sessions) that integrated other strategies. To develop the extended protocol, Villani and Riva (Villani & Riva, 2012) considered stress as having multiple components that typically involve cognitive, experiential, physiological and behavioral response systems that require multiple levels of analysis (Folkman, 2009). In accordance with Murphy (Murphy, 1996), authors combined different strategies used in cognitive-behavioral therapy (CBT) to yield better stress management than single-strategy programs. Specifically, the protocol aimed to increase emotional awareness (Greenberg, 2004), to learn to control emotions and to relax (Borkovec & Costello, 1993), to induce positive emotions (Folkman, 2008; Fredickson, 2001) and to substitute negative emotions through the imagination process (Roemer & Orsillo, 2002). Relaxation practices included in the training were autogenic training (Schultz & Luthe, 1969), Progressive Muscular Relaxation (Jacobson, 1938) and breathing techniques. Authors demonstrated that interactive media could be usefully used to reduce stress.

Recently, Gaggioli and colleagues (Gaggioli et al., 2014) carried out a block randomized controlled trial involving participants recruited from two different worker populations—teachers and nurses—that are recognized as highly exposed to psychological stress. The experimental group received a 5-week treatment course based on the Interreality paradigm that combines experiential virtual scenarios with real-time monitoring and support using advanced technologies (see the last paragraph of the chapter for a deeper description of the Interreality approach). Relaxation was induced through immersion in a natural scenario selected by the subjects where they could move and interact (see Figure 1).

The experience also integrated different pre-recorded audio narratives describing the specific setting and guiding the execution of different progressive muscle relaxation/deep breathing exercises. The control group received five weeks of traditional stress management training based on cognitive-behavioral therapy (CBT), and the waitlist group was reassessed and compared with the two other groups five weeks after the initial evaluation.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The natural interactive scenario

Although both treatments were able to significantly reduce perceived stress better than the waitlist group, only experimental group participants reported a significant reduction in chronic trait anxiety and a significant increase in the emotional support skill. These studies suggest the importance of integrating relaxation practices with other strategies in stress management interventions supported by new technologies.

Online and Mobile Meditation and Mindfulness

Many people use meditation to treat stress and stress-related conditions and to promote general health (Goyal et al., 2010). Interest in meditation, which comes from Eastern traditions that emphasise lifelong growth, has rapidly grown during the past 30 years in Western. The umbrella of meditation covers various methods whose backgrounds and techniques are quite different. Thus, meditation refers to a family of techniques that have in common a conscious attempt to focus attention in a non-analytical way (Shapiro Jr, 2008).

According to a recent review (Goyal et al., 2014), meditation programs can reduce the negative dimensions of psychological stress more than they can improve the positive dimensions of health and well-being. Uncertainty remains about the role of the specific features of the different meditation techniques in actually influencing psychosocial stress outcomes (Chiesa & Malinowski, 2011; Sedlmeier et al., 2012).

All forms of meditation imply that more time spent meditating will yield larger effects. Thus, long-term trials may be optimal to examine the effect of meditation on many health outcomes.

Among the meditation approaches, mindfulness meditation can be described as a process of present-focused awareness or mindfulness (Bishop et al., 2004; Kabat-Zinn, 1990; Kabat-Zinn, 2003). Several interventions using the Mindfulness-Based Stress Reduction protocol demonstrated good results in reducing levels of stress, anxiety and depression in both clinical and nonclinical populations (Chiesa, Calati, & Serretti, 2011; Eberth & Sedlmeier, 2012; Hofmann, Sawyer, Witt, & Oh, 2010; J. J. Miller, Fletcher, & Kabat-Zinn, 1995; Shapiro, Schwartz, & Bonner, 1998; Shonin, Van Gordon, & Griffiths, 2013).

Despite the efficacy of these programs, the commitment required could cause barriers to its widespread application (Carmody & Baer, 2009). In fact, these programs are time-intensive and require both in- and out-of-session practice; they are also sometimes difficult for people with minimal experience with meditation.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

To overcome these limitations, both online interventions and mobile applications offer several advantages, and both can provide helpful mental health resources that may be inaccessible otherwise. The Internet and mobile apps allow providers to deliver interventions, with reduced cost to the health services and to patients, to complete courses in their own comfortable, familiar surroundings (Powell et al., 2013; Zetterqvist, Maanmies, Ström, & Andersson, 2003).

There is growing evidence for online mindfulness courses being as effective as other face-to-face interven- tions (Glück & Maercker, 2011; Krusche, Cyhlarova, King, & Williams, 2012; Morledge et al., 2013). In this view, Krusche and colleagues (Krusche, Cyhlarova, & Williams, 2013) investigated the feasibility and effectiveness of an online mindfulness course for perceived stress, anxiety and depression. The programme consisted of 10 sessions, guided meditation videos and automated emails with elements of Mindfulness-Based Stress Reduction and Mindfulness-Based Cognitive Therapy. Participants could complete the programme at a pace that suited them individually (minimum length of four weeks), and the study evaluated the amount of practice as a mediator of change. Authors found that participants who were more stressed, depressed and anxious at baseline tended to practice less and take more time to complete the course. A longer course time predicted less of a change in stress, anxiety and depression, while more mindfulness practice significantly improved stress, anxiety and depression outcomes when accounting for baseline severity. Results for the effectiveness and feasibility of online mindfulness courses look promising.

Recently, brief mindfulness meditation protocols have also been integrated in self-help interventions supported by new technologies and mobile apps (Ahtinen et al., 2013; Cavanagh et al., 2013; Ly et al., 2014; Warnecke, Quinn, Ogden, Towle, & Nelson, 2011). The efficacy of brief mindfulness meditation protocols have been confirmed for nonclinical populations also at risk for stress-related health problems (Klatt, Buckworth, & Malarkey, 2009; Olivo, Dodson-Lavelle, Wren, Fang, & Oz, 2009).

Although a wide selection of mindfulness-based mobile apps (MBMAs) are available on the market (Plaza, Demarzo, Herrera-Mercadal, & Garcia-Campayo, 2013), the effectiveness of self-help intervention aimed toward helping people practice mindfulness techniques has not been broadly studied yet.

Recently, the effectiveness of a mobile app focused on a specific technique called thought distancing (i.e., a mindfulness technique that requires a person not to react in response to one's own thoughts but to be aware of them and observe them while they go away), which aims to enable decentering, has been tested (Chittaro & Vianello, 2014). Good results have been obtained in terms of achieved mindfulness, perceived level of difficulty and degree of pleasantness.

Carissoli and colleagues (Carissoli, Villani, & Riva, 2015) tested the effectiveness of a brief self-help protocol inspired by mindfulness meditation and delivered through a smartphone app in reducing stress for the nonclinical population. Authors used a controlled pragmatic trial that represents a trial typically designed to test the effectiveness of interventions in real life in order to maximize their applicability and generalizability (Patsopoulos, 2011). Sitting meditation was the focus, consisting of different exercises, such as mindful breathing and thought distancing. Authors found a reduction in hyperactivity and accelerated behaviors, which is consistent with meditation practice as mindfulness is a type of meditative technique that emphasizes an observant and nonreactive stance toward one's thoughts, emotions, and body states. Nevertheless, authors suggested that participants would need more time to become confident with the meditation approach—more time spent meditating could yield larger effects (Goyal et al., 2014).

Cyber-Stress Inoculation Training

SIT, or stress inoculation training (Donald Meichenbaum, 1977; D. Meichenbaum, 1985), represents a validated short, semistructured and active approach to managing psychological stress (for a review, see Stetz et al., 2007). SIT is a type of training conceived to prepare individuals for stressful events by helping them diminish the potential for a negative cognitive, psychological and behavioral reaction.

SIT is based on the premise that to effectively manage stress, it is crucial to change the way people see the events and how they use their own coping skills. Thus, SIT is generally implemented through gradual and repeated exposure to the elements previously identified as stressors. The clinical rationale behind this approach is to ''inoculate'' the stressor in a person's experience, in combination with the acquisition of effective coping skills, so that people could be prepared when they inevitably encounter similar situations in daily life.

The general objectives of SIT are threefold and related to the three phases of the protocol. First, SIT aims to change the maladaptive stress response of the individual, thanks to the acquisition of active coping strategies. Thus, the first phase, named conceptualization, aims at making individuals aware of the transactional nature of psychological stress (Lazarus & Folkman, 1987) by giving them general information about the main effects and symptoms that could appear in different stressful situations. Second, SIT aims to develop the activity of self-regulation. Thus, the second phase, named skill acquisition and rehearsal, aims at teaching individuals to manage emotions and maladaptive behaviors, as well as learn new active coping skills. Third, SIT aims to explore and modify dysfunctional cognitive appraisal related to stressful events. Thus, the last phase, named application and follow-through, aims at increasing self-efficacy (Bandura, 1998) by helping individuals use the acquired coping skills in real contexts. Typical techniques used in this phase are imaginative rehearsal (in which an individual has to image stressful scenarios and think about coping strategies), behavioral rehearsal (role-playing) and the graded in vivo exposure.

The main objectives and three stages of SIT have been recently implemented in cyber-interventions based on SIT methodology (cyber-SIT), which utilise advanced technologies to create simulations to teach individuals how to effectively cope with psychological stress (Stetz et al., 2007; Wiederhold & Wiederhold, 2006).

In a recent review, Serino and colleagues (Serino et al., 2014) intended to outline the state-of-the-art of cyber-SIT interventions. According to the results of this systematic review, cyber-SIT appears to be a promising clinical approach, and there are interesting researches that effectively combined traditional SIT clinical protocol within advanced technologies. However, at the moment it is an emerging field of research. Thus there are still few studies in the literature meeting the requirement of using cyber-SIT in all its clinical elements and phases. Authors found that two main groups of technologies have been used for delivering cyber-SIT: virtual-interactive environments and mobile technologies. Villani and colleagues tested the effectiveness of a cyber-SIT delivered through mobile phones by comparing it with a control group (neutral video through mobile phones) in a sample of oncology nurses (Villani et al., 2013). Results showed psychological improvement of the experimental group in terms of anxiety state, anxiety trait reduction and coping skills acquisition.

Furthermore, up to now, cyber-SIT interventions have been applied to different contexts, targeting both chronic stress (such as PTSD) and acute stress related to a specific situation (such as stress experienced before an examination). For this reason, Serino and colleagues (Serino et al., 2014) suggested the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

importance of critically choosing the sampling strategies and defining the inclusion/exclusion criteria according to the specific aim of the protocol.

Practically, how may advanced technologies efficiently support all three phases of SIT? As far as the conceptualization phase, the interactive virtual worlds can use motivation to teach users about the transactional nature of stress, its main causes and effects (Riva, Vigna, et al., 2012). Furthermore, thanks to multimedia presentations where information is enriched and distributed through several channels, new technologies could enhance both the reception of instructional material and also the profound understanding of it (Mayer, 2009).

As far as the skill acquisition and rehearsal phase, advanced technologies can help individuals in acquiring effective coping skills, such as relaxation and meditation strategies. Bandura (Bandura, 2004) suggested that interactive features are the greatest strength of new media. Thus, computer-based feedback can be specified to accommodate the individual's motivations, current self-efficacy levels, unique obstacles and setbacks and progress toward specific goals and positive reinforcements (Bordnick, Traylor, Carter, & Graap, 2011; Fox & Bailenson, 2009).

Finally, as far as the application and follow-through phase, digital environments can be used for patients' exposure to stressful stimuli. Researches demonstrated that the exposure to multimedia/virtual contents has therapeutic benefits for participants (Emmelkamp et al., 2002). Within a cyber-SIT, this could be particularly useful in the last phase by creating controlled, graded and safe simulations of stressful scenarios to allow participants to use the acquired coping skills.

Beyond the exposure, there are currently other techniques used to consolidate the acquired coping skills, such as self-attribution procedures, relapse prevention procedures, helping others with similar problems and booster sessions (Donald Meichenbaum, 1977; Meichenbaum, 1985).

Frontiers of Biofeedback

Several studies showed interesting results that support the feasibility of detecting affective states through psychophysiological data acquisition and analysis (Giakoumis et al., 2012; Magagnin et al., 2010). Led by Rosalind Picard, a computing group at MIT published several studies that highlighted the use of psychophysiological measures to deduce and classify emotional states while study participants were performing different kinds of PC activities (Mauri et al., 2010; Picard, 2000).

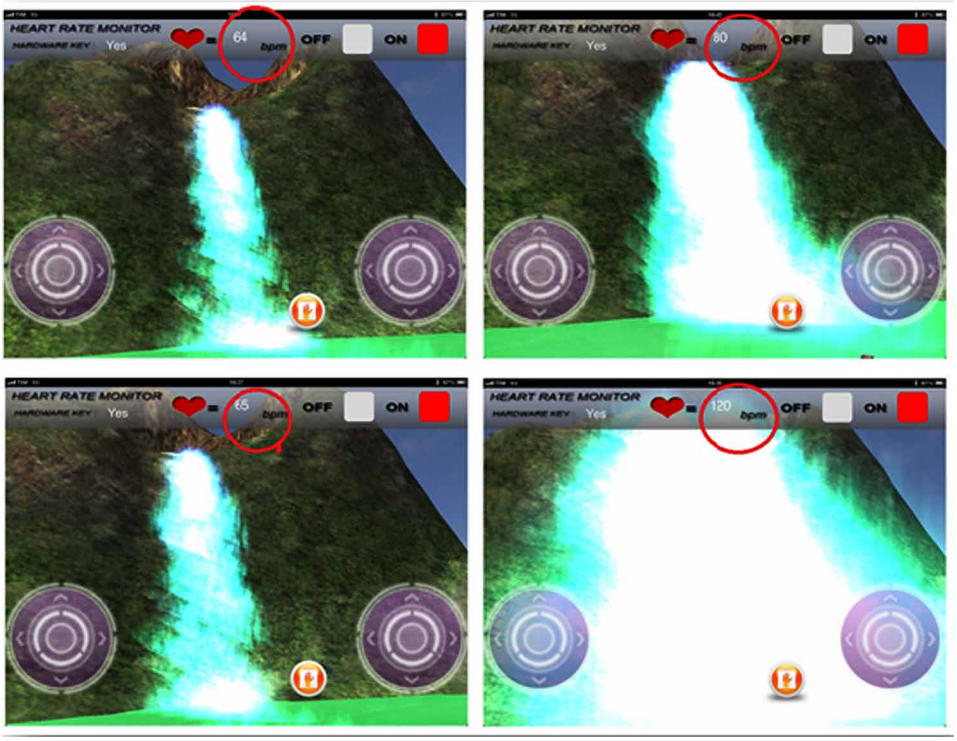
The potential capacity of sensor technologies to augment the mediated experience (through objective, automatic monitoring and feedback) has attracted some interest (Alcañiz, Botella, Banos, Zaragoza, & Guixeres, 2009). Thus, offering individuals the technology with which to monitor certain biological signals, known to be associated with stress, both over time and in real-time biofeedback, might serve to promote engagement with a mediated program for stress management.

Specifically, to detect changes in the physiological and affective states of subjects, researchers highlighted the usefulness of wearable biosensors in mobile platforms, virtual reality environments (Pallavicini, Cipresso, et al., 2013; Raspelli et al., 2012; Villani et al., 2012), or both (Repetto et al., 2013). This can be essential for situations in mobile clinical settings to share that information with the subject and, eventually, interested caregivers, such as professional medical staff, relatives, or even friends (see Figure 2).

An accurate electrocardiogram (ECG) analysis algorithm can be developed to elaborate and process signals generated from the wearable biosensors for effective real-time biofeedback. The QRS complex needs to be detected to generate heart rate and RR intervals. Thus, an accurate QRS detector is impor-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Biofeedback screenshots



tant in order to extract reliable HR or RR intervals to make meaningful HRV analysis and a correlation to mental stress. However, an accurate QRS complex detection may be difficult due to the physiological variability of the QRS complex and various types of noise that can be present in the ECG signal. Typical noise artifacts in ECG signals include power line interference, electrode contact noise, motion artifacts, and baseline drift (Friesen et al., 1990). Wearable monitoring systems used for out-of-clinic daily activity tracking utilise motion artifacts the most, where it is important to measure physiological signals accurately anytime and anywhere.

There are numerous detection methods for QRS complexes, including the Pan-Tompkins method (Pan & Tompkins, 1985). Moreover, morphological approaches were developed for baseline correction and noise suppression in clinical ECG signals (Sun, Chan, & Krishnan, 2002).

HRV measures provide a great opportunity to treat stress by using biofeedback based on relevant indexes. In a controlled clinical trial, Gaggioli and colleagues (Gaggioli et al., 2013) specifically tested HRV biofeedback for stress training and found results supporting the idea that it works very well when used alongside cognitive behavioral therapy. Furthermore, they found that specific indexes can be used for stressed patients—in particular temporal indexes, such as NN50, RMSSD, and spectral indexes, such as LF/HF (Malik, 1996). The combined use of respiration techniques and biofeedback would help in developing cognitive strategies for cardiorespiratory interventions aimed to reduce stress levels. Moreover, the use of LF/HF index gives patients indirect access to their sympathovagal balance information, which could greatly improve the impact of treatment for high stress levels.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another interesting challenge that could be further investigated is represented by electroencephalography (EEG), and, in particular, the use of neurofeedback. Asymmetry on frontal brain activation can be measured through Alpha waves from the EEG, which be used as neurofeedback for stress patients (Millings et al., 2015).

COMBINING ASSESSMENT AND INTERVENTION: THE INTERREALITY APPROACH

Assessment and intervention are inseparable parts of one general process and represent a dynamic spiral across time. To better integrate each other, Riva and colleagues (Pallavicini, Gaggioli, et al., 2013; Riva, 2009a; Silvia Serino et al., 2013) suggested the use of the "Interreality" paradigm (IR), which combines assessment and intervention within a hybrid environment and connects the physical and virtual worlds. The basic idea of IR intervention is to bridge mediated experiences with real experiences. In the IR strategy, behaviour in the physical world influences experiences in the virtual one, and behaviour in the virtual world influences the experience in the real one.

The assessment is conducted continuously in the virtual and real worlds through the tracking of individuals' behavioural and emotional status over time in the context of realistic task challenges. At the same time, the information is constantly used to improve both the appraisal and the coping skills of the patient through a conditioned association between effective performance state and task execution behaviors.

Within a recently funded European project "INTERSTRESS – Interreality in the management and treatment of stress-related disorders," a stress management protocol based on the Interreality paradigm has been proposed. The INTERSTRESS Project is intended to help individuals effectively manage psychological stress through the acquisition of techniques like relaxation and coping strategies within six weeks' treatment supported by advanced pervasive sensors and computing. Specifically, Gaggioli et al. (Andrea Gaggioli et al., 2014) evaluated the efficacy of Interreality for the management and prevention of psychological stress and compared it with a similar non-technological protocol based on the CBT approach. In that case, the main feature of Interreality was a twofold link between the virtual and the real world achieved through experiential virtual scenarios (fully controlled by the therapist and used to learn coping skills and improve self-efficacy) with real-time monitoring and support (identifying critical situations and assessing clinical change) using advanced technologies (virtual worlds, wearable biosensors, and smartphones). Findings provide initial evidence that a technology-enhanced IR protocol provides better outcomes than the traditionally accepted gold standard for psychological stress treatment, CBT, in terms of reduction of chronic trait anxiety and improvement of emotion-related coping skills.

Stressed people can be continuously assessed in the virtual and real worlds by tracking their behavioural and emotional status in the context of challenging tasks (customization of the intervention according to the individual characteristics), and feedback is continuously provided to improve individuals' skills (improvement of self-efficacy).

It is possible to identify two potential clinical advantages of the IR strategy. First, the integrated and quantitative assessment of the user's stress level using biosensors: the level of stress is continuously assessed in the virtual world and in the real world by recording the participant's behavioural and emotional status for the decision support system. Second, the provision of warnings and motivating feedback to improve self-awareness, compliance and long-term outcomes: on the basis of the decision support system,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

participants constantly receive feedback to improve their appraisal and coping skills in an entertaining and motivating manner both in clinical and mobile settings (Pallavicini, Gaggioli, et al., 2013; Riva, 2009a).

To better understand the potential of the IR approach, it is helpful to take another example—not specifically linked to a clinical scenario—such as the job interview, where individuals can be effectively helped to cope with stress (Villani, Cipresso, & Repetto, 2014). Typically, applicants feel anxious and stressed both because talking to strangers could provoke anxiety and because they could perceive a lack of control of the situation. Mediated interventions based on the different protocols (see previous paragraphs) can give applicants useful information, help them in acquiring effective coping skills, such as relaxation strategies, and let them experience, with controlled, graded and safe simulations, their competence to cope with a job interview. Applicants can do this training anytime and anywhere thanks to mobile technologies. Thanks to psycho-physiological assessment enabled by biosensors, the applicant's emotional states can be monitored during training to tailor the proposed experiences, to provide real time feedback and to administer positive reinforcement of good conduct. Furthermore, this assessment is possible until just a few minutes before undertaking a job interview. If biosensors reveal a high level of anxiety, the system could increase the comfort level by proposing ad hoc relaxation exercises and, by lessening anxiety, the system can support the applicant's performance.

The IR approach constitutes a sound foundation and rationale for future researches in technology-enhanced protocols for psychological stress management.

FUTURE RESEARCH DIRECTIONS

Despite the opportunities described in the chapter about how integrating technology in positive psychology can help people cope with stress, we have to consider important challenges that need to be dealt with.

First, as described in the chapter, it's easier to focus on the hedonic dimension of the experience by inducing positive emotional states such as relaxation, instead of developing the eudaimonic dimension by improving coping skills and promoting resilience. Nevertheless, as previously shown, if the goal is to promote self-empowerment, the better strategy is to work on both levels.

Second, to our knowledge there are still few studies that tested the effectiveness of experiences supported by technology and compared it with traditional methods. Because many stress management apps, blogs and digital tools are already available in the market, and the popularity of these services is increasing among people, trials showing the effectiveness of these approaches are needed. Pragmatic trials, typically designed to test the effectiveness of interventions in real life in order to maximize their applicability and generalizability (Patsopoulos, 2011), are encouraged.

Third, most apps and tools have been developed thanks to the support of research funding. As a consequence, they are focused on the rationale underlying the proposed content, but too often they don't have adequate usability features. Future researches should test and enhance the user experience of stress management apps and technological tools.

Finally, over the potential opportunities, it will be important to conduct more research on the possible inconvenience of using technology in daily routines so as to preclude constant accessibility and overuse (Thomee, Harenstam, & Hagberg, 2011).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

This chapter aimed to describe how positive technologies could be involved in helping people cope with stress.

On the one hand, thanks to the combination of traditional assessment measures of stress and the analysis of physiological correlates of this experience, it is possible to overcome limitations related to self-reported data and move towards self-tracking. Self-tracking is a fast-growing trend in the field of e-health that involves the collection of biological, physical, behavioural or environmental information that can be integrated within a feedback loop of introspection and self-experimentation. The fecund convergence between ICTs and wearable biosensors allows personal health data to be collected, aggregated, visualized, collated into reports and shared (A. Stone, Shiffman, Atienza, & Nebeling, 2007).

On the other hand, the emerging convergence of technology and health care is offering new methods and tools not only to assess but also to cope with stress. In this view, there is growing empirical support for the use of several technologies for stress management protocols.

This chapter focused on the hedonic and eudaimonic experiences supported by technologies in terms of inducing positive affective states and supporting personal growth by teaching strategies to reduce stress and enhance well-being. If natural virtual scenarios and technological devices can be helpful in inducing positive emotions, the content of the experience plays a critical role in changing the affective component and in supporting the development of psychological skills useful to coping with real stressful situations. To reach this goal, three approaches aimed to enhance well-being and strengthen specific mental abilities to cope with stress (such as guided relaxation practices, online and mobile meditation and mindfulness and cyber-stress inoculation training) have been described.

Assessment and intervention are inseparable parts of one general process and represent a dynamic spiral across time. The "Interreality" paradigm (IR) allows the combination of both and a connection between mediated experiences with real experiences.

To conclude, the positive technology approach offers researchers and clinicians new effective opportunities for the assessment and treatment of psychological stress in several contexts.

AKNOWLEDGMENT

This work was partially supported by the Italian funded project "VRehab. Virtual Reality in the Assessment and TeleRehabilitation of Parkinson's Disease and Post-Stroke Disabilities" - RF-2009-1472190.

KEY TERMS AND DEFINITIONS

Biofeedback: A technique people can use to learn to control their body's functions. With biofeedback, people are connected to electrical sensors that help them receive information (feedback) about their body (bio). In essence, biofeedback helps them focus on making subtle changes in their body; it is often used as a relaxation technique.

Mindfulness: A type of meditative technique that emphasizes an observant and nonreactive stance toward one's thoughts, emotions and body states. It involves purposeful attention to daily activities.

Physiological Signals: The body generates physiological signals during the functioning of various physiological systems. Hence, physiological signals hold information that can be extracted from these signals to find out the state of the functioning of these physiological systems.

Relaxation: Relaxation training can include several strategies that help a person to relax. Relaxation techniques are often employed as one element of a wider stress management program and can decrease muscle tension, lower blood pressure and slow heart and breath rates, among other health benefits.

Stress Inoculation Training: Developed by Meichenbaum in the 1960s, SIT is a form of cognitive restructuring. It is a method of changing an individual's thinking patterns about themselves and their lives. It is based on the assumption that people experience stress because they interpret an event or situation in catastrophising ways and their internal dialogue (their thoughts) are negative.

Chapter 39
Efficacy of Art Therapy in Treating Patients with Paranoid Schizophrenia

Deepali Bedi
Sukoon Psychotherapy Center, India

ABSTRACT

Paranoid Schizophrenia chronic mental illnesses according to DSM-IVTR characterized by the presence of delusion of persecution, suspicious, distrusting, guarded, reserved, tensed, and also sometimes hostile or aggressive. Patients also perceive exaggerated warmth and friendship by the professionals as attempt at bribery, manipulation or exploitation. But therapeutic relationship between patient and the professional is integral to the recovery process and the outcome. Good communication on the part of health care professionals is an essential element in developing the strong practitioner-patient relationship necessary in the treatment of schizophrenia. Professionals are usually at a look out for tools to build a working alliance best used in such cases. Usually behavioural therapy, supportive therapy and family therapy are used for such patients. But sometimes with chronic and resistant client will get stuck at the initial rapport itself. At this stage probably art therapy as an advance intervention strategy to work with patient as an advanced intervention strategies and treatment.

INTRODUCTION

Art therapy is based on the idea that the creative process of art making is healing and life enhancing and is a form of nonverbal communication of thoughts and feelings (Malchiodi, 1996). Like other forms of psychotherapy and counselling, it is used to encourage personal growth, increase self-understanding, and assists in emotional reparation and has been employed in a wide variety of settings with children, adults, families, and groups. It is a modality that can help individuals of all ages create meaning and achieve insight, find relief from overwhelming emotions or trauma, resolve conflicts and problems enrich daily life, and achieve an increased sense of well-being (Malchiodi, 1998). Art therapy supports the belief that

all individuals have the capacity to express themselves creatively and that the product is less important than the therapeutic process involved. The therapist's focus is not specifically on the aesthetic merits of art making but on the therapeutic needs of the person to express. With the advent of brief forms of therapy and the increasing pressures to complete treatment in a limited number of sessions, therapists are finding that art activities help individuals to communicate relevant issues and problems quickly, thus expediting assessment and intervention. Even the simplest drawing task offers unique possibilities for expression that complements and, in many cases, helps a child or adult to communicate what words cannot.

APPROACHES TO ART THERAPY

Rubin in his book, Approaches *to Art Therapy* (Rubin, 1987/2001), discussed the diversity of theoretical positions within the field of Art therapy.

Psychodynamic Approaches

The ideas of Freud and his followers have been part of art therapy since the earliest days, although contemporary writers are more likely to apply terms such as "transference" and "the defense mechanisms" to articulate a position rather than employ classic psychoanalytic techniques with any degree of orthodoxy. Kramer, Rubin, Ulman, and Wilson (all cited in Rubin, 1987/2001) and Levick (1983) all use psychoanalytic language and concepts. Interpretations of the newer developments in psychoanalysis such as the theories of Klein (Weir, 1987), self-psychology (Lachman-Chapin) and object relations theory (Robbins) can also be found in the art therapy literature (both cited in Rubin, 1987/2001). With his emphasis on images from the unconscious, it was natural for Jung's concepts of analytical and archetypal psychology to cross over into art. Work by Edwards and Wallace (both cited in Rubin, 1987/ 2001), Mcconeghey (1986), and Schaverian (1992) all reflect this emphasis.

Humanistic Approaches

Elkins and Stovall (2000) suggest that only a small number of art therapists operate from a humanistic position (among humanistic, Gestalt, existential, and client centered; the highest response was to the first category with 2.9%). Yet if these approaches can be defined as sharing "an optimistic view of human nature and of the human condition, seeing people in a process of growth and development, with the potential to take responsibility for their fate" (Rubin, 1987/2001), these figures belie a sentiment held by many art therapists. Garai (cited in Rubin, 1987/2001) has written from a general humanistic position, Rogers (1993) and Silverstone (1997) use a person-centered model, and Dreikurs (1986) and Garlock (cited in Rubin, 1987) have adapted ideas first articulated by Alfred Adler. Other models that fall under the humanistic heading include existential (Moon, 1990/1995), phenomenological (Betensky, 1995), and gestalt (Rhyne, 1973/1995) approaches.

Learning and Developmental Approaches

Perhaps because they are perceived to be mechanistic, those psychological theories that emphasize learning tend to be less popular with art therapists. In the Elkins and Stovall (2000) survey, cognitive-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

behavioural, cognitive, developmental, and behavioural received an endorsement of over 2%. Yet there are art therapy authors whose work has been informed by these theories.

Silver (2000) has written extensively on assessment using a cognitive approach, and the work of Lusebrink (1990) and Nucho (1987) is based in general systems theory. Art therapists working with children with emotional and developmental disabilities have also adapted concepts from developmental (Roth, cited in Rubin, 1987/2001).

Family Therapy and Other Approaches

A number of writers (Landgarten, 1987; Linesch, 1993; Riley & Malchiodi, 1994; Sobol, 1982) have built on Kwiatkowska's early family work, particularly in California where art therapists become licensed as marriage and family therapists. Riley (1999) also incorporates concepts from narrative therapy into her work. Relational (Dalley, Rifkind, & Terry, 1993) and feminist (Hogan, 1997) approaches question the hierarchy in the client/therapist relationship and empowering the client and have also shaped contemporary art therapy practice. Publications by Horovitz-Darby (1994), Farrelly-Hansen (2001), and Mcniff (1992) reflect an emphasis on spiritual and philosophical concepts over psychological theory. Franklin, Farrelly-Hansen, Marek, Swan-Foster, and Wallingford (2000) describe a transpersonal approach to art therapy. Allen (1992) called for a reversal of the perceived trend in overemphasizing the clinical orientation and encouraged art therapists to refocus on their artist identity. Writings by Lachman-Chapin (1983) and Knill (1995), who espouses an expressive arts therapies approach (Moon, 2002) reflect this studio approach to theory and practice.

Clinical Implication of Art Therapy

Art expression has been extensively used in therapy with children for several reasons. It is a natural language for most children and can be a valuable modality in enhancing expression of trauma, distress, or loss (Malchiodi, 1997, 1998). Also, children do not have the verbal capacity to articulate crisis and for those who have been violated or abused, art is a way to communicate feelings and experiences without words. Gross and Haynes (1998) hypothesized that there may be several reasons why art expressions are helpful adjuncts in child therapy:

1. They may reduce anxiety and help children feel more comfortable with the therapist.
2. They may increase memory retrieval.
3. They may help children organize their narratives.
4. They may prompt children to tell more than they would during a solely verbal interview.

Mental health workers may refrain from using art in counselling adults because many adults feel inadequate about their skills or embarrassed over expressing themselves artistically (Gladding, 1998). Nevertheless, there are many documented benefits of employing art as a part of a treatment plan with adult clients including:

1. Taps the unconscious and helps individuals express covert conflicts, bringing into awareness thoughts and feelings that were previously hidden (Liebmann, 1990).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Acts as a metaphor for the conflicts, emotions, and situations experienced by clients (Ulak & Cummings, 1997).
3. Assists people in picturing themselves or their situations in a concrete, objectified manner (Rubin, 2001).
4. Acts as a bridge between the counsellor and the client, especially when the subject matter is too embarrassing or difficult to talk about, such as family violence, illicit relationship and abuse (Brooke, 1995; Liebmann, 1990; Trowbridge, 1995).
5. Creates a visible trail, provides a tangible record, and allows clients and counsellors to review a series of past sessions and note development and change (Ganim, 2000; Liebmann, 1990).
6. Inspires and helps people become more connected with the transcendent and growth sides of their personalities (Mills & Crowley, 1986).
7. Provides a process that is energy enhancing (Kahn, 1999); art gets clients "doing" rather than thinking and therefore can be more activating than verbal counselling (France & Allen, 1997).
8. Can easily be combined with other expressive arts such as music, movement, creative writing, and imagery (McNiff, 1997).
9. The case mentioned here very well illustrates most of the benefits of using Art therapy with the client.

Psychoanalytic theories postulated that various symptoms of Schizophrenia have symbolic meaning for individual patient (Sadock & Sadock, 2003). Freud (1920) said that the symptom carries a meaning and is connected with the experience of the patient. According to Jones (1916), 'only what is repressed is symbolised; only what is repressed needs to be symbolised'. Grunbaum (1986) reminded that 'symptoms, as compromise formations, have traditionally been viewed as "symbols", but they are "symbols" in the no semantic sense of being substitutive formations affording replacement satisfactions or outlets, not linguistic representatives of their hypothesized unconscious causes'

The following case of a client who is married and denies her actually identity is because of her unconscious desire to be the wife of the boy she ones loved. In the reality her desire is unacceptable and illicit so her illness gives expression to her illicit desire.

In her art work she drew hearts and flowers on a same stem depicted her conflict. She wants to be a wife of the boy she loved but current a mother of beautiful children who she also loves. There was a huge social taboo to her desire but she could express this much easily with minimum anxiety through art work.

A house without an entry metaphorically depicted her delusive world which no one could entry. It was also about her anger of being unable to meet her loved ones in her ward.

Drawing of umbrella depicted the metaphor of longing for the love and protection of her father.

Thus clinically Art therapy is a very useful modality even with adults specially where the client if not able to verbally express their conflicts due to various reasons.

Art Therapy with Client Having Paranoid Schizophrenia

A patient with paranoid schizophrenia is mainly characterized by the presence of delusion of persecution i.e. a false, firm and fixed believe or a suspicion that people would harm him or her. The said patients are suspicious, distrusting, guarded, reserved, tensed, and also sometimes hostile or aggressive (Sadock & Sadock, 2003). The patient is likely to perceive exaggerated warmth and friendship by the professionals as attempt at bribery, manipulation or exploitation. On the other hand, we know therapeutic relationship

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

between patient and the professional is integral to the recovery process and the outcome of the illness (Ivezic, Ljubimir, & Urlic, 2001) which is also true for treating patients with Schizophrenia (Burns et al., 1999; Eisen, Dickey, & Sederer, 2000). This challenge of building a strong therapeutic alliance with the patient without it being perceived as manipulation or exploitation makes the situation tricky. So there is a constant need for multiple tools which can help a professional in communicating with the patient without making them hostile or defensive.

In the cases presented below, the team of mental health professionals had a similar challenge with the patient diagnosed with Paranoid Schizophrenia. The Psychiatrist tried various combinations of antipsychotics drugs with no change in the symptoms of the patient. During this phase she refused any interaction with any other professional and also denied attending any group activity sessions as she felt she was normal and unnecessarily forced to stay away from her family and the boy she loved. In reality she was talking of her parental family and the boy was actually a relative whom she liked before her marriage. She had denied recognizing her husband, children or any one from his family. At this stage where every other method of communicating with the patient seemed fruitless, a new clinical psychologist was assigned who got a break though with the patient using art therapy.

CASE STUDY

Mrs. H who is a 34 years old house wife, was brought to the clinic by her husband and family. The husband chief complaint was that she talks irrelevant about his illicit relationship with others including his sister. Since six months she is very irritable and use abusive language. There had been frequent incidents of unprovoked aggression. But the situation got worse just six days before this visit, when she left her home and was found wandering near the railway tracks in the absence of her husband. She was brought back home from there. Thereafter she stopped recognizing her husband and children and said she was not married.

To understand the current situation better let's know our Patient, Mrs. H right from her birth. She was born to a low middle class family in a small town in the north. She was the youngest of the five siblings. She had three sisters and one brother. As a child she was very emotional and had limited friends. Like many other girls of her age in her town, she used to be actively involved in house hold chores after returning from school or college. She lost her father in a rail accident when she was 14 years and in the 9th standard. The patient was very attached to her father, thus the event was a traumatic experience for her. Soon she lost companionship of her sister with the latter's love marriage after two years. This marriage led to her first episode of the illness. She would be irritable and would talk of illicit relationships of various people. This had to be treated. She was given electro convulsive therapy (ECT) and medication for the same which lead to remission.

In 1997, she completed her graduation and soon after that, she got married. The marriage was performed against her will as she was interested in a boy known to the family, whom she would have seen at her sister's marriage. Within few days of marriage she had a psychotic breakdown. She again was observed as irritable, used to physically hit people, throw things, smile while she was sitting alone and would eat excessively. She would also blame her husband of illicit affairs. Due to such behavior with in the short duration of her marriage, she was brought back to her parental home and psychiatric treatment was sought. During the same duration, she started calling herself as "Laxmi," who is in love with another boy and is waiting to get married to him. With medication and ECT, her condition improved and there

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

was partial remission after one and a half year of illness. She started helping her brother actively in his shop. However, during her phase of partial remission, symptoms like having doubts on her husband's intentions and having frequent fights with him subsequently continued which led to her divorce in 2007. In the same year she got re-married to a man who was 10 years elder to her and had a son aged 17 from his previous marriage. Since the very initial days of marriage, her husband noticed that she would not trust him and would doubt his intentions and would also blame him for being involved with any female who was around him. In 2008, she gave birth to a baby girl. In April 2012, she aborted her second pregnancy as the fetus was a girl child. After which she started talking irrelevantly about her husband's affair with his sister and would get irritable blaming him of the same. She would also use abusive language. Most of the time, she was observed sitting alone with reduction in her interaction with people. Around, she held the neck of the servant and slapped her without any provocation. Thereafter, six days back, she left home and was found by the police walking on the railway track when her husband was not at home. She could not recall how and when she reached there but gave details of her husband and family to inform them about her wellbeing. Since last four days, she claimed that she is "Laxmi" who has never been married. She is also denying recognizing her parents as her own and identifying her cousin brother as her real brother. During this period she also stopped taking care of her daughter and her step son.

Case Formulation by Using Psychodynamic Approach

Based on the attachment theory client's psychosis can be understood to be triggered by the loss of secured base with the death of the father which made the client insecure. The other boy she saw at her sister's marriage came as a loved object but under family pressure got married to another man this making her ambivalent towards the husband. To understand it further let's understands the attachment theory.

Attachment theory (Bowlby, 1969) has been used as a theoretical base for psychotherapy for many years but has more recently become a major focus of neuroscience and renewed interest among therapists. Siegel (1999) explains attachment as follows: "Attachment is an inborn system in the brain that evolves in ways that influence and organize motivational, emotional, and memory processes with respect to significant care giving figures" (p. 67). Schore (1994) offers a neurological model for the importance of infant attachment throughout life. He notes that soon after birth the caretaker and infant develop interactions that are important to the process of affect regulation. Face-to-face contact and soothing touch are examples of ways the infant learns to respond to stimulation from people and experiences. Perry, Pollard, Blakley, Baker, and Vigilante (1995) propose that successful attachment is critical to optimal development of specific parts of the brain. He believes that a healthy attachment between infant and caretaker sets the stage for the individual to develop the capacity to "self-regulate" stimulating experiences. Early childhood bonding is imprinted on the brain, laying a foundation for relationship patterns later in life; when trauma is present; brain imprinting is changed, but may be corrected with appropriate intervention.

Research in neuroscience is demonstrating that infancy is not the only chance a person has for healthy attachment and there seem to be ways to reshape and repair some early experiences. Art therapy is one way being explored to re-establish healthy attachments, both through therapist and client, and through encouraging healthy interactions between parent and child. Riley (2001) cites how art activities are being used in early childhood attachment programs and how simple drawing exercises can be used to resolve relational problems and strengthen parent–child bonds. She explains that the nonverbal dimensions of art activities tap early relational states before words are dominant, possibly allowing the brain to establish new, and more productive patterns.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Siegel (1999) and Schore (1994) believe that interactions between baby and caretaker are right-brain mediated because during infancy the right cortex is developing more quickly than the left. Siegel also observes that just as the left hemisphere requires exposure to language to grow, the right hemisphere requires emotional stimulation to develop properly. He goes on to say that the output of the right brain is expressed in "non-word-based ways" such as drawing a picture or using a picture to describe feelings or events. According to this idea, art therapy may be an important modality in working with attachment issues, among other emotionally related disorders or experiences).

TREATMENT AND THERAPY

She was given a diagnosis of episodic paranoid schizophrenia with marital discord and she was put on anti-psychotic drugs. She was also admitted in the psychiatric setup for close monitoring of drugs and intervention. There she denied participate in any group activity organized for the patients. Any intervention of any sort was not acceptable and she would keep sleeping in her room with minimal required communication with the staff. She only wanted to go back to her house, her parental house. As every other tool had failed to build a strong therapeutic alliance with the patient, a therapist was given this case, hoped that some innovation and creativity by her might work miracle with the patient.

The new assigned clinical psychologist wanted to use 'Art therapy' because she believed that being a non-directive method it will subtly allow the patient to symbolically reveal the inner conflicts without the fear of disclosure. As Susan Hogan and Annette M. Coulter (2014) said- 'Being revealed can be both cathartic and empowering for the patient.' Indeed, it is believed that even without direct interpretation of art in therapy it can be of great use with a patient with paranoid schizophrenia. Art therapy allows exploration of the patient's inner world in a non-threatening way through a therapeutic relationship and the use of art materials. Indeed, if we look at the history of Art therapy for treatment of schizophrenia has developed its initial stages within Pennsylvania's Western Psychiatric Institute and Clinic with the utmost of success. It was developed in adult psychiatric inpatient units and was designed for use with people for whom verbal psychotherapy would be impossible. Helping people communicate what they are unable to think and feel on a normal level is the ultimate goal of art therapy. Robyn Cruz, director of creative and expressive arts therapies has talked about the success of art therapy program for outpatients with schizophrenia. The reason that art therapy for treatment of schizophrenia is successful is because art therapy is a safe and effective tool to use with people who cannot share their thoughts and feelings adequately through the tried-and-true traditional methods of "talk therapy" conversation. Through art therapy, those with schizophrenia can develop ways to achieve self-expression while simultaneously being able to utilize social skills, new hobbies and personal interests through their creativity. Alison Cobb from the mental health charity mind said, "Art therapy is non-threatening and accessible therapies that can help people express their feelings without the need to talk them over." Thus art therapy with family therapy can be used successfully with eclectic components of other therapeutic approach also.

Being sure about the success of art therapy with such resistant patients of Schizophrenia she was allowed to work with the patient.

The first session with her was in her personal ward in the Psychiatric setup as she denied coming out for any activity or therapy. But this too started only with rejection from her. As she was drowsy with medicine she said she wants to sleep and turned towards the wall ignoring the psychologist's presence and went to sleep. She was found to be unkempt, disoriented and guarded.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Not losing any hope the psychologist went to her room the next day too. On being asked how she was, she again displayed the frustration of being held up in the hospital setup for no visible reason. Even that day too she was feeling drowsy with medicine. Thus, even on the day two nothing could be done with her but then psychologist plan to stay in her room in silence for the complete one hour.

On the visit by the psychologist on day three, she looked better and little receptive of the psychologist. She did complain about being refrained in the hospital with none of the family members with her. She added that her brother (actually her cousin brother who she identifies as her own bother) was not even informed that she is in hospital. MMSE was done on her, which proved she had started reciprocating to the medicine and thus was oriented to time and the place, her recent memory was intact but there was difficulty in recall. The insight into the illness was at Grade 1. She was not ready for any further intervention for the day.

Day four was very similar to day 3 where she was again complaining about being refrained in the hospital with none of the family members, including her brother around. Her insight was still at Grade 1 level.

For facilitating further intervention her family was called to visit her. Her brother knew much about the illness but the husband was ignorant so he psycho-educated about the illness. Besides his initial ignorance, he was very cooperative, and this made things easier. They were allowed to meet the patient with clear instructions not to challenge her delusions till we work through them therapeutically. The husband due to his business could not stay back to actively be part of the therapeutic process any further.

In the next session with the patient, as per the protocol of the clinical institution Sentence Completion Test (SCT) was done on the patient but the patient was not forced to fill all the columns. Expecting early discharge from the hospital she was trying to be very cooperative with the testing. Although she left lot of column unfilled saying she has nothing more to say.

On the analysis of the SCT, the principal conflict areas identified were her relationship with her father, interpersonal relationships with others and fear of her treatment and being alone. The index patient fear loss of her father whom she had already lost in 1993. She feels that people can betray her so she should not trust them. She also expressed her fear of being alone at home and fear of being treated with ECT.

Next day she was encouraged to do Rorschach, she was again very cooperative. The results indicated coping perceptual thinking problems. Further, it indicated that the patient has high vulnerability to loss of control and becoming stressed. There were indications which indicated possibility of chronic vulnerability to become disorganized by natural every day stresses of life. The protocol indicated possible history of numerous events of faulty judgment, emotional disruption and behavioral ineffectiveness.

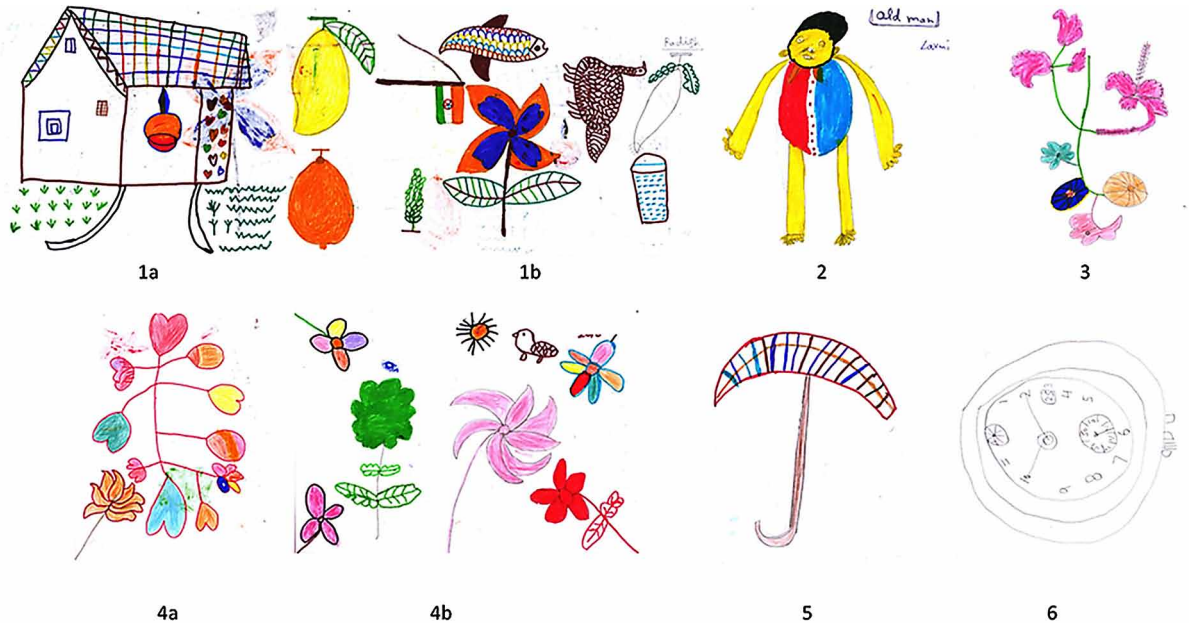
For adequate functionality, she needs to be in an environment which is highly structured, over which she has some sense of control. She seemed to be overwhelmed or flooded by emotions. This flooding of emotions could have impacted on thinking. There is a possibility of her experiencing seemingly random, disconnecting patterns of thinking due to her ungratified needs.

Relationships with others are likely superficial and thus regarded by others as distant, inept and helpless. She generally prefers passive role in a relationship and avoid the responsibility of decision making.

Now after completing the testing as per the protocol of the institute, we next started with free drawing so that she would easily express her inner conflicts in an indirect manner. She was introduced to the idea of drawing and coloring and expressing about her drawing. She drew Drawing No. 1, which has a house and fruits on 1 side and reddish, peacock, fish, flower, grapes and water on the other side. These drawings on both side of the paper could be pictographically representing the two separate worlds which she is experiencing in the in-house setup (see Figure 1). One is the world of her delusion, and other is the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Depicted by patients eight of her drawings



world of reality with basic necessary aspects of life. In her delusive world, she is closed in a house with no door to it. With the help of our understanding of drawing of a person with house tree, the analysis of her house showed that she feels she is in a restricted environment and has high sexual fantasy needs which could be the cause of psychotic breakdown.

The receptivity by the therapist about her psychotic delusions and absence of any refutation by the psychologist of her thoughts started bridging the therapeutic alliance between the psychologist and the patient which was visible in the next session. She was in a good mood and she drew a flower stem (Drawing No. 3) and for the first time she wrote her real name on the drawing which was an indication of a big break through. This flower can be interpreted as thanks to the psychologist for welcoming her emotions which would otherwise be seen as illicit and wrong. After her drawing she started talking about her liking for a boy before her marriage and how seeing her love at a common relatives' marriage resurfaced her love for him. She realized about her delusion as part of her illness. She with no hitch expressed her fantasy to have this boy whom she loved as her husband.

Next day was a Sunday, so there was no therapy session as the psychologist was on a holiday.

The following day her drawing had flowers as expression of her various emotions, hearts for the man he loved, ball for her daughter and her desire to connect emotionally to all what her bunch of life has for her. She wanted to connect with her current environment and seek sunshine here. She talked about her fantasy to get married to the young man known to her and thus a conflict of being with an elderly man.

Her mourning couldn't be completed without talking about her loss of her father at that early age. She was intensively attached to her father and he would give her whatever she demanded till his death. She also had a fantasy that had her father been alive he would have married the man of her choice. The next day's drawing was thus an umbrella and she talked elaborately about her father's love, care and protection for her.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

On the next day's visit by the psychologist she was asymptomatic of any active symptom. She seemingly didn't want to talk further about her fantasies and past as the realities of the day were very different and she realized the importance of her adjustment to her current situation. She also understood her family condition and lack of funds to work further extensively in therapy. She knew immediate discharge was important which was only possible if she adapts to the current reality and thus that day she drew watch in the newspaper kept in her room.

Being asymptomatic of any active symptom, her family that evening took her back home and the therapy had to be ended there. Although the end of the therapy seemed abrupt as no formal ending was defined but the therapist and the patient both at one level communicated the end in the form of need to live in today.

CONCLUSION

The author says that art therapy even without any formal interpretation during the therapy session communicated a lot of material in the therapy sessions which help the flow of therapy process leading to a successful result. This case is another feather in the hat of an art therapist for its accomplishment with a patient resistant paranoid schizophrenia. This case reassures us that art therapy is a safe, effective and successful tool for the management of schizophrenia with medication and family therapy for a complete biopsychosocial intervention. For sure art therapy is a tool to use with people who cannot share their thoughts and feelings adequately through the tried-and-true traditional methods of "talk therapy" conversation.

KEY TERMS AND DEFINITIONS

Art Therapy: Art therapy is non directive method that subtly allows the patient to symbolically reveal the inner conflicts without the fear of disclosure by the means of art.

Biopsychosocial Intervention: Approach stating that biological, psychological (which entails thoughts, emotions, and behaviors), and social (socio-economical, socio-environmental, and cultural) factors, all play a significant role in human functioning in the context of disease.

Paranoid Schizophrenia: Paranoid Schizophrenia is one of the chronic mental illnesses according to DSM-IVTR mainly characterized by the presence of delusion of persecution, suspicious, distrusting, guarded, reserved, tensed, and also sometimes hostile or aggressive.

Phases of Sessions: The progress of case of seen in phases like initial rapport building phase, middle phase and ending phase.

Therapeutic Techniques: Skills used in the treatment or management of the illness.

ABSTRACT

The most reliable prognostic factors associated with upper extremity (UE) recovery are localized motor impairments, especially in the musculature of the hand and abduction of the shoulder in the first days after a stroke. An evaluation of the biomechanics of the hand allows an accurate identification of the motion arcs of the digital joints. This article includes an assess the prognostic value of the range of motion of the finger joints using an instrumental glove (CyberGlove II®) for the time one week after stroke for UE functional recovery. A prospective, longitudinal, observational study is made with follow-ups at 3-4 days, 1 week, 3 and 6 months of the patients with UE motor impairment. Variables collected included: demographic data, level of stroke severity (NIHSS), deep sensitivity, sphincter incontinence, Fugl Meyer assessment of UE (FM-UE), muscle balance with the Medical Research Council (MRC), muscle tone (Modified Ashworth Scale) and pre- and post-stroke functional ability (Barthel Index and Modified Rankin Scale).

INTRODUCTION

Stroke is one of the leading causes of death in industrialized countries as well as of disability and economic cost in adults. Stroke is associated with a connotation of poor prognosis and difficult recovery. It has an impact at personal, family, social and work level, in addition to producing a high expenditure for all health and social services.

Therapeutic advances of the last years, both in prevention and in diagnostic and therapeutic complexity, have determined a change in stroke management towards the multidisciplinary approach and the creation of specific units that has led to a significant decrease in mortality and its sequels.

Most studies on the evolution and functional prognosis of patients with acute stroke are focused on the assessment of gait recovery and the performance of daily life activities. Predictors of survival, hospital discharge, hospital stay, and overall motor recovery have also been described. Studies on the prediction of recovery of specific neurological deficits, such as upper extremity (UE) function, have been increasing in recent years. In this sense, in the last years there are more studies on the specific evaluation of the functional recovery of the UE after having suffered a stroke. This increase in the prevalence of this type of clinical research could also be due to the recent development of validated predictive measures of motor function of UE useful also to establish appropriate therapeutic programs (Chen and Winstein, 2009).

Approximately 70-80% of patients with stroke have deficits in UE in the acute phase and 40% in the chronic phase (Nakayama et al., 1994, Broeks et al., 1999). These deficits limit voluntary movement, coordination, sensitivity, level of physical activity, as well as the realization of activities of daily living (Feys et al., 1998). This aspect implies a limitation and difficulty in their reintegration in their socio-labor environment (Nakayama et al., 1994) and it affects their quality of life (Nichols-Larsen et al., 2005).

Carrying out studies on prognostic factors of the functionality of UE paresis in people who have suffered a stroke is important because of its incidence, its prevalence, its sequels and disability, and its difficulty to predict recovery and functional prognosis of UE.

In another line, several authors are working in design and built an exoskeleton to help rehabilitate UE after stroke. In this sense, (Durairajak et al., 2018), work in a low-cost hand exoskeleton that is design and developed for rehabilitation while the safety rules and regulation kept in mind. Xiao et al. (2018), proposes seven degrees of freedom cable-driven upper limb exoskeleton (CABXLexo-7), which is compact, lightweight, and comfortable for post-stroke patients. For wrist rehabilitation (Saadatgi et al., 2018) presented an experimental implementation and comparative accuracy evaluation of five methods for estimation of human-robot interaction torques are. For rehabilitation of post-stroke patients (Plitea et al., 2017) presents the kinematics of an exoskeleton-based robot for elbow and wrist. There are representative works in rehabilitation after stroke, however, we propose a study that obtains data that can help to build and design these exoskeletons.

Therefore, the involvement of UE and specifically the hand in diseases such as stroke implies in these patients a significant alteration in the performance of many activities of daily living, as well as motor, sensory and body expression limitations that can seriously affect the relationship of these people with their environment.

Alt Murphy et al. (2018) work in kinematic analysis method for objective assessment of upper extremity movements in a three-dimensional (3D) space. In Department of Clinical Neuroscience at Institute of Neuroscience and Physiology at University of Gothenburg an active group are doing research in stroke based in kinematic analysis (Alt Murphy et al., 2017; Olsson et al., 2017).

The aim of the present study is the simulation in patients at the beginning and at the end of six months of suffering from a stroke. The intention of this work is to show a novel virtual environment to simulate the improvement of the functions of the upper extremity a few days after having suffered a stroke and to simulate its recovery under a rehabilitation program.

This document continues with a section of materials and methods. Next section is dedicated to the results, the next section is the discussion and it ends with the conclusions.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

MATERIALS AND METHODS

Patients admitted due to acute stroke and motor involvement of UE in the neurology department of Sant Joan de Deu Hospital who met the inclusion criteria and none of the exclusion criteria were selected. The inclusion criteria were:

- Patients older than 18 years;
- Patients who have suffered a stroke for the first time with motor deficit in the UE, admitted to the service of Sant Joan de Deu hospital, with confirmation of neuroimaging brain injury during the first 48 hours;
- Patients without cognitive impairment that makes it difficult for them to understand and follow up the assessments;
- Patients who before the stroke were independent in their activities of daily living (ADL);
- To accept to participate in the study and signing the informed consent.

The exclusion criteria were:

- Patients with deficits and sequelae in their UE of any pre-stroke etiology;
- Patients with subsequent follow-up and control difficulties;
- Patients with terminal illness with a life expectancy of less than six months.

Withdrawal criteria were also taken into account, such as:

- Appearance of a new stroke during follow-up;
- Onset of concomitant pathology affecting the patient's vital prognosis and/or subsequent follow-up;
- That the patient decides voluntarily;
- Lack of compliance and collaboration on the part of the patient;
- Death of the patient.

In total, 18 patients who met the inclusion criteria were selected. The first follow-up visit was performed 3-4 days after the stroke and data were collected during hospital admission. The next visit and data collection were performed at 7 days, at 3 months and the last at 6 months post-stroke. In this last visit, one of the patients was able to perform the whole validated Action Research Arm Test (ARAT) table. It is in this last visit that we will focus the simulation and in which we will create the virtual simulation environment.

Evaluation of the Functionality of the US With the ARAT Test (With CyberGlove II® Glove and Without)

This evaluation with ARAT was only carried out at the last follow-up visit (visit 4). The equipment to do this test was achieved thanks to an agreement with the School of Engineering of Manresa, who prepared it according to the instructions and measures obtained of the model described by Lyle (Lyle 1981), as can be seen in Figure 1.

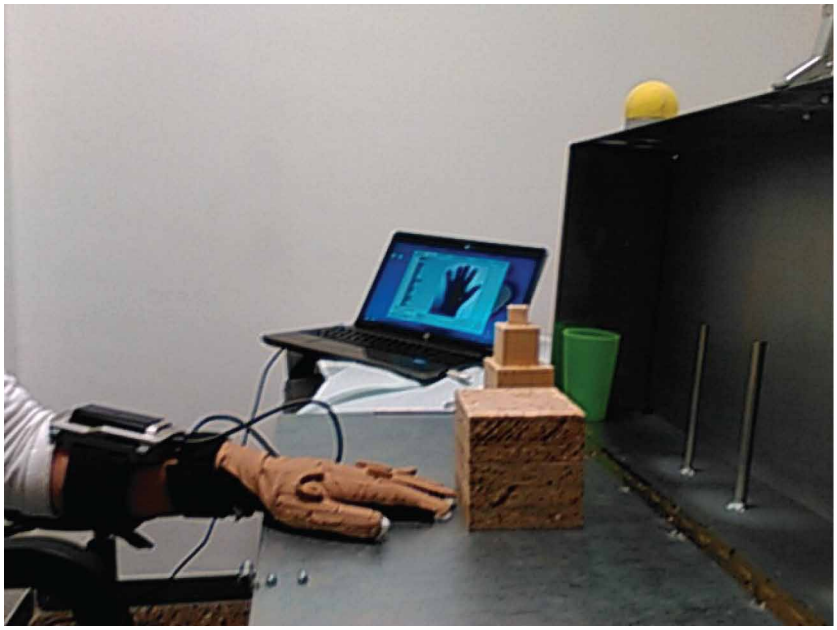
Figure 1. ARAT test

On visit 4, after evaluating the patient clinically and neurologically with the evaluations and scales described previously, the ARAT was first passed without the glove and then with it Glove, as shown in Figure 2.

Figure 2. Patient doing the ARAT test



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Assessment of Joint Balance With Cyber-Globe II® Glove

In order to obtain information on the angles of the joints of the hand, the 18-sensor Cyber-Globe II® glove was used, which also has a resolution of one degree, with a ratio of 90 measurements/s. An interface for capturing data with the glove was made, as shown in Figure 3. After obtaining all the data with the glove, the data were converted to the hand model proposed by the authors (Peña-Pitarch et al., 2014). The hand model is 25 degrees of freedom (DOF), not counting flexion/extension (F/E) and adduction/abduction (Ad/Ab) of the wrist, as shown in Figure 4.

Figure 3. Screenshot of the data collection and numbering of the sensors

The procedure to pass the readings of the 18 sensors of the glove to the 25 DOF model is the same for each joint with its movement (q). This procedure is based on a linear interpolation, since there are DOF that depend on the readings of one or more sensors and takes into account the maximum and minimum reading of the movement of each sensor and the maximum and minimum of the range of movement (flexion and extension) of each hand joint (q). Table 1 shows the movements of the joints that each sensor picks depending on where it is located. Sensors numbers are shown in Figure 3. Table 2 shows the range of motion for each joint.

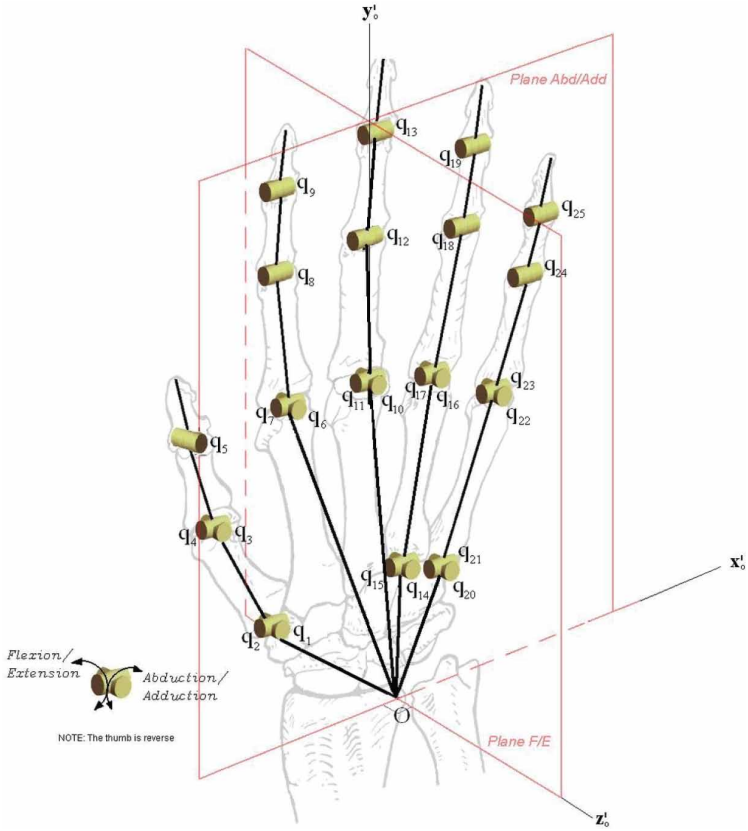
The minimum value corresponds to the position of the joint when you perform an extension or abduction, and the value maximum, when the joint flexes or enlarges. Table 3 shows the minimum values and maximum that collects the sensors of the CyberGlove II® glove.

F/E is Flexion/Extension and Ab/Ad is Abduction/Adduction movements.

DIP is distal interphalangeal.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Hand with 25 DOF. Rear view right hand.



The implementation of a virtual model of 25 DOF allows a very realistic simulation of the hand. The procedure for passing the readings from the 18 glove sensors to the 25 DOF model (hand only) will be the same for each joint. This procedure is based on linear interpolation, since there are some DOFs that depend on the readings of one or more sensors and takes into account the maximum and minimum reading of the movement of each sensor and the maximum and minimum of the range of motion of each joint of the hand.

Once the assessment of the joint balance of each union and its subsequent conversion to the hand model with the 25 DOF was made, its implementation in the virtual environment of Blender -free code program- was carried out.

Simulation

Our approach for each of the patients has been using the model shown in figure 5. In this model in addition to the 25 DOF of the hand were added 4 more DOF, two for the wrist, in order to simulate the F/E of the same and the other for Ab/Ad. About the other two DOFs remaining, one is for the F/E of the elbow and the other is for supination/ pronation of the arm. In this work we have only focused on the study of the arm, not counting the shoulder, since we have considered more DOF focused on object grabbing. The future simulation of the trunk up to the hand is not ruled out.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Movements of the joints that each sensor picks depending on where it is located

Sensor	Movement	Joint	Finger
1	F/E	Metacarpal trapezius	Thumb
2	F/E	Metacarpophalangeal (MCP)	Thumb
3	F/E	Interphalangeal (IP)	Thumb
4	Ab/Ad	Metacarpal trapezius	Thumb
5	F/E	Metacarpophalangeal	Index
6	F/E	Proximal Interphalangeal (PIP)	Index
7	F/E	Metacarpophalangeal	Middle
8	F/E	Proximal Interphalangeal	Middle
9	Ab/Ad	Between two fingers	Index/middle
10	F/E	Metacarpophalangeal	Ring
11	F/E	Proximal Interphalangeal	Ring
12	Ab/Ad	Between two fingers	Index/middle
13	F/E	Metacarpophalangeal	Small
14	F/E	Proximal Interphalangeal	Small
15	Ab/Ad	Between two fingers	Ring/small
16	Arch	Metacarpal	Middle/ring/small
17	F/E	Carp cubital radius	Wrist
18	Ab/Ad	Carp cubital radius	Wrist

Table 2. Range of movements for the joints of the fingers; H is hyperextension (in degrees)

Joint \ Finger	Index	Middle	Ring	Small
MCP (E/F)	0/80	0/80	0/80	0/80
MCP (Ab/Ad)	13/42	8/35	14/20	19/33
PIP (F/E)	0/100	0/100	0/100	0/100
DIP (F/E)	10H/90	10H/100	20H/100	30H/100

The mathematical formulation applied to the model was previously published in (Peña-Pitarch et al., 2014) and it is as follows. The position vector is defined by $p(q^i)$ which with respect to the local coordinate system will be:

$$\begin{bmatrix} p\left(q^{i}\right) \\ 1 \end{bmatrix} = {}^{0}A_{1}{}^{1}A_{2}\cdots{}^{n-1}A_{n}\begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \quad (1)$$

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Minimum and maximum values given by each CyberGlove II® glove sensor

Sensor	Minimum	Maximum
1	55	180
2	105	160
3	40	215
4	120	131
5	105	135
6	56	206
7	20	130
8	50	186
9	15	155
10	10	162
11	36	202
12	1	146
13	15	208
14	43	216
15	50	168
16	40	245
17	85	160
18	36	202

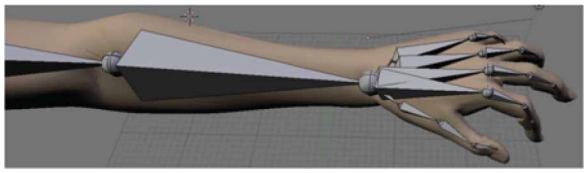
where $q^i = [q_1 \ldots q_n]^T$, i = I, II, III, IV, V, VI, VII, where I is the thumb, II is the index, III is the middle, IV the annular and V the pinkie, VI is for the wrist and VII for the arm. Where n is the total number of DOF, in this case it is 29.

To move it to a global coordinate system located on the shoulder, the position vector is now:

$$\begin{bmatrix} w\left(q^i\right) \\ 1 \end{bmatrix} = \left[{}^0 H_i\right] \begin{bmatrix} p\left(q^i\right) \\ 1 \end{bmatrix} \tag{2}$$

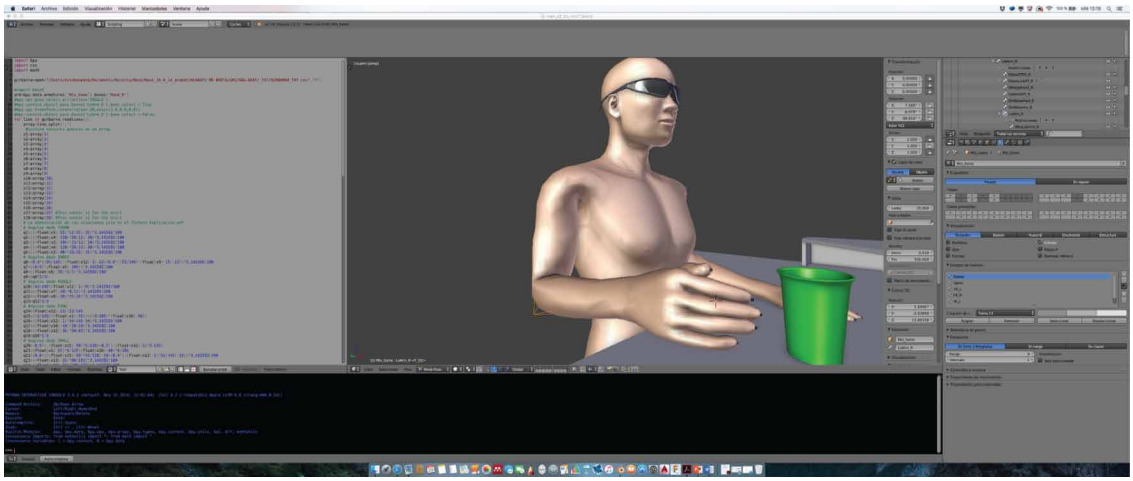
Figure 6 shows a screenshot of Blender, where on the left side we can see the code implemented with Python and allows to simulate each patient once the data obtained by the glove has been converted to the described model of 29 DOF, where the two of the elbows have been approximated by means of a goniometer.

Figure 5. Left arm implemented in Blender with 29 DOF



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Screenshot of a moment of the simulation of a patient



RESULTS

The prognostic capacity of each of the joints in the functional recovery at 6 months according to the ARAT was evaluated both for the motion without gravity and for the movement against gravity when performing F/E of the fingers as well as the gain of movement experienced by each of these joints at 6 months' post-stroke. The joints corresponding to the metacarpo-phalangic and interphalangeal joints of all the fingers were evaluated.

Joints q_7, q_8, q_9 - Index Finger (F/E)

The mean q_7 joint and during the six-month follow-up the ARAT group ≥ 10 experienced a gain of 65 degrees in the F/E movement range without severity. At three months, the gain of movement was 26 degrees higher in the ARAT group ≥ 10 than in the ARAT group < 10. However, at six months the ARAT ≥ 10 group experienced a gain of 41 degrees in the same movement but against gravity. As for the joint q_8 the gain was 21 degrees without gravity and between 19 to 39 degrees in the movement against gravity, for the group ARAT ≥ 10. The joint q_9, the same group obtained a gain of 14 degrees and against gravity a gain of between 13 and 26 degrees.

Joints q_{11}, q_{12}, q_{13} - Middle Finger (F/E)

Always referring to the same group (ARAT ≥ 10), in the joint q_{11} a gain of 22 degrees was obtained in the motion without gravity and between 14 and 17. The joint q_{12} without gravity experienced 21 degrees of gain and between 19 and 30 degrees in motion against gravity. Similarly, q_{13} gained 14 degrees and between 13 and 20 degrees with the same movement.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Joints q_{17}, q_{18}, q_{19} - Finger Ring (F/E)

Similarly, the q_{17} joint experienced a gain of 18 degrees without gravity and between 15 and 24 degrees against gravity. The joints q_{18} and q_{19}, had gains of 22 and 15 degrees, respectively, and between 15 and 31 degrees.

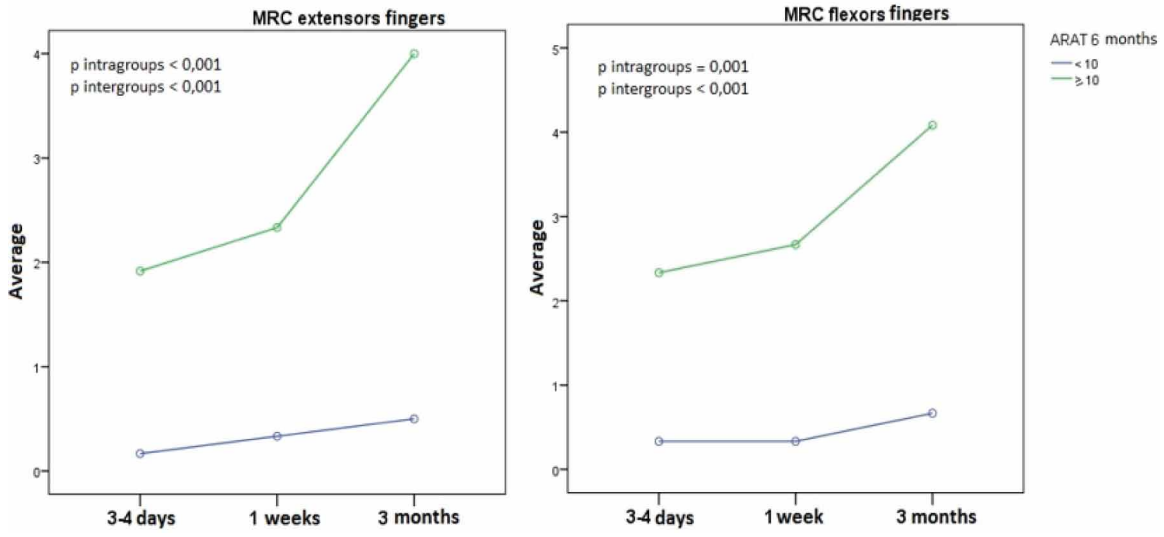
Joints q_{23}, q_{24}, q_{25} - Pinky Finger (F/E)

Likewise, the joint q_{23} experienced a gain of 19 degrees without gravity and between 12 and 24 degrees against gravity. The joints q_{24} and q_{25}, had gains of 28 and 18 degrees respectively and between 13 and 35 degrees.

Functional Status of the UE According to ARAT 6 Months Post Stroke

Figure 7 shows the evolution of the muscular balance, measured with MRC, of the extensors and flexors of the fingers in two groups of patients. Patients with ARAT < 10 in average scored below one, in the evaluation of the extensors and flexors of the fingers with the MRC in all the follow-up visits. In contrast, patients with ARAT >= 10 group, in the 3-4 days, presented average score between 1-2 for the extensors finger muscles, and between 2-3 for the flexor muscles of the fingers. Differences were observed significantly in the evolution of MRC between visits (intragroup) and between the two groups of patients according to the ARAT (intergroup).

Figure 7. Evolution of the MRC of the flexors and flexors of the fingers and of the hand according to ARAT at 6 months of the stroke



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Regarding the assessment of the NIHSS category of UE motor function, in Figure 8 it can be observed that in the ARAT < 10 group, 100% of patients in the 3-4 days and week evaluations they no presented movement or if they presented movement do not overcome gravity. However, in the ARAT group >= 10, 41.6% of patients had a movement that did not overcome the severity at 3-4 days and a week by 25%. Significant differences were observed in the evolution of the NIHSS UE engine between visits (intragroup) and between the two groups of patients according to ARAT (intergroup).

Figure 8. Evolution of NIHSS motor of the UE according to ARAT at 6 months of the stroke

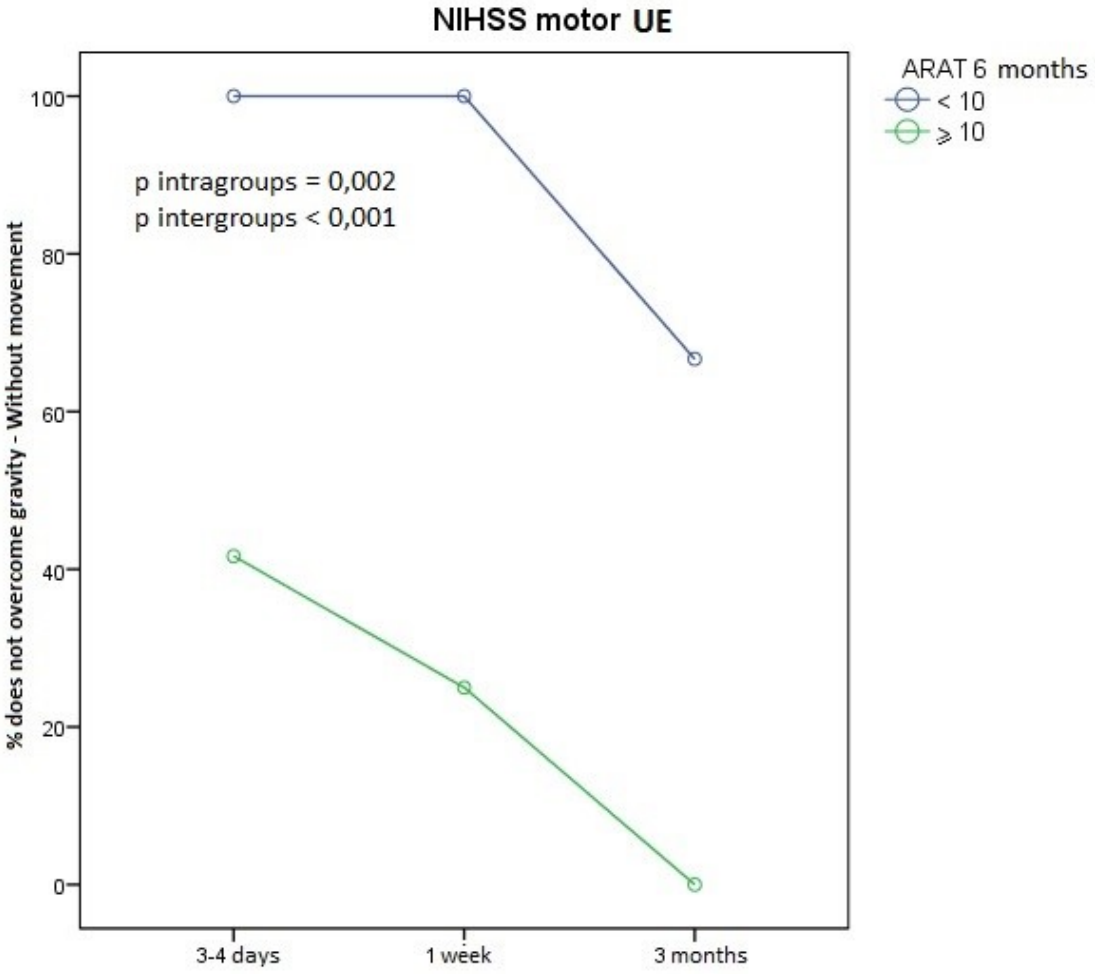


Figure 9 details the evolution FM of an average of the UE according to the ARAT groups. In the group ARAT <10, there were no changes in the average in the first two follow-ups of the 3-4 days and a week (4.8; SD = 2.0). Weekly, ARAT group patients >=10 had a higher average (38.33; SD = 20.8) than in the 3-4 days follow-up (31.8; SD = 22.3). Significant differences were observed in the evolution of FM-UE between visits (intragroup) and between the two groups of patients according to ARAT (intergroup).

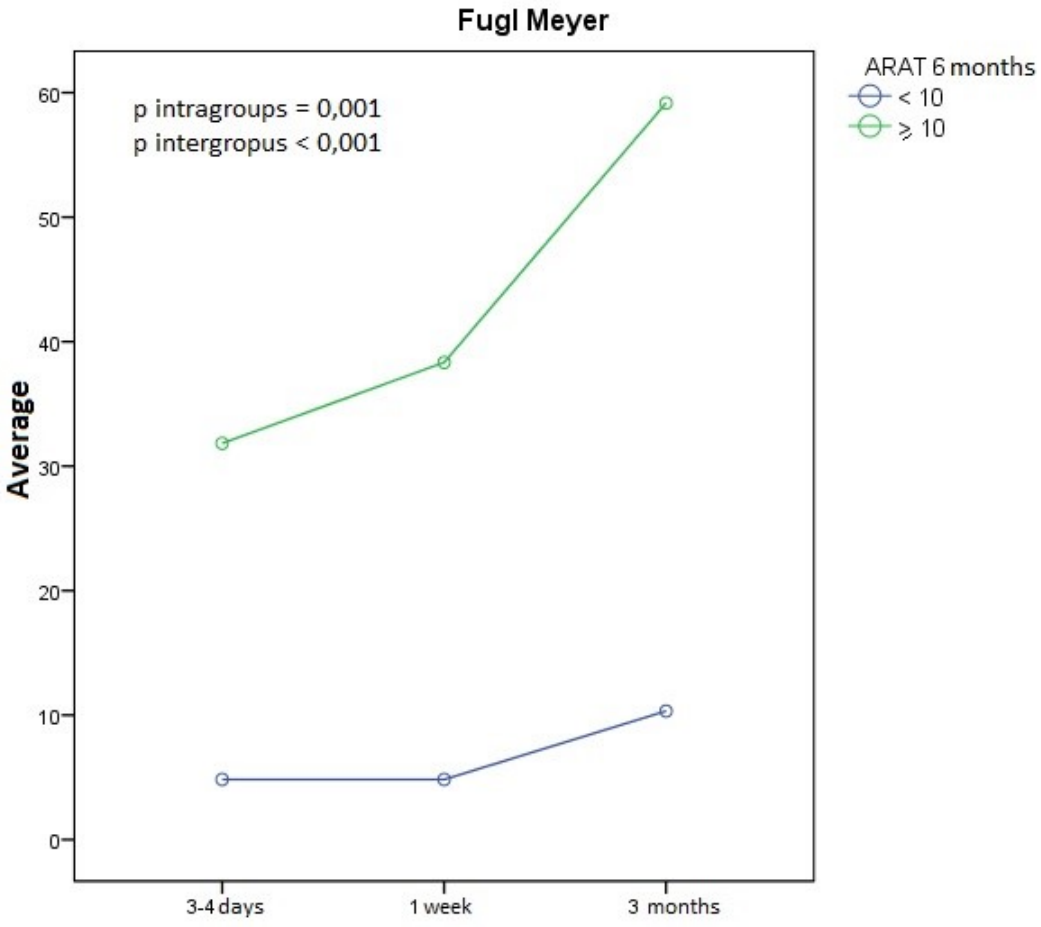
Figure 9. Evolution of Fugl-Meyer of the UE according to ARAT at 6 months of the stroke



ARAT Bivariate Analysis Table 6 Months (Clinical and Functional Characteristics at 3-4 Days Associated With ARAT)

See Table 4.

DISCUSSION

The measurement of the flexion and extension movement of the finger joints is a part of the basic exploration of many clinicians in their daily explorations. This measurement can be done quickly, simply and next to the patient's bed. The instrumentation of the measurement of the amplitude of the active range of motion has allowed us to obtain a more accurate data of the active movement of each joint and to implement it in the virtual environment as well as to simulate this movement for each patient.

[a]U Mann-Whitney;[b]Fisher exact prove;[c]p-value bilateral Monte Carlo.

When analyzing the range of motion (difference between minimum and maximum F/E) of each joint, significant differences were observed at 3 months between the two ARAT groups in the interphalangeal joints of the four fingers, and in the metacarpal joints -phalangeal of the ring finger and pinky in both positions, without and against gravity. Nevertheless, these data do not provide much information because at 3 months is considered that many patients have recovered most of the functionality, and it is not an early assessment that allows us to define individualized programs of rehabilitation treatment. Only in the evaluation of the initial week, there are significant changes in the proximal and distal interphalangeal joints of the index and the annular of the hand in the movement against gravity. Of these two fingers, the interphalangeal joints with more joint gain are those of the ring finger. The gain was 22 degrees with respect to 19 in the proximal interphalangeal joint, and 15 with respect to 13 degrees in the distal interphalangeal joint of the ring finger with respect to the index finger.

Thus, in the analysis of the range of motion between the two ARAT groups, the joints with the greatest capacity predicted at the week are the proximal and distal interphalangeal of the index finger and the annular one in the position against gravity, and of these two the ring finger.

The active range of flexion of each finger of the hand, flexion of the back and elbow, pronation and supination of the elbow, and flexion and extension of the wrist were examined in (Beebe et al. 2009). These authors observed that the active flexion of the middle finger and the presence of abduction in

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

the lower back evaluated in the first 3 weeks post stroke had better predictive capacity at three months of the stroke than the rest of the fingers and joints of UE. In contrast, in another study, it was the active extension of the index and middle fingers against severity at 3 weeks of stroke, which were strongly predictive of recovery at 13 weeks post stroke (Lang et al. 2006). Mirbagheri et al. (2008) identified the active range of motion and maximal voluntary contraction of elbow flexion and extension movements at 4 weeks of stroke as predictors of UE motor recovery.

Table 4 shows the evolution of the clinical and functional characteristics of the patients according to the ARAT and for each one of the evaluations that were performed.

The group of patients with ARAT ≥ 10 had a mean NIHSS score of 6.4 (SD = 3.3), whereas the group of patients with an ARAT < 10 had a mean of 14.8 (SD = 4.8) in the 3-4 days' assessment. At 3-4 days, in the ARAT group < 10 the patients had a mean FM-UE of 4.8 (SD = 2.2), and in the ARAT group ≥ 10, a mean of 31.8 (SD = 22.3). In the Barthel index, the mean was 7.5 (SD = 3.5) in the ARAT group < 10 and 27.5 (SD = 10) in the ARAT group> 10.

Each patient in the ARAT group≥ 10 presented alteration of the deep sensitivity, but had no urinary incontinence or hemi-neglect. All patients in the ARAT group <10 had an ERM ≥ 3 in all follow-ups that were made (see Table 4).

The movement of the fingers of the hand is important to acquire the skill and for the manipulation of objects that determine the proper functionality of the ES. The hand has multiple functions; the most important are touch, which is a sensitive function and grip, which is a motor function. To carry out these functions, the hand adopts different positions according to the type of grip it has to do. In all these positions involve more or less fingers, but in general, the little finger intervenes when it is necessary to grasp objects of greater weight and volume. All fingers are important for manipulation and grasping, but it is possible that the one that does not so much determine the functionality of UE is the little finger because, it is only used when objects are heavy and bulky.

The results of this study highlight the predictive capacity for the recovery of UE function at 6 months after stroke.

CONCLUSION

The biomechanical evaluation of the fingers and their simulation in a virtual environment may facilitate the stratification of the patients in groups at risk according to the prognosis of the recovery of the paresis UE. This fact would help health professionals to make a more individual planning of neuro-rehabilitating treatment of patients who have suffered a stroke. Adequate patient selection would increase the efficiency of rehabilitation services.

The data obtained with the Cyber-Globe II® instrumentation glove are useful for designing technical aids or orthoses that help to promote independence in the activities of the daily life of the patients who need it. These data have been adapted to the virtual model with 29 DOF, which has allowed the simulation of each patient, giving an approximation of the abilities and limitations in their ADL.

The virtual simulation of the arm and hand in patients with stroke gives a new objective tool to physicians that allows simulating the evolution of deficits in some patients. The relevance of this work for patients affected by these deficits is that in the first visit to the doctor after the stroke it is possible to know through the simulation the evolution of their functional recovery. Another relevance is that the arm and hand model has been implemented with parametric lengths and can be extrapolated to other

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

affected patients with the same deficits. Finally, ergonomists can be given data on hand movements and help design new products for people with reduced mobility due to a partial recovery after having followed the rehabilitation program.

Chapter 41
Social Context:
Visualisation of Cooperation – Evidence-Based Medicine in Neurorehabilitation

ABSTRACT

Evidence-based medicine (EBM) and Evidence-based practice (EBP) are sets of standards and procedures created to search, verify, and select up-to-date findings implemented by medical staff as a basis for decision-making process in a daily clinical practice. Despite efforts of scientists and clinicians, neurorehabiltiation is regarded as a difficult area for EBM/EBP practices due to huge diversity of cases, clinical pictures, interventions, and scientific methodologies. More advanced tasks, including application of brain-computer interfaces and neuroprosteheses, show the need for a new approach from medical practitioners. This chapter presents challenges, barriers, and solutions in the aforementioned area based on the personal experiences of the authors. Visualisation tools provide cognitive support for social context, cooperation patterns, and data interpretation. Taking into consideration that social issues may extend the visibility of the results and allow for easier dissemination of the results, the aim was to show how visualisation helps identify cooperation networks and disseminate research results.

INTRODUCTION

Evidence Based Medicine (EBM) and Evidence Based Practice (EBP) are sets of standards and procedures created to search, verify and select up-to-date findings implemented by medical staff as a basis for decision-making process in a daily clinical practice. Cause of emergence of EBM has been significant

increasing of data flow (e.g. easier access to electronical databases of medical articles). There become hard to distinguish reliable and unreliable medical evidences. As a result - there was hard to develop medical knowledge of the staff. The priority become selection and elimination unreliable findings at the beginning. It was noticed, that rehabilitation methods should be as reliable as other methods in clinical use. Concept Evidence Based Medicine licked into shape Evidence Based Practice (Bridges et al. 2007; Dean-Baar & Pakieser-Reed 2004).

The following chapter presents challenges, barriers, and solutions in the aforementioned area based on the personal experiences of the authors. Chapter begins from familiarizing of fundamentals of EBM/EBP, including also debate with opponents. Paper contains also outcomes of the own research, their useful visualizations, and results of practical implementation of EBM/EBP based on experience and findings in Poland and abroad. Vizualization tools provide cognitive support for pattern recognition and data interpretation toward usable information and knowledge (Osińska & Bala 2015, Osińska 2011). Our aim was to show how visualisation helps identify co-operation networks and disseminate research results.

BACKROUND: EVIDENCE BASED MEDICINE IN NEUROREHABILITATION – STATE OF THE ART

Neurological diseases are popular in main population and constitute one of the main cause of disability in adult people. Interdisciplinary rehabilitation teams deal with neurologically disabled patients applying the newest methods, drugs, and approaches to rehabilitation process (Członkowska & Sarzyńska-Długosz 2002). Rehabilitation should start as early as possible (Hömberg 2010). Integrative neurorehabilitation science based on dedicated rehabilitation research focused on neurorehabilitation is necessary (Kwakkel 2009; Gillen 2010). Therapeutic procedures should be evidence-based and modified to find patient-tailored solutions. General rules derived from neuroscience confirm their usefulness in designing new therapeutic techniques in neurorehabilitation. (Hömberg 2010).

Searching and reading the research literature seem be essential activities for enhancing the use of research and optimizing the quality of current clinical practice in neurorehabiltiation (figure 1). From the other hand neurorehabilitation is regarded very hard area for EBM/EBP practices, especially due to huge diversity of cases, their clinical pictures, interventions, and scientific methodologies. Thus neurorehabilitation may be perceived clinical area with lacking evidences (Grimmer-Somers et al. 2007; Iles & Davidson 2006).

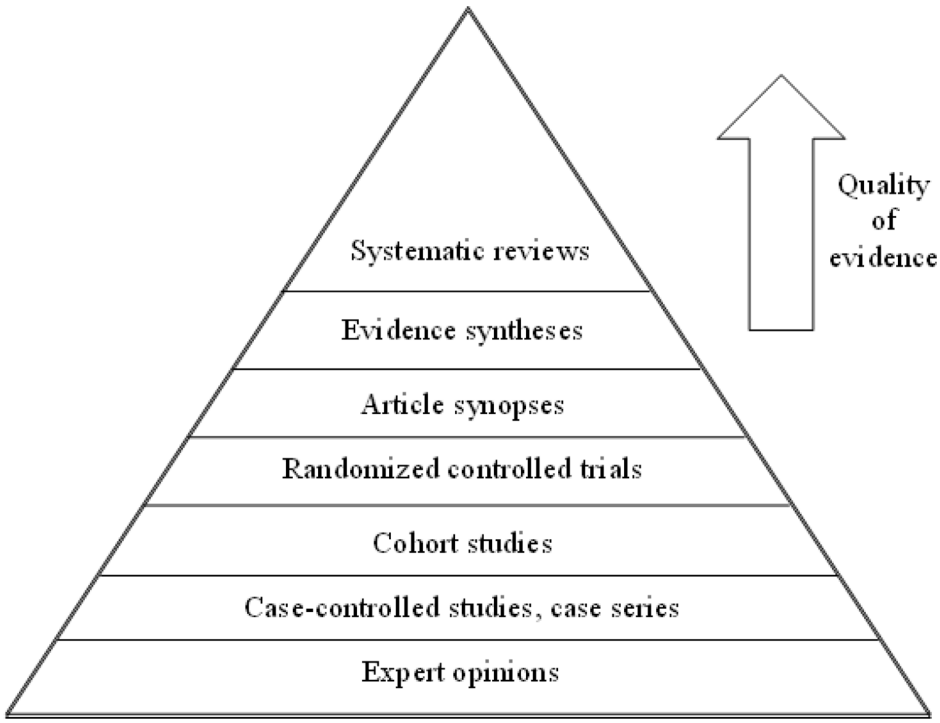
Enormous growth of knowledge in the neurosciences may cause significant progress in neurorehabilitation. EBM/EBP is a complex process that can be facilitated by the use of the Knowledge to Action Process model. It provides a sequence of phases for researchers and clinicians to follow in order to optimize knowledge translation (KT) across various fields of practice. Thus our ultimate aim is creating effective KT interventions to increase clinicians' knowledge and use of EBM/EBP among for clinicians, health care managers, and researchers (figure 2). Clinical application of the new tool/method, approach requires research on its:

- Reliability (interrater reliability, intrarater-reliability, test-retest reliability, etc.), i.e. measurement error associated with an instrument,
- Validity, i.e. extent to which an instrument measures itself in the absence of the "gold standard" (including compartmental studies with other existing clinical scores and scales),

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Responsiveness, i.e. minimal degree of change that is clinically significant (including *floor effect* and *ceiling effect*),
- Acceptability to patients and assessors (Prokopowicz et al. 2017; Jette et al. 2003; Stevenson et al. 2004; Palfreyman et al. 2003).

Figure 1. Hierarchy of evidences according to EBM/EBP paradigm

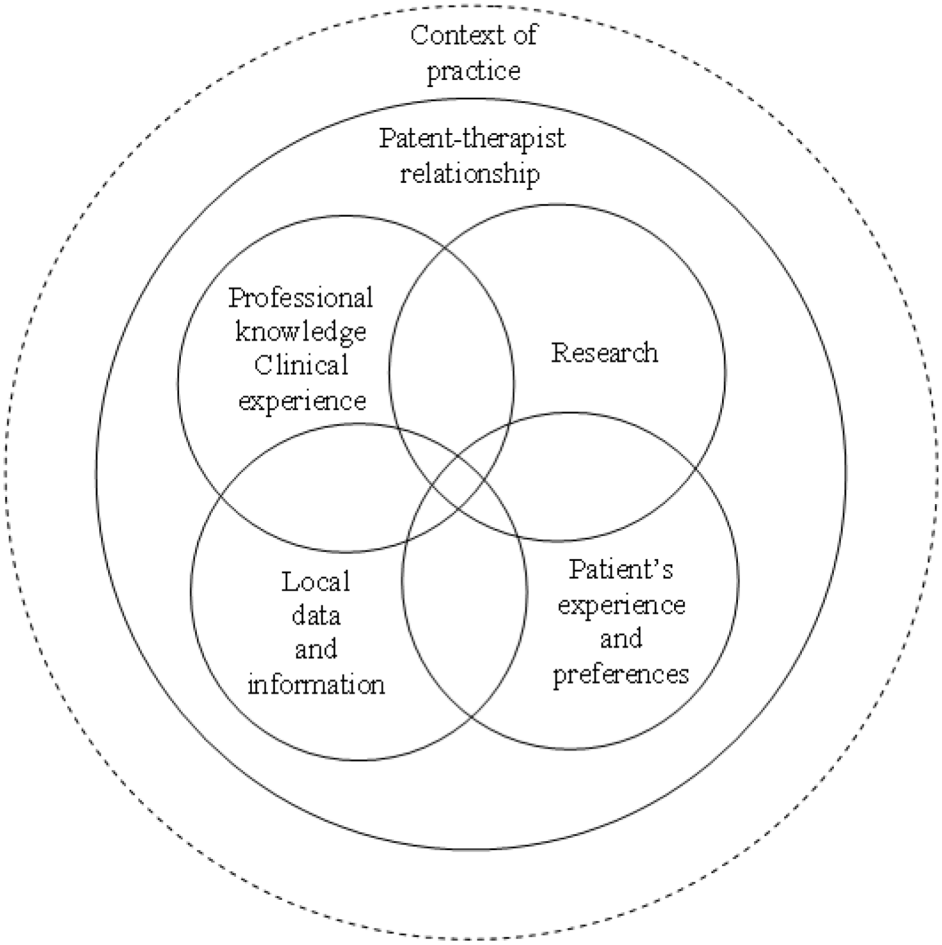


Despite many challenges in the implementation of evidence in neurorehabilitation the increasing use of EBM/EBP concepts and an early KT from the neurosciences into everyday clinical neurorehabilitation practice contribute to therapeutic advances, providing further occupations for enhancing results of neurorehabilitation (Ramírez-Vélez et al. 2015; Teasell 2012; Pereira et al. 2012; Hömberg 2010; Petzold et al. 2010; Sackett et al. 1996; Rosenberg & Donald 1995).

Scientists and clinicians should be aware general situation concerning publications in rehabilitation and physical therapy. Widely discussed review by Shadgan et al. showed 100 top-cited English language articles from 30 rehabilitation dedicated journals published between 1959 and 2002. Average citations per article was 200, ranging from 131 to 1109. The most common fields of the study were neurorehabilitation (41%), disability (19%), and biomechanics (18%). The most common article type was original article (84%), prospective (76%) case series studies (67%) on humans, what more 67% articles was published in the USA (Shadgan et al. 2010). Partial key may be also characteristics of bibliometric indicators and analysis of associated information. Review by Franchignoni et al. showed scientific productivity of 24 randomly selected leading European authors of publications in the area of physical medicine and reahabilitation (PM&R). Median values of their bibliometric parameters were not high: number of pub-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Sources of evidence for patient-centred evidence-based practice (Rycroft-Molone et al. 2003)



lication: 31 (Web od Science - WoS), 46 (Publish or Perish - PoP), number of citations: respectively 171 and 317, Hirsch index: respectively 6.5 and 8.5 (Franchignoni et al. 2011). Deeper assessment may show causes of such situation. Gender gap within peer-reviewed publication productivity in physical therapy were reported by Kaufman & Chewan: 0.51-0.58 fewer articles per year for women than for men was observed (Kaufman & Chewan 2011). Study by Ahmed et al. assessed top cited (($\geq$50, WoS) articles concerning disability published between 1980 and 2015. Collaborative studies enjoy wider citation, what more articles with 11 to 20 pages were the most often cited (Ahmed 2016). True may be an assumption that collaboration increases influence of publication, thus co-author network may be important factor.

EVIDENCE BASED MEDICINE IN NEUROREHABILITATION - BARRIERS

Scientists and clinicians can try subjectively, not always directly, assess the effectiveness of EBM/EBP implementation in neurorehabiltiation .There may be defined three primary areas of limitations to physical therapists' implementation of EBM/EBP

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Organizational Barriers:** Support and resources,
- **Practitioner Barriers:** Education, attitudes and beliefs, interest and perceived role, and self-efficacy,
- **Technical Barriers:** Quick development of innovative solutions requiring randomized controlled trials covering their efficacy, long-term effects observations, and clinical guidelines (Brandt & Bertram 2016; Sidiakina et al. 2015).

The most valuable clinical trials face problems of recruitment, retention, treatment fidelity, outcome measure selection, and control intervention selection. A problem may constitute even such basic factor as within-group homogeneity which contributes to successful conduct of a clinical trial.

Lack of education, negative perceptions about research and physical therapists' role in EBM/EBP, and low self-efficacy to perform EBM/EBP activities represent barriers to implementing them into neurorehabilitation that can be addressed through continuing education. Organizational provision of access to Web-based resources is likely insufficient to enhance research use by clinicians: despite Internet access at work for 80% of respondents, only 8% were given protected work time to search and appraise the literature (Salbach et al. 2010; Salbach et al. 2009; Salbach et al. 2007).

The evidence base on neurorehabilitation is often limited and clear definitions are lacking. The observed spread in opinion may reflect the absence of clear guidelines and knowledge in the particular area and need for further research (Lynch et al. 2017; Sjöholm et al. 2011). But EBM/EBP paradigm is not obvious: despite lack of clear agreement only 19% stroke care professionals required a large randomized controlled trial or a systematic review to be convinced of early mobilization after stroke benefits (Sjöholm et al. 2011). From the other hand awareness of an ongoing research trials among professionals may lead to changes in opinions before the efficacy of the experimental intervention is known (Lynch et al. 2017).

General tendency may be unfavorable. Recent review by Jesus showed discrepancy between number of clinical trials and systematic reviews in rehabilitation. Number of published yearly clinical trials increased, while number of systematic reviews did not change since early 1990s. What important neurologic conditions (particularly cerebrovascular) were the most addressed by aforementioned publications (Jesus 2016).

SOCIAL CONTEXT OF PUBLICATION IN MEDICAL AND ALLIED HEALTH SCIENCES

The social context must respond to the transformation in society due to global changes: environmental, cultural, technological, etc. Digital change may shorten distance between research and publication, but easier way may result in thousands of scientific publications a day. Current research should be more effectively disseminated and showed impact on state-of the-art to play a significant role in the global scientific discussion and development. Long lifespan and chances of survival have only the best of them. Aforementioned approach is linked with the model of science development chosen to follow. Popular scientists want to maintain their position, but more and more younger scientists want share similar achievements and lifestyle. The social analysis cannot remain marginal to global change concerning research. Despite pitfalls and mistakes, we need to find a path toward a more secure and sustainable development of science in the future. Some phenomenon within current system cannot be understood only by measuring traditional bibliometric parameters. Purely technical details may diminish the main

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

issue, uneven and inadequate elsewhere. Qualitative and quantitative studies need for novel methods and tools. Pressure on science to be relevant may fall heavily. Priorities and mainstreams may differ across the region. Traditional scientific paradigms and approaches may be increasingly distrusted and questioned. Interdisciplinary approaches with the capacity to investigate changes may help solve them. Thus current social analysis should be interconnected with a multitude of other point of view to the same question. No doubt interdisciplinary programmes and policymaking should be related to sound, independent research.

In the past the single-author paper was the common habit, but over the past decades, the average number of authors on scientific articles has drastically increased (Borry et al. 2006). Contemporary scientific success may be significantly influenced by cooperation and competition thus research collaboration occurs more frequently now than in the past. Levsky et al showed that number of authors per medical article increased from 4.66 to 5.73 between 1995 and 2005 (Levsky et al. 2007). But multiauthored publications have also disadvantages, e.g. in some disciplines authors publishing more often as first authors have fewer publications in the short period of time than authors publishing more often as last authors (Wardil & Hauert 2015). This may show variety of possible strategies applied by scientists/authors and evolution of cooperation in multi-authored publications. From the other hand rule that number of publications and citations is a principal factor for scientific career advancement may lead to natural selection of poorer science. Poor research design and data analysis is probably quicker and simpler. Rewarding full understanding instead of rewarding knowledge is hard but possible, e.g thanks to computational analysis of data sets showing potential correlations and gaps within current theories (Smaldino & McElreath 2016). Study by Slone (Slone 2016) showed that despite over half of the papers published in the American Journal of Roentgenology (AJR) have five or more coauthors, the first two authors made almost all of work in almost all researched papers. Honorary authorship is still discussed (Bonekamp et al. 2012, Eisenberg et al. 2014). Aforementioned trends are still challenges for the editors of journals. Moreover there is expected gender revolution: during the last 3 decades, the proportion of women authoring manuscripts in the 3 major general dermatology journals increased from 12% to 48% (Feramisco et al. 2009). There are proposed alternative indicators for progress in the field of publication: e.g. number of publications listed in the particular classification of the top publication in the particular medical discipline during recent years/decades (Bas et al. 2011). From the other hand study by Abu-Dawas et al. showed that despite an increase in quantitative research productivity of Gulf countries over the last 3 years, no increase in quality of research publications was noted based on the mean reports of mean journal IF (Abu-Dawas et al. 2015).

EVIDENCE BASED MEDICINE IN NEUROREHABILITATION:SOLUTIONS

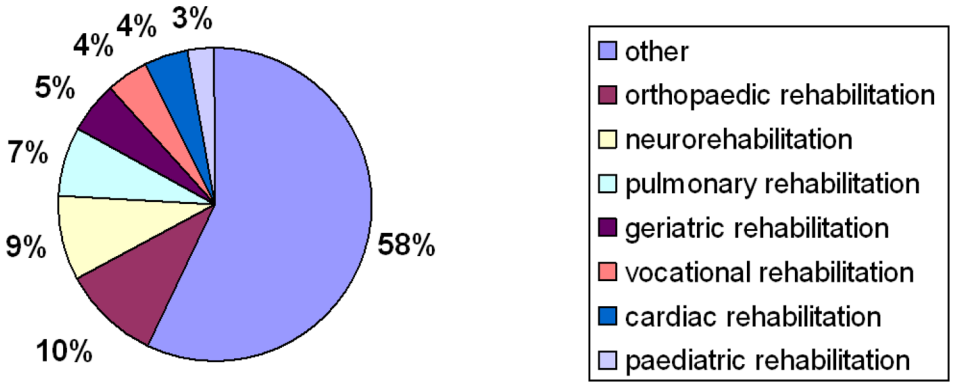
We need to begin from identification of characteristics that are associated with writing, searching or reading the research literature among physical therapists involved in neurorehabilitation. Results may point modifiable practitioner characteristics, including self-efficacy for implementing EBM/EBP and participation in research, appear to be key determinants of EBM/EBP. Own studies will focus on aforementioned factors.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Own Studies

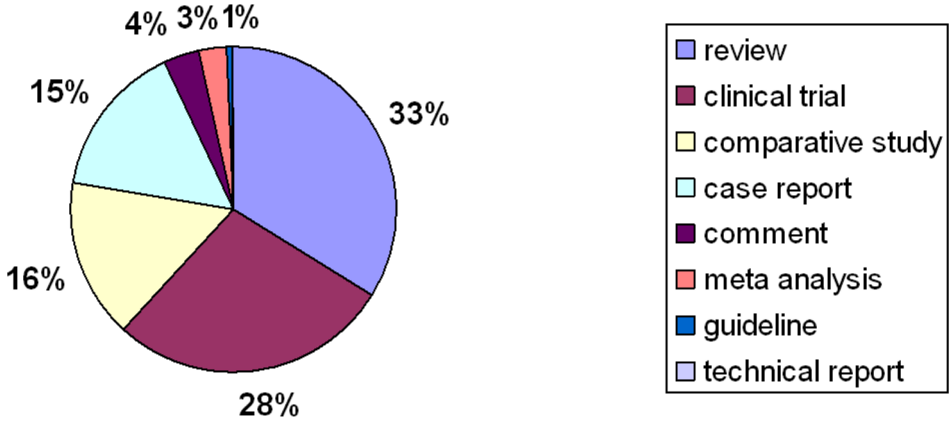
Publication analysis may help find collaborators, identify main trends and find your own scientific way/field. Our own study will show if previous studies concerning scarce evidence in neurorehabilitation were right. It is worth noting and comprehend current status in this field. First of all 45% top cited rehabilitation journals strictly covers field of neurorehabilitation or any subfield (e.g. stroke rehabilitation)[1], all of them publish articles in English only. Six main bibliographic databases was searched. The most of articles concern orthopedic rehabilitation, next neurorehabilitation and pulmonary rehabilitation (figure 3).

Figure 3. The percentage proportion of covered topics by publications analyzed within six main bibliographic databases



Article type influences the strength of evidence. The most common are reviews, then clinical trials and comparative studies (figure 4).

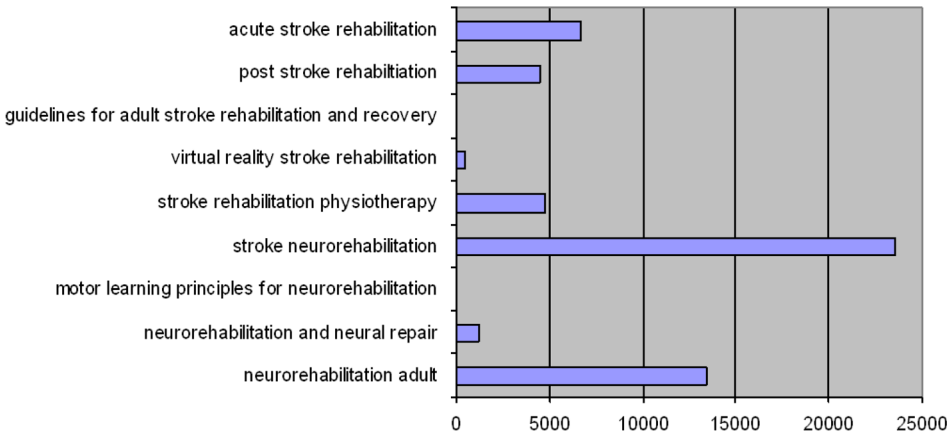
Figure 4. The percentage proportion of types of articles concerning neurorehabilitation analyzed within six main bibliographic databases



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Demands for evidences may miss needs. Where are there needs located? Figure 5 shows the most common searches within neurorehabilitation publication versus number of publications. The most frequent topic is stroke neurorehabilitation.

Figure 5. The most common searches within neurorehabilitation publication versus number of publications



The most common are articles concerning adult patients. The most popular age of patients are:

- **Adults Aged 65+ Years:** 8132 publications,
- **Adults Aged 19-44 Years:** 7509 publications,
- **Children (Birth-18 Years):** 2696 publications (while infants: birth-23 months: only 446 publications).

Compartmental study of co-author networks of four European specialists in neuroscience or neurorehabilitation show figures 6-9. Used data sets were gathered by Harzing's Publish or Perish ver. 5.28 (bibtex files) (Harzing, 2016) analyzed using Science of Science (Sci2) Tool (Sci2 Team, 2009; Börner & Polley 2014). Information on the similarity/distance/co-author weights is used to calculate node positions and distances. Similar nodes are proximal. More publications and more citations were associated with number of nodes and structure and density of connections with co-authors. Four GUESS layouts were selected: a) traditional, b) circular, c) GEM (Generalized Expectation Maximalization, Gupta & Chen 2010, Einicke 2012), d) MDS (Multidimensional Scaling, Cox & Cox 2001). Layout menu and BinPack use allows to "pack" the nodes more closely in space. Node degree shows the number of each individual's co-authors. MDS layout shows graph where node-node distances are defined by the connecting edge weight (co-occurrence frequencies). GEM shows projects more frequently acknowledged together in publications.

Reader should obtain from the graphs orientation concerning number of co-authors and frequency of co-operation. It seems even top level of publications is achievable for specialists in neurorehabilitation. But no doubt such achievements are rare and remarkable. Figures 6-9 provide increased information about the structure and direction of co-operation within research being done. Further enhanced analysis may increase aforementioned information to past successes (the most cited researchers, affiliations, col-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

laborations, and topics/areas of research) and future chances (frequently cited but rarely studied issues, occupations for future collaboration, etc.). Enormous number, diversity and complexity of diseases and injuries in neurorehabilitation makes particularly important that specialists in neurorehabilitation and neuroscience research, and scientists in the biomedical field in general (including biocybernetics and biomedical engineers) should pay particular attention to collaborate through resource sharing, exchange of ideas and knowledge dissemination, as far as information acquisition and analysis. No doubt scientists belonging to different institutions (countries, research areas) should be encouraged to collaborate. Focusing studies on diverse key issues accompanied by reasonable interdisciplinary suggestions, polices, and evidences may help to effectively diagnose, prevent, treat, rehabilitate and care (Huang & Huang 2006, Strotmann et al. 2009, Wu & Duan 2015, Morris &Yen 2004, Leydesdorff 2007).

Figure 6. Neuroscience publications co-author network of worldwide recognized expert in neuroscience, 980 papers, h=90, 30021 citations. Layouts: a) traditional, b) circular, c) GEM, d) MDS.

DISCUSSION

Wider dissemination and increased visibility of evidences in neurorehabilitation need for interdisciplinary studies and denser network of co-authors. Despite unquestionable quality of studies social issues remain very important. It may provide strengthening position of the EBM-based neurorehabilitation.

Individualization of therapy in neurorehabilitation creates severe limitations of scientific and clinical research. Even such relatively basic factors as hard to assess similar knowledge and experience of the therapists or environment and of exercises may influence results of the study. Various societal and cultural

needs of the patients may create diverse context of the treatment (Doucet 2013). Increasing number of RCTs may lead to misunderstanding: review by McIntyre et al. showed that number of RCTs in stroke rehabilitation have increased over the past forty years with an associated increase in methodological quality, but not sample size (McIntyre et al. 2014). Moreover careful analysis of publications may cause

confusion or malfunction: recommendations may be separated for target variables and time after accident thus huge specific knowledge and experience is needed to incorporate them into the particular neurorehabilitation programme. E.g. Dohle et al. showed that in the area of functional restoration of gait in post-stroke survivors:

- Many factors, including pathophysiological insights into functional restoration of stance and gait after stroke should be taken into consideration,
- Gait velocity may be improved by intensive gait training, including incorporation of rehabilitation robots,
- Gait distance can be improved by aerobic endurance exercises (with a cardiovascular effect) in a functional context,
- Balance may be improved by intensive functional gait training.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Functionally relevant training program may incorporate additional stimulation techniques (Dohle et al. 2016).

EBM/EBP did not answer all our questions (Tilson et al. 2008; Timio & Antiseri 2000; Turner & Whitfield 1997). Action observation treatment (AOT), derived from neurophysiology, constitutes novel but not explored approach in neurorehabilitation where patients observe an action and then execute it in context (Buccino 2014). Such reducing the evidence-practice gaps requires active management strategies (Walker et al. 2013).

DIRECTIONS FOR FUTURE RESEARCH

Professor Henry Markram established following challenges for neuroscience:

- Big teams alble to solve the big problems,
- Interlinked sets of data providing a complete picture of single areas of the brain at their different levels of organization,
- Efficient predictive tools,
- Hardware and software powerful to simulate the brain,
- New ways of classifying and simulating brain disease, leading to better diagnosis and more effective drug discovery,
- Brain-inspired technologies, with potentially huge benefits for industry and for society,
- Public awareness and support for neuroscience, associated research and possible benefits (Markram 2013).

Similar challenges for neurorehabilitation were established by Harris and Winstein:

- Primary and secondary prevention, including secondary prevention of lifestyle-related diseases and participation,
- Simple, environmentally relevant predictive measures,
- Cooperation of clinicians and researchers to provide deeper understanding processes such as exercise-induced brain plasticity effects via neuroimaging,
- Interdisciplinary cooperation on advances in mindful health and patient-centered clinical practice (Harris & Winstein 2017).

Neurorehabilitation focus on decreasing impairment and improving function toward higher health-related quality of life. Clinical evidence for most neurorehabilitative treatments is still sparse. Interventions (both conventional and modern)) are usually optimized toward needs of specific target groups of patients. The best direction of further research seems be better understanding of the neuroscience of self-healing and stimulated recovery coupled with outcomes from small-scale and well-focused clinical trials (Luft 2012).

Low number of the clinical trials to testing efficacy and effectiveness of therapeutic interventions within neurorehabiltiation constitutes huge problem. Our ultimate goal is to increase effectiveness of neurorehabilitation. There is need for three-fold development of existing approaches:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Development and validation of instruments quantitatively and qualitatively measuring functional outcomes,
- Dissemination of research that supports particular methods,
- Disseminate negative outcomes confirming lack of efficacy.

Academic-clinical alliances, objective assessment of evaluation and intervention methods, education of practitioners, and evidence-driven everyday clinical practice would be the best solution for current problems (Doucet 2013).

Visualization technology should be used to track scientists from various branches in neurorehabilitation research, and look for possible associations and occupations to co-operate with the most fruitful scientists. Topic-related visualization should be used to acquire more valuable information, identify the most popular issues, and promote rapid development of rare research areas. Exploring the knowledge domain of publications thanks to crossmaps of different entity pairs, should be complemented by identification of front timelines and base reference cluster timelines (Khosrow-Pour et al. 2016, Byrne et al. 2015, Rosiek & Leksowski 2016).

Unification of tools and methods in not always possible. Scientists and clinicians should be aware of differences between studies. It is worth a mention, that tool or method without evidence-based efficacy (or which did not show superiority) is not always non-effective (due to e.g. methodological problems) – scientists need to find them and provide doubtless evidences (Liepert 2012; Pereira et al. 2012).

Neurorehabilitation constitutes unique challenge due to the complexity of human nervous system (associated physiological and pathological motor and cognitive processes/responses), variability of interventions and wealth of clinical/research staff interaction. Variety of kinds and levels of impairment is remarkable as far as their causes: usually most patients have had a stroke, but other traumatic brain injuries, spinal cord injuries, severe poisonings, metabolic diseases, damaged nerves, etc. Thus translation of evidence to clinical practice and the improvement of patient outcomes and qualify of life requires close partnerships of scientists, clinicians, and administrators (Behrman et al. 2013). Three international solutions were described so far by Walker et al.:

- Development of an evidence-based consensus document combined with qualitative and quantitative methods (England),
- Research program covering synthesis of evidence, creation of user friendly information, and development of multimodal knowledge transfer strategies (Canada),
- Multistep process covering audit, feedback, identification of barriers, and tailored education (Australia) (Walker et al. 2013).

Proposed approach to vizualization of social co-author networks in neurorehabilitation is still at the beginning of its development. There is need for development of the most efficient tools, simple and practical in everyday use. Thus compartmental studies will be useful in the future. There is lack of one predominant approach to vizualization of the aforementioned data sets, thus careful tests and dedicated software modernization may be necessary, even as third party visualization tools supported by existing software, e.g. PoP 5.

CONCLUSION

There is a discrepancy between scientific research, current knowledge, and need of clinical practitioners. Positive attitude to EBM/EBP in neurorehabiltiation and interest of medical staff in learning about or improving the skills are necessary to adopt EBM/EBP in their clinical practice. More guidelines, RCTs, and research concerning long-term results of the particular neurorehabilitation programmes (approaches, tools, etc.) would be very valuable. New goals associated with patient-tailored therapy need new and more precise diagnostic tools, which can be the main challenge for scientists and clinicians from the aforementioned areas. Taking into consideration social issues thanks to application of visualization tools may extend visibility of results and allow for easier dissemination of results.

ACKNOWLEDGMENT

KEY TERMS AND DEFINITIONS

Evidence-Based Medicine (EBM): Approach of practicing medicine with the goal to improve and evaluate patient care. Requires the judicious integration of best research evidence with the patient's values to make decisions about medical care (i.e., make proper diagnosis, devise best testing plan, choose best treatment and methods of disease prevention, and develop guidelines for large groups of patients with the same disease).

Evidence-Based Practice (EBP): Way of providing healthcare guided by a thoughtful integration of the best available scientific knowledge with clinical expertise. It allows the practitioner to critically assess research data, clinical guidelines, and other information resources in order to correctly identify the clinical problem, apply the most high-quality intervention, and re-evaluate the outcome for future improvement.

ABSTRACT

This article describes how a neuropsychological assessment and rehabilitation are typically carried out using paper-and-pencil tools. However, these protocols cannot effectively evaluate the subject's performance of daily activities. More recently, the increasing accessibility of new and powerful technology has presented new possibilities. Virtual reality is one of the most promising tools with the increasing ecologicity in the neuropsychological field. The availability of new portable instruments has increased the accessibility and usability of this technology. Using this frame, the changes that have occurred over time in the neuropsychological practice up to the most recent VR-based tools have been explored. In particular, the focus will be on executive functions as the most sensitive cognitive domain within the

ecological validity of the tools. In accordance with the literature, the authors show the potential for the use of virtual reality in the assessment and rehabilitation of executive functions, highlighting the advantages, limitations, and potential future challenges.

INTRODUCTION

The aim of neuropsychological assessment has extensively changed over time. Before the neuroimaging, neuropsychological assessment was conducted for defining which brain area could have been damaged after cerebral lesions and was an extension of the neurological examination Benton (1984). After the diffusion of the neuroimaging techniques (for example, TAC), it has been possible to better determine the brain area damaged and the neuropsychological assessment aims to evaluate cognitive functioning in order to develop a personalized rehabilitation program (Ruff, 2003). Unfortunately, at the beginning, the change of purpose has not translated into a change of tools. The second step of the improvement of the neuropsychological assessment begins with the introduction of the computer-based tools. These tests use a computer interface, like computer or tablet, to administer and correct tests. Usually the test is the computer-version of the classical paper and pencil test. It is rare to find a new test developed specifically for this modern technology. On one side, the advantages of computer-based test are several: more accurate time data, easy administration, automatic data recording, increased standardization of administration. On the other side, the principal problems about the use of these tools are that the normative data cannot be simply applied to computerized version and, generally, don't give an additional useful information for the clinician (Parsey & Schmitter-Edgecombe, 2013; Parsons, 2015). In the light of what said before a great challenge for neuropsychology has been to find new way to better measure, understand, and predict daily life abilities. Indeed, one of the most relevant issues with respect to neuropsychological assessment in the laboratory is the lack of the validity of the protocols, those results in limitations for generalization of the investigated abilities in daily life situations. In the recent decades, neuropsychology, cognitive psychology and cognitive neuroscience have been worked together to understand the complexity of cognitive processes, the functional neuroanatomy underpinning those cognitive domains, and the implications of cognitive impairments in neurological patients for models of normal cognitive functioning.

Virtual Reality (VR) is a new technology that could help to improve neuropsychology assessment (Bohil, Alicea, & Biocca, 2011; Riva & Gaggioli, 2009; Rose, Brooks, & Rizzo, 2005) Technically speaking VR is composed by 3D environment, a user can interact with the environment thanks to different input or output computer devices (visual, auditory or haptic). Virtual environments could represent many everyday life scenarios and are programmed to record precise measurements of the individual's performance in a controlled situation. (Brooks & Rose, 2003). Thanks to these devices, the user can interact with the environment as if it were the real world.

In neuropsychology, VR is used to offer a new human-computer interaction paradigm in which patients are active participants within realistic virtual environments and not only a passive viewer (Riva, Mantovani, & Gaggioli, 2004).

In the literature are many jobs that demonstrate the important characteristics of VR. You in an article form 2005 (You et al., 2005) used fMRI to prove that virtual environments activate the same parts of brain of the real environments. The high ecological validity of the virtual reality training was demon-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

strated by proving that that the skills learned in a virtual environment can be reported in a real situation (Brooks & Rose, 2003).

VR offers several requirements for improving neuropsychological assessment: controlled and secure settings, multimodal and multiple stimulation, feedback about answers, (Bohil et al., 2011; Riva et al., 2004; Schultheis & Rizzo, 2001). It is also possible to control and manipulate the tasks within reasoned, ecologically valid and engaging environments using Virtual Environments (G. Riva & Gaggioli, 2009). The high level of engagement derives from a process call "transformation of flow", that is the ability of a subjects to use an optimal (flow) experience to discover and use psychological resources as sources of involvement (Riva, Castelnuovo, & Mantovani, 2006).

It is also important understand the limit of the use of VR system in the clinical settings.

First, VR requires high costs both for hardware and software creations and not all the hospitals are able to invest in new technology. Even maintain the equipment and have and adequate technical support is expensive.

Developing new functional task in some new virtual environments requires a close cooperation between clinicians and technicians and it is not always possible or easy. By designing intuitive VR applications and providing adequate training, developers may also help medical personnel in using these tools independently. It is hard to find a setting and an adequate number of patients for testing a clinical VR application.

Because of these reason in the community of clinicians and researchers there is low availability of standardized protocols that can be shared (Pedroli, Serino, Cipresso, Pallavicini, & Riva, 2015; Riva, 2009; Tsirlin, Dupierrix, Chokron, Coquillart, & Ohlmann, 2009).

In the literature there are a lot of example of applications of VR for several neuropsychological impairments: memory (Jebara, Orriols, Zaoui, Berthoz, & Piolino, 2014; Spreij, Visser-Meily, van Heugten, & Nijboer, 2014), unilateral spatial neglect (Fasotti & van Kessel, 2013; Mainetti, Sedda, Ronchetti, Bottini, & Borghese, 2013; Navarro, Lloréns, Noé, Ferri, & Alcañiz, 2013; Pallavicini et al., 2015), dementia (Allain et al., 2014; Cipresso et al., 2014; Serino, Morganti, Di Stefano, & Riva, 2015; Serino, Pedroli, et al., 2017), and dyslexia (Pedroli et al., 2017).

Considering what has been said so far below will be presented possible applications of VR in a neuropsychological clinical practice, focusing on executive functions.

As Fleming and colleagues (Fleming et al., 2016) argue in their perspective article, a paradigm shift is needed to increase the impact of E-Therapy mental health. This change will be feasible by increasing the focus on user-centered approaches, the emphasis on engagement, and the collaboration in program development, testing, and data sharing.

EXECUTIVE FUNCTIONS BEFORE VIRTUAL REALITY

The executive functions are one of the most investigate neuropsychological domains and their complexity makes it an excellent candidate for the VR applications.

The executive functions allow us to continuously orienting cognitive resources to effectively respond both to environmental and internal demands.

Specifically, the executive functions including a large number of cognitive processes and behavioral competencies like: problem-solving, planning, sequencing, the ability to sustain attention, resistance to interference, utilization of feedback, multitasking, cognitive flexibility, and the ability to deal with

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

novelty (Burgess, Veitch, de Lacy Costello, & Shallice, 2000; Chan, Shum, Toulopoulou, & Chen, 2008; Grafman & Litvan, 1999)

Several neurological impairments that involve the frontal cortex or some related structure can lead to an impairment of executive functions, the "Dysexecutive Syndrome" (Bechara, Damasio, Damasio, & Anderson, 1994; Robertson, Manly, Andrade, Baddeley, & Yiend, 1997; Snyder, Miyake, & Hankin, 2015).

The assessment of executive functions has been generally performed for clinical use in the hospital and clinician usually use paper-and pencil test or laboratory tasks and an increasing number of tests have been developed for the assessment of different kind of patients (Chan et al., 2008).

For example, the assessment protocol may include single task for single cognitive process like Wisconsin Card Sorting Test for ability to shift cognitive strategies in response to environmental changes (Anderson, Damasio, Jones, & Tranel, 1991; Caffarra, Vezzadini, Dieci, Zonato, & Venneri, 2004) or the Tower of London for problem solving (Allamanno, Della Sala, Laiacona, Pasetti, & Spinnler, 1987; Shallice, 1982). In the protocol can also be batteries for the assessments of executive functions like Frontal Assessment Battery (FAB) (Appollonio et al., 2005; Dubois, Slachevsky, Litvan, & Pillon, 2000).

Interestingly many patients with Dysexecutive Syndrome shown normal scores on traditional neuropsychological tests and, at the same time, they complain important difficulties in daily life activities (Shallice & Burgess, 1991).

This problem may result from the lack of ecological validity of the tests, this is a critical issue of the classical assessment of executive functions (Chan et al., 2008).

The traditional assessment does not capture the complexity of executive functions in a real environment. An ecological assessment may evaluate if individuals are able actually respond to external and/or internal demands provided from the task.

An ecological evaluation is also important to understand the neuropsychological profile and to plan a personalized rehabilitation for the patients.

These considerations should direct the clinician and researchers to develop some more ecological tasks for executive functions assessment. Some tasks have already been developed with these features: the Behavioral Assessment Of The Dysexecutive Syndrome (BADS) (Perfetti et al., 2010; Wilson, Krabbendam, & Kalff, 1997) and the Multiple Errands Test (MET) ((Alderman, Burgess, Knight, & Henman, 2003; Shallice & Burgess, 1991).

More specifically, BADS (Perfetti et al., 2010; Wilson et al., 1997) is a laboratory-based tasks that includes tasks that investigate abilities involved in everyday life: temporal judgement, rule shift cards, action program, key search, Zoo map, modified six and a dysexecutive questionnaire. The questionnaire is formed by 20 questions that investigate several domains like emotional or personality changes, motivational changes, behavioral changes and cognitive changes.

Instead, the MET (Nick Alderman et al., 2003; Shallice & Burgess, 1991) is a functional test specifically developed for high functioning patients because takes place in a real shopping mall or in a hospital environment. Particularly, the original version was also modified into two way: the simple version (Nick Alderman et al., 2003) and the hospital one (Knight, Alderman, & Burgess, 2002).

In the simplified version patients have to make three main tasks: buying six items (e.g., small brown loaf), finding and remember four items of information (e.g., the closing time of the library on Saturday) and meeting the clinician at a designated point. In addition, the patients have to stating the time 20 minutes after beginning the test. During the test patients have to follow several rules, such as for instance "Do not speak to the person observing you unless this is part of the exercise."

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

This procedure can be defined as "open" or "ill-structured" (Goel, Grafman, Tajik, Gana, & Danto, 1997) because there are many things that patients could do, both for the right or wrong outcomes.

For this reason, the clinician follows the patients during the task, both to control it and to score errors like task failure (e.g., failed to purchase keying) or rule breaking (e.g., shouted question to shop staff). The MET has good ecological validity (Burgess et al., 2006) and requires the implementation of several executive functions: plan the actions, list the steps necessary, describe and check the goals and compare the outcome with the desired aim.

Despite the many virtues, the test also presents limitations: the participants have to have a good motor skill to go to a real shop, the protocol is time consuming, for both the patient and therapist and all the procedure could be particularly challenging for a patient with medium or severe cognitive impairment. Moreover, the real environment is not a controlled and secure setting, and it is not possible to maintain an experimental control over the presentation and the recording of the stimulus.

EXECUTIVE FUNCTIONS AND VIRTUAL REALITY

The Multiple Errands Test

In order to overcome these limitations several groups saw VR like a possible solution.

Initially, Rand and colleagues have developed one version of the Virtual Multiple Errands Test (VMall) in a functional virtual setting, a large supermarket that was programmed via GestureTek's IREX video capture virtual reality system. The VMall is a task for post-stroke patients that allows making different shopping tasks without leaving the hospital. (Rand, Katz, Kizony, Shahar, & Weiss, 2005; Debbie Rand, Katz, & Weiss, 2007; Debbie Rand, Rukan, Weiss, & Katz, 2009).

Riva and his team developed and tested a virtual version of the Multiple Errands Test (VMET) (Raspelli et al., 2012). The VMET consists of a Blender-based application that allow active exploration of a virtual supermarket where participants are requested to select products on shelves. Moreover, the participant is able to navigate in the supermarket using an up-down joypad arrows and to collect products by pressing a button placed on the right side of the joypad, after having selected them with the viewfinder.

The virtual supermarket contains products grouped into the main grocery categories (beverages, breakfast foods, garden products, hygiene products, fruits and vegetables, frozen foods, and animal products) indicate at the top of each section with a signboard (see Figure 1).

The procedure has been adapted by Shallice and Burgess (Alderman et al., 2003; Shallice & Burgess, 1991).

Before the task, patients make a training session in another supermarket in order to understand how joypad works and how to move in the environment.

After the training session, the examiner shows the shop where the test takes place and describe all the sections.

Then the clinician gives a shopping list, a supermarket's map, some information about the supermarket (opening and closing time, products in sales, etc.), a pen, and a wristwatch to the participants. In addition, the clinician illustrates the rules and the instructions to ensure they are fully understood. When he finished the explanation makes starting the stopwatch.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The Supermarket

The four main tasks of the test are: find and buy the six items on the list, ask information about one item to the examiner, write what products you bought after five minutes from start and answer a series of questions after finishing the task using the given materials.

The rules are as follows:

- You have to execute all the proposed tasks, but you can run them in any order
- You cannot go in a place unless this is a part of a task
- You cannot pass through the same passage more than once
- You cannot buy more than two items per categories (look at the chart)
- Take as few time as possible to complete this exercise however without hurry
- Do not talk to the researcher unless this is a part of the task
- Go to your "shopping cart" after 5 minutes from the beginning of the task and make a list of all the products that you bought

During the test, the examiner cannot talk with participant, not even to answer to the questions. When the participant said, "I finished" the clinician stops the time. During the task, the examiner records all participant's behaviors in the virtual supermarket. The errors were divided as following, as suggest Shallice and Burgess (Shallice & Burgess, 1991):

- Task failure, namely a task not completed satisfactorily
- Inefficiencies and strategies, where a more effective strategy could have been applied to accomplish the task

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Rule Breaks, where a specific rule listed in the instructions has been violated
- Interpretation failures, where the requirements of a particular task are not misunderstood

This technology could create problems in the elderly patients who are not familiar with computers, and Chan and colleagues (Chan et al., 2008) say that should be carefully used in clinical setting.

To get on top of this issue Pedroli and colleagues (Pedroli, Cipresso, Serino, Riva, & Albani, 2013) analyzed the usability of the VMET in a sample of 21 healthy participants and 3 Parkinson's disease (PD) patients.

They administered The System Usability Scale (SUS) to assess the usability. This test is a "quick and easy to use" measure developed by Brooke (Brooke, 1996). For Brooke usability is "the subjective perception of interaction with a system."

Results showed that Healthy participants had perceived a good usability for the VMET. On the other side, for the patients is crucial an intensive training phase before the test.

These encouraging results led us to consider the VMET as a useful tool to evaluate executive deficits in every sample, even with elderly subjects with motor impairment.

To better understand the psychometric properties of VMET many studies with several samples were done.

The reliability of the VMET was evaluated using two different experiments: in the first one, two independent researchers analyzed 11 videos in which 11 healthy subjects were tested; in the second one, 7 researchers scored 2 videos of 2 healthy subjects running the VMET. The results showed that the test have a good reliability (Cipresso, Serino, et al., 2013).

In addition, the VMET has been validated in different clinical populations that may show signs of a dysexecutive syndrome or some impairment in executive functions.

The first study of a clinical sample was done by Raspelli and colleagues (Raspelli et al., 2012). They have analyzed three groups (9 post-stroke participants, 10 healthy young participants, and 10 healthy older participants) in order to demonstrate the ecological validity and initial construct validity of the VMET. All the groups were tested with VMET and a neuropsychological battery that focuses mainly on executive functions.

The results showed a correlation between some variables of VMET and some traditional executive functions neuropsychological tests. Moreover, the performances obtained at the VMET showed a distinction between clinical and control group and between the two age control groups.

These outcomes offer preliminary evidence of the ecological and construct validity of the VMET. Successively, La Paglia and colleagues (La Paglia, La Cascia, Rizzo, Riva, & La Barbera, 2012) assess, with VMET, 10 patients suffering from obsessive-compulsive disorder (OCD) and 10 controls. They used the VMET to evaluate the executive functions in daily life and a neuropsychological battery to test the executive functions in laboratory. The results show that OCD patients use much time than normal subjects to complete the task; probably this extra time is used to planning. Furthermore, patients showed more problems in following rules and sustaining attention than healthy subjects. Results show that there is a significant correlation between VMET and the executive functions tests i the OCD patients, this correlation underlines the good ecological validity anf the feasibility of the VMET in this sample.

In the 2013 Cipresso and colleagues (Cipresso, La Paglia, et al., 2013) analyzed a similar sample (OCD patients) to investigate deficits of volition during the assessment with VMET.

The sample include 30 participants: 15 OCD patients and 15 controls. The subjects were monitored during task execution and the relative interferences.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

OCD patients showed a specifically pattern of deficits, as defined in the following classification:

1. Break in time (i.e.: go to the shopping chart after 5 min)
2. Break in choice (i.e.: buy two products instead of just one)
3. Break in social rules (i.e.: go into a specific place and to ask the examiner what to buy")

One of the main field of application for the VMET is the assessing of the executive functions in Parkinson's disease (PD).

As we shall see below, the cognitive disorders in this condition may overshadow compared to other neurological disorders, probably because the motor symptoms are prevalent.

It is important the early Identification of executive deficits in PD because it could facilitate the identification of patients at risk of dementia. Having an early diagnosis could give the chance to develop early rehabilitation in order to avoid a quick cognitive decline.

The cognitive impairment in PD affects a variety of cognitive domains that received a relevant clinical attention: executive functions, visuospatial abilities, memory and language (Foltynie, Brayne, Robbins, & Barker, 2004; Kehagia, Barker, & Robbins, 2010; Muslimović, Post, Speelman, & Schmand, 2005; Williams-Gray et al., 2009). As Verleden and colleagues underlined (Verleden, Vingerhoets, & Santens, 2006) the cognitive impairments in PD patients can be extremely various, both for cognitive profile and the for onset and rate of progression.

Despite the heterogeneity of the cognitive profile the core of the cognitive impairment of PD patients is composed by the executive functions (Ceravolo, Pagni, Tognoni, & Bonuccelli, 2012; McKinlay, Grace, Dalrymple-Alford, & Roger, 2010). The impairment in the executive functions in PD patients is a little different to those seen in patients with a frontal lobe damage because involve a dysfunction of the frontostriatal neural circuitry (Rogers et al., 1998; Rowe et al., 2002).

The cognitive impairment has a negative impact on quality of life of both patient and caregiver, as well as the health-economic side (Aarsland, Larsen, Karlsen, Lim, & Tandberg, 1999; Aarsland, Larsen, Tandberg, & Laake, 2000; Schrag, Jahanshahi, & Quinn, 2000).

Early detection and rehabilitation of executive dysfunctions is crucial in the management of PD both for the cognitive and motor aspects. Is very important evaluate the cognitive component of the disease in order to reduce disability using a fully personalized rehabilitation program

Because of these problems, we argue that the VMET could be a useful test for the assessment of executive deficits in PD patients.

Therefore, the focus is to identify patients before they develop dementia through a specific assessment in order to prevent o decelerate the cognitive decline. All this process is very important because a relevant number of PD patients developed dementia (Aarsland, Andersen, Larsen, & Lolk, 2003; Bosboom, Stoffers, & Wolters, 2004; Dubois et al., 2007; Hely, Reid, Adena, Halliday, & Morris, 2008).

Several longitudinal studies prove that a deficit in the executive functions could be a precursor of a future dementia (Azuma, Cruz, Bayles, Tomoeda, & Montgomery, 2003; Janvin, Aarsland, & Larsen, 2005). Based on this information a new term was developed "mild cognitive impairment in PD"

In this perspective, it has been recently proposed to use the term "mild cognitive impairment in PD" (Litvan et al., 2012). Although the term "mild cognitive impairment" applied to PD is controversial (Tröster, 2008), it is more frequently used and more widely accepted than alternative terms.

Mild cognitive impairment in PD may be a useful clinically concept to de-fine a cognitive decline that is not normal for age, but it is essentially associated with normal functional activities. Several

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

studies demonstrated that mild cognitive impairment predicts the development of dementia, which can occur in up to 80% of PD patients over the long term (Azuma et al., 2003; Janvin, Larsen, Aarsland, & Hugdahl, 2006).

Evaluation of early executive deficits in PD could facilitate the identification of patients at risk to develop dementia and may give the chance to develop early neurorehabilitation interventions.

In such context, we argue that the VMET may significantly improve the traditional assessment of executive functions in patients suffering from mild cognitive impairment due to PD.

Thanks to the VMET, it will be possible to evaluate:

- The real functional status of mild cognitive impairment due to PD, as manifested in terms of executive dysfunctions, that had not been fully acknowledged in everyday life scenarios;
- The ability of patients with mild cognitive impairment due to PD in formulating, storing and checking all the goals and sub-goals in order to effectively respond to environmental demands in ecological situations.

Albani and colleagues (Albani et al., 2011) investigate the correlation between decision-making and alteration of sleep structure in 12 PD patients with and 14 controls. These alterations regard early-middle stages of Parkinson's disease and may lead to daytime drowsiness, loss of attention and concentration, feeling of tiredness. All patients have undergone polysomnography, compete neuropsychological assessment and VMET. Five PD patients showed sleep abnormalities and significant differences in the VMET performance compared to other patients with normal sleep and controls.

Few years later Cipresso and colleagues (Cipresso et al., 2014) analyzed the performance of three groups (15 PD patients with mild cognitive impairment, 15 PD patients with normal cognition and 15 healthy subjects) using a complete neuropsychological battery and the VMET. The aim of the study was to understand which instruments best discriminates between these three groups and investigate which components of executive functions are the most damaged. Significant differences in the VMET score were found between PD patients with normal cognition and control patients. Specifically, PD patients made more errors in the tasks of the VMET and showed a poorer ability to use effective strategies to complete the tasks. No difference was found in the classical neuropsychological tests. This is an important result because show that VMET result seems to be more sensitive in the early detection of executive deficits in PD patients and offers initial evidence that an ecologically evaluation of executive functions is more effective than classic paper and pencil tests.

This positive result encourages us to consider the VMET as a useful tool to evaluate executive deficits even in the early stage of Parkinson's disease. In this stage of disease, the cognitive disorders are not as evident, and their diagnosis tends to be delayed. Identification of early executive deficits in PD could facilitate the identification of patients at risk to develop dementia and could give the chance to develop early neurorehabilitation interventions.

Alternative VR-Tools

In the 2016 an international group (Oliveira et al., 2016) present an ecological task of cognitive assessment for older adults in VR (ECO-VR). In the article, the author shows the development, feasibility, content validity, and preliminary evidence of construct validity of the tool. The tasks were prepared based on theoretical and clinical backgrounds. Twenty-nine non-expert judges considered the virtual

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

visual stimuli and three-dimensional scenarios. In addition, five expert judges proceeded with content analysis and, at the end, developing a more appropriate instruction. Finally, six older persons participated in three pilot studies and thirty older persons participated in the preliminary study to identify construct validity evidence. The ECO-VR demonstrated feasibility for cognitive assessment in older adults, as well as content and construct validity evidences.

Dahdah and colleagues create a VR version of Stroop test (Dahdah et al., 2017) to determine whether immersive VR treatment interventions improve executive dysfunction in patients with brain injury. Authors selected 15 patients with brain injury and administered several tests, both virtual and paper and pencil. At the end of the training participants demonstrated an improvement in several parameters of different tests (VR and Automated Neuropsychological Assessment Metrics) and the authors concluded conclude by stating that an immersive VR intervention is effective in improving executive functions and information processing speed in brain-injured patients during the subacute period.

In the same year Davidson (Davison, Deeprose, & Terbeck, 2017) investigated a new immersive virtual reality (IVR) tool for the assessment of executive function in healthy younger and older adults. They analyzed 40 subjects with Stroop colour–word test, the trail-making test (TMT) and three IVR tasks (a seating arrangement task, an item location task and a virtual parking simulator). Significant correlations were found between performance on traditional neuropsychological measures and IVR measures. In addition, IVR measures were the most important contributors in predicting age-related cognitive decline. Younger adults demonstrated higher levels of performance compared to older subjects.

Another tool for the assessment of executive functions abilities in individuals with lesions in the prefrontal cortex was presented by Denmark and colleagues (Denmark et al., 2017).

The authors used the Jansari assessment of Executive Functions (JEF) with nineteen individuals with frontal lobe lesions and 19 matched controls. In addition, they have administered classical measures of neuropsychological functioning and questionnaire measures of everyday activity, anxiety and depression. There was a significant difference between groups on the overall JEF© score and on five of the eight individual constructs but there were no differences between groups on the non-VR EF individual measures apart from Trail Making A. The results demonstrate the potential and the importance of ecologically valid VR measures in detecting impairments in EF in individuals with frontal lobe lesions.

Parsons and colleague (Parsons & Barnett, 2017), in their study, compared a Virtual Apartment Stroop Task with paper-and-pencil and computerized Stroop modalities in older adults and young adults. The authors want to analyze how inhibitory control changes with aging. Three primary results have been found: (a) the classic "Stroop pattern" was observed in the Virtual Apartment Stroop Task; (b) the Virtual Apartment "Stroop scores" were consistent with significant differences found between the two groups on the other tasks; and (c) older subjects performed significantly worse on the Virtual Apartment Stroop Task than the other group. Authors suggest that the Virtual Apartment Stroop Task are able to distinguish between prepotent response inhibition and resistance to distractor inhibition in aging adults.

Another VR-based intervention was developed by Vieira and colleagues (Vieira, Melo, Machado, & Gabriel, 2018) in order to analyses the effect of a six-month home-based phase III cardiac rehabilitation (CR) specific exercise program. The training was performed in both VR and conventional environment and was designed to improve executive function, quality of life and depression, anxiety and stress. A randomized controlled trial was conducted with subjects divided in three groups: two intervention groups (VR vs. non-VR) and a control group. Several cognitive domains were analyzed in three different moments (baseline, 3 and 6 months): the ability to switch information, working memory, selective attention, conflict resolution ability, quality of life, depression, anxiety and stress. Descriptive and inferential

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

statistical measures were used, with significance level set at .05. The analysis revealed that virtual reality format had improved selective attention and conflict resolution ability, revealing the potential for the improvement of executive function in cardiac patients.

According to all these previous results, it is clear that VR tools are more sensitive and more adequate that the classic paper and pencil protocols. Obviously, a future study is needed to deepen knowledge and to make these tools suitable for clinical practice.

CONCLUSION

The instruments presented are just examples of an innovative approach to clinical practice in neuropsychology. To improve the neuropsychological assessment and rehabilitation the innovative technologies are in first line. Specifically, VR is one of the best candidate to replace the classical paper and pencil method. Thanks to its multiple advantages VR allow to the clinician to observe the behavior of patients in a setting like the real one but more safe and customized. To manage the variables of an ecological task allows a better understanding of deficits and potential of the patients. In addition to the portable technology various other tools for immersive virtual reality are being develop. These devices could be very useful for neuropsychology because of the possibility of acting in a virtual environment like in the real one.

The two most important devices are VR wearable visors and the Cave Automatic Virtual Environment (CAVE). The first one is developed for virtual reality systems and video games. This tool uses tracking technology and can create a stereoscopic 3D view. The 3D view cold be obtaining thanks to depth, scale and parallax by presenting unique and parallel images for each eye and using a 3-axis gyroscope, accelerometer and magnetometer to process data.

In alternative to VR, a new way to present ecological stimuli using an immersive tool are 360° environments (immersive photographs or videos) delivered via smartphones or wearable visors. Thanks to this technology, participants could be immersing into a real environment from a first-person perspective. The use of 360° videos require to subjects to sequential focusing on different pieces of the environment and multiple elements at various times. These specific characteristics required the ability to make a sequential planning of visual search (Serino, Baglio et al., 2017).

Roberton and colleague (Robertson, Hermann, Mynick, Kravitz, & Kanwisher, 2016) demonstrate that, to facilitating subsequent perceptual judgments, individual scene views prime associated representations of the panoramic environment. This dynamic relationship between memory and perception plays a key role in weaving the fabric of continuous visual experience and could be an important mechanism for the cognitive assessment and rehabilitations. Accordingly, Serino and colleagues (Serino, Baglio et al., 2017) used this technology to assess executive functions Parkinson's disease; the results indicated the proposed tool (PIT 360°) are able to distinguish between patients with PD and healthy controls.

The CAVE is a room where stereoscopic projectors project on the walls, floors and, ceiling a 3D virtual environment in high-resolution. These characteristics allow an increase in the sense of presence. In the CAVE the head-trackers and hand-trackers are using to allow natural movements to interact with the virtual environment. CAVE is used mostly for design and fashion applications, but recently there have been some clinical applications, principally for the treatment of phobias and emotional disorders (Bouchard et al., 2013; Meyerbröker, Morina, Kerkhof, & Emmelkamp, 2010).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The hope is that these great technological improvements lead to an increase in the development of new tools and new protocols. The goal is to improve practice neuropsychological to allow her to break away from the classic test.

ABSTRACT

Virtual and Augmented Reality are technologies widely used in a variety of areas, including the medical sector. On the other hand, regular mirrors have been traditionally used as tools to aid in mental health treatment for a variety of diseases and disorders. Although it is possible to build Virtual and Augmented Reality experiences based on mirror metaphors, there are very few contributions of this kind in the medical sector. In this chapter, the great benefits that regular mirrors have brought for mental health treatment are addressed. In addition, a review on the state of the art in mirror-based Virtual and Augmented Reality applications is given, highlighting the potential benefits that these enhanced mirrors could bring for the mental health treatment.

INTRODUCTION

A regular mirror can be defined as a special kind of object usually flat and made of polished metal or reflective glass that is capable of reflecting light in such a way that it provides a faithful representation of the objects reflected on it. Mirrors have a natural attraction for human beings since they allow people to see themselves in a third-person view, which is not the one we usually have of our own body, and have been referred to provide uncanny experiences (Rochat & Zahavi, 2011).

Although the daily use of mirrors is commonly associated with cosmetics and superficial activities, they have been used in medical therapy for a long time in order to treat several medical conditions, many of them related to mental health. Pain relief (such as in phantom limb pain (Desmond, O'neill, De Paor, McDarby, & MacLachlan, 2006)), rehabilitation (such as motor rehabilitation or the treatment of patients with cerebral palsy), psychological disorders (such as body dysmorphic disorder or anorexia nervosa) and neurological disorders (such as asomatognosia or mirror agnosia) are some of the areas where Mirror Therapy (MT) has been used in the past, to name a few.

One characteristic of regular mirrors is that they are constrained to reflect a real image of the environment where they are located (although some optical distortion can be applied using curved mirrors) and are thus limited by the physical space and vision angle that the specific set-up offers. Therefore, their potential uses are rather restricted to a set of certain conditions. However, the use of Information Technologies (IT), such as Virtual Reality (VR) or Augmented Reality (AR) can radically change the way mirrors are used in medical therapy, extending their use to other medical problems such as phobias, autism spectrum disorders (ASD) or even neurodegenerative diseases. VR and AR can be presented with many different set-ups, using different display devices and exploiting different interaction paradigms and metaphors. One of these paradigms is the mirror metaphor, by which a VR or AR system is designed to behave like a mirror, regardless of whether it is implemented using an actual mirror or not.

This chapter has three major goals. The first one is to clearly define and classify the different mirror-based IT solutions that are based on either VR or AR. As these enhanced mirrors are relatively new, the literature offers different terminologies for similar proposals, which can be confusing. The chapter will try to clarify the different options and methods that can supply mirror-like images using IT solutions. The second goal is to review the works that already exploit the use of VR and AR mirrors for mental health treatment, reviewing the state of the art. Since the technology is relatively new and the research area of this particular review is restricted to mental health applications, the number of works is relatively small. Nevertheless, they are enough to demonstrate the benefits of this technology and show its potential. Last, but not least, the chapter aims to discuss the possible benefits of these technologies for the treatment of other mental health illnesses, disorders, syndromes, problems and conditions, which are currently not explored with IT solutions. The chapter will try to identify opportunities, strengths, weaknesses and future research lines, so that readers and practitioners get a clearer picture about these devices.

This chapter is organized as follows. In a first place, a short review is given regarding to the use of regular mirrors in mental therapy. In this regard, several illnesses and mental disorders are addressed. Afterwards, the use and potential of VR and AR in mental therapy is discussed. First, the VR and AR mirror metaphors are given, and then a review on the state of the art is provided. The review also covers a few applications of enhanced mirrors to other (mind-related) medical fields, since the number of applications of this technology for mental health is still small. Finally, some conclusions and further directions are outlined.

THE USE OF REGULAR MIRRORS IN MENTAL THERAPY

Regular mirrors have been traditionally used in a variety of medical therapy applications for a long time, which is referred as Mirror Therapy (MT). In this sense, mirrors have been mainly used in pain relief, rehabilitation, in the treatment of anxiety disorders or in the treatment of phantom limb pain (PLP), among others. Several works have dealt with the use of MT for PLP (Chimes, Bernstein, Cortazzo, & Huber, 2009) and it has been proven to be effective (Chan et al., 2007) in the treatment of this condition, although the amount of pain relief obtained is controversial. MT for PLP and other conditions causing limb impairment is used in patients with unilateral limb impairment (such as unilateral amputation). It consists in the use of a mirror so that the motion of the healthy limb is reflected and creates the illusion that the opposite (impaired or amputated) limb is present or healthy and moves appropriately.

MT in rehabilitation includes the treatment of patients with recovery from hemiparesis (Altschuler et al., 1999; Dohle et al., 2009; Stevens & Stoykov, 2003), cerebral palsy (Feltham, Ledebt, Deconinck, & Savelsbergh, 2010) and motor rehabilitation after a stroke (Rossiter, Borrelli, Borchert, Bradbury, & Ward, 2015; Thieme, Mehrholz, Pohl, Behrens, & Dohle, 2012, 2013), to name a few. For instance, in Harmsen, Bussmann, Selles, Hurkmans, and Ribbers, (2015) 37 participants in chronic stage after a stroke were instructed to perform an upper-arm reaching task as fast and as fluently as possible. In Colomer, Noe, and Rodríguez, (2016) 31 post-stroke chronic subjects with severely impaired upper limb function were evaluated. In Park, Chang, Kim, and Kim, (2015) a group of chronic stroke patients were tested to perform a comparison based in paretic upper-extremity function and hand coordination abilities. In Vural, Yuzer, Ozcan, Ozbudak, and Ozgirgin, (2016) the participants were 30 patients with first-time stroke and simultaneous complex regional pain syndrome type 1 of the upper extremity at the dystrophic stage. The huge amount of research in this topic is an indicator of the benefits that MT brings for patients needing rehabilitation.

Other uses of MT include the treatment of anxiety disorders, such as anorexia nervosa (Key et al., 2002) or body dysmorphic disorder (Windheim, Veale, & Anson, 2011), and other rarer conditions such as mirror agnosia, mirrored-self misidentification or asomatognosia (Connors & Coltheart, 2011; Fotopoulou et al., 2011; Paysant, Beis, Le Chapelain, & André, 2004). For instance, in Probst, (2015) patients with eating disorders, where the body image is a problem, were evaluated. The relationship between mirror exposure and body satisfaction has been widely studied. According to the literature, it has been proved that mirror exposure increases satisfaction in patients with normal weight eating disorder (Hildebrandt, Loeb, Troupe, & Delinsky, 2012), anorexia nervosa (Key et al., 2002), obese adolescents (Jansen et al., 2008), normal weight and overweight in binge eaters (Hilbert, Tuschen-Caffier, & Vögele, 2002) or in body unsatisfied students (Luethcke, McDaniel, & Becker, 2011). For instance, in Jansen et al., (2016) a study is presented that shows that the exposure to one's body using a mirror increases body satisfaction in body-dissatisfied young women. They proved it in two experiment conditions: focusing on attractive body parts and focusing on unattractive body parts. In both cases, mirror exposure led to increasing body satisfaction.

Another study about MT is the one presented in Deconinck et al., (2015), where a review on the effect of mirror visual feedback (MVF) on the brain is presented. This study concludes that MVF can exert a strong influence on the motor network, mainly through increased cognitive penetration in action control.

As it can be seen from the many examples given above, the use of regular mirrors has been proved beneficial for the treatment of a variety of medical conditions and disorders. It can be added that Mirror Therapy has been used for a long time with little economic impact, as mirrors are inexpensive devices.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The question now is if new technologies, such as VR and AR could bring additional benefits to Mirror Therapy, while keeping a simple setup and without increasing costs.

USE AND POTENTIAL OF VR AND AR MIRRORS IN MENTAL THERAPY

Whereas the application of MT with regular mirrors for mental health treatment is limited to some particular applications due to the small amount of set-ups that can be considered, the combination of mirrors and Information Technologies (IT) provides the possibility of using MT for mental health treatment in many different ways and applications. Unlike a real mirror, which is constrained to its optical and physical properties, the image in a mirror-like IT-based application can be augmented by means of virtual objects (AR mirrors) or can be substituted by a virtual depiction (VR mirrors). Therefore, the possibilities are almost unlimited.

VR and AR Interaction Paradigms and the Mirror Metaphor

The concept of VR was born around 1930. Already in 1929, E. Link created the Link Trainer, which is considered the first flight simulator, being completely electromechanical. During the same years, the science fiction writer S. G. Weinbaum writes a story (Pygmalion's Spectacles) that contains the idea of a pair of goggles that makes users experience a synthetic world through holograms, smell, taste and touch. He further describes uncanny experiences for those wearing the goggles, aligned with the modern concept of VR. Some years later, M. Heilig developed the Sensorama (patented in 1962), which resembled a kind of arcade-style theatre cabinet. That technology allowed a user seeing stereoscopic films enhanced with seat motion, vibration, stereo sound, wind, and aromas, which were triggered during the films (Heilig, 1962). Since then, many works have arisen that use VR as platforms that support a variety of fields, such as learning and training (Gavish et al., 2015; Gimeno, Fernández, Morillo, Coma, & Pérez, 2007; Pan, Cheok, Yang, Zhu, & Shi, 2006), entertainment (Díaz, Boj, & Portalés, 2016; Vargas González, Kapalo, Koh, & LaViola, 2017), driving and flight simulation (Casas, Coma, Portalés, & Fernández, 2016; Cox et al., 2010; Tudor, Carey, & Dubey, 2015), digital cultural heritage (Gaitatzes, Christopoulos, & Roussou, 2001; Portalés, Alonso-Monasterio, & Viñals, 2017; Richards-Rissetto et al., 2014), and scientific or medical visualizations (Cruz-Neira et al., 1993; Chirico et al., 2016; Moro, Stromberga, & Stirling, 2017), to name just a few.

Overall, VR can be defined as the technology by which one or several individuals experience the sensation of belonging to an alternative reality, which is not the one they are actually living in (outside the VR world). This alternative reality is generated by a computer or by a network of computers and it is important that the participants of this simulated experience accept this virtual synthetic world as a suitable deception of the real world. In this sense, it can be argued that VR is all about perception. For this reason, VR applications need to incorporate visual, aural, gravito-inertial, haptic, tactile, or even olfactive and gustatory perceptual cues (Anthes, García-Hernández, Wiedemann, & Kranzlmüller, 2016) in order to induce a feeling of immersion in the virtual world. However, as a complete recreation of the real world is usually impossible, it is often acceptable that the feeling of immersion and the perception of belonging to this new virtual world be only partial. Some of the characteristics of VR that makes it valuable as a medical tool are (Casas Yrurzum, 2014; Perpiñá, Botella, & Baños, 2003):

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The recreated VR experience is a 'safe environment', since none of the issues can harm patients.
- The fact that, within VR, 'protected' contexts are generated, makes it more feasible to persuade the patient to take the step and enter into action.
- Within VR, it is possible to graduate the situation, progressing from simple to complex settings.
- As events can be synthetically recreated, it is not necessary to wait for those events to take place in the real world.

On the other hand, AR is a technology by which a view of the real world (or even the world itself) is augmented using synthetic images that are superimposed or projected over this image of the real world. However, AR systems need to provide some other features to be considered as true AR applications. The definition currently accepted is that AR systems are those that simultaneously (Azuma, 1997): i) combine virtual and real objects; ii) are completely interactive in real time and iii) are registered in 3D. The interaction and 3D registration are essential features of an AR application since they allow a seamless blending of virtual and augmented objects. AR applications should provide virtual objects that fit in the real world regardless of the position from which the user observes them. AR is a fairly popular technology because it provides a number of advantages that other technologies cannot offer (Bimber & Raskar, 2005):

- *The ability to enhance/augment reality*. By using this technology, physical entities can be enhanced with additional elements, such as images, sounds, virtual models, etc. that are not present in the real scene.
- *Seamless interaction between virtual and real objects*. Interfaces are said to have seams (Ishii, Kobayashi, & Arita, 1994) if there is a functional, temporal, spatial or cognitive element that forces the user to change the way in which he/she interacts with the interface. When using properly designed AR applications, interaction is performed in a natural seamless way, since users can visualize and interact with virtual elements as if they belong to the real environment.
- *It supports a tangible interface*. In AR applications, there is a very intimate relationship between virtual objects and the physical world. Physical objects can be augmented through virtual elements, allowing the overlap of these elements dynamically. These objects can be accessible to all users (public use) or may be individualized for each user (private use), so that particular interactions can be defined for different users. Similarly, physical objects can be used to manipulate virtual elements in an intuitive manner.
- *The presence of spatial cues for face-to-face and remote collaboration*. Augmented Reality allows that the elements generated *in silico* (by a computer) be spatially distributed according to the physical environment.

Perhaps because of these benefits and the increasing capabilities of computers, AR is being widely used in a variety of scenarios such as medical treatment and rehabilitation (Casas, Herrera, Coma, & Fernández, 2012; Tang, Kwoh, Teo, Sing, & Ling, 1998), learning and training (Dunleavy & Dede, 2014; Wu, Lee, Chang, & Liang, 2013), engineering and construction (Boyer, 2009; Gimeno, Morillo, Casas, & Fernández, 2011), entertainment (Díaz et al., 2016), culture heritage (Galatis, Gavalas, Kasapakis, Pantziou, & Zaroliagis, 2016; Gimeno, Portalés, Coma, Fernández, & Martínez, 2017), etc.

The use of mirror metaphors in VR and AR systems leads to VR Mirrors (VRM) and AR Mirrors (ARM). A VRM can be defined as a VR application that displays a virtual depiction of the user's own

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

image on a display device as if that device was a mirror. The virtual depiction can be based on previous photographs of the user or it can be an avatar acting as the person being "reflected" on the VRM, for instance. The fact that the virtual world replicates and communicates with the real world is something that makes VRMs be slightly different from most of the rest of VR applications, where the goal is to extract the user from the real world and teleport them to a different virtual world where there is no communication whatsoever with the real world. VRM are not typically built with actual mirrors, but with computer-based immersive displays that render a mirror-like image of the user.

Augmented Reality Mirrors (ARM) are AR applications in which a real mirror-like real-time image of the user is augmented by means of virtual objects registered in 3D and properly blended with the image of the real environment (Giner Martínez & Portalés Ricart, 2005; Portalés, Gimeno, Casas, Olanda, & Martínez, 2016). The image of the user can be captured by means of a video camera (video-based ARM, e.g. (Giner Martínez & Portalés Ricart, 2005)) or can be produced by a real mirror on which virtual objects are projected (optical-based ARM, e.g. (Alhamid, Eid, & El Saddik, 2012)). Video-based ARMs are more commonly used than optical-based ARMs, because optical setups usually require the use of semi-transparent mirror displays (to create virtual objects with a rear projection) where the blending of virtual and real objects could be difficult, whereas the setup of a video-based ARM typically requires a simple camera and occlusion problems are easier to handle. Education, entertainment and retail are the areas of application where ARMs are more frequently used, although medical therapy has also been explored.

In Figure 1, the mirror metaphors in VR and AR are depicted, in comparison to regular mirrors. As it can be seen, while in an ARM the user sees its own image merged with virtual objects, in a VRM the visual reference to the real environment disappears. Therefore, strictly speaking, face-to-face interaction of users is only possible with the ARM metaphor, although a VRM can eventually simulate that effect. Some works use different terms to refer to VRM or ARM, such as *magic mirror* (Bork et al., 2017; Kim, Lee, & Kim, 2004), *magic face* (Javornik, Rogers, Gander, & Moutinho, 2017), *mixed-reality (MR) mirror* (Sato, Kitahara, & Ohta, 2009) or *real-time mirror* (Gonzalez-Franco, Perez-Marcos, Spanlang, & Slater, 2010). The terms *virtual mirror* or *immersive mirror* are also sometimes used for either VRM or ARM, creating some additional confusion. For this reason, it is important to clarify and define these terms.

Figure 1. The mirror metaphors in VR and AR: regular mirror, AR mirror and VR mirror

VR and AR Mirrors in Medical and Mental Therapy

Medicine has been traditionally, and still is, one prominent application area of VR and AR. As computers have gradually invaded our societies with smarter and more computationally efficient devices, the application of IT solutions to medical procedures has become increasingly common. Examples of IT applications in medicine include computer vision and imaging (Doi, 2007), robotics (Taylor & Stoianovici, 2003), database and information systems (Müller, Michoux, Bandon, & Geissbuhler, 2004), and also VR (Krijn, Emmelkamp, Olafsson, & Biemond, 2004; Malloy & Milling, 2010; Rose, Brooks, & Rizzo, 2005) and AR (Chicchi Giglioli, Pallavicini, Pedroli, Serino, & Riva, 2015; Kilgus et al., 2015; Thomas, 2016), to name a few. On the other hand, VRMs and ARMs are typically used in applications for cosmetics, clothing and optical retail, since they provide a way for customers to see how products would look like if they wore them. These *virtual try-on* applications have become very popular for entertainment, commercial or even cultural applications (Javornik et al., 2017), but can be used also for medical purposes. For instance, AR has been used in the field of plastic surgery to depict the results before the intervention of the patient (Ilusio, 2016). This application can be considered as an ARM, since the potential patient is able to see how a particular breast augmentation surgery would result, simply looking at an augmented mirror. Nevertheless, the use of ARMs and VRMs can be extended to other medical areas of application, such as medical treatment for mental disorders, where only a few cases have been reported by the research community up to date, such as Perpiñá et al., (2003), where the VRM paradigm is employed to treat eating disorders (anorexia nervosa and bulimia nervosa) or Mölbert et al., (2018) where a VR mirror scenario is used to analyze desired body weights in patients with anorexia nervosa. Although enhanced mirrors (not only VRMs but also ARMs) could provide a very important role for treating eating disorders, in which the mirror image is usually problematic for patients, there is a clear lack of research in the use of mirrors with IT technologies for these applications.

Since the first X-Ray images were taken back in 1896, a great deal of effort was driven to create devices that allowed physicians to see inside the human body. After Computer Tomography was invented in the 1970s, and MRI became available in the 1980s (Sielhorst, Feuerstein, & Navab, 2008), research for innovative medical imaging procedures focused on the development of VR and AR tools that allowed physicians to obtain more information about the patient's body. In this regard, VR technology can be relevant to reconstruct the human body for educational and training purposes. On the other hand, other research focused on the X-Ray paradigm to obtain see-through images of the body in real time, without having to perform surgical incisions (or making small ones) in the patient's body. In this sense, AR is especially important in microsurgery where minimum invasive techniques are required (being spine and brain surgery the main reference in microsurgery). The smaller the incision the less the surgeon is able to actually see. Thus, the use of AR is fully justified in order to enhance the view of the surgeon. Examples of these ideas can be seen in Birkfellner et al., (2002); Fuchs et al., (1998); Marescaux, Rubino, Arenas, Mutter, and Soler, (2004). A short review can be looked up in Shuhaiber, (2004).

Regarding to VR in the medical sector, many works can be found. For instance, in Connelly et al., (2010) a pneumatic glove was developed for hand rehabilitative training after stroke, that can be used to train grasp-and-release movements either with real objects or with virtual objects. In Hoffman et al., (2011) VR was used as a non-pharmacologic analgesic for some medical procedures (VR used as distraction). In Rizzo, Hartholt, Grimani, Leeds, and Liewer, (2014) a flexible VR system was created that offers significantly enhanced prolonged exposure treatment possibilities to be used as therapy in post-traumatic stress disorders. In Gromala, Tong, Choo, Karamnejad, and Shaw, (2015) a system was

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

developed that includes biofeedback sensors and a virtual environment, which can be used as a form of meditation in order to reduce stress. However, very few examples can be found that use the VRM metaphor in the medical sector, and usually they are not referred as such and/or cannot be considered as pure VRMs, but the described setup indicates that they use some kind of mirror metaphor. For instance, in Johnsen et al., (2005) a projector-based life-sized system was developed that allows medical students to experience the interaction between a patient and a medical doctor – though the student is not represented by an avatar, the setup is similar to a VRM and there is tracking of the student's head and hand movements. On the other hand, in Sucar et al., (2014) a VR-based platform for upper limb rehabilitation was presented. This work uses the rehabilitation exercises as actions within computer games – in this case, only the upper limb is represented in the VRM. Similarly, in Lozano et al., (2005) a VRM is employed for mental practice in post-stroke rehabilitation, where the mirror is also representing the arm and hand which are being rehabilitated, whereas Roosink et al., (2015) uses a virtual mirror to help in physical rehabilitation tasks. A different set-up is the one presented in Liao et al., (2015) where a Wii Fit device is used to improve obstacle-crossing performance and dynamic balance in patients with Parkinson's disease. This setup cannot be considered as a pure VRM, although it somehow acts like a mirror since the Wii Fit tracks the motion of the patient's center of mass, and this motion is then mirrored and shown with a virtual avatar.

Another interesting work is the research presented in Waltemate, Gall, Roth, Botsch, and Latoschik, (2018) where a VRM is utilized to study emotional responses and body ownership with respect to different avatars representing the body of several persons. Although this application is not currently used for the treatment of any particular mental health condition, it could be used in patients with visual agnosia, or for the study of the psychological and psychophysical factors in therapies relying on embodied virtual interfaces. VRMs can also be utilized to analyze or identify racial biases (Groom, Bailenson, & Nass, 2009). It is interesting that racial biases extend beyond digital spaces and these findings could be used to address racial identity problems and racial prejudices with VR applications.

Similarly to VR, there is a variety of AR applications in the medical sector, some built for the treatment of disorders such as phobias (Botella, Bretón-López, Quero, Baños, & García-Palacios, 2010; C. M. Botella et al., 2005; Juan et al., 2005) or cognitive problems (Richard, Billaudeau, Richard, & Gaudin, 2007). AR is being used also for the treatment of PLP, as in Carrino et al., (2014), for cerebral palsy rehabilitation (Correa, Ficheman, do Nascimento, & De Deus Lopes, 2009) or for the treatment of motor impairment (Alamri, Jongeun, & El Saddik, 2010). In summary, the capability of adding virtual objects to the real life environment seems to be a very useful tool for the treatment of a big variety of day-to-day difficulties related to the mind.

Immersive VR (IVR) applications represent another area where VR can be successfully applied in medicine, like in Mathur, (2015); and Won et al., (2017). IVR has many uses in the medical sector, and can be used as a pain distractor (burn wound cleaning, cancer, dental work, etc.) or as an educational tool for children (Bailey & Bailenson, 2018), to name a few. However, the powerful nature of IVR experiences may also pose some risks and should be utilized with caution in children (Won et al., 2017).

IVR can be used as well for the treatment of different specific mental conditions and disorders. For instance, IVR with a Head-Mounted-Display (HMD) has been repeatedly used for the treatment of PLP (Ambron, Miller, Kuchenbecker, Buxbaum, & Coslett, 2018; Bach et al., 2010; Henriksen et al., 2016; Murray et al., 2007; Rodriguez, Aruanno, Bordegoni, Rossini, & Molteni, 2017; Zanfir, Georgescu, Turturica, Eczedi, & Mironiuc, 2017). Although further studies are necessary, it seems that IVR can be effective in the treatment of PLP for some patients (Murray et al., 2009) or at least encourages patient's

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

motivation leading to a potential analgesic effect (Osumi et al., 2017). A deeper study of the effectiveness of these approaches can be found in Herrador Colmenero et al., (2017).

These systems can be considered partial VRM applications, because they are based on the Mirror Therapy. Although the view of the patient is not a third-person view and therefore they do not see a complete mirror image of themselves, the VR application tracks the motion of the healthy limb and (virtually) mirrors these movements to the other limb, creating a mirror effect that enhances the traditional mirror-box therapy used for the treatment of PLP.

Eating disorders can also benefit from immersive VR mirrors (IVRM), such as the experiments described in Riva, Bacchetta, Baruffi, and Molinari, (2001) where virtual mirrors were utilized in patients with bulimia and anorexia nervosa.

There are also immersive ARM applications for the treatment of PLP, like Ortiz-Catalan, Sander, Kristoffersen, Håkansson, and Brånemark, (2014), where a video input is used to track a fiducial marker placed on the amputated arm and several electrodes provide myoelectric signals corresponding to some common movements. This particular application can be used for bilateral amputees since it does not mirror the other limb. However, it can display a mirror image of the patient and, therefore, it can be considered as a true ARM application.

Although some ARM works can be found in other related medical fields, such as anatomy education (Blum, Kleeberger, Bichlmeier, & Navab, 2012; Bork et al., 2017; Kugelmann et al., 2018), it is harder to find ARM systems for medical therapy use, such as Mouraux et al., (2017), where an augmented mirror is used to treat neuropathic pain. There are also some related works, such as Bach et al., (2010); Desmond, O'Neill, Paor, McDarby, & MacLachlan, (2006); Regenbrecht, Franz, McGregor, Dixon, and Hoermann, (2011); and Trojan et al., (2014), although they are partial ARM systems based on adaptations of the Mirror Therapy. They make use of the mirror paradigm but in a first-person fashion instead of allowing the users to see a complete reflected image of themselves. Also, the VirHab system introduced by Feintuch, Tuchner, Lorber-Haddad, Meiner, and Shiri, (2009), targeted at treating pain and impairment of upper extremities, is based on video processing rather than providing a 3D registration of virtual and real objects. An example in which a true ARM is used for medical therapy is the work presented in Lozano-Quilis et al., (2014); and Lozano-Quilis et al., (2013), where a Kinect-based ARM is used in patients with multiple sclerosis. This is one of the very few examples of the use of enhanced mirrors with neurodegenerative diseases, an area where enhanced mirrors are still not commonly used.

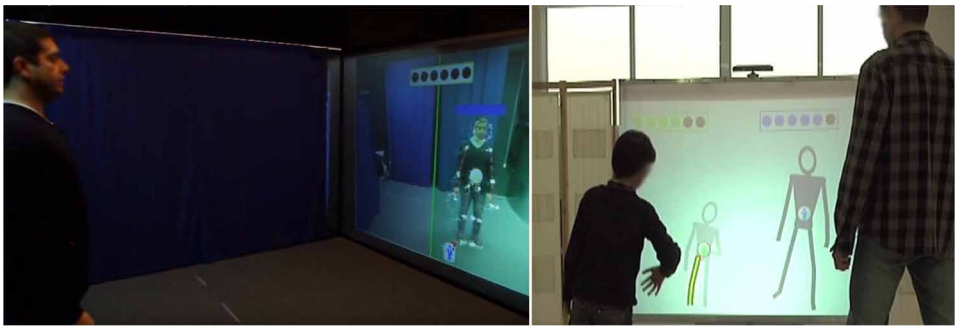
One of the most interesting contributions in which the use of both VRM and ARM technologies is combined for mental health therapy can be found in the Pictogram Room (Casas et al., 2012; Herrera, Jordan, & Gimeno, 2006; Orange, 2012). This system was designed to aid children with ASD to advance in basic aspects of the communication (such as joint attention), to improve knowledge about their corporal scheme and to achieve imitation skills. These critical skills can be addressed in an entertaining way, so that children with ASD can learn while playing (see Figure 2). In order to build the mirror methapor in both VR and AR, a back projection screen is present in front of users. The movement of the users is tracked with a Kinect (for both VRM and ARM setups), as well as the image of the real environment (only for the ARM setup). The Pictogram Room is nowadays installed in multiple schools and centres, being a successful case study. In fact, autism disorders are one of the few areas where enhanced mirrors (either VRM or ARM) have been repeatedly proposed for mental health. Several research works can be found in this regard (Bai, 2012; Bai, Blackwell, & Coulouris, 2013; Bhatt, De Leon, & Al-Jumaily, 2014; Chen, Lee, & Lin, 2015). These systems exploit the advantages that augmented or virtual objects can offer to autistic people, which have difficulties with imagination, communication, imitation and self-body

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

recognition. Even the Diminished Reality (DR) paradigm in combination with the mirror metaphor - it could be called Diminished Reality Mirror (DRM) - has been explored (Yantaç, Çorlu, Fjeld, & Kunz, 2015). DR is useful for eliminating, rather than augmenting, elements of the real world that could be distractive for some patients, such as people with autism.

One of the main benefits of the use of VRM/ARM for people with ASD is in the improvement of self-recognition (Escribano, Herrera, Jordan, & Gimeno, 2010) and in the development of their body outline. People with autism and intellectual disabilities tend to show a lack of sense of self-recognition (Ferrari & Matthews, 1983). One of the most used experimental procedures to study the development of self-awareness in young children has been the use of mirrors and the "test of the mark" (Amsterdam, 1972). In this procedure, the child's nose is marked with some kind of mark and using a mirror it is possible to check if the child touches more times his/her own nose than the one in the mirror; in that case it is considered that they have self-recognition. Using VRM and ARM setups it is possible to develop activities to help users acquire these self-identification skills. In addition, with the incorporation of some kind of picture with the body outline in a virtual mirror (controlled and synchronized with the motion of the user in front of it), patients could improve the recognition of his/her body and the understanding and identification of each part of it. Another important aspect where VRMs and ARMs offer significant potential benefits is in the differentiation of oneself with respect to others, in which people with ASD show many difficulties. Using a virtual representation of the patient in the mirror, and integrating elements to facilitate the distinction of each user in the scene, it is possible to develop in the patient the awareness of himself/herself with respect to others. In addition, ARM technologies allow us to easily analyze the salience of the cause-effect reactions of patients with respect to environment changes (such as light intensity, sounds, colors, textures, a blur of the scene, etc.) without having to wait for them to happen.

Figure 2. Dealing with autism with the ARM developed in Casas et al., (2012), where: in the left image the ARM setup is shown; in the right image, the VRM setup is shown.



As seen from the literature review shown above, very few examples exist where the VR and/or AR mirror metaphor is used in mental health therapy. However, successful examples exist, such as the Pictogram Room. In these setups, little has to be invested in hardware technology. Basically, a projector, a screen and a Kinect is enough for both setups. However, building AR and VR experiences is not always trivial, and usually an IT expert is required to deal with modelling, building the virtual environment and implementing the interaction. This fact might be the main reason that makes the use of VRM and ARM in mental therapy more complex than the use of regular mirrors. Therefore, the question is whether the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

benefits that VR and AR technologies might bring for the medical sector do compensate for the bigger efforts needed to build them.

CONCLUSION AND FUTURE DIRECTIONS

In this chapter, the topic of VR and AR mirrors is studied as an emerging but little explored solution to deal with mental health treatment. As it has been shown through the paper, there is an extensive literature related to the use of regular mirrors in medicine, though when referred to VR and AR mirrors the examples are just a few. From these examples, the Pictogram Room stands out as an application where both mirror metaphors are used (VRM and ARM) to successfully aid children with ASD. In fact, autism-related disorders are one of the few mental-health-related areas in which enhanced mirrors have been repeatedly proposed. Phantom limb pain has been also repeatedly treated with immersive VRM applications; although these latter applications are not complete mirrors but partial interactive mirrors, these systems represent the continuation of the Mirror Therapy through the use of IT technology.

As the VRM and ARM metaphors can bring enhanced experiences to regular mirrors, the authors argue that the combination of mirrors or mirror-like perspectives with the use of the VR and AR paradigms can bring a completely new set of applications and therapies, and can enhance and improve the traditional uses of medical therapy. However, because of the very few examples found in the literature, the authors believe that the potential of VRM and ARM systems for medical therapy is not being fully exploited, probably because not all the medical therapies require a mirror image, and simpler VR or AR systems are sufficient in most cases where IT solutions are employed, or maybe because the shortcomings of current technology prevent to achieve better results. Regarding to costs, the hardware technology needed to build VRMs or ARMs is not cumbersome. However, the need of an IT expert to build the experiences can increase costs. In this sense, one has to value the potential benefits that AR and VR might bring compared to regular mirrors, and decide if it is worth investing on that.

Besides, ARM and VRM can radically change the way mirrors are used in medical therapy, extending their use to other medical problems where Mirror Therapy is still not commonly used, such as phobias, eating disorders, or even neurodegenerative diseases. For instance, an ARM application could be used to depict an entire image of oneself but with other virtual elements that cause phobias, such as insects or animals – this purpose has been explored in AR, but not with the use of a mirror metaphor. In this case, an application could be built where the doctor could choose between different virtual elements (spiders, snakes, rats, etc.), select the number of elements (one, tens, hundreds, etc.), select the kind of followed path (around the user, on its head, on its hands, etc.), select the time, the speed, etc.

Another potential use would be to treat eating disorders. In this sense, the image of the patient could be easily distorted (enlarged, widen, etc.), only processing the video feed of a camera. In this way, an application could be built where doctors could choose the degree of distortion, and interactively modify it according to the patient's feedback. In this particular case, the IT application is extremely simple and it would be as having hundreds of regular mirrors embedded in a single application, so the cost/benefit ratio would be optimal compared to regular mirrors. More sophisticated applications with ARMs or VRMs (such as in Perpiñá et al., (2003) could be also built. A possible set-up could include an avatar with the face of the patient, which could gain or lose weight. In this case, the doctor could choose to show the avatar with a specific weight (50 Kg, 100 Kg, etc.).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another possible use for mental therapy would be to reinforce the personality of patients by providing an enhanced image of themselves. The influence that a change of the perceived oneself image might bring in oneself behavior in AR experiences has been reported through artistic pieces (Giner Martínez & Portalés Ricart, 2005; Portalés Ricart, 2009), but not yet in the medical sector. For instance, with VR and/or AR technology one can be a superhero, a famous actor, a composer, etc. Even, a change in gender (for the treatment of gender dysphoria) and/or race (for racial identity disorders) can be explored. In the case of the VRM paradigm, a complete avatar would replace the user's body, whereas in an ARM the patients' body would be complimented with virtual elements that transform them in a new person. Therefore, imagine an application were the doctor could choose between different persons to infer in the way patients perceive themselves and thus modify certain aspects of their behavior.

On the other hand, it has to be pointed out that an additional reason on why these systems are not fully exploited might be that the medical community is not fully aware of the last advances in AR and VR, the benefits that they might bring, and the possibility to build a mirror metaphor within them. Therefore, it is in the aim of this chapter to serve as a catalyzer to boost new applications in this field.

KEY TERMS AND DEFINITIONS

Augmented Reality Mirror: An Augmented Reality application that follows the mirror metaphor, allowing users to see an image of themselves enhanced with virtual information.

Face-To-Face Interaction: Regarding to ARMs, to have direct visual contact with the own depicted face on the mirror-like surface.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Image Blending: Mixing two images. The output image is a combination of the corresponding pixel values of the input images.

Regular Mirror: A surface that reflects light. Regular mirrors have been traditionally used in medical therapy.

Seamless Interaction: Interaction free of functional, temporal, spatial or cognitive elements that force users to change the way in which they interact with the interface.

Uncanny: something that is so remarkable that it is beyond what is natural.

Virtual Reality Mirror: A Virtual Reality application that follows the mirror metaphor, allowing users to see an avatar of themselves.

ABSTRACT

Online chat and email are two of the most popular ways of providing e-mental health. Online chat is synchronous communication in a virtual chat room where client and counselor meet at the same time. In contrast, email is referred to as asynchronous because it can be accessed without the synchronous presence of client and counselor. There has been a rapid increase in the demand for chat and email over recent years and much of the demand has been met by services that have traditionally provided helplines or crisis support. This chapter provides an overview of the key issues associated with the delivery of e-mental health services and workforce development. This includes an examination of the range of options for providing e-mental health and key issues to consider when working online. The chapter concludes with a brief exploration of issues associated with client suitability for e-mental health via chat and email.

INTRODUCTION

E-mental health (or e-therapy) involves the provision of mental health services via computer mediated communication. E-mental health via chat and email provides many benefits to clients, as well as to the mental health worker. For the client, they provide easy access to expertise without the need to travel or attend appointments. There are no technical barriers in that no special software is required to send or receive messages. These options are increasingly popular with clients because of the increased flexibility they provide. Services around the world are reporting increased numbers of clients accessing help by chat or email. Although online counseling has been available for more than 10 years for a range of mental health conditions, including depression, anxiety, and addictive behaviors, there is limited information to guide mental health services in the development and delivery of chat and email.

The aim of this chapter is to provide an overview of the key issues associated with the delivery of e-mental health services and workforce development. This includes an examination of the range of options for providing e-mental health from single session work through to follow-up and after care, as well as identification of the potential pathways into online services. The chapter then describes key issues to consider when working online, including a discussion on how to develop good working relationships in the absence of verbal and non-verbal cues. The chapter concludes with a brief exploration of issues associated with client suitability for e-mental health via chat and email.

Background

E-mental health can be accessed anonymously to ask about a mental health concern that a person might find embarrassing. It appears especially attractive where there are barriers to help-seeking due to associated stigma. It can be an effective treatment approach in its own right or can be used to build confidence in help-seeking and counseling or therapy. Indeed, e-mental health can provide a means for the client to become familiar with the service or service system, and can provide an easy place to start before moving to telephone or face-to-face options if needed or wanted (Car & Sheikh, 2004). For the novice or new help-seeker, e-mental health is less confronting than face-to-face or phone counseling, in that it allows the person to control how quickly they engage with the content (i.e., how quickly they write) and how much information is made known to the clinician (i.e., the client can delete content that they have written prior to sending the text information) (King et al., 2006). Moreover, there is a great deal of research indicating that writing has a therapeutic effect (Pennebaker, 1997). E-mental health allows clients to re-read their sessions as well as reflect on responses by the clinician. Having access to a hard copy transcript of the session may also prevent memory bias or forgetting (Gilat & Shahar, 2007).

Email, which is the most common of all online activities generally, is an integral part of our daily lives. Email is asynchronous in that it can be used to communicate with individuals or groups regardless of where they are located, or the time of day. Email has been a part of our lives for the last 15 to 20 years since internet service providers first began allocating email addresses as a component of service connection. Every day, billions of emails are sent and received around the world. Most of us send and receive emails for professional and personal reasons.

In addition to professional and personal communication, email is used for consulting and counseling and to provide support to clients of mental health services. As the most frequently used electronic modality in mental health (Chester & Glass, 2006), it can be used to provide administrative information, such as appointment reminders, as well as initial screening or assessment, information on services, and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

referral through to low-intensity interventions. Compared with other regularly used technologies, such as text messaging for appointment reminders, email is used to provide a broader range of interventions. A systematic review of 24 studies involving email communications in primary healthcare settings found that medical and medication information was the most common topic discussed, followed by updates on medical conditions to patients (Ye, Rust, Fry-Johnson, & Strothers, 2010).

In the mental health field, chat and email have been used to provide low-intensity interventions including counseling, information and support, as well as a whole host of other novel programs. In addition to delivery of treatment, chat and email can be provided as an adjunct to telephone or face-to-face treatment. Chat and email can also be an easy way to provide post-care follow-up. Research into this area has to date focused on the following.

- Personalised feedback on self-assessments (Te Poel, Bolman, Reubsaet, & de Vries, 2009).
- Single session question and answers (Nieuwboer, Fukkink, & Hermanns, 2014).
- Prompt to access resources as part of a prevention program (Cremers et al., 2014).
- Delivery of psycho-education and self-help messages (Morgan, Jorm, & Mackinnon, 2012).
- Tailored one-way information (Abroms, Gill, Windsor, & Simons-Morton, 2009).
- Unstructured support or advice (Finn & Barak, 2010).
- Single session consultations (Nieuwboer et al., 2014).
- Guidance for self-directed programs (Cuijpers, Donker, van Straten, Li, & Andersson, 2010).
- Relapse prevention, such as providing support at critical times (e.g., quit date) (Lenert, Muñoz, Perez, & Bansod, 2004).

Synchronous chat (also called text chat, instant messaging or IM) is available through multiple platforms such as Facebook and Skype. Chat more closely replicates the traditional face-to-face environment than email, as it involves a back and forward conversation between at least two people at the same time and in the same virtual space. Chat based counseling has been offered since the 1990s, and is often delivered as a stand-alone intervention similar to helpline interventions (Urbis, Keys, & Young, 2003). Similar to helpline interventions, chat can be provided anonymously and as a single-session intervention or multiple sessions by appointment. A recent systematic review of chat based interventions found that chat was effective in reducing client-reported distress and perceived burden, as well as improving well-being and global functioning for a range of issues, including depression, work place issues, and anxiety (Dowling & Rickwood, 2013).

How Online Services Are Provided

There are two ways generally in which clients access an email or chat program. These are through the "contact us" tab or via a specific entry point for email or chat, such as a "sign up here" or "send an email here" tab. The "contact us" tab usually requires the provision of an email address, name, and issue or concern that may or may not be selected from a drop down list. This method of access is delivered to administrative or reception personnel and the email is then forwarded to a clinician. In contrast, when signing up for email or chat via an organized program, clients are usually presented with a series of terms and conditions which must be agreed to before accessing counseling or support (Urbis et al., 2003).

Terms and conditions specific to electronic communication may include client use of email, such as not forwarding communication to another party or using materials derived from the session in a way that

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

was not intended. The benefit of this approach is that screening and/or assessment can be built into the registration, and the registration details can be presented at the start of the session to the mental health worker. In addition, terms and conditions can guide client expectations in regards to the duration of the program, frequency of the exchange, and responsiveness of the clinician (i.e., when a response can be expected) (Roy & Gillett, 2008). Clients should be advised whether they will be allocated a clinician (which is common with email exchange) or whether they can access any available clinician. Where the client is allocated a clinician, contingency planning should be in place when the clinician is on leave or out of the office (Cartwright, Gibbon, McDermott, & Bor, 2005).

An issue to be considered in service provision is speed of clinician response. Services that are synchronous may be offered with or without an appointment but this can mean wait times of up to an hour. It also means that people can get help when they really need it (i.e., in the evening when they are thinking about the problem). In contrast, email can be responded to at any time of the day or night, and response times are usually within 24 hours (Urbis et al., 2003). These response times depend on the organizational capacity to respond, which is dependent on the amount of funding (and staff) available. Given the nature of working with people with mental health conditions, there is a risk that emails may contain indicators or harm to self or others. This means the content of emails should be monitored, even if they are not responded to until a later time or date.

Help-seeking email content received through administrative pathways is not unusual. Receiving a clinical contact via administration, however, means that the client has not undertaken screening or agreed to the organization's terms and conditions of service use. Even when clients have disclosed important information, it is a good idea to gently help them complete the registration pathway.

E-COMPETENCY

Developing competency in an online environment requires the same communication skills as face-to-face or telephone counseling, but there are at least five differences that need to be considered. These include:

1. Developing therapeutic alliance in an online space.
2. The use of language, abbreviations, and emoticons.
3. Client and clinician multi-tasking.
4. The use of email templates, especially for the first response.
5. Integrating screening and self-help into chat and email.

Practice Element 1: Developing a Therapeutic Relationship Online

Empathy, warmth trust, liking, and congruence play a pivotal role in the development of a therapeutic relationship (Lambert & Barley, 2001). In online environments, being warm and empathic are arguably more challenging because counselors and clients cannot see each other smile, hear emotion in each other's voices or send or receive positive non-verbal cues. Perhaps surprisingly, recent research suggests that not only can the helping relationship be developed when interacting online, but that it can be developed in such a way that it is rated similarly to face-to-face settings (Sucala et al., 2012). This is important because the therapeutic relationship has been shown to predict client outcomes (Lambert & Barley, 2001), and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

feelings of warmth and liking towards a clinician are reasons that people recommend online services to others (Rodda, Lubman, Dowling, Bough, & Jackson, 2013).

There are both disadvantages and advantages of online environments in the development of a therapeutic relationship. Clients (and clinicians) can forget to attend a session because they physically do not have to go to an office. The absence of travel can make e-mental health accessible to people who are in rural or remote areas, are time poor, do not wish to travel, or lack requisite transport to access services. While travel becomes less of an issue, some clients may find that the need to type to express and convey emotions can be difficult especially in times of distress. However, the lack of physical presence can mean greater spontaneity and less self-censorship (King et al., 2006). This is different to other settings, in that the client can delete or add to their disclosure before pressing "send" and more easily control exactly what is disclosed. Clients can also read and review their sessions and consider the interaction and advice provided within online sessions at a later date.

For the clinician, the characteristics of the online environment can make the development of a positive helping relationship challenging. Online sessions start with fewer pleasantries and clients tend to develop a sense of trust and rapport earlier on in the session (i.e., right from the start) (Urbis et al., 2003). This process, which is the opposite to the normal order of counseling, is possibly due to the client being in a familiar environment (e.g., their home), or at a time that they are ready to talk (e.g., emails can be written at any time of the day or night). Furthermore, clients engage and disclose serious issues more quickly online.

This disinhibition effect, which is characterised by reduced self-censorship, likely occurs because of the lack of physical presence between client and counselor, and the feeling of being anonymous (Suler, 2004). This effect places clients in a position of greater power in that they have more control over the message and flow of information (Bambling, King, Reid, & Wegner, 2008). They also have more control over the time spent in the session and the amount of reflection in which they engage. In email or chat based counseling, clients can discontinue by clicking on the close screen button, which makes terminating a session much easier than physically walking out of a face-to-face counseling session. Sometimes sessions end prematurely because it has proceeded slower or faster than the client is comfortable. This situation can mean clinicians feel frustrated, guilty, disappointed or annoyed. The content of sessions should be reviewed in supervision and include review of the events leading up to the end of the session.

When working with chat, clinicians are likely to be speaking to a younger cohort, and people who might not otherwise engage in a clinical intervention. This can be challenging, especially when the client types quickly. Line by line communication is the way people, particularly young people, deliver their thoughts in this environment. This provides an opportunity for the clinician to allow the client to take control and contribute the greatest amount of content and gives the clinician space to think about their responses. Clients writing one line at a time may appear that they are pausing for a response, but it can be difficult for the clinician to identify when the client has stopped talking. The clinician really needs to listen to identify the best time to contribute (e.g., when there is a natural pause). Being able to scroll back and review the interaction is also a good tool for the clinician as this can provide useful content for reflecting back to the client.

In the online environment, the challenge for the clinician is to provide a sense of social presence (or telepresence). Social presence is the moment-by moment awareness of the other person (Tu & McIsaac, 2002). In face-to-face or video settings, the sense of social presence is strongest because the person is physically present. In telephone or online communication, however, the social presence is more difficult to establish. Being engaged and present to the other person requires a different set of skills than face-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

to-face settings. One of the most common criticisms of clinicians working online is the sense that they emulate a computer, by using drop-down pre-prepared responses, speaking to multiple clients at once, or generally not paying attention (Bambling et al., 2008).

Social presence can be enhanced by adapting writing style, punctuation, emotional expression, tempo, and flow. Practical options for creating social presence suggested for counselors during online communication are outlined below.

- Use simple language, and avoid misunderstandings by explaining things simply.
- Stay engaged in the session. This means avoiding long periods of silence. If reflecting or considering your response, use trailer dots to indicate pause or thinking, or say that you are thinking and need a moment. Long periods of silence are often viewed by clients as disengagement and may lead to them ending the session abruptly.
- Write frequently and often to indicate encouragement and engagement.
- Move at the same pace as the client and avoid rushing forward to give advice or provide solutions to problems that have not been fully articulated.
- Overtly express emotions. This can be through the use of capitals (I feel HAPPY for you), punctuation (you showed such strength!!!!) or emoticons (☺).
- Swearing is generally not permitted according to the terms and conditions of most services and should be avoided.
- Be ready to jump into the session and be where the client is from the start. Research suggests online clients are ready to take action but need help in developing their skills and confidence (Rodda, Lubman, Iyer, Gao, & Dowling, 2015).
- Describe your own thoughts, emotions, or physicality [big smile on my face]. Alternatively, use emotional bracketing, which involves placing feelings in square brackets to convey concern or warmth [feeling happy for you] (Murphy & Mitchell, 1998).
- Ask directly about distress or other emotions the client might be experiencing. Readiness rulers can aid this process. For example, "On a scale of 1 to 10, 1 being not distressed at all and 10 being very distressed, where would you be right now?"
- Ask questions that move the client forward and are relevant to their current readiness. For example, asking about the past when the client has asked for help developing strategies for change may not be helpful.
- Change pace to make a point through the use of shorter sentences or reflections. Avoid getting into a question and answer session.

To manage space, it can be tempting to ask multiple questions at once. While this information gathering technique is perhaps efficient, it interrupts the flow of the conversation and means that the clinician then has to provide reflections or feedback to multiple responses received concurrently. Clients respond best to one question at a time (Bambling et al., 2008). Indeed, one study found that young people found it frustrating when the session became out of sync due to the clinician asking a follow-up question before waiting for a response to the first question (Haberstroh, Duffey, Evans, Gee, & Trepal, 2007). This imposes another challenge in terms of giving the client the space to reflect while also retaining social presence.

Client non-responsiveness can occur during a chat session and may be a consequence of technology problems, interruptions, or client distress. It is helpful to have a policy on how long to wait for the client and also appropriate wording to let them know that you are still there. Non-responsiveness can also occur

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

in email communication. This could be due to a whole range of issues related to client attrition that are relevant to any kind of intervention, such as sufficient treatment having been received, the client being focused on other priorities, or the treatment moving too fast. It might be, however, that the email has been delivered to a spam mailbox or has been missed. In any case, contacting the client to offer support and providing details of how to re-engage when they are ready or willing to continue is recommended.

Practice Element 2: Language, Abbreviation and Emoticons

Working in an online environment requires the clinician to be aware of language rules specific to text-based interactions. Online communication is guided by an explicit list of rules (sometimes referred to as net etiquette). These rules are related to language characterised by abbreviations, phonetic spelling, and low use of rules related to grammar. Mobile phone text messaging and social media sites such as Twitter that impose character limits (<120 characters) mean abbreviations and acronyms have developed for common phrases (e.g., HTH means hope this or that helps). These have been applied for faster communication in terms of typing speed, while also using as few words as possible to communicate the message.

Text speak can be a challenge for the clinician in terms of the language of their response. Client sentences may be brief and may not follow traditional conversation rules. For example, traditional conversations involve turn taking, where one person says something and the other responds. This goes back and forward until the theme is extinguished and another is started. In e-mental health, clients will often type a statement and present it to the clinician in the chat window (usually by pushing the enter key). This statement will be quickly followed by another statement without waiting for a response from the clinician. This can be challenging for the clinician to know when to respond, and it can be difficult to get into the flow of the conversation. An option is to allow the client to take the lead by letting them use the space therapeutically by writing out their concerns. The role of the clinician in this situation is to ask very good questions that help clients solve their own problems. This is congruent with counseling approaches such as Egan's Skilled Helper Model (Egan, 2009), which place clients as the experts on their own problems.

In face-to-face settings, non-verbal posturing, such as facial expressions and body movements, are associated with rapport (Trout & Rosenfeld, 1980). In online settings, spelling and abbreviations are part of the non-verbal vernacular. Facial expressions can be expressed as emoticons (e.g., faces created from colons and parentheses ☺). The text-based facial expressions are as important when communicating online to reflect, mirror, and convey emotion (Derks, Bos, & Von Grumbkow, 2007). Neuroscience research has found that the brain responds in the same way as seeing an actual face when we look at emoticons (Churches, Nicholls, Thiessen, Kohler, & Keage, 2014).

Multiple qualitative studies have reported the use of formal language and even the clinician's speed of typing can impact on feelings or warmth and connection between the client and clinician (Gibson & Cartwright, 2014; King et al., 2006). A study of text messages sent and received from the New Zealand agency Youthline reported young people preferred texting over talking because it was more private ("Cn I jus txt cos I don wanna b heard"), and because it was an easier way to communicate when distressed ("I cnt talk wen I cry") (Haxell, 2015). How the clinician responds is influenced by their service provider's clinical guidelines and their own personal style and preferences. For example, a typical Youthline response was "Hi there, sounds like things r bit rough 4 u right now. Since there r thngs ur wanting 2 get clearer about, u culd call us free @0800Youthline NZ to tlk" (Haxell, 2015). This response mirrors the client's language in terms of abbreviation, spelling, and punctuation.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Practice Element 3: Client and Clinician Multi-Tasking

Chat based environments are susceptible to multi-tasking. This is because chat based sessions do not generally occur in the clinician's office, but can occur in any place where there is internet access (e.g., on a bus, at work or in private spaces such as at home or in bed). Research suggests young people are heavy multi-taskers in the same medium (swapping between windows and programs), as well as switching between media (like watching television while using a computer or mobile device) (Prensky, 2001). This means that during an e-mental health session, the client might be watching television, browsing other websites, going to the toilet or getting a drink, on the phone, texting, or consuming alcohol, drugs, or engaged in gambling activity.

There are two ways clinicians can determine if the client is multi-tasking. The first is to ask directly (e.g., "Is there something else happening for you at the moment?"). This, however, could negatively impact on the client's sense of comfort as they always engage in multiple activities when they are online. The second is to notice change in session speed or tempo. Multi-tasking becomes apparent in the session when the pace or speed of the client's responses change (Bambling et al., 2008). There might be long gaps or a period of inactivity that is punctuated by multiple responses or questions directed back to the clinician as a means of filling the space. Clinicians may not notice the change in tempo (or their own change in tempo) when they multi-task. Some online services, especially those offering services provided by volunteers, require clinicians to respond to multiple clients at the same time. Clinicians also consult with colleagues, surf the net, or multi-task themselves while in an online session. In addition, the move towards open plan environments means clinicians are often not in a closed room but in a similar shared space as the client.

Research suggests that when attention is split between multiple activities, the cognitive load increases. Multi-tasking while using a computer can therefore be related to reduced efficiency and increased distractedness (Ophir, Nass, & Wagner, 2009). This means that when counseling in this environment, it may be helpful to reaffirm conversations by providing attachments or handouts following the session, or encouraging clients to print or save their transcripts. Another option is to set up expectations prior to the session by providing videos or information on how to get the most out of an online session. This should include being physically located in a safe quiet space.

Practice Element 4: Email Template for the First Response

Email provides mental health workers with multiple benefits in terms of session preparation and responsiveness. Clinicians can also benefit by having additional time to construct responses and consult with peers or supervisors. In addition, there is time to locate other resources and information before responding. However, some clinicians are wary of having a written record of their therapeutic exchange. This is because each email correspondence is a permanent record of the conversation that could be examined outside of the context in which the conversation occurred (e.g., subpoenaed by a court or examined by a third party).

Email provides the option to increase or decrease client contact as required. The client can access more care when needed (e.g., when at risk for relapse), and easily step down from more intensive treatment (e.g., face-to-face therapy). In general, email counseling is shorter-term than face-to-face counseling, with around five sessions provided per client (Chester & Glass, 2006). There is very limited research in

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

this area, but some studies suggest that around 20% of sessions are provided as a single email (session), and around 20% as more than 10 emails (Finn & Barak, 2010).

The asynchronous nature of email means that materials can be prepared prior to the session. A way to do this is through the use of structured templates. Templates can be developed and then tailored for the individual (Abroms et al., 2009), and other resources can be appended to the communication (e.g., referral or homework sheets). Templates are more efficient than starting a response with a blank page every time a new client presents. They can be prepared in advance and this can mean a faster response time. Templates can also be developed in response to common presenting issues (e.g., crisis response, counseling, or information).

Structured emails developed from a template require around 15 minutes for the clinician to prepare, but can range up to 60 minutes depending on the amount of personalization (Abroms et al., 2009). This is a significant time saving for the clinician. A review of services using unstructured emails suggests the average email takes around 20 minutes to compose, with around 10% of emails taking more than 30 minutes to write. A risk of structured emails is that they may appear less personal. This can be overcome through tailoring which means adapting content to reflect individual needs and their use of language (e.g., formal or informal).

Structured emails are especially helpful for the first client response. There are a number of important components of the initial email including what, how often, how long, and what no response means. An ideal way to structure emails is with a beginning, middle, and end.

Beginning of the email.

- The beginning of the email should identify yourself by name, your organization, and your role. It should then explicitly congratulate and reinforce help seeking and normalize the approach indicating that reaching out can be both challenging but exciting.
- To reduce the chance of misunderstanding, it is helpful to restate the client's words from their initial email. In the absence of minimal encouragers (e.g., nodding and utterances that encourage continued disclosure), this can also indicate that you are listening and have heard what has been said.

Middle of the email.

- The middle part of the email should integrate the results of any screening into the response. This could be feedback on the level of severity of the problem, readiness to change, or treatment goals. This really depends on the types of screening tools offered during the registration process.
- At this time, it is tempting to ask a lot of questions. Usually the first email from the client will be brief and this leaves the clinician with many more questions than there are answers. It is helpful to focus on the data that is available (i.e., screening) and the content of the client's email.
- A strengths based approach can be used in terms of highlighting the client's identified strengths rather than weaknesses. For example, responding to the first email with a request for information on how the problem developed may move the client backwards rather than forwards.
- A benefit of templates is that key questions which are important can be decided both at an agency and individual level in advance. Given that there is so little room for questions, it is important to only ask those that you think are important to respond to and move your client forward.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

End of the email.

- At the end of the email, it is helpful to offer hope and reflect that the majority of people do improve after they access your service. It is helpful to revisit the terms and conditions and check on suitability and treatment preferences. For example, clinicians can say "there are many ways to get help and I am wondering if email is your preferred option?".
- It is then helpful to provide an overview of the service and set up expectations. This might include the length of the program (often six weeks), how many emails might be exchanged each week (perhaps 1-2), and how often the client might send emails to the clinician (usually this is as often as required, but they would only be responded to once or twice a week).
- There are a whole range of other online resources, tools, and materials that can support email counseling. It is helpful to point the client in the direction of relevant resources that might include self-help materials or peer support groups. The agency might also have additional reading or resources that can also be appended to the email. When appending to the email, the clinician should introduce the resource in the email and explain why it is relevant.
- Lastly, invite further contact and provide a warm sign off. Remember that using this modality means the client cannot see the clinician smiling or gesturing warmth, so it is important to convey this both in the email and at the email conclusion.

A challenge when communicating via email as a clinician is word length. Years ago, when we received an email it was often composed like a letter and this was appreciated as we did not receive emails very frequently. Today, emails are shorter and people are sensitive to their length. This is mostly due to the number of emails people receive a day which is estimated to be upwards of 120 or more (Jenkin, 2014). Generally, the absolute maximum words per email should be around 250, which is about a page of text. A good rule of thumb is that an email should be not more than 2-3 times the length of the client's initial email. This process of mirroring can help to avoid placing the client in a position where they feel overwhelmed and less powerful in the therapeutic exchange.

Practice Element 5: Integrating Screening and Self-Help

A chat counseling session is often around an hour in duration, but the amount of content that is shared is much less than in phone or face-to-face settings. Only around half the total words expressed verbally are shared in an online session, because typing is slower than talking and significantly reduces the amount of content that can be covered. Research indicates clients spend a great deal of time telling their story, and given the constraints of the medium, this seems to be at the expense of a range of other online options that could be incorporated into the session (Rodda et al., 2015). Options that are known to improve outcomes such as online screening (or self-assessment) and self-directed options such as self-help could be offered before, during, or after an episode of care (Rodda, Lubman, Cheetham, Dowling, & Jackson, 2015).

Most services conduct screening or assessment as part of intake into their service. Screening provides a consistent method of collecting information about how much the identified behavior is a problem. In comparison, assessment defines the nature of the problem, determines a diagnosis, and develops specific treatment recommendations. In online work, screening and assessment may be used for:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Administrative purposes.
2. Background information to inform the session.
3. Assessment of problem and areas to work on.
4. Assessment with tailored feedback that is integrated into the session.

In practice, the different ways screening and assessment are incorporated into online sessions can mean that the client:

- Is asked the same questions that they have previously answered in a screening tool
- Is invited to tell their story without reference to screening information
- Information is reflected, but in such a way as to check whether the information is correct
- Responds to here and now information in the screening tool (such as levels of distress), but this is not responded to even when the client says that they are upset
- Asks what their score means but the clinician is unable to readily interpret the responses
- Information is reflected and integrated into the session (such as linked to goal setting or session planning).

How clinicians respond to screening sets the tone for the session. Firstly, it is important to let the screening tool do the work of gathering information and use the information to provide feedback. Self-assessment has also been shown to elicit change and tailored personal feedback can increase the impact of assessments (Morrison, Moss-Morris, Michie, & Yardley, 2014). To do this, clinicians need to know the purpose of screening, be aware of the cut-off scores for interpretation, and be able to provide feedback on where the person is compared to others of a similar demographic. This information should be pre-prepared and ready for the session. There is no need to check the correctness of client responses as the relative anonymity can actually elicit more honest answers than may be reported in other settings.

The clinician should then work with the information that has been provided. It is helpful to recognize that the client has started the intervention before you meet in the virtual chat room. They have already thought about the responses to the assessment items and this may have increased their awareness of their situation. It is therefore important to integrate this information into the session. The example below demonstrates how screening can be reflected and used to reaffirm readiness and importance to change. This example demonstrates how to identify past strengths and capabilities and then sought to provide focus for the session.

You say it's a high priority to change & very important to you, and you are moderately confident that you can deal with it. Since you've done so well in the past staying off it for years you clearly have the strength & capacity to do it again. I'm wondering what prompted this last relapse…

The above example also used abbreviations and punctuation to render the response briefer, avoided questions, demonstrated positive regard, and shared an internal process. In addition to screening at the start of the session, clinicians might also consider checking in at the end of the session. The example below demonstrates how this can be integrated into the initial response.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

I can hear that you are feeling pretty stressed about it all and have read that you are not feeling confident about addressing it, perhaps we can talk some more tonight about what has been happening and see how you feel at the end of our chat - how does that sound?

Online screening need not only include formal or forced choice questionnaires and screening instruments. Given that writing can be therapeutic and clients want to tell their story, an option may be to assist clients to tell their story more efficiently. For example, templates could be developed that prompt a history taking narrative. This could be offered to the client while waiting for the session to commence. The clinician could then provide feedback and guidance on the text. This approach would significantly reduce the amount of time spent on history taking in the session. This is important because wait times, data gathering, and reduced session content are the main sources of client dissatisfaction with this modality (King et al., 2006).

In addition to screening, self-directed options can be integrated into chat and email. Self-directed options include online tools and resources that the client can undertake before, during, or after the session. Self-directed programs (also called internet therapy) are available for almost every mental health condition. These programs offer self-paced access to motivational or cognitive-behavioral treatment over around six sessions. Other options include smart phone applications (that can support self-monitoring or goal setting) and community forums (that can offer peer-to-peer support). A list of suitable options can be appended to emails or chat sessions for clients to follow-up. However, client outcomes might be improved if the clinician works to integrate these options into the session.

Integrating self-directed options into the email or chat session requires some planning. First, as a source of information, the clinician should be familiar with self-directed options. They should know the range of options available, how they work (in terms of content and technology), and whether there is research indicating they are effective (Baguley et al., 2010). It is helpful to know whether there are any costs associated with access and the amount of disclosure required of the client (some programs may require disclosure of personal details such as name or address). Associated with this is the likelihood of shame or embarrassment (i.e., community forums involve other people and this could be challenging for new clients). Indeed, comfort in contributing in an online forum may be improved if moderated well and this can provide an important source of support and understanding. The clinician should also provide guidance and instruction in the use of self-directed materials. Guidelines for the use of self-directed materials suggest strategies such as planning and allocating a time each day for the activity can improve outcomes (Williams, 2006). Throughout the use of self-directed options, it is helpful to support and encourage change through regular review of the client's progress. Review may include supporting the client's self-efficacy and motivation to continue as well as re-administration of assessment tools to monitor progress.

ISSUES, CONTROVERSIES, PROBLEMS

Client Suitability

There has been a great deal of discussion and debate over the years on client suitability for seeking help online. The debate has been influenced by guidelines written for the International Society for Mental Health Online (Suler, 2001). This paper identified three key issues related to suitability - technical ex-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

pertise, treatment preferences, and text-based skills. Technical expertise refers to whether the client has access to the internet in a private or convenient setting. It also refers to the client's experience of talking online, especially in the selected modality (i.e., "have they tried chat previously if wanting to use chat?").

A frequent concern when working online is the interplay between client anonymity and client safety. E-mental health is attractive to at least some clients because they can access it without disclosing any personal information. A dilemma faced here is when working with clients evidencing risk of harm to self or others is whether to request contact details other than an email address (Pollock, 2006). Some advocate contact details such as phone number, address, or next of kin contact details. Alternatively, the initial assessment could be conducted by telephone. These are methods to increase physicality with the client, but this approach arguably detracts from some of the known benefits of this modality. Some clients will not want to provide contact details and being asked to do so could be unwelcome. The limits of anonymity can be outlined in the terms and conditions of service use and links provided to online services that can provide greater anonymity.

All types of treatment can now be delivered online via video conferencing, chat, email, or self-directed modules. It is helpful to determine whether the client prefers in the moment communication (such as chat), or to reflect and edit or think before they speak (such as email). For some people, there could be benefits of using online options even when they are not the preferred modality (such as relapse prevention), and this should also be considered when determining suitability.

Suler (2004) suggests clients may not be suitable for online work if differences in language or culture impede the flow of communication. In New Zealand, chat and email could be viewed as an appealing option for Māori and Pasifika especially given the perceived stigma, shame, and confidentiality issues associated with accessing mental health services. Care should be taken however in ensuring screening tools and other written communication is culturally appropriate and that misunderstandings in wording are minimized. Given the importance of non-verbal communication and visual diagrams to enhance learning, chat and email may need to be delivered with greater flexibility and creativity. For example, clients and counselors could upload videos, photos of drawings, or other images as part of the therapeutic exchange.

Workforce Issues

Almost all of the competencies required for telephone and face-to-face counseling apply online. However, online communication has special challenges in terms of how emotions and thoughts are conveyed and the use of relevant and accessible language becomes even more important in the text-based environment. There is an urgent need to develop and make widely accessible workforce development initiatives and resources for this modality. Translation of practice from a face-to-face environment to online delivery is complex and requires supervision that is informed by the best available evidence. Postgraduate counseling programs need to include e-mental health in curriculums to ensure graduates have the requisite counseling competencies to work in this new environment.

Clinicians should also be informed by guidelines developed by their professional associations. There are multiple guidelines that can guide clinicians in providing ethical e-mental health. E-mental health guidelines are available for members of the American Psychological Association, the American Counselling Association, The Australian Psychological Society, and the British Association of Counselling and Psychotherapy (usually available in the members only area of each site). The main areas covered in these guidelines are related to confidentiality (e.g., sharing of information for supervision or professional purposes), disclosure of personal information (e.g., how far does anonymity extend), as well as

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

client use of emails and the security of correspondence (e.g., providing information to clients on how to safeguard and save their correspondence). It is also recommended that information on the limits of e-therapy is provided at the outset and this is discussed as the treatment proceeds.

FUTURE RESEARCH DIRECTIONS

E-mental health has been offered to people for a range of mental health conditions for more than 10 years in New Zealand and around the world. To date however, there has been limited longer-term evaluation and much of the evidence is based on descriptive studies, case studies, or clinical observations. The exponential growth of e-mental health has meant that few services have been evaluated. This is due to the speed of growth in a relatively short time period. This is challenging for treatment providers as well as the mental health field more broadly, as practice is moving faster than the evidence base can be established. Ideally all new e-mental health services are established with funding for longer-term evaluation and this evaluation is embedded in everyday service delivery.

Longer-term evaluation is also required so that evidence-informed workforce development programs and clinical governance frameworks are relevant to online settings. This chapter presents evidence that skills obtained in face-to-face training and delivered in face-to-face settings may not always be sufficient when working online. There is a great need to identify specific online skills and to test whether clinical observations described in the literature are correct. For example, there is currently no longer-term evaluation demonstrating that the development of therapeutic rapport is required when working online. To inform training programs, information is also required on whether processes such as developing social presence, using pre-prepared email templates, and the use of text speak impact on client outcomes. Clinicians also need to feel confident in recommending e-mental health to clients. Knowing what works and for who is a key priority so that clinicians are better informed on client suitability.

CONCLUSION

Chat and email provide unprecedented opportunities for mental health workers to expand their client base and reach people who otherwise would not access help. The aim of this chapter was to provide an overview of the key issues associated with the delivery of e-mental health services and workforce development. Formal and informal pathways into chat and email have been described along with an outline of several considerations for service planners and developers.

For clinicians, e-mental health may pose new challenges in terms of developing therapeutic rapport, and warm and trusting helping relationships. The use of writing style, punctuation, emotional expression, tempo and flow can be adapted to the online environment to overcome the absence of both non-verbal and verbal cues. The physical environment for text-based counseling is completely different to face-to-face, in that the client is usually in their own home or other familiar space. While this can support more open and honest dialogue, there is a risk of multi-tasking and becoming distracted or otherwise occupied during online sessions.

Clinicians can integrate pre-prepared materials to overcome time constraints. By far, the biggest disadvantage for clients is the slowness of the typing medium, but this can be overcome through clever integration and the use of evidence-based tools. This includes screening and assessment tools adapted for

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

online environments and self-directed materials. Services can also develop templates for email contact that can be tailored to the client's specific situation. This may be especially helpful for the first contact.

E-mental health is providing services in a way that many people now want and expect, when help is required. Not all people, however, will be suitable for e-mental health. It is therefore important to provide clients with information on a range of treatment options, so they can choose the option that is most suited to their needs.

KEY TERMS AND DEFINITIONS

Chat Counseling: A text based therapeutic exchange between a clinician and individual or groups that is synchronous. Interactions require the clinician and client to be present in the same virtual room at the same time.

Email Counseling: A text based therapeutic exchange between a clinician and individual or groups that is asynchronous. Interactions do not require clinician and client to be present in the session at the same time.

Email Templates: Structured emails that have been prepared prior to the session that can be tailored for the client.

e-Mental Health: Any therapeutic exchange that occurs via technology including chat, email, video conferencing or text messaging.

Social Presence: The feeling of being in the presence of another person. In text based settings, social presence can be enhanced by adapting writing style, punctuation, emotional expression, tempo and flow.

Text Speak: Social conventions for online communication related to the use of language including sentence length, abbreviations, phonetic spelling and low use of rules related to grammar.

Therapeutic Alliance Online: The development of a positive helping relationship in the absence non-verbal cues.

Chapter 45
Will Patients Accept Daily SMS as a Communication to Support Adherence to Mental Health Treatment?
Daily SMS: Acceptance, Feasibility, & Satisfaction

Bonnie A Clough
Griffith University, Queensland, Australia

Leanne M Casey
Griffith University, Queensland, Australia

ABSTRACT

The aim of this article was to investigate the acceptability and feasibility of a daily Short Message Service (SMS) communication system to support patients attending weekly psychotherapy. The patients (N = 32) received daily SMS messages for the duration of a group therapy treatment program. Measures relating to engagement, treatment satisfaction, acceptability of the intervention and treatment outcome were administered. The patient satisfaction and acceptability were high, with patients reporting positive attitudes towards the SMS messages, particularly with regards to increased motivation and perceptions of support. Symptom reduction over the course of treatment was consistent with expectations for transdiagnostic group psychotherapy. The current study indicates that SMS is a well-received form of communication that can be used to support engagement in psychotherapy treatment programs. Future research should focus on exploring the range of adjunctive technologies that may be used to support face-to-face therapies.

1. INTRODUCTION

Psychological interventions are efficacious for the treatment of a range of mental and physical health conditions (e.g., Hoffman, Papas, Chatkoff, & Kerns, 2007; Kahana, Drotar, & Frazier, 2008; Lipsey & Wilson, 1993). However, there remains a high level of unmet need for psychological services, with most individuals in need of mental health services failing to receive treatment (Kazdin, 2017; Clough, B. A., Zarean, M., Ruane, I., Mateo, N. J., Aliyeva, T. A., & Casey, L. M.). Technological adjuncts to psychological interventions may provide greater outreach and increased cost-efficiency of current services (Barnett & Scheetz, 2003; Clough & Casey, 2011b, 2015). Short Messaging Service (SMS) may have an important role to play in enhancing patient adherence to treatment tasks and recommendations. These messages have been helpful in prompting attendance in physical health settings (Guy et al., 2012), however, appointments in these settings are usually infrequent. Mental health appointments are typically associated with greater frequency and different demand and task characteristics. As such, it remains unknown as to whether patients will accept this technology on a frequent basis during psychotherapy. The study examined patients' responses to an adherence related SMS communication delivered on a daily basis during a psychotherapy program.

1.1. Adherence

Patient adherence in psychotherapy refers to the extent to which patients' behaviours align with the advice given by the therapist or healthcare professional (Nose, Barbui, Gray, & Tansella, 2003). Despite the benefits associated with patient adherence to homework tasks, non-adherence is common. Whilst adherence to clinical medications has been estimated at approximately 50%, adherence with behavioural change programs is often even lower (Haynes, McDonald, & Garg, 2002). Poor patient adherence can result in increased costs associated with treatments, poor use of resources, and reduced treatment efficacy (Chen, 1991; Casey, L., & Clough, B., 2016). Use of adjunctive technologies in therapy has considerable potential to improve patient adherence (Clough & Casey, 2011c).

1.2. SMS Interventions

To date, SMS technology has primarily been researched in the periods before and after therapy. Several studies have demonstrated that text messages may be effective in increasing patient readiness to change and facilitating help seeking behaviours among participants not already engaged in treatment programs (Joyce & Weibelzahl, 2011; Mason, Benotsch, Way, Kim, & Snipes, 2014). However, there have been mixed findings with regards to the use of SMS appointment reminders in psychotherapy clinics. Whilst some studies have found positive effects associated with these interventions (Branson, Clemmey, & Mukherjee, 2013; Sims et al., 2012), Clough and Casey (2014) found no beneficial effects associated with the messages and that patient dropout was in fact higher in the SMS condition. Similarly, Delgadillo, Moreea, Murphy, Ali & Swift (2015) found that SMS appointment reminders failed to influence therapy attendance or completion rates.

Text messaging has been used to target patient engagement and adherence following discharge from inpatient programs (e.g., Bauer, Okon, Meermann, & Kordy, 2012). However, the only study that has investigated SMS during treatment is that reported by Laursen (2010). A series of retrospective qualitative interviews with young people engaging in programs for cannabis use, indicated that regular text

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

messages were generally well received and that the messages prompted reflection and awareness. This study did not however contain a quantitative analysis of satisfaction or feasibility. The acceptability and feasibility of SMS as an adjunct during a treatment program has yet to be investigated.

Daily use of SMS has not previously been tested within the treatment of adult anxiety and depression. As such, we felt it important to examine the feasibility and acceptability of using this form of communication. Acceptability refers to whether an individual perceives an intervention as being appropriate, fair, and reasonable for a given problem (Elliott, Witt, Galvin, & Peterson, 1984). Feasibility is a broader concept, and concerns whether an intervention can be successfully implemented with consideration to acceptability, intervention outcomes, participant engagement and retention, and practicality of the intervention (Kazak et al., 2005).

In order for SMSs to be successfully implemented as an adjunct to psychotherapy, its use should be associated with high patient acceptability, satisfaction, and feasibility. Consistent with the previous definition of feasibility, the feasibility constructs investigated were patient acceptance of the intervention, treatment effects (an expected reduction in symptoms from pre-to-post intervention time points), patient engagement and retention, and practicality of the intervention. In addition, therapeutic process factors such as group cohesiveness, conflict, and working alliance were also examined. A common therapist concern regarding the use of technology in psychotherapy relates to the potential for such technologies to interfere with therapeutic process (Rees & Stone, 2005; Rochlen, Zack, & Speyer, 2004). As such, the inclusion of process measures was deemed an important component of feasibility testing for the current study. Therefore, the primary aim of the current study was to assess the acceptability of SMS communication as part of a group therapy program. A secondary aim was to examine treatment effects, retention, and overall program satisfaction for the group therapy program that included SMS messages.

2. METHODS

2.1. Participants

Minimum sample size for the study was determined based on an a priori power analysis for the hypothesis with the smallest associated effect size, that is, that symptom reduction would be observed from pre to post treatment. The power analysis was conducted using G*Power version 3.1 (Faul, Erdfelder, Lang, & Buchner, 2007). Minimum sample size was calculated to be 28 patients, based on one tailed testing with an estimated medium effect size of $d = .5$, $\alpha = .05$, and power of .8. An allowance of 10% was made for dropout, giving a final minimum sample size 31 patients.

Patients were recruited through advertising on social media sites and search engines, as well as through community and healthcare referral agencies. Patients were included in the study if they met diagnostic criteria for an anxiety or anxiety related disorder as their primary diagnosis (based on DSM-IV-TR criteria), were aged 18 years or older, and were able to attend face-to-face group therapy sessions. Exclusion criteria included current or previous history of psychosis, mania or hypomania, chronic or significant suicidality, current substance abuse or dependence, or were already engaged in psychological treatment. Thirty-two patients who volunteered to participate in an ongoing project focusing on group treatment for anxiety formed the sample for the current study. One patient was later excluded due to under reported alcohol use that became apparent during the treatment program. The final sample size consisted of 31 patients (12 male, 19 female) with ages ranging from 18-74 years ($M = 39.45$, $SD = 16.60$).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Patients were assessed for diagnostic inclusion in the study using the adult Anxiety Disorders Interview Schedule (ADIS; DiNardo, Brown, & Barlow, 1994) in accordance with DSM-IV-TR criteria (American Psychiatric Association, 2000). Frequency of primary disorder diagnosis for the group is displayed in Table 1. Mean chronicity of the primary diagnosis was 15.23 years ($SD = 18.43$).

Table 1. Frequency of primary disorder diagnosis

Disorder	SMS Condition ($n = 31$)
Panic Disorder	3
Panic Disorder with Agoraphobia	1
Social Phobia	12
Generalised Anxiety Disorder	9
Obsessive Compulsive Disorder	1
Specific Phobia	2
Post Traumatic Stress Disorder	1
Hypochondriasis	1
Mixed Anxiety/ Depression	1

2.2. Design

The study was a within groups design. Dependent variables included dropout, patient engagement, group cohesion, group conflict, working alliance, self-reported measures of treatment satisfaction, and self-reported and clinician administered scales of anxiety, depression, and related constructs.

2.3. Materials and Measures

2.3.1. ADIS-IV

The ADIS (DiNardo et al., 1994) is a semi-structured interview that was used to identify eligible patients with a current primary diagnosis of an anxiety disorder or anxiety related disorder, as well as provide indications of relevant exclusion criteria such as suicidality, substance use, and mania. The ADIS was also used to provide Clinician Severity Ratings (CSR) of diagnoses, as well as an estimate on the Global Assessment of Functioning (GAF) scale. A CSR of four or greater is generally considered a clinically significant severity level.

2.3.2. Satisfaction

Patient satisfaction with the program was assessed using the Client Satisfaction Questionnaire 8 (CSQ8; Nguyen, Attkisson, & Stegner, 1983). The CSQ8 contains eight items relating to patient satisfaction with treatment services, with higher scores indicating greater satisfaction.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Patient satisfaction with the homework tasks was assessed on completion of the therapy program. Patients responded to five questions (1 – "Overall, how satisfied were you with the between session tasks?", 2 – "How enjoyable did you find the between session tasks?", 3 – "How easy was it to integrate the between session tasks into your daily activities?", 4 – "To what extent was the between session material presented in an interesting way?", and 5 – "To what extent do you believe the between session activities helped toward your therapeutic progress?") written specifically for the purposes of this study. Participants responded using seven-point rating scales (ranging from 1 to 7) for each question.

Patients also completed an additional five self-report questions relating to the acceptability and feasibility of the SMS intervention. The questions were designed to examine the previously defined key elements of feasibility, including acceptability, relationship to outcomes, engagement, and practicality of the SMS intervention from the patients' perspective. Using seven-point rating scales, participants responded to the questions "How helpful were the mobile phone text messages throughout therapy?" ("Very Unhelpful" to "Very Helpful"), "To what extent did receiving the mobile phone text messages cause interference in your life or bother you?" ("Not at all" to "Very much so"), and "If you didn't have the mobile phone reminders, how much of the between session tasks do you think you would have done?" ("None" to "Much more"). Participants then reported how often they carried their mobile phones with them on a seven-point rating scale from "Never" to "All the time". The final question relating to the SMS communication was an open response invitation to comment on the use of SMS messages in therapy.

2.3.3. Process Measures

Working alliance was measured using the Working Alliance Inventory – Short Form (WAI-S; Hatcher & Gillaspy, 2006), group climate was measured using the Group Climate Questionnaire – Short Form (GCQ-S; MacKenzie, 1983), and group cohesion was measured using the cohesion subscale of the Therapeutic Factors Inventory (TFI-C; Lese & MacNair-Semands, 2000).

2.3.4. Patient Engagement

Patient engagement was assessed by recording the number of sessions patients attended as well through the number of treatment dropouts. Dropout was defined by completion of 5 sessions, which was equivalent to greater than 50% attendance for the program.

2.3.5. Symptom Outcome Measures

Depression and Anxiety were measured using the Depression Anxiety Stress Scales 21 (DASS21; Lovibond & Lovibond, 1995), overall distress was measured using the Outcome Questionnaire-45 (OQ45; Lambert, Harmon, Slade, Whipple, & Hawkins, 2005), positive and negative affect was measured using the Positive and Negative Affect Scales (PANAS; Watson, Clark, & Tellegen, 1988) with the reporting period of "over the last few weeks" used, and functional impairment was measured using the Work and Social Adjustment Scale (Marks, 1986).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.4. Treatment Protocol

Treatment was delivered in accordance with a manualised group therapy program ("Facing the Fear") for the transdiagnostic treatment of anxiety and unipolar mood disorders (Clough & Casey, 2011a; 2015). Content for the program was based on the principles of cognitive behavioural treatment for anxiety and depression, with the addition of mindfulness and motivation enhancement modules. Content was delivered over nine therapy sessions, each of two hours in duration. Adherence to the session-by-session protocol for "Facing the Fear" was assessed by regular supervisor observation of sessions. A random 10% sample of session recordings were also coded with the use of a protocol referenced checklist by an independent observer. Average protocol adherence was high, at 85.30%.

2.5. Procedure

Ethical approval for this project was granted by the university Human Research Ethics Committee. Participants completed an initial screening interview by telephone with the first author, which was designed to assess for risk, initial eligibility, and provide information on the program. Patients then completed the ADIS interview, which was used to determine eligibility as well as provide assessment of diagnosis, diagnosis severity, and functioning. Provisionally registered psychologists conducted the ADIS interviews. All interviewers received training in the administration of the ADIS interview. In addition, all interviews were presented by the interviewers in regular supervision meetings, with all diagnoses, ratings, and GAF scores discussed with senior clinicians for consensus.

All self-report symptom questionnaires were completed via a secure online website. Study information was also presented on this website with participants providing consent online. Treatment consisted of nine group therapy sessions, as previously outlined. Sessions were held weekly, with between five and eight participants in each group and two therapists. Therapists were provisionally registered psychologists completing postgraduate clinical training who attended a training workshop on the Facing the Fear program. They received weekly supervision from the second author for the duration of the program. Patients completed the three process measures (WAI-SR, GCQ, TFI-C) at the end of the second attended appointment.

Each patient received a daily text message for the duration of the program. Messages were sent using web-based text messaging software (www.esendex.com.au), with each week's messages scheduled in advance. Text messages were tailored for the patients by the group therapists. Over the course of the week text messages were structured so that participants received one text message praising attendance at the therapy session (e.g. "Hi [insert name]. Congratulations on completing session one. Starting a new treatment can be difficult, but it is a strong decision. We hope you enjoy the program."), two text messages relating to therapy content (e.g. "Hi [insert name]. Remember motivation can change over time. Sometimes it's helpful to reconsider your reasons for change and set goals for how you will achieve this."), three text messages reminding patients of homework tasks and providing tips for completion (e.g. "Hi [insert name]. Remember to try completing a 3 component model form for an emotion that you experience during the week. Try to notice as much detail as possible."), and one text message designed as an appointment reminder for the next session.

Patients were advised that there would be no reply to the messages and were provided with emergency contacts. Scheduling of the text messages was completed by therapists at the end of each weekly session and took approximately five minutes per patient to complete. Timing of the delivery of text messages

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

was varied (to prevent habituation), but typically occurred during business hours each day. Although loan phones were available for the study, each patient had their own phone.

On completion of the therapy program patients completed a post treatment ADIS interview as well as the online questionnaire package. Included in this package were the additional questionnaires relating to treatment satisfaction. Patients were provided with two free movie tickets for completing the end of treatment assessments.

3. RESULTS

Data was analysed using SPSS version 21 (IBM Corp, 2013). Data was screened at each step of the analysis in accordance with guidelines by Tabachnik and Fidell (2013). Skew and univariate outliers were found on a small number of variables and transformations were performed as needed. As transformations resulted in no substantive differences in the results, untransformed data is reported for all measures and analyses.

3.1. Acceptability

To address the primary aim of acceptability of the SMS messages, descriptive statistics were obtained for the four questions relating to acceptability of the SMS communication. On the seven point rating scales, participants rated the SMS messages as being helpful throughout therapy ($M = 5.13$, $SD = 1.45$), that they carried their mobile phones with them most of the time throughout the intervention period ($M = 5.96$, $SD = 1.43$), and that they believed they would have completed less homework if they did not receive the messages ($M = 3.21$, $SD = 1.02$). Patients indicated that the SMS messages did not interfere or bother them throughout the day ($M = 1.62$, $SD = 1.06$).

Strong acceptability for the SMS communication was also indicated in the review of responses to the open-ended question regarding satisfaction with the messages. A number of responses indicated that patients found the messages to be supportive, e.g. “They always brought a smile to my face and my heart. It was like a guardian angel watching over me!!!” and “The texts were fantastic. If I was having a bad day, and I received a helpful message it really did make me focus and remember what I should be doing. They were GREAT”. Patients also indicated that the messages were helpful in prompting them to complete homework (“They were a nice way of being reminded to do your homework”) although one patient commented on the timing of the messages predominantly occurring during business hours, “If the messages could be sent a bit later in the day, that would be good. The messages tended to arrive when I was still at work, which meant I was unable to action them”. One patient also commented on interplay between the messages and her difficulties with anxiety, “As I can’t go without checking a message as soon as I receive it (in case something bad has happened to someone) getting a message while driving was quite interfering”. However, comments also indicated that the patients may have perceived the messages as being a part of a strong working alliance, “Even if the phone messages didn’t prompt me to do the exercises, they did provide a friendly connection with [Therapist 1] and [Therapist 2]. The messages appeared as an extension of their friendly personalities during the sessions”. Of the 23 patients that completed the post measures, only one patient (the previously noted response of the messages interacting with her anxiety) response indicated a lack of acceptability for the SMS communication. All other responses indicated positive attitudes towards the use of SMS as a form of adjunctive communication in therapy.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.2. Patient Engagement, Outcomes, and Satisfaction

To address the secondary aims of examination of treatment effects, retention, and overall program satisfaction, descriptive and within group analyses were conducted and referenced to previous literature in the field.

3.2.1. Dropout

Using the 50% session attendance rate as a cut off for treatment dropout, five patients (approximately 16%) were identified as treatment dropouts in this study.

3.2.2. Group Process

On the GCQ patients reported being engaged in the group ($M = 3.37$, $SD = .97$), a lack of conflict within the group ($M = .63$, $SD = .50$), but that there was some avoidance experienced within the group ($M = 2.58$, $SD = 1.14$), an unsurprising finding given the nature of the presenting problems. The mean ratings on the GCQ in the current sample were similar to those observed among patients experiencing comorbid disorders engaged in cognitive behavioural group therapy (M engagement = 3.9, M avoidance = 2.3, M conflict = .5; Johnson, Burlingame, Olsen, Davies, & Gleave, 2005). It is possible that the avoidance experienced by the group may also have impacted group cohesiveness. Although mean group cohesiveness on the TFI-C was scored positively by patients ($M = 49.63$, $SD = 8.02$), the mean score was slightly lower than that reported by Lese & MacNair-Semands (2000) in their development of the scale ($M = 54.91$). Patients in the current study also reported strong working alliance in terms of goals ($M = 5.40$, $SD = .99$), tasks ($M = 5.32$, $SD = 1.07$), and bonds ($M = 5.46$, $SD = .92$) on the WAI-S, with mean scores being comparable to that reported in psychometric analyses of the scale (M Task = 5.92, M Goals = 5.80, M Bond = 5.94; Busseri & Tyler, 2003).

3.2.3. Patient Satisfaction

Overall patient satisfaction with the program was found to be high on the CSQ8 ($M = 27.43$, $SD = 3.23$). This score is approximately equivalent to the reported norm of 27.80 for this scale among adults in mental health settings (Atkinson & Greenfield, 2004). Satisfaction was also high on the five original questions relating to satisfaction to the homework tasks, with descriptive statistics displayed in Table 2.

Table 2. Descriptive statistics for homework satisfaction scales

Measure	Mean
Q1 – Homework Satisfaction	4.74 (1.25)
Q2 – Task Enjoyment	3.91 (1.20)
Q3 – Task Integration	4.17 (1.56)
Q4 – Presented Interestingly	4.48 (1.41)
Q5 – Helped with Progress	5.05 (1.15)

Note. $N = 23$, standard deviations are shown in parentheses

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.2.4. Check of Treatment Effects

Treatment effects were examined to determine whether results were consistent with what would be expected for this treatment approach, as is deemed important for feasibility examination. Treatment efficacy was evaluated using the completer and intent-to- treat (ITT) samples. The ITT sample comprised all participants allocated to treatment with post treatment scores imputed using the Last Observation Carried Forward (LOCF) method. Of the 31 participants originally allocated, 23 completed the post treatment questionnaires and 24 completed the post treatment ADIS interview. Results of the ITT analysis were consistent with the completer analysis. As the ITT analysis was consistent with the completer analysis, and because evaluation of treatment efficacy was not the primary purpose of this paper, only the completer analysis is reported.

Within subjects t tests were conducted to investigate intervention effects from pre to post treatment. Descriptive statistics are displayed in Table 3. Significant improvement was observed for patients from pre- to post- treatment on the depression ($t(22) = 2.240$, $p = .036$, $d = .467$), anxiety ($t(22) = 3.168$, $p = .004$, $d = .660$), and stress ($t(22) = 3.272$, $p = .003$, $d = .682$) subscales of the DASS21. Improvements were also observed on the OQ45 ($t(22) = 4.489$, $p < .001$, $d = .936$), negative affect subscale of the PANAS ($t(22) = 3.488$, $p = .002$, $d = .727$), and the WSAS ($t(22) = 4.080$, $p < .001$, $d = .851$), such that participants experienced a reduction in symptoms and related interference over the course of treatment. No significant effect was found from pre- to post- treatment on the positive affect subscale of the PANAS ($t(22) = 1.029$, $p = .315$, $d = .215$). However, results of the clinician administered measures supported the improvement in symptomology, with a significant effect of time found for the CSR ($t(23) = 4.226$, $p < .001$, $d = .863$), GAF ($t(23) = 4.794$, $p < .001$, $d = .978$), and mean number of disorders present ($t(23) = 4.253$, $p < .001$, $d = .868$).

Table 3. Descriptive statistics for the completer analyses on treatment outcome variables

Measure	Time Point	
	Pre treatment	Post treatment
DASS-D	11.66 (9.58)	7.92 (6.54)
DASS-A	11.92 (7.68)	7.48 (7.46)
DASS-S	19.56 (10.68)	12.78 (8.46)
OQ45	79.00 (22.72)	60.57 (17.75)
PANAS-P	28.83 (6.53)	30.78 (6.68)
PANAS-N	27.48 (8.55)	22.13 (6.93)
WSAS	16.91 (9.13)	12.00 (7.27)
Primary CSR	5.83 (.87)	4.21 (2.34)
GAF	55.71 (4.84)	65.58 (9.90)
Mean number of Diagnoses	2.42 (1.44)	1.29 (.96)

Note. $N = 23$ for self-report questionnaires and $N = 24$ for clinician administered (CSR, GAF, Number of diagnoses) measures. Standard deviations are shown in parentheses.

4. DISCUSSION AND CONCLUSION

4.1. Discussion

This study examined patient satisfaction and acceptability of a daily SMS communication. Technological adjuncts have the potential to increase adherence and treatment outcomes within psychological interventions. However, research into patient response to this form of communication has been limited.

Analysis of qualitative feedback indicated high acceptability of the adjunctive communication. Patients reported primarily positive attitudes and responses to the SMSs, both with regards to integration in their daily life and fit with their treatment program. Satisfaction with the intervention was also high, with patients reporting they would have completed somewhat less homework if they had not received the messages and that the messages did not bother or interfere in their daily lives. Patients also reported that they carried their mobile phones with them most of the time, highlighting the importance of establishing this additional form of communication. Review of the qualitative feedback also indicated overall high satisfaction with the intervention, with patients perceiving the messages to be motivating, supporting, and an extension of a strong working alliance with their therapists. The cost of the SMS communication was less than $1AUD (<$1USD) per patient per week. Feedback from therapists in the program indicated that the SMS communication was easy to implement and not time intensive.

The SMS communication was successfully integrated as an adjunctive communication without detrimental effects on group process or outcome. Dropout in the current study was also considerably less than that found in other psychotherapy research (e.g., Wierzbicki & Pekarik, 1993), further supporting the efficacy and satisfaction of the program. Inspection of the measures of group process suggests that the messages did not interfere in the functioning of the group, with participants reporting good group cohesion, group climate, and working alliance. Furthermore, treatment gains were observed on self-report and clinician administered measures of symptomology. When compared to a recent meta-analysis of transdiagnostic treatments, the observed effect size for the DASS-D was somewhat smaller than would be expected for transdiagnostic group therapy for depression (Hedge's g = .89; Newby, McKinnon, Kuyken, Gilbody, & Dalgleish, 2015). However, it should be noted that in the current study only 25% of the completer sample (six participants) met criteria for Major Depressive Disorder as an additional diagnosis at pre-treatment, which may have contributed to the small observed effect size from pre to post time points. The effect size observed for the reduction in anxiety symptoms on the DASS-A was consistent with those reported for transdiagnostic group therapy for anxiety (hedge's g = .70; Newby et al., 2015). These results suggest that the inclusion of the SMS adjuncts did not interfere with the efficacy of the group therapy program.

4.3. Limitations and Future Directions

Although the results of the current study are promising, they should be considered within the context of a number of limitations. Firstly, a lack of a control condition inhibits conclusions being made about the effect of the adjunctive reminders in comparison to a no control condition. This specific effect requires examination in future research by means of a multiple arm trial. In addition, the specific link between the effect of the reminders on engagement and adherence behaviours was not examined in this pilot research. A larger study with increased sample size would allow for more in depth examination of these intervention effects and the mechanisms of change.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The adjunctive reminders used in this study were also based on broad behavioural and motivational principles of change. It is possible that the effect of these reminders will vary person to person, based on presenting problem, individual motivations and personality, and other client characteristics. These factors were not examined in the current study. It may be of interest in future research to examine these influencing variables more closely, to determine the client and situational characteristics in which such an intervention may be recommended.

4.3. Conclusion

It is clear that the SMS communication can be successfully implemented as a technological adjunct in a face-to-face psychological intervention. This investigation is an important first step in understanding the effects of an adjunctive communication for psychotherapy patients, particularly given that SMS communications have produced mixed findings in previous research (e.g., Clough & Casey, 2014; Delgadillo et al., 2015; Sims et al., 2012). The next step in this investigation is therefore to determine whether the SMS communication results in significantly greater patient adherence and treatment effects when compared to a treatment as usual group.

4.4. Practice Implications

Use of technological adjuncts to support adherence in psychological interventions may allow for greater reach and efficiency of limited mental health services. This study has demonstrated that SMS communications may be successfully implemented and accepted in psychological treatments without a negative impact on therapeutic process.

Chapter 46
An Internet-Based Quantum Biofeedback and Neurotechnology Cybertherapy System for the Support of Transpersonal Psychology

Raul Valverde
Concordia University, Canada

ABSTRACT

Transpersonal psychology is the study of human nature and proceeds on the assumption that human beings possess potentials that exceed the limits of their ego and integrate the spiritual experience within a broader understanding of the human psyche and consciousness. Altered states of consciousness have been used as psychotherapy in transpersonal psychology for decades. A Cyberpsychotherapy system is proposed to support transpersonal psychotherapy. The system can be used to induce non-ordinary state of consciousness that can be used by transpersonal psychologists as a healing tool to cure his patients with psychological problems such as psychosis at a distance location with the help of Internet technologies. The Cyberpsychotherapy system uses quantum signal generator for the induction of altered states of consciousness based on the God's helmet of Persinger (1983). The Cyberpsychotherapy has integrated an EEG that serves as a biofeedback device in order to assess if the patient has reached the desired level of consciousness and can be used it to adjust the frequencies of the signal generator in order to improve the psychotherapy experience of the patient if necessary. A sample of 10 patients was used to test the Cybertherapy system based on Neurotechnology and quantum biofeedback, data was collected and analyzed. Although the results show that the patients were not able to reach the desired level of consciousness for the psychotherapy, there is statistical significant evidence that the proposed system can help to raise the level of consciousness; this can help with future designs that will eventually assist to reach the desired level for the psychotherapy.

BACKGROUND

Cybertherapy is an Internet based computer-mediated system used to facilitate psychotherapy (Botella et al. 2009). This includes new applications of technology within psychology and healthcare, which utilize augmented and virtual reality components in order to facilitate psychotherapy (Botella et al. 2009). Although there are many Cybertherapy systems in the literature (Takacs, 2005), none of them addresses transpersonal psychotherapy and are based on quantum biofeedback. Transpersonal psychotherapy that is based on transpersonal psychology, considers that the psyche is multidimensional and there are several "levels of consciousness" and each has different characteristics and is governed by different laws. Transpersonal psychology is the study of human nature and development proceeds on the assumption that human beings possess potentials that exceed the limits of ego developed normally. A main goal of transpersonal theory is to integrate the spiritual experience within a broader understanding of the human psyche and consciousness (Grof, 1988).

The trend to explain consciousness by applying quantum theories has gained popularity in recent years and, although clearly disdained by neuroscientists, more and more researchers direct their steps this way up. Brian D. Josephson (1962) of the University of Cambridge, winner of the 1973 Nobel Prize in Physics for his studies on the quantum effects in superconductors (Josephson effect), proposes a unified field theory, quantum nature, that would explain not only the consciousness and its attributes, but also all the phenomenology observed to date in terms of psychological and mystical experiences.

The human being experiences different altered states of consciousness, that is, consciousness can be altered in different ways. Stanley Kripner (2000) defines altered states of consciousness as mental states that can be subjectively recognized by an individual or by an objective observer than the individual who experiences it as different in mental functions, the normal state of the individual, the alertness and the waking.

Altered states of consciousness have been used as psychotherapy in transpersonal psychology. One of these techniques is known as holotropic breath work that is produced by using hyperventilation making the individual breathing deeply and rapidly for several minutes. Grof (1988), with this technique, causes a crisis that leads to an altered state of consciousness and allows the study the consciousness of the individual from that new state. Stanislav Grof (1988) uses the experiential healing power of this new state of consciousness to cure his patients. Although holotropic breath work induces these altered states of consciousness, biofeedback and neurotechnology offer an alternative way to induce altered state of consciousness for transpersonal therapy that can be easily implemented with the use of quantum computer technology and used in combination with the internet to facilitate online transpersonal therapy (Valverde 2015a).

Quantum biofeedback uses sensors to monitor physiological relaxation indicators, as the temperature of the skin and muscle tension. It expands classical biofeedback by using galvanic skin response (GSR) together with modern computer technology to detect the response of the built-mind-spirit body (sometimes called the super-conscious) to a large array of stress indicators. Quantum Biofeedback is a sophisticated biofeedback technique based on advanced quantum scientific principles that promote a deeper understanding of health and healing. Seeing the body as a complex electrical circuit and the application of the principles of electrical engineering, who are able to analyze and balance the body electric.

Quantum Biofeedback interacts with all cellular matrix of the body, which allows communication with the conscious and unconscious reactions of the body. This is accomplished by establishing electrical communication using 12 electrodes are attached to the head, wrists, and ankles of the patient. A loop and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

cyber handshake between Quantum Biofeedback System and the patient using a calibration procedure is then created. By connecting in this way all 200 billion cells in the human body are included in the the exchange of information. On this basis, it is now possible to identify and prioritize the tensions and toxins that are a major concern and bring them into balance.

Classic Biofeedback is based on electrical measurements taken from the front (frontal cortex). In this information it is presented to the customer who then tries to consciously change their internal reactions to modify electrical results. Quantum Biofeedback uses your link to all body cell matrix interface, not only the conscious aspects, but also with the unconscious. This provides greater gain in the understanding of health, as our conscious perception of the world is limited by design to 17% of the stimulation we receive.

An application of quantum physics (neurotechnology) in the altered states of consciousness was carried out by Persinger (1983). Persinger (1983) was able to induce visions of God and other religious and mystical experiences in the laboratory by using a computer and with what he called the Koran helmet that has also the nickname of the God helmet. He found that the temporal lobes of the brain are the source of the most spiritual experiences and other alternate state of consciousness.

This God helmet is a device to induce altered states of consciousness using weak magnetic signals to direct brain activity that can induce spiritual experiences that helps with transpersonal exploration and transformation of many people that is able to heal because of these transpersonal experiences (Persinger 2000). It is suggested that altered states of consciousness such as sensed presence and out-of-body experience whether they are produced by magnetic, electric or other stimulations or circumstances can be most effectively explained as the changes of the relative contents and/or intensities of the test subjects' neural quantum entanglement with their surroundings including possibly spiritual environments or information (Hu & Wu 2012).

With the aid of quantum biofeedback and neurotechnology, people can discover hidden deep events and conflicts in their subconscious that can lead to healing experiences. The proposed research has the objective of creating a cyberpsychoterapy system that uses quantum biofeedback and neurotechnology to facilitate transpersonal psycho therapy by inducing altered state of consciousness over the internet.

The work has the intention to contribute to the existing literature in the application of quantum biofeedback and neurotechnology to psychology by suggesting a cyberteraphy system for the facilitation of transpersonal psychotherapy.

LITERATURE REVIEW

Quantum Consciousness

The trend to explain quantum consciousness by applying quantum theories has gained popularity in recent years (Valverde 2016), a character that has stood in defence of a theory quantum of consciousness was the physicist Roger Penrose (1994), famous for its friendly Stephen Hawking differences regarding certain cosmological aspects and a world authority with regard to the theories of relativity and quantum. Penrose (1994) attacks and almost ridicules those who argue that the artificial intelligence of computers can reproduce human attributes, including consciousness.

Penrose, based on the mathematical theorem of Gödel and based on subsequent his elaborations, concludes that no system deterministic, that is, which is based on rules and deductions, they can explain the creative powers of the mind and your judgment. This nullifies the claim of physics classic, computer,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

neurobiology, etc., to structure themselves into a complex phenomenon of consciousness. Penrose says that only the peculiar characteristics non-deterministic quantum physics could issue an approximate judgment on consciousness, within a theory that involved quantum phenomena, macro physical and conditions of non locality. At this point perhaps it would be interesting clarify that local conditions are not known in quantum physics those capabilities that either has a quantum system, communication instant between parts, ie, without there being time duration between communication of an event from one point to another system.

Albert Einstein called this peculiarity that occurs in the innermost parts of matter, the universe, "that mysterious action at a distance '. If some concepts explained at the time in the course of "Matter and Energy" understand the model proposed by Penrose relates to the concept of Universe "Nonlocal" to quantum levels, in the sense that everything that happens in a corner any of our cosmos is immediately 'felt', "meaning" for any another.

In his last conference Penrose ventures even indicate that probably It is in microtubules, microscopic tubes that form the skeleton of cells, including neurons, where the complicated interactions occur quantum kind that give their "magic" character, "mysterious" from the point of view of science, consciousness. Hameroff (1994), claims to have found evidence that loss of consciousness by providing anesthesia is due to some inhibition of the flow and movement of electrons within the microtubules. Hameroff argues that certain cellular elements such fluctuations occur quantum-relativistic that "somehow" do emerge consciousness. The major objection to this theory by neuroscientists is that all animals, including elementary, have microtubules in the cells which it seems to imply that they all possess consciousness. Hamenoff argues that such statement would be indefensible, but it is inevitable the observation of "some degree of apparent intelligence" in all animal species. There is still another favorable group to this explanatory theory of consciousness, which is headed by Dr. Ian N. Marshall (Marshall and Zohar 1997) who through empirical testing system claims to have the key to the issue. Marshall and Zohar (1997) showed that conscious thought emerges from quantum effects. Indeed, it has been found that the ability of subjects to carry out work simple while they are connected to an electroencephalogram (EEG).In general, we can say that the Achilles tendon of this group of theories lies in the extreme conditions in which the quantum interactions are observable, for example, the effect of local not manifested in conditions close to absolute zero temperature is absolutely clear that they are not exactly those of our brains. However, supporters of quantum school, as expected, they find answers to these problems and many other objections, in which are indistinguishable from the other schools that obviously do the same to defend their ideas.

Neurotechnologies

Interest in neutechnological devices has grown strongly since the release of 1986's classic text of Michael Hutchison "Megabrain" (1986). Besides neurotechnological machines, the industry has developed a range of related devices including peripherals-tapes, subliminal tapes, hypno-peripheral processing, sound meditation devices and altered state induction software programs for personal computers, etc. It seems like neurotechnology combined with contemporary psychology may seem to be revolutionary but its roots are much older as humanity has made many attempts in the past to involve consciousness with technology. The flashing LEDs in a light and sound machine can be traced back to the old practice of starting a fire in order to induce trance. Sound recordings of brain entrainment undoubtedly have their roots in the ritual singing and shamanic use of wind instruments.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

This current era of neurotechnology was born from the experiments made in biofeedback that resulted in the work of some researchers of consciousness as Masters & Houston (1966) that created the AVE (an abbreviation of Audio Visual Environment) that is one of the first electronic brain entrainment devices. The AVE was the first device to use visual and auditory stimuli as a means of altering consciousness. Not much different that many of audiovisual devices of today, the AVE consisted of a wrap-around screen and headphones to bomb the sense in these two stimuli.

These signals generated by AVE devices and detectable by electroencephalogram (EEG) tests at specific frequency ranges; seem to vary from one state of consciousness to another for their users. The products of neurotechnology appear to make possible to "tune" the brain to these different alternating frequencies, and in turn achieve new psychological states. When you "tune" into these frequencies at a slower pace, our thought processes and central nervous system are altered, causing the brain to fall into a deep level of activity. In addition, when one is tuned to a frequency faster and a higher range, the wave activity can have a highly stimulating effect on the brain.

Altered states of consciousness have been used as a therapy for modern psychological paradigms as transpersonal psychology (Valverde, 2015). Although there are several techniques such as holotropic breathing used to induce these altered states of consciousness, terotechnology offers an easier to control alternative to the transpersonal therapies.

The area called Neuro includes all types of technology that any it contributes to the advancement of knowledge related to the brain. Despite that neurotechnology is relatively old, its most significant advances occurred in the last 30 years. The 90s were even proclaimed by the US government American as the "Decade of the Brain". Much of the responsibility for this development exacerbated is due to the advent and popularization of brain imaging techniques, including MRI, CT, PET (Positron Emission Tomography), among others. With technological advances, some of these techniques at first provided only structural information from the brain but now it allows us to study the brain dynamics.

Experimentation and published research on the altering of brain activity has been going on for decades. A vast amount of applicable data has been collected by researchers and scientists concerning the manipulation and influencing of brain waves and states of consciousness. One effect discovered by German scientists in the 1930's is called the Ganzfield effect (Hyman 1985). It is an effect in which the eyes are exposed to a totally uniform visual field, with no edges, color changes, or movement. This effect can be achieved by looking up at the sky on a clear, cloudless day or with very specially constructed illuminated glasses. It affects the circuitry in the brain, which normally is constantly scanning the visual field for edges and movement. The eye responds primarily to changes, and with visual sensations shut off and the brain finding absolutely nothing, the subject cannot tell if his eyes are open or closed. This is an example of an altered state of consciousness resulting from the shift in brain waves to the theta state.

The effects of flickering light stimulation have been known for centuries. Ancient shamans used flickering lights to achieve a trance state, a key component in the development of the spiritual practices of a wide variety of ancient cultures. In the literature of the common era, Ptolemy noted around 200 A.D. that the flickering of sunlight seen through the spokes of a spinning wheel could cause patterns and colors to appear to the observer, producing a feeling of light headedness and euphoria. The onset of modern times, (1940's and 50's) brought the research of neuroscientist W. Gray Walter (Walter and Walter 1949). Walter used a strobe light to create flickering light stimulation, noting that the brain wave pattern of the cortex—just the area associated with vision—was changed. Ever since the adrenaline rush brought about by dancing around the tribal fire, the intent of scientists, researchers, and ancient religious practitioners has been to create relaxation and altered states by affecting the vibrational frequency of

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

the brain waves. The use of technology is a modern day attempt to create desired changes in the brain's functioning, bringing about states of well-being and health.

Robert Monroe, one of the most prominent people in neurotechnology in particular in the field of sound with neurological efficiency, devised the method HEMI-SYNC: (Synchronization of the cerebral hemispheres by means of sounds). Like a glass resonates when a pure tone is emitted, the brain resonates when receives certain frequencies of waves, being synchronized with these, (similar to the previous with the flashes of light) effect is known as FFR Frequency Following Response (Response a frequency tracking).

Machines created based on FFR began to be popular, the typical machine based on the principle of Monroe using stereo headphones that are used are separately sent sound to each ear signals, for example 2 signs of 300 and 304 Hz. In one ear will be heard only 300 Hz signal and the other only 304, but since the sounds are combined in the brain, this will hear a third signal of 4 Hz which is the difference between the two sound impulses.

This third sign is not an audible sound, but an electrical signal that can only be created by the cerebral hemispheres acting in unison, and may go unnoticed, producing as a result, the two hemispheres are focused simultaneously on the same state of consciousness, increasing and brain power.

The Monroe Institute was created based on the principles of Monroe. This institute was founded by Robert A. Monroe, who began studying the effects of sound on accelerated learning in the 50's.The work is the result of thousands of hours of laboratory sessions.

Participants listen volunteer's specific combinations and sequences of sound patterns and simultaneously are reporting their experiences; while electronic instruments measure the effects on the activity of their brain waves.

W. Grey Walter (1964) conducting experiments in which strobe devices used to send rhythmic flashes of light in the eyes, watched amazed that the flickering light could alter the activity of the entire cerebral cortex, rather than exclusively associated areas with vision. The subjective experiences of those who received the flashes were even more curious reported seeing "lights like comets, ultra fantastic colors, color mental". Moreover, Walter discovered that certain visual stimuli of a certain frequency could cause the brain to respond quickly adjusted to the same frequency of the stimulus it received.

In 1982 a psychiatrist Denis Gorges created a machine called brain wave synchronized energized, patented and sold by his company, Synchro-Tech Inc which applies the latest technology in the first device designed optical-acoustic stimulation. This is able to promote as its inventor claimed, "an increase in the capabilities and functions of the human mind" unleashed a wave of unprecedented research and experimentation, catalyzed by M. Hutchinson (1986) through his famous book Megabrain that is being developed in and outside universities around the world.

Studies on this type of equipment is underway in North American universities, in areas including education and training, substance abuse, gerontology, pharmacology and physiology as well as pain reduction. In Europe, at the University of Vienna, it has created a special subject for further study of these devices. The neurological investigations in the last 15 years have shown that our cerebral hemispheres work independently. Each hemisphere collects the same information that its sensors (eyes, ears, taste, touch, smell) and processed differently. Our scheme of thought is influenced by the predominance of left hemisphere, logical and analytical thinking. Right hemisphere, creative thinking, visualization, and which carries out a holistic synthesis.

On the back of the brain is where the intuitive thought (Subconscious). Obviously use one of the two hemispheres or either of the Brain regions severely limits our abilities. The optimal functioning of our

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

brain, is given by the synchronization of the two hemispheres: By left-right and front-back alternating stimulation occurs almost simultaneously, an issue of brain wave amplitude and frequency identical. It is that how you might think with our whole brain.

Neurotechnology are typically used for process brainwave entrainment to tune brainwaves any range brainwave. With these machines, you may experience theta waves, alpha, delta or including combinations of ranges using frequencies layered that mix several ranges brainwave in a brainwave pattern synergistic as pattern brainwave.

Hemi-Sync is a patented process sound pulses to create the same electric waves in frequency and amplitude simultaneously in both hemispheres of the brain for specific purposes.

Our brains have a hemisphere left and right. The left brain is linear, logical, practical, and time -oriented. The right hemisphere seems to be much more nonlinear, abstract, creative, holistic, and not logic. We tend to use one hemisphere at a time, or better said, will favor hemispheres particular in terms of what we're doing. An accountant probably uses less of his right hemisphere that an artist would during the course of their workday.

If the person is doing math, the staff would be using more of your left hand. If the person is going to paint a picture, the person would have the activity hemispheric more right. Both hemispheres are constantly interacting and both can be in use simultaneously. By merging both hemispheres, a person is allowed to work together and with this the person can increase his or her ability mental and improve his or her performance cognitive in general. Basically it's like having a computer processor faster able to work at faster speeds. The greater integration creates better performance.

The mind machines that help the brain synchronizes naturally to balance hemispheric activity and adjusts the activity of brain waves to match the carrier frequencies embedded brainwaves. This hemispheric coherence induced audio produces an optimal state of comprehensive synergy of the entire brain.

These hemispheres are connected by the corpus callosum. It serves as a conduit or a bridge between both sides. This bridge literally be exercised and strengthened until it is physically larger and more capable of transmitting data, ideas and feedback between the hemispheres.

The advance occurs when you use this principle to synchronize our brain wave frequencies chosen with the help of specific mental machines. We can do this easily by using technology binaural beat audio and ringtones monophonic. This phenomenon is called trailing phenomenon.

The scientific principle of drag can be used to resonate, or synchronize your brain to tune specific frequencies. The drive is quite simple. If you have two tuning forks of the same pitch, if you strike one and hold it near the other, which both resonate at the same frequency. Given this fact and the fact that our brains function as a resonating chamber. Oscillating pulses and patterns of neural excitation ripple through our brains like endless waves on a pond of subtle dynamic electric field.

The creation process frequency binaural beat - brainwave entrainment is very simple to explain. First, you create two audio tones two frequencies slightly different (ie 100 Hz and 107 Hz). When playing a tone in the ear left and the other tone in his right ear, the brain reacts to the stimulus audio by resonance brain activity to the difference between these two tones. His brain waves adjust to match this frequency differential.

For example, if you play a frequency of 100 Hz in the ear and left 107 Hz in the right ear, your brain tune the 7 Hz differential (107 Hz - 100 Hz = 7 Hz). This frequency tracking response makes your brain to resonate at 7 Hz frequency falls within the range of brainwaves theta . This guide psychoacoustics state of the art can create phenomenal results.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The electrical activity of neurons is changing patterns of electrical potential through all cell membranes. Each cell generates in the membrane potential can be detected in about one micrometer of the cell but large sets of brain cells that can work in harmony to generate potential of few micro volts, that can be detected through the skull and scalp using electrodes. The variation of the electrical potential around the scalp is the basis of operation of the electroencephalogram. This method of recording the electrical activity of the brain, digitized maps produces the electrical activity of brain.

The state in which the two hemispheres are synchronized, that is, showing similar activity in both hemispheres, sometimes known as "whole brain" naturally occurring randomly for short periods. Stimulation through the differential tone makes it possible to sustain this state for longer periods.

EEG based on data collected in the laboratory of Gateway Institute, it is clear that after a brief period of use of frequencies of Hemi-Sync, it can be demonstrated the benefits of the technology without the use of external sources.

The Hemi-Sync process has already been tested and implemented in many ways for:

- Sleep better
- Reduce tension or stress
- Control pain
- Accelerate learning
- Study and concentration
- Enhance creativity
- Find solutions to problems

Light and Sound Machines have the purpose to create a relaxed state through the use of sound and light stimulation. It was discovered in the 1930's that repetitive light stimulation (strobing) caused brain waves to follow and pulse at the same frequency (Walter & Walter 1949). This discovery had profound implications for the human condition, giving rise to an entire industry that explores the possibilities in using outside stimulation to provide a functioning aid to the workings of the brain. The devices on the market today are set at predetermined frequencies of 1 to 40 Hz. The user is then free to experiment on just how these vibrational frequencies influence their affect on the mind's eye. Most users report patterns of colors that pulse in synch with the frequency of the beats. The patterns are often quite psychedelic and geometrical.

Light and sound machines are often used for meditation assistance, or to aid the learning process. The technologies are referred to as audio-visual stimulation systems, light and sound machines, or mind machines.

Varying patterns of light and sound are used to create different states of awareness, attention, relaxation, creativity, and receptivity to information. Most systems are controlled by a microprocessor. The sound and music sometimes comes on a CD, with the frequency patterns embedded in the music.

A typical system is made up of three components: a light/sound synthesizer, stereo headphones, and stimulation glasses with pulsating lights. A carefully composed sequence of rhythmic light and sound patterns direct the stimulation synthesis, creating light and or sound sessions for the desired effect. Some systems connect to your music CD player, or have one built in. The process employs a technology called an audio strobe system, which creates inaudible, high frequency beats that drive a light/sound system. Other systems have computer interface capabilities that allow the user to vary the tone, frequency, pitch and other parameters to tailor the program to individual needs. Some metaphysical technology compa-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

nies have downloadable programs that allow for even more growth, variety, and individual tailoring. A few make a point of offering customer service where the company provides you with specifics that are designed to individual needs (Dumit 1995).

The light and sound systems are designed to blank out the visual and auditory stimulation that the mind generally receives, and replaces it with very simple, rhythmic stimulation. Some light systems come with glasses that block certain colors so that the brain focuses on others to create the desired stimulation. The basic rhythms of light and sound cause the mental processes to change in response. Thus, the rate of brain waves adjusts to the desired vibrational rate.

Another technology designed to create specific body changes is biofeedback. Biofeedback is a non-invasive, painless, non-pharmaceutical method of teaching you to become aware of your body processes and help you learn to change them. Electrodes are placed on the skin and feed information into a small box attached to your computer via a serial port. The equipment feeds information back to you about your body. The feedback is usually auditory, a soft beep, and, by concentrating on this sound, the user can focus on specific bodily processes and learn to relax in very specific ways. The process is designed to provide the individual with an ongoing progress report as to how their body is responding to their own internal controls. In this way, one can learn to change heart rate, skin temperature, muscle tension, and certain brain wave patterns (Turnbull & Ritvo 1992). Biofeedback information is used to teach the patient what are the brain regions responsible for a certain behavior and thus be able to learn to control these areas and monitor the progress of the training.

The difference between the two technologies is that light and sound machines provide direct stimulation that affects the rate of brain waves, whereas biofeedback places the impetus on the individual to control their body's processes themselves. The goal of biofeedback is to train oneself to respond to intrinsic cues, which contrasts to the light sound stimulation machine's purpose of matching one's brain frequencies to outside stimulation.

Neurothecnology is for healing, and affecting one's mental and physical state in a positive way. However, in order to best apply the technologies to one's personal circumstances, diagnostic processes may be needed in regards to one's individual circumstances. One such diagnostic tool is called Kirlian Photography.

This process was discovered in 1939 when Semyon Kirlian (1973) found that if a living object on a photographic plate is subjected to a high-voltage electric field, an image is created on that plate. The image looks like a colored halo or coronal discharge. This process captures what the spiritual community refers to as the "aura," and the scientific community calls the "Meissner" field. This field is the area of gas ionization that is produced when electricity enters a living object. The image of the moisture is transferred from the subject to the emulsion surface of the photographic film. The field is visible to the photographic process because of the exchange of photons, or light particles, which takes place as our cells communicate through the chemical process with each other and with the surrounding environment. The light particles the body produces carry information in the same way that fiber optics carry information from one point to the next.

The color and densities that appear on the photo will vary due to the variances of energy output as a result of the different quantities and balances of acids and alkalis the body gives off as it attempts to optimize its chemical processes. The appearance of this gas ionization process on film varies in ways that are consistent. Thus, diagnosis of one's chemical balance can be inferred from the colors and densities that appear on the film.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, a good interpreter can detect specific energy imbalances from the color variances in the field surrounding the image of the body. Pulsed electromagnetic fields—which induce measurable electric fields—have been demonstrated to be effective for treating slow-healing fractures and have shown promise for a number of other conditions. This has opened up a huge effort to market a wide variety of magnetic products to assist with the healing process. A whole range of products is available for what is referred to as "magnetic therapy." Small spot magnets can be used at the point of pain on the body. There are wraps, belts and pads, which are held on the body in some fashion. In addition, there are mattress pads that claim to balance the body's energies while one sleeps. Various types of jewelry incorporate magnets into their design, including a wide variety of bracelets and necklaces. Many magnetic necklaces, bracelets, and earrings are formed from silver and gold-rich magnetic alloys and are promoted as both fashionable and therapeutic. One catalog claims that magnetic earrings "stimulate nerve endings that are associated with head and neck pain," and magnetic bracelets "act upon the body's energy field" and "correct energy imbalances brought by electro-magnetic contamination or atmospheric changes" (Vallbona, C., & Richards 1999).

The broadest explanation of the use of magnets in treating physical ailments was presented by Dr. Kyochi Nakagawa of Japan (Nakagawa, 1976). Dr. Nakagawa claims that many of our modern ills result from "Magnetic Field Deficiency Syndrome." The earth's magnetic field is known to have decreased about 6 percent since 1830, and indirect evidence suggests that it may have decreased as much as 30 percent over the last millennium. He argues that magnetic therapy simply provides some of the magnetic field that the earth has lost. Magnetic therapy is also prominent in the treatment of thoroughbred racehorses. The incentive to try "alternative medicine" to supplement mainstream veterinary treatment is considerable; an injured racehorse represents potential loss of a substantial investment. Magnetic pads, magnetic blankets, magnetic hoof pads, and more are used for a variety of leg problems. All get ringing endorsements from many horse trainers, and even some veterinarians. One marketer of magnetic products for humans reports that he first became convinced of their effectiveness when he used them on his llama. Some argue that the placebo effect might be taking place in these circumstances, but the psychological aspects of the healing treatments are obviously not happening with the animal. However, magnet therapy enthusiasts forget that it may influence the human who is interpreting the effect of magnetic therapy on the animal.

Clinical studies report between 75-85% of patients experience relief using magnetic therapy. Whether or not the placebo effect is taking place is always part of the debate. One point of contention in the argument is that the magnetic back braces used by many senior golfers may help ease their back pains through providing mechanical support, through localized warming, and through constant reminder to the aging athletes that they are no longer young and should not overexert their muscles. All these effects are helpful with or without magnets. One British study of pulsed-field bone-growth stimulators, which were approved decades ago by the FDA, found that they were equally successful when the devices were not activated. It concluded that their effectiveness resulted from the enforced inactivity associated with their use rather than from the pulsed magnetic fields. The logical conclusion is that with circulation increased, the body's natural healing mechanism can work more efficiently. Some doctors believe that the magnetic field affects the iron component of blood, hemoglobin, thereby increasing circulation to the area where magnets are applied. Another theory is that the magnetic field energizes and oxygenates the white corpuscles in the blood stream, and these white corpuscles are nature's healing agents. In this regard, the charged ions increase the blood flow, which provides increased oxygenation to the blood. This increased oxygenation is the prevalent factor to enhancing your body's natural healing powers, and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

the results are less pain, decreased inflammation, and the possibility of increased energy levels. Other specialists believe that, since nervous signals travel via tiny electromagnetic charges, an electromagnetic field may actually tune out "false" signals. The actual pain relief mechanism of magnetic energy may never be truly understood, since it operates within the tissues at such a microscopic level. What is clear, however, is that belief is necessary for effective healing.

Studies of magnetic therapy practices and results are more common in Eastern Europe and Asia where there is less access to pharmaceutical drugs. There is evidence that magnetic therapy does improve circulation and oxygenation in the bloodstream, and thus it would serve the purpose of facilitating healing for areas of the body recovering from injury or weakened by age or disease.

One property of magnetic energy is that it has no measurable mass. This is also true for another kind of energy relevant to this course, Orgone energy. Orgone energy was objectified and scientifically demonstrated by Dr. Wilheim Reich (1951). Reich built on Freud's early work, which strongly suggested that emotions and sexuality were expressions of a tangible energetic "something." It was Reich who provided the clearest evidence that the Freudian libido was a real energy, discharged during emotional expression and sexual orgasm. Reich discovered that this same discharging energy was present in a single cell, which apparently caused him to question whether that energy could be collected and harnessed.

In 1940 Reich discovered a way to accumulate that energy, and labelled it Orgone Energy. His work was not taken seriously at the time. There was no social context providing an atmosphere of acceptance for the idea of energy from repressed sexuality. However, a simple Internet search reveals 23 published articles on the treatment of a wide variety of ailments, from cancer to rheumatoid arthritis, by the application of Orgone energy. However, despite being used to treat specific ailments since at least 1971, there are numerous qualifiers in the dialogue on its applications. The point is frequently presented that science and society will have to go through some significant changes before its use will be accepted by the general public. Orgone energy is the primordial life energy, the fundamental creative force long known to people who are in touch with nature. Perceived as "chi" by acupuncturists, Orgone energy is accumulated naturally in biological organisms by food, water, breathing, and through the skin. In 1940 Reich discovered a way to collect or "accumulate" Orgone energy from the atmosphere. Reich's research revealed that energy is attracted to and absorbed by organic substances, but is attracted to and instantly re-radiated by metallic substances. He developed a special enclosure resulting from his experiments with the Faraday cage, a device built in 1836 by Michael Faraday to exclude energy. Reich's accumulator was made from layers of organic materials which absorb and hold the energy, and inorganic materials which attract and then rapidly repel Orgone energy. He found that the inside of a metal-lined enclosure that is layered with organic and inorganic materials contained a higher concentration of Orgone energy which was detectable by a higher temperature reading inside the accumulator.

Reich's device allowed him to isolate Orgone radiation from its environment, and then accumulate the energy within his device. Orgone radiation is not foreign to the body. The Orgone energy in the atmosphere is just another form of the same Orgone energy within the human body. The accumulator concentrates that energy and helps the body to help itself. Reich discovered that the energy moves in the direction of a magnetic field. Thus, when a person with their own energy field comes into contact with an accumulating device, the two fields make contact and excite each other. This creates a stronger excitation called "lumination." This strong, orgonotic charge has been found to be very beneficial to living systems. It may help to strengthen the immune system, improve circulation, and raise one's energy level. Investigations have shown that contact with energy from the accumulator stimulates the body's parasympathetic nervous system, inducing relaxation and a feeling of expansion.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Modern research has found ways to manipulate and focus the energy, thus resulting in applications to the medical field. The motion is a pulsating expansion and contraction, and a flow normally along a curved path. Inside an accumulator, the energy is emitted as a spinning, pulsating wave. A wide range of devices, and even blankets, are available on the market that makes use of this technology.

Another use of technology that has its roots in Asia is the adaptation of modern technology to the ancient art of acupuncture. Electro-acupuncture is the application of a pulsating electrical current to acupuncture needles as a means of stimulating the acupoints. The acupoints connect the individual's body to the universal, cosmic energy that connects us all. The stimulation of these points has been an ancient healing tradition that reaches back through the millennia. In 1934, according to Subhuti Dharmananda (2003), the Director of the Institute for Traditional Medicine in Portland, Oregon, Chinese healers added electronic stimulus to the process as an extension of hand manipulation of the acupuncture needles. The process is described, though only briefly, in most comprehensive texts of acupuncture. The procedure for electro-acupuncture is to insert the acupuncture needle as would normally be done, attain the qi reaction by hand manipulation, and then attach an electrode to the needle to provide continued stimulation. The idea was to help ensure that the practitioner, who may otherwise pause due to fatigue, gives the patient the amount of stimulation needed. It was also thought that Electro-acupuncture could produce a stronger stimulation without causing tissue damage associated with the twirling and thrusting of a needle.

The stronger stimulus provided by the electronic current is better for treating more difficult cases of paralysis. Positive results have also been seen from treating patients with the chronic pain and spasms associated with neurological diseases. The application of modern day electronic technology to an ancient healing art was developed to reduce total treatment time by providing a specific continued stimulus. The assumption was that it would be easier to control the frequency of the stimulus and the amount of stimulus than with hand manipulation of the needles. An added benefit was that it would free the practitioner to attend to other patients. However, the subsequent inattention to the patient receiving the electro-acupuncture limits the opportunities to respond to changes that are taking place during treatment. In addition, the literature cautions against using the technique on patients with serious cardiac diseases. It is generally recommended to avoid placing electrodes near the heart, as the heart can respond adversely to electrical impulses.

Another use of electrical impulses in the healing arts is Cranial-Electro Stimulation machines (Gilula & Kirsch 2005). The use of these machines involves placing sensors under the ears to send a minute electrical impulse. A slight tingling sensation on the skin is felt. The stimulation has the affect of tricking the brain into releasing the body chemical serotonin. Serotonin is a neurotransmitter that plays an important role in the biochemistry of depression, migraine headaches, bipolar disorders, and anxiety. There is also evidence that its presence or absence in the body influences sexuality and the appetite. The serotonin released can help relieve anxiety, tension, and the feeling of being "on edge."

There are portable versions of this machine, powered by a 9 Volt battery, that are small enough to put in a pocket. The sensors are placed on the neck below the ears, and can be used while walking or using the computer. They are designed to be used once a day in response to feelings of anxiety. It generally provides adjustments to the body chemistry and the ensuing relief from anxiety within 5 to 10 minutes. Another device in the category of neuro technology facilitates lucid dreaming. Lucid dreaming is being aware of the fact that you are dreaming while you are doing so. This allows the dreamer to gain insight into the purpose and symbolic meanings behind the dream, thus facilitating their analysis and the ensuing psychological healing process.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The technology for this process was developed by Stephen LaBerge, Ph.D. (1990), during twenty years of research at Stanford University. Dr. LaBerge developed a device called the NovaDreamer, a mask-like device that detects the time that one is in REM sleep, the state of rapid eye movement that one experiences when dreaming.

The device gives cues, such as flashing lights or specific sounds, that remind one to realize he or she is dreaming. In other words, one "wakes up" while still in the dream. The purpose is to give the dreamer detachment from the dreaming process during the course of the dream. This provides the impetus for the analytical process of dream interpretation to take place during the course of the dream. Users have reported that having lucid dreams have allowed them to make spontaneous choices that enable them to learn from, and even guide, the dream to constructive ends. Anecdotal evidence of these choices includes suddenly deciding to fly away from situations, empowering the dreamer to feel safer and have more free choice. There are also reports of incidents of making an old friend appear and talking to that person about consequential matters or resolving conflicts. Dreamers report being able to feel textures, hear sounds and smell odors in the dreamscape. The users reported that these sensations were as real as any in the physical world, and they were able to make conscious decisions and choices.

The entire process of lucid dreaming gives the spiritual sojourner tools and techniques, developed deep within the psyche, to explore and use their dreams for self-discovery, creativity, fantasy fulfillment, emotional healing, and profound spiritual insights.

Full Spectrum Lighting, another simple use of technology is the use of full spectrum lighting (Veitch et al. 1991). Full spectrum lighting is a process that uses specifically designed lighting fixtures that mimic the full spectrum of colors provided by our sun's rays. The purpose is to treat Seasonal Affective Disorder, a psychological malady that is brought on by the deprivation of light. This is generally a result of the changing of summer, with its bright sunshiny days, to the fall season, with its shorter and darker day-time periods. The onset of this change can result in depression and lack of energy (Veitch et al. 1991). The use of full spectrum lighting fixtures allows for the same kind of light energy that the sun offers.

The ultimate achievement so far in modern day development of neurotechnology is the Hemi-Sync device, or Holistic Sensory Response Audio. In 1956, Robert A. Monroe founded the Monroe Institute to study the effects of various sound patterns on human consciousness, including the feasibility of learning during sleep. Monroe was a highly successful businessman, the owner of several radio and television stations. In 1958 he began to have out of body experiences in which, while relaxing or attempting to fall asleep at night, he found himself hovering above his body. At the time, he thought he was having some kind of health problem, but was reticent to discuss it openly for fear it would interfere with his dealings with a very conservative business community. Monroe soon began to quietly but thoroughly examine the circumstances of his experiences. The discoveries made in exploring this phenomenon were validated later by the work of Dr. Melvin Morse and others in their work exploring Near Death Experiences. But as the work continued, and technology was developed to stimulate out of body experiences, the information gathered was to have a profound affect on the whole of our collective perception of the nature of reality (Monroe 1977).

In 1976 Monroe was issued an original patent for technology that altered brain states through sound. Hemi-Sync produced binaural beats, which are a series of barely audible tones which play in the background of soft music, barely noticeable beneath the music. The beats are at one rhythm in one ear, and a different rhythm in the other, producing a combination that takes the brain to a specific output rate of brain waves. The two hemispheres of the brain act in unison to "hear" a third signal—the difference between the two tones. The tones counter balance each other in a way that forms an anchor, or a signal

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

which helps you quickly and easily re-enter the trance state when your unconscious mind begins to hear them in the background. The tones begin by synchronizing with the brain waves associated with the normal awakened state of the mind, and then slowly changing them to assist the listener in reaching the "alpha" level. The signal can only be perceived within the brain by both brain hemispheres working together. The result is a focused, whole-brain state known as hemispheric synchronization, or "Hemi-Sync." This relaxed level was the exact state of mind, it was discovered, to facilitate not only healing, but out of body experiences (Monroe 1977).

The process has been subjected to decades of research and thousands of lab sessions, and has been refined with over 40 years of research and development. Ongoing experimentation, data collection, and analysis are conducted at the institute's laboratory facilities to demonstrate the correlations between subjective experiential reports and objective electronic measurements. Healing benefits have been extensively documented, ranging from enhanced alertness to relief from insomnia and the myriad of circumstances that fall between.

There are also testimonials regarding profound healing experiences. One woman with an undiagnosed brain injury suffered in a car accident reports using Hemi-Sync to reverse a very frustrating condition. After being released from the hospital the same day of an accident that totaled her car, she noticed a severe change in her ability to concentrate. After many months of forgetting how to cook, getting lost, and "losing her train of thought" in a middle of a conversation, she began using Hemi-Sync to produce a state of relaxation. Within weeks, she became aware of regaining her sense of humor. From there she noticed a gradual regaining of her ability to concentrate (Monroe 1977).

The device, which looks like a bulky set of headphones, is designed to move one's consciousness past the limitation of being within a body. The spectacular success this device has had in facilitating astral travel has been documented in Omni magazine, amongst others, and experienced by thousands. The most profound research for the Hemi-Sync device was done by the founder of the Monroe Institute himself. Monroe said, "The greatest illusion is that mankind has limitations." This implies that we have limitless possibilities.

The work of the Monroe Institute, with its profound breakthroughs in the use technology for spiritual exploration, has the potential of enabling vital specifics in the evolution of humankind. Despite Monroe's death in 1995, his institute continues to attract and change forever the visitors to its campus as well as the thousands who have visited the virtual reality of its web site.

The implications of Monroe's work developing the Hemi-Sync device take on a whole new meaning when viewed as to the potential for learning from other times, places, and species. The development of this technology, a technology that enables astral travel and contact with guides and other beings with purposes that are highly relevant to both personal and planetary evolution, brings focus and significance to the whole idea of pursuing the potential ramifications of neuro technologies.

Royal Rife is the inventor of the Rife Machine (Hess 1996), it is said that "one day Royal Rife will be acknowledged as one of history's greatest medical geniuses." In 1902 he discovered the human cancer virus with a microscope that he had to invent himself, since no microscope at the time was powerful enough to detect it. Through endless and exhaustive experimentation and laboratory testing, he discovered that this virus could be killed using certain frequencies that were emitted from a prototype machine he created. He was then successful at destroying cancer in patients who sat within 10 feet of the machine. His legend built from there, and by 1931 he was the most honored among the medical society for his track record of being able to cure cancer almost 100% of the time. The cure for cancer has been found long ago! However, by 1939 these same doctors and scientists who so highly praised him denied that

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

they had ever met Royal Rife. A violent attack was set upon Rife by unseen forces, but they could most likely be identified as the drug companies (through the American Medical Association) who had the most to lose from the Rife Machine, and a miffed Morris Fishbein who tried to buy the rights to Rife's work unsuccessfully. After that, people who worked with him were harmed and poisoned, Rife's papers were mysteriously lost, and his labs were destroyed by arson.

He was shortly indicted and taken to trial for "fraudulent medical practices," and for the most part, his life was undone. He became a ruined man. All the doctors who were associated with him lost their medical licenses if they did not stop using Rife's invention, even though they were having incredible success at curing people of cancer. Rife became an alcoholic in order to deal with the terrible turn of events his life has taken. Rife himself was later killed in 1971 by a very lethal dose of valium at a hospital which some do not believe was an accident.

For a long time, Rife's work lay dormant. However, it has been recently re-visited. Others are picking up where he left off. It has been discovered that far more than just the cancer virus can be killed with the Rife technology. Any virus can be killed. It just has to be identified and the right frequency that kills it must be found.

Others have begun to catalog this list. Work on cataloging viruses and the frequencies that kill them has begun again. There are now thousands of viruses that can be addressed using the Rife Machine. It is not that expensive, either, compared to what the medical costs of drugs, doctor's visits, surgeries and hospitalizations would cost. A Rife Machice could be purchased for anywhere between $500 and $5000, depending on how many bells and whistles you want it to come with. If you do an internet search on Rife Machine, there will be plenty of results to peruse, but the only place you will be able to purchase one is from overseas. It is still illegal to use them in the United States. Almost all other countries in the world allow the use of the Rife Machine, at least for personal purposes or experimental purposes, if not for the public. This does seem quite strange.

A Rife Machine works by generating a field of frequency, or frequencies, and anything within that field that it has been discovered to kill will be killed. It works one of two ways. Some of the less expensive machines entail two metal, or glass, cylinders that you grasp in your hands while frequencies pulse through them, and thus into your body. Some of the more expensive machines entail detailed digital readouts and the ability to diagnose your condition by finding out which viruses are present. You also do not have to hold onto cylinders and you are able to go about your business in the room as the machine generates the frequency field that addresses the virus (Hess 1996).

Kilner (1965) proposed a device that is a way for the naked eye to see the first three layers of the human aura. The device consists of two plates of glass with a dycanin dyed liquid between them. Dicyanin is a coal tar dye. Some say that a subject's aura can be seen through the screen, while others say that one must look at a bright light first, and then look at the subject through the screen. There have been several doctors in the past years who have used this technology for discerning illnesses in their patients and diagnosing their condition.

Transpersonal Psychology

Transpersonal psychology integrates the spiritual experience within a broader understanding of the human psyche. It is with the study of states of consciousness and the full potential of man, that transpersonal psychology assumes that humans can achieve harmony and transcend through spiritual development.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Transpersonal is something that exceeds the range of human's own experience or personal history. Transpersonal refers to that which is beyond of the person who is the essential being.

Transpersonal psychotherapist Anthony Sutich (founder and first editor of the Journal of Transpersonal Psychology) provides one of the first formal definitions of transpersonal psychology in 1969 at the inaugural edition of the *Journal of Transpersonal Psychology:*

"The emerging Transpersonal Psychology refers specifically to the empirical, scientific study, and the responsible application of relevant results, becoming meta-needs individual and species-wide, the final values, conscience unitive, peak experiences, values, ecstasy, mystical, amazing experience, being, self, essence, joy, wonder, ultimate meaning, transcendence of self, the spirit, unity, cosmic consciousness, synergy of individual and species level, maximum interpersonal encounter, sacralization of everyday life, transcendental phenomena, self-cosmic humor and joy maximum sensory awareness, responsiveness and expression; and concepts, experiences and activities " (Sutich, 1969).

Stanislav Grof, co-founder of transpersonal psychology with Abraham Maslow, defines transpersonal psychology as "The psychology that respects the entire spectrum of human experience, including holotropic states, and all domains of the psyche - Biographical, perinatal and transpersonal "(Grof, 2000).

Transpersonal psychology covers a multitude of experiences and behaviors produced by spontaneous or altered states of consciousness, impulses into higher states of being, and extraordinary spiritual practices induced. Transpersonal phenomena include the meditative experiences, dreaming, drug-induced psychedelia, peak experiences, cosmic consciousness, enlightenment, mysticism, out of body experiences, channeling trance, near death experiences, memories reincarnations, extrasensory awareness, archetypal phenomena, accelerated learning, exceptional state of health and well-being, the mind-body healing and miraculous cures. Parapsychological phenomena are important for the reduction of science and spirit implications.

Altered States of Consciousness and Transpersonal Psychology

Ludwig (1966) defines an "altered state of consciousness" as any mental state(s) for various manoeuvres of physiological, psychological or pharmacological agents, which can be recognized subjectively by the same (or an objective observer of the individual person induced) as representing a sufficient deviation in the subjective experience or psychological functioning of certain general rules for that individual during alert awareness. This deviation can be sufficiently represented by a greater concern than usual with internal sensations or mental processes, changes in the formal characteristics of thought, and the deterioration of the test of reality to varying degrees.

The cognitive approach to altered states of consciousness has revealed that similar features that are characteristic of many altered states of consciousness including alterations in thinking, sense of disturbed weather, loss of control, change in emotional expression, change of body image, perceptual distortions,change in the meaning or importance, sense of the ineffable and feelings of rejuvenation(Ludwig, 1966).

By applying the disruptive force requirement for the basic state of consciousness (either through some physiological action, such as drugs or deployment of attention and meditation), the current organization of cognitive subsystems is destabilized until a new force patterns (such as mental set, setting, expectations, drug effects) is applied to shape the subsystems in a whole new system, the production of a new discrete state of consciousness with its own stabilization processes.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Cognitive awareness approach has helped differentiate transpersonal psychologists' grades waking state of consciousness. Awareness, for example, is not one homogenous thing, but varies and changes as the colors of the rainbow. It is possible to stratify and states order to raise awareness of alert and focused relaxed concentration and spread the cosmic consciousness. A range of altered states of consciousness have been identified as drug-induced states, hypnosis, biofeedback, daydreaming, night dreaming, sensory deprivation, and paranormal experiences. With each state consisting of many levels and functions, in each region or area of consciousness, individuals are able to process different types of information at different levels of control (Goleman &Davidson, 1979; Ornstein, 1972).

Transpersonal psychologists tend to see the experiences of "mystical union", "enlightenment", "nirvana", and related experiences as natural and beneficial non-ordinary states of consciousness that may be subject to effects of state-dependent learning. The idea that the experience of the sacred can be interpreted as altered states of consciousness arose from the observation of twice that (a) psychedelic drugs have been used through the centuries and cultures to induce religious experiences and (b) reports from some drug experiences are phenomenologically (descriptively or experiential) indistinguishable from accounts of natural mystical experiences (Smith, 1964).

Transpersonal psychologist Charles T. Tart has examined the altered states of consciousness from a cognitive perspective in terms of changes in the configuration and operation of the underlying mental processes (Tart, 1971; 1976; 1983; 1992). A state of consciousness involves cognitive functioning following subsystems: exteroceptors (receives sensory information), interoceptors (kinesthetic receives input), input processing (working memory), the subconscious processes, sense of identity, evaluation and decision making, emotions, space / time sense, long term memory, the motor output (behavior) plus latent functions. These 10 subsystems (more possible latent functions) define any discrete state of consciousness. The particular configuration of the subsystems in a given time is shaped and limited by the deployment of attention, the body's energies, characteristics of the structures themselves and the particular social and cultural environments in which they operate.

Grof (1988) suggested that the term "altered states of consciousness" cover transpersonal experiences; however, there are certain types of altered states of consciousness that do not meet the criteria for being transpersonal (involving an expansion or extension of consciousness beyond the limits of the usual and limitations time and space). For example, a living and complex childhood memory occurs in an altered state of consciousness (e.g., hypnosis or psychedelic sessions), but do not meet the criteria for being transpersonal.

The cultural context of the 1960s and 1970s provided fertile ground for the emergence of transpersonal studies as an independent field of study in psychology. The infusion of ideas Eastern contemplative traditions of Zen, Advaita, Vedanta and Taoism, along with the institutionalization of the humanist revolution in academic psychology, and the growing interest in consciousness and altered states of consciousness that are triggered by the widespread use of psychedelics, paved the way for the birth of transpersonal psychology movement in California in the late 1960s (Ferrer, 2002).

Since the 1970s, transpersonal psychology, as the humanist movement that preceded it, has been divided into three different groups; the first group represented by the ideas of Grof (1988) that believes that transcendence can only occur in the presence of an altered state of consciousness. This group produces conceptual models of non-ordinary states of consciousness. The second group, led by Wilber (1975), include those trying to assign internal states of consciousness and identify with the monistic and perennial philosophy of Aldous Huxley. Wilber believes that all expressions of the highest state of consciousness in each tradition are the same as the psychopathic conditions occurring at the bottom, the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

normal waking reality in the middle and meditative states of higher consciousness in the top. The third and by far the largest segment of the transpersonal movement has no identifiable bearer, it sees the self as getting up and go to work in the morning, the higher consciousness is sweeping the floor, washing dishes, and raking leaves. The lighting is doing everything we are supposed to be doing at this minute. There is a preconceived thing; is not an altered state of consciousness, it is simply the deep philosophy, which is to be found most clearly in the mundane.

Altered states of consciousness answer the question "who we really are?" The answer to this question is that we are a part of God and that humans are spiritual beings having human experiences that somehow reveal the direction of our full identity of our cosmic status.

Brain Waves

Our brain works primarily with bioelectrical energy. Although the power of electricity that handles our neurons is low (measured in mill volts), this power processes, manage, distribute and use vast amounts of information and generates multiple answers (almost infinite in possibilities). So by using micro electricity, we can conclude that the brain is a machine of low frequencies. Our brain, in addition to process information that comes by the senses, is capable of emitting extra-sensory information received via similar "electromagnetic waves", but with lower intensity similar to the frequencies of a radio transmitter-receiver. Our brain can act as a radio station, similar to numerous species of birds that in their migrations are guided by a genuine receiver of terrestrial magnetism located in the pituitary gland. With this receiver, they know where they have to fly and in what direction. It's like having a real compass incorporated into the brain. The mind could be defined as the "sense" of the brain (like sight is the sense of the eye).

A German psychiatrist, Hans Berger (1843-1941), demonstrated that a device "amplifier" that was called later electroencephalograph could capture electrical potential (voltage fluctuations) in the human brain. Before him, the English physician Richard Caton (1842-1926) showed similar potential in dogs. The first types of brain frequencies that were discovered were the "alpha" and "theta". Later, these findings were complemented by research in the range frequencies captured by the electroencephalograph. Each type of wave results in a different neuropsychological state. That is, our mind, our body and our physical and physiological activity are completely different in each of these states or frequencies. The type of neuro-chemicals and hormones substances discharged into the blood flow varies depending on frequency and as much as the presence and quantity of such substances as the mood we have, interact to produce a physiological-mental-physical-end that involves a mental state. A level of consciousness is conscious thought that is always thinking even in moments of apparent inactivity, but trivial ideas continually pass by consciousness. Most of the thoughts are accompanied by reactions in behavior, and small involuntary movements. When you're not actively thinking then you're probably dreaming, according Signer and Streiner (1966) a person has throughout the day about 200 daydreams. Therefore, consciousness is the sum of all the different perceptions. The most common consciousness are wakefulness and sleep; however, changes in expressing both cerebral and psycho states change according to conscious or subconscious feelings of each person are distinguished. These changes are directly related to the electrical activity of the brain. This activity can be measured by the number of oscillations per second (Hz) that are linked to different states of consciousness in the brain: our brain only perceives a limited range of frequencies indispensable to operate with ease in this three-dimensional medium. 20 to 20,000 vibrations per second are perceptible by our ears, the colors perceived by our eyes range from red to violet (although extending beyond, up and down), all possible smells and tastes (which are

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

also vibrations) and the endless textures that we can distinguish with our skin. But the brain is not only receiver but also is sends vibrations. It has been proven thanks to the EEG that the brain emits waves of varying intensity and frequency depending on the mental state of the person being observed. These waves are classified into those shown in Table 1.

The alpha state is when, if we would connect to an electro encephalogram, our brains would work between 7.5 to 14 cycles per second. When "operate" in this state, we rank among the border of the conscious and the unconscious. Is the gate between both states of consciousness and this makes "alpha state" therefore a special status because it allows us, on the one hand, still have a conscious activity of our mind and body, that is, we realize what we think and happening around us? On the other hand, since the "lift" of consciousness in the "lower floors" of the mind, gives us access to information and own subconscious states, can use all the wealth of the 90% of "power" mental residing in the subconscious. This state is a "being comfortable" in inner peace and happiness, in deep relaxation. Greatly increases the power of suggestion and auto-suggestion, that is, anything that we suggest alpha, will be more easily accepted and less "filters" by our conscious rationality.

Table 1. Types of brainwaves

Types of Brain Waves	States of Consciousness
BETA WAVES: 14 Hz to 30 Hz	This type of waves is recorded when the person is awake in a state of normal activity. Correspond to states of conscious attention, anxiety, surprise, fear, stress.
GAMMA WAVES: 25 and 100 Hz	They express pathological conditions of maximum tension, excitement and the individual enters a state of STRESS in which the coordination of ideas and normal physical activity are seriously altered.
DELTA WAVES: 1 Hz to 3 Hz	It arises mainly in the states of deep sleep and unconsciousness. Very rarely can be experienced being awake unless with a very hard training (Yoga, Meditation, Zen, Hypnosis, Self-hypnosis) or with a synchronizer of hemispheres. It corresponds to deep sleep, hypnotic trance, REM sleep. It corresponds to sleep without dream, trance, deep hypnosis. Delta waves are very important in the healing process and strengthening the immune system.
THETA WAVES: 3.5 Hz to 7 Hz	During sleep or in deep meditation, autogenous training, hypnosis, yoga (whenever the formations of the subconscious act). The state stimulates creative inspiration. Considered a state for maximum capacity of learning. Fantasy, imagination. Hypnagogic images.

Magnus & Van der Holst (1987) speak of frequencies whose frequency ranges from 3.5 to 7.5 cycles per second. They are associated with the states of creative and decisive hallucination. During its broadcast, the person can discover events deeply hidden in the recesses of your subconscious, as well as conflicts and personality in particular. Is the wave of imagination and dynamic contact with other possible "dimensions psi" offering you the opportunity to research our personality and deep in our psychology?

METHODOLOGY

The state of consciousness of someone can be measured by using possible physiological changes. Some physiological changes are typically associated with altered state of consciousness so measuring these physiological changes may provide evidence to more accurately determine the state of consciousness someone is in. Cade and Coxhead (1979) was able to map altered state of consciousness with alpha brain waves between 10 to 8 cycles.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

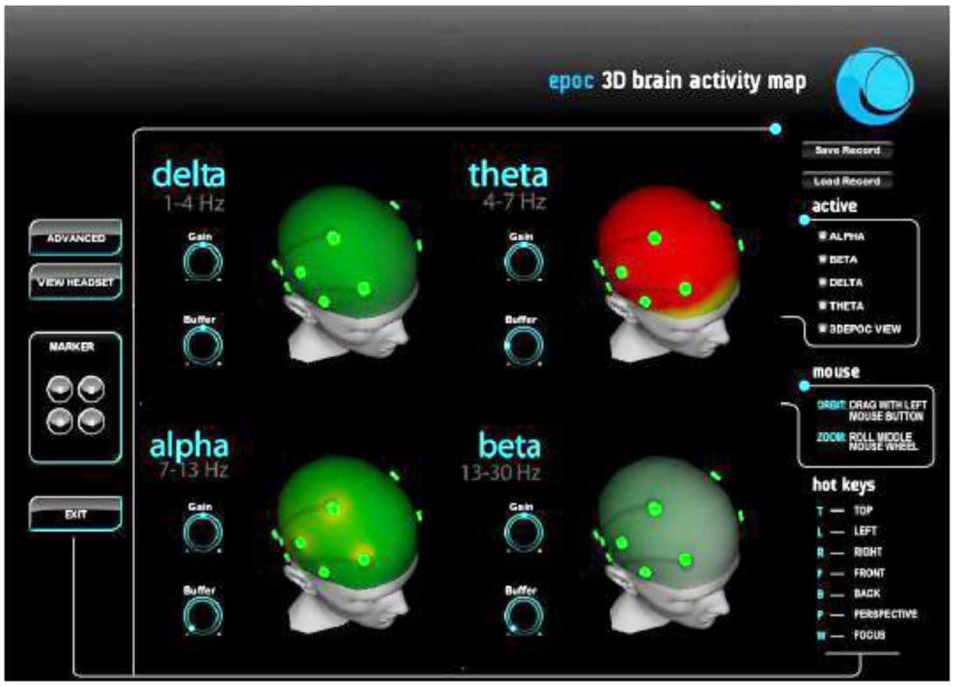
This research uses EEG that was specifically designed to show the ephemeral patterns of the electrical signals from the two hemispheres of the cortex as they are happening (Cade & Coxhead 1979).

The EEG technology used for this research is the Emotiv 3D Brain Activity Map EEG software (Emotiv 2016) that works with the Emotiv EPOC neuroheadsets. The neuroheadset captures the users' brainwave (EEG) signals. After being converted to digital form, the brainwaves are processed, and the results are wirelessly transmitted to the USB receiver. The Emotiv 3D Brain Activity Map interprets these signals to displays mental activity in real time. The software displays brain activity in four significant brainwave frequency bands (Delta, Theta, Alpha, Beta) and uses the headset EPOC to read data. The software displays a colored gradient map showing the distribution of the indicated frequency band activity where red indicates the highest level of activity, falling away to orange, yellow, green, blue then black.

Figure 1, shows theta frequency bands with the highest level of activity indicating that the individual in this case indicating deep meditative states, daydreaming and automatic tasks. Emotiv 3D Brain Activity Map EEG software has data collection and replay functionalities that can be use to analyze the collected data.

An application of quantum physics (neurotechnology) in the altered states of consciousness was carried out by Persinger (1983). Persinger (1983) was able to induce visions of God and other religious and mystical experiences in the laboratory by using a computer and with what he called the Koran helmet that has also the nickname of the God helmet. He found that the temporal lobes of the brain are the source of the most spiritual experiences and other alternate state of consciousness.

Figure 1. 3D viewer



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

This God helmet is a device to induce altered states of consciousness using weak magnetic signals to direct brain activity that can induce spiritual experiences that helps with transpersonal exploration and transformation of many people that is able to heal because of these transpersonal experiences (Persinger 2000). It is suggested that altered states of consciousness such as sensed presence and out-of-body experience whether they are produced by magnetic, electric or other stimulations or circumstances can be most effectively explained as the changes of the relative contents and/or intensities of the test subjects' neural quantum entanglement with their surroundings including possibly spiritual environments or information (Hu & Wu 2012).

Intense experiences are based in the temporal lobes (Persinger 1983), The sessions used in the research are intended for eliciting altered states of consciousness, and use the coils over the temporal lobes, which is understood to be the source of mystic experiences (Persinger 1983).

This research uses a product called Shakti (Shakti 2016) that is based on the Koran helmet of Persinger (1983). Shakti Software produces audio analogs to EEG signals. These are applied to the brain using modified commonly available magnetic coils. The magnetic signals are applied to the head at very low strength. The signals are short bursts, followed by intervals of silence. Each signal speaks a language that only one brain structure understands and responds. The brain has two hippocampi and two amygdalas, one on each side. Shakti is applied using the structures own signal, but only over the side of the head where it supports something positive. When these structures respond, they put the person in a positive altered state of consciousness (Shakti 2016).

The Shakti sessions that were used for this research are 'interhemispheric' (switching from both hemispheres to one) sessions, incorporating the same principles used in the study of Sculthorpe & Persinger(2003). In this last study, it was showed that the most effective sessions turned out to be two-phase sessions. This study applies the Modulated 40 Hz signal to both temporal lobes, followed by the amygdala signal to only the left temporal lobe as indicated in figures 2 and 3. This is the session design that comes closest to the sessions used in the "God Helmet" experiments (Shakti 2016).

Electromagnetic frequency emissions (EMF) emissions are varieties of radiation, and/or electrons. The Shakti helmet uses magnetic fields, which are neither radiation nor electrons. Electromagnetic radiation is composed of photons. Magnetic fields are not. Magnetic fields are not composed of the elementary particles than can interact with some organic compounds, nor are they composed of electrons, ions, or anything else that is encompassed by the word 'emission'. These are simple magnetic fields created by two poles, and are not composed of ions, electrons, or photons. Fields from an electromagnet are made of the same matter as the earth's magnetic field. These are 'made' of 'lines of force', and are not 'EM emissions'. These do not pose a health risk of any kind (Greenland et al 2000).

The Shakti helmet uses magnetic coils connected to a computer sound card. The output of a sound card is modulated DC. The polarity - one wire is positive and the other wire is negative - is always the same, no matter how the amplitude varies. A speaker or headphones uses a magnetic coil to move a diaphragm to make sound. Generally, the goal is to move the coil two ways to make sound. However, because of the springiness of the coil you only need one polarity. For example, a given voltage might push the coil. When the voltage drops lower, the voice coil will rebound and move the other way. EM fields reach deep inside the brain. Magnetic fields cannot be blocked (Hatch, G. P., & Stelter, R. E. 2001). The proposed helmet's magnetic signals reach deep inside the brain because there is nothing in or around the brain that can stop them (Persinger 1997).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Left side of the session used

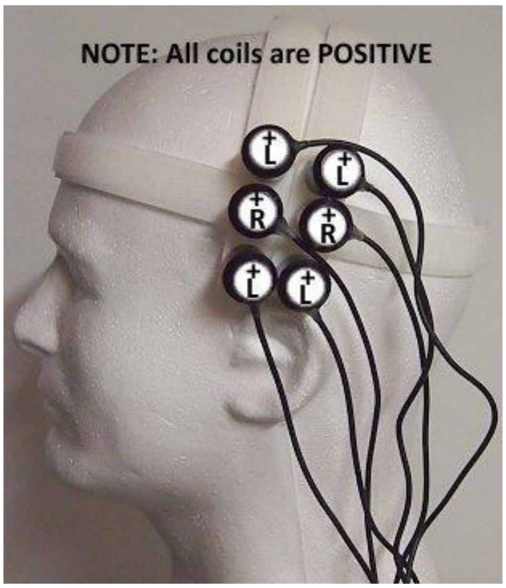


Figure 3. Right side of the session

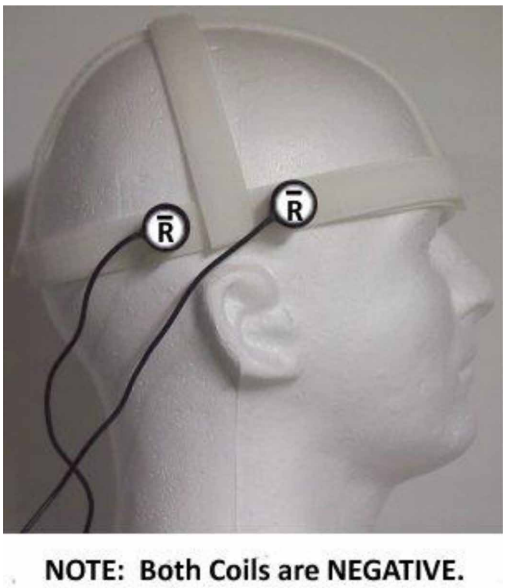


The proposed architecture of the cybertherapy is depicted in Figure 4. The therapist computer has installed 3D activity map software and Skype. Skype is a telecommunications software that allows verbal and text communications with the patient, the 3D activity map software allows the therapist to visualize the states of consciousness of the patient by detecting the frequency band with the highest level of activity.

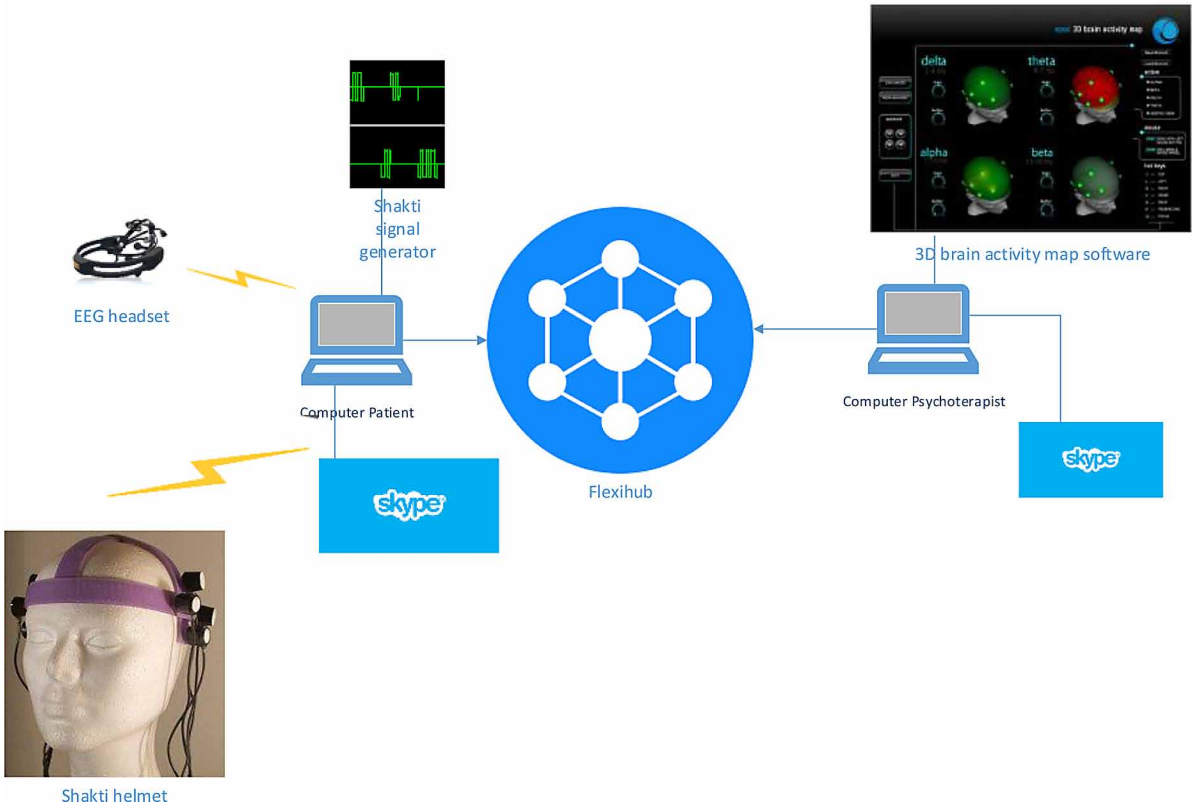
The therapist is able to access the EEG signals collected by the EEG headset wore by the patient. These digital signals are transmitted over the internet by using Flexihub software (Flexihub 2016), FlexiHub is a USB over IP software solution, it enables sharing access to USB devices over Internet. The EEG headset is connected to the USB of the patient's computer via a USB wireless adaptor. The Shakti helmet is worn by the patient and is meant to induce altered states of consciousness by receiving modulated 40 Hz signals to both temporal lobes from a signal generator installed in the patient's computer.

A sample of 10 patients was used to test the cybertherapy system and quantum biofeedback data collected and analyzed to confirm that the patients were able to reach a desired level of consciousness for the psychotherapy. Each patient was required to sit down and relax in a quiet room for a period of 40 minutes wearing an EEG headset without being exposed to the Shakti system (Figure 5), the therapist recorded the session during this 40 minute (pre-test). After, the patient was required to be exposed to the Shakti signals by wearing the Shakti helmet, the therapist also recorded the session for 40 minutes (post-test). Information about the difference between the two tests was not given to the patients in order to avoid bias in the measurements.

Each recording for each session displays the different frequency bands that represent each level of consciousness including alpha, beta, theta and delta. For the analysis, we quantified the different states of consciousness according Cade and Coxhead (1979) that conducted EEG tests in 70 subjects and measured the ESR (electrical resistance of the skin) and with the application of its results to the work of Terry Lesh (1970) were able to build in the table below that represents the objective and subjective correlates of these states. The targeted level is 5 as this represents altered state of consciousness but it is

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Proposed cybertherapy system



expected that the average of the levels is under 5 as the patient needs go from 0 to 5 at different stages. However, it is expected that the post test average is higher than the pre-test as we want to probe that the cybertherapy system is capable of raising the level of consciousness.

A mean and standard deviation for these levels were calculated for each pre-test and post-test sessions for each patient. The mean values of pre-test and post-test results were compared to check if there is an improvement in state of consciousness with the use of the cybertherapy system. The mean values were tested using the t-Student test, and the t-values were calculated by using the following formula:

t-value = (Mean of post-test – Mean of pre-test) / square root (Variance of post-test / Sample size of post-test + Variance of pre-test / Sample size of pre-test)

The Alpha level used was 0.05 of one tail test; with 18 degrees of freedom (sample size of pre test + sample size of post test – 2). According to the t-distribution significance table, the critical value is 1.734 for one tail test for this alpha and degrees of freedom. The Null Hypothesis is that there is no difference between the pre test and post test sample means for the states of consciousness because of the use of the cyberteraphy system.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Patient during session

ANALYSIS OF RESULTS

Table 3 shows the results of the study, a mean of the pre-test and post-test for each patient was calculated during the 40 minutes sessions for each patient because of the use of the cyberteraphy system. The levels of consciousness for each patient reached over time during each 40 minute pre-test and post test sessions are documented in the graphs included in the Appendix, each graph indicates the levels of consciousness reached at each second over the session. The results present that each patient had a different reaction to the use of the system, while some patients showed very little difference from the pre-test and post-test (e.g. patient 8) or even a decrease of the level of consciousness (e.g. patient 2) some patients observed a great level of improvement with the post-test session (e.g patients 3, 6 and 9). The mean of means for all the patients for the pre-test is 2 (Calm and relaxed) while the mean of means for all the patients for the post-test is 3 (Feeling of floating with increased imagination and more concentration sustained). While it seems that the cybetherapy system contributes to raise the level of consciousness, none of the patients were able to maintain an altered state of consciousness (level 5) during the sessions although this level was reached for few minutes by few patients.

Table 4 displays the standard deviation for the pre-test and post-test for all the patients, these results show that all the patients experienced variability of the states of consciousness during the sessions as expected but this variability was of not more than one level of consciousness. The standard deviation for the pre-test was calculated as 1.34 and the standard deviation for the post test is 1.108 for all the patients. The t-value for the sample is 1.75. Based on this last value, the null hypothesis can be rejected; this means that there is enough statistical evidence that the cybertherapy system is able to raise the level of consciousness. However, this is not enough to raise the level to an altered state of consciousness that is required to conduct transpersonal therapy.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. States of consciousness and frequency measurements

Level	Consciousness	Measured Frequency	Types of Waves
0	Just he is beginning to relax with difficulty quieting the mind.	25-20	alpha and beta
1	Not very clear conscience or sense of anesthesia	20-16	Guests beta alpha continuous
2	Calm and relaxed with flash back memories	16-13	Alpha continues without beta theta intermittent
3	Well defined state. Feeling of floating with increased imagination and more concentration sustained	13-10	Alfa falling Continuous theta
4	Extremely vivid awareness of breathing heartbeat, or other bodily sensations. Living consciousness. Sometimes an alternation of internal and external awareness	10-8	alpha continuous theta falling Frequency
5	Awareness with satisfaction and deep intense alertness and calmness and detachment. Feeling of altered state lacking in previous levels 0 to 4.	8-5	Theta continuous alpha close to theta
6	New way of feeling by intuitive vision synthesis of opposites in a higher unity	below 4	Delta occasionally

Table 3. Results of the experiment

Patient	Mean Pre-Test	Mean Post-Test
1	2.82	3.19
2	2.73	2.48
3	2.45	3.55
4	2.73	3.00
5	1.73	3.55
6	1.45	2.95
7	0.91	2.18
8	2.27	2.36
9	1.64	3.27
10	1.36	3.18

Table 4. Standard deviations of the results

Patient	Standard Deviation Pre-Test	Standard Deviation Post-Test
1	1.53741223	1.569046
2	1.190874392	1.167007
3	1.213559752	0.687552
4	1.420627262	0.894427
5	1.489356176	1.29334
6	1.035725481	0.218218
7	0.301511345	0.873863
8	1.103712743	0.924416
9	1.361816968	0.64667
10	1.120064933	1.32802

The results suggest that although it seems that the proposed system is on the right track, the system should be enhanced by including other known means to reach altered states such as music therapy (Bonny 1975), guided meditations (Brown & Engler 1980) and channeling (Valverde 2015b).

DISCUSSION AND CONCLUSION

Inducing altered states of consciousness with neurotechnology is a relatively new concept and although there are serious studies, they are not incorporated into psychology or traditional medicine more than anything because of a lack of understanding of this technology.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

This study introduces technologies that are based neurotechnology including quantum biofeedback, the latter has proven curative value much of particular diseases that seem to tend to be psychosomatic.

Transpersonal psychology was presented as a paradigm that recognizes the immortality of consciousness and relies on spiritual concepts that have roots in mystic religions as reincarnation and survival of consciousness brain death. The immortality of consciousness is based largely on the quantum theory explaining the origin of consciousness and its connection to the universe.

Neurotechnology explores the use of technologies of sound, light and radiofrequency to control the frequency of brain waves with the reason to induce altered states of consciousness. Altered states of consciousness have been proposed as therapies for healing in transpersonal psychology, these therapies recognize the spiritual essence of the individual and are based on the concept that psychological illnesses are rooted in the spirit and not in the brain. The patient to know the root of their problems, seem to find the answer to your anxieties and can self heal with these transpersonal experiences.

In this research, a cyberpsychoterapy system is proposed to support transpersonal psycho therapy. The system can be used to induce non ordinary state of consciousness that can be used by transpersonal psychologists as a healing tool to cure his patients with psychological problems such as psychosis at a distance location with the help of internet technologies. The proposed cyberpsychoterapy system uses quantum signal generator for the induction of altered states of consciousness and has integrated an EEG that serves as a biofeedback device in order to assess if the patient has reached the desired level of consciousness and can be used it to adjust the frequencies of the signal generator in order to improve the psychotherapy experience of the patient if necessary. A sample of 10 patients was used to test the cybertherapy system based on neurotechnology and quantum biofeedback, data was collected and analyzed.

The researched showed that with the aid of quantum biofeedback and neuroquantology, people can discover hidden deep events and conflicts in their subconscious that can lead to healing experiences. Although the results show that the patients were not able to reach the desired level of consciousness for the psychotherapy, there is statistical significant evidence that the proposed system can help to raise the level of consciousness, this can help with future designs that will eventually assist to reach the desired level for the psychotherapy.

The aim of this study is to open the eyes of the therapists about the potential of the covered technologies for this purpose and the ability of the use internet technology to be able to conduct transpersonal therapy at a different location than the therapist. Although the results do not probe that the presented technologies are effective to induce altered states, they show that there is potential for this as there is statistical significant evidence that they are able to aid to increase the level of consciousness.

The work contributed to the existing literature in the application of quantum computing to psychology by suggesting a cyberteraphy system that uses quantum biofeedback and neuroquantology for the facilitation of transpersonal psychotherapy. Although there are many cybetherapy systems in the literature (Takacs 2005, Wiederhold& Wiederhold 2004, Botello et. Al 2009), none of them addresses transpersonal psychotherapy and are based on quantum biofeedback and neurotechnology.

A recommendation for future research is the inclusion of supporting methods such as music therapy, guided meditations and breath work in the cybertherapy system in order to reach the desired state that can help the therapist to heal patients at distance with the use of transpersonal psychology. It seems that the use of neurotechnology alone is not enough to reach desired results but a combination of methodologies can be the solution for the creation of the altered states of consciousness induction machine.

Chapter 47
An IoT-Based Platform for Rehabilitation Monitoring and Biosignal Identification

Volkhard Klinger
Department of Embedded Systems, FHDW Hannover, Hannover, Germany

ABSTRACT

This article describes how as a result of technological advances of the embedded system, the Internet-of-Things (IoT) has created a wealth of new applications and tailored solutions, even in the area of health and medical technology. The integration of state-of-the-art IoT-systems in an existing prototype platform for biosignal acquisition, identification, and prosthesis control provides new applications for prevention and rehabilitation monitoring. This article concentrates on an IoT-based platform for rehabilitation monitoring and biosignal identification. The IoT-characteristics for the application in the area of medical technology are discussed and the integration of such IoT-modules in the given architecture is introduced. Based on this extended architecture, new applications in the field of biosignal measurement, signal processing and biosignal monitoring are presented. Some results of a rehabilitation monitoring system, based on a self-designed IoT-module, integrated in the whole platform, are shown.

1. INTRODUCTION

New technologies allow more powerful, smaller, and more energy efficient embedded systems. Based on these systems, the Internet of things has emerged. Legio of applications are existing taking benefit of the IoT-evolution (Lee and Lee, 2015). New services and applications, new business models and ecosystems are arising with this application domain. Apart from the financial aspects of IoT, where the increased focus on value-based care shifts financial incentives to a model in which providers are compensated based on how their patients fare, rather than by the number of tests, visits, or procedures performed, new challenges are existing in the area of medical technologies due to architectures, big data, process modeling, machine learning, cloud services and, last but not least, security and energy harvesting (Al-Fuqaha et al., 2015; Kumar et al., 2017). In this paper the focus is on the integration of IoT-devices into the prototype

platform of a biosignal acquisition, identification and control system and on new application scenarios using IoT-devices and smart devices, like smart phones (Islam et al., 2015). The IoT-devices provide mobile and flexible sensor and actor nodes, while the smart device provide enough power to perform a number of computing activities and provide communication and positioning (Global Positioning System, GPS) characteristics. The integration of these technologies offers new application scenarios and a powerful extension for example of the platform for biosignal acquisition, identification and prosthesis control. In particular, a mobile application become possible, providing continuous measurement of biosignals and therefore in many cases a better diagnosis, treatment and rehabilitation process. In addition, these mobile applications take care of the personal life situation (Ahmed et al., 2017).

The objectives of the present work pass in the integration of IoT-devices in a HW- and SW-platform solution. The development of intelligent sensors and actors by using IoT technology enables to integrate a variety of sensors and actors into the existing platform. Besides, in particular the radio communication plays an important role which allows a flexible positioning of sensors according to the individual user's needs.

Due to the flexibility of the platform, different use cases with application-specific solutions, based on adapted platform-related modules, can be realized.

So, new application scenarios, in particular continuous measurements, providing better prevention and rehabilitation monitoring, can be developed.

The central objective of the present work is the sensor fusion of the integrated sensor data to improve the identification based on a machine learning method. The sensor fusion allows new therapy procedures, for example to improve the gait analysis (see subsection 4.2). Furthermore, the fusion of sensor data also supports already the identification of the so-called zero space movements from the prosthesis control (Klinger, 2015).

In this article, first, the characteristics of Internet of Things-systems (IoT) are introduced and some examples for medical applications, based on IoT-modules, are described. Then a brief overview of the smart modular biosignal acquisition, identification and control system (SMoBAICS) is given, describing the integration of IoT-components into its architecture. Subsequently two IoT-based applications are introduced. Before concluding, some results are shown, using a self-designed IoT-module for the rehabilitation monitoring system, introduced in subsection 4.2.

2. THE INTERNET OF THINGS

The Internet of Things (IoT) covers the use of connected devices and systems providing intelligence based on computing capabilities to leverage information acquired by embedded sensors and actuators integrated in smart clothes, technical components and other physical objects. The Internet of Things creates new opportunities to link sensors, actuators or intelligent decentralized systems either with each other or with other systems (Bajaj et al., 2017; Bassi et al., 2013; Streitz and Markopoulos, 2017). The IoT-Roadmap promotes new technologies and, therefore, new challenges.

To establish an IoT-System, a system of devices, functions, and services is required. Without any type of quality of service, such an IoT-system is not applicable.

The IoT-system has to provide the following capabilities:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Sensor:** Sensing Data and providing a conversion from the measurement value to digital data. If continuous data are acquired, an analog-digital converter has to be integrated;
- **Processing:** The data from the sensor can directly be sent to a consumer, but in most cases a data processing takes place, providing for example threshold values or other data preparation;
- **Memory:** For data processing or for data storage (raw data!) memory is necessary;
- **Communication:** The communication channel connects the IoT-system to a server infrastructure, providing databases or higher level functions. Using several different sensors and IoT-Systems sensor fusion is one of the challenging topics;
- **Actor:** If the IoT-system has to perform a specific task, an actor is necessary to execute this task, e.g. switching a LED on, closing a valve, etc.;
- **Application:** There are several possibilities using an application with the IoT-device. Of course, the IoT-device is able to execute a local application, for example for detecting events or for computing histograms or other statistical data. The prerequisite is enough computing power, integrated during the platform design process. Second a smart device, for example a smart phone can be used as GUI for the application and is able to host the application. And thirdly, a cloud-based server is able to host any application while the smart device again serves as a GUI.

Keeping these different key and service capabilities in mind, specific IoT characteristics with the objective to engineer and integrate an IoT-System in the biosignal acquisition, identification and control platform has to be defined (see section 3).

2.1. IoT Characteristics

An analysis of different use cases for IoT systems shows the need of establishing IoT-platforms providing a flexible and application specific IoT-system configuration. Such a platform is formed by a specific hardware (HW) and software (SW) architecture which allows for an exchange/configuration of HW-/SW-modules to fit the application requirements on the basis of a HW-/SW-core system. The connectivity is here one key factor. Lots of smart devices, like smart phones or tablets, provide a communication- and computing-infrastructure. Based on this the flexibility and scalability of the platform can be increased significantly using the present-day infrastructure. In addition, the number of intelligent components, providing sensors with local computing capability, rises within the scope of the IoT rapidly (Bassi et al. 2013, Streitz and Markopoulos 2017). Thus, intelligent sensors can be integrated to the platform. This decentralized periphery extends the application spectrum of the platform considerably via adding more sensor and actor devices. Nevertheless, some key aspects have to be taken into consideration:

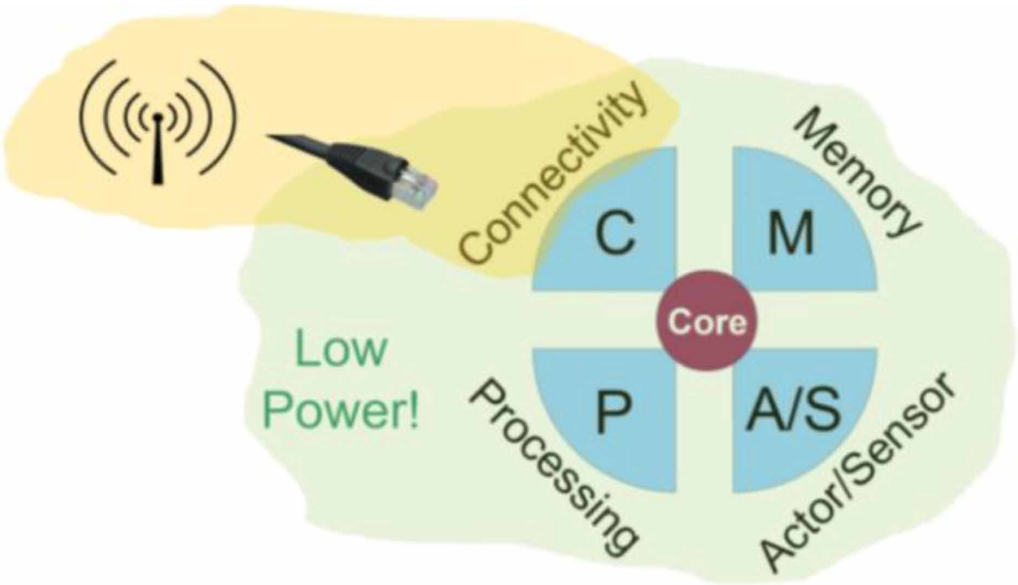
- The IoT-module is based on layer architecture; the core is an essential part, providing interfaces for the different module-based capabilities: sensor, processing, memory, communication and actor. It enables an efficient and performant integration of different modules and provides smart services;
- The modular character of hardware and software and their platform characteristics is of particular relevance. The platform paradigm provides a flexible partitioning and relocation of functions and services on specific hardware and software modules. Especially the open system gateway initiative (OSGI) or other platform concepts are one of the key features realizing the software platform;

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Connecting more than one or two devices, the Smart-Device and/or the CPU-module of the IoT-system has to provide gateway functionality. Based on new Bluetooth- (>BLE4.2) or Wi-Fi- (802-11ah) standards, the communication environment with these characteristics can be realized;
- The service orientation of the interface is an essential aspect due to the integration of IoT components. An efficient linking and communication require a defined quality-of-service level to realize a seamless integration of services and modules;
- Using IoT-modules security aspects are a further key point. Without secure data transfer and a secure module interconnection an IoT-based system is applicable in a limited way, especially in medical applications (Kumar et al. 2017). Every connection has to be secured using pairing-based or certificate-based strategies. This is not in the focus in this article.

In Figure 1 the essential features of an IoT-device are depicted, forming a platform circle including the mentioned key aspects. The base functionality of an IoT-module contains an actor/sensor element, and processing, memory and connectivity features, adapted to the specific application. For example, the connectivity may be based upon a wireless or wired connection. Moreover, all modules are designed regarding low-power strategies providing an autonomously operation. Here, energy harvesting is one of the main future topics for IoT-systems due to implantation or the requirement of mobility. The core of the IoT-platform allows for a flexible integration of different modules to configure the platform according to the application requirements. For example, the sensor element can be exchanged to support a gas sensor instead of a pressure sensor.

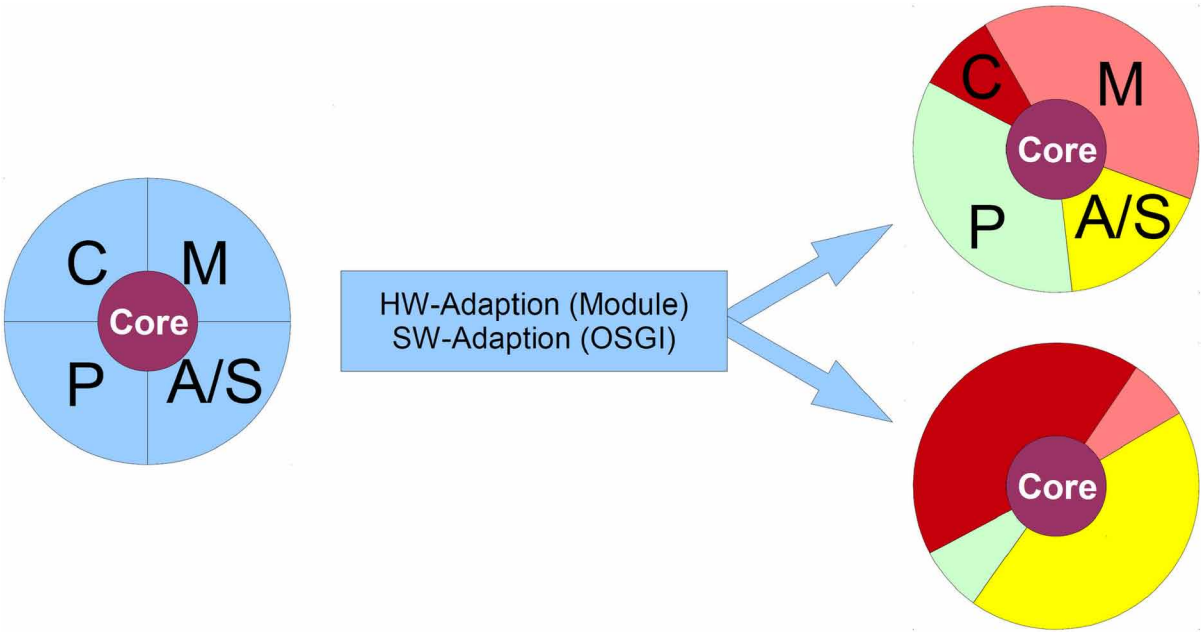
Figure 1. Platform circle, covering the major system features



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2 shows different specifications of IoT-systems designed for specific applications. For example, processing features or connectivity are more pronounced than other features. Based on the platform paradigm every IoT-system can be designed according to its specific project requirements. Exchanging or reconfiguring modules, the platform can be adapted to provide a lot of memory (see Figure 2) or to support a complex sensor/actor frontend (Figure 2).

Figure 2. IoT instances based on an IoT-platform



2.2. IoT-Systems in the Area of Medical Technology

IoT-systems can be used in any application area, even in the area of medical technology, prevention and rehabilitation. In this section two examples help to understand the platform paradigm, introduced in the last section. In section 3.2 additional examples are given, focusing on applications of the developed IoT-module.

The prerequisite for both examples is an existing IoT-platform, which consists of two different modules, where one module (Core) is providing the IoT-core interfacing the communication, the memory and processing features and a motion sensor. The other module (Analog Frontend (AFE)) provides specific sensory equipment.

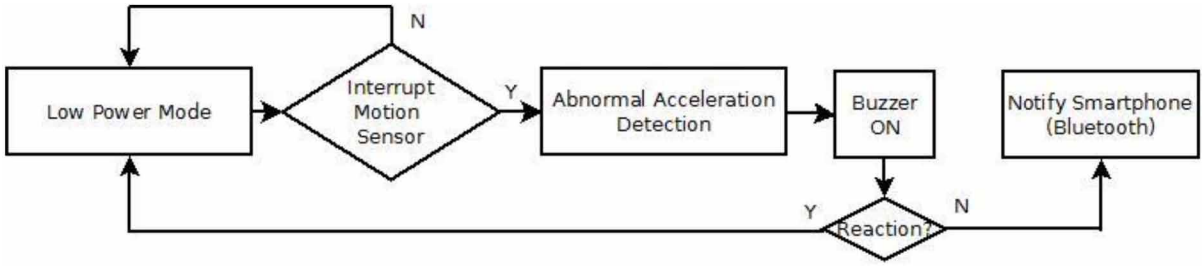
2.2.1. Example 1: Fall Detection (Core Stand-Alone, No Frontend)

The core used separately provides a motion detector and can be helpful in everyday life of elderly people. According to (Centers for Disease Control and Prevention, 2016), only in the USA more than 700000 people a year are hospitalized as a result of fall injury. The motion sensor can detect abnormal accel-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

eration values in the ground direction and inform emergency department using Bluetooth and mobile phone connectivity. In addition, GPS coordinates from the smartphone can be included in the emergency message. The time of the event and additional raw data can be saved for example on an integrated SD-card. An illustrative flow of such an event is presented in Figure 3. The system can operate in a low power mode, until an interrupt from a motion controller is triggered. When no user reaction is detected, a smartphone notification and alarm are generated.

Figure 3. Fall detection and emergency notification overview

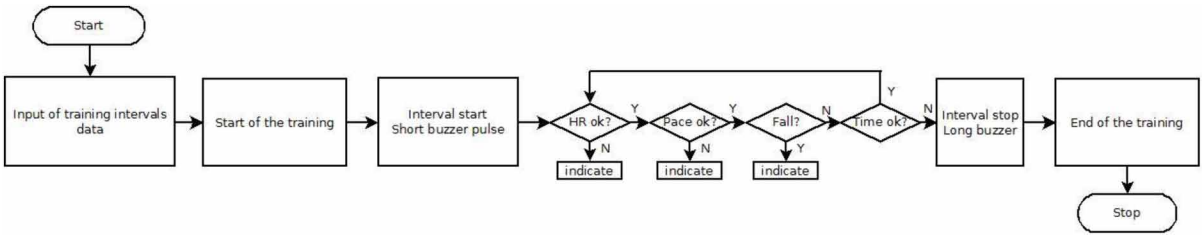


2.2.2. Example 2: Vital Functions Analysis (Core and Frontend Used)

If the IoT-system is equipped with a specific frontend module – here for heart rate detection – it can be used by people with heart disorders, as well as, by sportsmen. Patients suffering from heart problems may benefit from parallel heart rate and fall monitoring. In case of any abnormal behavior, a relevant person may be notified by smartphone application. The functionality for sportsmen presented in Figure 4 would be implemented differently. An accelerometer combined with heart rate monitoring would be a useful tool for interval training for runners. The plan of the training might be set on the Android smartphone and imported to the memory of the device. A timer interrupt might indicate a start/stop of an interval and trigger a buzzer. Heart rate and pace of the run, monitored by motion sensor might be indicated by LED diodes. In addition, the platform can constantly transmit data to the smartphone and save it on the SD-card, if no smartphone is carried. The system is constantly on and monitors interval timing, as well as dangerous events, such as fall.

Similar monitoring applications can be implemented with ECG front-end and other non-health related sensors, such as smoke, or gas sensors.

Figure 4. Heart-rate analysis for athletes, interval running mode



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. THE SMOBAICS-PLATFORM

Embedded systems provide new approaches in biotechnology and medical therapy. Based on modelling and simulation methods, biological, physical and technical relationships can be described and verified (Kandel, Schwartz, and Jessell, 2000; Law and Kelton, 2000; Zeigler, Praehofer and Kim 2000; Klinger 2014).

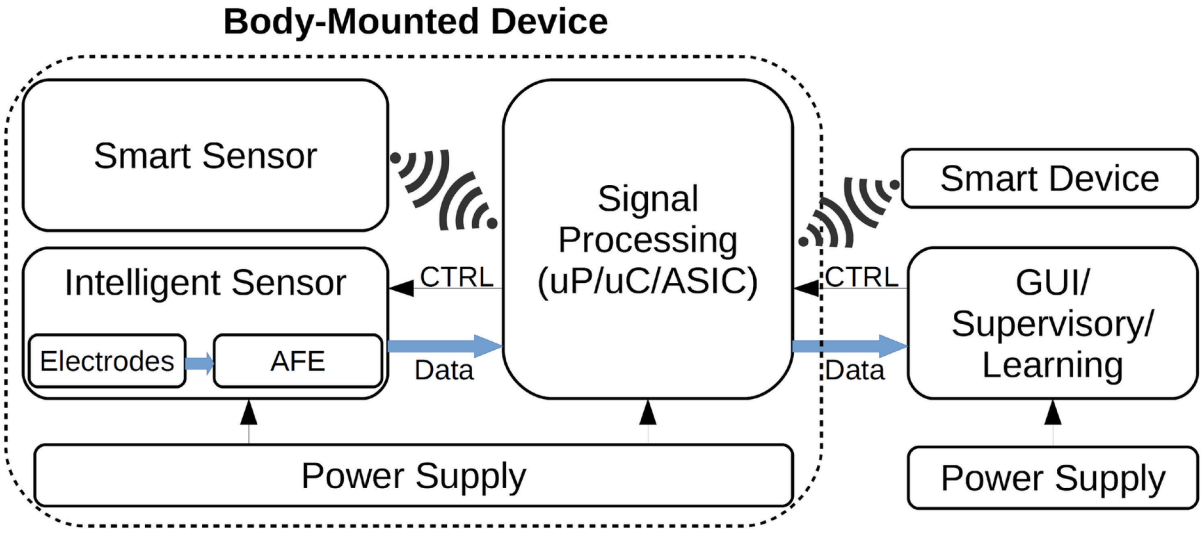
The integration of hardware- and software-components provides an intelligent, smart and application-specific system. Using a platform paradigm, the partitioning between hardware- and software-components is adaptable concerning project-specific requirements. Further-more the platform characteristic enables a modular architecture with high-level flexibility. The integration of sensors and actors in this adaptive hardware/software-platform increases flexibility and provides a measurement and identification platform for lots of applications.

In (Klinger and Klauke 2013), (Klinger 2014) and (Klinger 2015) a modular platform is presented focused on the acquisition of electromyogram (EMG) and electroneurogram (ENG)-signals and a data-based identification approach.

3.1. Architecture and Characteristics

In addition to a continuous improvement of the system core features (in particular the identification), new fields of application and an enhancement concerning flexibility are in focus. In Figure 5 the block diagram of the smart modular biosignal acquisition, identification and control system (SMoBAICS) is shown.

Figure 5. Block diagram of SMoBAICS



EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The SMoBAICS-platform consists of several stages and modules, briefly described in the following overview:

1. **Data acquisition and stimulation:** The ENG or EMG (ExG) data or further sensor data have to be acquired and sampled according to their signal characteristics. The number of channels has to be determined by the application. In particular applications stimulation is necessary, for example to trigger movements by activating muscle groups;
2. **Data processing:** Data processing focuses on two key priorities: Data conditioning and identification:
   a. **Data Conditioning:** The acquired data have to be processed to improve the signal conditioning. Besides the programmable filters and amplifiers are resampling functions available to provide periodic samples. The acquired data (action potentials) are disturbed by intrinsic and a substantial extrinsic noise, originated for example by EMG from surrounding muscles. Using integrated analog filters and additional digital filters the signal quality of the recorded data has to be improved. Several filters like specific high-pass, low-pass, band-pass and notch filters are available. A further data processing is necessary to generate events from the action potentials like the activity level of a muscle group or the detection of an exposure scenario;
   b. **Identification:** The identification feature is required for prosthesis control or any type of high level signal evaluation, like gait analysis. The identification is based on machine learning and recognizes different information sources: The action potentials from brain to muscle, the action potentials from the proprioceptors and additional sensor data from microelectromechanical system (MEMS) of force sensors. The identification method and the corresponding verification scenario have been introduced in (Klinger and Klauke 2013), (Klinger and Klauke 2015) based on results in (Bohlmann, Klinger, and Szczerbicka 2009), Bohlmann, Klinger, and Szczerbicka 2010), (Bohlmann, Klinger, and Szczerbicka 2011), (Bohlmann, Klinger, and Szczerbicka 2012). The identification is subdivided into three levels. In the first level, the algorithm recognizes patterns of axon related action-potentials. This set of solutions is checked to well-known parameters, like impulse frequency, the relative magnitude of the nerve impulse amplitude and the refractory period. In addition, clusters are built up to model the different groups of activation and their related sensory information (proprioceptors). So, certain clusters in the neural bundle can be arranged to map muscle groups and their corresponding receptors. In the second level the agent-based set of solutions is combined to global solutions taking the causality between actor and sensory information into account. The third level correlates the first and second level solutions with trajectory information from the camera-system or the MEMS, using inverse kinematic algorithms. Data acquisition and stimulation;
3. **Data archiving:** A local data archive is necessary due to two scenarios, online and offline operation:
   a. **Offline Operation:** For offline operation the identification needs sets of model parameters, data from the learning outcomes and RAM for algorithm execution. Furthermore, all data can be logged on the system for a later offline analysis. During event recognition all data are logged, only event data, for example an exceeding of a maximal force, are sent to the host system;
   b. **Online Operation:** During online operation all local algorithms need memory for an efficient execution. This local memory reduces the requirements for data bandwidth to the host system;
4. **Data exchange / Connectivity:** With regard to Figure 5, the processing of data goes in two different directions, either the local signal processing (operating phase (Klinger and Klauke, 2013))

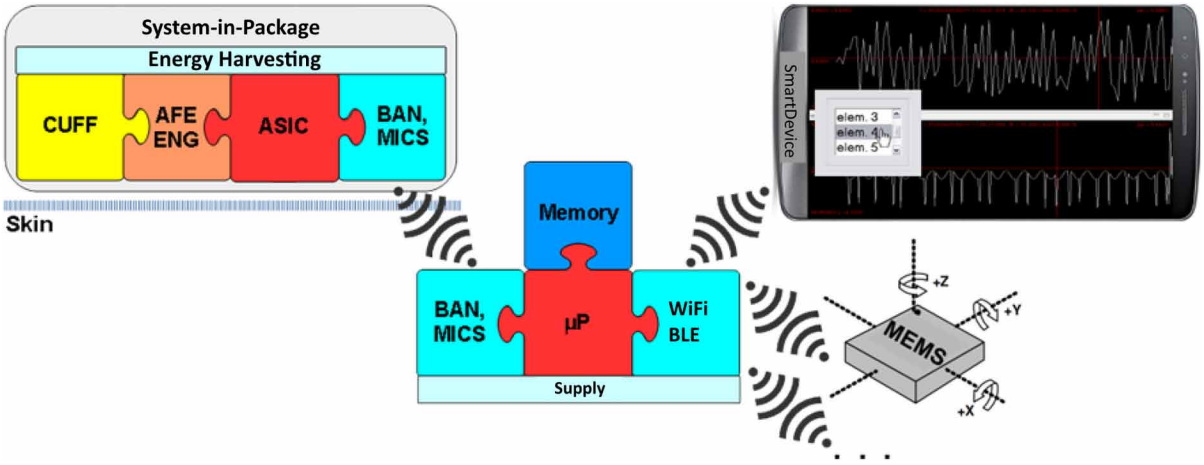
EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

or the host processing (learning phase (Klinger and Klauke, 2013)). Furthermore, the data can be saved locally or on the host, transferred using the communication link (cable or wireless);

5. **User interface:** The graphical user interface (GUI) allows for access to the different system functions and presents either a configuration or a data display;
6. **Configuration:** The system functions can be configured for different use cases and specific GUI:
   a. **Learning:** The control application helps to adapt parameters and to initiate different learning phases;
   b. **Operating:** The operating GUI allows to start and stop the application and to load specific parameters;
   c. **Logging:** The logging collects not only events but all system data for a later offline analysis;
   d. **Event:** The different events and their corresponding limits have to be defined and selected.

In Figure 6 the block diagram is transformed in the platform layer, where the architecture and the functional system components are visualized. This figure shows the design roadmap, where the key component is integrated into a system-in-package (SIP) to provide an implantable device. Furthermore, this figure shows the wireless integration of the MEMS-device, a smart sensor providing the required connectivity shown in the block diagram (Figure 5). This wireless connection improves the flexibility and simplifies the system integration.

Figure 6. Platform layer of SMoBAICS



With regard to the platform, the advantages (+) and disadvantages (-) of this wireless connection type are opposed in Table 1.

Based on this comparison and with regard to platform paradigm, system flexibility and mobility, the wireless connection has been chosen for the integration of all external sensors into SMoBAICS. This decision opens the perspective of using Internet of Things (IoT)-modules which have the added benefit of the future availability of legion of IoT-sensors and actors. The internal sensors, like the cable wired cuff-electrode (Klinger and Klauke 2013), cannot be connected using wireless techniques according to the current state of the art.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Comparison of selected connection opportunities and ranking from the wireless point of view

Issue	Ranking	Comment
The device has to provide an own power supply	-	Cable linked, the device can be powered by the main system
Wireless connection flexibility	+	No number of inputs have to be specified; No galvanic coupling
The device has higher design complexity	-	Design effort
Local intelligence	+	Local intelligence provides more features and functions
No cable link	+	Cable link makes trouble due to mobility; No galvanic coupling

3.2. The SMoBAICS IoT-Modul

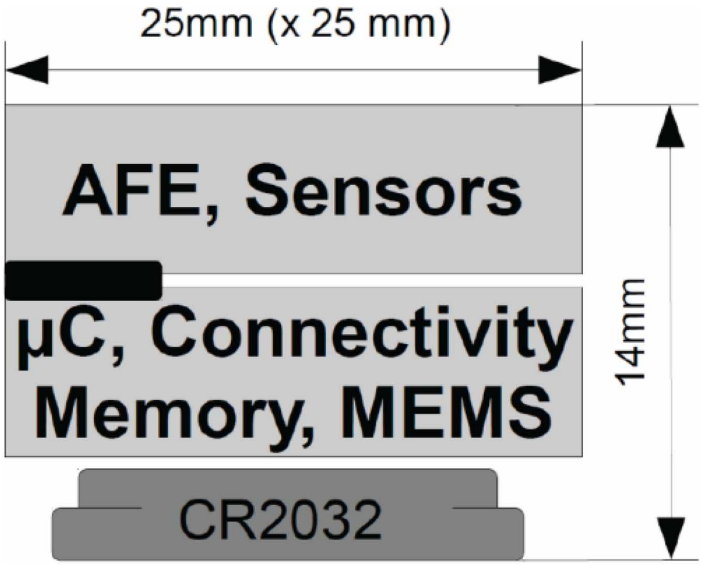
As described in (Klinger and Klauke 2013) and (Klinger 2014) the SMoBAICS is a modular system for identification and prosthesis control. The extension or adaptation of the system may then, depending on the application, benefit from existing developments and/or modules. The SMoBAICS platform is used to acquire EMG- and ENG-signals and to provide a data-based identification of movements and trajectories. The identification method is model-based and uses simulation for the continuous model improvement and for verification purposes. The data of the external sensors, here especially of a 9-axis tracking device, are essential for the model- and simulation-based identification method. Here the focus is on the first own designed IoT-module for SMoBAICS that already uses components developed based on this new technology.

Based on the acquisition of action potentials via ENG, the information of the peripheral nervous system is used to identify movement patterns. A micro-electro-mechanical system (MEMS) (mobile phase (Klinger and Klauke 2013)) and/or camera system (learning phase (Klinger and Klauke 2013)) is necessary to get information about the movement trajectories. To integrate the MEMS, an IoT-module was designed to improve flexibility and to simplify the integration of the sensor using wireless connection. Figure 7 shows the block diagram of the SMoBAICS IoT-module. The first prototype with a rectangular base has the system dimensions shown in this figure. The design can be shrunk massively, due to design for test considerations we did not shrink the prototype further.

It is realized according to the platform paradigm and is based on a modular design. The main task of the IoT-system is data processing and Bluetooth Low Energy connectivity. As the system's main task is data acquisition, one of the main requirements was sufficient number of analog inputs and integrated analog-digital converter. Other required features were an integrated Bluetooth 4.1 transceiver and SPI interface (serial peripheral interface). A microcontroller CC2650 (CC2650F128RGZ) of Texas Instruments (Texas Instruments Incorporated 2015) was chosen. The device has a 48 pin VQFN 7x7 mm package with 31 GPIOs (general purpose IOS). The main core of the component is 32-bit ARM Cortex-M3 running at 48 MHz in the active mode. The device is equipped in 8 analog IOs and 12-Bit ADC (analog-digital converter). A separate ARM Cortex-M0 processor is responsible for Bluetooth connectivity. This feature ensures that specific Bluetooth timing will be kept and the main core can go in the low power mode without losing Bluetooth connection. The microcontroller is equipped with a standard SPI interface that is used for the communication between the components. The CC2650 was chosen mainly, because it contained all necessary functionalities and no additional components were

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. System configuration of the SMoBAICS IoT-system: Base system (lower board); Sensor extension (upper board)



needed for Bluetooth transmission and analog conversion. This microcontroller is available in different packages; this offers the option of shrinking the system for specific applications.

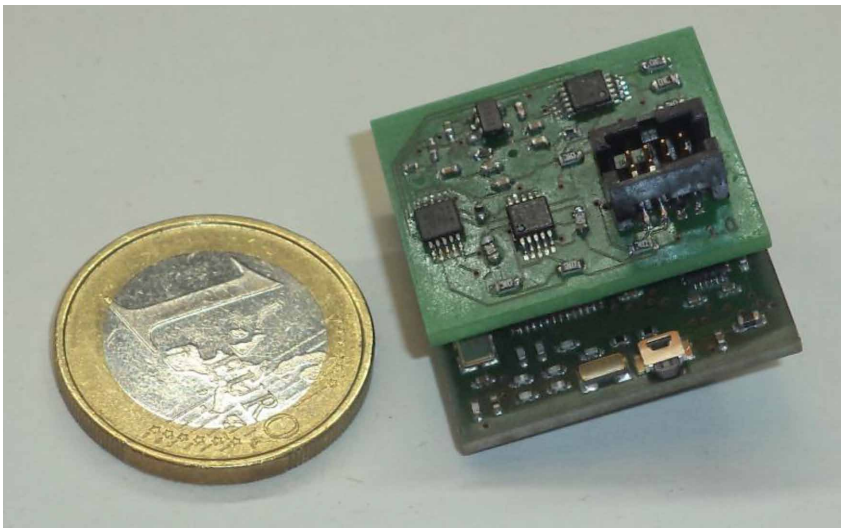
The task of this IoT-system, apart from data processing and radiofrequency connectivity is motion detection. As a motion sensor MPU-9250 (InvenSense 2014) was chosen. The sensor is equipped with 3-axis accelerometer, 3-axis gyroscope and 3-axis magnetometer. The communication with the microcontroller can be implemented with SPI and I2C bus. One of important features is "wake-on-motion", which means that the accelerometer can generate interrupt signals for the main processor when movement is detected. This feature was the main reason why the component was chosen, additionally to the SPI interface.

The platform is equipped with a standard micro SD-card slot, which also determined the minimal size of the PCB board (printed circuit board). Moreover, several LEDs, two standard buttons for user interaction and a magnetic buzzer is integrated to provide interaction. For radio connectivity a standard 2,4 GHz SMD (surface mounted device) antenna for Bluetooth connectivity is used. The choice of the voltage regulator depends on the maximal power consumption of all components. The maximal theoretical power consumption of all platform components that require stabilized voltage, including microcontroller with RF on, motion sensor, 2 LEDs and buttons pressed was theoretically estimated for ca. 50 mA. This value will not be achieved in practice - it would require all components to be constantly on. A maximal value estimated with 15 measurements was oscillating around 10 mA. As the voltage regulator in the platform may also supply front-end components driven by microcontroller outputs, 50 mA was chosen as a minimal reference for voltage regulator selection.

In Figure 8 the current design of the CPU-module is shown. To realize the IoT-system according to the platform paradigm the large CC2650-package providing more I/Os is chosen. Realizing a product-based design, the IoT-system can be shrunk considerably.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. New IoT-platform



According to the platform circle, shown in Figure 1, all essential features are realized:

- **Controller:** ARM-based controller for data and event processing, system control and analog-digital conversion;
- **Connectivity:** In the current version Bluetooth is supported to provide a communication link to the body area network (BAN), connecting all devices of the platform;
- **Memory:** For logging and data buffering a SD-card is integrated;
- **Sensor:** The MEMS is an integral part of this IoT-module because the acceleration and gyro data are important for all relevant applications around this project. To provide further sensor support an interface is designed to connect additional sensors to the IoT-system. This additional sensor system can be connected to the base system as shown in Figure 7. In section 4 we show corresponding application scenarios using additional sensor support.

The prototype attached button-cell battery provides enough energy to independently operate the IoT-device for several days. The intelligent power management helps to reduce power consumption according to the activity cycles. In Figure 9 activity cycles for different use cases are shown, ranging from training applications to different rehabilitation scenarios.

The four operation modes are characterized by power consumption and wake-up capability:

- **Off:** The device is powered off, no power consumption;
- **Standby:** The device is in the lowest power consumption mode, waking up by interrupt of the MEMS-device;
- **Activity:** Data acquisition is activated automatically from standby; depending on the communication status (logging, event mode, transmit continuously, transmit periodically) the power consumption differs considerably;

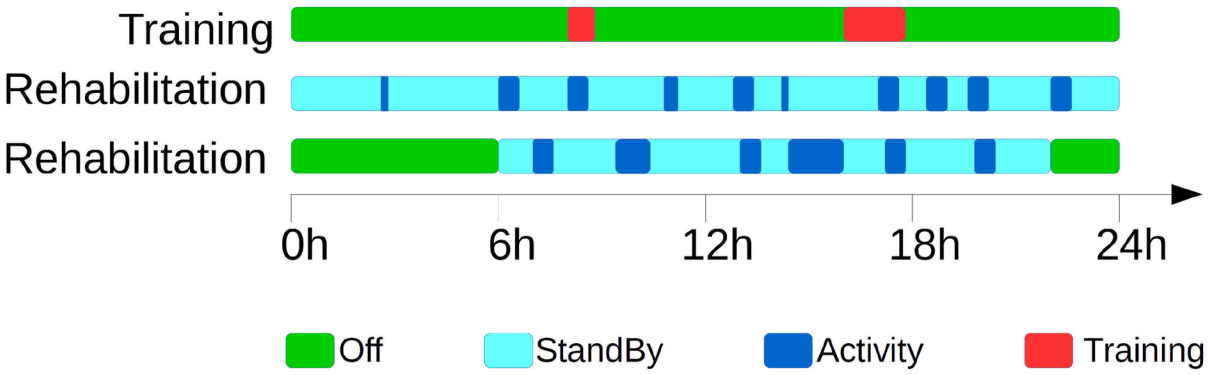
Figure 9. Application specific time-of-use: Day schedule



- **Training:** Data acquisition is activated manually and the communication mode is selectable according to the activity mode.

4. APPLICATIONS

A wide range of applications in the field of biosignal measurement, signal processing and biosignal monitoring are existing. The focus is on two specific examples, demonstrating the further development of the known platform (Klinger and Klauke 2015) and the flexibility of the platform paradigm.

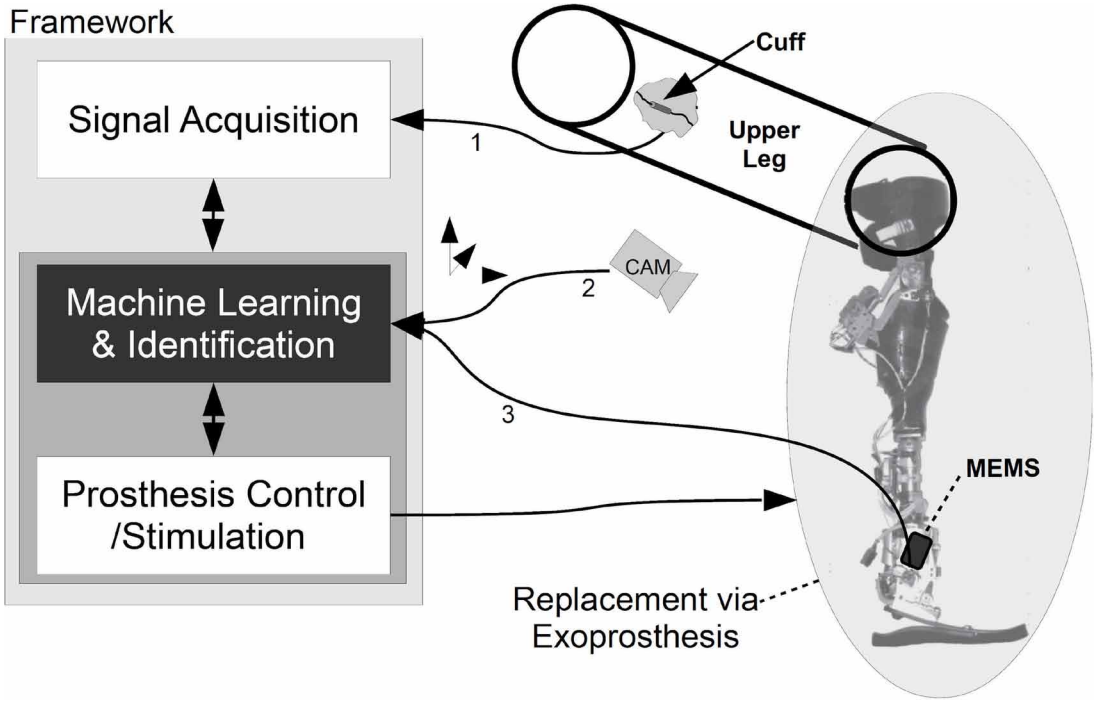
4.1. Prosthesis Control System and Gait Identification

Based on the idea of an ENG-based arm prosthesis control we are still working on the identification to improve the identification algorithms and to make it more robust. Using signals from the peripheral nervous system, the objective of a prosthesis control is adaptable to leg prosthesis, too. In Figure 10 the application schematic is shown, consisting of the same elements, like the system for the arm prosthesis control (Klinger and Klauke 2013).

According to this scenario a MEMS is integrated to get information about zero space movements during the operating phase (Klinger and Klauke 2013). This MEMS contains a 9-axis motion tracking device (gyro + accelerometer + compass). During the first identification runs it turned out, that the MEMS-signals are not sufficient to correlate with the information from the nervous system due to signal drift. So, it was not possible to realize a gait identification which is necessary to provide a leg prosthesis control. Therefore, we add force sensors to the MEMS, called now MEMS+F. Using force sensors, it is possible to get more precise information about the force progression over time and therefore about the gait cycle, shown in Figure 11. The gait cycle information and the force sensors are essential requirements for an identification process (Aziz, Park, Mori, and Robinovitch, 2014), (Ito 2008), (Kugler et al., 2012), (Tao, Liu, Zheng, and Feng, 2012). Furthermore, the gait cycle information triggers another application, shown in the following subsection.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. System concept: Prosthesis control



4.2. Rehabilitation Monitoring System and Gait Evaluation

Deploying the MEMS with additional force sensors (MEMS+F) there are a lot of rehabilitation monitoring systems and gait evaluation systems possible:

- **Rehabilitation Monitoring:** Using the MEMS+F device it is possible to measure, evaluate and archive all forces acting on the foot vertically (z). With additional sensors, adaptable to the MEMS+F-device, it is possible to take the other forces (xy) and torques into account. During a rehabilitation phase after a fracture, dislocation, etc. the physical stress can be observed continuously. Therefore, a correlation between stress type, stress duration and recovery progress is possible. In addition, the accumulated load per time period can be taken into account. Furthermore, the monitoring can be used to optimize the gait during rehabilitation to realize a normal gait. If the specific permitted limits are exceeded, an event can be triggered, informing the patient or the treating physician to take the situation into consideration;
- **Gait Monitoring:** The evaluation of gait of apparently healthy persons is an important method to analyze an imbalance or dysfunction which can result in health problems. These problems can be evaluated using continuous gait monitoring to identify pathological or abnormal gaits. Paying attention to how you walk and run reduces unnecessary muscle strain. In addition, this gait monitoring can be used to monitor and optimize movement sequences within the sports segment. In Figure 11 a single gait cycle including the different phases is shown.

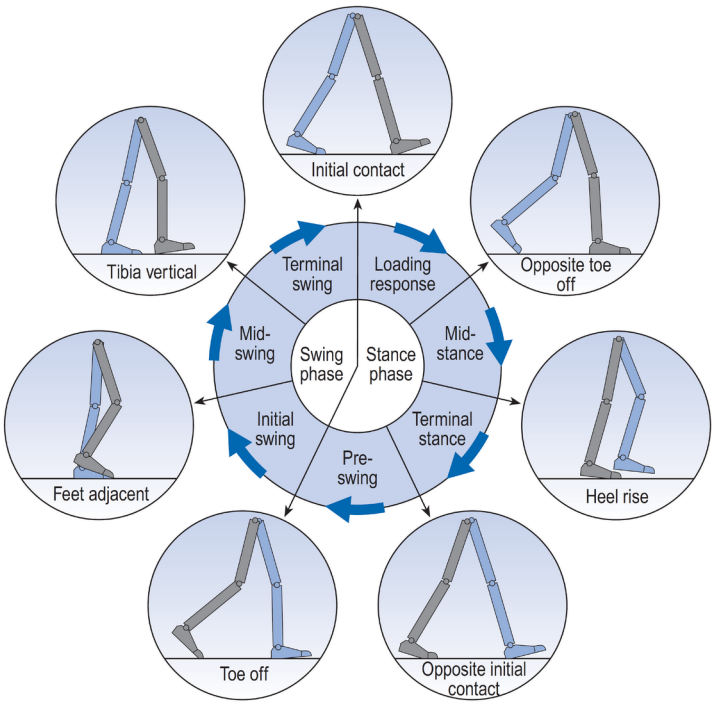
Figure 11. Single gait cycle (Levine et al., 2012)



5. RESULTS

The focus is on the first measurements taken by the new SMoBAICS IoT-device. This device is necessary for all applications and use cases with identification to provide positioning information. Both applications in section 4 are using this device as MEMS+F-device. Focusing on the second use case in subsection 4.2, the whole system can be downsized with regard to the platform paradigm. In Figure 12 a small cut-out of the block diagram in Figure 5 is shown, emphasizing an additional direct connection between the smart sensor MEMS+F and the smart device used in this class of application. In addition to the 9-axis motion tracking device, the prototype is using currently three force sensors to provide a mobile measurement of forces as well of accelerations and gyro data according to a gait evaluation. The current resolution of the analog digital converter (ADC) is 12 bit at a sampling rate of 10 kHz for all force, acceleration and gyro data. These parameters are adequate to detect all effects with sufficiently accuracy.

The position of the three force sensors, used by the current prototype, is depicted in Figure 13. The force sensors extend the information from acceleration and gyro data to identify the centre of gravity and to determine the different phases of the gait cycle (see Figure 11). In contrast to fixed installed measurement plate (Heidenfelder 2011), providing a one dimensional data stream for the vertical force, the mobile MEMS+Fdevice supports in the current version three force sensors as shown in Figure 13.

In Figure 14 the user interface is shown, presenting the data based on an Android application. Figure 15 shows this one dimensional data stream for the vertical force during two steps (Fzl: Left leg; Fzr: Right leg). Using three force sensors a far more detailed force level and force progression can be detected. In Figure 16 to Figure 18 the load distribution for the sensors 1 (red), 2 (green) to 3 (blue) (see Figure 11) for different scenarios, like step, run, jump and changes in balance are shown:

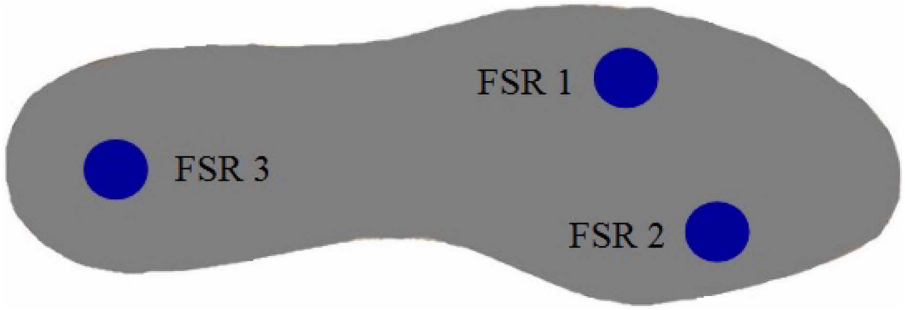

Figure 14. Android App for displaying force data

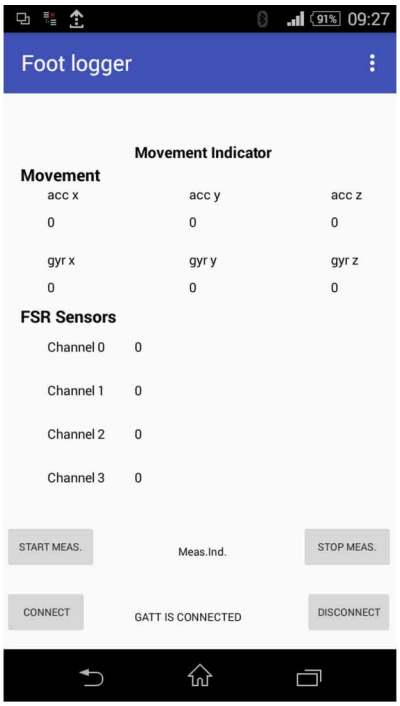
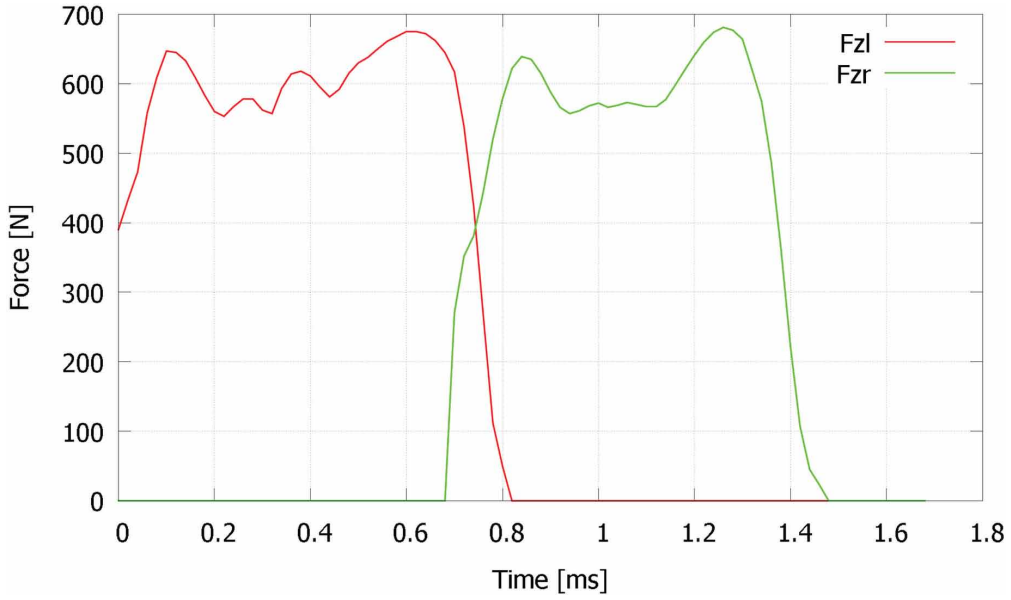


EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Figure 15 and Figure 16 - Normal gait:** According to the gait cycle the different force levels and the force progression for all force sensors over time are shown with regard to one step. In Figure 15 the force levels are shown based on a fixed installed measurement plat. In Figure 16 the force sensor configuration, shown in Figure 13, is used. From the initial contact on the heel up to the push off, the force levels for all sensors are available over time. It is obvious, that the measurement plate shows only the sum of all forces, while the three sensors show a more detailed time and spatial resolution function;
- **Figure 17 – Running:** In comparison to the gait, here the shorter and more intensive force level, dependent on the way of running, is shown over time;
- **Figure 18 – Jumping:** All phases of the jump including the short flight (forces=0) between 930 ms and 1110 ms are evident.

Figure 15. Normal gait: Vertical force plotted over time on a fixed installed measurement plate (Fzl: Left leg; Fzr: Right leg)



6. CONCLUSION

In the following summary, all aspects of the paper are recapitulated. An additional subsection presents the further work on the SMoBAICS-platform.

6.1. Summary

The presented approach for a platform-based embedded biosignal acquisition and identification system integrating IoT-devices offers a wide range of medical applications. The modular system character, based on the platform paradigm, provides adaptability to different diagnostic, rehabilitation monitoring and control scenarios with regard to computing power, connectivity and analog frontend characteristics.

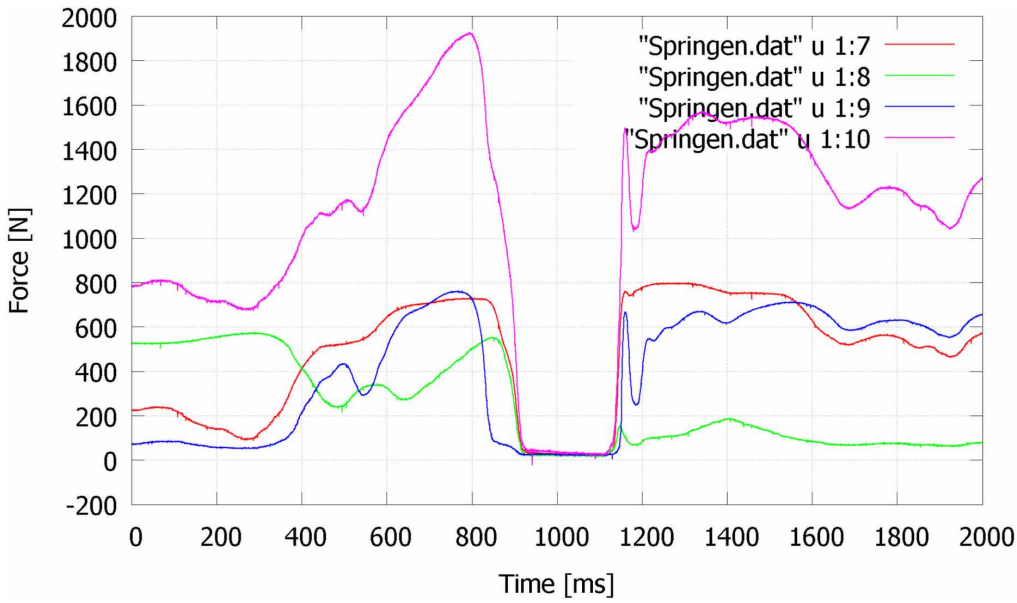
Figure 18. Jumping, right leg: Vertical force plotted over time for 3 sensors (1 (red), 2 (green) 3 (blue), sum(1,2,3) (magenta), see Figure 15)



The integration of IoT systems further expands the range of applications and allows for the correlation of data and thus the sensor fusion and context recognition. IoT has the potential to deliver solutions that improve in particular health applications. The first objective of the present work is achieved. The new IoT-device, also designed according to the platform paradigm, helps to acquire missing data, like MEMS- and force data for identification, and provides a smart integration into the platform using wireless links. Based on the developed IoT-device new applications are constantly emerging, like rehabilitation monitoring, gait evaluation and training-based motion sequence optimization.

The central objective an improved identification of biosignals using sensor fusion based on machine learning is an ongoing task allowing new therapy procedures, for example to establish gait analysis for prevention or rehabilitation services (see subsection 4.2).

6.2. Further Work

Additional tests and clinical applications are ongoing to improve the system characteristics and the identification method with regard to different applications further.

The embedded EMG- and ENG-based biosignal data acquisition and identification system, using a flexible hardware and software-platform, offers considerable potential. The use of monitoring platforms based on platform architectures allows flexibly tuning the system to different application scenarios. The current research and development activities have a dual focus: On the one hand the further development and verification of identification algorithms and the further integration of MEMS- and force data, on the other hand the deployment of a software framework for and graphical user interface for monitoring applications.

Chapter 48
Is It Real or Not?
Experiences of Synchronous Learning and Training for Counseling Graduate Students

Katie Koo
Texas A&M University – Commerce, USA

ABSTRACT

Counseling graduate trainings, in-person discussions, one-on-one supervision, group supervision, and in-person mentoring are key components of clinical trainings. Thus, developing and delivering diverse counseling trainings by utilizing effective synchronous learning cannot be emphasized more in the field of counseling training. The purpose of this chapter is to explore effective, efficient, and achievable synchronous learning methods by analyzing current counseling graduate trainees' practical experiences on synchronous learning. The chapter will discuss diverse synchronous learning tools that counseling graduate programs offer and the effectiveness of these methods as well as the directions and implications for researchers, educators, and counseling practitioners in higher education.

INTRODUCTION

With the impact of distance learning and highly equipped technologies in higher education, online learning has become one of the most frequently discussed topics in the field of higher education (Young, 2011). Online learning has been considered as a vehicle for enhancing pedagogy, and improving opportunities for students to access education with lower costs (Taplin, Kerr, & Brown, 2013). Along with this educational trend in higher education, graduate training programs for counseling (e.g., counseling, counselor education, counseling psychology, and student affairs) utilize online learning tools to educate and train future counselors. However, counselor educators have been questioning whether students can develop micro-counseling skills and interpersonal skills (Ivey & Daniels, 2016) through online training and whether online delivery methods are appropriate.

Although the advantages and positive impact of online courses in higher education are well documented: student retention rate, student enrollment, diverse pool of student population, and degree completion rates (Allen & Seaman, 2013), the effectiveness and implementation of online courses in the counseling field is still underdeveloped. Online counselor training programs have been examined by counselor educators, and researchers in the past. However, existing literature primarily focuses on specific areas of trainings such as ethical issues of online counseling programs (Abbass et al., 2011; Rousmaniere et al., 2014), clinical supervision issues (Abbass et al., 2011; Rousmaniere et al., 2014; Rousmaniere & Frederickson, 2013), facilitating interactions (Walker & Rockinson-Szapkiw, 2009), and counseling skills development (Ilieva & Erguner-Tekinalp, 2012; Nelson, 2014). Therefore, relatively little is known about the students' and trainees' perspectives on effectiveness of online counseling courses and online training tools. In addition, studies of online counseling courses focus on asynchronous tools using quantitative research methods except for a limited number of mixed method studies (Nelson, 2013).

This gap suggests that exploring counseling students' and counseling trainees' perspectives and experiences of online counseling courses and synchronous learning tools and effectiveness of this learning method will be beneficial to understand special learning methods in this specific field and to develop more effective and accessible training programs for future counselors. The purpose of this chapter is to explore effective, efficient, and achievable synchronous learning methods by analyzing current counseling graduate trainees' practical experiences on their online courses and synchronous learning methods using a qualitative inquiry. This chapter will also discuss future research recommendations and practical implications for both trainees and trainers as well as counseling program developers.

BACKGROUND

Online Learning

According to Allen and Seaman's (2015) definition, online education is defined by the percentage online courses compared to in-person courses. For example, if 80% or more of course content and interactive activities are offered online, the course is considered an online course. There are multiple online course platforms such as Blackboard, eCollege, D2L (formerly Desire 2 Learn), Canvas, and BBlearn. Each platform provides different methods of content delivery, discussion board, and assignment submission tools. As educational technologies including the internet have dramatically evolved, educators have developed different types of online courses (Clark & Mayer, 2011). According to Allen and Seaman's (2015) report, more than 34% of all undergraduate and graduate students in U.S. higher education institutions have taken at least one online course since they entered college. Public four year institutions reported a seven percent increase in online enrollment, and private four year institutions experienced growth rates for online enrollment by 13 percent during the 2016-2017 academic year (Hall, 2017). Due to the increase in online courses and programs across diverse disciplines in higher education institutions, educators have developed various tools and learning methods to deliver knowledge and skills effectively.

Technological Teaching Tools for Online Courses

Two major online learning technological tools to facilitate diverse online courses are asynchronous method and synchronous method. According to Oztok and colleagues (2013), asynchronous learning methods

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

is providing learning environments for teachers and students to engage and interact at different times. Examples of asynchronous modality are powerpoint slides or video-recorded lectures that learners can access at any time, online discussion board that both instructors and learners can engage in discussions at their convenience, and Q and A sessions that learners can post questions and instructors can respond to those posted questions. Because asynchronous learning provides learners enough time and space to reflect on their learning and react to educators' instructions before their actual responses, asynchronous methods are more attractive to students. In addition, both leaners and educators can select their most convenient time and place of engaging in learning, giving more flexibility and benefits of online courses to students and instructors (Degiorgio & Kampfe, 2009).

On the contrary, synchronous learning methods delivers an educational environment where students and instructors can meet and interact online simultaneously: learners and educators cannot select their convenient time and space to learn and teach, but their learning space and time is limited to a mutually agreed and pre-arranged time. The primary methods of synchronous learning is audio and video conference, video presentation, and live chat (Brett & Hewitt, 2013).

Although these learning tools cannot be utilized by every student and teacher because some individuals are not familiar with utilizing these live methods, students and educators can present their thoughts and information, and interact live as if learning is happening in a traditional in-person class space.

Benefits of Synchronous Learning

Advantages and benefits of synchronous learning methods have been well-documented. Giesbers and colleagues (2014) found that synchronous methods in education are helpful in students' group decision-making process and cognitive complexity, Oztok and colleagues (2013) reported that synchronous learning methods make students more satisfied with online courses. For educators, synchronous learning methods help teachers to understand students' learning attitude (Huang & Hsiao, 2012). In addition, e-conferencing using a synchronous learning method promotes both students' and educators' social presence (Rienties & Toetelel, 2016). Although synchronous learning tools appear to be less convenient compared to asynchronous methods because educators and students need to present and interact at the same time, synchronous methods are widely used to overcome disadvantages of asynchronous instructions. In the next section, counseling online programs and methods will be discussed.

Counseling Online Programs

Although counseling professionals have not been active to utilize and adopt new forms of learning technology due to the unique characteristics of counseling training (Rousmaniere, Abbass, & Frederickson, 2014), the use of computer based technologies in the counselor training has evolved. The Council for Accreditation of Counseling and Related Educational Programs (CACREP) reported that 12 counseling graduate programs (e.g., Clinical Mental Health Counseling, School Counseling, and Counselor Education) are online degree CACREP accredited programs (CACREP, 2016).

Researchers (Arredeondo & Arciniega, 2001; Corey et al, 1993; Giovannelli, 2003; McAuliffe & Eriksen, 2000) investigated necessary counseling skills and critical areas require training through counseling training programs: building empathy, self-awareness, self-reflection, compassion, being open-minded, being comfortable with ambiguity, being comfortable with silence, being open to diverse worldviews and perspectives, being open to clients' diverse background and experiences, and being flexible with

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

emotionally or cognitively dysfunctional clients. Although the above mentioned necessary counseling skills are well-documented through traditional counseling courses, empirical studies and explorative studies on counseling skills developed through online counseling courses are still underdeveloped. The main focus of existing literature on online counseling training programs has been specific outcomes on counseling skill development and counseling competencies (Ekong, 2006; Lundberg, 2000).

As the counseling field becomes more diverse and international, development of cultural competencies is considered as one of the important counseling skills that needs to be learned through counseling training, and Ilieva and Erguner-Tekinalp (2012) examined the effectiveness of online training for students' cultural competency development. They found that learners appreciate the convenience and flexibility of online counseling courses, and students showed positive reactions on opportunities of reflections. In addition, participants reported that they felt comfortable sharing their personal experiences, reflections, and opinions through online space compared to the face to face format.

Supervision is a significant componentof counseling training, and online supervision through online counseling training (Abbass et al., 2011; Chapman, Baker, Nassar-McMillan, & Gerler, 2011). Students reported the positive side of online supervision through online counseling training is easier access to licensed and well-qualified clinical supervisors, productive supervision sessions, better access to clinical supervisors for students from out of the country (e.g., international students) or students who reside in rural areas (Abbass et al., 2011; Chapman, Baker, Nassar-McMillan, & Gerler, 2011). Additionally, Conn, Roberts, and Powell (2009) reported that supervisors preferred being trained by the hybrid supervision group indicating that easy access to supervisors was essential. Coker et al. (2001) found that students reported online supervision as very positive, and Perry (2012) also indicated that the online supervision is an effective modality for supervisees' professional identity development.

Despite the benefits of online supervision, counseling supervisees also reported negative side effects of online supervision: limited ability to capture and recognize non-verbal communication among supervisees and supervisors (Coker, Jones, Staples, & Harbach, 2002); now being comfortable with technologies and less nuanced verbal and non-verbal ques including reduced eye contact (Sorlie et al.,1999).

Synchronous Learning in Counseling Training

Although there is a growing number of literature on online learning in counseling programs, studies on synchronous learning methods specifically related to counseling trainings are still underdeveloped. However, a few researchers have focused on different synchronous learning methods for counselor training programs. For example, Rousmaniere and Frederickson (2013) examined the effectiveness of online clinical supervision by using online live one-way mirror supervision sessions. They found that online live one-way mirror clinical supervision is beneficial and effective for both supervisors and supervisees and the tool can be utilized for those individuals who have limited access to their clinical supervisors.

Synchronous chat is a widely used synchronous method for counselor training. It involves a group talking online simultaneously. Instructors use text chats, verbal chats, or both (Osborn, 2009). By studying online chats for counseling graduate students, Jin (2005) reported effectiveness of synchronous chat and students' positive reactions on live chats. In Liebowitz's (2003) study, students rated live chat role play methods higher compared to the role play practice in traditional classrooms. Liebowitz's (2003) highlighted the effectiveness of role play using online live chats. In addition, synchronous tools for counselor training is not limited to the classroom only. By using a live chat for virtual office hours, McKeage (2001) reported that many trainees enjoyed the idea of a live virtual office while they still like

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

the face-to-face office hours. Ling (2007) also found that an online synchronous tutorial chat was very effective for both educational and social purposes. Schwier and Balbar (2002) reported students' sense of community as one of benefits of synchronous chats in counselor training programs.

Although a growing number of studies have focused on online counseling programs and learning tools, and synchronous chats for counselor training programs, relatively little is known about the effectiveness of diverse synchronous learning methods for diverse counseling programs and students' experiences and perspective on synchronous learning methods. Given the dearth of empirical and exploratory studies on this specific topic and population, systematic studies on counseling students' and trainees' perspectives and experiences on synchronous learning tools are necessary. The present study will add to the body of research on synchronous learning in counseling training, and is significant as the study will contribute to the field of counseling, student affairs and higher education. This study will help inform the practice of counseling professionals, scholar practitioners, and researchers in their work with this growing and complex constituency.

RESEARCH METHODS

The basic qualitative approach was employed as the study design of this research given the exploratory nature of the data and inquiry. Basic qualitative studies seek to "discover and understand a phenomenon, a process, or the perspectives and worldviews of the people of the world involved" (Merriam, 1998, p. 11; Creswell, 2009). Therefore, the author tried to explore counseling graduate students or counseling trainees' perspectives and experiences who study and experience synchronous counseling learning tools as part of their graduate degrees in online counseling programs.

Participants

Participants were recruited through purposeful sampling for qualitative study (Palinkas et al., 2015) based on characteristics of a population and the objective of the study. The final sample consisted of 15 graduate students who are currently enrolled in online counseling graduate degree programs at large research universities (e.g., mental health counseling, school counseling, counseling student affairs, and counseling psychology). For representation of geographical locations, participants were invited from different regions (e.g., West, East, South-West, Mid-West, and Mid-Atlantic). To capture students' genuine experiences, graduate students who took at least two online courses were invited to participate. Table 1 displays participants' pseudonyms and demographic information.

Data Collection

Data was composed of brief field notes including reflections on the interviews, audiotaped records, and the transcripts of one individual semi-structured interview with each participant. Each interview was conducted between 1 to 2 hours. Interviews were conducted during the spring 2018 semester (from January to May, 2018) by the author of the study and a ten dollar gift card was given to each participant as compensation. The semi-structured interview began by completing a brief demographic information survey asking participants' basic information including marital status, estimated family income, and parents' educational background. Open-ended questions were used, such as participants' positive and

negative experiences of synchronous chats, video conferencing, and synchronous virtual office hours, effectiveness of synchronous learning tools, what participants want to add to improve effectiveness of synchronous methods. Table 2 presents the full interview questions.

Data Analysis

All interviews were transcribed by the author and shared with author's research team members. A constant comparisons method by Glaser and Strauss (1967) was employed to code and analyze transcripts. Keywords in the transcripts were highlighted and similar concepts that emerged consistently and frequently were grouped together under a common category. The respective emergence from transcriptions

Table 2. Interview questions

1.	Please list all online courses that you have taken.
2.	What kind of synchronous learning methods did your instructors use?
3.	Do you think those synchronous methods were effective? If yes, why? It no, why not?
4.	What was the most effective and helpful synchronous method, and why?
5	What was the least effective synchronous method, and why?
6.	What would you recommend to add to improve synchronous methods for online counseling programs?
7.	Tell me about your relationship with your clinical supervisor. Do you believe online meeting with your supervisor is as effective as in-person meeting?
8.	Feel free to share any experiences, reactions, and memories about synchronous methods in counseling program.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

was compared with that of the other data in order to check similarities or dissimilarities, and then the author compared all transcriptions in order to search for specific answers to the guided research questions (Corbin & Strauss, 2008).

Trustworthiness

To strengthen the trustworthiness of interpretation for the qualitative inquiry, member checks were used. Randomly selected participants were contacted by the author after the first draft of the manuscript was developed and were asked to provide any type of feedback and reactions on the analysis interpretations of their conversations if they were compelled to do so. It was confirmed that no participants expressed questions or disagreement on the analysis or their quotes.

Researcher Positionality

The author participated in the entire research process including conducting individual interviews, data analysis, and interpretation. The author is an assistant professor in education and completed her counseling master's program and student affairs doctoral program. The author worked as a counselor at the university counseling center for four years and received clinical supervision for her practice. Although she had not taken any online counseling courses in her graduate education, she is currently teaching two online doctoral courses every semester. While the author recorded the field notes from the interview for the study, she reflected on her own experiences as a counselor trainee.

Results

Six key themes were identified on counseling graduate students' experiences on synchronous learning methods for counseling training: 1) synchronous chats were effective; 2) video conferencing was effective; 3) synchronous virtual office was effective; 4) synchronous learning is beneficial for those who cannot access instructors or clinical supervisors; 5) synchronous learning is not the best for group supervision; 6) in-person class is preferred for counseling training programs.

1. **Synchronous Chats Were Effective:** All fifteen participants reported that synchronous chats were very effective and they learned a lot about necessary skills and lessons through interactive sessions. Allison, a 25 year old female student in Master's clinical mental health program said,

It worked really well to me. I was able to write all questions and issues that I had with my mock client, then I talked to the professor through live chat. Because I was able to prepare what to ask and what to learn, I could use the live chat time very effectively.

Some students indicated that online chats were more helpful for them to engage discussions and academic conversations compared to face-to-face conversations. Iris, a 22 year old female Master's student in clinical mental health program indicated,

You know, I am very introverted and quiet. I struggled a lot at the class discussions because I did not feel comfortable to talk in front of the class. But, this live chat, it was different. I did not need to worry

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

about what to talk or care about what others would think about my opinions. I felt comfortable sharing my thoughts through the live chat. To me, online class was better. I wish there were more online courses in college, then I would not be that quite.

Participants also reported that they were able to share their thoughts and opinions more honestly in online environments. Doris, 25 year old female doctoral counselor education student said.

I think online setting makes people more brave and honest. At least to me. I don't really talk about in class because sometime I am not quite sure whether I am on the right track, or I just don't want to be judged by other. So I used to be not very active in class. But for this online class, I noticed that I became brave. I was able to talk honestly not caring that much about what professor would think or what if this is wrong. In terms of that, online class was more effective to me.

As mentioned above, synchronous live chat for counseling programs appear to be effective and students benefits its unique environments and opportunities.

2. **Video Conferencing is Effective:** participants reported effectiveness of video conferencing for their group supervision and groups counseling class. Regular supervision is required for counseling training programs. For online trainings, live video conferencing is the only method for synchronous and interactive engagement for supervision, and all of participants' current degree programs utilize video conferencing for supervision meeting. Dylan, a 33 year old Master's student in school counseling program said,

How can you meet your supervisor? I think video conferencing is the sole method for supervisee-supervisor conversations. I audio-recorded my internship session and I played the audio file in my live video conferencing session. Then my supervisor listened and provided me her feedback on my sessions. How effective! I think I maximize this an hour long supervision session not only because it is mandatory for graduation, but also I definitely learn a lot from my supervisor. As I prepared for the supervision meeting, I could reflect on my works and think what I have done well, and things that I did not like as an intern counselor. Then, I could talk to my supervisor.

Learning about diverse perspectives from fellow trainees who live in different places was another reason why students think video conferencing is effective. They reported that they enjoyed learning diverse perspectives about their clinical experiences and mental health issues from their classmates who live different states or different countries. Peggy, a 41 year old doctoral student in school psychology program indicated,

I am an old woman. I think I am the oldest in my cohort. But in online learning environment, it does not matter. The class is so diverse. As I open the computer window for live video conferencing for supervision, I see a student who is visiting to UK logged in and share her experience interning in UK. Isn't that interesting? That is not the only case. Because online learning helps learners to overcome geographical restriction, we are able to meet diverse trainees in the field. I think it's a fortune.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Synchronous Virtual Office Was Effective

In addition to live chats and video conferencing, students benefit from synchronous virtual office provided by the instructors. Many online courses offer virtual office hours where instructors can provide class related information and answer to students' questions. Some educators also hold synchronous live virtual office sessions so students can visit their professors for questions and advising sessions via online tools. Students of the present study also reported that they visited their professors' virtual office using video conferencing or live chat depending on the instructors' and students' mutual preference. Students reported that synchronous virtual office was very effective as instructors held weekly office hours (e.g., approximately 1-2 hours per week, regularly) and students were able to sign up for a virtual meeting. They indicated that virtual office hours worked well similar to in-person office hours. Patricia, a 32 year old female student in the Master's counseling student affairs program shared her experiences with synchronous virtual office,

To me, live virtual office worked great. My professor treated her virtual office hours as if it is the real physical office hours. She set up a sign up sheet for the office hours in advance, then students signed up and we met with the professor at assigned time using either Skype, Google Hangout, Zoom, or whatever worked for both student and professor. I believe that I maximized my signed time and I brought with many questions. Professor managed the virtual office hours professionally and I received great support. I think virtual office hours made my online courses more positive because I felt I was supported enough.

Similar to other regular face-to-face counseling programs, students of online programs meet their faculty advisor or dissertation chairs on a regular basis using synchronous office hours. Callie, a 29 year old female doctoral student in counselor education program addressed how she liked the virtual office hours,

In my master's program, my advisor was extremely busy and sometimes she had to cancel our regular advisor-advisee meetings due to her unexpected schedule. But for this online program, my advisor never cancelled our virtual meetings because she was able to make it to the synchronous online meetings. I think this is a great advantage of the synchronous online meeting, especially for busy students and faculty. I have bi-weekly advising meeting to report my research progress and to ask any research related and dissertation related questions to my advisor. I feel very comfortable working with my advisor online and this virtual office hours on a regular basis worked for us really well for the past 2 years. Looking back my master's program, I really think that this synchronous virtual office hour is a wonderful tool to me.

4. Synchronous Learning is Beneficial for Those Who Do Not Have Access to Instructors or Clinical Supervisors

Most participants indicated that synchronous learning methods made their online education possible, especially for those who do not have access to the instructors or clinical supervisors. For counseling students who worked full time or who reside in different cities or states, they were not able to enroll in the counseling programs because they could not commute to institutions to take courses or attend required meetings. Given that clinical supervision and in-person counseling practicum are significant for the counseling trainings, traditional face-to-face programs were not able to accommodate students who work full time or who live in different locations. However, as universities provide online counseling

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

programs, students from different states or different countries are able to enroll in graduate programs and take classes online. In addition, synchronous learning methods such as synchronous video conference for individual supervision and group supervision made online counseling programs real and possible because these clinical supervisions are required for program completion as part of supervised clinical practice. Dylan, a 33 year old part time counseling master's student shared his experiences as a full time K-12 teacher who takes counseling practicum class.

This is my 8th year teaching full time at a middle school and I decided to earn a master's degree in school counseling to be eligible to provide counseling to my students. But it was not easy to find a good program that I can enroll while I am teaching full time because many school counseling online programs required certain number of face-to-face clinical supervision and group supervision hours. So it took me a little while to figure out the program that I can receive approved online clinical supervisions. The current program allowed me to meet with my clinical supervisors online, so I was able to enroll in this program. Ah, they required synchronous online supervision, so I need to meet with my supervisors at the synchronously using a google hangout program. I even meet with my supervisors online while I am visiting other cities due to teachers' conference. It's very effective. I like it.

Peggy, a 41 year old school part-time psychology doctoral student who is currently working full time as an assistant principal addressed how much she appreciated her online counseling class.

I only take one or two classes in regular academic year because my work schedule is full as an assistant principal. Last semester, I took a clinical assessment online class and I met with my clinical supervisor every week via synchronous video conferencing. While I was visiting China to learn about China Initiative Partner Program in our school district, I continued my regular weekly clinical supervision meetings using video conferencing for three weeks and those worked beautifully. Without this synchronous clinical supervision sessions, I was not able to finish the class last semester. I really appreciated this opportunity that I can keep my job while taking the Ph.D level classes. I admire this online program.

5. Synchronous Learning is not the Best for Group Counseling and Group Supervision

Although most participants reported positive experiences on online courses and synchronous learning methods, many of them also addressed that there are some limitations to online groups supervision. Students reported that online courses are not effective for group supervision even though they use synchronous meeting tools because group counseling and group supervision require complicated and sophisticated group dynamics which video conferencing cannot fully capture despite of high technology. Stephanie, 25 year old female student in master's counseling student affairs program said,

I think this online counseling student affairs program is almost perfect or even better than the traditional face-to-face program except for my internship class due to our group supervision sessions. Twenty students who enrolled in this internship class get to share our internship experiences and my cohorts and the instructor provide feedback, recommendations, suggestions, or sometimes emotional support. But, how can you really provide well-advanced emotional support when you talk to your computer via webcamera? They are real people, but it's not real. They are there. But they cannot hug me or pat on my bag to comfort me or encourage me whenever I collapse or show my emotion. One of my cohorts was

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

sobbing while she was sharing her internship experience at the student advising center. She felt strong connection with her student because her student struggled with very similar family issues that she had with her own family. She looked lost. She looked devastated at that time. But she was in her room and no one in that class was able to visit her and hugged her to help her, of course. All we could do was talking and encouraging verbally which I don't think very effective. I am sure that instructor felt the same. She is a wonderful teacher, but she could not travel to the student and help her. I noticed that it was the limitation of the online internship program. Don't you think so?

Students also indicated that the level of conversations and sharing in group supervision and group counseling was not deep but shallow because it was a video conference. Jenna, a 27 year old counseling psychology doctoral student shared her experiences about taking an online group counseling program,

Group counseling was the only program that I did not like, that I could not like. Our group dynamic was way too shallow. The reason why I can tell for sure is because I took a group counseling class in person in my master's program three years ago, then I am taking this online group counseling now, so I can compare those two. In the past in-person group counseling class, our conversations were genuine. We showed our authenticity to one another as future counselors. Those conversations and non-verbal language were real and genuine. I believe that we all learned a lot through our genuine conversations and openness. But for this current online group counseling class, I definitely see that my professor struggles a lot because students are not participating in engaging. I think the online environment is not the best for us to share, talk, and validate. Also, it is not easy to understand other classmates' intention or real conversations simply because it's synchronous video conferencing. How can we catch sophisticated emotions and feelings which is very important for the group counseling settings? I wish that I could take this class in person, but I know it is not possible.

6. In-person Class is Preferred for Counseling Training Courses

The last and the sixth emerged key theme is that counseling graduate students prefer to take in-person counseling training courses over online counseling courses. Seven participants indicated that they would not recommend taking online counseling or clinical supervision courses if there are other class options because genuine and supportive interactions are lacking in counseling practice online class. Students reported that in-person counseling classes and supervisions are more effective and more real compared to online counseling courses. Olivia, a 38 year old counselor education doctoral student said,

I am not sure if this is because I am a low tech person or because I am relatively older than other traditional students. But video conferencing for my individual counseling practicum and weekly supervision is not the same as the regular face-to-face meeting. How can you comfort or encourage your supervisee through video chat? How can you capture your supervisor's non- verbal sign well? Although I believe the power of online classes, especially for a busy woman like me, I have four children and my husband is out of town for 6 months of the year, online class works well for most of cases. But I would prefer to take in-person class if it's a counseling class.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

SOLUTIONS AND RECOMMENDATIONS

The present study explored current graduate students' perspectives and experiences on online synchronous learning methods in their counseling training courses. Most students showed positive experiences on their synchronous learning tools for counseling such as virtual office hours, video conferencing, and video counseling sessions while they still believe that there are limitations on online counseling courses compared to the traditional face-to-face counseling course due to limited humanistic and emotional interactions for online courses. Given the fact that the nature of counseling training requires genuine interpersonal interactions and non-verbal communications, students' struggles and challenges with online counseling courses are considered as common issues for the area of the study. However, if the limited aspect of synchronous learning methods for online counseling graduate training can be updated and modified, online counseling courses can be more powerful, accessible, and effective to accommodate diverse students and trainees who cannot access traditional face-to-face education. As students indicated from this study, trainees wanted to have genuine and authentic conversations and supervision through their courses and clinical supervisions. To support their needs, advanced technology for real interpersonal interactions is recommended. Although the counseling graduate programs have not yet developed more advanced learning tools to capture the real humanistic side of online synchronous communications, if both trainees and trainers are fully aware of limitations of online counseling courses and clinical supervision, they may invest more energy and focus to participate in those programs to overcome the challenging part of online trainings. Also, adding monthly or quarterly in-person meetings to support students' and supervisee's needs may be another recommendation to overcome limitations of synchronous online learning methods. Students indicated that they wanted more genuine and real support from their clinical supervisors because meeting with supervisors via online is limited to exchange more real interactions and hard to catch trainees' strength and weakness of non-verbal body language or interpersonal skills. Therefore, hiring and assigning a clinical supervisor who resides in the same city where trainees reside in addition to students' faculty supervisor can be a solution to fill the gap between online and in-person clinical supervision. For this solution, graduate programs need to be supportive and professional to locate and hire licensed, professional, and well-known clinical supervisors of each location.

FUTURE RESEARCH DIRECTIONS

This study's findings inspire future researchers. One of the important issues that emerged from the present study was that students reported their genuine connections with trainers and supervisors via online programs become weak as the semester proceeded. Although Orzok and colleagues (2013) reported that online student-instructor communication via synchronous video conferencing is as effective as traditional face-to-face communication, this study indicated that there are limitations to synchronous online communications. Therefore, it is recommended for researchers to investigate the effectiveness and impact of student-educator synchronous video conferencing communications on learning to understand specific areas of limitations. An interesting aspect of counseling graduate students' experiences with online courses was students' employment status. Whether students were working full time or part time impacted the quality of their education quality. As full time employed students indicated that they appreciated online courses more because online training options were the only opportunity for them to enroll while they were working full time. Because full time working students did not have many options

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

of taking in-person courses at their desired institutions, they appreciated their current online programs and their satisfaction level was higher. Therefore, more investigations of students' employment status or work experiences related to their reactions and experiences on synchronous online trainings are recommended. It is shown that students had different reactions on different synchronous learning tools (e.g., video conferencing, virtual office hours) in their programs. To provide more effective and individualized services and trainings to students, studying on effectiveness and unique characteristics of each synchronous learning tools is strongly recommended. Evidence based knowledge on technology will enlighten both educators and students as it will help them understand what they are teaching and what they are learning, so that they can select the most effective and beneficial learning tools. As the findings of this study indicated, geographical locations of learners were important factors to students' experiences and their perceived effectiveness on synchronous learning methods: participants who lived in major cities or suburbs reported more positive experiences on online counseling programs compared to those who resided in rural areas. Given the fact that students in the cities can easily access learning resources and possible clinical internship sites and clinical supervisors in town, it is inferred that students in the cities or suburbs consider online learning tools more positively believing that they may have diverse resources in addition to their online courses while students in rural areas consider their trainings and learning opportunities as limited due to geographical restrictions. Therefore, further systematic explorations on students' experiences and reactions on synchronous online counseling learning methods depending of their geographical locations are recommended. This detailed information will provide valuable insight on the program and what individuals want.

CONCLUSION

As online learning continues to be one of the major issues in higher education, many interpersonal skills related majors (e.g., counseling, medical school, nursing) synchronous online learning technologies play an important role in supporting both educators and learners. Furthermore, along with growing student population in online counseling graduate programs, synchronous online learning tools have become important in light of supporting and advancing educators' and students' quality of education. Therefore, online counseling graduate programs and higher education researchers and online instructors have a responsibility to address the needs and concerns of graduate students in counseling training programs. The findings of this study will contribute to assist professors, advisors, and higher education administrators better meet the needs of counseling graduate students who enroll in online programs who depend on synchronous online learning tools and who benefit from the programs.

KEY TERMS AND DEFINITIONS

Clinical Supervisor in Counseling: A formal and disciplined supervisor who reviews and evaluate counseling trainees' clinical works, and provide advice, suggestions, professional support, and encouragement as part of training procedure.

Counseling Psychology: A general practice and health service provider in professional counseling. Counseling psychology deals with personal, emotional, social, work-related, and physical concerns to improve wellbeing of people.

Licensed Counselor: A nationally licensed individual who is qualified to provide personal and group counseling to their clients. To be qualified, individuals need to complete at least a Master's degree in counseling from accredited institutions and fulfill 200 hours of supervised clinical practicum hours.

School Counseling: A professional help from a licensed school counselor by providing academic planning, exploring future careers and future school options, counseling students with academic concerns and challenges, and consulting with teachers about classroom management and student issues.

Student Affairs Professionals: Individuals who work with students in higher education settings by providing individual support, academic guidance, campus resource, personal counseling, and appropriate referrals to help students grow and develop in college.

Synchronous Conferencing: A real time online meeting that participants meets at the same time with the help of advanced technologies. Participants can engage in the meeting lively and receive feedback instantly.

Chapter 49
The Perception of Muslim Clients Towards Non-Muslim Counselors

Siti Salina Abdullah
University Malaysia Terengganu, Malaysia

Kamarul Md Shah
University Malaysia Terengganu, Malaysia

ABSTRACT

Having a counselor with a different religious background from the client might lead to conflicting perspectives. This chapter intends to explore the perceptive of a Muslim client in choosing a non-Muslim counselor. The concept of helping process, which is highly respectable in the teaching of Islam, is explicated. Muslims are encouraged to help each other, especially those who are in need. Preferably, a non-Muslim counselor should have some basic understanding of the Pillars of Islam prior to conducting a counseling session with a Muslim client. The knowledge will facilitate the counselor understanding process of the clients without bias. It is anticipated that the information presented herewith would benefit non-Muslim counselors and help them in understanding their Muslim clients better. This chapter also examines the cultural issues that may influence the effectiveness of a counseling session between Muslim clients and non-Muslim counselors.

INTRODUCTION

The challenges in human life today are highly complex. Counselor nowadays has become a place of reference to express a problem, seek advice, and a source of motivation. In addition, they also become a place of discussion about the various human scenario and diverse problems, which are getting increasingly critical and community-specific. Consequently, they need to equip themselves with vast knowledge and various skills not only to strengthen their existing counseling skills but also to deal with diverse clients of a different background. It is essential to streamline the counseling services offered to address the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

growing societal complex problems. However, there are counseling methods that emphasized the Western way of thinking, which are incompatible with the culture, religion, and norms of the society in Malaysia.

A counselor with good counseling skills but lack knowledge in the field of religion, or vice versa, has limitation in offering counseling services. For instance, if a client is facing a critical religious issues, the counselor will not be able to help the client, effectively. This is because religious issues must be handled with due care, especially matter related to the legal aspect of the religion. Hence, the question; could a non-Muslim counselor provide an effective counseling service to a client, especially when it involves religion-related issues?

Counselling is a process that involves a counselor and a client in which the intention is to have a better outcome for the client. Both the client and the counselor are important to the counseling process. Having a counselor from a different religious background from the client might contribute to conflicting of perspectives between the counselor and the client. Multicultural counseling, as explained by Sue and Sue (2008), refers to the role and helping process that employed a method and a goal setting consistent with the client life experience and values. It also takes into account the client identity as an individual and a member of a society by using a strategy that is universal and specific to the client's culture when making an evaluation, diagnosis, and a treatment for the client. The cultural diversity between a counselor and the client makes the counseling process unique, which should be taken into account by the counselor. This is explained by Hays and Edford (2010) who asserted that the role of a client's cultural identity must be given due consideration during a counseling session because it has a strong influence on the client experience. A client who attends a counseling session with a counselor of a different religious belief is expected to undergo a unique experience. The limitation of understanding of the belief as well as the different values between a Muslim client and a non-Muslim counselor will somehow affect the counseling session effectiveness.

Counseling also occurs in the Islamic teaching. The concept of a helping process is highly commendable in the Islamic perspectives. It strongly indicates that Muslims are encouraged to help each other, especially towards those who are in need. The Quran and hadith also emphasize the need for a Muslim to be kind and helpful towards each other. A counselor needs to have some basic understanding of the Pillars of Islam to conduct counseling sessions with Muslim clients. The knowledge and understanding of this fundamental aspect of Islamic teaching help to ease the process of helping a client without prejudice. As a multicultural counselor, the combination of knowledge, awareness, and skills are the three main components required to conduct a counseling session, efficaciously. This paper explains counselling from the perspective of Islam, the duties of Muslim clients and issues regarding Muslim clients and non-Muslim counsellor. It is anticipated that the information offered in this paper would benefit non-Muslim counselor to have a better understanding towards their Muslim client. The non-Muslim counselor restricted understanding of the clients' belief as well as the different values between a Muslim client and a non-Muslim counselor will somehow affect the therapeutic relationship and the efficacy of the counseling process. This chapter also examines the cultural issues that may influence the effectiveness of the counseling session between a Muslim client and a non-Muslim counselor.

Counseling From the Perspective of Islam

Counseling is a process of a helping relationship between a counselor, who is trained and specialized in the field of counseling, and a client who needs an assistance and guidance. The helping nature of a counseling process between a counselor and a client is a noble feat, which is commendable in the Islam

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

religion. This deed is clearly stated in Surah Al Ma'idah [5:2], which means, "Rather, help one another in acts of righteousness and piety, and do not help one another in sin and transgression." This verse indicates that the nature of counseling, which is to help a client resolve the test he or she is currently facing, is highly praiseworthy by the Islamic teaching.

The counselor role in encouraging a client who is experiencing an impasse is greatly regarded in Islam. This is evidenced by the numerous hadiths narrated with regard to helping others. The first hadith mentioning this notion was narrated by Abu Hurairah r.a., who said, Prophet Muhammad (PBUH) decrees that "If anyone relieves a Muslim believer from one of the hardships of this worldly life, Allah will relieve him of one hardship of the Day of Resurrection. If anyone makes it easy for the one who is indebted to him (while finding it difficult to repay), Allah will make it easy for him in this worldly life and in the Hereafter, and if anyone conceals the fault of a Muslim, Allah will conceal his fault in this world and the Hereafter. Allah helps His slaves as long as he helps his brother." Another hadith narrated by Tabarani and Daraqutni stated, "The best of people are those that bring the most benefit to the rest of mankind." This means that the earnest assistance provided by a counselor to a client will be rewarded in this life and his adversity in the Hereafter will be eased. Thus, a career as a counselor who benefits the client through the counseling sessions is regarded a noble and respected profession in Islam.

A counselor plays a role in helping a client in distress or facing difficulties. The Quran speaks of the challenges faced by humans. The tests take various forms including physical (property and poverty), emotional (fear and concern) and personal as well as family trials. Tests are considered a mechanism to strengthen the trust and belief of a client as a believer of Islam. The following are some verses from the Quran, which explain the trials that befall humans.

We shall certainly test you by afflicting you with fear, hunger, loss of properties and lives and fruits. Give glad tidings, then, to those who remain patient. Al Baqarah [2:155]

Do you supposed that you will enter Paradise untouched by the suffering endured by the people of faith who passed away before you? They were afflicted by misery and hardship and were so convulsed that the Messenger and the believers with him cried out: "When will Allah's help arrives?" They were assured: "Behold. Allah's help is close by." Al Baqarah [2:214]

(Believers!) You will certainly be put to test in respect of your properties and lives, and you will certainly hear many hurtful things from those who are granted the Book before you and those who have associated others with Allah in His divinity. If you remain patient and God-fearing this indeed is a matter of great resolution. Ali Imran [3:186]

Know well that your belongings and your children are but a trial and that with Allah there is a mighty reward. Al Anfal [8:28]

These Quranic verses clearly stated that God always tests humans with various trials. No matter what trials befell a person, they are resolvable. The verse of Surah Al Baqarah [2:286] said, *"Allah does not lay a responsibility on anyone beyond his capacity. In his favour shall be whatever good each one does, and against him whatever evil he does."* This verse specifies clearly that God does not test a man beyond his capacity. In other words, whatever issue faced by a client can be resolved with the help of a counselor.

Understanding Muslim Clients

The Muslims believed that God is to be worshipped. As a Muslim or a believer in Islamic teaching, there are two sources of reference underlying their life as a Muslim—the holy Quran and the Prophet Muhammad's (PBUH) Sunnah. These two sources play an important role in providing guidance to the Muslims in their daily living. The Quran is the main guide for the Muslim due to its comprehensive content that explain all the elements required in a man's life (Rosmizi, Fazrul, Munira, & Roslizawati, 2012; Sue & Sue, 2008), which include social matters, family life, economics and business, sexuality, and other fundamentals of life (Sue & Sue, 2016). In fact, the Quran stated laws and rules that the Muslim need to obey. The second source of reference is the Sunnah or hadith that serves as a guide to the way of life, such as speech, adherence, character, personal disposition, and the nature of events based on the Prophet Muhammad (PUBH) conduct. In terms of cultural and religious values, the Muslims engage in the ritual prayer five times a day. They are also committed to fast during daylight for the whole holy month of Ramadan. In addition, those who could afford, they would devote a certain amount of their wealth for *zakat* and almsgiving and perform the pilgrimage at the holy city of Mecca (Nobles & Sciarra, 2000).

In addition to the two main sources of reference, a Muslim is required to adhere to the teaching of Islam in the aspects of faith, Islamic law, and morals (Rosmizi, Fazrul, Munira, & Roslizawati, 2012). A Muslim gains knowledge and understanding of the divine and prophethood through the teaching of faith or *akidah* as outlined in the Pillars of Faith. Through the Islamic law and morals outlined in the Pillars of Islam, every Muslim learn about the relationship of life with God, man, and nature. With the general understanding of Islam, every Muslim client practiced the understanding and teaching in their daily lives. The Muslim clients practice the knowledge and teaching of Islam in their daily lives according to their religious belief.

Some knowledge of the Islamic teaching could help a non-Muslim counselor to understand a client from the client's cultural perspective. Knowledge is one of the important components required in order to increase the competency of a multicultural counselor apart from awareness and skills (Sue & Sue, 1996, 2008, 2016). Othman Mohamed (2017) also agreed on the need for the counselor to have a profound knowledge of a client's culture. A counselor that acts as a facilitator will strive to understand a client from a personal aspect and the client's cultural background (Mohamed, 2017). The need to understand a client's cultural aspect is highlighted in the Multicultural Counseling Theory as proposed by Sue and Sue (1996) through the following six suggestions:

1. Multicultural Counseling Theory was introduced to identify the cultural elements more clearly and objectively within the existing counseling theories. In the context of a Muslim client, counseling theories were applied to understand the client issues without neglecting the Muslim client's cultural aspect.
2. The identity of a counselor and a client is formed as a result of a certain level of experience and context. This means any intervention need to consider the client as a Muslim in entirety by looking at the root cause of the issue; not only focusing on the client but also the client's surrounding, such as the family, society, and his/her culture as a Muslim.
3. The development of the cultural identity as the core that shaped the attitude of the counselor and the client towards himself/herself and others, with the client or outside the client community group. The attitude will affect one's feeling and behavior as well as one's worldview towards others. This

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

means the level of development of the Muslim client cultural identity must be clearly understood so that the conceptualization of the issues and goal setting of the counseling can be made accordingly.

4. A counselors' competency increased when he/she take takes into account the experience and the Muslim client's cultural values when setting the goals of the session. This means any goal setting should consider the fundamental doctrine set out in the Islamic teaching. Hence, the need for the knowledge and experience about Islam is essential when conducting a session with a client to improve the counselor competency.
5. The importance of using the society's role, effectively, to help a client of a multicultural background. This means, in addition to the general organization such as the Welfare Department (JKM) and the National Population and Family Organization (LPPKN), organizations that are specific to Muslim clients such as the Department of Religious Affair and the State Islamic Religious Control can be utilized to assist the client further.
6. The counselor awareness towards the importance of the cultural aspect of a Muslim client in a counseling session. This means the counselor understanding of a Muslim client's issues should include his/her relationship with the family, society, and organizations related to the client as a Muslim.

Cultural Assumptions and Misunderstandings

The counseling practiced in Malaysia is mostly based on counseling practiced in the West. Theorist such as Sigmund Freud, Carl Rogers, and others in the field are well-known to the counseling practitioners in Malaysia because they are used as the main references in the study of counseling at various level of education. The theories describe aspects such as human events, goals, techniques and the counseling process, the roles of counselor–client, and their application in the counseling sessions. The descriptions are quite convincing that those theories were chosen to guide the local counseling practice.

However, the current development of counseling knowledge, especially in Malaysia, indicate the emergence of a view that the counseling theory from the West lack in the spiritual aspect. Undeniably, counseling of the West disregard the spiritual aspect in its analysis. Several researchers such as Badri (1994) and Langgulung (1990) found that spiritual aspect was not emphasized by the western psychologists. It indicates the inappropriateness of the western counseling to be practiced in Malaysia due to several reasons related to the local culture and Islamic teaching. Islam believes that if humankind does not adhere to the revelation of the Quran and the Sunnah, they will not find the true resolution and gain the Creator pleasure, which is the ultimate life goal of a Muslim.

Nevertheless, this does not mean that western counseling cannot be practiced in Malaysia, however, it has to be adapted according to the practice and teaching of Islam. Philosopher Imam Al-Ghazali said, "there is a relationship between faith and religion with the spiritual enrichment." As a result, Islamic researchers are constantly trying to adjust the practice of western counseling to make it relevant to the culture of Muslim society. The main reason for this is because the principles of Islamic teaching is pertinent to every aspect of human life. Raba and Othman (1998) opine that Islamic counseling is applicable to all target groups, including children, adolescent, and adult. Two important points that are part of the major differences between the western counseling approach and Islamic counseling approach are:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Religion and life are inseparable because religion rules a major part of the human lives. This means humans will not do things against the religious teaching on the principle of fearing God's punishment.
2. Values have many roles in counseling because they underlie the selection of counseling theories and techniques as well as determine the treatment process and decision-making. In other words, the counselor's values also play an important role in the counseling process undertaken towards the development of a therapeutic and conducive relationship.

The difference in view between the western and Islamic approaches as indicated by numerous findings has brought many benefits by means of improving the effectiveness of the counseling sessions. Any difference of view should become a reason to assess and examine the principle of counseling as the medium of helping service. A point of similarity should be sought and an appropriate adjustment should be made as both will contribute to the development of counseling knowledge. Misconception should be minimized and an understanding should be optimized so that the religious and cultural elements become part of the aspect that helps the development and success of the counseling sessions.

Hamdan (2007) states that Islam is a religion that covers all aspects of life, such as spiritual, social, economic, political, and family. Islam is considered a way of life that does not separate religion from other aspects of life. Furthermore, Islam provides a variety of functions, such as the provision of comfort, meaning, identity, spirituality, and society (Abu-Raiya & Pargament, 2010). Pew Research Centre (2007) conducted studies on American Muslims and found that 72% of the respondents affirmed that religion played an important role in their lives. In addition, although Islam is like other religions, there are unique factors to be understood and need to be given thoughtful consideration (Abu-Raiya & Pargament, 2011). Therefore, it is important to understand the effect of religion on the treatment of counseling and how it affects the counseling process.

There is a growing need for a definite information on how to treat Muslim clients and how to engage them in a treatment process. The implications of this for the current psychologists are that there is no available source of reference when working with Muslim clients. Amer (2009) states that psychologists often gave up looking for published research that could explain the appropriate services and eventually turned to the mainstream media or colleagues to seek for advice and resources that were usually inaccurate due to false and biased information. This may suggest that the therapists did not use the best practice for the Muslim clients. Abu-Raiya and Pargament (2010) propose that there is a need for empirical studies that examine the effectiveness of some of the techniques used as suggested by psychotherapists working with Muslim populations. Hence, creating an important gap in examining the effectiveness of the techniques in the previous studies. In other words, there is a need to provide therapy with empirical-based information to ensure the best treatment is given to the Muslim clients.

Prior to seeking a professional help, a Muslim may be more likely to seek help from religious leaders (Kobeisy, 2004; Springer et al., 2009). Springer et al. (2009) indicate the Muslims believe that in trying to solve personal and family problems, they have to turn to Islam (page 232). Padela et al. (2012) studied 13 focus groups of Muslims that revealed the majority of respondents reported they consulted the Imam instead of mental health professionals. In general, Muslims view their religion and religious leaders as entities that would help them in dealing with their problems.

Additionally, the cultural norm and religious belief emphasize families' responsibilities in teaching children on the proper behavior in the society; thus, problematic children reflect negatively on their parents and families (Daneshpour, 1998). This view suggests that the family will be blamed for any

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

psychological problems arose and their inability to properly deal with the problem led them to seek out-of-the-kind assistance. This may be an important point for a non-Muslim counselor to consider when helping Muslim clients. Seeking out help may indicate that the person's faith is weak and a manifestation of a missing support system (Kobeisy, 2006).

Expectation of Muslim Client Toward Non-Muslim Counselors

The counseling process should take into account the cultural aspect of the counselor and client, thus, both the counselor and client should consider the meaning of culture. When an individual becomes a client, it means he/she is presenting his/her identity in the context of his/her culture to the counselor. The culture embodies the client identity, which comprises ethnicity, language, genus, economic status, family, learning style, and spirituality (Othman, 2005). A competent counselor always takes into account the cultural factor of the client and such counselor is said to have a multicultural competency. *Theory Multicultural Counseling and Therapy* by Sue, Ivey, and Pedersen (1996) and *Model Multicultural Counseling Competencies* by Sue, Arredondo, and McDavis (1992) suggest three characteristics or domains of competency, namely awareness, knowledge, and skill. Likewise, there are three dimensions of competency, which are:

1. Counselors' awareness of his/her own assumption, values, and cultural bias.
2. Understand the client's worldview from the perspective of the client's culture.
3. Develop appropriate intervention strategies and techniques for the client.

Counseling services in Malaysia are provided by counselors to clients of multicultural background. By the same token, clients met counselors of various cultural background including in the aspect of religion. A question arose; how does a Muslim client feels having a counseling session with a non-Muslim counselor? Ahmad Raba and Abdul Halim (1998) explicate that non-Muslim counselors have to master the knowledge of Islam as best they could before they can be a good counselor, particularly to the Muslim clients. This includes the understanding of the causes and the fundamental of helping in Islam. This requirement is deemed a major concern for non-Muslim counselors. Counseling from the perspective of Islam can be used to assist clients regardless of race and religion. The implementation of Islamic counseling has to be done systematically, similar to the western counseling. The Islamic counseling is based on the Al-Quran and Sunnah, which are being practiced by the Muslims. This aspect needs to be understood and taken into consideration in the counseling practice by non-Muslim counselors. If non-Muslim counselors can embrace this practice, it will give a good impression to the Muslim clients, hence, they will be more willing to undergo counseling sessions with non-Muslim counselors.

There is a growing need to get specific information on how to get Muslim client involved in the treatment process. The reason for this is because in the United State for instance, despite the increasing number of Muslim citizen, they are less likely getting psychological treatment (Kobeisy, 2004). Inayat (2007) notes several reasons for this occurrence, which include a feeling of distrust towards the counseling service provider, fear of the treatment process, fear of racial and discrimination, language barrier, communication differences, and cultural and religious issues. Khan (2006) conducted a survey on 459 Muslims in the Ohio region regarding client attitude towards therapy. Only about 11.1% indicated that they have been using a professional counseling service within two years while 15.7% of the respondents agreed that they actually need the service. The Muslim society is facing numerous difficulties, such as

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

anxiety, depression, psychosomatic difficulties, PTSD, alcoholism, family problems, adjustment disorder, difficulties with prejudice and discrimination. For these reasons, Muslims need the clinical services as much as other population. Therefore, it is important to understand the concerns and uniqueness of Muslim society.

The study of 121 Muslim clients in Washington DC and Chicago by Kelly, Aridi, and Bakhtiar (1996) found that a small majority (52.9%) preferred Muslim counselors while 43.8% chose either Muslim or non-Muslim counselors. They also found that if they need to go to non-Muslim Counselors, more than 50% of respondents said it was very important and 25% felt it was important for the counselors to have similar religious values with them. It is also important for the counselors to understand Islam; 56.2% believed it is very important and 29.8% thought it is quite important. Carolan et al. (2000) found the same outcome in his study in which while seeking out help, a Muslim counselor was the Muslim client first choice. Nevertheless, non-Muslim counselors are known in the Muslim community as a cultural-sensitive professional (Carolan et al., 2000) and would be an ideal option if a Muslim professional is unavailable. In addition, there are some clients who may prefer non-Muslim counselors who are sensitive towards their culture (Keshavarzi & Haque, 2013; Kobeisy, 2004). These findings suggest that what is important for the Muslim client is to seek help from a professional, however, there is a concern of trust towards non-Muslim counselors and the need for them to understand Islamic teaching.

These studies reveal that Muslim clients also need professional counseling services although they could fulfil these needs according to their culture and beliefs. This is because Muslim clients are experiencing the same difficulties as other clients. Similarly, they are willing to undergo counseling sessions with non-Muslim counselors who are, professionally, deemed dependable counselors. However, the multicultural skills of non-Muslim counselors play an important role and could impact the perception and trust of the Muslim clients. This means that the multicultural competency of non-Muslim counselors should be improved from time to time in line with the changes that occur in the society, especially Muslim community.

In a counseling session involving a Muslim client, the role of the therapist may be different. A therapist can play a role as an advisor or a teacher and the client as a student (Ahmed & Amer, 2012; Keshavarzi & Haque, 2013). This situation differs from the western culture approach in which the therapist may suggest to a client an option of to do something but the client does not necessarily have to act on the suggestion. According to Hedayat-Diba (2000), even though Muslim clients do not believe in the therapists, they generally give a lot of power to the therapists and adhere to what is recommended or set by the therapist, at least in the initial stage. If they indicate otherwise, it would be considered offensive, hence, the client passive attitude in the treatment process. Hedayat-Diba (2000) also states that because psychological symptoms are often tangibly expressed, they are often expected to heal without involving the spiritual aspect; just like a person going for his/her doctor's appointment. Such circumstance gives a lot of power and responsibility to the therapists. However, Keshavarzi and Haque (2013) assert the role of a practitioner in assisting and guiding a client through the process towards self-realization and willingness to contemplate. It is important for the therapists to determine a collective approach; balancing the power given to them and keeping in mind the client wellbeing.

One of the concepts and fears felt by Muslim clients is likely to reflect their perceptions of how the therapeutic process will take effect. Kobeisy (2004) propose that the lack of information about the preparedness and expectation of counseling and misinformation on counseling from others may prevent Muslims from seeking professional help. This circumstance is different from those who are living in the United States or who have been receiving their education from the US academic institutions (Kobeisy,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

2004). In general, information about therapy is rather limited. Kobeisy recommends the type of information considered beneficial for the clients, including therapeutic function, education and training of the therapists, helpful therapeutic issues, and counseling expectations. In addition, it is also important to inform clients of the therapy procedure, such as what to expect during the sessions and the financial liabilities (Kobeisy, 2004). Hedayat-Diba (2000) also suggest educating clients on the importance of time boundaries, such as appointment, delays, and non-attendance sessions. Graham et al. (2008) propose to improve the information and information sharing by safeguarding confidentiality and to clarify the roles and goals of social service agencies. Overall, the provision of information when giving a treatment to a client is deemed an important step to change clients' negative attitude towards therapy.

However, there are other challenges to be considered during a therapy session such as the religion aspect. One possible reason for this related to the psychological training. More than 90% of the psychologists studied revealed that their education and training in religious issues are scarce or non-existence (Shafranske & Malony, 1990; Shafranske, 1996), in other words, less than 20% reported that they have some knowledge of religious psychology. Therefore, a possible hypothesis for the difficulty of combining religion with the treatment is that psychologists lack training in the field of religion. Another possible reason for the difficulty of incorporating religion into the treatment is the therapists own religious belief (or lack of it). Religion seems to play a minimal role in the lives of most psychologists in the United States. The study by Jones (1996) found that only 33% of the clinical psychologists described religious beliefs as the most important influence on their lives. In addition, in a national survey, only 29% of the therapists found that religious beliefs were important in the treatment process of most of their clients (Bergin & Jensen, 1990). This may be another hypothesis of why psychologists are reluctant to consider religious belief as part of the therapy and this gives an indirect message to the clients that religion has no place in the treatment process. Consequently, this circumstance confirms the Muslim clients' reservation with regard to trust and values that seem to be ignored in the therapy process.

CONCLUSION

The difficulties faced by the Muslim clients in getting treatment call for a solution to include this group in professional treatments to address their apprehensions. The present researchers offered various suggestions to help Muslim clients going through the counseling process. These suggestions are largely based on the clinical work experiences with Muslim clients. The main objective is to build a relationship. Muslim clients may be reluctant to attend the counseling sessions, therefore, building a relationship at the initial stage is critical (Keshavarzi & Haque, 2013). Generally, if a counselor does not get involved with the clients or their family, the possibility of the counseling session to continue will decrease (Kobeisy, 2004). Kobeisy (2004) identifies several important factors that will ensure the continuity of the counseling sessions, which include clients' first impression of the counselors, clients' feelings towards the counselors, and positive expectations towards the counseling relationships. Apparently, creating a positive relationship with Muslim clients is an important initial task of the counseling process. Counselors should also be aware of bias and discrimination that could happen to Muslim clients. In general, counseling sessions may also be a medium of discussion for issues relating to Islam that lead to discrimination and bias, hence, augmenting mutual trust between the counselor and the client.

Chapter 50
Community-Based Rehabilitation in Hong Kong: Opportunities and Challenges

Kar-wai Tong
City University of Hong Kong, Hong Kong

Kenneth N. K. Fong
The Hong Kong Polytechnic University, Hong Kong

ABSTRACT

Community care is one of the worldwide strategies for governments to manage contemporary healthcare challenges and long-term care. In response to an ageing population, the Hong Kong government has been promoting the concepts of community care and made initiatives, inter alia, in community-based rehabilitation (CBR). Despite these new drives, there is insufficient supply of CBR services. Provisions of CBR are currently fragmented, project-based, or on a self-financed basis. The authors argue that there is a lack of longer-term plan on CBR and that the government still relies on the heavily subsidized public hospital system. In this chapter, the authors share their views on the opportunities and challenges of CBR in Hong Kong.

INTRODUCTION

Contemporary societies have been exploring appropriate approaches to promote and sustain health (World Health Organization ("WHO"), 2005) and identifying healthcare strategies to help those in suffering (Arnott & Koubel, 2012). Community care is one of the healthcare choices to take care of the needs of those requiring long-term care (Campbell et al., 2016), to manage inherent rising costs (Chappell, Dlitt, Hollander, Miller, & McWilliam, 2004) and to address issues arising from an ageing population (Sau Po Center on Ageing & Department of Social Work & Social Administration, 2011). Other tactics may include patients' self-management, telemedicine, cross-disciplinary disease management programmes, care paths, and financial incentives to minimize preventable admissions to casualties, etc. (Bardsley, Steventon, Smith, & Dixon, 2013).

Developing countries welcome the concept of community care. In Thailand, for instance, community care provisions such as "the Bangkok 7 Model" have been in place to integrate health care and social services (Kespichayawattana & Jitapunkul, 2008). In China, in view of the increasing social care demand for older people, scholars have advocated that more emphasis should be placed on community care and partnering with families, whereas institutional care should be the last recourse (Zhou & Walker, 2016); and the Chinese government has been developing community care since 2004 to provide care at levels of provinces, municipalities, and counties (Li & Chui, 2016). A number of other developing countries have also realized the need for community care and established national strategies to manage mental patients (Jacob, 2001) and support patients with tuberculosis (WHO, 2003), for example.

Developed jurisdictions have also advocated community care for decades. In the UK, for instance, the policy debate on community care could be dated back to mid-1950s (Smith et al., 1993) and a recent successful story in practice involved a National Health Service foundation trust which satisfactorily piloted a community-based therapy scheme, allowing patients to receive treatment at home or at a health centre to help save bed days ("Antibiotic clinics provide 'incredible' community care", 2015). In the United States, section 10202 of the Patient Protection and Affordable Care Act 2010 has provided for a "State Balancing Incentive Payments Program" to increase financial incentives for states offering home and community-based services as a long-term care alternative to nursing homes. In Canada, the government expanded community care as one of the tactics to ease the financial pressure in the 1990s (Naylor, 1999) and it has become "a vital part of health systems in Canada" (The Conference Board of Canada, 2012, p. i). In Western Australia, community care has been regarded as a non-inpatient means to improve the overall efficient flow of patients and alleviate hospital pressure on space and equipment, on top of increased staff satisfaction gained through new models of community care (Health Reform Implementation Taskforce of Western Australia, 2007). In Japan, the government has put in place an integrated model of community care as a national long-term care policy to facilitate ageing in place (Nakanishi, Shimizu, Murai, & Yamaoka, 2015). In Hong Kong, "[a]geing in place as the core, institutional care as back-up" is the guiding principle of the elderly care policy (Labour and Welfare Bureau ("LWB") & Social Welfare Department of Hong Kong ("SWD"), 2014, paragraph 2). In this chapter, the authors discuss community care, with a special focus on the opportunities and challenges of community-based rehabilitation ("CBR") in Hong Kong.

COMMUNITY CARE

Health is a resource for everyday life (the Ottawa Charter for Health Promotion, cited in WHO, 1986). Various modes of care delivery have impacts to different degrees on the quality of life and the cost effectiveness . Elders in institutionalized care, for instance, may feel alienated from their usual living environments and practices, thus resulting in a drop of their perceived quality of life (Kong, Fang, & Lou, 2016). In terms of healthcare financing, home-based care may be more cost-effective than hospital-based care in a shorter term of health maintenance (Knapp et al., 1998). In fact, care shifting from hospitals to the community has been a global trend (Royal College of Nursing of the UK, 2014).

Community care is defined by the WHO (2004, p. 16) as "[s]ervices and support to help people with care needs to live as independently as possible in their communities". The WHO Centre for Health Development has further elaborated the meaning of community care from the perspective of elderly care (WHO, 2004, p. 3):

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Community health care aims to add new scope and value to the existing primary health care approach in providing integrated health and social services by public and private partnership to meet the increasing health and welfare needs of older persons and their families at community level.

Community care complements the concepts of active ageing, i.e. "the process of optimizing opportunities for health, participation and security in order to enhance quality of life as people age", as advocated by the WHO (2002, p. 12) and active ageing allows older people to make full use of their potential and thus less dependent on family members and societies (United Nations Economic Commission for Europe / European Commission, 2015). In Hong Kong, there is no principle for active ageing and supports to services for the ageing population are provisioned on an incremental approach across various government bureaus and departments (Legislative Council Secretariat, 2015a).

In practice, service scopes of community care programmes vary on a case-by-case basis and are subject to changes over time (Means, Richards, & Smith, 2008). For example, Murphy (1987) reported that the British community care policies served four overlapping groups of people, namely the aged with physical or mental problems, patients with mental handicap, those with chronically mentally illness, and physically disabled younger people. Sharkey (2007) suggested two decades later a broader perspective of community care to serve not only mental and physical health issues, but include at least three elements, namely people previously living in long-stay institutions, vulnerable persons such as the aged and the disabled with a preference of being cared in a community rather than in institutions, and volunteer support from carers like relatives, friends, and neighbours. In 2014, the UK government outlined a new multispecialty community care model in the "Five-Year Forward View for the NHS" (National Health Service of the UK, 2014), allowing general medical practitioners to work with other healthcare practitioners and social care providers to set up a cross-disciplinary community network to provide integrated out-of-hospital care.

COMMUNITY-BASED REHABILITATION

Developments of CBR

CBR is one of the models of community care (Chatterjee, Patel, Chatterjee, & Weiss, 2003). It has been attracting academic attention for decades, as reflected in the increased number of academic publications on CBR (Finkeflügel, Wolffers, & Huijsma, 2005; Cleaver & Nixon, 2014). At the international level, following the concept of managing health issues in the community as stipulated in the Declaration of Alma-Ata (1978; Article VII(2)) and the principle of making care accessible to all people in the community through their full participation and at affordable costs (Article VI), the WHO commenced the development of CBR strategies, with an aim to integrate rehabilitation, health care, and other development activities at the community level (WHO, 1994). Subsequently in 1979, the WHO published a CBR manual in collaboration with other United Nations agencies, and this manual was translated into thirty languages (Helander, Mendis, Nelson, & Goerdt, 1989). In the 1994, the WHO issued *Joint Position Paper on CBR* with the International Labour Organization ("ILO") and the United Nations Educational, Scientific and Cultural Organization ("UNESCO") to address the concept of CBR (ILO, UNESCO, &WHO, 2004). In 2003, these three UN specialized agencies worked with the International Disability and Development and developed a set of CBR guidelines (WHO, n.d.(b)). One year later, the same three

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

UN agencies made further revisions to the aforesaid joint paper and issued *Joint Position Paper 2004*, describing CBR in the title of the paper as "a strategy for rehabilitation, equalization of opportunities, poverty reduction and social inclusion of people with disabilities" (ILO, UNESCO, & WHO 2004). In 2006, the United Nations General Assembly adopted the Convention on the Rights of Persons with Disabilities, where its Article 19 requires member states to recognize the equal right of all persons with disabilities to live in the community. Throughout these decades, CBR has been developed from a focus solely on rehabilitation to advocating people's access to education, employment, health care, as well as social services, and more than ninety countries in the world have optimized their CBR programmes (WHO & the Gulbenkian Global Mental Health Platform, 2015).

Concepts and Service Scopes of CBR

CBR is a concept subject to different interpretations (WHO & Swedish Organizations of Disabled Persons International Aid Association, 2002). It involves basically three components. "Community" in healthcare sense may refer to groups of people who are connected "through culture, occupation, conditions based on a common workplace, prognosis, stage in the care process, intensity of care needed, and more", and people having a particular disease is one of the examples of a healthcare community (Institute of Medicine, 2013, p. 206). The second component is "community-based care", which is in general described by the WHO (2004, p. 16) in the way below:

The blend of health and social services provided to an individual or family in his/her place of residence for the purpose of promoting, maintaining or restoring health or minimizing the effects of illness and disability. These services are usually designed to help older people remain independent and in their own homes. They can include senior centres, transportation, delivered meals or congregate meals sites, visiting nurses or home health aides, adult day care and homemaker services.

For the last component, i.e. "rehabilitation", CBR is more than the conventional understanding of functional or health-related rehabilitation, and it has been re-defined to incorporate a broader sense in accordance with the Convention on the Rights of Persons with Disabilities (2006) (Geiser & Boersma, 2013), where its Article 26 requires member states to "organize, strengthen and extend comprehensive habilitation and rehabilitation services and programmes, particularly in the areas of health, employment, education and social services". The WHO (n.d.(a)) considers CBR a multiparty strategy to satisfy the basic needs and promote the quality of life of the disabled and their families through the concerted efforts of various stakeholders in the areas of health care, education, vocational training, and social services, thus enhancing the public's access to rehabilitation services in the community and creating social integration and equitable opportunities for needy people for inclusion in the society.

CBR differs from the traditional institutional-based rehabilitation in that CBR is based in community settings, and programmes of which are planned and evaluated subject to the perceptions of the community (Sharma, 2007). CBR is not confined to people with disability but serves also the elderly as well, as the prevalence of disability increases, among other factors, with the rising number of ageing population (Paudel, Bhandari, & Bhandari, 2017). The scope of CBR covers, for example, social, educational and vocational rehabilitation, early interventions to geriatric care, disease and disability prevention, intensive individualized rehabilitation, and sports rehabilitation, etc. (Hoeman, 1992). Programmes under CBR include, for instance, training for the welfare of patients and families, educational assistance, improv-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing physical access, referral services, financial assistance, social and recreational support, as well as facilitating employments (Shrivastava, Shrivastava, & Ramasamy, 2005).

In Hong Kong, "Enhanced Home and Community Care Services" and "Integrated Home Care Services" are local examples of CBR (Lai et al., 2009). Both programmes materialize the concepts of "ageing in place" from a perspective of continuous care. The former caters for frail or ordinary elders' needs to allow them to age at home as well as to provide support to carers and to strengthen family cohesion (SWD, 2016(a)). The latter takes care of elders (assessed to be of moderate or severe level of impairment), people with disabilities, and families in need in a community by experienced and trained professional staff through a network of collaborative and supportive services in the community (SWD, 2016(b)), services of which include basic and special nursing care, personal care, home rehabilitation exercise, day care services, carer support services, day respite service, counselling services, 24-hour emergency support, environment risk assessment and home modifications, home–making and meals-on-wheels services, as well as transportation and escort services, etc.

A BRIEF ABOUT HONG KONG

Hong Kong runs a dual-track health care system consisting both public and private sectors (Hong Kong government, 2013). There is a significant imbalance between the two sectors, with the public sector shouldering 87% of total hospital beds and approximately 90% of in-patient services (Food and Health Bureau of Hong Kong ("FHB", 2013). Also, the public healthcare services in Hong Kong are heavily subsidized by tax and the government charges, for instance, only HK$100 per day of hospitalization for an acute general beds with a cost estimated at HK$4,910 in 2015/16 (FHB, 2015b).

Population ageing is a primary concern leading to reforms of health care and welfare provisions (Duff, 2001). Hong Kong is no exception as it is a society with very long life expectancy, if not the longest, in the world (Census and Statistics Department of Hong Kong ("CSD", 2016b). The proportion of people aged 65 or above in Hong Kong jumped from 8% in 1986 through 12% in 2006 to 16% in 2016 (CSD, 2016a), and it is further projected to rocket to 36% in 2064 (CSD, 2015a). To further exacerbate the situation, the reduction in fertility rate continues. The total number of live births per 1,000 women in Hong Kong is estimated to drop from 1,355 in 1994 through 1,234 in 2014 to 1,182 in 2064 (CSD, 2015a). The combined effect of an ageing population and continuously decreasing fertility rate leads to a rise of median age of the population from 39.6 in 2006 through 41.7 in 2011 to 43.4 in 2016 (CSD, 2016b).

The demographic changes make healthcare financing an imminent challenge in longer term in Hong Kong. It is projected that there will be fewer and fewer people paying tax in the future as a result of the ageing population with low fertility rate. Together with the heavy subsidy from the government (FHB, 2014 & 2015b) and the narrow tax base in Hong Kong (Financial Secretary of Hong Kong, 2015), these phenomena will affect the sustainability of its healthcare financing system (Tong & Fong, 2014), especially when the underlying principle of healthcare policy in Hong Kong is that "no person should be prevented, through lack of means, from obtaining adequate medical treatment" (section 4(d) of the Hospital Authority Ordinance). There is a genuine worry as elders in Hong Kong consume six times the inpatient bed-day resources (FHB, 2010) and nine times in general specialty bed utilization than non-elderly patients below the age of 65 years (Hospital Authority of Hong Kong, 2012). To give a further example, as far as residential services are concerned, as at 31 July 2016, there were a total of 34,749

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

elders waiting for various subsidized residential care services and the waiting time may last for as long as 38 months (SWD, 2016(d)).

Hong Kong is keen on managing how to sustain its healthcare system arising from the ageing population due to increased longevity and low fertility, as well as other contemporary challenges such as escalating healthcare costs and rising public expectations (Tong & Fong, 2014). Demographic changes, together with the underlying principle of healthcare policy in Hong Kong, require the government to take care of the healthcare needs of people, especially those of the expanding elderly community, in a practical, feasible, and sustainable manner (Yip, Lee, & Law, 2006). In particular, long-term strategies for healthcare financing have been one of the burning challenges in Hong Kong and the government explicitly announced the impracticability to increase public healthcare expenditure indefinitely (Chief Executive of Hong Kong, 2007). The present strategies to tackle healthcare issues are diverse, including, for example, the establishment of a central health education unit with a vision to build a healthy society (Central Health Education Unit of Hong Kong, 2015), the development of reference frameworks for preventive care for children and the aged in primary care settings (Task Force on Conceptual Model and Preventive Protocols, Working Group on Primary Care, & FHB, 2012(a) & 2012(b)), promotion of preventive health screening services for well people like breast cancer (Cancer Expert Working Group on Cancer Prevention and Screening & Department of Health of Hong Kong ("DH"), 2016), the then controversial policy to encourage Mainland mothers to give births in Hong Kong to address the issues of low fertility rate and ageing population (Chief Secretary for Administration's Office of Hong Kong, 2012), as well as the enhancement of public-private partnership initiatives and a HK$200-billion ten-year blueprint for hospital development (Chief Executive of Hong Kong, 2016), etc. Furthermore, the government has also developed initiatives in the context of community care, though the supply of such services is limited.

Snapshots of the Current Status

The ageing population has called for the need of CBR. In an ageing society, there is a rising demand for care in connection with the elderly's losses of physical, functional, and mental abilities and such impairments will in turn enhance their reliance on others' assistances (Cox, 2005). In Hong Kong, the old aged persons have had common health problems in areas of dementia, stroke, bones and joints, cancer, digestive, urinary and sexual problems, hypertension, heart diseases, infections, and mental illness (DH, 2016a). A few observations arising from these common diseases are shared below.

Chronic Diseases and Disability

The increase in number of chronic patients and persons with disabilities is alarming. In 2013, there were about 1.38M persons with chronic diseases (19.2% of the total population), equivalent to a rise of 20% from 2007; and among them, 0.7M with hypertension (9.9% of the total population), 0.32M with diabetes mellitus (4.4%), and 0.14M with heart diseases (2%) (CSD, 2015b). Also, the number of persons with disabilities (excluding those with intellectual disability) in 2013 was estimated at approximately 0.6M (8.1% of the total population), representing an increase of 60% in comparison with the corresponding data in 2007; among them, 0.32M with restrictions in body movement (4.5% of the total population), 0.18M with seeing difficulty (2.4%), and 0.16M with hearing difficulty (2.2%) (CSD, 2015b). Woo and colleagues (1997) studied 1,902 recipients of the age and disability allowance schemes in Hong Kong

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

and revealed that disease burden was the highest for arthritis, hypertension, cardiac disease, and peptic ulcer for people falling into the age group of 70-79.

Healthcare and Social Burden from Stroke Patients

In Hong Kong, it was estimated that stroke patients alone would require HK$1,900M in 2001 for treatments in hospitals owing to the insufficiently developed primary healthcare system (Woo et al. 1997). The direct medical expenditures (e.g. hospitalization, outpatient services, rehabilitation, and community allied health services) for stroke patients was projected to increase to HK$3,979M per annum by 2036 (Yu, Chau, McGhee, & Chau et al., 2012). The Hong Kong government also acknowledged that with longer life expectancy, the number of chronic patients with non-communicable diseases like diabetes mellitus, heart diseases, cancer, etc. has increasingly become a burden to patients themselves, their families, and the society as a whole (DH, 2008). CBR may help reduce the financial burdens and enhance patients' wellbeing, as reported by the study of Legg and colleagues (2004) that therapy-based rehabilitation services for selected stroke patients residing in the community could improve their daily-activity abilities and decrease the risk of further deterioration in ability.

Healthcare and Social Burden from Dementia Patients

An ageing population inevitably leads to a prevalent population of dementia patients (National Institute on Aging, National Institutes of Health, & WHO, 2011). In Hong Kong, the life expectancies at birth for male and female in 2016 were respectively 81.2 and 87.3 years old (DH, 2016b), and the number of mild dementia patients increased with age from 0.8% in people aged 60-64 to 19.1% in people aged 85 and above (Centre for Health Protection of the DH, 2012),. The number of dementia patients at 60 years old or above was projected from 103,433 in 2009 to 332,688 in 2039, representing a rise of 222% (Yu, Chau, McGhee, & Cheung et al., 2012).

In fact, dementia has been considered a healthcare and social burden in developed countries (Wimo, Jonsson, & Winblad, 2006). In a systematic review of 27 previous studies from fourteen healthcare systems, Schaller and colleagues (2015) estimated that the total costs for each dementia patient per annum may go as high as US$70,911, with an average annual total cost estimate per capita at US$30,554, and a significant portion of such costs come from informal costs arising from home-based long term care and nursing home care, instead of direct medical expenditures. Despite this review did not include Hong Kong, the financial burden of dementia patients arouses a real concern in Hong Kong as its public health services and social welfare are heavily subsidized by the government (FHB, 2014; Financial Secretary of Hong Kong, 2016(a)).). In another study, the number of people aged 60 or above with dementia in Hong Kong was estimated in 2010 to be 105,069 and the expenditure for their institutional care was at HK$ 1,624M, which was projected to rise to approximately HK$4,212M per annum for 273,449 elders with dementia in 2036; and the corresponding costs for informal care were estimated at HK$10,368M in 2010, with a projected increase to HK$27,000M by 2036 (Yu et al., 2010). Unfortunately, there is a general ignorance of this disease (Chan, 2012).

OPPORTUNITIES

The Hong Kong government has made some improvements to pave the way for the future to tackle foreseeable healthcare and social challenges. A few examples are cited below.

Empowerment of Patients-Led Support Groups

The concepts of community care and CBR are not new to Hong Kong. Dating back to 1990, the Hong Kong government suggested in a key policy paper entitled *Health for All – The Way Ahead* to provide quality care in the community for the elderly (Working Party on Primary Health Care of Hong Kong, 1990). In 2000, the Hong Kong government articulated in another consultation document bearing a title of *Lifelong Investment in Health* to improve the outcomes and cost efficiency of health care through, among others, a community-focused, patient-centred and knowledge-based health care system (Health and Welfare Bureau of Hong Kong, 2000). The Hong Kong Society for Rehabilitation, a non-government organization ("NGO"), provided a good example of such a care system when it set up the Community Rehabilitation Network ("CRN") in 1994 (Poon, So, & Loong, 2014). There are six CRN centres in different regions of Hong Kong subsidized by the Social Welfare Department since 1997 (Hong Kong Society for Rehabilitation, n.d.). The CRN provides a very good linkage and resource support to most of the patients-led support groups in the society.

Centre-Based CBR in the Community

The Hong Kong government has made some initiatives for community-based care and CBR since the publication of a further consultation document in 2005, *Building a Healthy Tomorrow* (Health and Medical Development Advisory Committee of Hong Kong, 2005), which was considered the first attempt to outline a future healthcare model by better differentiating the roles of primary, secondary and tertiary care as well as home care and community support (Lam, 2005). For example, in his *2005-06 Policy Address*, the Chief Executive of Hong Kong (2005) announced the plans to strengthen community support services to the disabled and their family members, including, for example, transitional residence, day training, as well as nursing and support services for people with severe disabilities, continuous day rehabilitation and infirmary care for discharged patients with mental, physical or neurological impairments, and a new scheme for visiting doctors for the disabled residing in rehabilitation facilities, etc. Since 2007, the Social Welfare Department (n.d.) has also funded the development of four community rehabilitation day centres ("CRDCs"), aiming at providing goal-oriented and time-defined rehabilitation services for discharged patients from the Hospital Authority, with a view to enhancing their independent living in the community and social integration. The original idea of setting up CRDCs is good. With payments to services comparable to the charges of outpatient rehabilitation in public hospitals, the establishment of CRDCs aims at building up patients' physical functioning and self-maintenance abilities, reinforcing their domestic living and community living skills, and facilitating them to redesign a healthy lifestyle and productive life roles to assist their integration into the community; more than that, CRDCs provides respite care service and education for patients' families and caregivers to improve their quality of living (SWD, n.d.). In addition to CRDCs, following the direction stated in the *2008-09 Policy Address* to explore the use of community health centres to enhance primary care (Chief Executive of Hong Kong, 2008), the Hong Kong government set up the Tin Shui Wai (Tin Yip Road) Community Health Centre,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

which was built and designed based on the primary care development strategy and service model of the government, opened in 2012, and is a one-stop centre to provide comprehensive primary care services by multi-disciplinary primary care professionals in the community (Hong Kong government, 2012a).

Ambulatory Care and Support

Since 2009, an elderly healthcare voucher scheme has been launched (FHB, 2015a) under the concept of "money follows patients" (Elderly Commission of Hong Kong, 2009) to enable elders aged 70 or above to choose primary care services in the community (Chief Executive of Hong Kong, 2007), and this scheme has become a recurrent support programme and the vouchers can be used for rehabilitation services (Chief Executive of Hong Kong, 2014). The Chief Executive of Hong Kong (2015) further promoted the concepts of community care in his *2015 Policy Address* by, for instance, providing more choices for the elderly via other voucher schemes in the contexts of community care services and residential care services, building mutual help community networks among residents of new public rental housing estates, along with encouraging active ageing through senior volunteerism, a HK$2 public transport fare concession scheme, and residences and reverse mortgage programmes for the aged. The importance of developing an age-friendly city and promoting active ageing in Hong Kong and the use of community resources to improve home care services, elderly services, ambulatory care, primary care and community care were iterated again in his *2016 Policy Address* (Chief Executive of Hong Kong, 2016). In the *2017 Policy Address*, the Chief Executive (2017, paragraph 173) also reported that the public and different stakeholders in general supported the principle of "ageing in place as the core, institutional care as back-up" and recognized the need to strengthen community care services. To follow the Chief Executive's policy directions, the Financial Secretary of Hong Kong (2016(b)) announced a series of initiatives, e.g. the establishment of three new community health centres at the district level to provide additional 410,000 general outpatient attendances annually, and appropriation of additional recurrent budgets of HK$170 million and HK$17 million respectively in 2015-16 and 2016-17 for the provision of 1,600 and 160 extra places for the Enhanced Home and Community Care Services to strengthen the support for the overarching principle of "ageing in place". The Community Care Fund (2016) also provides pilot schemes on subsidy for people with severe disabilities, and living allowance for low-income caregivers of people with disabilities (SWD, 2016(c)).

CHALLENGES

The opportunities mentioned above have laid a foundation stone, but there are still barriers on the road to a nourished supply of community care. A few limitations are elaborated below.

Lack of a Longer-Term Policy

Social policy and healthcare policy serve as a mechanism to redistribute resources and make use of intersectional health actions to reduce inequities in health status (Baum, 2008). The resource allocation targets to meet a society's dominant values, which means in practice the underpinning values of the government of the day (Jamrozik, 2001). Without a longer-term policy, the current strategies used in community-based care and CBR may be changed subject to the values of the government of the day.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

This anticipated change is not theoretical but real, as exemplified by the development of private hospitals in Hong Kong. Mr. Donald Tsang, the second Chief Executive of Hong Kong, announced in his *Policy Address* for two years that the government had reserved four pieces of land to develop private hospitals (Chief Executive of Hong Kong, 2008; 2009). However, the direction of developing private hospitals has been changed after Mr. Tsang's stepping down from the government. Out of the four pieces of land, only the land in Wong Chuk Hang is used for building a new 500-bed private hospital, whilst the site in Tseung Kwan O is reserved for the construction of a self-financing public Chinese medicine hospital (Chief Executive of Hong Kong, 2014), and the land in Tai Po has been returned to the Development Bureau for other development purposes (Legislative Council Secretariat, 2015b). The use of the fourth piece of land in North Lantau is not clear. Hong Kong needs a longer-term community-based care policy.

Heavy Reliance on Public Hospital Services

As mentioned above, the most important principle of healthcare policy in Hong Kong is that no one is to be deprived of access to adequate medical treatment because of lack of means (section 4(d) of the Hospital Authority Ordinance). It is also projected that the number of taxpayers will be decreasing because of the ageing population and low fertility rate. In Taiwan, Lee (2002) projected that the supply of long-term care could not meet the ever-increasing demand and suggested expanding community care instead of continuing to rely on institutionalized care as well as Taiwanese government reviewing financing options and integrating various fragmented services. In fact, the Taiwanese government has recently launched a "10-year long-term care 2.0 plan" to facilitate ageing in place through a comprehensive community care service system (Executive Yuan of Taiwan, 2017). Hong Kong faces similar issues as those in Taiwan. However, rather than going to the direction of community-based services as per the basic principle of the elderly care policy that ageing in place should be the core with a back-up by institutional care (LWB & SWD, 2014), it seems that the government continues to rely on public hospital services which are heavily subsidized by tax payers' money (FHB, 2014), as shown by the allocation of HK$200 billion for hospital development in the ten years up to 2026, on top of other hospital development projects already in the pipeline such as the expansion of the United Christian Hospital and the re-development of Kwong Wah Hospital (FHB, 2016). The study of Tin and colleagues (2016) further supports the authors' viewpoints about the Hong Kong government's reliance on hospital services, where they found that the expenditures for rehabilitative and extended care as a percentage of the total health expenditure in Hong Kong in the period of 1989/90-2012/2013 increased from 2.3% in 1989/90 to a peak at 4.2% in 2003/04 and then gradually reduced to 3.5% in 2012/13, and similar pattern of ups-and-downs was also observed in the expenditures for long-term care in the same period of time, with the lowest share at 2.3% in 1998/90 and the highest at 5.5% in 2002/03 before it dropped to 4.5% in 2012/13, whilst the corresponding expenditures in hospitals were 28.2% of the total health expenditure in 1989/90 to 46.8% in 2002/03, with subsequent reduction to 42%-44% in the period 2005/06-2012/13. A significant proportion of the total health expenditures in the past few decades were spent in hospitals and less than 10% were allocated for rehabilitative and extended care and long-term care. It seems that this trend will continue as discussed above.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Attitude of the Hong Kong Government

Attitude of the Hong Kong government may be an issue. In 2007, the Rehabilitation Advisory Committee published a document entitled *Hong Kong Rehabilitation Programme Plan*, setting out two major strategic directions for rehabilitation services to establish (a) individual capacity of persons with disabilities and their family members through social investment, and (b) an appropriate environment socially, economically and physically to facilitate full integration of these persons into community; and among proposed specific measures, one was to provide a barrier-free environment for access and transport services for full integration of persons with disabilities into the society (Health, Welfare and Food Bureau of Hong Kong, 2007). However, as a result of ineffective implementation of this special transport measure, a number of people in need took unauthorized rehabilitation transport services, and pursuant to the Ombudsman Ordinance, the Ombudsman of Hong Kong (2014) subsequently conducted a direct investigation into it. In early 2017, the Ombudsman (2017) pointed out explicitly the passive attitude of the Hong Kong government in carrying out this measure, as reflected in the following observations: (a) the LWB setting no timeframe to implement the policy of "Transport for All"; (b) treating the policy of "Transport for All" as a concept by the LWB and the Transport Department; (c) the failure of the Transport Department in proactively and professionally supporting the subvented rehabilitative vehicle services, i.e. the Rehabus services; and (d) the failure of the Transport Department in adjusting its mentality about the demand for special transport services. In the investigation report, the Ombudsman (2017) made a few findings: (a) serious under-supply of the Rehabus; (b) government's failure in seriously assessing the demand and setting targets for the special transport services; (c) government's failure in making full coordination for effective use of the special transport services; and (d) government's failure in adequately managing the issues of unlicensed rehabilitation vehicles. The Ombudsman recommended that government continue to introduce wheelchair accessible taxis and minibuses and make more efforts in publicity and public education.

In response, the government expressed that it has been promoting "Building a City for All" by providing barrier-free access in public transportation and pedestrian pathways to every destination. The Hong Kong government (2017b) issued a press release with a headline of "Ombudsman recommendations noted" and stated that the LWB and the Transport Department would enhance the rehabilitative services for the physically repaired accordingly. In another press release issued on the same day, the LWB iterated its commitments to develop barrier-free transport for persons in need, particularly the Rehabus under government subvention, and would examine the investigation report of the Ombudsman seriously and make a new rehabilitation programme plan including the long-term strategy for special transport services when the Elderly Commission has formulated the elderly services programme plan in the second quarter of 2017 (Hong Kong government, 2017a). As mentioned before, success of community-based care and CBR depends on multi-sectoral collaborations, not just confined to healthcare providers but also the assistance of stakeholders in other fields such as education, vocational training, social services, communities, concerned government departments, and NGOs, etc. (WHO, n.d. (a); Iemmi et al., 2013). The findings of the Ombudsman shown above illustrate the importance of the multiparty strategy in community-based care as advocated by the WHO (n.d.(a)) and the significant roles played by the Hong Kong government.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Coordination of Inter-Sectors in the Government

The Hong Kong government may wish to review its policies in health care and elderly care, which are now managed respectively by two bureaus, and strike an optimal balance between hospital developments and community-based care. To facilitate the aged to live and function less dependently in the community as far as possible requires multi-sectoral cooperations among, for instance, people with disabilities, family members, communities, concerned government departments, and NGOs in the fields of health care, education, career development, and social services, etc. (Iemmi et al., 2013), and one of the underlying principles of community care is its flexibility in implementation, so as to cope with local contexts and take into account any local chances and limitations (Davies & Challis, 1986). In the UK, for instance, Bernard and Phillips (2000) advocated an integrated social policy to take care the broad needs of an ageing society in contrast to those narrowly defined services for specific age groups or cohorts with particular problems or stigmas. In fact, Hong Kong attempted to formulate a central policy about ageing services in the 1980s and 1990s but the difficulty in making inter-departmental coordination made issues of ageing focus on health and personal social services and become the responsibility of the then Health and Welfare Bureau (Chan & Phillips, 2002). After the changeover of sovereignty from the UK to China, the government machinery responsible for health and social welfare issues in Hong Kong has changed a number of times. The "Health and Welfare Branch" before 1997 was restructured to establish the "Health and Welfare Bureau", which was subsequently re-named the "Health, Welfare and Food Bureau" in 2002 under the Principal Officials Accountability System (Ma, 2007). In 2007, it was further re-named the "Food and Health Bureau" and the welfare function was transferred to the "Labour and Welfare Bureau" (FHB, 2008). In accordance with the CBR strategy developed by ILO, UNESCO and WHO (2004) to consider collectively rehabilitation, equality of chances, poverty reduction and social inclusion, these hierarchical changes in the government structure could not help improve the inter-departmental coordination for community-based care, not to mention CBR.

In recent years, it appears that the government has realized the importance of inter-departmental coordination and participation by different parties, as illustrated by a government setup with a name of "Energizing Kowloon East Office", which was set up in 2012 to coordinate the work of relevant departments in the government machinery and more importantly, to play the role of place-maker, and to serve as a platform for all walks of life to work together to generate innovate ideas for the optimal use of public space and environmental improvement in the Kowloon East region of Hong Kong (Hong Kong government, 2012b). As reported in a panel of the Legislative Council, "Energizing Kowloon East Office" serves as an advisor and facilitator for development projects of both public and private sectors in Kowloon East, and it has so far provided one-stop advisory and coordinating services among all concerned government department for over sixty private development projects and has had extensive engagements and cooperations with the public and different stakeholders at various stages of initiatives and projects (Development Bureau of Hong Kong, 2016). Another example is the establishment of a tripartite platform to mend the broken relationship between the government, doctors, and patient advocates after the failure of the Medical Registration (Amendment) Bill 2016 to pass through the Legislative Council in July 2016 (Hong Kong government, 2016). In rehabilitation services, the government has proposed to upgrade the rank of and strengthen the role of the Commissioner for Rehabilitation (Chief Executive of Hong Kong, 2014), who is responsible for making rehabilitation policy for the disabled persons and enhancing coordination with other government bureau and departments, public organizations and NGOs in the provision and formulation of rehabilitation services (LWB, 2014). The realization of better coordination

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

of inter-sectors, particularly the role delineation of the FHB and the LWB in rehabilitation, may help break down the current compartmentalization and fragmentation of health care and community care.

Domiciliary Services

In 2014, only 1.05% of persons aged 60 and over in Hong Kong lived in institutions including homes for the aged, care and attention homes, and nursing homes (The Hong Kong Council of Social Service, 2017). Given that most of the elderly live with their families and not in institutions, the ageing-in-place concept has been advocated by the Hong Kong government in recent years to enable older people to remain living in a familiar and preferred environment. Ageing-in-place is a world-wide trend that even vulnerable older people can live in their own domestic housing with community-based in-home support services and innovative housing designs to meet their needs when they become aged and frailer (Chui, 2008). At present, clients of both "Enhanced Home and Community Care Services" and "Integrated Home Care Services" have to be assessed and arranged by the Standardized Care Need Assessment Mechanism (SCNAM) for Elderly Services through multidisciplinary teams consisting of accredited assessors from various professional disciplines such as nurses, social workers, occupational therapists, and physiotherapists, etc. who have gone through training and accreditation on the use of assessment tools (SWD, 2017). The SCNAM teams also serve as a gatekeeper to cover applications for residential services such as admissions to homes for the aged, care and attention homes, nursing homes, day care centres for the elderly, enhanced home and community care services, and integrated home care services (for disabled and frail cases). There are only 5 SCNAM teams in Hong Kong and the current level of manpower and resources may not be enough to serve the increasing number of elders in the population, which may increase the waiting time under the Central Waiting List, particularly for those who are in urgent health and care needs.

Centre-Based CBR in the Community

With regard to the CRDC project, it still operates on a trial basis since its inauguration a decade ago. At present, there are only four CRDCs in four districts (Kwun Tong, Wanchai, Shatin, and Tuen Mun) funded by the Social Welfare Department (n.d.) since 2007, the services provided are far less than the demand of people with disabilities. There are no district centres in the Kowloon West and the Central districts, for instance, and each existing centre may not be able to cope with the demand of rehabilitation needs from people with chronic diseases and physical disabilities. To cite an example, most of the clients visiting the CRDCs are stroke survivors, and this is not surprising as the incidence of stroke cases increases in an ageing population as the risk of stroke increase with age (Sheppard & Ko, 2009). In Hong Kong, there was an average of 25,247 people yearly suffered from stroke in the period of 2008-12 and among them, there was an average of 21,813 survivors per year with a survival rate about 86% (Hospital Authority of Hong Kong, 2014). Most of them might end up with various degrees of sensorimotor impairments, physical and cognitive disabilities, and require varying degrees of rehabilitation. It is not difficult or unreasonable to infer that services offered by only four CRDCs are insufficient. As regards other subsidy schemes from the Community Care Fund for people with severe disabilities, they are also on a pilot basis.

Self-Management of Chronic Diseases by Patients

The Chronic Disease Self-Management Programme ("CDSMP") facilitates patients with chronic diseases to gain self-management skills and behavior based on the theory of self-efficacy, social learning, mastery of skills, and problem-solving (Bodenheimer, Lorig, Holman, & Grumbach., 2002), and is a 6-week standardized programme to help participants to join in self-management skills training and set up health action plans (Chan, Siu, Poon, & Chan, 2005). However, to the best knowledge of the authors, there has been no plan to implement the CDSMP in the long run. The Hospital Authority has also partnered with NGOs since 2010 to offer a patient empowerment programme as a pilot public-private-partnership project, mainly for patients with diabetes mellitus and high blood pressure with an aim to enhancing their disease specific knowledge and self-care capabilities, and an enhanced model with more emphasis on personalization has commenced since April 2016 (Hospital Authority of Hong Kong, 2016). There is no indication either as to whether such a pilot project would become recurrent in the near future.

NGOs' Running CBR Programmes on a Project Basis

In addition to the call for enhanced coordination within the government, there is also a need to strengthen the coordination of NGOs which are playing an important role in the provisions of community-based care and CBR. The Hong Kong government allocates resources to NGOs in accordance with the Lump Sum Grant Subvention System, which was introduced in 2001 and is considered as a "a major revamp of the public funding and management" of NGOs in the social welfare sector (Lump Sum Grant Independent Review Committee, 2008). In terms of community care, sustainability is a concern. There may not be empirical studies on the number of self-financed community-based services in Hong Kong, and according to the authors' personal observations, a number of community-based programmes run by NGOs in Hong Kong are operated on a project or self-financed basis, e.g. self-financing day care centres for elders with dementia (SWD, 2012), and when budget is exhausted, the programmes concerned have to put a stop to provisions of services. The authors argue that because of the sustainability concern, NGOs may see other counterparts as competitors rather than partners, and this has created a further stumbling block to the development of community care in Hong Kong.

CONCLUSION

Ageing population has been challenging governments to give new initiatives and policies in the provision of care (WHO, 2013). This requires linking comprehensive and consistent policies, services, and other supports together (Cox, 2005) in a sustainable manner. Hong Kong is no exception.

To enable healthy ageing and reduce the number of chronic patients, the Hong Kong government must reduce the reliance on hospital and institutional care and considers increasing community care in the long run for frail aged persons (Chu & Chi, 2006). Although there have been some social programmes by NGOs and public healthcare programmes in place in Hong Kong, CBR and other community-based services are still limited and fragmented, as exemplified by the facts that there is a lack of a longer-term policy of community-based services, that the Hong Kong government continues to rely on public hospital services, that there is still room to improve coordination of inter-sectors, and that NGOs are running community-based programmes on a project or self-financing basis, the services of which are susceptible

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

to termination when funding is exhausted, not to mention the need to strengthen inter-departmental coordination within the Hong Kong government (Chan & Phillips, 2002), interagency coordination between the government, the Hospital Authority, the Social Welfare Department, and NGOs, and, last but not least, inter-NGOs coordination.

Hong Kong goes in a similar direction of community care as other contemporary societies, but without a longer-term policy in Hong Kong, the so-called guiding principle of "ageing in place as the core, institutional care as back-up" (LWB & SWD, 2014, paragraph 2) is far words more than action. The authors suggest that the Hong Kong government make community-based care a longer-term policy which is free of interruptions because of changes of government leaders, and for the sake of long-term sustainability of Hong Kong, review the present heavy reliance on public hospital services and revamp the existing financing model to optimize the imbalance between hospital care and community care. In practice, to strengthen the Hong Kong government's coordinating role, in addition to the upgrade of the rank of the Commissioner for Rehabilitation, the authors further recommend that the government make reference to the success of the "Energizing Kowloon East Office" (Hong Kong government, 2012b) and establish an appropriate coordination mechanism among different policy bureaus to allow different stakeholders like practitioners in the health care and community care fields, NGOs, and patient advocates, to join hands to discuss and improve the longer-term planning in community care to rectify the current fragmented approach. Once an appropriate context of community-based care is in place in Hong Kong, the authors are confident that there should be no doubt as to the quality of care provisions, as evidenced by the very long life expectancy of citizens (CSD, 2016b).

Chapter 51
Career Counseling for International Students:
Using the Framework of Social Cognitive Career Theory

Gökçe Bulgan
MEF University, Turkey

Ayşe Çiftçi
Purdue University, USA

ABSTRACT

International students are a group with diverse career needs and concerns. The challenges international students face (e.g., psychological and sociocultural adjustment issues, language barriers, sense of loss, financial problems, getting used to a new educational system) when they come to study in the United States, as well as their expectations of coming to a new country, may significantly influence their career needs and decision-making processes. In this chapter, the authors suggest social cognitive career theory (SCCT) as a framework for working with the undergraduate and graduate international student population by emphasizing intervention strategies and making specific recommendations.

INTRODUCTION

This chapter examines the use of the Social Cognitive Career Theory (SCCT) as the framework for engaging career counseling interventions and strategies for international students in U.S. undergraduate and graduate education. The term *international student* refers to students who study at an educational institution in a country other than their country of citizenship (Paige, 1990). Several colleges and universities in the U.S. may have seen their highest number of enrollments of international students in academic year 2016-2017 with an overall total of 1,078,822 (Institute of International Education, 2017). This figure represents a 3.4% increase in the total number of international students over the previous academic year.

The growing number of international students suggests that there is greater diversity of career needs and interests to which U.S. institutions must respond. The Institute of International Education reported that in 2017 of the total number of international students, 40.7% were in undergraduate studies, 36.3% were in graduate studies, 16.3% were in optional practical training, and 6.8% were in non-degree programs. Considering that moving to another country to pursue undergraduate or graduate education is an important career decision, there is need for greater understanding of the role of career counseling in international students' success. Therefore, the authors present SCCT as a framework for better understanding and addressing the career needs of international students.

International Students' Career Needs and Challenges

Coming from different cultural groups, international students represent a heterogeneous group of people with diverse career needs and concerns (Paige, 1990; Yang, Wong, Hwang, & Heppner, 2002). First, international students face the immense challenge of cultural and emotional adjustment when they come to study in the U.S. (Bulgan & Çiftçi, 2017; Cozart & Rojewski, 2015; Nilsson & Anderson, 2004; Wang, et al., 2012; Wei et al., 2007). Previous studies have indicated that international students' common difficulties include lack of social support, sense of loss, culture shock, language barriers, financial problems, and adjusting to a new educational system (Arthur, 2016; Carr, Koyama, & Thiagarajan, 2003; Kilinc & Granello, 2003; Lee, Koeske, & Sales, 2004; Mori, 2000; Russell, Thomsom, & Rosenthal, 2008).

Second, taking into account that the choice of studying in another country is a significant career decision, international students need support to deal with their career needs and goals. Fortunately, studies addressing the career-development needs of international students are increasing in number (Cozart & Rojewski, 2015; Nunes & Arthur, 2013; Popadiuk & Arthur, 2014). Specifically, international students need to make sure that their academic and vocational training in the U.S. will be of use to their future status either in the U.S. or in their home country (Leong & Sedlacek, 1989). Thus, career counseling will prove useful in guiding their choices.

Third, international students face numerous vocational challenges like language and cultural barriers in job search and legal requirements and bureaucratic procedures for employment in the United States (Spencer-Rodgers, 2000; Spencer-Rodgers & Cortijo, 1998). Spencer-Rodgers (2000) found that vocational needs of international college students are focused on getting work experience, overcoming interview barriers, and developing job-search skills. In another study, international students felt that they need help with preparing for careers of interest and exploring job opportunities (Manese, Leong, & Sedlacek, 1985). In addition, Leong and Sedlacek (1989) found that career needs of international students are different from those of American students. Particularly, international students are more interested and in need of vocational guidance compared to American students. The career needs of international students become more complicated since they consider employment in the U.S., in their country of origin, or even other foreign countries (Shen & Herr, 2004; Spencer-Rodgers, 2000). In other words, international students' career development needs tend to focus on the U.S. or on foreign job markets (Spencer-Rodgers, 2000). Given their future plans, they require different steps for the counseling process.

Fourth, career needs of international students also vary due to their developmental stage and level of career planning and preparation (Arthur, 2016; Shen & Herr, 2004). Shih and Brown (2000), in a study on undergraduate and graduate Taiwanese international students in the U.S. found that age and acculturation levels were important predictors of vocational identity. Specifically, older students were more likely to have a clearer understanding of their career interests, abilities, and goals (Shih & Brown,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

2000). For graduate international students, Shen and Herr (2004) found that the factors influencing students' future plans regarding employment in the U.S. ranged from individualism (e.g. chances of career promotion) to collectivism (e.g., needs of the home country). More specifically, participants discussed the need to be with family and relatives (e.g., parents needing them to stay) and need to advance their career individually in the U.S. with more possibilities and resources. Thus, on one hand, if international students' vocational needs are focused on employment in the U.S., their career concerns would include the need to get practical training in the U.S., prepare an American-style resume, and obtain the necessary rules and regulations for work as a foreigner (Spencer-Rodgers, 2000). On the other hand, going back to one's own country or to another foreign country would require culturally sensitive career planning, that is, developing country-specific curriculum vitae, or obtaining permanent employment in the selected country. Further, Shen and Herr (2004) found that work experience—internship, teaching assistantship—in the students' fields as well as general career services—training in resume writing and American style interviewing skills—helped improve the students' career foundation. However, international students, especially those in need of assistance with returning home, criticized campus career services as mostly U.S. in focused.

International students coming from countries that do not have an established career counseling systems that function will have limited career exploration, search, and planning experiences (Singaravelu, White, & Bringaze, 2005). Furthermore, some international students may feel the need to reassess their career choices and majors, particularly if there is incongruence among their interests, abilities, and cultural and parental expectations (Singaravelu, White, & Bringaze, 2005). Cultural and parental expectations may be prioritized for some international students rather than their personal interests and goals. For example, Tang, Fouad, and Smith (1999) in a study on Asian American college students found that parental preferences and self-efficacy beliefs were the major components of career choices rather than students' interests.

Considering different career development concerns, career counseling for international students may be challenging (Spencer-Rodgers & Cortijo, 1998). In this chapter, Social Cognitive Career Theory (SCCT; Lent, Brown, & Hackett, 1994) is used as the approach to offer career counseling to international students at undergraduate and graduate levels.

Social Cognitive Career Theory

Lent, Brown, and Hackett (1994) developed SCCT as a framework of career development to explain (a) the development of academic and career interests, (b) the performance of career related choices, and (c) achievement of performance outcomes. Social Cognitive Career Theory is mainly based on Bandura's (1986) general social cognitive theory, with a focus on self-efficacy, expected outcomes, and personal goals and how they connect to other personal, contextual, and learning factors (Lent, Brown, & Hackett, 1994). In other words, SCCT is based on the idea that personal attributes, the environment, and overt behaviors influence each other while working together. Social Cognitive Career Theory also highlights the role of proximal and distant factors that can be either supports or barriers for the individual's career development.

Bandura (1986) defined self-efficacy beliefs as "people's judgments of their capabilities to organize and execute courses of action required to attain designated types of performances" (p. 391). According to the social cognitive view, self-efficacy beliefs are dynamic and specific to certain performance domains (Lent, Brown, & Hackett, 1994). They provide answers to questions related to if individuals can

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

perform specific tasks. For example, "Can I defend this dissertation?". Individuals' self-efficacy beliefs are important in the career decision-making process. For example, people move toward occupations for which they think they possess the required capabilities and move away from those for which they think they lack the necessary capabilities (Niles & Hartung, 2000).

Next, outcome expectations are beliefs regarding the outcomes of performing certain behaviors (Lent, 2005). They involve imagined consequences of certain courses of action (e.g., What job opportunities will I have if I get a degree in sociology?). Self-efficacy beliefs and outcome expectations are related to each other in the sense that individuals expect to receive positive outcomes in performing tasks for which they feel competent (Lent, 2005).

Finally, personal goals, which are a person's determination to engage in particular activities that lead to certain outcomes, influence career behaviors (Niles & Hartung, 2000). Setting goals help individuals organize, direct, and maintain their behavior over long periods of time even without external reinforcement (Lent, 2005; Lent, Brown, & Hackett, 1994). According to SCCT, people's personal goals are significantly influenced by their self-efficacy beliefs and outcome expectations (Lent, 2005). Personal inputs (e.g., age, gender, education level) interact with contextual factors (e.g., culture, family) and learning experiences to affect self-efficacy beliefs and outcome expectations, which in turn form interests, goals, actions, and achievements (Niles & Hartung, 2000).

Due to the fact that the preparation and implementation of career choices are generally associated with late adolescence and early adulthood (Lent, Brown, & Hackett, 1994), international students at the university level were selected as the target population of the current chapter. When working with international students in the career counseling process, it would be important to take into account the students' cultural factors and how these factors might influence their career choices. Depending on where the student is on the continuum of individualism to collectivism, his/her needs and expectations might have different levels of influence on his/her career choices. Social Cognitive Career Theory emphasizes the influence of the individual's inputs in addition to his/her background contextual factors (Lent, Brown, & Hackett, 2000), which makes it relevant to use with the international student population. The following section will explain how to use this theory on the career needs of the international student population.

SOLUTIONS AND RECOMMENDATIONS

Application of Social Cognitive Career Theory to Counseling International Students

Career counseling is a significant intervention that helps guide international students in planning their current and future career options (Shih & Brown, 2000). Social Cognitive Career Theory has been successfully applied to unique career needs of diverse populations such as first-generation college students (Gibbons & Shoffner, 2004), immigrants and refugees (Yakushko, Backhaus, Watson, Ngaruiya, & Gonzalez, 2008), and female offenders (Chartrand & Rose, 1996). Although there have been research studies using SCCT as the framework for studying the international student population such as Korean-Americans (Chang, 2005) and Asian-Americans (Tang, Foaud, & Smith, 1999), applied studies focusing on SCCT for counseling international students are lacking in the literature. Therefore, this chapter aims to highlight some important points for counseling international students for career development needs.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

To begin with, it would be important to include a strong cross-cultural component to the counseling process while working with international students (Paige, 1990). The cross-cultural component for international students could be thought as part of the clients' contextual factors in SCCT. While working with international students, it would be helpful for the counselor to be aware of the different counseling needs of this diverse student population as well as ways to reach these students. Therefore, being aware of the basic propositions of Multicultural Counseling and Therapy (Sue, Ivey, & Pedersen, 1996) such as both the counselor and the client having multiple identities at the individual, family, group, and cultural levels; cultural identity playing a major role in one's attitudes toward self and others; the importance of taking into account the client's culture while working with him/her; and respecting clients with different cultural backgrounds are important. Establishing good rapport and working alliance with the international student is also important for better understanding his/her needs and expectations (Gysbers, Heppner, & Johnston, 2003).

Considering the basic components of SCCT, counselors could help clients with assessing their level of self-efficacy, evaluating their outcome expectations, and looking at their actual and perceived supports and barriers concerning their goals (Wachter, Shoffner, & Newsome, 2009). For an international college student who is indecisive about his/her major, focusing on career interests, exploring different career options, and setting short- and long-term goals could be helpful. After getting the necessary information regarding the client's goals and expectations of the counseling process and of the counselor, the client could be given an interest inventory to help understand his/her interests better. After getting a sense of the client's interests, different career occupations could be explored with the client. During discussion of different career options, it is also important to take into account whether or not the client's abilities and skills are in line with his/her interests. While walking through the steps with the student, it is important to consider his/her values (i.e., cultural, parental, and personal), especially whether or not his/her personal values are congruent or conflicting with his/her parental and cultural values. The student's indecision could be due to conflicting value systems that s/he may not even be aware of. For example, for an undergraduate international student who is studying in a field that is not aligned with his/her interests but with his/her family's expectations of him/her, exploring personal and familial value systems and conflicts could be very helpful. If the client is a graduate student, his/her career needs might be different because of his/her developmental stage, which requires a different focus on career planning and preparation (Arthur, 2016; Shen & Herr, 2004). For example, a graduate student might be struggling with career indecision about job opportunities after graduation. More specifically, s/he may want to stay in the U.S. for a couple of years after graduation but is not sure how to go through the process and may be struggling with the status of being an international student–visa, work permits (Buchanan & Lee, 2008). Two student examples (i.e., an international male undergraduate student and an international female graduate student) will be used to explain different intervention strategies discussed in the following section.

Intervention Strategies Based on SCCT Components

The counselor could assess clients' needs within the systematic thinking process of SCCT by focusing on their self-efficacy beliefs, outcome expectations, goals, as well as their supports and barriers (Brown & Lent, 1996; Lent, Brown, & Hackett, 1994). In other words, the counselor could assess clients' self-efficacy level due to its importance in the decision making process. The client might have low self-efficacy because of going through some challenges as an international student. However, it is important for the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

counselor to keep in mind that international students also have strengths such as strong motivation for learning and working, global perspectives and experiences, international connections, and adaptability (Fuhrman, Lee, & He, 2007). It would be beneficial for the counselor to be able to use these and the client's personal strengths to increase the client's self-efficacy level. An intervention strategy that career counselors could use to help increase clients' self-efficacy beliefs is asking the client to create a lifeline that includes significant past experiences and anticipated future events (Chartrand & Rose, 1996). This lifeline could be used to explore the strengths and accomplishments in the client's life and could provide further discussion. The graduate student in our example might have low self-efficacy beliefs such as "I will not be able to manage the job application process." or "I cannot go through the bureaucratic paperwork all over again.". After drawing the lifeline and exploring it with the counselor, the client may come to realize that she has accomplished so much in life than she thought she had and feel motivated to plan her career. After the intervention strategy is successfully implemented the client's self-efficacy beliefs could increase to the level that she would say "I will be able to manage the job application process because this is what I want to do and I have done similar things in my life before." or "I can go through the bureaucratic paperwork once more.". As seen in the example, this strategy could help increase self-efficacy beliefs and motivate the client to take further steps in career planning (Chartrand & Rose, 1996).

Outcome expectations could also be evaluated with the client. Some of the negative outcome expectations for international students thinking about changing majors could be staying for an additional year, financial strains, disapproval of their family members, and additional paperwork to stay in the U.S. for an extra year. On the other hand, some positive outcome expectations could be enjoying the career to be pursued, having higher levels of work and life satisfaction as well as psychological well-being. The counseling process should be built on ways to help the client reach positive outcome expectations. Some of the interventions that could be used are identifying the client's coping mechanisms to deal with negative outcome expectations (Wachter, Shoffner, & Newsome, 2009), discussing pros and cons regarding different academic majors and career options, focusing on the strengths of the client, and looking at the big picture including the personal and contextual factors of the client together.

Let us turn back to our undergraduate student example at this point. The international student at the undergraduate level who is undecided about his major and is considering changing majors could have negative outcome expectations such as "I might have to stay for an additional year if I switch majors." or "My parents will probably disapprove my decision to change majors.". An intervention strategy that could be helpful in this situation is creating a career genogram (Gibson & Taylor, 2017; Okiishi, 1987) and talking about family members' career paths and their worldviews. Because the client has brought up the probable parental disapproval regarding his decision to change majors, this intervention could help the client explore parental and cultural values, which could be influencing his career options. While going through the genogram, the counselor and the client could talk about what careers the client's relatives have, how they view education and work, and how gender roles are perceived as in the client's culture. After discussing these and similar topics in detail, the client could come to the realization that the biggest thing which is holding him back from changing his major is the internal conflict of personal and parental values and aspirations and that he actually wants to change majors. This intervention strategy could make a change in the client's outcome expectations. For example, the client might be able to say "Staying for an additional year will make me happy and satisfied with my major and future career, so it is worth it." or "My parents will eventually understand and approve my decision to change majors because this is what I want to do in life.". However, the client might not change his negative outcome expectations directly to positive ones. In that case, the counselor could help the client realize some positive outcome

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

expectations that he has and at the same time could work on ways to recognize coping mechanism (e.g., the client's strengths) that could help deal with negative outcome expectations. As counseling is a process, the client will be able to change his negative outcome expectations to positive as he continues to gain self-awareness and feel understood and supported throughout the counseling process.

Furthermore, it is important to identify the client's perceived supports and barriers along the way. Some of the support systems for the graduate student who wants to stay in the U.S. for a few years after graduation could be future job opportunities, possibility of higher income, quality of life, professional network opportunities, supportive family members, friends, and any environmental resources (Han & Appelbaum, 2016). Some of the barriers could be family (depending on whether or not they are supportive), alternative job opportunities in her home country, bureaucratic paperwork, and legal issues. The counselor could help the client overcome the barriers and identify further support systems that could guide the client through the decision making process. A way to do this could be simply writing down the barriers and supports in the client's life and discussing how the barriers could be dealt with and even turned into supports (e.g., finding appropriate ways to talk with family members and being able to explain the client's point of view could change an opposing family into a supportive family). The counselor and the client could brainstorm alternative ways to cope with the barriers in the client's life. It is important for the counselor to work on helping the client discover her strengths and resources, and to build on them for dealing with the barriers. Arthur (2017) in her recent paper talks about the power of fostering three types of social resources for international students, which are academic faculty, counselors, and local students. Talking to faculty members could help international students learn about their experiences with career decision making, job search and recruitment processes; getting help from counselors could increase their self-awareness, which would lead to making decisions that are more aligned with themselves; and having local students as friends could be supportive in their experiences with the U.S. educational and employment systems as well as having social and emotional support. Making use of these and similar resources could help the client feel even more supported. The counselor could also give constructive feedback and continuously empower the client through counseling.

Throughout the counseling process, the counselor and the client could work on setting short-term goals that could help the client reach his/her long-term career goals. For instance, some of the short-term goals for the graduate student who is U.S. employment focused could be identifying job openings from the internet, updating his/her resume, writing a cover letter for a job opening s/he is interested in, and getting information about the bureaucratic paperwork that needs to be done for extending his/her stay in the U.S. If the counselor could help the client set realistic short-term goals and follow him/her up in terms of achieving those goals, things that need to be done in order to reach the ultimate goal may seem less burdensome for the client. It is important to go step-by-step and achieve relatively simple and short-term goals that will lead to the client's long-term goal.

It is important that the counselor spends time and energy to build and maintain a trusting and supportive relationship with the client. Having a good working alliance and trusting relationship will let the client explore his/her conflicts and/or emotions regarding the decision making process. Another point to keep in mind is that it is important to incorporate the client's personal inputs, cultural background, past and present experiences, important life events, and current life situation in SCCT (Chartrand & Rose, 1996) to get the whole picture and interactions among different variables. Different intervention strategies explained throughout this chapter could be used through the counseling process to help explore and provide discussion as well as to give an idea and help generate new interventions in working with international students. Whatever strategies are used as tools in counseling, it is important to keep

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

in mind that clients need to be continuously encouraged to explore, think about, and discuss different issues that could be relevant to their career needs during the counseling process.

FUTURE RESEARCH DIRECTIONS

Future research could focus on examining the current state of career counseling services provided for international students in the U.S. How international students perceive the career counseling services, what they find most useful for them, and how these services could be further developed to better meet their needs could be studied. Researchers could also focus on investigating the effectiveness of different career counseling strategies used with the international student population. Continuing to conduct studies on international students studying at the undergraduate and graduate levels would enable career counselors to better understand and help these students with their specific career needs.

CONCLUSION

Career needs of international students could be further complicated due to the challenges they face in the United States. The current chapter focused on some intervention strategies that could be used within the framework of SCCT for addressing the career developmental needs of international students at the undergraduate and graduate levels. It is important that career counseling focuses on empowering these students by concentrating on their strengths to increase self-efficacy beliefs, which in turn may change their perceptions of outcome expectations, supports, barriers, and goals.

Chapter 52
More Than Achievement:
Grit as a Key Component of Positive Psychology

Emily Hotez
City University of New York – Hunter College, USA

ABSTRACT

The last decade has witnessed an extraordinary interest in the concept of grit (i.e., "perseverance and passion for long-term goals"). Grit has garnered widespread attention in both the research and public spheres due to its association with lifetime educational and professional achievement. However, research indicates that grit has more far-reaching implications than simply educational and professional achievement; in fact, the literature suggests that grit is a key component of positive psychology, which aims to promote well-being more broadly. The current chapter will explore grit in the context of the positive psychology by reviewing the literature that supports grit as an important component of positive psychology. This chapter will also highlight the limitations of our current understanding of grit, discuss how these limitations implicate the field of positive psychology, and discuss next steps for grit research in light of these limitations.

INTRODUCTION

The last decade has witnessed an extraordinary interest in the concept of grit; i.e., "perseverance and passion for long-term goals" (Duckworth et al., 2007, p. 1087). This burgeoning fascination initially stemmed from intelligence researchers seeking to address why certain individuals accomplish more in life than others with equal intelligence (Duckworth et al., 2007, p. 1087). Although measures of effortful persistence (e.g., conscientiousness) have long been recognized as important components of success, grit has garnered specific attention in both the research and public spheres because it is suggested to predict lifetime outcomes above and beyond traditional measures of effortful persistence. In fact, research suggests that grit accounts for an average of 4% of the variance in success outcomes (Abuhassan & Bates, 2015, p. 2; Duckworth et al., 2007).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Indeed, numerous studies have found that grit is predictive of educational success (e.g., first-year grade point average [GPA] in college; Akos & Kretchmar, 2017; Duckworth et al., 2007; Duckworth & Quinn, 2009; Strayhorn, 2013) and this effect has been found to be predictive above and beyond IQ, standardized test scores, and high school grades (Akos & Kretchmar, 2017; Duckworth et al., 2007). Angela Duckworth, the foremost researcher on grit, noted in an interview that grit "beats the pants off of IQ, SAT scores, physical fitness, and a bazillion other measures to help us know in advance which individuals will be successful in some situations" (Scelfo, April 8, 2016).

In addition to educational success, grit has been found to be predictive of professional success later in life. For example, in a series of six studies, Duckworth et al. (2007) found that grit is an important predictor of professional success after college. Specifically, individuals with higher levels of grit not only attained higher levels of education and scored higher GPAs, but also reported making fewer career changes when surveyed at age 25 or older. Beyond basic educational and professional measures of success, grit has also been found to predict cadet retention at West Point and competitor ranking in the Scripps National Spelling Bee (Duckworth, Kirby, Tsukayama, Berstein, & Ericsson, 2011).

However, the implications of grit are farther reaching than simply predicting educational and professional success. In addition to these metrics, grit has been linked with personality traits (i.e., lower levels of neuroticism and higher levels of extraversion; Duckworth & Quinn, 2009), as well as positive affect, happiness, and life satisfaction (Singh & Duggal Jha, 2008). Indeed, grit is among the widely discussed soft or non-cognitive skills (i.e., "personality traits, goals, motivations, and preferences," Heckman & Kautz, 2012, p. 2). These soft skills (e.g., conscientiousness, self-control, trust, attentiveness, self-esteem, and self-efficacy) have been shown to foster hard academic skills as well as a diverse array of meaningful life outcomes across a range of domains (Diris, ter Weel, & Borghans, 2014; Kautz & Heckman, 2012).

In fact, grit has been found to be an important quality to consider in the field of positive psychology. Positive psychology is "the scientific study of positive experiences and positive individual traits, and the institutions that facilitate their development" (Duckworth, Steen, & Seligman, 2005 p. 630). Broadly speaking, the field of positive psychology aims to shift the emphasis of psychology away from pathology (Seligman & Csikszentmihalyi, 2014) toward building "human resilience, strength, and growth," as a means to achieving well-being, or other desired outcomes (Gable & Haidt, 2005, p. 107). Given this focus, it is clear that the construct of grit aligns well with the goals of positive psychology. As a result, it is a fruitful endeavor to look toward positive psychology as a framework to understand predictors of and associations with grit. In doing so, we can better understand how grit can be cultivated as well as the implications of grit more broadly.

The current chapter will review grit in the context of positive psychology in order to address the overarching goal of this textbook to utilize positive psychology as a means to offer best practices and practical ingredients for living a positive, happy, meaningful, and fulfilled life. Specifically, this chapter will address the following aims:

1. To discuss how grit is defined and conceptualized;
2. To review empirical and theoretical literature that supports grit as an important component of positive psychology; and
3. To highlight the limitations of our understanding of grit, discuss how these limitations implicate the field of positive psychology, and discuss next steps for grit research in light of these limitations.

BACKGROUND

Defining Grit

Grit has been broadly defined in the literature as "perseverance and passion for long-term goals" (Duckworth et al., 2007, p. 1087). To better understand grit, there have been numerous efforts to precisely differentiate grit from conceptually related constructs, including resilience (i.e., the ability to bounce back from, or have a positive response to, failure or adversity, Perkins-Gough, 2013), self-control (i.e., "the capacity to regulate attention, emotion, and behavior in the presence of temptation," Duckworth & Gross, 2014, p. 4), conscientiousness (i.e., "being hardworking, responsible, self-disciplined, and thorough," John & Srivastava, 1999; Muenks et al., 2017, p. 602), and work ethic (i.e., "a multidimensional set of values reflecting the importance of work in an individual's life," Meriac, Slifka, & LaBat, 2015, p. 401). Although grit has been found to be associated with many of these constructs (e.g., conscientiousness, Duckworth et al., 2007), grit is unique in its emphasis on "the tenacious pursuit of a dominant superordinate goal despite setbacks," and often requires "working assiduously toward a single challenging superordinate goal through thick and thin, on a timescale of years or even decades" (Duckworth & Gross, 2014, pp. 1-2). Simply put, grit is distinct in its "emphasis on stamina" (Akos & Kretchmar, 2017, p. 165).

Measuring Grit

An important consideration for defining grit is how it is measured in the empirical literature. Duckworth's laboratory developed the twelve-item (Grit-O) and eight-item (Grit-S) self-report scales and these are the primary measures of grit applied across the most recent research studies. Factor analysis procedures with these measures have identified that grit is comprised of two components, or factors (Duckworth et al., 2007). The Grit-S (i.e., the Short Grit Scale) retains this two-factor structure with four fewer items and improved psychometric properties (Duckworth & Quinn, 2009).

The first factor, consistency of interests, has been defined in the literature as goal- and action-oriented long-term behavior, rather than an individual or situational interest (Muenks et al., 2017). Consistency of interests is assessed via six items on the Grit-O, each measured using a five-point Likert scale: 1) I often set a goal but later choose to pursue a different one; 2) New ideas and new projects sometimes distract me from previous ones; 3) I become interested in new pursuits every few months; 4) My interests change from year to year; 5) I have been obsessed with a certain idea or project for a short time but later lost interest; and 6) I have difficulty maintaining my focus on projects that take more than a few months to complete.

The second factor, perseverance of effort, is conceptualized as the tendency to continue working toward a particular goal (Muenks et al., 2017). Perseverance of effort is also assessed via six items on the Grit-O, each measured using a five-point Likert scale: 1) I have achieved a goal that took years of work; 2) I have overcome setbacks to conquer an important challenge; 3) I finish whatever I begin; 4) Setbacks don't discourage me; 5) I am a hard worker; and 6) I am diligent.

EXPLORING GRIT IN THE POSITIVE PSYCHOLOGY FRAMEWORK

Given the importance of grit and the widespread interest in defining, measuring, and understanding grit, researchers have called for the need to investigate the extent to which it is associated with conceptually overlapping constructs (e.g., resilience, conscientiousness, etc.). A deeper dive into the constellation of constructs that comprise positive psychology, a field that theoretically aligns with grit, allows us to better understand this important concept.

Positive psychology can be defined as "the scientific study of positive experiences and positive individual traits, and the institutions that facilitate their development" (Duckworth, Steen, & Seligman, 2005 p. 630). The roots of positive psychology are based in the Humanistic perspective on psychology (Maslow, 1962), which seeks to address the questions, "What is the good life?" and "When are individuals at their best?" as well as "How can we encourage growth in ourselves and others?" (Duckworth, Steen, & Seligman, 2005, p.632). Over the past two decades, researchers have proposed a range of ways to effectively measure central components of positive psychology, beyond measures of happiness or well-being which are less conducive to empirical study. For example, Carol Ryff (1989) proposed a model based on self-acceptance, personal growth, life purpose, environmental domain, and positive relationships. Duckworth, Steen, and Seligman (2005) described the pleasant life (i.e., positive emotions about the past, present, and future); the engaged life (i.e., the use of one's strengths of character and talents to meet challenges); and the meaningful life (i.e., serving positive institutions).

Indeed, the field of positive psychology has evolved substantially over the last two decades, in part spurred by the work of Martin Seligman, a key pioneer in the field of positive psychology. According to Seligman, the best measure of well-being is flourishing (i.e., achieving an existence of greater meaning) (Scorsolini-Comin, Fontaine, Koller, & dos Santos, 2013). In turn, the goal of positive psychology is to increase flourishing (Seligman, 2012). Flourishing, according to Seligman (2012) is based on five pillars: 1) Positive emotions; 2) Engagement; 3) Positive relationships; 4) Meaning; and 5) Accomplishment (i.e., the PERMA model). This section will investigate grit in the context of the PERMA framework proposed by Seligman (2012) in order to better understand the correlates of and sources from which grit is derived (Hill, Burrow, & Bronk, 2014), as well as to further conceptualize grit as a key concept in positive psychology.

The purpose of this section is not to provide an exhaustive review of empirical and theoretical research in these domains; rather, it is to highlight research that demonstrates the relationship between grit and positive psychology constructs. Importantly, many of the studies that will be discussed do not specifically measure grit—rather, they assess conceptually related constructs that can inform our understanding of grit. This limitation should be considered when evaluating these research findings. In addition, the studies outlined below represent research with a range of populations and methodologies, so research findings should be interpreted with appropriate caveats.

Grit and Positive Emotions

The first pillar proposed by Seligman (2012), *positive emotions*, includes an emphasis on constructs such as satisfaction, contentment, fulfillment, pride, serenity, optimism, hope, confidence, faith, and trust (Seligman, 2002). Positive emotions may have important implications for understanding grit because they have been recognized as key components of conceptually similar constructs, including resilience (Cohn, Fredrickson, Brown, Mikels, & Conway, 2009).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

As an example, Cohn et al. (2009) investigated the broaden-and-build-theory—that is, the idea that positive emotions represent "evolved adaptations that function to build lasting resources…" (p. 2). In other words, the broaden-and-build theory posits that positive emotions are, in essence, the building blocks for resilience. In the context of this particular study, the authors investigated 86 college students' every day experiences of positive emotions (e.g., amusement, awe, compassion, contentment, gratitude, hope, interest, joy, love, and pride) and their role in facilitating resilience. Daily positive emotions were assessed via the completion of online daily emotion reports, which consisted of the Differential Emotions Scale (mDES, Fredrickson et al., 2003). In this questionnaire, participants rated their strongest experiences of 18 emotions in the past day on a 5- point scale (0 = not at all, 4 = extremely). Resilience was assessed via the ER89 (Block & Kremen, 1996), which consisted of fourteen Likert scale items assessing responses to challenging and shifting circumstances, e.g., "I enjoy dealing with new and unusual situations." Findings from this research demonstrated that individuals who were experiencing more daily positive emotions had higher levels of resilience. The authors interpreted these results by concluding that individuals with more positive emotions were better equipped to deal with challenges in their lives.

Indeed, other studies have yielded consistent results, also finding that resilient individuals experience more positive emotions. For example, resilient college students tested before and after the September 11, 2001 terrorist attacks reported experiencing gratitude, interest, love, and other positive emotions (Fredrickson et al., 2003). Additional findings with college students suggest that experiencing positive emotions contributes to an individual's ability to achieve efficient emotion regulation and find positive meaning in negative circumstances (Tugade & Fredrickson, 2004). These studies focus on resilience, which is conceptually akin to the perseverance of effort dimension in grit (e.g., "setbacks don't discourage me"), so they offer a useful lens into understanding the potential role of positive emotions in explaining grit. Thus, from the broaden-and-build perspective, research on resilience among college students suggests that the experience of positive emotions on a daily basis may be an important factor in promoting grit.

Grit and Engagement

The second pillar proposed by Seligman, *engagement*, is a "multi-dimensional construct that is associated with being deeply involved in an activity" (Muenks et al., 2017, p. 602). The notion of engagement is grounded in research from Mihaly Csikszentmihalyi on flow (i.e., a state of being completely absorbed in, and concentrating on, a challenging activity ((Csikszentmihalyi, 1991). In an interview with Csikszentmihalyi, he notes that engagement is a broader concept than flow, and is often manifested through flow (Beard, 2014). Specifically, engagement focuses on the question, "how do you find positive ways to relate to your environment and the opportunities of life?" (p. 357). In this interview, Csikszentmihalyi explains that experiencing flow is an important skill that promotes achievement because it facilitates working intentionally toward a particular goal. Indeed, survey research suggests that flow may be a strong predictor of job satisfaction among employees with a range of jobs (Maeran & Cangiano, 2013). Further, preliminary research suggests that engagement is a predictor of job success. For example, case study research has highlighted the role of flow for an educational administrator in closing a district's school achievement gap (Beard, 2015).

Researchers have begun exploring the relations between engagement and grit. For example, Von Culin, Tsukayama, & Duckworth (2014) explored how individual differences in grit may be explained by distinct approaches to pursuing happiness. The researchers conducted two cross-sectional studies with adults recruited over the internet to address their research question. In both samples, individuals with

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

higher levels of grit tended to seek happiness through engagement, a relationship driven primarily by the perseverance of effort component of the Grit-S. This finding is consistent with additional studies that suggest that those with a higher level of educational and professional success are more likely to endorse engagement as a path to overall happiness (Schueller & Seligman, 2010). Indeed, grit and engagement have been explored in additional contexts with consistent results. For example, Martin, Byrd, Lewis Watts, & Dent (2015) investigated a sample of wheelchair basketball athletes and found that those reporting the highest levels of grit and resilience tended to be the most engaged in their sport. Taken together, research suggests that individuals with higher levels of grit may have higher levels of engagement in a particular activity, and may, in turn, derive more satisfaction from being highly engaged in activities.

Grit and Positive Relationships

The third pillar in the PERMA framework focuses on seeking out and maintaining positive relationships. As stated above, grit has more far-reaching implications than simply predicting educational and professional achievement. Indeed, researchers increasingly conceptualize success not only in terms of hard skills, but also in terms of soft skills, including the capacity to develop and maintain social relationships (Heckman & Kautz, 2012). In fact, research reveals that social relationships are intricately connected with physical and mental well-being (e.g., Holt-Lunstad & Smith, 2012).

As an example of the literature that suggests grit and social relationships are related, Feeney and Collins (2015) present a theoretical model on thriving (i.e., "flourishing [growing or developing vigorously], prospering [being successful; gaining wealth or possessions], and progressing toward or realizing a goal despite or because of the circumstances", p. 114). In this model, the authors highlight two contexts that are conducive to thriving: 1) "coping successfully with life's adversities," and 2) "actively pursuing life opportunities of growth and development"—both of which are conceptually related to grit.

In this theoretical model, the authors propose that thriving is promoted by social support, particularly by way of "well-functioning close relationships." Specifically, the authors note that an individual's relationships not only serve as protective factors in stressful situations, but also facilitate the individual's capacity to flourish in the face of adversity. In addition, our social relationships advance our capacity to engage in opportunities to promote well-being. Specifically, close relationships allow individuals to "fully embrace life" and thrive (Feeney & Collins, 2015, p. 116-119). If we apply the theoretical model from Feeny and Collins (2015) toward understanding the relationship between positive relationships and grit, we can postulate that positive relationships bolster an individual's capacity to harness grit. Empirical research is needed to further explore this theoretical model.

Grit and Meaning

The next PERMA pillar focuses on the notion of meaning, which in positive psychology refers to "belonging to and serving something that you think is bigger than you are" (Seligman, 2010, p. 234). There are two components to meaning: 1) the presence of meaning in life (i.e., the current attribution of meaning in one's life) and 2) the search for meaning in life (i.e., motivation toward finding meaning in life, Steger & Shin, 2010; Vela, Lu, Lenz, & Hinojosa, 2015). There is limited research that explores whether individuals with greater presence of or search for meaning also have higher levels of grit.

As an example of this research, Vela, Lu, Lenz, and Hinojosa (2015) explored several positive psychology constructs, including presence of meaning in life, search for meaning in life, hope, and family

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

importance among 128 Latina/o college students, with a particular eye toward the relationships between these constructs and grit. Presence of and search for meaning in life were assessed using the self-report Meaning in Life Questionnaire (Steger, 2006), which includes ten Likert-scale statements assessing presence of meaning (e.g., "I understand my life's meaning") and search for meaning ("I am always looking for my life's purpose").

Findings revealed that search for meaning in life was a significant predictor of grit, such that higher levels of search for meaning in life negatively predicted grit. In other words, those who reported a greater search for meaning had lower levels of grit. The authors posited several interpretations of this finding. One such interpretation is that students who search for meaning in life may have lower levels of grit because individuals with inadequate meaning in life may possess fewer resources to cope with stressful situations. As a result, the authors recommended that a presence of meaning in life should be fostered in this population, which may, in turn, enhance grit. However, the authors found no relationship between presence of meaning and grit, suggesting that future research is needed to better understand these relationships.

Grit and Accomplishment

The final PERMA pillar is accomplishment, which refers to the motivation to "achieve, to have mastery, and to have competence," (Seligman, 2010, p. 234). Importantly, there is a distinction in the PERMA model between achievements for extrinsic versus intrinsic value, with an emphasis on the latter. Seligman uses the example of playing bridge to demonstrate this distinction, noting that "great bridge players divide into two categories: those who, when they play, are engaged and happy, and those who just play to win." (Seligman, 2011, p. 234).

Generally speaking, accomplishment and achievement have been the most widely discussed constructs in relation to grit. As previously mentioned, grit initially gained widespread attention because of its associations with a diverse range of achievement outcomes across various populations and contexts (e.g., Duckworth et al., 2007; Duckworth & Quinn, 2009). However, not all studies have yielded consistent findings with respect to the predictive role of grit in educational performance (e.g., Maddi et al., 2012). For example, Credé, Tynan, and Hams (2017) note that there are several potential moderators to the relationship between grit and future performance, including the nature of the performance domain. The authors posited that grit may not predict performance on certain tasks, particularly those that are easy, do not require substantial grit, or those that require creativity, flexibility, or other qualities beyond grit.

As a result of the inconsistent findings, there are still ongoing efforts to better understand the role of grit in predicting achievement. For example, Muenks, Yang, and Wigfield (2017) investigated the two components of grit (i.e., consistency of interests and perseverance of effort), and how they overlap with future-oriented motivation (i.e., motivation that reflects an "ability to imagine or consider the future," p. 3) among high school students. The authors also investigated how grit relates to other motivational variables, e.g., self-efficacy (i.e., "individuals' beliefs that they can accomplish a given activity," p. 4), task values (i.e., the extent to which students find tasks interesting and "important or useful") and goal orientations (i.e., "approaches students take to [meet] their learning [goals]," p. 4), as well as how grit predicts achievement. The authors conducted exploratory factor analyses to investigate these variables. Findings revealed that perseverance of effort was strongly associated with self-efficacy, task values, and goal orientations, and was a significant predictor of end-of-semester grades. The authors interpreted these

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

findings by concluding that the perseverance of effort component of grit is a key component not only of achievement, but also of motivation, and this component is more predictive than consistency of interests.

LIMITATIONS AND NEXT STEPS FOR THE FIELD

As is evident throughout the current chapter, research on grit and related constructs has significantly expanded over the past two decades. At the same time, there are clear limitations to our current understanding of grit. The following section outlines some of these limitations and proposes next steps for the field.

Conceptualizing the Theoretical Foundations of Grit

As grit has gradually received increased attention in the research and public spheres, it has also received critiques on its fundamental theoretical foundations. One such critique is that grit and related constructs minimize the influence of structural injustices in society that impede an individual's ability to attain success (Scelfo, April 8, 2016). This critique is parallel to a broader critique of positive psychology, namely that positive psychologists fail to sufficiently recognize the role of societal factors (e.g., inequality) in predicting life outcomes (Gable & Haidt, 2005). For the most part, limited research has been conducted to address whether grit is, in part, a byproduct of broader contextual factors. As an example of this research, Akos and Kretchmar (2017) statistically controlled for gender, race, and first-generation college student status in their analysis of grit. Although they found no differences in total grit scores between racial minorities and non-minorities, they found that racial minorities rated themselves lower on the perseverance of effort scale relative to non-minorities. The finding that minorities may rate themselves lower on grit should be further investigated in additional research studies, particularly in light of the self-report nature of the Grit-O and Grit-S. In a recent interview, Duckworth responds to some critiques of grit by noting, "That's not message…It's not that poverty or racism doesn't matter, it's just that hard work does matter" (Scelfo, April 8, 2016). In other words, although grit is an important factor to investigate, it should not be analyzed without consideration of broader contextual factors.

Critiques on the theoretical foundations of grit also suggest that the study of grit minimizes the importance of additional influences on development, including genetics and IQ scores (Brown, May 7, 2016). As a result, research has been conducted to determine the utility of taking these factors into account when assessing the predictive role of grit. For example, Abuhassan and Bates (2015) conducted structural equation modeling among 494 adults to assess whether grit does indeed predict achievement over and above personality and IQ scores. The authors examined several metrics of achievement, including school grades and overall life-course accomplishment, which included a self-report measure capturing a wide variety of domains in achievement the U.S. Indeed, this work supported that all three factors (i.e., grit, IQ, and conscientiousness) predicted achievement. Specifically, conscientiousness and IQ predicted school grades and the perseverance dimension of grit predicted higher life-course achievement. Taken together, findings indicate the need for future research to examine grit in the broader social and developmental context.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Investigating the Measurement of Grit

In addition to theoretical critiques, there are also empirical critiques of grit. For example, grit is primarily measured using either the twelve- or eight-item self-report scales, which are subject to the limitations of other self-report assessments (e.g., response bias, memory bias, and internalized prejudice). As a result, it has been recommended that researchers consider other methodologies for assessing grit, including informant reports, diaries, structured interviews, or other alternatives to self-report questionnaires (Akos & Kretchmar, 2017; Duckworth, Steen, & Seligman, 2005). As an example of an attempt to expand on existing methodology, Akos and Kretchmar (2017) tested undergraduates' self-report grit scores against informant grit scores (i.e., grit ratings from teachers, parents, guidance counselors, employers, etc.) as a means to understanding potential self-report bias. The researchers found differences between the self- and informant-report grit data, with informant-report data yielding generally higher total grit scores. However, the two measures of grit were highly correlated with one another (i.e., below-average self-report scores tended to coincide with below-average informant-report scores). Future research should continue to test the utility of using an informant approach as a means to account for potential bias derived from self-report.

In addition to the self-report bias as a potential measurement limitation, researchers generally cite the need to expand on cross-sectional findings with longitudinal and experimental designs. These designs would allow researchers to determine whether grit is a stable characteristic that persists across the lifetime. Current research suggests that, as is the case with several of the non-cognitive skills, grit is likely not a fixed characteristic. For example, Duckworth et al. (2007) found that older individuals tend to be higher in grit than younger individuals. The authors interpreted these findings to suggest that grit may increase across the lifespan (Eskreis-Winkler, Gross, & Duckworth, 2016). Researchers have called for more rigorous research designs in order to further investigate grit over time. This research would clarify the directional influences of grit and other positive psychology constructs. Further, more rigorous research designs would allow researchers to rule out potential confounds and explore interaction effects (Von Culin, Tsukayama, & Duckworth, 2014).

Investigating Approaches to Enhance Grit

Understanding the importance of grit immediately calls into question whether or not grit can be fostered through interventions or other educational approaches. There is clear utility to this line of research; if grit can be cultivated over time, can we improve outcomes in educational, professional, and interpersonal domains? Indeed, several research studies with different populations have lent support to the potential benefits of developing such interventions. For example, among college students, Vela, Lu, Lenz, and Hinojosa (2015) recommended interventions to increase Latina/o students' meaning in life and grit. They propose several possible interventions to explore, including positive interventions, which are techniques that seek to build pleasant, engaged, and meaningful lives (Duckworth, Steen, & Seligman, 2005). Also in development are interventions or educational approaches that would enhance PERMA qualities associated with grit. For example, Seligman and Csikszentmihalyi (2000) argue that flow should be fostered in schools and other institutions. This work is well underway, with research focused on developing ways to assess behavioral engagement, i.e., "effort exertion, persistence, attention, and concentration" among elementary school students (Muenks et al., 2017; Skinner et al., 2009, p. 10).

Despite these ongoing efforts, Angela Duckworth herself cautions against the widespread applications of grit in educational or policy contexts, particularly in light of the preliminary nature of much of the research on grit. For example, in a recent interview she notes that emphasizing grit in the classroom may be "another reason to blame kids for not doing well, or to say that we don't have a responsibility as a society to help them." She notes that "kids need to develop character, and they need our support in doing so" (Dahl, 2016). In order to ensure that her research on grit is appropriately translated into educational contexts, Duckworth is initiating collaborations among teachers and scientists to translate the evidence into practical applications for the classroom (Dahl, May 9, 2016). As research continues to emerge that speaks to the potential relevance of grit, careful consideration of how to apply research findings in practice and policy will be increasingly important.

Understanding Grit Across Cultures

Several research studies have investigated whether the aforementioned findings on grit hold true in different cultural contexts. In these efforts, research findings were not always replicated across cultures, suggesting that the findings discussed throughout this chapter may not apply universally. For example, Suzuki, Tamesue, Asahi, and Ishikawa (2015) investigated grit among a sample of working adults in Japan. This research found that orientation toward meaning, rather than engagement, was more strongly related to grit. However, consistent with findings from the U.S., this research also found grit to be a strong predictor of both work and academic performance (Suzuki, Tamesue, Asahi, & Ishikawa, 2015). Along these same lines, Datu, Valdez, and King (2016) investigated the relationship between grit, education, and well-being outcomes among Filipino high school students. The authors found that the two dimensions of grit were not significantly correlated, which is generally inconsistent with the Western body of literature. These findings call into question the universality of Western findings on grit and suggest that there may be untapped cultural differences that should be explored in future research.

CONCLUSION

The current chapter discussed how grit is defined and conceptualized and subsequently reviewed empirical literature that supports grit as an important component of positive psychology. In concluding, this chapter highlighted the limitations of our understanding of grit, discussed how these limitations implicate the field of positive psychology, and suggested next steps for the literature on grit in relation to positive psychology in light of these limitations.

In reviewing grit in the context of positive psychology, this chapter summarized the relationship between grit and key positive psychology constructs, namely positive emotions, engagement, positive relationships, meaning making, and accomplishment (i.e., PERMA; Seligman, 2010, 2011). The research on grit in a positive psychology context suggests several general trends. First, grit may be promoted or facilitated through daily experiences of positive emotions, positive relationships with others, and a sense of meaning or purpose in life. Second, individuals with higher levels of grit tend to have higher levels of engagement in a particular activity, and may, in turn, derive more satisfaction from being highly engaged in activities. Finally, grit may strongly predict performance in certain contexts, but not in others, and the two grit components may differentially predict outcomes.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Although there have been great strides in research on grit over the last decade, researchers should seek to address the gaps in the research moving forward. There is a particular need to further investigate grit in the context of broader socioeconomic, developmental, and cultural factors. Additional measurement techniques, including informant reports, may elucidate any measurement biases due to self-report. Longitudinal analyses will be particularly fruitful for studying grit; evaluating change over time will help disentangle the utility of grit relative to conceptually related constructs, clarify the extent to which grit predicts long-term outcomes, and provide information on how grit changes over time. This type of work will also provide insight into the feasibility and utility of grit-focused interventions or educational programming.

Chapter 53
Psychotherapy in Indigenous Context Psychotherapy in Indigenous Context:
A Ghanaian Contribution towards Provision of Culturally Competent Care

Frances Emily Owusu-Ansah
Kwame Nkrumah University of Science and Technology, Ghana

Gordon M. Donnir
Komfo Anokye Teaching Hospital, Ghana

ABSTRACT

This chapter posits that the science of psychotherapy is a culturally defined art. Psychological theories must, of necessity and efficacy, be adapted and responsive to the context within which they are practiced. The Ghanaian cultural context is deeply spiritually-oriented. Socio-religious beliefs in this cultural context define the Ghanaian concept of health, ill health, and health-seeking behaviours. Therefore, effective psychotherapy and culturally competent care must be context specific and suited to the needs, norms, practices and beliefs of the indigenous people. Yet, it is not unusual to find clinicians who practice in one cultural context but were trained in another; a situation that sometimes hinders effective service delivery. The chapter discusses some of the challenges faced by Ghanaian psychotherapists, practicing in Ghana, who were trained in a non-African cultural context. Excerpts of clinical case studies are used to illustrate these issues and suggestions for culturally competent care conclude the chapter.

INTRODUCTION

Many clinicians will agree that the practice of psychotherapy is both science and art (Yalom, 2002). The science of psychotherapy is well established in the numerous empirically validated treatments bequeathed to the field. However, the delivery of these in the actual client-therapy encounter is an intricate art; and

the efficacy of it is moderated by the clinical skills, flexibility, and sensitivity of the practitioner to the context-specific needs and best treatment options for clients (Wendt & Gone, 2011). Attentiveness to cultural effects facilitates the development of a therapeutic alliance, one of the most important ingredients in any psychotherapy. Establishing rapport with clients relies partly on culturally determined effective communication, which entails negotiation of differences and nuances in language, communication style, and non-verbal expressions (Yalom, 2002). Challenges notwithstanding, these nuances can be better negotiated by indigenous therapists even though the indigenous therapist may have an added hurdle of combining indigenous knowledges with his or her western knowledge and skills.

In this chapter authors examine some of the challenges inherent in the 'art' of the practice of psychotherapy and focus specifically on how indigenous therapists trained outside of own cultural context can be effective in their service delivery. Authors' insights, shared here, come from own struggles and reflections over years of clinical practice in Ghana having been trained in a western cultural context. Wrestling with questions of application and how to 'unpack' western acquired knowledge and skills for the Ghanaian cultural context brought on a somber realization that there are more questions than ready answers and a strange sense of alienation in own country. These reflections motivated the authors to examine cultural competence challenges of 'foreign-trained-local' clinicians; that is, indigenous therapists who were trained in western contexts but are practicing in own cultural context.

The method of phenomenology, rooted in Husserl & Heidegger's philosophical traditions (Reiner 2012), as an inductive qualitative research, guides this discourse. According to Heidegger's interpretive hermeneutic approach, considered suitable for this discussion, it is impossible to negate own experiences about a phenomenon under study (Giorgi 2007). Therefore, the authors' experience as 'foreign-trained-local' clinicians are not 'bracketed'. Thus, experiences of the authors are presented and exemplified with selected cases, and interpreted to highlight challenges within the Ghanaian cultural context.

Psychotherapists who return to own country after training elsewhere face the challenge of re-acquainting self with indigenous knowledge of health and illness in order to adapt acquired knowledge to own context for meaningful culturally competent service delivery for which a good knowledge and understanding of own cultural context is necessary (Nsamenang, 1995; Mpofu, 2002). The need for awareness, support, and discussion around the issue of alienation and other challenges experienced by some African health professionals who were educated and trained outside their cultural context when they return to practice in own cultural environment cannot be underestimated (Idemudia, 2004; Nsamenang, 1995) and particularly so in this day and age when migration to greener pastures is the norm (Hagopian, Ofosu, Fatusi, Biritum, Essel, Hart & Watts, 2005). Yet there is a paucity of literature on the experiences of 'foreign-trained-local' health practitioners to inform clinical practice in a way that promotes indigenous knowledges and context-specific interventions.

Therefore, the objectives of this chapter are twofold: first, to highlight some of the cultural beliefs that affect psychotherapy in the Ghanaian context and second, to examine challenges experienced by Ghanaian psychotherapists who were 'foreign' trained but who have returned and are practicing in the country. Three steps are taken to actualize these objectives. One, some culture-specific health-related beliefs within the Ghanaian context relative to the practice of psychotherapy are discussed. Two, culturally embedded challenges faced by Ghanaian psychotherapists trained abroad are highlighted with excerpts from selected case studies and finally, implications of findings for the provision of culturally competent care are discussed.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

An understanding of the practice of psychotherapy, and its related challenges, in Ghana necessitates a good grasp on the people's concept of health and illness since these are culture bound (Azuma, 1984; 2002; Mpofu, 1994; Nsamenang, 2006; Sarpong, 1991; Harley, 2006; Hewson, 1998; Jahoda, 1979; Moylan, 2009; Mji, 2009; Ofori-Atta & Linden, 1995; Tseng, 2006). Likewise, culture determines what is acceptable, what is forbidden, and what is perceived stressful (Sarpong, 2002). Western definitions of these concepts, treatment options, and or expected responses to stress are not necessarily applicable in other cultural contexts (Tempany, 2009).

Relatedness theory appropriately contextualizes this discussion of psychotherapy in the Ghanaian society. The three components of the theory – ways of knowing, ways of being, and ways of doing – are central to the understanding of behaviours in indigenous cultural contexts (McGinty, 2012). A people's world view, and the consequent inherent beliefs, determine to a large extent their cultural practices as well as the ways in which they relate among themselves and with the environment (Moylan, 2009). In predominantly communal cultural contexts, levels of relatedness have been associated with growth, health, and or ill health (Hagerty, Lynch-Sauer, Patusky, and Bouwsema, 1993). In such contexts the concept of health is defined as biopsychosocial, spiritual, and environmental health. In other words, good health is neither merely the absence of illness nor simply physical wellbeing of the individual but also refers to the social, emotional and cultural wellbeing of the whole community (Moylan, 2009; Shai-Mahoko, 1996; Campbell-Hall, Peterson, Bhana, Mjadu, Hosegood & Flisher, 2010).

In Ghana, health and wholeness are anchored in relationships and essentially associated with being 'truly human' ("*nnipa*"). A 'human being' relates; and has good relationships with others that foster health and wholeness. Initiating and maintaining meaningful social networks and relationships are therefore believed to be very important to harmonious living and good health. Among the Akan of Ghana, for example, a person referred to as "*nnipa*" ('a human being') is one who lives in right relationship with self, others and the environment. Someone who has no regard for others, self or the environment, is rightfully referred to as an "*aboa*" (an animal!). Therefore, in the Ghanaian cultural context, like some other African contexts (Harley, 2006; Mji, 2009; Campbell-Hall et al., 2010), it is not unusual to associate ill health with 'broken' relationships – with self or others.

The Ghanaian cultural worldview, like other African cultures, is communal and spiritually oriented (Lambo, 1974; Osei, 2001; Sarpong, 1991, 2002). Life is understood and lived from perspectives that reflect beliefs in oneness, interdependence and interconnectedness; a universe perceived in unities, not opposites, one in which there is no clear distinction between the sacred and secular, the natural and supernatural, the living and the non-living. The invisible is believed to be just as operative as the visible and the non-living as influential as the living (Sarpong, 1991, 2002). In this 'spiritually charged' cultural context, there are no 'accidents'. Everything happens for a reason. Therefore, causal attributions for events are essentially influenced by the people's understanding of wholeness and illness (Ae-Ngibise, Cooper, Adiibokah, Akpalu, Lund, & Doku, 2010); just as the choice of treatment for illness, particularly mental illnesses, is similarly culture determined (Berry & Crowe, 2009; Shai-Mahoko, 1996; Tempany, 2009; Ae-Ngibise et al., 2010).

The perception of the etiology of illness (physical or mental illness) expands beyond the biological to include moral, social, and spiritual dimensions (Ae-Ngibise et al., 2010; Harley, 2006; Lauer, 2006; Nelms & Gorski, 2006; Ross, 2008; Tanner, 1999). Breach of socially acceptable behaviours are not only believed to be morally wrong but punishable through misfortunes and ill health (Sarpong, 2002).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The punishment can extend beyond the culprit to the one's family as well as generations unborn. Influence of evil machinations, witchcraft and hostile ancestral spirits are also believed to be possible causes for ill health (Sarpong, 2002). Aside moral and supernatural causes, etiology of ill health might be attributable to disturbance in social relations and improper conduct (Harley, 2006; Osei, 2001; Sarpong, 1991); hence the intimate link between cultural constructions of etiology of mental illness and treatment seeking behaviors (Osei, 2001).

Use of traditional and faith healers is popular and wide spread not only because of their availability and affordability, but also because "people think mental illness is not physical, but spiritual and they [clients] believe these [spiritualists and traditional healers] are the custodians of spiritual issues so they go to them" (Ae-Ngibise et al., p. 561). This practice, of seeking traditional healing for illness, is not only common in Ghana (Foster, 2012) but also observed in other African countries (Campbell-Hall et al., 2010; Berry & Crowe, 2009; Tempany, 2009; Babb, Pemba, Seatlanyane, Charalambous, Churchyard, & Grant, 2007; Lauer, 2006; Mpofu, 2006; Idemudia, 2004; Adele, 1998; Hewson, 1998; Shai-Mahoko, 1996;) and even among Africans in the diaspora (Harley, 2009).

As culture changes with time so too does the 'foreign-trained-local' professional who returns after years of being away from home environment. The intrapersonal changes add to the initial feelings of alienation, and frustration that accompany the struggle to adapt knowledge and skills to context. The realization, for example, that within own cultural context unlike place of training treatment is not solely the prerogative of orthodox facilities and professionals but includes consultation of faith healers and traditional medicine men and women can be initially disparaging.

In effect, within the Ghanaian cultural context it appears that 'westernized' conceptualizations of health and wellbeing, and psychotherapeutic interventions arising out them are inadequate when solely used for responding to treatment of Ghanaian mental health problems. Could it be that western therapeutic interventions whose underpinning values are primarily secular, individualistic, and materialistic do not fit congenially into a cultural context underpinned by philosophical values that are communal, spiritual, inter-related, and ecological as suggested by Moylan (2009)? Or are professionals trained in the western individual-centered theories, even when indigenous, poorly equipped to comprehend and effectively respond to the complexities of mental health issues in communal cultures? What can be gleaned from the experiences of the 'foreign-trained-local' to inform better context-specific therapeutic approaches? These are complex, multifaceted questions; and possible answers are yet to be delineated and empirically validated through research.

UNDERSTANDING THE GHANAIAN CULTURAL CONTEXT

The authors practice of psychotherapy is situated in the department of psychiatry in a general hospital. This is not unusual as the few psychologists in the country are mostly not in private practice but are affiliated with hospitals. The practice of psychotherapy in Ghana and its related challenges would be better understood against the backdrop of the history of psychiatry practice in the country.

The history of the practice of psychiatry in Ghana is relatively recent. While general hospital psychiatry began in 1728 and 1902 in Great Britain and the USA respectively, the then Gold Coast was in the early 1900s beginning to respond to the need to provide for its mentally ill citizens some form of care under the then new system of custodial segregation for the mentally ill which led to the establishment of the Accra Psychiatric hospital in 1906. For many years the entire West Africa sub-region suffered a

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

paucity of psychiatrists and other mental health care professionals including psychologists. This paucity of specialists in this field reflected the general negative and stigmatized attitude held toward psychiatry, as it was locally shrouded in witchcraft, juju, taboos, religious cults, and fetish influences (Lambo, 1959). Therefore, treatment for mental ailments had been in the hands of spiritualists, pastors, and herbalists.

In recent years, there has been a gradual positive change of attitude towards the mentally ill, the field of psychiatry and related disciplines. However, the function of the fetish priests, pastors and spiritualists continues to exist. Sometimes after a patient has been discharged from hospital recovery is regarded as only partial, becoming complete only after the performance of certain customary rites or prayers and vice versa. It is not uncommon for a patient to be unceremoniously removed from hospital by a relative in order to consult a traditional or spiritual healer because of a widely held belief that supernatural evil forces cause psychiatric illness that can best be banished by traditional medicine. This is the reality in which psychiatric practice has existed for a long time in Ghana (Foster, 2012) and the context within which many cases for psychotherapy are referred in the general hospital setting.

The American Psychological Association (APA) and the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) define psychotherapy as *specific* and specialized efforts/actions directed towards or taken for the purpose of *positively* influencing the human mind, feelings and behavior with the objective of promoting good mental health and wellbeing. If psychotherapy is essentially aimed at the promotion of human wellbeing, carried out through a variety of institutionalized processes, then within the Ghanaian cultural context it is intricately woven with the people's way of life and the *sine qua non* in all activities in which human suffering or distress is alleviated and wellbeing restored. Most cultural activities are ritualized and these span relatively simple occasions like child-naming ceremonies, burial and funeral ceremonies, to complex rituals of cleansing, appeasement, and purification observed during festivals such as the *Akwasidae* or *Homowo* festivals. Thus, though the indigenous practices may not be so termed as 'psychotherapy', it is very clear that before the advent of westernized forms of psychotherapy the Ghanaian people have practiced effective psychotherapeutic interventions that restore health, celebrates life, and promote wellbeing.

In the rural and traditional settings, therapy is practiced by women and men who are greatly respected in the community and who, through their long years of training, meditation, self-disciplined way of life is believed to possess mystical powers in the practice of healing art. These include the '*odunseni*' ('medicine man'), the '*okomfo*' (the 'fetish'), '*osofo*' (the pastor/spiritualist) or simply '*opanin*' (wise 'elder'). The diagnosis of psychological or emotional disorder within this cultural context often involves several processes, socio-communal and interpersonal, though the individual is at the center of it all, to determine immediate and remote cause of illness and to inform the action to be taken or therapy to be followed.

In this highly spiritual oriented culture attribution of cause for every happening is just as important as the happening itself and people readily attribute illness to supernatural causes when the physical/biological fail to provide satisfactory explanation for the condition. The perception is that there is and should be some spiritually remote reason or answer to just about any happening where physical explanations cannot be fathomed. This way, many therapists are confronted with the constant and persistent question from clients "and so what actually caused this illness you describe as depression", for example. This would usually occur after the therapist has taken the time to explain the biopsychosocial factors bringing about the illness. The recurrence of this kind of question throughout the therapeutic encounter tells the therapist that the client is not settled in his/her mind about the 'true' cause of illness and thus does not believe in the prescribed mode of treatment; sometimes leading to defaulting in treatment or abandoning therapy all together.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, in the quest for explanation and healing from illnesses, many 'players' are consulted: traditional healers, pastors and spiritualists, and 'western' trained medical personnel at hospitals. It is not uncommon that the hospital or 'western medicine' is not the first consulted (Ae-Ngibise, et al., 2010; Laugharme & Burns, 1999). Even where it may be the first consulted, many abandon it for the traditional and faith-based healers. Mental health patients sometimes remain in the care of traditional healers for several weeks before they are seen at a hospital. At the Komfo Anokye Teaching Hospital (KATH), one of the tertiary hospitals in Kumasi, Ghana, nearly 70% of all mental health patients seen at the psychiatric unit had been to a traditional healer, pastor, or spiritualist before coming to the hospital (Ae-Ngibise et al., 2010; Laugharme & Burns, 1999). Many of those who present at KATH either do not adhere to the treatment and or vascillate between traditional healers and the hospital. It is noteworthy that this challenge, of adherence to treatment, is not only found in Ghana but also observed in other contexts (Beach, Eboni, Gary, Robinson, Gozu, Palacio, Smarth, Jenckes, Feuerstein, Bass, Powe & Cooper, 2005)

PSYCHOTHERAPY PRACTICE WITHIN THE GHANAIAN CULTURAL CONTEXT: CHALLENGES AND PROSPECTS

Ghanaian cultural beliefs and practices present unique challenges to the practice of psychotherapy. These challenges are more pronounced when the psychotherapist has been trained in a culture alien to own and faces the arduous task of reacquainting self with own culture and also having to seek ways of 'translating' knowledge and theories of psychotherapy for a meaningful application within the indigenous context. However, the rudiments in the practice of psychotherapy per se are arguably not that different from any elsewhere.

The American Psychological Association (APA) broadly defines psychotherapy as the process by which a person seeking personal growth or desiring to relieve symptoms or resolve problems in living enters into an implicit or explicit contract to interact in a prescribed way with a trained person (i.e. psychotherapist). In the same way, Ghanaians seeking therapy from the traditional or unorthodox health professionals enter into a contractual relationship with implicit or explicit understanding of the rules of engagement. What differs, from observation and practice, are *patient factors* (e.g. patient beliefs about cause of illness, adherence to treatment, frequent defaulting attitude, level of acculturation to another culture), *treatment options and methodology* (e.g. use of eclectic treatment methods; that is, complexity of cases that do not readily lend themselves to the use of one method of treatment; individual focused or communal focused treatment, suitability of choice of treatment by health professional and patient), *process and outcome* (e.g. how treatment proceeds, premature termination, and whether or not treatment is effective), all of which are influenced by cultural dictates. Selected clinical cases, actually seen by authors, are used to highlight some of the issues and challenges existent in the practice of psychotherapy in Ghana. These cases were selected because they are illustrative of *patient factors, methodology, process and outcome* that influence the practice of psychotherapy in Ghana. However, as already noted, the challenges exemplified in these cases may not be particular to the Ghanaian society but present in other cultural contexts as well. In the narratives, the words 'client' and 'patient' are used interchangeably.

Case A: *A 39 years old mother of two, tested positive for HIV but refused to enlist on the government sponsored antiretroviral treatment program and also declined psychotherapy. Instead she was determined to go to her hometown to perform the necessary rituals that would "unbuy" her illness*

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

convinced that it had been spiritually "bought" for her by enemies even though her husband had died a couple of years earlier from symptoms suggestive of HIV/AIDS.

Once this client knew her HIV/AIDS status, she became less open to the government sponsored treatment being provided in a hospital setting plus the free psychotherapy that would go with it because of her beliefs about the etiology of the illness even though the evidence pointed to a clear mode of transmission through husband. It was frustrating to observe client's tenacious decline of necessary treatment. Yet her strong belief in the traditional rituals that would '*unbuy*' the illness could not be denied. Her belief was rooted in a cultural belief in evil machinations in the onset of illness for which 'spiritual' remedy is believed to be most efficacious. Client's beliefs about the etiology of illness influenced her decision to seek treatment elsewhere and her lack of adherence to the treatment offered her in the hospital. Her choice of treatment option was consistent with the culturally accepted belief that "nothing happens out of nothing" and that spiritual explanations exist for every happening. This case illustrates culture-bound paranoia that is pervasive and cuts across social and educational classes; a belief that somehow an enemy or someone is behind the spiritual 'workings' aimed to 'do the client in'. Whether or not her choice of treatment was effective could not be ascertained since she did not return to the hospital for a follow up.

Aside the challenge of patients choosing alternate forms of treatment that may, in the psychotherapist's professional opinion, is inappropriate for the presented problem, an eclectic treatment approach that has respect and validation at the core is often effective. Client's receptivity and response to treatment is enhanced by a sense of 'being heard' and validated. Respect for client's views and beliefs is most essential for cooperation with the therapeutic process and for a positive treatment outcome as illustrated by the next case.

Case B: *A 47 years old mother of three and a wife to same husband for close to 20 years presented with 'unidentified' and generalized stomach pains, significant weight loss, and depression. There was no organic cause for the observed symptoms and for months she had experienced no relief from pharmacological treatments. She strongly believed that the pains were "dancing balls" placed in her stomach by a woman with whom the husband had had an affair and who she believed to be a witch. Patient dated the onset of her symptoms to a time she had confronted her rival who had threatened to 'harm' her. Patient's belief in the effect of witchcraft was strong and initially impacted her response to therapy.*

This case demonstrated the influence of cultural beliefs in symptom presentation and a clear example of culture-bound paranoia which influenced patient's view of illness onset and duration. An eclectic approach that included power of suggestion, elements of cognitive behavioural therapy (CBT) and Interpersonal therapy (IPT) in the context of strong therapeutic alliance greatly influenced the positive outcome obtained in this case. Respect for and validation of her views, however irrational, greatly contributed to her improved mental and physical wellbeing and in her words: "*I am glad that someone believes me…and doesn't think am crazy"*. By the fourth session, her symptoms of depression had abated, and the pains from the 'balls' in the stomach had also subsided and her vegetative behaviours were much improved. In a short time, patient had regained weight and was looking much better.

Inclusion of significant others in the therapy process is not uncommon. Sometimes individuals or entire community may be involved to bring proper resolutions to presenting complaints. Patients and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

therapists sometimes struggle with a belief that a combined method of formal psychotherapy and traditional rituals would be most efficacious for some conditions. The two cases following are examples.

Case C: *A 27 years old man presented with erectile dysfunction secondary to severe depression and anxiety. His condition appeared psychosomatic since several tests showed no physical cause. Patient later disclosed that some years back he had impregnated a former High School girlfriend and denied responsibility for fear of his parents. This offense, he believed, was the root cause of his presenting problem. He believed that the young lady had cursed him. Reconciliatory efforts with offended party were accompanied by significant symptom relief in patient.*

A belief that 'right' relationships is essential to health and wholeness is evident these cases. Offenses committed against another, blatant or inadvertent, are believed to affect health and wellbeing. Hence the belief that restoration of relationships is necessary for recovery from illness, particularly in mental or emotional illnesses. The cultural belief in the unity and influence of the non-living on the living makes restoration of 'broken' relationship a two-tier exercise, physical and spiritual; an exercise in which the traditional healer or spiritualist is often perceived to be more adept. Psychotherapeutic intervention would be part of the physical aspect while forgiveness and reconciliatory rituals, for example, would be considered spiritual. This dichotomy of symptoms into physical and spiritual can influence how much information a client gives the psychotherapist, believing that matters of spiritual origin and nature are not understood by the 'western' trained professional who dwells in the physical only and therefore must be told to the spiritualists instead and vice versa.

Authors also observed that patient's willingness to seek traditional and spiritually inclined treatment intervention is influenced by their level of acculturation. Having lived outside the cultural context, in a 'westernized' society might predispose one to consider traditional forms of treatment as 'primitive' and superstitious while at the same time believing that the cause of illness is 'spiritual'. Such situations create a state of cognitive dissonance in the patient. This case is illustrative of such conflict.

Case D: *A 45 years old man, and an eldest son in a large family, presented with bipolar depression and unspecified schizophrenic tendencies. Three other siblings reportedly suffered similar disorders. Even though both patient and family members believed that illness was an ancestral punishment for misappropriation of the extended family lands by patient's nuclear family, they were hesitant to engage in the traditional rites that had been prescribed earlier by a traditional practitioner because having lived most of their lives outside Ghana in the United Kingdom they were quite acculturated and conflicted about obliging traditional treatment.*

For positive outcome, a collaboration between traditional cleansing rites and aspects of interpersonal therapy were employed. These cases underscore some of the challenges psychotherapists encounter in working within the Ghanaian context. The influence of patients' beliefs on their conceptualization of illness and their symptom presentation is clear. Beliefs also influence patient's choice of treatment and increases or decreases the likelihood of adherence to treatment; a challenge that is not unique to the Ghanaian setting (Beach et al., 2005).

Belief in supernatural forces to effect illness is common in Ghana (Ae-Ngibise et al., 2010; Osei, 2001; Foster, 2012) and among other indigenous peoples (Berry & Crowe, 2009; Babb et al., 2007; Harley, 2006). When patient believes that the cause of illness is supernatural, he or she is more likely

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

to seek treatment from a spiritualist than from a hospital. Likewise, those who seek treatment from a hospital readily oscillate between 'western' treatment and traditional treatments believing that both types of treatment are needed for complete recovery (Ae-Ngibise et al., 2010). This sometimes has detrimental effects on the progression of illness and adherence to treatment, particularly hospital prescribed treatment regimen. In Ae-Ngibise et al., (2010), for example, mental health patients sought indigenous methods of healing because of the general perception of the spiritualist or traditional healer as more understanding of presented issues, less costly, and readily available than 'western trained' health professionals.

Patient's level of acculturation to other cultures influences choice of and response to treatment with mixed effects. Sometimes acculturation to other cultures creates conflict within patient – traditional beliefs about etiology of illness coupled with hesitancy to consult traditional healers. Other times, it facilitates adherence to western psychotherapies since patient would not oscillate between traditional and hospital treatment. Patients of certain social class and literacy respond well to structured therapies such as cognitive behavioural therapy (CBT) (Danquah, 1982). CBT has been found effective for building resilience among indigenous, less acculturated, communities in Ghana (Offori-Attah, 2015). In other words, the so called western methods, when appropriately adapted, do and can work in indigenous cultural context when acculturative effects are minimal.

Differences in patient's developmental stage needs, education, religion, social class, and life experiences warrants a tailoring of choice of treatment to patient's unique characteristics, aware of the existence of diversity even within a seemingly homogenous cultural context. Proliferation of Pentecostal churches in Ghana, for example, influences health seeking behaviors. More and more patients seek treatment and counseling for emotional problems from pastors and prayer camps (Ae-Ngibise et al., 2010; Laugharme & Burns, 1999; Ofori-Atta & Linden, 1995). Therefore, sensitivity to the specific needs of patients as individuals within a certain cultural context is essential for efficacious outcome in therapy.

IMPLICATIONS FOR PROVISION OF CULTURALLY COMPETENT CARE

So what can be gleaned from these experiences of the 'foreign-trained-local' health professionals for improved mental health care delivery? In this section, authors attempt to address this question. Authors acknowledge that their experience is specific to Ghana. However, since many of the challenges observed are not unique to the Ghanaian cultural context, they submit that the insights from their experience may inform the practice of psychotherapy in other cultural contexts.

The practice of psychotherapy in a culture such as Ghana, with its complex belief systems and a generally spiritual worldview, presents unique challenges as well as rich learning opportunities. Collaboration with traditional healers is an opportunity with great learning opportunities. The role of traditional healers in the restoration of health in indigenous communities is recognized and accepted in many cultures as a necessary adjunct to western oriented interventions (Adele, 1998; Babb et al., 2007; Campbell-Hall et al., 2010; Harley, 2006; Hewson, 1998; Jahoda, 1979; Janse van Rensburg, 2009; Mpofu, 2006; Nelms & Gorski, 2006; Shaikh, Haran & Hatcher, 2008; Ross, 2004). Challenges exist (Mills, Singh, Wilson, Peter, Onia & Kanfer, 2006; Sorsdahl, Stein & Flisher, 2010; Tanner, 1999), but despite these challenges a clarion call for collaboration between modern and traditional health practitioners cannot be ignored. For effective work with patients who believe in and freely consult traditional healers, a respectful understanding of their perspectives and its impact on treatment is important. Ghana has taken a step towards

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

ensuring this collaboration and has been recognized and provided for by Ghana's new and modern mental health law, Act 846 of 2012 whose implementation is still on going.

Keen awareness of and sensitivity to diversity and plurality even in a seemingly homogenous and collectivist culture is another insight worth noting - 'one size does not fit all'. The experience, understanding, expression and expectations of patients about their psychological symptoms differs to the extent that they are influenced by these variables. Patients' own unique explanatory models of illness and therapist's understanding of this can provide insight into how patient formulates and or contributes to own problems. Therefore, patient is to be considered as both a member of the cultural group and also as a unique individual. Therapist's perceptiveness about cultural issues affords a richer and deeper understanding of patient beyond the concepts and formulations afforded by the dictates of formal training in western traditional psychotherapies.

Understanding patient as member of a cultural group can heighten awareness and sensitivity to patient nuances. However, over attribution of presumed causes to cultural factors may overlook other psychological factors that underlie presenting problems. Experience has shown that process-oriented techniques, and an eclectic approach to therapy, with sensitivity to cultural influence on patient's understanding of the etiology of presenting problems allows for flexibility in the direction and goals for therapy suited to patient's needs.

Equally important is flexibility in handling issues of boundaries. Without violating ethical conduct, in a culture in which relationships are highly valued, particular attention must be paid to sensitivities in the patient-therapist relationship to avoid inadvertent offense and or behaviors that suggest lack of care. Therapist needs to be aware of the ways persons in the culture communicate care and concern which may be different in the culture in which one was trained. Home visits, for example, in the Ghanaian context would communicate care but could be frowned upon in other less communal cultural contexts. Similarly, rigid application of guidelines on boundaries, such as touch, may not always work.

Genuine respect for and validation of patient's cultural orientation, indigenous beliefs and practices, as well as attentiveness to differences facilitate the development of a therapeutic alliance which is important to treatment outcome. Core to the art of connecting with patients is effective communication which enhances patient's perception that he or she is being 'heard' and validated. Validating a patient's experience or belief does not necessarily mean agreement. It means, however, that patient is respected enough to ascribe same valence to what patient deems real or important to the self. Trust is essential to the art of effectively convincing patient of the efficacy of proposed treatment or different perspective on a problem. Related to trust is respect for patient's beliefs and perspectives even if therapist does not subscribe to same. In effect, genuineness and good rapport are particularly important to treatment adherence and outcome in a cultural setting such as Ghana where patients value meaningful relationships and freely oscillate between traditional and 'modern' mental health services.

A posture of 'expert-learner' by the therapist is essential to effective practice. To learn, one must reflect on own experiences and be modified by them. Interactions with patients provide growth and learning opportunities for both patient and practitioner. This is particularly important for the 'foreign-trained-local' therapists. Though equipped with knowledge and valuable skills through years of training, a constant self-reflection that facilitates experiential learning is necessary if one is to be effective. That is, the culturally competent care provider must constantly examine the appropriateness and suitability of 'imported' knowledge and skills to the specific needs of the people served.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

DIRECTIONS FOR FUTURE RESEARCH

Insights shared by the authors from the Ghanaian context has implications for cultural competency training. However, the literature on cultural competency has mixed findings. There is evidence to suggest that cultural competency improves quality of service delivery (Beach et al., 2005). Other findings from some review studies suggest that lack of methodological rigors in evaluating cultural competency training limit the evidence for the impact of its efficacy on the quality of health care delivery (Price, Beach, Gary, Robinson, Gozu, Palacio, Smarth, Jenckes, Feuerstein, Powe & Cooper, 2005). Treatment adherence still eludes trained culturally competent professionals (Beach et al., 2005). It appears that more knowledge is needed to know and delineate *what* aspects of cultural competency techniques are effective (Brach & Fraserirector, 2000). The '*when*' and '*how*' of '*what*' works must be informed by context-specific knowledges such as what is shared from the Ghanaian experience. 'Foreign-trained-local' practitioners must document their experiences and insights obtained clinical practice. This would be a step in the right direction.

Research on the efficacy of 'adapted' methods of psychotherapy within an indigenous cultural context such as Ghana is impeded by clients' premature termination, failure to adhere to treatment, and vacillation between the therapist and traditional healers or pastors. These challenges make systematic or longitudinal study of positive therapy outcome variables difficult. Future research focusing on the efficacy of collaborative treatment between traditional or indigenous healers and pastors on the one hand and western trained psychotherapists on the other would, for example, be in the right direction since such studies would better elucidate 'what treatments' are effective for 'what presenting problems' within the Ghanaian cultural milieu. Interest in research in this area, that is collaboration between traditionalists and 'western' therapies ought to be encouraged among practitioners across the African continent since similar challenges exist in many countries.

In depth qualitative multiple case studies may be the way to go. Existing published studies from other settings and also qualitative multiple case studies from Ghana and parts of Africa, reinforce the intuition that a lack of attention to cultural issues leads to less than optimal health care, and that addressing these concerns or using certain cultural competence interventions leads to improved outcomes. However, the intricacies of the '*how tos'* are yet to be delineated. To advance a cultural competence research agenda involves many tasks. Specific research questions need to be identified and availability of funds ensured. Specific questions, for example, in the area of developing a working consensus on the parameters and specifics of cultural competence interventions for the purposes of conducting such health care delivery and health outcomes research. Additionally, a cadre of indigenous and non-indigenous researchers may need to be networked for such research to explore novel methodologies. The creativity needed for this kind of research requires a willingness to 'think outside the box' of the usual ways of conducting research. This way, more information can be gathered to boost awareness about the efficacy of eclectic culturally sensitive interventions.

Most importantly, the results of research once completed must be made widely disseminated and made available to practitioners and policymakers. While no single study is definitive and additional research is always needed to confirm the validity of initial studies, better awareness of, and coordination of efforts, could advance critical areas of research more efficiently.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

In summary, this chapter brings to the fore some of the challenges and opportunities in the provision of culturally competent care in Ghana; embedded in the experiences of 'foreign-trained-local' health professionals. Observations and suggestions made are most likely applicable to other indigenous cultural contexts. The art of the science of psychotherapy must be culturally sensitive to be effective because culture influences mental health in various ways, from the formation of a disorder (*pathogenic effect*), its clinical manifestation (*psycho-plastic effect*), frequency of occurrence (*psycho-facilitating effect*) to what is deemed appropriate coping response or health seeking behaviours (*psycho-selective effect*) (Tseng, 2006). Therefore, 'imported' knowledge, skills, and methods cannot be applied 'wholesale' and without some adaptation to the needs of the people served especially in cases where therapist is a 'foreign-trained-local'. Respect for indigenous beliefs and practices, and a critical examination and indigenizing of 'foreign' concepts and methods cannot be overemphasized. Hopefully, these insights from the clinical practice of authors add to and enrich existing literature on the subject.

KEY TERMS AND DEFINITIONS

Client or Patient: Someone seeking therapy.
Culture: The customs, beliefs, and social behaviour of a particular group of people.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Cultural Competence: A set of congruent behaviors, attitudes, and policies or generally recognized and accepted procedures among professionals that enables them work with effectively in cross-cultural settings or situations.

Culturally Competent Care: Provision of culturally sensitive and context-specific care that takes into consideration the cultural norms, beliefs, needs, of persons being served.

Foreign-Trained-Local: Natives of a certain culture and locality who have received formal training in a context different from own.

Indigenous: Originating from or native to a particular place.

Psychotherapy: Process by which a person seeking personal growth or desiring to relieve symptoms or resolve problems in living enters into an implicit or explicit contract to interact in a prescribed way with a trained person (i.e. psychotherapist).

Chapter 54
Prison Environments

Willem Frederik Muller Luyt
University of South Africa, South Africa

ABSTRACT

This chapter deals with the historical development of prison environments, linked to the context of inmate development. Since early days, the prison environment has always accounted for some form of inmate development. New-generation prisons have brought a more profound influence in the area of inmate development. However, there has been a larger emphasis on security in the prison environment, compared to inmate development. In addition, the inmate subculture has a fundamental influence on the interaction between the prison environment and inmate education and development. With this in mind, the chapter provides an overview of prison environments through the ages up to post-modern times. It constantly addresses the interaction between environment and education from the perspective of the relevant era of prison evolution.

INTRODUCTION

People react differently to their living environment. One often-neglected living environment is the prison environment. Prisons are microcosms of society (Holvey, 2005) and can be classified as physically aggressive, the result of adaptations for survival and retention of physical existence (Hartmann, 1936). Individual responses to prison environments include dependence, helplessness, exploitation, masculinity, withdrawal, isolation, and loneliness (Singer, 2012).

Nelson Mandela (1995) observed that prison robs you of your freedom and identity. It is authoritarian and tolerates no independence and individuality. These words applied to Apartheid prisons, but echo approaches to incarceration in most modern-day prisons. According to Mwende and Pasha (2016), African imprisonment originates from colonial roots, inflicting cruel punishments with little rehabilitation. Even (post)modern prisons are not utilized for rehabilitation. Luyt (2008) emphasizes how South Africa, for example, fails to optimally utilize new-generation prisons to benefit inmates. Instead of utilizing two private prisons to pursue development these facilities became maximum security prisons. Through it the system indicates that security has higher priority than rehabilitation.

The aim of this chapter is to give insights into the factors that create prison environments including the history of prison, the ethical context of prison and other dynamics.

BACKGROUND

There is reason to believe that correctional education reduces recidivism (Davis et al., 2013). Inmates who receive correctional education improve chances of employment. There is a negative relationship between correctional education and prison environments, as prison environments impede on successful completion of educational programs.

The prison environment is one of learning, but does it educate? Gendreau and Goggin (1999) identify three schools of thought. Firstly, prisons suppress criminal behavior. Unpleasant prison life and negative stigma serve as deterrents to criminal behavior. Secondly, prisons increase criminality. Inhumane conditions make offenders more likely to recidivate. Thirdly, prison effects on inmates are minimal. Offenders enter prison with antisocial attitudes/behavior that remains during incarceration. According to Coates (2016) education should be more important in prison systems, as it is the engine of inmate rehabilitation.

ISSUES

It is impossible to discuss the complete history of prisons here, but the reader must obtain an overview of the influence of different prison systems on education during incarceration. Selected historically familiar prison systems that have made a contribution to learning ideologies are highlighted here.

Imprisonment has not always been common as punishment. Physical punishment and social ostracism were historically common. Major transitions, from physical punishments to imprisonment occurred in the eighteenth century. Factors that facilitated the shift from bodily harm to institutional interventions are complex (Sellin, 1930). At first, incarceration was meant to detain people until sentencing could occur. Allen and Simonsen (1995) maintain that the purpose of imprisonment as punishment is to avoid cruel punishments. The first two prisons that illustrate humane correctional aims are the Hospice of San Michelle (Neser, 1997) and the Maison de Force (Delierneux, 1931).

Incarceration as punishment developed from the concept that restricting liberty would be significant retribution when aligned to the severity of the crime. Imprisonment gained increased favor over corporal punishment and prisons are increasingly erected in Europe.

MAIN INFLUENCES ON PRISON DEVELOPMENT

The Hospice of San Michelle, the Maison de Force, English developments, and the Pennsylvania, Auburn and Elmira systems have been influential on prison development and are now discussed.

The Hospice of San Michelle

Inhumane treatment is reported to be an awful chapter in the Roman history. Cruel primitive conditions trigger humanitarianism and growing revolt against absolutism. A distinct movement to educate offend-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

ers during punishment originates in the sixteenth century. In this movement, the House of Correction in San Michelle Hospice fulfils an important role. Wider application of the practices at the House of Correction is later found, but the initial focus is on the education of a group of young men (Sellin, 1930).

John Howard brings the House of Correction to the attention of the English-speaking world. It detains 200 inmates who study different trades. San Michelle has played an important role in inmate education. Sellin (1930) reports that inmate education covers a variety of trades. Inmates are later assisted to set up business in acquired trades.

The Maison de Force

The Maison de Force was erected in 1775 to replace corporal punishment. It is an advanced workhouse cited by Howard as a model institution and is the inspiration for the American Auburn system. The Philanthropist (1817) reports that at last there was a prison for education and incarceration. Paid work is introduced here for the first time (Tennant, 1841). Many elements from the system are still observed in modern prison environments. Napoleon and disastrous economic conditions result in the closure of the Maison de Force (Delierneux, 1931).

English Developments

Around 1776 England experienced extreme prison overcrowding. Abandoned ships are regarded as an immediate solution. The English Government enacts the Hulks Act of 1776 (Silverman, 2001). Old navy ships (hulks) are used to house offenders for 82 years (legislation intends to use hulks for two years only). The hulks are themselves characterized by overcrowding, poor sanitation, harsh discipline, and lacking education. Diseases cause high inmate death rates. Prison reformers demand changes to stop inhumanity. England starts transportation to Australia and America as the discovery of new worlds contributes to the demise of the hulks (Victorian Crime and Punishment, 2006). Today, a few prison ships still exist, like the educationally unproductive Vernon Bain Correctional Centre in New York (Stango, 2014). Both history and modern-day practice show that prison ships do not contribute to inmate education.

The hulks were replaced by goals like Millbank prison. Inmates receive religious education and perform work (Victorian Crime and Punishment, 2006). Continued development results in larger institutions, including Pentonville, Portland (1848), and Dartmoor (1850). These institutions adopt colonial type labor regimes where inmates perform pointless work (Victorian Crime and Punishment, 2006). Little education features in these prisons. Today, very little has changed. The Prison Reform Trust (2015) reports that in modern-day Pentonville 20-30% of inmates have learning difficulties and 47% have no qualifications.

The Pennsylvania System

Pennsylvania becomes the leader of penal reform in the USA as penal thought departs from revenge-based arguments. The death penalty is abolished for robbery, burglary, and sodomy and replaced with imprisonment (Bradford, 1972). Bodily punishments like branding are abolished (Barnes, 1972). By 1820 most penal codes reflect the classical school principle, which suggest that the punishment must fit the crime (see key terms) (Blomberg & Lucken, 2000; Seiter, 2005).

Public humiliation in punishment vanishes through increased imprisonment. Pennsylvania originates (Sellin, 1970) as a system of prison discipline characterized by solitary confinement and commonly known

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

as the separate system. Inmates are confined to cells and only have contact with staff (Sellin, 1970). Education focusses on moral education and inmate behavior (Historical Society of Pennsylvania, 2006).

The Pennsylvania philosophy influences Europe. Dickens (Free Encyclopedia, 2016a) concludes that Pennsylvania is cruel, because daily brain tampering is worse than bodily torture. The idea of redemption in solitude becomes punishment in itself. The separate system becomes difficult to maintain. Intended to hold 300 inmates, incarceration has increased to 2000 by 1920. In 1913 the separate system is discontinued (Woodham, 2008) and the penitentiary officially closes in 1971.

Pennsylvania would permanently influence future prisons. Traces of draconian Pennsylvania hardships remain today. One example is Nigeria, where the 1917 Prison Regulation prescribes admission, custody, treatment and classification. These processes are not geared towards treatment of inmates, but represent containment policies (Orakwe, 2016). Despite the 1999 Special Prison Reform Program (Orakwe, 2016), Nigerian Vice-president Osinbajo reports in 2016 that prisons are draconian and without reform (PUNCH, 2016). The Howard League (Wright, 2016) argues that the more draconian security measures are, the more violence is present and the less development takes place.

The Auburn System

The Auburn system is established in 1817. It is renowned as the congregate or silent system. The system aims to rehabilitate offenders through industry, obedience, and silence (Randol, 2014). The system uses individual cells and workshops, rigidly enforced silence and harsh punishments. Inmates are identified by a number, a practice that still subsists today in some systems. A military-style discipline is the cornerstone of inmate/staff interaction (Free Encyclopedia, 2016b). Strict routines are omnipresent. Inmates work, eat and pray together but return to solitary cells at night (Capo, 2011).

The Auburn system is considered weaker than Pennsylvania. It is prevalent in America, while the Pennsylvania system is favored in Europe (Capo, 2011). Over time abuses occur, including corporal punishment, assaults, rape, and slave-labor practices. These abuses influence penal reforms that give rise to the Elmira Reformatory (Randol, 2014).

The influence of Auburn on humane conditions can still be observed. For example, South Africa introduced beds to sleep on in 1993 in all prisons, even though inmates are still racially segregated and oppression remains part of the system (Luyt, 1994). Additionally, while continuing with certain forms of artisan training and educational programs, various inmate labor practices are abandoned, which gives origin to increased humanity.

The Elmira Reformatory

The Elmira system delivers the most remnants still observable in modern prison systems. Examples include the use of professionals, classification, and parole. The Reformatory Movement gave origin to Elmira (Colvin, 1997). It is designed around the recommendations in the Declaration of Principles at the Cincinnati Conference. At Elmira inmates are studied, classified and treated. "Changing" inmates becomes dependent upon the knowledge of experts. Terminology becomes part medical and part educational. Inmates are addressed as students or patients (Blomberg & Lucken, 2000). Outcomes are measured and inmate-release is linked to self-regulated discipline and evidence of reformation. Inmates perform paid work and vocational training. All modern systems utilize psychologists, teachers, social workers, and medical practitioners to enhance rehabilitation, all remains of the Elmira system.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Elmira hallmarks classification (Blomberg & Lucken, 2000), another feature still observed in modern systems. Grading occurs according to participation/performance in educational activities. Three grades exist. Inmates start at the middle grade, allowing for promotion/demotion. Conformation for six months results in upgrading with more privileges (Blomberg & Lucken, 2000). The main difference between work in reformatories and prisons is economic incentive to instill industrial labor discipline (Simon, 1993). Classification systems have since developed and today influence decisions about the future of individuals.

Elmira officially gives origin to indeterminate sentencing (Blomberg & Lucken, 2000), as recommended in the Declaration of Principles at the Cincinnati Conference. Intermediate sanctions are punishments that are more severe than probation or suspended sentences, but less severe than imprisonment. Intermediate sanctions are useful for keeping non-violent offenders in the community.

Intermediate sanctions are important for three reasons. They provide:

- Sentencing options in which the severity of punishments is scaled to the seriousness of crimes;
- Punishments for offenders for whom incarceration is too severe and ordinary probation is inappropriate, and
- Effective ways to deal with violations of conditions. For example, a more restrictive intermediate sanction can be imposed rather than ignoring the violation or revoking the sentence and incarcerate violators (Tonry, 1997).

Common intermediate sanctions are intensive probation, house arrest, electronic monitoring, and fines. It can be run as front-end or back-end programs. Entry into front-end programs is controlled by judges and precedes imprisonment. Prison authorities control entry into back-end programs (Tonry, 1997). Probation officers can increase/decrease the level of severity, depending on the response to rehabilitation. In worst cases, offenders can be re/incarcerated.

Because of indeterminate sentences the Elmira system has become instrumental in modern-day parole development. A typical sentence is a minimum of one year incarceration without a maximum time indicated. Reformatory boards indicate when inmates may be released. Credits gained/lost in the reformatory for work participation and education contributes to earlier release. Other factors are also considered.

Schmalleger (2005) argues that although Elmira was not entirely successful, its principles remain in practice today. The influence of Elmira resurfaces strongly, for example, after the death penalty was declared unconstitutional in South Africa. Parole of inmates sentenced to life imprisonment is directly influenced. Even though the period at which most correctional systems consider release from life imprisonment has increased from ten to twenty-five years (life imprisonment seldom results in spending the rest of your life in prison), release on parole after the minimum period of incarceration is not guaranteed, but is decided by a parole board.

Indeterminate sentences have become the new norm for punishment. Few inmates have certainty about release from incarceration. Therefore, the Elmira influence is alive today.

PRISONS IN ETHICAL CONTEXT

Law is important in criminal matters. Law is mainly cast in concrete, because it must be followed as prescribed. Ethics are different. One could argue that ethics is more important than law in correctional environments. Law is a learned profession (Kimmelman, 2015), but ethical conduct requires integrity,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

wisdom, and life experience. Like law, ethics should be integral to successful prison systems. Unlike law, ethical conduct is inherently expected, rather than prescribed. Ethics is the result of proper upbringing and acceptance of societal and occupational responsibility.

The use of imprisonment in sentencing has an influence on prison management. Countries like the USA have incarceration rates exceeding 650 per 100 000 of the general population. European countries generally have rates below 100. India has a rate as low as 33 (Walmsley, 2015). Prison crowding has a direct influence on inmate and staff behavior and the ethical approach followed in the prison environment.

Ethical issues are considered from the design phase of modern prisons. Jiang and Fisher-Giorlando (2002), Homel and Thompson (2005), Muntingh (2009), and Luyt et al. (2010) have documented how prison design promotes ethical conduct, and reduces violence and recidivism. Architects today ensure that prison designs promote rehabilitation and peaceful coexistence (Kimmelman, 2015).

Concerning design, Stott (2014) asked the legitimate question whether buildings designed to facilitate human rights violations can amount to violation itself. The problem with most prison systems is that old structures still dictate the approach to various ethical issues. For example, less than a decade ago some Scottish prisons were still "slopping out", a system where no modern toilets exist. Large dormitories promote overcrowding, sexual misconduct and negative influences on development programs.

The United Nations Human Rights Committee declares in 2016 that South African correctional centers are overcrowded, violent and unsanitary (Savides, 2016). Allegations of torture are reported, an aspect regarded as the worst possible form of unethical conduct in prisons. While human rights are universal, it is especially significant for prison officials, because sentenced people do not lose their human rights. Imprisonment influences how inmates exercise their rights, but cannot deprive them of these rights. Their rights may be limited but not taken away (Luyt et al., 2010). Therefore, special measures are needed to ensure ethical conduct is maintained in prisons.

Prisons and education have different purposes and desired outcomes (Whitehead, 2013). These differences create conflict between education and security in prisons. Ethical environments with ethical employees are essential. Career ethics for educators is unlike criminal justice ethics. Also, there is no formal code of ethics for correctional educators. These differences in ethical approaches create conflict and may contribute to distortion in prisons as educational environment.

Whitehead (2013) argues that some elements of ethical formalism, utilitarianism and the ethics of care are aligned to the theories of education. An ideal correctional education code of ethics would incorporate the practical elements of ethical systems, along with informational, occupational, recreational, and political typologies. The role of ethics in prison education is important, because educators can guide students to crime-free lives (Whitehead, 2013). Therefore, a holistic positive ethical environment in prisons is essential.

Sarkin (2008) argues that ethics in African prisons are considered the worst, but many other prison systems are worse off regarding violence, overcrowding and development. Rehabilitation and successful reintegration remain the most elusive and controversial aims of imprisonment (Sarkin, 2008), while education has a positive impact on recidivism and reintegration (Munoz, 2009).

In Africa South Africa, Uganda, and Botswana have improved rehabilitation, notwithstanding a variety of challenges. Focus is on education/vocation, psychology, religion, and reintegration. African countries like Gambia, Cameroon, and Namibia have also sought to promote human rights legislation. Successful ethical and program commonalities include employment, individual needs, ongoing monitoring, collaboration, restorative justice, and minimum program durations (9-12 months) (Sarkin, 2008). Ethically, incarceration should allow for productive sentences.

PRISONS AS DYNAMIC INSTITUTIONS

Prisons contain large numbers of stimuli that impact on inmate/staff attitudes/behavior (Bradford, 2006). Wright (1985) groups stimuli into universal dimensions of inmate concerns, including structure, privacy, support, activities, freedom, relations, and safety. They represent intervening variables between person and environment. They are influenced by organizational structure, and influence organizational behavior (Wright, 1985).

The dimensions are dynamic factors, because they address interaction between inmates and staff. These are not the only dimensions that influence prison dynamics. Architecture type, for example, is static, but it influences inmates' behavior dynamically. Although Coyle (2002) suggests that the prison environment may be regarded as static because of its autonomous operation and its hierarchical organizational structure, many prisons experience constant instability and therefore a number of dynamic situations. Many changes influence prisons directly, firstly because prisons detain political inmates (think of Nelson Mandela). Secondly, prisons often form part of security services and have to review their mandate when political conditions change. Thirdly, human rights are more important than ever before. All prison systems are overwhelmed with dynamic factors and complexities in prison management that necessitate change.

Historically, prisons have changes since San Michelle. Today, constant change is still experienced. While daily working conditions may largely be static, prison management remains dynamic, as witnessed throughout history. Prison (over)crowding, the abolition of the death penalty, an increasing number of long-term sentences, HIV and AIDS, and political and societal expectations are all influencing the dynamic nature of prison environments. Coyle (2002) maintains that prison management must take account of its political and cultural environment. As a result, prison management focuses on creating mechanisms to influence individual inmates to change their behavior.

Courts express the necessity of prison environments to develop with the times. In the English judgement *Raymond vs Honey* Lord Wilberforce (1982) determines that a convicted inmate retains all civil rights that are not forfeited expressly or by necessary implication. Consequently, the following factors strongly influence the dynamic nature of prisons:

- Maintenance of human dignity.
- Proper health care.
- Personal safety of all.
- Contact with the outside world.
- Access to activities like work, education, cultural activities, physical exercise, and religion.
- Legal representation.
- Respecting the needs of special categories (women, youth, elderly, minorities).

Significant factors have proven to be indicators of poorly managed prisons, including bad physical environments, inhumanity, poor communication, and the frequency of complaints. Efforts to sustain a specific environment inside prisons include physical coercion. Physical coercion is a socially structured and highly organized form of unacceptable guard behavior (Marquart, 1986). More positive intervention alternatives exist, for example dynamic security and education as a form of rehabilitation.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

DYNAMIC SECURITY

Dynamic security differs from the dynamic environment described previously. Dynamic security is a unique form of security within prison environments. Basic security starts with physical security. Physical security includes the architecture, the strength of walls, the types of bars, specifications of the perimeter barrier, and watchtowers. It includes locks, cameras alarm systems and metal detectors (UNODC, 2015).

Today, security increasingly depends on staff/inmate interaction. Members are expected to know inmates they are responsible for, to develop positive inmate/staff relationships, and to have general awareness about prison matters. Fair treatment and constructive/purposeful activities are essential. This active interaction is described as dynamic security and is increasingly being adopted globally (UNODC, 2015).

Dynamic security has the benefits of engaging individual inmates, and gaining intuition, insights, information and material into real-time events. Dynamic security fosters positive relationships, fairness within firmness, professionalism, understanding, and collecting and exchanging information. Implemented effectively, dynamic security contributes to inmates feeling comfortable when approaching staff members with problems. Staff members take every opportunity to interact directly with inmates without suspicion.

Through regular contact with inmates, staff members are responsive to situations outside the norm. In this way staff members are able to prevent escapes and security-breaching incidents. Dynamic security also contributes to improved inmate development. The nature of relations between staff and inmates remains important in dynamic security. It contributes positively to maintain dignity and the legitimate concern about security in prisons.

EDUCATION AS A FORM OF REHABILITATION

A study into the impact of education on rehabilitation in the Westville Correctional Centre shows that educational programs have a positive impact on inmate rehabilitation (Ngubane, 2007). Sentenced and ex-inmates that participate in educational programs experience positive transformation and have positive attitudes towards their families, communities and life in general.

According to Jones (2010) successful rehabilitation is when individuals discover new directions, making crime no longer their only option. Education remains important for inmate rehabilitation (Coley & Barton, 2006). According to Linden and Perry (2008) education programs are common in prisons. They suggest that these programs succeed if they are intensive, can establish an alternative community within the prison, and if they offer post-release services. All three of these areas are problematic. Dedicated prison schools and post-release services hardly exist, while low intensity of programs set inmates up for failure.

Inmates who receive education are less likely to return to prison after release and are more likely to find employment than peers without such opportunities (Davis, 2013). Research suggests that prison education programs are cost effective ($1 investment in prison education reduces incarceration costs by $4 to $5 during the first three years post-release) (Davis, 2013).

PHYSICAL PRISON ENVIRONMENTS

Whether the dynamics are positive or negative, it will be enforced within the physical prison environment. The physical prison environment originates from architectural design.

According to Redding (2004), the physical structure of prisons is important, as they contribute to keeping inmates safely inside. The physical layout directly contributes to security. Traditionally, security is mainly vested in design, in the building itself. The more secure the building, the higher security classification is assigned to it. In many instances, it is not possible to discern the differences between a maximum and medium security institution, based on design and the physical security features of the building. This security classification of the building will determine the type of inmate to be housed therein.

A different type of classification, inmate classification, is the tool to ensure appropriate institutional placement. Similar offenders (based on crime and sentence length) are crowded into one space. Each institution becomes a space where housing arrangements, security features, and the perceived security threat from inmates become the most important security factors. These factors inform institutional characteristics, or the physical prison environment (Bradford, 2006).

This physical prison environment has a direct influence on inmate well-being. The influence can be positive (as experienced within new-generation prisons to be discussed later), or it can be negative. Older-design prisons are still used all over the world and deliver various negative influences. Structural layout, poor management, overcrowding, and violence are major contributors of negative influences. Poole and Regoli (1983) argue that prison violence is a direct result of the combination of traditional structural characteristics and personal inmate characteristics.

Over time inmates adapt to the physical environment. This adaptation is termed prisonization (Clemmer, 1940), the process of adapting to the culture and social life of the prison society and dominant prison subculture (Naderi, 2014). Clemmer (1940) emphasizes that sentence length is positively related to adoption of the norms and values of the prison subculture. Although good environments will ensure positive adaptations, and vice versa, the length of time under incarceration becomes the most important prisonization factor. The longer inmates are exposed to the prison environment, the harder it would be to avoid prisonization. Haney (2001) argue that these adaptations represent individual survival mechanisms.

Rotman (1998) describes prisons as closed organizations with specific norms requiring constant adaptations. The physical prison environment strongly influences adaptation, mainly because inmates are exposed to it for long periods. Excessive time is spent inside cells (sometimes 23 hours) and a prison routine is enforced. The physical environment influences become stronger than the influences from available programs and inmate/staff interaction. For this reason, more inmates conform to the prison subculture than to rehabilitation and reintegration.

THE DEPRIVATION AND IMPORTATION MODELS IN THE PRISON ENVIRONMENT

Clemmer (1940) argues that the higher the degree to which inmates internalize prison values, the more immune they become to the influences of conventional value systems. Several factors influence internalization, including:

- Susceptibility and personality of inmates.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Nature of relationships outside prison.
- Membership of primary groups inside prison.
- Placement inside prison (section, cell and who cellmates are).
- Acceptance of prison culture and codes.

Wheeler (1961) supports the prisonization concept. The degree of prisonization varies according to the phase of sentence where the inmate is at. Inmates are more receptive to values from the outside world during the first six months of incarceration and six months before release. During the middle period, inmates respond more to institutional factors. The middle phase is called the prison career phase. Wheeler (1961) suggests that it should be included as variable in the prisonization theory.

Since Wheeler's prisonization theory is studied with new vigor, two models, namely the deprivation and importation models now form part of theoretical explanations of the inmate subculture (Reid, 1981).

The Deprivation Model

Sykes (1958) refers to the effects of deprivation of liberty as the pains of imprisonment and theorizes that the inmate subculture originates through adaptation to deprivations. Losses caused by incarceration can be mitigated through inmate social interaction (Sykes, 1958). Inmates unite for mutual cooperation, or they withdraw into self-satisfaction. Both reactions are adaptations to deprivation.

Exchanged favors, security in numbers, and cooperation minimize the pains of imprisonment. Isolation is avoided and protection is obtained through favors (Reid, 1981). The system feeds on itself to replace deprivations. Inmates believe that high-valued scarce material possessions can be obtained from connections, rather than work. Cooperation leads to better distribution of available wealth among deprived inmates (Reid, 1981).

Conditions of deprivation are not limited to male inmates. Women are also affected. Slotboom et al. (2011) find that the deprivation factors regime type, discrimination, bullying, and family separation induce stress and suicide risks among females. Jiang and Winfree (2006) conclude that incarcerated women experience more social support from co-inmates than incarcerated men.

Prison officials are viewed as objects that deprive inmates and threaten their self-esteem. Slotboom et al. (2011) conclude that the most important deprivation factors are staff treatment and environmental stress. Trammell and Rundle (2015) report that staff ignore/disregard inmates. Haney (2001) states that factors that influence inmate adaptation, including the staff factor, form part of natural and normal adaptations to the unnatural conditions of inmate life. The fact that staff members are inherent to the system makes them to be regarded as integral to deprivation.

The Importation Model

Irwin and Cressey (1962) argue that not all inmate behavior result from the prison environment, but scientists have over-emphasized internal influences to explain prison subculture. There is a clear difference between prison subculture and the criminal subculture. Inmates are divided into three categories:

- Those oriented toward a criminal subculture, due to values inherent to dimensions of the professional thief/career criminal.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Those oriented toward the prison subculture, inmates who seek positions of influence, power and sources of information.
- Those oriented toward a legitimate subculture. They are not part of the criminal or thief subculture before entering prison and also reject involvement in the prison subculture while incarcerated.

A combination of the thief and career criminal dimensions gives origin to the prison subculture. Although these two subcultures are conflicting, in some areas they share values. Irwin and Cressey (1962) argue that it is not known how much the first two subcultures influence the third (legitimate subculture), but they hypothesize that all three subcultures import patterns of knowledge, skills and attitudes from past experience into the prison.

The importation model regards the unique characteristics and prior experiences of inmates as critical components of adaptation to conditions inside prison. These characteristics include demographic factors like age, ethnicity, education, and income as well as personal factors like prior incarceration, offence type, and family life (Reid, 1981). The inmate culture is nothing other than adjustment to these three subsystems within the larger system of deprivation and control (Irwin and Cressey, 1962).

Integration of the Deprivation and Importation Models

Several researchers (Lahm, 2002; Jiang & Fisher-Giorlando, 2002; MacDonald, 1999) find support for both the deprivation and importation models. Schwartz (1971) mentions that pre-prison experiences must be considered, but that embedded situational behavior also influences reaction to the physical environment. Akers et al. (1977) conclude that inmate culture varies from one institution to the next according to differences in the organizational environment. Inmates do not conform to staff norms, because the inmate subculture is stronger.

Akers (1989) remarks that integration of theories without considering compatibility is pointless. There can be tendencies to read into a theory and misinterpret the intention of the original author (Burke, 2001). Cheeseman (2003) argues that integrated theories have offered new understanding of the crime phenomenon.

Both the deprivation and importation models influence the dynamics within the physical prison environment. For example, South African prison gangs have largely been limited to the prison environment. During the 1990s a new phenomenon occurred. Prison gangs started to function outside the prison environment. These new gang activities are largely limited to the Western Cape (Roloff, 2014). This occurrence gives origin to what the author coins the exportation model, where the prison environment executes typical prison-like influence on society. With this new development, there is little doubt about the influence of the prison environment on society.

REHABILITATION AND PUNISHMENT

Security and dignity in prisons are interdependent (Coyle, 2010). Security and control are best ensured in environments that respect the inherent dignity of inmates. To achieve inherent dignity, there needs to be a balance between rehabilitation and punishment.

The Standard Minimum Rules for the Treatment of Prisoners (United Nations, 2015) dictate prison regimes should utilize classification for two purposes, namely:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- To separate inmates by reason of criminal records or characters.
- To divide inmates into classes to facilitate treatment and rehabilitation.

Most think of prisons as institutions where offenders are punished and deprived of freedom. However, imprisonment is also intended to rehabilitate inmates. The initial idea of rehabilitation was that an inmate will never want to return to prison. Unfortunately, high recidivism rates show that imprisonment is unsuccessful to rehabilitate. Therefore, rehabilitation must be applied more rigorously to achieve the holistic aims of punishment.

The consequences of incarceration represent significant impediments to post-prison adjustment (Haney, 2001). These consequences interfere with transition from prison to society, impede successful reintegration, and compromise the ability of incarcerated parents to resume family roles. Institutionalization, untreated mental illness, and improperly addressed developmental disabilities are all consequences of inadequate rehabilitation efforts.

Camp and Gaes (2005) ask whether prisons are criminogenic or rehabilitative. A total of 561 male inmates whose admission classification scores indicate that they pose the same risk to commit institutional misconduct were included in research. Half of them were assigned to the lowest security level prisons in California, while the other half were assigned to the second highest security level. If prisons are criminogenic at different security levels, then the probability of misconduct should vary with the security level.

Camp and Gaes (2005) conclude that inmates were equally likely to commit misconduct regardless of the security level they were assigned to. The analysis provides evidence that the types of inmates who are housed together may not be as important as often thought. A main concern is that the prison environment itself may be punishment above and beyond the effects of incapacitation and removal from society (Camp and Gaes, 2005).

Terzi (2015) argues that prisons remain effective in punishing inmates, but ineffective at rehabilitation. Rehabilitation programs are sharply criticized. For example, the New York State Governor Andrew Cuomo was forced to abandon plans to use State funds for inmate college education. Education is pivotal in preventing relapse into crime, but the notion outraged citizens. The solution must be found in the fact that the focus of American prisons must change from punishment to rehabilitation (Terzi, 2015).

The focus of most prison systems does not benefit inmates. Benson (2003) confirms this by stating that most prison systems are so punitive that it is difficult to develop effective rehabilitative programs. Gilligan (2012) reports that an intensive re-educational program with violent San Francisco male offenders completely eradicated violence for a year at a time. Participation in this program for four months reduces the frequency of violent reoffending after release by 83%, compared to a matched control group without intervention.

There is enough evidence to believe that there are alternative ways to develop a substantial number of inmates through rehabilitation programs. The rehabilitation versus punishment debate is not only influenced by programs. Crowding and design are two further fundamental influences.

THE INFLUENCE OF CROWDING ON PRISON ENVIRONMENTS

There is a difference between crowding and overcrowding. Crowding refers to the number of inmates that can be legally and humanely housed in a specific space. Crowding is determined by the design ca-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

pacity of the prison and can be measured objectively in several ways, including floor space per inmate, inmates per living unit, and the institutional population relative to design capacity. Design capacity is the bed space allowed for in the original design. Design capacity is different from operational capacity, or the physical number of beds available. The rate of crowding is calculated in percentage. Prisons that are occupied at half of the design capacity would have 50% crowding, while one that is fully occupied will be crowded at 100%.

Overcrowding occurs when the demand for space (number of inmates) exceeds the design capacity. Overcrowding is defined with reference to the occupancy rate and the official capacity. A prison designed for 100 people while housing 200 people is 100% overcrowded, but crowded at 200%. Operational capacity normally contributes to overcrowding, mainly because prison management makes provision for more beds than the design capacity allows. Occasionally, operational capacity may be less than design capacity, for example when a part of the prison is closed for maintenance.

Prison capacity planning involves:

- Forecasting future trends, based on current crime and incarceration trends.
- Developing long-term strategies to meet forecasted demand.
- Responding to short-term capacity shortfalls (Pearson, 2012).

The expansion of prison capacity without adding supporting infrastructure compounds the influence of overcrowding and simultaneously reduces access to rehabilitation.

Penal Reform International (2012) reports that overcrowding largely contributes to poor prison conditions. Data suggests that overcrowding is experienced in at least 117 countries. Apart from compromising basic human needs like healthcare, food, and accommodation, the effectiveness of rehabilitation programs, education, and recreation are affected negatively.

Gaes (1985) and García-Guerrero and Marco (2012) argue that overcrowding correlates with an over-use of imprisonment This is regarded as not entirely true, as the link between imprisonment rates and overcrowding is rather weak for Europe (Albrecht, 2011). Africa is regarded as being particularly exposed to overcrowding (Albrecht, 2011).

There are various negative effects associated with overcrowding. Overcrowding exposes inmates to severe levels of stress, deprivation, degradation, and danger (Haney, 2012). Overcrowding introduces complexity, instability, and collective frustration. There are signs of enforced idleness, deprivation, isolation, and psychological challenges in overcrowded prisons.

The Criminal Justice Alliance (2012) emphasizes that additional pressure originates with overcrowding. The rehabilitation of inmates is severely undermined. The Criminal Justice Alliance (2012) propagates urgent steps to limit the unnecessary use of imprisonment, ensuring it is reserved for serious, persistent and violent offenders for whom no alternative sanction is appropriate.

Although many reasons exist for increasing inmate populations, many of these reasons fall outside of the control of prison administrators. There is little doubt that overcrowding has a pervasive negative impact on inmates and staff alike. What are more important for this discussion are the effects of overcrowding. These effects have a holistic negative influence throughout prisons (Criminal Justice Alliance, 2012). The following effects should be scrutinized more intensely by prison regimes:

- Strain on staff to maintain safe and rehabilitative environments.
- Deterioration of living conditions.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Lack of access to education/training/work.
- Increased mental health problems and decreased treatment thereof.
- Lack of holistic and specific health services.
- The increased risk of reoffending.
- Negative financial implications.

These negative effects manifest in the following experiences:

- Insufficient officials to escort inmates to appointments/classes. Inmates cannot improve post-release skills.
- Longer waiting lists for education, counselling, and work.
- Inmate transfers, causing course interruptions and disrupted resettlement plans.
- Double bunking in single cells.
- Higher stress levels and tension.
- Longer in-cell times.
- Less family involvement.
- More referrals (Criminal Justice Alliance, 2012).

Prison systems cannot build their way out of overcrowding. It is time to re-evaluate who should be imprisoned and what we can realistically expect prisons to achieve. All avenues should be exhausted to get people out of the system. Inmate participation in education and rehabilitation should be an indicator of who could be released.

PRISON DESIGN

The discussion below addresses the evolution of prison design. Prison activities are influenced through design, architecture and physical layout. Design sends a message to everyone entering the designed space. Prisons are the same. Design is crucial in creating an environment in which inmates are able to live without the risk of institutionalization. The space must provide opportunity for visits, work, education, and relaxation. Prisons are microcosms, complete societies outside of society.

Antiquity in Design and Its Influence on Modern Times

A large number of different prison designs have come and gone. Some have had more influence than others. New designs differ from traditional designs. Prisons are not erected for short-term use. Many outdated structures (regarding design and penal philosophy) are still operational. Many are mega-structures with detrimental effects on humanity, healthcare, and efforts to develop/rehabilitate. These structures are costly and staff-consuming for security purposes. They do not contribute optimally to inmate education, but cannot be declared redundant due to large overcrowding in most prison systems.

Many of the structures mainly contribute to inhumanity. For example, Bentham describes the Panopticon (a 1917 design that survived until the 1990s) as a new mode of obtaining power of mind over mind in a quantity hitherto without example (Bowring, 1943). These observations of Bentham contributed to the continued use of harsh inmate treatment. Bentham was, after all, the father of utilitarianism and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

a legal reformer who regarded human rights as less important (Geis, 1972). After World War II human rights received new emphasis, influencing prison design and the way inmates were to be treated.

The New-Generation Environmental Design and Beyond

Architecturally, four generations of prisons are discernible (Siegel & Bartollas, 2014). Each generation is influenced by the physical prison design. The first-generation building is designed to provide linear and intermittent surveillance. Inmates are observed and supervised from time to time when linear designed cellblocks are visited. The second-generation prison allows for indirect remote surveillance in podular units. Where first generation prisons rely on intermittent surveillance, second generation prisons are characterised by constant remote/indirect surveillance. A critical feature of these prisons is the physical separation of inmates and staff. Control remains the over-emphasising philosophical approach (Wortley, 2002). Inmates suffer from program shortages, overcrowding, inadequate physical separation between different types, and physical maintenance problems (American Correctional Association, 1991).

Third generation prisons evolved from the podular design and are known as new-generation prisons. They entail a direct-supervision model where the prison design and layout also contribute to improved services. Each unit inside the prison is self-contained and provides all services. They offer a softer, human-friendly physical environment through architectural features (Luyt et al., 2010; Wortley, 2002). The new generation concept is currently applied widely throughout the world, including South Africa and Namibia. More than 500 new-generation prisons exist in the USA alone.

Third generation prisons have the unit management philosophy at their core. Luyt et al. (2010) define unit management as a decentralised approach to inmate management that divide prison populations into small, manageable entities to improve control through direct supervision, foster good relationships and inmate development, and to deliver effective services. Unit management adheres to all the needs emanating from prison environments. The most important contribution from new-generation prisons is holistic inmate development, including education.

The fourth-generation prison is largely still limited to America. It aims to eliminate inmate rape after the implementation of the Prison Rape Elimination Act in 2004. Supervision teams are located centrally in high-strength mirrored glass control centers with 100% panoramic surveillance of all inmate areas (Siegel & Bartollas, 2014).

HUMAN BEHAVIOR AND INMATE RIGHTS IN THE PRISON ENVIRONMENT

Homel and Thompson (2005) observe that prisons are abnormal environments that assemble troubled humans into confined spaces against their will, many with histories of violence and victimization. Concerning human behavior, Howells (2000) mentions that the inmate subculture acts antithetical to the goals of rehabilitation. Instead of promoting participation in rehabilitation, the prison environment mandates avoidance. This is also the case for inmate rights, which are under constant threat.

Some inmate rights are more exposed to infringement (Luyt et al., 2010). For example, the right to privacy is more at risk than the right to citizenship, because the prison environment can exercise more power over the right to privacy. Human rights can be limited under certain conditions. No right is absolute. Limitation of rights must be reasonable and justifiable, which is not always the case inside

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

prisons. Many reports confirm large-scale human rights violations inside prisons. Tucker (2014) calls imprisonment a violation of human rights.

Sarkin-Hughes (2008) reveals that human rights reforms in prisons are under way across African nations. Imprisonment does not justify fewer human rights. Inmates have the same rights as any other citizen. In other words, inmates do not have fewer rights than other citizens, but their rights do not extend as far as those of other citizens (Luyt et al., 2010). Human rights cannot be terminated or removed because of imprisonment. Prison officials cannot limit inmate rights at will. They can only execute such limitations as provided for by enabling legislation (Luyt et al., 2010).

Prisons have two main objectives, namely, keeping inmates in safe custody, and contributing to their development and reintegration. Jonker (Luyt et al., 2010) argues that prison officials executing the powers granted by legislation to ensure safe custody of inmates are in fact executing a limitation on the rights of inmates. The rights of inmates are indirectly limited through the execution of powers granted by legislation. Such limitation is not a result of the initiative of officials or the absence of powers granted by legislation. If this were the case, it would be an infringement of human rights, and not a limitation.

Although human rights may be limited, such limitation must be in accordance with strict legal requirements, clear boundaries and defined purposes. The main aims in protecting human rights are to recognize and affirm human dignity by protecting the individual against the collective powers of the state. Prison officials (in their relationship with inmates) represent the state. Inmate rights (representing the individual) must be protected against the power of correctional officials (representing the powers of the state). Prison officials have a duty and moral obligation to maintain a balance between keeping inmates in safe custody and protecting their rights (Luyt et al., 2010).

This should include access to education as basic human right. Education should be compulsory for young offenders and illiterates. Prisons are closed environments, but the Standard Minimum Rules for the Treatment of Prisoners dictate that the community should be actively involved in prison education (United Nations, 2005). The UN Prison Special Rapporteur on the right to education (Munoz, 2009) reports that major infringements on the right to education in prisons include courses being unfairly interrupted by prison staff, long waiting lists for programs, limited/no access to information technology training, dated-paths-to-nowhere vocational courses, and withdrawal of educational rights as punishment.

Females particularly suffer from infringed educational rights. Women are generally young, poor, and unemployed with little education. In many countries, the quality/quantity of programs is inferior to those for men. Programs often cover inadequate traditional female roles, like sewing and handicrafts. Child inmates receive inadequate education. After incarceration, more than two thirds of them do not return to school (Munoz, 2009).

Luyt et al., (2010) argue that the main differences between countries that protect human rights are in their limitation of rights. Consider the following examples:

- In the USA, the death penalty still exists in certain states. In South Africa, it has been declared unconstitutional. In both countries, the right to life is protected, but there is a difference in the grounds for limitation of the right.
- The Canadian Charter of Rights and the South African Bill of Rights contain a separate limitation clause, but this is not the case in the USA, where it is left to the courts to develop limitation standards.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Inmates do not have fewer rights. Their rights may be exercised to a lesser extent. Their rights are not less in quantity but may be so in quality. Human rights contribute to the protection of human dignity (Luyt et al., 2010). The right to education should not be limited inside prisons, because it fundamentally contributes to human dignity.

The prison guard subculture jeopardizes inmate rights (Kauffman, 1988), a phenomenon that creates an ethical dilemma where most prison officials view inmates as worthless, untrustworthy, and manipulative (Irwin, 2005). Irwin (2005) argues that the subculture leads to underreported employee misconduct, including the denial of the right to education.

ALTERNATIVE ENVIRONMENTS

Alternative environments exist in the management of criminal justice. These environments include private prisons and community settings. Approaches to inmates may differ in these environments.

Private Prisons

Many prison systems operate private prisons. Private prisons originate for a number of reasons, including rapidly rising inmate numbers and overcrowding in public prisons. Other reasons include failure of the public prison system to rehabilitate offenders and the high costs of imprisonment (Austin and Coventry, 2001).

South Africa, as an African example, also follows the privatization route. Two private prisons are managed by two different private companies. They differ in philosophy and operations, but are obliged to function according to legal and contractual mandates. Private prisons create an alternative environment for prison operations. Sometimes these alternative environments are positive. Other times the negative influence of privatization cannot be ignored.

The USA is the largest privatizer of imprisonment. The Bureau of Justice Assistance has funded a nationwide study to investigate various issues pertaining private prisons. The study concludes that American private prisons over time were only 1% cheaper than public prisons (instead of 20% savings projected). Privatization has a positive effect on prison administration, is more responsive to rehabilitation and provides improved quality of service (Austin and Coventry, 2001). Studies report that private prison management problems can be linked to poorly drafted contracts, lack of oversight, and transferring risk (through inmates with high security classification levels instead of rehabilitation potential) (Luyt, 2008; Austin and Coventry, 2001).

In August 2016, the US Federal Department of Justice announced that all private Federal prisons will be phased out, citing excessive levels of violence, lack of rehabilitation and extensive costs as reasons. Less than 1% of the American inmate population is affected, as most inmates in private care are incarcerated in State prisons and local jails (Kilgore, 2016).

Private prisons remain controversial. Opponents argue that:

- Inmate care ought to be a State responsibility.
- The profit motive incentives are inappropriate/unethical practices.
- There is a lack of transparency due to contract confidentiality (Tanner, 2013).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The operation of private prisons has more or less stabilized world-wide (very few new prisons become operational). The future of private prisons remains stable to uncertain. The decision to discontinue US Federal prisons may become a watershed moment for the future of private prisons.

Community Corrections and Inmate Development

The 1980s witnessed the rapid development of home detention, electronic monitoring, and intensive community supervision (King, undated). Through this a philosophical position emerged that contains elements of risk control and risk reduction as two separate approaches to offender management.

Risk control has become popular in correctional management. It allows for discretion from correctional managers to concentrate resources on high risk offenders. Risk is controlled through a range of mechanisms, including electronic monitoring; urine analysis; breathalyzer tests; intensive supervision; home detention and curfews. These mechanisms do not so much control the risk, but rather present a deterrent effect (King, undated).

Risk reduction counter-balances the risk control philosophy. Risk reduction emphasizes the need for staff to become involved in social policy development and rehabilitation. The risk reduction philosophy advocates rehabilitation based on offender needs, adult literacy, and intensive employee training (King, undated).

Inside prisons the risk control factor is enhanced by the prison structure. In community corrections, risk cannot be prevented by high walls or steel gates. Community corrections is more reliant upon risk reduction. Through risk reduction offenders have to bear more responsibility to prevent relapse into crime. Therefore, community corrections provide a positive platform for change and resumption of offender responsibility for own development.

RECOMMENDATIONS

Prisons are not static environments. It is possible to change an environment without changes to the physical structure. In other words, even though the physical structure contributes to the prison environment, management interventions and operations can be used to improve perceptions about the environment and the environment itself.

Solutions for Overcrowding

Recommendations for overcrowding should differ from one system to another. Generic areas exist, allowing for lessons to be learnt from other systems. For example, the Netherlands have reduced the number of active prisons without a real reduction in the number of inmates. Historically the country made use of single cells, but then decided to double-bunk. Through this, millions of euros were made available for alternative use, like inmate education and reintegration. To address overcrowding, we have to think smarter within the parameters of our individual systems, while also learning from others. Consider the following:

- Sentence fewer people to imprisonment for drug crimes. Instead, adopt harm reduction strategies.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Allow for wider sentence reduction policies through credit for good behavior, in particular successful completion of education programs.
- Release the elderly.
- Transfer foreign inmates to their own countries through bilateral agreements.
- Divert minor cases.
- Prevent pre-trial incarceration.
- Implement non-custodial alternatives.
- Decriminalize selected offences.
- Review sentencing policies without negating the punishment-must-fit-the-crime principle.
- Amnesties/pardons.
- Divert mentally ill offenders to community structures.
- Reduce sentence lengths and do away with the minimum sentencing policies.
- Develop and maintain parole and community corrections alternatives to get offenders out of the system at the earliest possible opportunity.

Offender Development

Offender development remains a neglected area of imprisonment. One only needs to think about the amount of resources allocated to it to realize that prison systems are not educating inmates optimally for successful reintegration. Consider the following:

- Avail more money for offender development.
- Appoint and retain development specialists. Many systems appoint rehabilitation specialists, but frustrate them with administration.
- Broader use of community structures, faith-based organizations, non-governmental organizations and other resources to benefit development.
- Provide financial incentives for progress in education programs.
- Rejuvenate prison labor programs to benefit inmates– not all labor can be regarded as slavery. Instead, extensive idle hours in locked cells is more inhumane than work.
- Explore/use more alternatives that would keep offenders employed (day fines, periodic imprisonment, victim compensation).
- Design a classification flow matrix to move inmates into and through programs. Classification instruments should be development-focused, not security-focused.
- Intensive societal employment programs after release.
- Intensify sentence plans through structured days.

The lists above are not exhaustive. The reader should realize that alternatives can improve both the prison environment and inmate development.

FUTURE RESEARCH DIRECTIONS

Prisons remain breeding grounds for research initiatives. Certain areas for future research can be recommended. The idea is not that only academics engage in this research, but criminal justice functionaries

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

should contribute with the aim of improving prison systems from the inside. The areas below can be considered.

Minimum Sentencing Reform

Minimum sentencing laws are overly punitive and impose excessively long sentences (Law Enforcement Leaders, 2016). Most systems using this form of sentencing already experience growing overcrowding and pressurized physical prison environments.

Non-Governmental Organizations and Inmate Services

There is reason to believe that organizations outside prison departments have more success with certain inmate rehabilitation programs. More research must be done, particularly in the area of education and its influence on recidivism tracked over a prolonged period of time. Systems should open up to accept the assistance of organizations that can contribute to more acceptable physical prison environments and positive outcomes on the future of inmates.

Extended Provision of Prison Education

Systems do not do enough to implement and sustain prison education. Even child and youth systems struggle to reach this aim, particularly in Africa. More research needs to be done in this area.

Warehouse or Reform: What the Future Holds

Luyt (1999) remarks that all prison systems are confronted with two groups of inmates. One group can only be warehoused for security purposes, because the possibility of reform is extremely low. The other group has the potential for partial/complete rehabilitation. Prison managers are not doing enough to distinguish between these two groups scientifically. Resources are not actively applied to benefit the second group. This area is underdeveloped.

Fourth Generation Prison Design

More research is needed to determine how successful the fourth-generation design is.

CONCLUSION

Prison environments influence inmates. The more violent the environment, the less rehabilitation occurs. It is important to consider the varying circumstances that exist within different prisons, across security levels, and in different countries. Circumstances like violence, theft, insecurity, and boredom exercise fundamental influence over inmate emotions, safety, social structure, privacy and freedom.

Presence of these dimensions often negates and sometimes destroys the rehabilitation ideal. The function of a particular prison also impacts on efforts to rehabilitate. The higher the security classification the less the emphasis will be on rehabilitation. Rehabilitative ideals become even more difficult through

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

public demands for longer sentences, harsh sentencing conditions, and little or no recreational activities, while they simultaneously demand successful rehabilitation and reduced recidivism.

After nearly 300 years of imprisonment, prisons are still plagued by the same demons. The prison environment still does not allow for proper education. The prison subculture exercises the same negative influences that prevent proper inmate development. These factors are compacted by negative staff attitudes, too little resources, and a lack of trained specialists to fulfill the required duties.

Resources have to be applied to the individual inmate, rather than the total inmate population. Those who aspire to improve themselves should be the ones who benefit (with caution about manipulation of the system). Attention should be directed towards prisons that are designed for certain rehabilitation efforts (like new generation prisons), rather than towards those designed for security. Resource availability should be built on a hierarchy that demands resources and attention being placed where they are most needed.

KEY TERMS AND DEFINITIONS

Auburn System: A 19th century penal system where sentenced offenders worked in groups during the day, but slept in solitary confinement at night, with enforced silence at all times.

Classical School Principles: A school of thought known as the classical school of criminology originated during the Enlightenment. It emphasizes the ideas that people make choices to commit crime and that punishment should prevent crime. There are five principles; rationality (people have free will and select to commit crime), hedonism (people seek pleasure and avoid pain), punishment (informed by the consequences of hedonism, punishment must fit the crime), human rights (before the classical school punishment was harsh and horrific), and due process (including presumption of innocence).

Community Corrections: The supervision of sentenced offenders in the free population, as opposed to incarceration in prison. The two main types of community corrections supervision are probation and parole.

Crowding: Crowding in prisons refers to the number of inmates that can be legally and humanely housed in a specific confined space. Crowding is determined by the design capacity of the structure and can be measured objectively in several ways, for example in terms of the floor space per inmate, inmates per living unit, and the institutional population relative to the stated design capacity. The rate of crowding is calculated out of 100 per cent. A prison that is occupied at half of the design capacity would have 50% crowding.

Deprivation Model: A model that states that prison subcultures develop as a response to a number of deprivations that originate from inside prison. There are five deprivations; liberty, goods and services, heterosexual relationships, autonomy, and security.

Dynamic Security: The actions of staff members during interaction with inmates that contribute to a safe working and living environment for staff and offenders, and a key tool to assess an offender's adjustment and stability.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Elmira System: A system of penology based on the indeterminate sentence with possible commutation. The system classified and separated various types of inmates, gave them individualized treatment emphasizing vocational training and industrial employment, used indeterminate sentences, rewarded good behavior, and paroled inmates under supervision.

Importation Model: The model states that prison subcultures are formed from what inmates bring into the prison. Prison subculture codes, languages, roles and values are from pre-prison characteristics of the inmates, rather than the deprivations caused by incarceration.

Incarceration: The state of being confined in prison, also known as imprisonment.

Intermediate Sanctions: Intermediate sanctions are conceptualized as punishments on a continuum between prison and probation. They are more intrusive and burdensome than standard probation. Intermediate sanctions are likely to save money or prison beds only if they are used primarily for offenders who otherwise would have been imprisoned.

New-Generation Prisons: The New-generation approach to prison management seeks to manage human behaviour positively, consistently and fairly. New-generation prisons allow for continuous observation of inmates.

Overcrowding: Overcrowding in prisons is a social phenomenon occurring when the demand for space in prisons exceeds the design capacity for inmates in the space. Overcrowding is generally defined with reference to the occupancy rate and the official capacity of prisons. Overcrowding refers to the situation where the number of inmates exceeds the official design capacity. The rate of overcrowding is defined as that part of the occupancy rate above 100%. A prison that holds double the design capacity would be 100% overcrowded.

Pennsylvania System: Also known as the separate system, Pennsylvania encouraged solitary confinement for inmates. It was designed to keep inmates separate at all times, even when they worked, to keep them from being distracted and impeding their repentance.

Prison: A building to which people are legally committed as a punishment for a crime or while awaiting trial.

Private Prisons: A private prison is a place where offenders are incarcerated by a third party that is contracted by the State through a specific Government agency or department.

Chapter 55
Community-Based Rehabilitation Program for Acid Assault Victims of Bangladesh

Tahmina Islam
Shahjalal University of Science and Technology, Bangladesh & University of Malaya, Malaysia

Siti Hajar Binti Abu Bakar Ah
University of Malaya, Malaysia

ABSTRACT

This chapter is a PhD research proposal of the first author based on qualitative research design. The study aims at exploring some community-based rehabilitation interventions for the acid victims (women) in Bangladesh. The proposal was submitted by the first author to pursue her PhD studies at the Department of Social Administration and Justice, Faculty of Arts and Social Sciences, University of Malaya, Malaysia. It contains major components of a research proposal that includes the background of the study, problem statement, research questions and objectives, literature review: conceptual and theoretical framework, the scope and significance of the study, and research methodology. This proposal also includes the work plan of the study. The proposal will be helpful to the students and readers who are interested in conducting research in this field.

BACKGROUND OF THE STUDY

Violence against women is a universal phenomenon. It is a serious human rights abuse and has a significant public health concern with substantial consequences on physical, mental, sexual, and reproductive health (Yount, Vander Ende, Zureick-Brown, Anh, Schuler & Minh 2014). Because of its nature and pattern, the scholars such as, Adams, Sullivan, Bybec & Greesom (2008) and Das, Olga, Peck & Salek (2014) termed violence against women as gender-based violence). According to Hasam and Islam (2016), any activity committed by someone to (or "intending to") hurting or harming anybody physically is named as violence, and gender violence is a daily and a deadly matter of life for millions of women and girls around

the world. It kills tortures and maims girls and women physically, mentally, sexually and economically. Women experience different types of violence throughout their life cycle, as, for instance, a girl child may be the target of sex-selection abortion. During childhood, she may suffer from malnutrition, and may not get access to the education and medical, may force into early marriage in her teenage, a female may experience genital mutilation, forced prostitution, forced pregnancy and dowry-related violence, even during widowhood; women may experience different types of abuses (Vlachova & Biason, 2005).

The volume of violence against women may differ a little from region to region, from continent to continent but the scenario is almost similar. Violence against women occurs both in the developed and developing countries. In case of Latin American countries such as, Columbia, Guatemala, Brazil, Mexico and Ecuador, women subordination position is prominent and the forms of violence are visible as kind of structural violence like, feticide, women trafficking, force prostitution, rape by intimate partner etc. (Wilson, 2014). Again, in African countries, violence against women is not a new phenomenon. In a joint report by the UNHR & UN Women (2016) revealed the same truth for African and sub Saharan countries where women cannot enjoy their rights. They experience violence in street, in home, working place. According to the report, in Africa, one in three women have suffered different forms of physical or sexual abused by their intimate or non-intimate partner in their lifetime. The report mentioned that the nature of culture of Africa plays vital role to justify discrimination against women. Here, women and girl child experience female genital mutilation, forced child marriage, unsafe abortion and they are under threat of HIV. Vlacova & Biason (2005) mentioned that dowry related violence, honour killing and female genital mutilation (FGM), sexual violence during armed conflict as severe forms of violence against women in countries like Benin, Egypt, Kenya, Niger, Sudan, Tanjania, Yemen, Mali and Ethiopia.

In South Asia, violence against women begins immediately after birth and continues throughout their lives, it is viewed as a normal phenomenon (Wahed & Bhuiyan, 2007). Farouk (2005) argued that South Asian women suffer from different types of violence in their entire lifetimes including domestic violence, rape, dowry tortures, sexual harassment, suicide, forced marriage, trafficking, and other psychological and economic oppression. In a word, violence against women has become one of the most prominent social issues in this region . The women and the girl child of Bangladesh, Pakistan, and India sometimes experience same types of violence.

Being a part of the South Asian region, Bangladesh is no different from its neighbours (Rahman, Bhuiyan & Lovely, 2014). In some cases, the intensity of violence against women in Bangladesh is much higher than that of many other countries. Parvin & Naved (2016) mentioned that violence against women in Bangladesh is occurring in almost every aspect of their lives. It is a grave threat to the overall development and progress of women in Bangladesh. Hossen (2014) focused that, women in Bangladesh facing different forms of violence like physical (i.e., hitting with fists, punching, pushing, kicking, beating/ stabbing), mental abuse, sexual abuse, acid throwing, murder, rape, sexual harassment of multiple types, eve-teasing, abduction, trafficking, oppression by fatwa (religious verdict) and suicide etc.

One of the most barbaric forms of violence against women in recent time specially found in South Asian and African and in some cases of European countries of the world is acid violence or acid assault. Dubey (2015) called it as a brutal act. Though acid violence is a global problem, the frequency of this attract is critical particularly in Bangladesh, India, Pakistan, Nepal, Cambodia, Vietnam, Laos, China, Iran, Hong Kong, Kenya, Uganda, Ethiopia (Swanson, 2002). The developing countries like Malaysia and China have also experienced such cases in the recent past (Ahmad, 2012). Acid violence is not limited to a specific race, region, or geographical location. It happens in many countries in South Asia, Sub Saharan Africa, the West Indies and the Middle East also. In the 18th century, sulfuric acid,

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

which is known as vitriolage was first manufactured in the industrial purpose in England in the 1940s but later people began to use it for violent action in Western Europe and the United States. The Person Act 1861 was formulated to combat crimes like corrosive substance violence, such as acid in the UK over a century year ago. Dubey (2015) added some other countries like Vietnam, Laos, Hong Kong, Kenya, South Africa, Uganda, Ethiopia in his list where the occurrence of acid assault was taking place in several times. While acid violence is most prevalent in Bangladesh, Cambodia, India and Pakistan, they have also been reported in Afghanistan and parts of Europe.

However, in Bangladesh, acid violence is considered as a wicked problem and damaging form of gender-based violence which has significantly increased and spreading like terrorism in recent time (Kalantry & Kestenbaum, 2011). It is an act of throwing acid or similarly corrosive substance onto the body of another with the intention to disfigure, maim, torture or kill (Acid Survivor Foundation, ASF). According to the Project against Torture (2003), the perpetrators of acid assault usually do not want to kill the victims. They want to do something worse than murder. Typically, the nitric and sulfuric acids are used in acid throwing which has catastrophic effects on human flesh. It causes skin tissue to melt, often even dissolving the bone. In particular cases, the ears and noses, including eyes are lost completely. The scars left by acid are not just skin deep. Many survivors suffer from a psychological breakdown and identity crisis due to their lost and distorted appearance.

The general causes of acid violence can vary from country to country and society to society. As, for example, domestic disputes, family related matter, financial disputes, marital disharmony, extramarital affair, etc. are common reasons for throwing acid in Taiwan, Colombia, SriLanka, Cambodia (Guerrero, 2013; Karunnadasa et al., 2014). Asaria,Kobusingye, Khingi, Balikuddembe, Gomez, Beveridge (2004) highlighted house or motorcycle robbery, suspected affair or domestic disputes are major reasons for the acid attack in Uganda. The Acid Survivor Trust International Nepal (2011) showed that besides domestic disputes acid is largely used for suicide in Nepal. Surprisingly, some common trends of causes of acid violence are found among South Asian countries like India Pakistan and Bangladesh. Experts mentioned some basic motives for acid throwing in this region are the rejection of love, sex or marriage proposal, dowry, land or money related disputes (Jafreen, Wahab, Islam, 2010; Rahman, Bhuiya & Lovely, 2014; Zia ,2013; Ahmed, 2012; Dubey, 2015).

Acid violence, as an extreme form of criminal activity in Bangladesh, needs to bring under special attention for ensuring women right and social justice. The need is in line with the constitution of Bangladesh that ensures the equal right for men and women (Section 28, Bangladesh Constitution). Acid violence is a threat to the women, which hampers the empowerment process of women and overall development. Acid violence does not destroy the victim's life; it also destroys the hopes and dream of a family. The entire society suffers, and the state has to bear unforeseen financial and social cost to tackle the problem of acid violence. Thus, it has become an crucial aspect for the social scientist particularly to the social workers to address such brutal crime with particular priority and offer a suitable solution to end the violence.

Statement of the Problem

In Bangladesh, acid violence is an extreme form of repression and violation of women's rights (Rahman, Bhuiya & Lovely, 2014). Although acid violence has become a common social problem throughout South and Southeast Asia, a review of the scientific literature of the past two decades reported the highest incidence in Bangladesh (Mannan, Ghani, Sen, Clarke & Butler, 2007). According to the Bangladesh

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

National Women Lawyers Associations (BNWLA), acid violence represents 6% of the total violence against women in Bangladesh (Farouk, 2005).

The first case of acid violence in Bangladesh was reported in 1961 (Begum, 2004; Milton, Mathieu, Hall & Maibach, 2009). The majority of the victims are women, and many of them are under 18 years of age. The Acid Survivors Foundation, ASF (2011) reported that since 1999, there had been an astonishing 3240 incidents. Voice (2013), a Quarterly Newsletter of Acid Survivor Foundation, reported that in Bangladesh, among the victims between 1999 and 2013, 69% victims were female and 51% fall into the age group of 19 to 35, and 97% of the incidents occurred in rural areas. A study was conducted an on 90 acid victims who were admitted to Dhaka Medical College Hospital, revealed that 90% of the victims were female, 60% of the victims were unmarried, and 51.1% were students. The vital reasons for throwing acid were for dowry, and the second highest reason was the refusal of the perpetrator's proposal for marriage, sex or romantic relationship (Zafreen, Wahab, Islam, and Rahman, 2010).

The victims of acid receive medical treatment once they come in contact with ASF (Acid Survivor Foundation) or in the Burn Unit of Dhaka Medical College Hospital. The victim has to enter into lifelong treatment cycle for the rest of her life. She needs physiological care, treatment, physiotherapy, psychological support or therapy, legal assistance, economic support, education help etc.(Akhter &Islam,2013). In Bangladesh, a victim receives some psychological counselling, while she was under the treatment of ASF, but a widespread service of counselling is not available all over the country in Bangladesh, which is a prior need for the victims of acid. Moreover, they become burdens to their family and sometimes the family treats her as the reasons for bad luck. A victim cannot perform her family duty properly. In many cases, the husband of the victim remarries. However, the victim has no chance to get married even she is unmarried (Anwari, 2003; Dubey, 2015). Most of the victims are from poor family, as Kamruzzaman & Hakim (2016) mentioned in their study that 65% of the acid victims were living under poverty line and they had to face, biological, sociological, economic, security issues and social exclusion. The provisions of help for acid assault victims from Government is very limited. It is, therefore, very significant to understand the underlying needs of the acid victims in Bangladesh. The recent literature poorly addressed such needs of victims after the occurrences of acid throwing. An extensive study is required to find out the prime needs of the victims of violence of acid.

The victim of acid embraces a new life with so many dramatic changes when she comes back home after a long-term treatment. However, what happened to her life when she returned to her own community after a long-term treatment is still not studied well. She may face new challenges as she suddenly enters into a new world with new experiences. Earlier, she was a woman with fare appearance. Suddenly she greets her life with disfigure face and body. The new situation may create problems, not only for the victim but also for her family and her relatives. ASF Report (2015) quoted the verbatim of one victim;

I was seven months pregnant when the incident occurred, I dreamt a lot about the future of my child. But the incidents shattered all those. I had nothing to say except for the fact that I am no longer attractive

Family breakdown, divorce, etc. are associated with the problem like acid violence. Victims may become stigmatized and socially excluded. The Report on "Coping with Disfigurement" by the Acid Survivor Foundation 2015 explores some realities including physical, psychological, economic and social situation after the incidents of acid violence. Victims embrace physical disfigurement and disability. Acid dissolves skin and flesh, which can even damage bone. If it goes to the eyes, it creates permanent blindness. They suffer from partial or full blindness with visual impairment. They face the problem with

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

mobility and breathing. They sometimes have to go under several surgeries that have a post-surgical effect and distress. The victim cannot work under the sun. They totally become depended on their family members and thus become a burden for their family. According to Rahman, Bhuyan & Lovely (2014), the acid attack leaves a survivor traumatized, disfigured, and sometimes disabled, socially excluded and economically vulnerable. The victim has to bear a big amount money for treatment. She has to face economic, physical, psychological, social, educational challenges in every steps of her life. Survivors suffer from emotional and psychological trauma. They become disfigured, marginalized, disabled and socially excluded (Rahman, Bhuyan & Lovely, 2014). Shah (2016) also added that rejection, criticism, discrimination etc. increase the misery of a victim of acid. There are few studies those investigated the life of the victims after such brutal attack and challenges faced by the victims from a multidimensional point of view.

Another important thing is that before the late nineties, acid throwing was not recognized as a form of violence against women in Bangladesh. The Acid Survivors Foundation (ASF) was established by UNICEF, on May 1999 as the first organization to challenge the issue, and to set up a forty-bed hospital for acid burned patients (Langerhans, 2007; Haque & Ahsan, 2014). The agency also provides plastic and reconstructive surgery, psychological care, legal assistance,and financial support for economic rehabilitation. Despite the structured and unstructured services from both the government and other organizations, it is also important to know what acid victims feel and how they survive. Are they being socially excluded? What are the challenges of their reintegration in the mainstream community? Current literatures of Bangladesh cover issues like socio economic demographic profiles, causes or motives of acid throwing, impacts of acid violence on victim' s life, health and other psychological sufferings of victim (Haque & Ahsan, 2013; Zafreen & Wahab, 2010; Rahman, Bhuyan & Lovely, 2014; Shah, 2016; Das, Khondokar, Quamruzzaman, Ahmed & Peck, 2012; Akhter & Farzana, 2013). Besides theses, there are other studies which include various issues like health hazards of acid violence, medico legal aspects, medical surgical treatment, acid burn management system, psychological outcome etc of acid assault victims. But no single literature is found which states the needs, challenges, reintegration process or rehabilitation process of acid victim after the brutal attack of acid. Neither government nor other the NGOs adopted any kind of community based rehabilitation program for the wellbeing of the victims of acid violence in Bangladesh. Despite seriousness of the issues like rehabilitation for acid victims is a little studied subject especially in Bangladesh, so an explorative study is needed towards develop some community-based rehabilitation for the acid victims of Bangladesh.

AIMS AND OBJECTIVES OF THE STUDY

The aims or objectives of the study are as follows,

1. To identify the needs faced by the acid assault victims when they are reintegrated into the Community.
2. To look the challenges faced by the acid assault victims and the community in Accommodating the acid victims
3. To reconstruct the existing community based rehabilitation programs for their better Services

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

RESEARCH QUESTIONS

In connection with the above statement, the study will seek answers to the following questions:

1. What are the needs faced by the acid assault victims during the reintegration process?
2. Why is the community not being able to accommodate the acid assault victims?
3. How can the existing community- based rehabilitation programs in Bangladesh be reconstructed for their better services?

LITERATURE REVIEW: THE CONCEPTUAL AND THEORETICAL FRAMEWORK

Acid Violence

The term "acid violence" is synonymous with acid assault, acid burns, acid throwing, and vitriolage, chemical assault etc. According to Vij (2003), acid attack is more formally known as vitriol age; which is defined as "… the act of throwing acid into the body of a person with the intention of injuring or disfiguring her out of jealousy or revenge (p 462). The report by New York Avon Global Centre for Women (2011) stated aid violence as, "acid violence" and "acid attacks" are used interchangeably in this Report. "Acid attacks" refer to specific incidents usually involving throwing acid at one or more individuals who are the intended victims of the attacks.The report also added that acid violence1 comprises intentional acts of violence in which perpetrators throw, spray, or pour acid onto victims' faces and bodies "Acid violence" is a broader term that includes acts such as forcing a victim to ingest acid. Zafreen, Wahab & Rahman (2010) mentioned acid violence as a worst form violence against women which brings permanent injury and disfigurement to ones life. Hakim & Kamruzzaman (2016) and Watson (2002) described acid violence as an attack on a person with sulfuric, hydrochloric and nitric acid, which causes severe burns and disfigurement associate with blindness and hearing loss.

In another report by LICHADO: Project against Torture (2003, p1) stated acid throwing as kind of torture which never ends. According to the report, acid throwing is usually an action of revenge, driven by jealousy or hatred, because of a personal relationship problem such as rejection of proposal of love affair or marriage, unfaithfulness, or rejection. Akhter & Islam (2012) defined acid violence or acid throwing or vitriolage as a barbaric form of violence, where strong corrosive are thrown on face or body of victims with an intention to disfigure or permanent scar. In an article, Chandrasekhar & Johny (2017) defined acid violence as "acid throwing or vitriolage is characterized as damaging acidic chemicals onto the body which reasons distorting skin, in Medical obsessive clarification". The Cambodian Acid Survivors Charity (2010) mentions that acid violence, as a deliberate form of assault involving the throwing, pouring, or administering of acid, or other similarly corrosive substance, on an individual, with the intention to seriously maim, disfigure, torture, or kill. The Acid Survivor Trust International mentions that acid violence is deliberate use of acid to attack another human being. Acid attacks rarely kills but causes severe physical, psychological and social scarring, and victims are often left with no legal resources, limited access to medical or psychological assistance and without the means to support themselves (ASTI, 2011).

Bangladesh has its own legal definition of this crime. The Bangladesh Government has enacted two laws named Acid Offense Control Act, 2002 and the Acid Crime Control Act 2002. The Acid Offenses

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Prevention Act 2002 defines 'acid' as any kind of burning, corrosive and poisonous substance (Yasmin, 2014). As per section 4 of the Acid Control Act 2002, death or life imprisonment will be given to the offenders for causing death or other harmful injuries by throwing acid. The law named 'Nari O ShishuNir-jaton Daman Ain 2000' has also mentioned punishment as well as rehabilitation, treatment and justice for the victims (Yasmin, 2014). The Indian Penal Code, 1860 by virtue of Criminal Law (Amendment) Act, 2013 under the Explanation 1 of Section 326B has defined acid to include, "any substance which has acidic or corrosive character of burning nature, capable of causing bodily injury leading to scars or disfigurement or temporary or permanent disability"."Acid throwing and burn Crime Bill, 2014, was introduced in the Parliament in Pakistan. The bill mentioned acid attack on section 5, "acid attack means any act or omission caused by corrosive substance/acid to be thrown or administered in any form on the victim with the intention that such person is likely to cause to the other person permanent or partial damage / injury or deformity or disfigurement to any part of the body or organ and cause death of such victim".

The Avon Global Centre for Women and Justice at Cornell Law School and the New York City Bar Association (2011) mentioned that acid violence is a form of gender-based violence and discrimination prohibited under the international law, including the Women's Bill of Rights, i.e., the Convention on the Elimination of All Forms of Discrimination against Women. In an article, Zia (2013) claimed acid violence as a gender-based violence, where cultural background, gender bias, socio-cultural imperatives are major factors for throwing acid against women in Pakistan. In the case of Bangladesh, the perpetrators are relatives or unknown person, whereas in Pakistan the major perpetrators are husbands and in-laws. According to the Avon Global Centre (2011) gender inequality is one of the major reasons for throwing acid in Bangladesh, India and Cambodia. Anwary (2003) linked acid violence with the impact of globalization in a broader sense. Mannan, Ghani, Clarke & Butler (2006) focused that in Bangladesh, acid crime has been labelled as a 'gender crime' as maximum victims are female.

Literature explored some motives or factors for such barbaric action. For example, Farhad, Naghibzadeh, Nouhi & Rad (2011) found that the reasons for acid violence in Iran were usually the marriage related issue, extra-marital affairs, divorce, poverty and illiteracy. Wilott, Ayebare & Warah (2011) conducted a study in Uganda and found that the causes are linked with business and property related matters. In another study in Uganda, Asaria et al, (2004) found two major reasons for acid throwing; robberies and family dispute. In another study, a group of doctors in Sri Lanka identified some reasons for acid throwing are the conflicting love affair, adultery, family disharmony, issues related to land, money and business (Karunadasa et al., 2010). The Burn Violence Survivors Nepal (BVS-Nepal, 2011) showed that dowry related problem and land disputes are leading causes of throwing acid in Nepal. Also, people use acid for committing suicide in Nepal. In Pakistan, acid is thrown to women by their intimate partner such as, husband, in-laws. (Zia, 2013). Motives like spurned love and affairs, sexual jealousy, financial and land disputes, hate or revenge, etc. are the main reasons for the acid attack in India (Dubey, 2015). Ahmed (2012) argued that the lack of poor law in force is another cause of such kind of violence in India.

The sulfuric acid, hydrochloric and nitric acid is usually used for this heinous violence. The consequences of acid violence are dreadful as well as painful. A victim suffers physically, psychologically, economically and socially. The acid attacks leave the survivors traumatized, disfigured, disabled, socially excluded and economically vulnerable (Rahman et al., 2014). A survivor of acid suffers physically, psychologically, socially and economically. The acid attack against women brings a dramatic change in their entire life. They have to go under several surgeries which are painful. Their faces and parts of the body become disfigured. They face, hair loose, with partial or total blindness. Acid has a catastrophic effect on human flesh, which can dissolve skin and flesh, it can even destroy the bone of the victim. She is

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

disfigured. Acid can create partly or completely blindness. The face, neck, and chest are damaged badly. If the breasts are affected by acid may stop developing or destroy (Haque & Ahsan, 2014; Rahman et al., 2014). It leads to permanent scarring, destroy vital body organ. It may affect the respiratory system of the victim and cause a serious respiratory problem. Any physical disabilities may arise from such violence what may add another dimension of suffering to the victim daily life (Ahmad, 2011; Ahmad, 2012).The victims suffer from psychological agony with other symptoms like a headache, insomnia, nightmare, fear, fear of facing outside. The acid attack leaves the victims traumatized, disfigured, socially excluded, psychological scars can be even more dreadful than physical scars, the victim suffers from social isolation with poor self-esteem suffer from psychosis, depression, ashamed and loneliness, and low self-confidence which may lead her to suicide (Anwary, 2003 & Ahmed, 2014).

Operational Definition

The proposed study will consider all the cases of violence against women performed by throwing acid as acid violence. The study will select these women whose age is 20-35 years and who were attacked by acid between 2005 and 2015 and took treatment from the Acid Survivor Foundation Bangladesh.

Community-Based Rehabilitation (CBR)

The concept of CBR was promoted by WHO in mid-70. Community-based rehabilitation is a term that has been used in different literature in different names. As Momm and Konig (1998) used 'community integration' and Miles (1998) introduced the term 'information-based rehabilitation'. In another paper, Miles and Medi (1994) used 'community-based support' as CBR. Frye (1992) applied the term 'community-based integration of rehabilitation' instead of CBR in his writings. Samuel (2015) mentioned "CBR as a philosophy" . A booklet named *CBR Guidelines as a tool for Community-Based Inclusive Development* published by IDDC (International Disability and Development Consortium) termed CBR as 'community-based inclusive development' (Thomas, 2012).

According to Mpagi ((2002) rehabilitation includes all measures aimed at reducing the impact of disability on an individual, enabling him or her to achieve independence, social integration, a better quality of life and self-actualization. On the other hand, community-based rehabilitation is a strategy, a coordinated method, a complementary and institutional approach, a way of thinking, a concept, an ideology and decentralized way to rehabilitation service delivery (Geert, 1998). Community-based rehabilitation (CBR) stands on three principles of equity, equality and equal rights and social justice. The approach is for the disadvantaged group of the community. CBR provides disadvantaged people with a support system which ensures their survival, growth, progress and complete rehabilitation. It aims to ensure disadvantaged people with a productive life (Punani, Rawal & Sajit, 2002).

Heinicke-Motsch (2010 in World Health Organization (WHO) 2004) CBR involves

measures taken at the community level to use and build on the resources of the community, including the impaired, disabled and the handicapped persons themselves, their families and their community as a whole (p. 188).

Thomas (2012) cited from, WHO, ILO and UNESCO issued their joint position paper (1994) which is revised in 2004, with the following definition of CBR. According to the organizations, CBR is:

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

…a strategy within community development for the rehabilitation, equalization of opportunities and social integration of all people with disabilities. CBR is implemented through the combined efforts of people with disabilities themselves, their families and communities, and the appropriate health education, vocational and social services. (p. 4).

The above definition indicates CBR as a multispectral approach which includes both governmental and nongovernmental services needed for the community (ILO, WHO & UNESCO, 1994). To complement the definition, CBR is a strategy for enhancing the quality of life of disabled people by improving service delivery, by providing more equitable opportunities and by promoting and protecting their human right (Lang, 2011). The primary aim of such rehabilitation is to create such environment which will facilitate the victims to become self-actualized and become integrated socially (Lang, 2011, p. 167).

CBR strategy encompasses some key components of wellbeing those are health, education, livelihood, social participation and empowerment of people with disability and their families. This inclusive approach is followed by CBR Matrix. The matrix helps to plan community development program and to manage them. The matrix is supported by the principles of inclusion, participation, self-advocacy, accessibility, and sustainability (Heinicke-Motsch, 2010; WHO, 2004, Thomas, 2012). Following the objectives of Dutch Coalition on Disability and Development of 2007, Samuel (2005) pointed out some of the major objectives of CBR. He said that CBR tries to include victims in mainstream services that they may get full access to education, employment, healthcare services and soon with equal opportunities. Capacity building and local fundraising, and enabling a community to promote the rights of the disabled people are also the aims of such program. CBR also tries to enhance the physical and mental ability of the victims and always focuses on improving the quality of life of disabled people with community integration. 'Education for all' by WHO, Millennium Development Goal (MDGs) and United Nations Convention on the Right of Person with Disabilities (UNCPRD) etc. are international legal and political backgrounds for spreading the ideas of CBR all over the world (Heinicke-Motsch, 2010).

In a nutshell, community-based rehabilitation is a worldwide recognized approach which is applied to intervene different problems at a community level. The study aims at exploring some community-based rehabilitation programs for the acid victims of Bangladesh. In Bangladesh, the rehabilitation approach in the study covers physical, social, economic, psychological aspects of acid victims, and also provides them with solutions to the problems they suffer. The community-based rehabilitation program will be developed in such a way that acid victims will have proper rehabilitation for their future life. It is expected that the CBR will ensure their human rights and will help them to become self-actualize.

In Bangladesh, ASF is the sole and only specialized organization who provide multiple services to the acid victims. Besides medical and psychological treatment ASF provide small grant and livelihood grant to the victims so that they may continue their study and can servive.ASF engages government and civil society at the national level for policy changes (Annual Report of Acid Survivor Foundation, 2011). Other organizations such as BRAC, Naripokkho, The Daily Prothom Alo, Ain o ShalisKendro, Burn Unit of Dhaka Medical College Hospital, etc also provide medical care, legislative, economic and social supports for the survivors of acid. The Bangladesh Government enacted two laws; the Acid Control Act 2002, and the Acid Crime Control Act to protect and control the heinous crime of acid violence (Haque& Ahsan, 2014). The manage grant for acid victims there are district and divisional acid control committee . Very few governmental attempts were made to rehabilitate acid victims in their community's and Brac arrange some community awareness meeting when the victim goes back to her community after lengthy treatment procedure.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Operational Definition

In line with the aims of the study, the operation definition of community-based rehabilitation for this study refers to rehabilitate acid assault women who are also disabled in a sense that they become physically, psychologically and socially and economically vulnerable. Thus, the community-based rehabilitation strategy is implemented for the betterment of the acid victims. Also, for this study, the CBR means a combination of such programs provided by the joint venture of government and non-government and community effort to bring desire change and positive outlook toward the acid victims. It covers the entire range of activities to tackle physical, social, economic and psychological barriers of a victim so that they can enjoy a fruitful life. The primary objective of the CBR program is to provide them with comprehensive services near their community. Thus, they can access and enjoy social equity and dignified life.

Theoretical Framework

This study underpins with two main theories such as the Social-ecological Model and the Patriarchy Approach for a better understanding of my research questions. Pardeck (2015) argued that ecological model can be applied to treat different types of problem in societal level. The ecological approach offers a comprehensive theoretical base that social practitioners can draw upon for effective social treatment. It is suggested that the ecological perspective can be a useful treatment strategy for improving the social functioning of the client system the famous theorist Uric Bronfenbrenner mentioned five systems named the microsystem, the mesosystem, the exosystem, the macro system and the chromo system. Each system has their distinct features, which include family, friends, neighbours, greater community, culture, state etc. to get understanding on an issue like acid violence and its impact on their lives the ecological model can be matched better. The Ecological approach explains the human problem as the complex mixture of psychological, social, economic, political and physical forces the theory will help to analyse acid victims from different dimensions. The *micro system* Bronfenbrenner's theory refers to those interactions where the person in direct contact and directly engage with others. The next level is *meso system*. The meso system refers the interaction between the two micro systems. The exo system refers to the social structure both formal and informal in which micro system is in influence. The macro system consists of a set of cultural values and beliefs (Perdeck, 2015; Heise, 1998). The theory will help the researcher to get better understanding of the needs and challenges of acid victims. Hence it can help to develop some community based rehabilitation for the acid victims. Also the perspective suggests the human problem is derived from the complex interplay of psychological, social, economic, political physical forces (Perdeck, 2015). Acid violence or acid throwing problem is a social problem originated from the society. In most cases, men are the main perpetrators and reasons behind such violence is combination of psychological, social, economic and political factors of society. As for example, patriarchy or gender discrimination are some of social or political factor, which contribute such problem in society. Dowry demand, land dispute, poverty etc. are some economic preseasons behind such types of violence against women. Therefore, the social ecological model will best fit to analysis problem like acid violence and the theory will show the way to develop community-based rehabilitation for the reintegration of acid victims. The approach will help to develop effective intervention (Pardeck, 2015).The major aim of the study is to find out the needs and challenges a victim's face in her reintegration process and to find out suitable community base rehabilitation for their better rehabilitation. We can see acid violence through different system of the social ecological model. We can put an acid victim in micro system and can analyse her

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

situation. A victim may suffer due to various reasons like, dowry, rejection of the proposal of a suitor, land dispute, etc. can directly affect the acid victims. The family, in laws, neighbourhood, peer, friends, and colleagues are consisting of victim's meso system, which directly influence their life after the acid attack. The major needs and challenges of a victim can be understood through different systems of social ecological model. The macro system can help to find out cultural and societal variables for such brutal crime. The system can help to develop intervention strategies for rehabilitation of acid victims' women. As the aim of the study is to develop community based rehabilitation for the acid victims of Bangladesh, the systems combine can contribute to mold such intervention for the victims

Again the needs and challenges faced by the acid assault women and their suffering and agony or coping mechanism aspects can be best explained by the Patriarchy approach by Silvia Walby (Walby, 1989). The concepts patriarchy is an important tool in the analysis of gender relations. The patriarchy approach deals with gender inequality, including men's domination over women. As Walby (1989) stated patriarchy as a system of social structure and practices in which men dominate, oppress and exploit women. As acid violence is gender based violence and Walby mentioned six components/structures of patriarchy. Male violence and patriarchal culture are the two important structures of patriarchy, which could help to analyse the main issues related to acid violence and will help to develop community based rehabilitation program for their better service.

SCOPE OF THE STUDY

The scope of the study are those things what will be covered in the research. The current research is in the domain of human right approach. The study will not mainly emphasis on its gender aspect .The study also attempts to find out the needs and challenges a victim face after they come back to their community, impacts of acid on the life of victims, and formal and informal rehabilitation system for the acid victims. In doing so, the study chooses to adopt the Ecological Model by Urie Bronfenbrenner and the patriarchy theory of Silvia walby as its analytical framework. The scope of the study will encompass the entire system of the social ecological model. The patriarchy theory will guide the study to understand and find out the major needs of the victims from multidimensional points of view. The study will conduct in Bangladesh, and the focus of the study is on the acid affected women of Bangladesh, who took treatment and are the direct beneficiaries of Acid Survivor Foundation (ASF) Bangladesh. The study will not cover the legal system or support system for the victim and it will not focus on the status of current laws against acid violence in Bangladesh. The study will involve acid affected women either married or unmarried. The major objectives of the study will look for the needs and challenges they face in their life after the attack of acid. The study will examine current needs either basic or felt, expressed or unexpressed needs of acid victims. The current study will also examine social, economic, physical, psychological challenges a victim greet in her whole life after the victimization of acid. Finally the research will develop some community based rehabilitation program for their wellbeing. The study will also look the state of current rehabilitation process of the victim following the social ecological model.

SIGNIFICANCE OF THE STUDY

The aim of the study is to explore a comprehensive community based intervention for the acid victims in Bangladesh. This model will help the acid victims to overcome their suffering. They can able to reintegrate with the society in an easy way. They will be benefited physically, mentally, socially, economically and legally. The final outcomes of the research will help acid victims to be self-dependent and cope their life battle in a more dignified way. The findings of this research will be beneficial to various stakeholders that involve in the prevention and treatment of violence of acid. Since. The aim of the study is to find out the needs and challenges of acid victims in the context of Bangladesh, it may open a new door to the policy makers and lawmakers to rethink about the issue from a different perspective. The findings will provide a platform to the policy maker about a real direction to minimize such kind of brutal form of violence like acid violence. Both Government and NGOs' are working with the problem. The research will show some new guidelines and ways to Government, NGOs', development workers, legal workers, social workers, the International Agency, local media, human rights activists, women activists, and donor agency for better solution to the problem of acid violence.

METHODOLOGY

Research Approach and Research Method

This research is based on a qualitative study. A case study method will be followed to conduct the research as the principal method of research. Yin (1984) defines the case study research method "as an empirical inquiry that investigates a contemporary phenomenon within its real-life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used." Yin (1984) discussed case study as unique one that examines a number of small sample in detail with its real life context. Case study method will allow researcher to get deeper understanding about acid victims in detail. Again case study allow a researcher to explore and understand a complex issue like acid violence, and case study research method is considered as a robust method of research when in-depth enquiry is mandatory (Baxter, Jack, 2008 & Zainal, 2007). The case study method will follow multiple or collective case study design as it will involve several individuals (Creswell, 2007). A case study is comparatively a perfect method for the researcher who can clearly identifies case within boundaries.

Data Collection Techniques

The research will use a multi-method data collection procedure. Data will be collected using in-depth interview method. In-depth interview will allow researcher to know in detail about the victims of acid, their life, sufferings and challenges they face in every steps of their life. Data will be collected from them, who will willingly show their interest to be my participants. I shall discuss the objectives of my research and will share the ethical issues with them. A recorder will use to record the interviews and field note will be taken. This interpretative technique will give an opportunity to discuss elaborately with the acid victims about research objectives and their understandings. The researcher will arrange to visit several times to the victims to build rapport and gather data. The study will also use two Focus Group Discussions (FGDs) with the staff members at Dhaka Acid Survivor Foundation (ASF).One FGD will be

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

conducted by the policy makers, practitioners and members of civil society for having suggestions from them for the rehabilitations of the acid victims. The research will also use the key informant interviews (KIIs) in order to get some experience from the experts such as the representatives of the Ministry of Social Welfare, local leaders, journalists, international human rights activists, NGO workers, Executive director of Acid Survivor Foundation and academics in Bangladesh.

Sample Size and Sampling Technique

The study will a purposive sampling technique. Patton (1990) argued that the purposive sampling technique is considered as a useful technique in case of descriptive study of qualitative research. The current study is descriptive in nature. The respondents will be selected from the listed beneficiaries of the Acid Survival Foundation (ASF). As Creswell (2007) argued that there is no specific number for the case, rather the researcher can select no more than four to five cases for conducting case study. It is sometimes difficult to select the exact number of sample in case of qualitative study (Fusch & Ness, 2015). I will select 10-15 acid victims for in-depth understanding about different aspects of their acid victims considering my capacity, time, funding and research objectives. The sample size will follow the rules of saturation that is a key to excellent qualitative work (Marshall, 1996). The researcher will continue interviewing as long she reach the target point of saturation. The research aims to conduct two FGDs, one with 6-8 staffs of Acid Survivor Foundation. Another FGD will be conducted in Sylhet city, where the number of the participants will be from 6-12 from civil society. Besides these, the study will conduct six KIIs. As acid violence is a sensitive gender based violence and purposive sampling enables a researcher to understand the situation or a phenomenon in detail, and in-depth directly from the people who experienced the situation. The researcher will follow maximal variation sampling types of purposive sampling (Creswell, 2008). As acid victims are not available so I would rather apply purposive sampling rather than convenience sampling techniques.

Research Instruments

To conduct the interviews a semi structured interview protocol will be used. The guideline will be developed according to the objectives of the study. A separate set of guidelines will be prepared for FGDs and KIIs.

The methodological framework of the proposed study can be presented in Table 1.

Data Analysis Techniques

Collected data from the respondents will be transcribed verbatim. Later I will use the NVivo. NVivo is a new, powerful computer package in qualitative research. It provides the researcher with an extensive range of tools that can be used to support standard qualitative analysis techniques such as coding, theory building, and theory testing, cross sectional analysis, modeling and writing. I will get opportunity to verify my data concerning the different theory and rhetorical approaches.

Table 1. Research design against research questions

Research Questions	Research Approach	Research Method(s)	Data Collection Methods	Data Collection Instruments	Number and Type of Participant	Type of Data
1. What are the needs faced by the acid assault victims during the reintegration process?	Qualitative	Case study	In-depth Interview	Guide line	**10-15** in-depth case study with acid survivors women	Demographic and socio-economic information of acid victims, causes, impact of acid throwing -
			KIIs	Interview protocol	(Local leaders, human right activists, journalists, lawyer, NGO workers, academician) total=6	Identification of the needs of victims and possible rehabilitation for them
			FGDs	FGD Guideline	**2 F**GDs With the staff mewmbers of Acid Survivor Foundation (6-8) and with civil society development workers (6-8)	Need identification and suggest for possible rehabilitation
2. Why is the community not being able to accommodate the acid assault victims?	Qualitative	Case study	In-depth Interview	Guideline	**10-15** indepth case study with Acid survivors women	Informal and formal services available for acid victims
			KIIs	Interview protocol	**6** (Local leader, Human right activist, journalist, lawyer, NGO worker, Academician)	Informal and formal services for acid survivors women
			FGDs	FGD Guideline	2 FGDs With the staffs of Acid Survivor Foundation(6-8) and with civil society 6-10)	Formal and informal service system for acid victim
3. How can the existing community based rehabilitation programs in Bangladesh be reconstructed for their better services?	Qualitative	Case study	In-depth Interview	Guideline	10 in-depth interview with acid survivors women.	Expectations of acid victims from the community
			FGDs	FGD Guideline	2 FGds With the staffs of Acid Survivor Foundation(6-8) and with civil society (6-10)	Possible community interventions and policy implications
			KIIs	Interview protocol	(Local leader, Human right activist, journalist lawyer, NGO worker ,academician) total 6	Possible community interventions and policy implications.

Ethical Issues

We will follow the ethical guidelines of the University of Malaya. A written prior permission will be taken from the the authority of the ASF. During data collection period, We will explain the research objectives and benefits of the participation to the selected respondents very clearly so that they can be aware about their participation. We will take their written or verbal consent (if needs) from them. We will

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

give full freedom to the respondents about to withdraw their opinions in any time of the data collection period. We will strictly maintain the confidentiality and anonymity of the respondents.

Time Schedule

See Table 2.

Table 2. Study plan

Tasks	September 2016-February 2017	March 2017-August 2017	September 2017-February 2018	March 2018-August 2018	September 2018-February 2019	March 2019-August 2019
Task-1 Proposal Defense						
a. Desk Study and preparation for proposal writing b. Selection of Title, research objectives and research questions						
c. Literature review: Conceptual and Theoretical d. Research Methodology Course						
e. Proposal Defense						
Task-2 Completion of Language course and Field Work and Data Collection						
a. Completion of Bahasa Malaysia course b. Development of data collection Instrument c. Field setting and contact d. Conducting pilot survey e. Data Collection f. Data Translation g. Data editing and coding						
h. Presenting paper in a national conference						
Task-3 Report Writing						
a. Data anlysis plan b. Adding recent literature c. Results d. Discussion e. Policy implications						
f. Submission of journal publication						
Task-4 Compile of Draf Report and Submission						
a. Finalization of Report						
b. Report submission						
c. Defense

Chapter 56
Faces of Grief: Cross-Cultural Bereavement and Support in Malaysia

Anasuya Jegathevi Jegathesan
HELP University, Malaysia

ABSTRACT

Death, bereavement, and grief are natural processes that are experienced by every individual who is born into this world. The level of trauma experienced from such loss can be mitigated by internal factors and the external environment faced by the individual. Spiritual belief systems and culture play a critical role in the experience of bereavement. This qualitative study applies the phenomenological approach to explore the lived experience of bereavement of 15 Malaysians from five different religious groups, namely Buddhism, Christianity, Hinduism, Islam, and Taoism. Rituals and belief systems impact an individual's experience with bereavement. The likelihood of individuals to seek emotional and psychological support depends greatly on individual belief systems, family support, support facilities set up by religious groups, and the perceived availability of professional services.

INTRODUCTION

While 'Death' is a universal experience, the process and philosophical construct of death varies between cultures and religions. As Victor Frankl in his book 'Man's Search for Meaning' (pg. 51, 1984) said "When we are no longer able to change a situation… we are challenged to change ourselves." Death of a loved one or a family member is an ultimate example of a situation where we are unable to change. The event of death in a family is a universal experience that leads to changes in family roles and in an individual's life. Cultural norms and traditions have been developed by all groups to support and come together in the times of grief, examples of such norms are Wakes where friends and family come together to share memories of their loved ones, *Cheng Beng* festival by the Chinese to honor the graves of their ancestors, daily prayers from 10 to 35 days by the Hindus where family is supposed to take turns bring-

ing food to ease the financial burdens of the family in mourning. Internal and external factors which are possibly influenced by upbringing and culture have a mitigating effect on the trauma experienced upon the death of a loved one. Rituals to face grief and death is different in every culture and society worldwide, but according to Weeks (2004) the common factor of all these rituals is that they "enable us to remain connected with the past, the future and with each other. They also serve to provide us with comfort and security." (pg. 115)

Malaysia, with its rich multi-cultural and multi-religious heritage, allows for unique insights into the lived experience of individuals who may have differing religious backgrounds. However, it does share a common nationality, and a broadly common Asian upbringing.

The qualitative methodology is an appropriate means of studying the matter of multicultural approaches to grief because it aligns with the philosophical underpinnings of the approach as proposed by Cresswell (2013). The qualitative methodology is ontological, allowing for the study of the multi-dimensional reality of the nature, its properties and interrelated relationships of human experience. It is also epistemological, axiological and rhetorical. This allows for the study of knowledge and the justification of meanings, how experiences are value and made sense of in the daily experiences of the individuals. The approach allows the researcher to study grief from both an individual and societal standpoint.

A phenomenological qualitative research design was employed for purposes of conducting this study to provide insight into the essence of the lived experience of those whom are undergoing a particular phenomenon. The phenomenological approach allows for the identification of differences and commonalities in individuals' experiences of complex social phenomena (Barnard, McCosker & Garber, 1999). At the same time, generalizing these ontological narrations of subjective understanding to encompass broader social and cultural discourses. The approach provides insights into the objective as well as the subjective experiences as reported by individuals (*Ibid.*). Hence, ensuring that the discourse on the personal experience of bereavement provided by respondents was descriptive as well as reflective in nature. It also provided for rich and thick data that is relatively free of the researchers' personal framework (Edmonds & Hooker, 1992).

The subjective experiences of individuals in the phenomenological approach according to German philosopher Husserl looks at the subjective experiences of the moments that matter, moments that give meaning to an individual's experience. As quoted in Bailey (2013) "To live, Husserl says, is to experience (*leben ist erleben*)" (p. 39). Grief as experience by an individual is very much a personal experience and through the phenomenological approach the moments that creates meaning for individuals are captured and applied.

Therefore, in the context of this study, the phenomenological approach has allowed for an in-depth examination of how Malaysians responded to the universal phenomenon of grief and bereavement within their unique cultural and religious context.

METHODOLOGY

This qualitative study applies the phenomenological approach to explore the lived experience of bereavement of fifteen Malaysians from five different religious groups; namely, Buddhism, Christianity, Hinduism, Islam and Taoism. All respondents had completed the first year anniversary of the death of their loved ones and were English speakers. Semi-structured interviews were used to collect data from individuals.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The intentional-expressive approach of interviewing was applied to enter the life world of individuals and obtain narratives, concepts and in-depth experiences of individuals (Merriam, 2009; Salkind, 2009; Sin, 2010). To ensure the veracity of the research and to avoid unwarranted conclusions that may arise from personal bias, epoch and bracketing was employed in the course of data analysis. (Bryrne, 2001, as cited by Pitney & Parker, 2009; Merriam, 2009). Multiple means of data modification was employed. To ensure validity and reliability of the data finding two methods of triangulation was employed in the collection of data. Data was collected via multiple methods; namely, through semi-structured face-to-face interviews, researcher field notes, and review of existing literature on culture-specific grief and bereavement. This is for the dual purposes of broadening the scope of its focus as well as narrowing it down to one or several issues in the review scholarship that would benefit from further investigation (Richards, 2005). Further, three peer researchers were engaged to independently analyze the data and their individual findings were compared to ensure consistency of the analysis (Merriam, 2009).

Purposive sampling was used to ensure that all respondents had experienced the first anniversary of the death of their loved ones. The maximal sample variation was applied in selecting more than two respondents in each group in order to develop a comprehensive picture of the experience of bereavement as narrated by the respondents. The respondents were made up of three Hindus R1-R3, four Buddhists R4-R7, four Christians, two of whom were Protestant and Catholics R8-R11, two Muslims R12-13 and two Taoist R14-R15. All of the respondents had experienced deaths of close family members.

Data collected through fifteen face-to-face interviews were approximately 45 to 90 minutes in length. All interviews were audio recorded and transcribed. Transcripts were sent to the participants and were reviewed by peers for accuracy verification. The research was in compliance with the ethics standards of HELP University.

LITERATURE REVIEW

An inevitable consequence of life, is death. Yet, across nations, religions and cultures, the topic of death is not considered a topic of polite conversation. The experience of the death of a loved one may be met by tears, disorganization, and by a sense of helplessness and hopelessness. Bereavement is defined as the state of deprivation that arises from the death of a loved one, and from the continued feeling of loss that endures well past the actual death of the individual (Attig, 2004).

The permanence of death results in a unique loss in an individual's life, the loss of someone that can never be returned. This state of deprivation has a deep impact on individuals. The loss experience cuts across the mental, emotional, psychological, spiritual and even physiological state of the individual. (Love, 2007; Worden, 2009) Bereavement potentially disrupts the certainty one has in the ebb and flow of life, it can shake the foundation of one's core beliefs, priorities, values, worldview, spiritual and religious beliefs (Love, 2007; Gillies & Neimeyer, 2006). The grieving process is increasingly recognized as a method of preserving ties and connections with our loved one. These connections, memories and ties that have were formed with our loved ones in the past inform and mold out views of the present and help us shape our futures (Purkiss, 2006).

From the pyramids to the catacombs, death and the subsequent process of mourning is influenced by (and at the same time) greatly influences religious and philosophical beliefs, as well as the expression of culture. While the experience of bereavement may be universal, the expression and process of grief

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

is culturally bound, with each culture providing a distinct approach to the loss and the transitions that follow after the death of a loved one (Anderson, 2010).

Strobe and Schut (1999) put forward a modal of grief to have a more universal application beyond gender and cultural specificity modals. Instead looking at the universal issues of stress and coping generated by the grieving process. The Dual Process model of coping with bereavement looks at how individuals go through two processes; loss orientation process and the restoration orientation process. These two processes are separate. Healthy grievers focus on the daily living challenges and then focus on the issues of managing their grief. The oscillation between these two processes promotes recovery and health coping.

Research has been done on the relationship between grief, spirituality and coping, where Bruke and Neimeyer (2014) found that religion provides mourners with an opportunity to seek meaning; to get some level of inner control and receive comfort and love from the Divine. Beyond the personal comfort, religion provides a shared platform to provide support and gives structure that can facilitate the process of managing the loss of a loved on. Religion is seen as providing a positive coping experience as it creates a sense of spiritual alliance and support system with those of the same faith and group.

Malaysia, as a multi-ethnic society has a rich diversity of culture and religions. The rationale of this research is to understand the bereavement experience of individuals, who while sharing a nationality (Malaysian) are from different and unique cultural and religious backgrounds. While the research adds to the literature of Asian grief and bereavement studies, it is also a potentially solid guide to counselors and therapists in dealing with bereaved clients in a culturally sensitive and professional manner.

DISCUSSION OF LIVED EXPERIENCES OF RESPONDENTS

Respondents reported that many factors played into the experiences of grief and loss. There are universal experiences that are nuanced by the personalized cultural experiences.

Emotions elicited by grief are complex and overwhelming. As a universal experience, all respondents felt the loss but how that loss was expressed varied between respondents. All respondents reported experiencing sadness and pain in a highly personalized manner. R8 reported, “Grief means I feel acute pain, a sharp pain...”, and R5 reported, “I was really in a great depression… most of the time I will cry alone.” While expressing and describing grief was actionable for most, some of the respondents were unable to articulate their grief experience. R7 for instance said “Ok, em, ok, it feels sad that this person is not around (M...), guess you’ll miss um...his guidance and advice (Ok...), but other than that I can’t think of a.. Can’t think of anything say...very traumatic ah...”. The individual could express the cognitive loss but was unable to express the emotions that went with it. In the respondent’s voice and manner the sadness was apparent but they were unable to express the depth of their emotions because their family saw crying as a ‘luxury’ and that they needed to be logical about the situation.

An important emotional impact of death is that it generates within human beings a sense of helplessness and being overwhelmed by the situation. “I was very confused at the time, I particularly like blank-out” R4. “I couldn’t cope with it” R2. “I wasn’t very well prepared, I broke down” R8. In remembering the death of their loved one during the interviews, some respondents still displayed an emotional reaction to the loss by tearing up, stuttering and other minor physical cues. However, the lack of external displays of grief does not indicate a person in unaffected, the opposite may be true. R3 who faced the sudden loss of a sibling stated “it’s like being in a situation, being and seeing from the outside what is actually

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

happening. It's like I didn't feel part of the…I felt like I was watching a movie. I didn't feel that I was part of the... one of the actors in that scene. I felt like I was standing out of the whole thing and I was watching what was happening, because I couldn't believe what was happening before me….. I may not be able to, would have been able to... would not have been able to handle myself at that time. So, I don't know, maybe it's a system working within myself that took me out of that." Respondent R3 was hurt by the situation so much that till today she is able to recall the moment and feel a similar sense of pain. But at the event to others she seemed in control and slightly aloof. This may be very much part of Asian cultures where those in charge need to appear strong and in control, therapists approaching this situation need to trend lightly to ensure clients have the space to manage their internal state.

Psychologically, this can be seen as a sign of the individuals' defense mechanisms reacting to the painful situation and a sense of disassociation is generated. This feeling of numbness or aloofness allows the individual to function, albeit somewhat mechanically in this situation, temporarily locking down the otherwise deliberating emotions.

In terms of anticipated death, emotional expressions of loss that was reported was no different from when there was no prior warning of the death. R14 who was caring for her terminally ill mother was still surprised at the moment of death "you were prepared, but did not expect it to really come that fast la, it was so sudden, so sudden, ya, and your immediate reaction to it was stunned, shock and you know, you just can't cry, right?' Respondent R2 who was in hospital with her father experienced a similar sense of overwhelm, "… my dad is gone.. there was a lot of blankness is like, the cold you know this thing that he is supposed to get up.. never got up. I cannot think." Despite being the main care-giver, despite being hospitalized and aware on a cognitive level of the impending death of the loved one, the actual moment of death is still a uniquely overwhelming experience. The anticipation of the death seems to have little impact on the actual emotional experience of the moment of death. Reasons for this is layered and varied ranging from the loss of a role of care-giver in the family, feelings of guilt related to robustness of caregiving, physical loss of the individual and loss of a sense of identity and purpose.

Among respondents, reactions to the death was reported to be mitigated by the sense of responsibility that they bore to making arrangements and looking after the last rights. Respondent R14 for instance had to maintain calm while her younger sister could kick the wall and shout at people around her. Respondent R2 related that she had to keep it together for her mother's sake. At the time of the funeral she could not give in to the grief as her mother needed her to be strong. Even in grief respondents were empathetic and aware of the needs of those around them, tampering their responses to support those they perceived as more needy around them.

Aside from emotional control, the roles one plays in the family also influences expressions of grief. When a key family figure is gone, the role has to be taken over by surviving members. R11 as an eldest son felt keenly the new responsibilities on the death of his father, "Er I was I was sad, the thing that immediately I..I feel that I am the er....responsibility, to...to handle, all my younger... My brothers, and uh and and the children, and and..to settle the.. er.. all the..job after he died." The need to fulfil obligations and care for those around, to an extent blocked an individual's ability to openly express their loss. So while all felt loss and sorry, the emotions are not expressed the same way across the board. Cultural and societal roles mitigate the freedom respondents had to express their grief.

The range of emotions experienced by those in the first few hours of grief covers almost the entire darker spectrum of emotions; from pain to numbness, even hidden relief. It is therefore best to not make assumptions of what the grieving should be doing or how they should be acting. The impact can be expressed or internalized but the impact of the loss of a loved one is there.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the face of such personalized uncertainty, the rituals, prayers and cultural activities surrounding funerals provides a sense of structure and guidance. Which is sorely needed in a time of such acute upheaval.

Respondents reported that prayer was a common coping mechanism used to mitigate the pain of bereavement. Common elements in the prayers to cope with bereavement included a prayer for guidance, a sense of companionship or strength to face the painful situation that they are in. Respondent R1 stated that she prayed that for "...the wound to heal, you have to have some kind of a guidance or some support or something to that extent for me to heal from within." R10 prayed for a sense of 'relinquishment' asking God to support her in moving forward. She was able to hold it together and not have a breakdown at home because "but God really was with me, with me la. God was with me." Respondent R15 stated that the chanting and the many days of prayer brought the family together. The chanting gave her a sense of "being connected to the ground, connected to ourselves, connected to the, the Buddha" thus supporting her in the process.

While prayer is a common element in the bereavement process, the nature and focus of prayer between the religious groups seems to differ. For instance, the Christian respondents reported that in prayer, they connected with Jesus to save the soul of their loved ones: "I hoped Jesus will come and save his soul" R9. The Hindus, who believe in the rebirth of the soul in their prayers, focused on being connected with the soul of their loved one as the soul continues its journey after death: "I speak to them through my prayers"R2. The Muslim respondent R12 believes that the prayers help the soul of the departed to find peace and gave a sense of control in the situation. He stated "..for those who really, really believe that, yes this is what you should do, you know, when people who pass on, and that you're gonna help their soul, and stuff like that, this is what you should do. So, in that sense, you know, because you can't really help anybody when they've, they've, you know (passed away) passed away right. And if you think that you know this might help by saying a few prayers here and there and then you feel like you're doing your part la." From the rituals this respondent received a sense of purpose and direction.

The Buddhist focused on the sense of community, continuance and comfort provided by their prayers and chanting, R6 'We are coming together, offering prayers." The Taoist had rituals to ensure the wealth and happiness of their loved on after death. The difference in the nature of their prayers is most likely due to the different views of death and afterlife held by each religious group. The benefit of the prayers as experienced by the respondents therefore ranged from a sense of community, personal support, to empowerment from assisting the souls of their loved ones, to a continued sense of connection with their loved one.

Whatever an individual's personal opinion of religion and rituals for death, respondent R7 said it very nicely"… the departed has departed, and you know it's just the living needs some way of coming to terms with their grief and we've got all these funeral rituals... if it makes my mom and family feel better, then they are okay."

Among the Buddhist respondents, there was a willingness to address the topic of death before the loved ones passed on. Planning for the passing and subsequent funeral was reported by all respondents. According to R6, "I already discuss with him before that, when he was alive we sort of discuss what I want, what he wants for his funeral." With the numerous taboos, sensitivities and cultural norms in the Asian context, this is neither a normal nor an easy conversation. None of the respondents from the other groups reported similar conversations among family member. On a personal level, most of the respondents reported that they have not had discussions of death issues with their family.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Discussions of death did however occurs on a more philosophical and spiritual level among the Muslim and Christian community, where death reactions from a religious perspective was discussed. The Muslim respondents in particular reported having deeper discussions on death and the relationship between death and religious belief. This philosophical view of death allowed for a more cognitive processing. It is the respondent's belief that the philosophy supported him in moving forward from his personal loss.

Funeral rites return a sense of purpose and power to the individuals on two distinct levels. Firstly, there is a solid belief that the rituals have a positive impact on their loved one's after life. A Hindu respondent went as far as having a second funeral ceremony conducted in India. The individual felt that upon having the second ceremony that was more traditionally complete and detailed, he had truly advanced the liberation of his loved one's soul. Respondent R10, a Catholic shared that, "It was frustrating that we could not do anything, but we prayed for her soul that she will have a better time in heaven."

The second and more pragmatic purpose provided by funerals is that the funeral itself forces the grieving into motion. It provides a clear purpose that allows grieving space, to avoid emotional overload because they are dealing with physical and societal needs. As reported by R5 who stated, "I was holding on, you know, short of holding on to it lah. Because I have to make sure everything is done perfectly well." The need to conduct the funeral, to an extent, allows the space to process and filter emotions so that individuals can function without being overwhelmed immediately after a traumatic loss.

While the rituals helped respondents focus on what needed to be done, some respondents felt that they rituals put extra pressure on them and interfered with their grieving process. "When my mother-in-law passed away I had no time to cry." R1. People were coming to her home all day, there were things to do. The respondents were unable to make time for themselves to grieve. There is a clear need to strike a proper balance and ensure that grievers have space for themselves to do what is necessary for the funeral and the family around them.

One of the most common problems noted by the grievers was adapting to the change of role that the death of the loved ones created. Death impact individuals and families in every aspect of their lives--emotionally, mentally, physiologically, financially and spiritually. In the collectivistic cultures of the East, death creates a tremendous shift in an individual's role in their family. Respondents were at loss when they are faced with new responsibilities, on top of the grief-reduction in household income, changes in maturity and emotional responses that were required of them. This was especially apparent in the loss of a parent or the loss of a major care giver in the family. Children felt the need to be "tougher" than their surviving parent and to support them in their time of need. Others felt as though, "I was just thrust into this role that I couldn't.. I couldn't turn back you know" R2.

Across cultures at the time of need, friends and family were a source of support and comfort. Human presence, kind empathic words and touch are important in times of need. While all participants were supported by family and friends, it is important to note that Christian participants received direct support from their church. Christian respondents recognized their church pastors, religious counselors and support groups as being an active part of their grieving process. The Buddhist and Hindu participants, while receiving a great deal of support from family, friends and the rituals of their religious practice, neither identified their place of prayer, nor their prayer group, as an active source of support.

Eight respondents however reported that while family and friends were supportive, their support was ineffective at the time. Use of platitudes such as "I know how you feel" and "they are in a better place" was not helpful in minimizing the experience of grief. One respondent felt that there is an artificial social guideline to how long and how much a person should grieve. The misconception that one should recover fast led to inappropriate and hurtful comments being made during the funeral.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Respondents reported that friends and family who attended funerals seemed to be confused on how to console those in grief. Some of the more unhelpful statements by family and friends are as follows. "When someone around you dies, the people around you keep telling you don't cry. Don't cry for your parents, don't cry for your mom, don't cry for your brother" R10. If one cannot cry in mourning, when else can they cry? It is perhaps good to realize that when in funerals the words 'Don't cry" translates into "I am uncomfortable with your tears, so please stop crying." The supports are asking grievers to stop crying not for their sake but for their own.

Statements such as "be strong" to those already taking charge and leading the funerals placed extra pressure. Contrary to the healing of the respondents. They felt that telling someone to stay strong was not supportive and locked them in a role they were unprepared for. Respondent R11 reported "I have no idea how to let go of being strong" and felt that they had still not properly grieved.

Grievers reported that they were inundated by platitudes such as "Are you okay". Although the respondents were not okay, what else they could say except 'I'm fine thank you.' Griever also reported feeling unsupported when people offered help without really meaning it. ".. they tell me what they feel is respectable to say for example, please let me know if you need anything. I believe that is a scripted speech." R15. Vague statements of support and generalized offers of help did little to actually support the respondents, who would be rote give negative responses to offers to help.

Grievers also felt pressured and alienated by having to repeat what happened over and over again. When friends and family visited, they often out of natural curiosity asked what happened. Repeating the story was painful to the respondents. It created a feeling as if their own emotional state were being disregarded by the supporters. Gossip, passing negative remarks and judgements made during funerals within ear-shot distance of the griever is obviously the exact opposite of support. These are negative habits but given that even funerals are social gatherings, it is an unfortunate outcome of being unable to filter the guests, where some carry their bad behaviors with them.

Most helpful behaviors experienced by grievers was when people were there for the bereaved. Respondents felt what was most beneficial was having a friend or a family member by their side, providing comfort. "People wanted to spend time with me," R1, "People actually took the time to get to know me and listen to my thoughts" R8, "Just being there is important, just think I am there." R14. The presence of genuinely caring individuals or a warm hug provided the most positive support. When griever felt that they were not being judged or criticized, was when they were most consoled. "She said look you don't have to stay strong, you don't have to do anything. If you want to cry – cry… if you want to scream-scream. Do anything you want and there is no how to do this thing." R13. The unconditional acceptance of the griever's needs and behavior conveyed the most active support on those in grief. Finally what was most helpful post the death of a loved one was consistent support. Not just turning up during the funeral, but being there and being available over a period of time to support the grieving was important.

The final aspect of the culture of grief looked at were the meta-physical manifestations of loved ones in dreams and various symbolic forms. These symbols were obviously very influenced by the religious belief and spiritual philosophy of the individual. Dreams of loved ones seemed to be common occurrence, and the dreams shared corresponded with the cultural and religious context of the dreamer. For a Muslim respondent, the visitations of the departed in dreams was not a good sign as it meant that they had blocks in their journey. Other religious groups seemed to see it as a positive occurrence. They saw their loved ones in familiar settings, such as the swing in the back garden, in their bedrooms, at places of prayer, and during special festivals. These kinds of dreams gave respondents a sense of a continued bond with the deceased and were in themselves a source of comfort. However, unresolved issues with

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

the deceased were a source of disturbance. Two respondents dreamed of their loved ones in need, crying and lost. The dreams seem to correspond with the relationship of the living to those who had deceased. Perhaps as means by which unresolved issues can be processed and even overcome.

INTERTWINING GRIEF AND RECOVERY

The process of grief emerging from this research is that of an intertwining modal, where the socio-cultural environment and the grieving process is very much intertwined. The death rites and rituals of cultural groups are perhaps not so much for the benefit of the deceased but for the benefit of those that they leave behind. Certain rites of cultural group facilitate both the grieving and the process of moving forward in the bereaved journeys through life.

The sharing of Damma in Buddhism allows individuals to feel that they are actively supporting the soul of the departed as it is carried on its journey. The prayers of the living mitigate and ease the burdens of pain and sin carried by their dearly departed. Prayers of all the groups while aimed at the departed, have the more practical impact of giving those in grief a feeling of purpose. It has, can and does have an impact on the positive fortunes of those who have departed. This is a huge buffer to of the feelings of hopelessness and helplessness, providing guidance, purpose and a sense of direction in an otherwise unmanageable situation.

The processes are intertwined with the act of grieving and the activities of reconciliation with a new lifestyle without the loved ones, occurring together in mentally healthy individuals. Some acts may require the focus to be more on an emotional grief journey, but both states of a person move forward.

Moving forward and emotional processing of grief are not the only two intertwining threads in an individual's journey through grief. Other threads of shame, loss, fear, guilt and so forth are intertwined in the individuals' grief experience. Methods of managing these darker emotional threads can be sourced from spiritual practices, wellness plans and therapeutic interventions. It is in the experience of the author as a counsellor practitioner whom has worked with grief that the negative emotions can be elevated to an extent, if individuals are able to accept their grieving as a sign of the respect and love that they have of their loved ones. Regardless of time and space, the reality that the ones we love are gone remains. The pain and loss is unique and will last as long as we live. If individuals are able to see their grief not as a continued sign of trauma, but rather as he legacy of love and reverence that they carry for their loved one, the moments of STUG (Sudden Temporary upsurge of Grief) can be seen as moments of bitter sweet nostalgia and moments of reverence. Also reflecting the importance and the enduring impact of the one who has passed on, rather than traumatic reminder of death.

Culturally and traditionally, there are events that honor the passing of our loved ones. From Cheng Beng among the Chinese, to yearly death anniversary prayers of the Indians, it is to achieve the purpose of giving reverence to the memory of those who have departed. These traditions make individuals pause in their busy hustle and bustle of life to give moments of deep importance, respect and reverence to the memory of individuals who impacted us. These traditions allows for the intertwining of grief, family unification and reconciliation to occur in an organic and family focused manner.

When these threads become entangled, the grieving process may be choked to a halt. The halting of the grieving process, potentially interferes with an individual's ability to move forward and function in their everyday life. Thus the situation develops into complicated grief. Complicated grief here is in reference to grieving that interferes with daily functioning.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Individual philosophy on death and bereavement, which may be very much influenced by religious beliefs, is a critical factor that allows for the processing of bereavement in a healthy manner.

DISCUSSION: IMPLICATIONS FOR COUNSELORS

In working with one of the most traumatic times that an individual may experience, the first call to any counsellor, social worker or supporter is respect. Respect for the individual's grieving process, their personal beliefs, the unique emotional state they are in and respect for the culture that is governing the last rites. Counsellors may not believe in the faith, philosophy and religion of the clients. But therapists, in order to work with grief and loss must be able to respect the rights of the clients to believe and worship as they see fit.

The second criteria is to recognize and understand the client's current state of mind. Any intervention therapy is only effective if the client is functioning both emotionally and mentally. Clients who have just experienced loss are in a state of crisis. They are emotionally overwhelmed and their normal coping strategies are unable to meet the unique challenge of grief, leading to a state of cognitive and emotional disequilibrium. This is a classic sign of disequilibrium that is associated with crisis management. The death of a loved one is a state of personal crisis and individuals to an extent must be treated as if there are in crisis. In the first few days after a loss, therapy focuses on Crisis Management rather than counselling per say. The role of the counsellor is to ensure immediate safety of the client rather than trying to start the healing process. The healing process only begins after the state of crisis is over and this can be a few weeks or even a few months after the funeral.

The third criteria needed by therapists in multi-cultural grief work is to be open, curious and courageous. An open and curious therapists is willing to learn about other religions and cultures. While it is impossible and not recommended that one try to learn everything about other religions, it is crucial that the therapists have some knowledge of the basic principles of the various major religions in their area or country. The researcher will always recall a pointed lesson that occurred in a group therapy session, the facilitator said to a member, "How do you think God would feel about that action." The participant responded "I'm a Buddhist, I don't believe in God." A very awkward moment followed that statement, as the facilitator stammered and changed the subject. If a therapist is going to embark on any form of spiritual therapy, that basic understanding of major concepts is critical for long term success. Courage is needed because we are talking about religion. We are breeching a topic in therapy that has caused wars through the centuries. But when it is relevant to the client's healing we need to be courageous enough to address the issue in a supportive and respectful manner.

From the experiences of respondents shared across the different religious groups, it is apparent that while grief and bereavement is a universal experience, the religious, social and cultural context of those going through grief makes it a highly unique experience (Cowles, 1996). This uniqueness calls for the need for sensitivity and understanding of cultural and religious norms when managing grief. The universality of grief response can be seen by how all spiritually inclined respondents used prayer as a key coping mechanism. The differences between groups arose in terms of what was the content of the prayer and the meaning the prayer carried for the individual that was highly influenced by their religious philosophies. In therapy it is probably prudent to check with spiritually inclined clients on how they can incorporate prayer into their healing. Assuming that prayer is universal and that individuals approach prayer in the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

same way with similar intentions (especially if the therapist is from the same religious group) can lead to the activity missing the mark and the client feeling that the therapist has imposed their beliefs on them.

In terms of coping current literature indicates that the Dual Process Model suggests that in managing grief, individuals either coped with the loss caused by the death of a loved one, or with restoration-orientated coping that refers to the reorganization of life. It's only after they masters new skills required in meeting daily challenges post bereavement (Stroebe & Schut, 2001 as cited in Neimeyer, 2001). Current literature suggests that grievers alternate between loss and restoration orientation, with both orientations a necessary part of grief work. The findings of this research suggests that in the collectivistic cultures of the East, especially in from Buddhist and Hindu perspectives, the rights and rituals focus on loss and restoration simultaneously. The Buddhist transfer of merit and the offerings of the Hindu's to feed the needy as part of their funerals, address both orientations. It addresses loss as the ritual is done for the deceased and the restoration orientation as it adds meaning to the rituals besides fulfilling obligation to culture and society. The significance of the rites and rituals surrounding death, therefore, play numerous roles in ensuring the continued welfare of the living.

In dealing with the grieving process incorporating activities unique to that culture and religion may have a more intense impact than simply relying on generic activities such as journaling or simple service activities. Feeding the needy in the name of those who have passed on is highly significant to Hindu's and Buddhists. Reciting the Al-Fatihah is important to the Muslims. Reading the Holy Books, chanting, activities in memorial can all be incorporated into a comprehensive grief management plan with clients, that is highly personalized and meaningful to them.

In Western literature, the continuing bond that an individual maintains with the deceased is viewed at times as an unresolved source of grief (Bowlby, 1980) or a part of the global meaning making mechanism of certain cultural groups (Benore & Park, 2004). Findings of this study were more aligned to studies on grief done in Japan (Klass, 2001) which found that the continuing bonds, impacted moral, social and spiritual growth. Both Hindu and Buddhist respondents found continuing bonds with the deceased a normal part of life and karma. Their task in mourning is not to move on, instead it is to "find an enduring connection with the deceased in the midst of embarking on a new life" (Worden, 2010, p.50). This means that it is important that therapists understand what the continuing bond means to the culture and religion the client. This is a nuanced difference that can in the opinion of the researcher be critical to the healing of the client.

How the therapists develops the continuing bond between the client and their dearly departed is important. Especially in terms of catching the client's internal view of the death and the afterlife as well as the theoretical or therapeutic approach. Individuals may see themselves in ways such as carrying on the legacy of the departed, as the one who remembers, as the one who has picked up the burdens, source of spiritual solace, as a guardian and so on. Spending time exploring and understanding the clients view will allow for a robust development of the continuing bond that is match to the client's needs.

Mental health workers need to appreciate that this may mean what can be considered delusional or imaginary by other cultures, may be wholly culturally appropriate to the grieving individual. With the exception of the Muslim respondents who saw dreams of the departed as a sign that not all is well on their journey, most of the religious respondents took comfort in dreams and even saw having visions of the departed as a positive occurrence. Dreams, visions, signs and ghosts may be normal and appropriate to the clients world view and not in any way a sign of developing mental aberrations. Therapists need to process that at times 'supernatural' occurrences with a sense of confidence and detachment are only pathological if they interfere with the daily functioning and the mental health of the client. If these events

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

do not interfere with a client's functioning, therapist need to monitor the situation, be respectful to the client's needs (silence is golden), listen empathically and focus on the emotional content of the client's story rather than trying to align cognitive and physical beliefs.

The likelihood of individuals to seek emotional and psychological support depends greatly on individual belief systems, family support, support facilities set up by religious groups and the perceived availability of professional services. Among grieving Malaysians, there is still a high resistance and lack of awareness of counseling services for the grieving. Those who grieve will attend prayer meetings, general sharing session and talks offered by their religious groups, but two participants, both who were already involved in helping services reported that they approached a counselor for support.

In order to reduce the stress created by funerals, it is important for mental health workers to have a conversation of the best practices during a funeral. First off avoid platitudes, be genuine and if you do not know what to say just say "My deepest condolences" and provide a warm hug. No other statements is needed when individuals can lend active presence. At times, we can just stand beside the mourner for a period of time allowing the person to know they are not alone without needing them to say more. If individuals sincerely want to provide help it is the advice of the researcher that we ask specific questions. Instead of asking the general "Do you need anything" ask "When was the last time you ate / had a drink / slept?" People are more likely to give correct information to well-thought questions. From that specific answer, you will know what needs to be done to best support the individual in grief.

There is a definite need for counseling to be provided to grieving. Such service, to be effective, must cover the grief process, the cultural and religious idiosyncrasies of their clients, as well as, address the changes in the roles of those going through grief. Dreams and manifestations of the deceased need to be understood within correct cultural contexts in order to avoid misinterpretations of the phenomenon.

The role of spirituality and religion in mitigating and processing grief cannot be denied. It was perhaps best expressed by respondent R3 who said, "I know he is there. If you think death is removing, completely wiping out somebody's existence, soul, then you should grieve." Cultural and religious grounding allows the perceived bond with the loved ones to persist after death. They provide support and structure in an overwhelming situation and are an active part of individual coping mechanisms. Thus it is the responsibility of those who venture into grief work. To recognize and appreciate the influence of culture and religion in the healing process, to gain relevant knowledge and develop the skills that will allow for active support of clients.

Chapter 57
Losing a Friend:
Social Media's Impact on Child and Adolescent Grief

Tamara L. Wandel
University of Evansville, USA

ABSTRACT

This chapter focuses on the role of social media consumption on older children and adolescents during the bereavement process of a childhood friend. Using case study methodology surrounding an 11-year-old girl's tragic death, surveys were administered to peers and semi-structured interviews with peers, counselors, and the deceased's mother were conducted in order to collect in-depth information on the opinions and feelings of those utilizing social media as they cope with loss, specifically the loss of a friend. The idea of virtual mourning is significant to explore as social media is ubiquitous for most older children and adolescents.

INTRODUCTION

The Loss of Kate

It was July 26, 2015, and it was a beautiful, sunny day in southern Indiana. It wasn't a day a kid should die. It was a day to play. And that's what Kate Bruggenschidmt was doing. It was a day of playing softball and playing at a friend's home. Unbeknownst to her parents, Kate drove a large all-terrain vehicle (ATV) for the first time. She wasn't wearing a helmet. Kate lost control, and the ATV overturned and rolled on top of her. Kate was 11 years old.

According to the Centers for Disease Control and Prevention, the leading cause of death for children is unintentional injuries sustained from car accidents, drownings, guns and other sources. On average, over 12,000 children 0-19 years of age die each year in the United States from an unintentional injury (CDC, 2017).

Figure 1. Kate Renea Bruggenschmidt. March 30, 2004 – July 26, 2015. (Used with permission by parents Eric and Ashlee Bruggenschmidt)

The fight between Kate and the ATV was a mismatch from the beginning. The ATV, weighing in at 750 pounds, was a far heftier load than her 73-pound frame which went unprotected.

"When you get the news someone you are close with has passed away, it's not easy," said Layla, a 13-year-old who was 11 at the time her friend Kate died. "This was the same friend I'd danced in my living room with, made science experiments with in the kitchen and sold art projects with on the sidewalk. This was the same friend that I had been making plans to play sports with and have classes with in college. While that might be a tad unrealistic, at the time we just thought our fun never had to end" (Personal communication, July 15, 2017).

Layla said while the news would be horrible no matter how she heard about it, she's at least glad she got the news from her mother in person about Kate's death. Kate was a kind, well-loved little girl, and news of her passing spread like wildfire on social media. Many of her friends found out about her death

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

by seeing postings on Instagram and Facebook. Layla worries about this modern-day reality of news dissemination, as she doesn't feel it's personal enough to present such tragic information. She thinks about how the family or close friends who found out through this medium must have felt, and she wonders if people should wait longer to post tragic news for the sake of feelings and accuracy.

She does believe it was helpful, though, for many people to post messages and photographs as they were mourning during the days, weeks and months following Kate's death. After Kate was gone, her Instagram account was inundated with messages. "Lots of humanity finds comfort in posting pictures in tribute to a lost one. In a way, it's like you are writing *to* them. If it helps a person out to post these, then it's good because there's really no other way to talk to them," said Layla (Personal communication, July 15, 2017).

Research findings support this observation. A number of scholars have noted that social media commenters rarely interact with each other on a deceased's profile page and instead prefer the feeling of speaking directly to the deceased (DeGroot 2008; Dobler 2009). Moreover, other areas of Layla's reflection help to elucidate key components of the process of grief studied and analyzed in this chapter: attempts to find meaning when losing a friend, how older children and adolescents crave a safe space to express sadness and vulnerability, the desire to keep the memory of a loved one alive, and how social media plays a thread throughout all these.

Chapter Focus

No person is immune to grief. It defies age, gender, race and sexual orientation. It does not adhere to rules of logic. It cares not for geography nor good timing. Losing a loved one may have occurred from diphtheria or cholera years ago as opposed to cancer or a car accident today, but the feelings of loss remain painful, natural and life-altering. For older children and adolescents, those spending hours upon hours every day on social media, it is worth learning what grief looks like and how technology may be impacting it.

Young people are the fastest growing adopters of new online platforms, with nearly a quarter of teens reporting being online 'almost constantly' (Lenhart, 2015). As such, it becomes necessary to consider how they communicate surrounding a tragedy which could impact their emotional and behavioral well-being, in particular when the grieving process may be removed from their home life and instead involve a peer. This chapter in no way intends to negate or lessen the pain and lifelong impact a child experiences losing a parent or other relative. It is indeed very sad that one in nine Americans lose a parent before age 20, and that most people are exposed to at least one violent or life-threatening situation during the course of their lives (Ozer, Best, Lipsey, & Weiss, 2003). As people progress through the life cycle, they are confronted with the deaths of close friends or family. Most of the literature involving children and adolescents experiencing grief depicts the circumstances surrounding the death of a parent (Worden, 1996; Melhen, et al, 2011), not a peer. What is known, in those cases, is that another parent or close relative is often able to step in and assist the child. When a child or adolescent loses a friend, however, there may be less understanding of the impact if much of the emotion is not directly impacting the family household.

As Sylvia Buck, director of counseling at a private university said, "Both kinds of loss can be deep and intense, but they are very different. Losing a peer does not seem to be the natural order of things," she said. "Many young people seem to grieve the loss of a grandparent more easily than parents would expect, for instance," she said (personal communication, August 30, 2017). Karen Stenstrom, who leads grief sessions for adolescents, agreed and said, "It seems that they rely on the other parent and extended

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

family to help work through their grief" and are " … actually helped by the face to face hugs and tears" (Personal Communication, September 1, 2017).

But what about children and adolescents confronted with the death of a peer? The case study presented here allows for a structured and purposeful attempt to gain knowledge about the relationship of online communication during the process of grief. The protocols related to online grief are still being developed and the norms surrounding it continually constructed, but patterns begin to emerge.

BACKGROUND

The linguistics of bereavement, grief and mourning overlap in how they are used in everyday vernacular. At times they are used interchangeably and even inconsistently, so it is imperative to identify nuances of each. For purposes of this chapter, *bereavement* may be thought of as the actual fact of the loss of a loved one. The term *grief* is referred to in regard to the emotional, cognitive and behavioral responses to a death. *Mourning* is referred more specifically to the behavioral manifestations of grief, which are influenced by social and cultural rituals, such as funerals, visitations or other customs (Zisook & Shear, 2009).

The case study laid out in this chapter was chosen in part because the accident took place in 2015 and allows for an opportunity to look at social media practices of those from the acute grief reaction through several years post-accident.

Stages of Grieving

The first major theoretical contribution on grief and mourning was provided by Sigmund Freud in his 1917 seminal work titled *Mourning and Melancholia*. In this paper, Freud defined mourning as the reaction to the loss of a loved one and called that loved one "the love object", showing a focus on the process and need for the survivor to slowly lessen his or her emotional attachment to the deceased (1922). While no exact science dictates how the process unfolds, there exists a predictable course according to Freud, and it involves breaking the emotional ties that bind those surviving to the deceased. Initially, there is much confusion and acute grief upon news of the death. Emotions and behavior are often erratic at this time, and this stage according to Freud could last anywhere from a few weeks up to three months. A less disruptive stage typically follows over the next one to two years.

After Freud, a few theories were found to show grief in a series of fairly predictable stages (Kübler-Ross, 1969; Bowlby, 1980; Parkes & Weiss, 1983). Elisabeth Kübler-Ross, a Swiss-American psychiatrist who passed away in 2004, is widely known as the individual associated with the five-stage response on awareness of terminally ill patients of their impending death. Eventually this stage theory of grief was generalized to a range of losses including reactions to death or even by children to parental divorce (Bowlby, 1980).

Kübler-Ross's model of adjustment to death is still used by physicians, psychologists, counselors and others in understanding the complicated process that the death of a loved one brings. The five stages are part of the framework that make up our learning to live with the loss of a family member or friend. The five stages are 1) denial; 2) anger; 3) bargaining; 4) depression and 5) acceptance.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. *Denial* is the buffering stage best phrased by the idea of *this really can't be happening*. It is a refusal to accept facts, information or any reality relating to the situation, whether consciously or unconsciously. This can be a healthy defense mechanism as long as it is temporary and an individual moves on from this toward a more real understanding of healthy acceptance.
2. *Anger* can manifest in a number of ways. Some people may be angry with themselves, or they might be angry with others they feel were part of causing the death, or they may be angry that others don't understand what they're going through. They can even be angry with the person who passed away for causing the pain.
3. *Bargaining* involves attempting to bribe, coerce, beg or otherwise bargain with whatever higher being the person believes in. This stage is an ill-attempted expression of hope that the death is somehow reversible or that we can control the ultimate outcome.
4. *Depression* is a type of acceptance with emotional attachment. It is natural to feel sadness, regret, fear and uncertainty, and it shows that the person has begun to accept the gravity of the situation.
5. *Acceptance* can be mistaken for happiness, yet it is often marked by withdrawal and calm. It is a stage identified with some detachment of emotion and much objectivity.

Another framework widely utilized in more recent times is that of Theresa Rando's six steps for incorporating the reality of mourning into one's life (Rando, 1993). As with the others mentioned here, this framework is not linear, but does provide a somewhat natural progression toward healing. Rando's six requirements for healthy mourning include: 1) recognition of the loss—acknowledging the death and understanding the death; 2) reaction to the separation—experiencing the pain and identifying, accepting and expressing reactions to the secondary loss; 3) recollections of the deceased—realistically reviewing and remembering the deceased, as well as reviving and reexperiencing feelings; 4) relinquishing of attachments to the deceased; 5) readjustment to the world without the deceased; and 6) a reinvestment of energy into other people and activities—putting emotional energy into new people and new goals. Paramount to Rando's framework is that the six requirements are collectively necessary elements to work through for the bereaved in order to reorient themselves to a reality that incorporates the loss they have experienced.

How this framework works with older children and adolescents, and how technology fits into the equation, makes the subject feel a bit like a labyrinth with moving passageways. Although these older children and adolescents stem from a generation defined by sending and receiving messages online, many educators and parents express frustration and dismay as they sense rapid declines in the ability of these individuals to express themselves verbally and in writing. Moreover, when they do express themselves, the act of the expression appears more important to them than whether others can understand what was, in fact, intended to be expressed (Feiertag & Berge, 2008).

Some of this may be attributed to what has always been known: the teen years are tumultuous, confusing and emotion-ridden. Over 100 years ago, G. Stanley Hall (1904) proposed that adolescence is inherently a time of storm and stress. Teens are no longer children, yet neither are they adults. Other than infancy, no developmental period is so filled with change as adolescence. While the teens may be the same in stature as an adult, they typically do not have the emotional maturity to process their feelings.

Grief is a complex emotion adults struggle with, so it is understandable it may be exacerbated in children and adolescents. Furthermore, many adults feel inept in helping young people cope. It is not that adults are being insensitive, but they may simply lack the skills to support youth in their own grieving process as they often discourage teens and pre-teens from sharing their grief or rush them along in

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

the process wanting to see them back to their happier selves. Bereaved teens may feel as if they need to pretend they are fine. Meanwhile, these children may be experiencing psychological, physiological and academic pressures, all of which can amount to a vicious cycle in an already multifarious grieving process.

"The reality is that you will grieve forever," said Kübler-Ross (1969). "You will not get over the loss of a loved one; you will learn to live with it. You will heal and you will rebuild yourself around the loss you have suffered. You will be whole again but you will never be the same. Nor should you be the same nor would you want to."

So how does this play into technology? While teens have always been categorized, fairly or not, as moody and with a tendency to disassociate themselves, social media has changed an element of this. The year Kate died, CNN reported that teens spent an average of nine hours each day on some sort of media (Wallace, 2015). While they may retreat to a room in the house to be alone, not necessarily breaking down the stereotype of moodiness or isolation, they are only alone in the physical sense. They may be in communication with several – or hundreds – of individuals. The digital bond brought about by social media can at times, in fact, assist older children and adolescents in escaping emotional struggles they are facing offline (Turner, 2015).

Methodology of Study

Researcher Robert K. Yin defines the case study research method as an empirical inquiry that investigates a contemporary phenomenon within its real-life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used (Yin, 2014).

Case study research has existed since the day of Charles Darwin's biography (Stewart, 2014). Growing in scope and reputation, case studies offer a means for in-depth insight. Case study research is a versatile form of qualitative inquiry when striving to understand complex phenomena (Yin, 2014). A major feature of case study methodology is that different methods are combined with the purpose of illuminating a case from different angles. Snow and Anderson (Feagin, Orum, & Sjoberg, 1991) asserted that triangulation can occur with data, investigators, theories and methodologies. Stake (1995) further asserted that the protocols used to ensure accuracy and alternative explanations are called triangulation. The need arises from the need to confirm validity of processes. In case studies, this could be done by using multiple sources of data (Yin, 1984).

According to Yin (2014) a case study design should be considered when: (a) the focus of the study is to answer "how" and "why" questions; (b) you cannot manipulate the behavior of those involved in the study; (c) you want to cover contextual conditions because you believe they are relevant to the phenomenon under study; or (d) the boundaries are not clear between the phenomenon and context.

This study revolved around the death of a child in a Midwestern city with a county population of 62,500. For this study, data was gathered in both survey form and interview form. Data for the study was gathered in the following manner: a total of 198 youth participants from a Midwest region of the United States participated. Each had experienced grief surrounding the death of their friend Kate. In addition, Kate's mother, Ashlee Bruggenschmidt along with three grief counselors discussed their thoughts in regard to social media usage by teens during the grieving process.

While experiences of grief resulting from bereavement are complex and can be unpredictable, it is accepted that under normal circumstances, the average person is able to re-establish a sense of physical and emotional equilibrium after 6-12 months (Kübler-Ross, 2005). The respondents for this study were

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

selected because the timeframe allowed them to have sufficient time to reestablish patterns, yet the grief process was not far off in their memory and may, in all actuality, still be quite present.

As part of the case study, the Critical Incident Technique (CIT) provided a means for exploring feelings. CIT was developed in the 1940s by John Flanagan, an American researcher in the field of occupational psychology (Flanagan, 1954). CIT is a form of qualitative research offering a practical approach to collecting and analyzing information about human activities with significance to certain activities. CIT is now widely recognized as an effective investigative tool (Woolsey, 1986) and has been used in numerous social science disciplines (Query & Wright, 2003).

CIT fits well with this research study, as it centers around a major crisis, and possesses a subset of a personal crisis, which represents aspects of the human experience significant to the individual concerned. For this study, child and adolescent respondents recalled experiences of social media usage when posting about the death of their friend Kate.

In terms of limitations, since the method relies on memory, the passage of time may dilute reporting accuracy. In addition, a relatively small sample size could skew results. This chapter attempted to frame this case in terms of both a story – a case study and not numbers alone – as "we live in stories, not statistics" (Gilbert, 2002).

The future research of this topic should include a sample size that is more diverse and larger compared to the one in this study. It would also be interesting to look into the differences between opinions based on specific social media, for instance Facebook, Twitter, Instagram and Snapchat, as this study combined all social media and didn't denote differences in the online social networks.

Data and Discussion

The case study used here has both an explanatory and theory-building purpose. The interpretive piece uses known variables and stages to provide historical explanation. Basically, in layman's terms, it was used to show an expected outcome in terms of stage of grief. It also serves as a deviant case study, which provides interest as new variables – that of social media – are introduced.

Table 1. Means and standard deviations of emotion-ratings using social media

	Communicating via Social Media 0-6 Months		**Communicating Via Social Media 6-12 Months**

Table 1 shows that communicating via social media six months to one year after the death of a peer significantly elevated the emotions intended to be expressed of happiness, acceptance, pleasure and fondness as one sought to think of, remember or honor a friend. The table also indicates a significant decrease in social media's use to express sadness or confusion. The average absolute effect size of changes across the six emotions was d = 1.07 which is considered above an effect size conventionally seen as large (d = .8). Effect size, a quantitative measure of the strength of a phenomenon, is a basic descriptive statistic showing the power of the relationship between two variables.

In this case, it appears social media was utilized during the acute grief stage that occurs in the early aftermath of a death. It is that time when bereavement is intensely painful and characterized by emotions that are extreme in nature. It is a time when there is a preoccupation with thoughts and memories of the deceased and a difficulty in thinking about much else. In the case of this survey, respondents found utilizing social media significantly helpful in expressing their confusion (both of actual events surrounding the death and confusion over finding meaning and reasoning of the death).

Later, six months to one year after the peer had passed away, respondent found social media helpful in expressing more positive thoughts, a sign of natural progression through the stages of bereavement. Stenstrom said this is consistent with what she has observed. In particular, she noted the happiness and acceptance seen as anniversaries of deaths are highlighted on social media.

Jana DeCristofaro is a children's grief services coordinator at the Dougy Center, the National Center for Grieving Children & Families nonprofit based in Portland. She said the research data was helpful because it affirmed what she believed adolescents were feeling whom she had observed. "At the beginning, some have a difficult time accessing feelings of happiness while recalling memories," she said. . "They may be more engulfed with thoughts of the death and painful memories. Over time, they are better able to access positive memories and experience corresponding positive emotions while recalling those memories" (Personal communication, August 31, 2017).

Sylvia Buck agreed. The data " … make sense considering the normal flow of the grief process. People tend to need to express their sadness during the beginning of the grief process. Much later, it is very comforting and heartwarming to post pictures and tributes which memorialize loved ones" (Personal Communication, August 30, 2017).

While the stages are not rigid or linear, Kate Bruggenschmidt's mother, Ashlee, said, "I look back on my posts days after Kate's accident until now and I think you can see the stages of grief in my posts. I may have posted a song about denial or quote about depression. Then my friends, families and other parents who have lost a child may have commented or reached out and helped move me through that phase of grief or helped me to process my feelings and regrets. In the days following Kate's tragedy, we were so touched by the pictures, messages and outpouring of support that we received from Kate's friends, family and the community. The posts and pictures and online messages provided us so much comfort. Our hearts were shattered, but we felt so much love by the support of all of these groups via social media and texts. We still love seeing the posts and messages today; however, we utilize social media more to continue to keep Kate's legacy alive, to be a vehicle to deliver her message, and to increase awareness about ATV safety, how to be an advocate for safety, and how to handle tragedy by choosing hope and trying to persevere" (Personal Communication, June 28, 2017).

Unfortunately, death is often a taboo topic. There is a tendency to expect people to hide their emotions to avoid making others uncomfortable. Bereaved individuals of all ages may find it easier to hide or downplay their grief, which is counterintuitive in helping them heal. For children and adolescents, DeCristofaro explains, they may be so unfamiliar with grief – how it acts, what it needs, how it is af-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

fected by time and context – that they are particularly vulnerable. When it comes to social media, this means they may be extra vulnerable to how others respond to them because they are still figuring out how to respond to themselves. A year out, teens may feel more secure in their grief and also have more endurance and the ability to withstand how others respond.

"Most teens appreciate people sharing stories and photos of the person who died, as long as the person doesn't make the post about their own feelings," said DeCristofaro (Personal Communication, August 31, 2017).

DeCristofaro offered this example:

- *Helpful Post: I loved spending time with Maria on our annual vacation. She always told the best stories and so many were about her children.*
- *Less Helpful Post: I miss your mom so much. I don't know how I'll go on without her. (Personal Communication, August 31, 2017)*

She said a sense of community is felt by teens when they post sentiments that are well received in comments or likes. On the other hand, there are times when people respond in ways that don't feel as connecting, or do not respond at all, and then the teen may feel more isolated than ever. One survey respondent said he felt more isolated after communicating online with strangers because he was sharing a great deal of personal information and he realized they "… didn't even know me or really care," extending the feeling of isolation and grief even further. He said when he wasn't online, he "…had to act like everything was fine. Everybody just goes on and you're supposed to act like nothing huge has even happened." Or, as several survey respondents of this chapter's research noted, it made them feel "mad" or "annoyed" when people glorified who the deceased was " … and acted like they were perfect." "Some people post without really knowing them and make it about themselves," said another respondent.

An overwhelming majority – 87 percent – of respondents found social media a beneficial means to communicate feelings and memories during the bereavement process. Nine percent said they did not find it beneficial nor negative, and four percent found it unhelpful.

FUTURE RESEARCH DIRECTIONS

Peer to Peer Groups

Previous research has illustrated the positive impact that grief counseling groups have among adolescents (Battle, 2017). Yet nowadays it appears many adolescents view social media as their counseling group, often not seeking out a separate meeting group with supervision of experts. Social media allows a feeling of recognition of an individual's grief. They post and feel a sense of satisfaction that other are reading it and recognizing the grief.

While Stenstrom said she is not against using social media for bereavement healing, she believes it is important to strive for balance in written declarations and verbal exchanges. "I do think it is somewhat of a problem that teens today are having difficulty learning to express themselves in direct verbal interactions," she noted (Personal Communication, September 1, 2017).

People of all ages can struggle with intimate conversations, but for older children and adolescents the associated anxiety can be heightened. "They simply do not know what to say or how to act," said

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bruggenschmidt. "It is easier to post a picture, a memory, or a story online instead of saying it face to face or in an intimate social setting. I also think kids today are so technologically savvy that online is their main way to communicate or express themselves" (Personal Communication, June 28, 2017).

In addition, with social media, it is often peers on their own and without adult input who are viewing the content. "The subtle nuances of facial expressions, sighs or quiet interactions seem to bring grief to the forefront rather than just ranting on social media or making the circumstance more than it is," Stenstrom explained (Personal Communication, September 1, 2017).

For most individuals, uncomplicated grief is naturally self-limiting, with longitudinal studies of bereavement show naturally occurring declines in bereavement symptoms (Ott & Lueger, 2002; Raphael, Minkov, & Dobson,2001). What needs to be monitored, however, is silent and extended grief, that in which the loss cannot be socially sanctioned, openly acknowledged or publicly mourned. That is when the healing process is not naturally working and when an individual requires more assistance in moving on with their life in a healthy manner.

"With the advent of new websites such as SLAP'D (Surviving Life After a Parent Dies), Hello Grief, and Modern Loss, teens are better able to connect with others who are also grieving, even if they don't have access to in-person support groups" said DeCristofaro (Personal Communication, August 31, 2017). There are areas for improvement, however. Within these websites, there is a notable focus on children grieving the loss of a parent or other family member. The loss of a peer seems lesser known or understood in searches for websites to assist peer-to-peer loss. At a natural time when older children and adolescents may already feel detached or misunderstood from adults, a lack of peer-focused groups may intensify feelings that nobody understands them.

And while the good news is that any support group may lead to a decrease in isolation and confusion while increasing a sense of community, validation and acceptance around their experiences with grief, there is also the potential for negativity. DeCristofaro notes that there " … is a concern about the information, judgments and harsh comments that older children and teens may encounter online" (Personal Communication, August 31, 2017). She said, "I wonder if with the increase in more public ways of grieving if teens will turn less to themselves and more to others for ideas and suggestions, or if they will feel more empowered to honor their own thoughts, feelings, and wishes, especially when it comes to significant events such as anniversaries or birthdays" (Personal Communication, August 31, 2017).

Virtual Memory Walls

Social media remains undeniably constructive as a means of connecting individuals regardless of geographic constraints. The aftermath of the April 16, 2007 massacre occurring on the campus of Virginia Tech University provided one of the first clear precedents into the unique value online social networking can play during a tragedy. Teens and college students throughout the U.S. united after the Virginia Tech deaths by creating online groups and posting comments expressing their concern and grief. The language was often candid, emotional and sentimental. One of the many group descriptors read, "In memory of those lost and those grieving at Virginia Tech. This is a group to honor those who have lost someone just know that you are not alone the world is watching and we are all praying."

It is this idea that forms the basis of a virtual memory wall and offers an opportunity and place for people to emotionally embrace. While the Virginia Tech tragedy received national – even international headline – it serves to show the desire people have for a lasting online memory.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

To illustrate, up until May 2007, Facebook's policy was to delete profiles of the deceased. That policy was altered after online protests and a letter campaign were initiated in response to friends and family of Virginia Tech victims learning that profiles of victims were to be removed (Hortobagyi, 2007). " … these pages are what's left of their voices, and the rest of their voices have been stolen from us," said Virginia Tech student John Woods.

The respondents for this chapter's survey echoed those sentiments. Layla said, "It's nice to go back and see how Kate looks. Her Instagram account reminds me of what she was like."

Kate's mother agrees. "We haven't touched Kate's Instagram page since her accident. It still contains her quotes, her thoughts, her pictures and characteristics that made her who she was. It still has her fingerprint. Pages created since her accident allow us and others the opportunity to teach others or share with others about Kate or Play for Kate (the foundation created in her honor). We feel that Kate would die a second time if no one spoke her name or talked about her or posted about her. So we encourage others to talk openly and frequently about her. I believe silence increases suffering. So if posting pictures, comments, memories or thoughts about Kate on an Instagram account or Facebook page helps kids heal, then I think it is a great thing. We all know that social media or an online presence can be used in negative ways. However, we only use it for positive messages and memories and try to police that others are doing the same. We want to keep Kate's memory alive in a positive, healthy way" (Personal Communication, June 28, 2017)

This brings about an interesting area for future research. How often and by whom should pages or postings be monitored? For Ashlee Bruggenschimdt, she said it takes a village to not only raise a child but to monitor the Facebook page highlighting the foundation in Kate's name. "It is monitored probably hourly between all of us. We would delete anything that was inappropriate or illegal. Thank goodness we haven't had to do that. I have had some tough conversations with a few family members that posted something that wasn't part of Play For Kate's mission and asked them to remove it, and they did. They didn't post it out of malice or with ill will, but we were worried someone would take it the wrong way" (Personal Communication, June 28, 2017).

Monitoring the page is important for the virtual memory to remain helpful to the deceased family and friends. "The pictures, posts and memories help us heal. Opening up about traumatic events can improve mental and physical health. The virtual memory is like a virtual journal. It helps us put our feelings into words and share them with other and allows others to do the same through their posts. Turning feelings into words or pictures helps us process Kate's accident and our grief. I really believe it helps us overcome adversity, gives us strength, and makes our emotions easier to deal with. Putting feelings into words, posting your feelings, a quote, a picture or a memory gives you power over your emotions, gives you strength, helps you get your confidence back that you lose after the death of your child or someone you love" (Personal Communication, June 28, 2017).

Many of the respondents for this chapter's work discussed the sense of sense of community and feeling of belonging to a larger group thanks to technology. Hashtags – those brief links preceded with a pound sign – allow content to be organized around a singular topic or discussion. "When people post old pictures they had with Kate, or a picture in honor of Kate, they sometimes use the hashtag "#play4kate" or "#playforkate", said Layla. "There are around 450 Instagram posts with that hashtag" (Personal Communication, July 15, 2017).

Intervention Tools for Those in Danger of Self-Harm

The mourning process can be healthy, giving us time to grieve yet slowly move on to accept new roles and new people in our life (Horowitz, 1990). It is the identification of users who continue to struggle with depression, thoughts of suicide or an inability to eventually move back to a handling normal routines and responsibilities that becomes disconcerting. Intervention tools need to be part of a regular social media system and have been slow to arrive on the technological scene. In 2016, Facebook added functionality allowing content to be reported when it appears a user is possibly suicidal. It is considered the biggest step to date by a major technology company to incorporate suicide awareness and prevention tools into its platform. The tools allow friends to flag each other's posts with "self-harm" or "suicidal content". The posts are then reviewed by a team and, if deemed appropriate, a message is sent along with information on suicide prevention.

"The area I see most problematic using social media for self-expression in grief would be related to suicide deaths. Sometimes teens tend to glamorize suicide deaths, and the language in social media posts can influence other teens to consider suicide a viable option and a way for others to remember them forever," said Sylvia Buck (Personal Communication, August 30, 2017).

The novel turned Netflix series *13 Reasons Why*, popular among older children and adolescents, also brought to light a concern over this glorification of suicide, particularly revenge suicide. Following the series, the search phrase 'how to commit suicide' rose 26 percent above normally expected searches for the same time period (Ayers, 2017).

As the posting of suicidal thoughts on social media is a relatively new phenomenon, it will become necessary for parents, educators, guidance counselors and grief assistance professionals to be aware of this new type of self-harm disclosure and how to help those in need as they struggle with coming to grips over a friend's death. "To date, it is unclear if the overall effect of such notes will in fact lead to greater encouragement of suicide or to greater opportunities for suicide prevention" (Ruder, 2011). Careful evaluation of these competing factors will be necessary in the future given the growing adoption of social media.

CONCLUSION

The data and discussions surrounding this case reveal that social media is deemed worthy and often valuable by children and adolescents in aiding the bereavement process. From their perspective, the online component was not seen as a separate piece to their grief. Instead, they saw it as a highly integrated and obvious part of their experience. It was *not* noteworthy to them that they communicated online intense emotions of sadness, fear, anger or even celebratory happiness. It was, for them, normal and expected.

A key contribution of this chapter is illustrating not only the reality and depth of feeling as one experience's the death of a peer, but also how we can reach a better understanding of the experience of bereavement in an ever-evolving digital world. Social media allows for new possibilities of engaging in rituals and finding means for creating, sharing or obtaining material and memories to remember the pain, sorrow and celebrations of those who have passed away. These children and adolescents may grieve differently than adults (Himebauch, 2008), with new grievances arising at each stage of age and maturity. They may place the death in a context of further experiences and understanding. At times, this

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

may mean the grief process is rekindled and that they have new or "out of order" stages of setbacks and progressions.

What social media provides, the grief counselors agree, is the opportunity for students to express themselves openly and not feel restrained. This concept has become so widespread that a phrase has been coined for it – the online disinhibition effect. Children and adolescents are often reluctant to talk about difficult subjects in front of an authority figure. But online, there is the feeling of an equalizing effect. Authority appears minimized, the playing field seems level, and children and adolescents feel like they can speak their feelings much more openly.

As Ashlee Bruggenschmidt said, whether as a parent or peer, social media can help you reach out to people who have gone through something similar. "You can see that they survived. You may learn things that helped them, and you may learn things not to do. My suggestion would be to go at your own pace, your own comfort level, but don't be afraid to reach out to someone who has suffered a similar loss or comment on someone's post to try to help them. You may help them just as much as they could help you" (Personal Communication, June 28, 2017).

The piece to the puzzle for parents and educators appears to be making sure valuable conversations and offline outreach are taking place alongside the use of social media by children and adolescents, whether that be with parents, counselors or trusted family or friends. "I see more significant progress in group settings than with those students who just try to talk it out on social media," said Stenstrom. "Nothing compares to human interaction for support, encouragement or other feedback for growth and healing" (Personal Communication, September 1, 2017).

"As far as helping with a peer's death," offered Buck, "I always encourage teens to stay in contact with the parent of the deceased via a note, letter or text if the parent is open to it. Most times they are. If a student wasn't close with the peer's family, I still encourage a letter or card a few weeks after the funeral to share a memory. It not only helps the parent after the chaos has calmed down to remind them others are still thinking about their child, but it also helps the teen remember and put it on paper to mail. Just the act of getting the address has been helpful for teens" (Personal Communication, August 30, 2017).

As adults, it's crucial to acknowledge the depth of feelings surrounding a child's bereavement process. By remaining patient and communicative, it's easier to help the individual accept the reality of the loss, adjust to a new circumstance and move forward emotionally. Attending a memorial service, encouraging them to talk with mutual friends and doing something to honor the friend who died can all be useful, said Sylvia Buck. "They want to somehow make meaning out of the person's short life and feel that the person will not be forgotten" (Personal Communication, August 30, 2017).

Children and adolescents experience death through many means – family, pets and, as the focus of this chapter, even friends. To ignore discussions on the topic is to ignore their development, growth and healing. In addition, without these conversations, children and adolescents will use their own imaginations to fill in gaps about death, consequences, and what are normal feelings versus abnormal. Therefore, they will be forced to process on their own or with minimal guidance if they are not steered in the right direction for meaningful conversation.

The death of a childhood friend can be a traumatic experience. Ongoing research will help us better understand how to assist grieving children and adolescents toward a place of acceptance and, ultimately, to become empathetic, healthy adults. As Danielle Bernock (2014) wrote in her book *Emerging with Wings*, "Trauma is personal. It does not disappear if it is not validated. When it is ignored or invalidated the silent screams continue internally heard only by the one held captive. When someone enters the pain and hears the screams healing can begin."

ACKNOWLEDGMENT

Thank you to the family of Kate Bruggenschmidt for supporting the exploration and understanding of how social media has affected and continues to impact those children and adolescents who lose a friend far too young. It should be noted that Kate's family and friends have fought tirelessly for a law in Indiana requiring minors to wear a helmet when riding an ATV. That law – Play for Kate's Law, as it is affectionately known – came into effect July 1, 2017.

KEY TERMS AND DEFINITIONS

Acute Grief: The intense physical and emotional expression of grief occurring as the awareness increases over the loss of an individual.

Adolescent: The years of age between 13 and 19 considered to be the transitional stage from childhood to adulthood.

Bereavement: The actual fact of losing a loved one.

Critical Incident Technique (CIT): A method of gathering facts (incidents) from domain experts or less experienced users of the existing system to gain knowledge of experiences in a singular incident or experiences surrounding an incident.

Grief: The emotional, cognitive, and behavioral responses to a death.

Mourning: Refers to the behavioral manifestations of grief, influenced by social and cultural rituals.

Online Disinhibition Effect: The lessening of restraint one senses when communicating online versus face-to-face communication.

Social Media: Websites and internet-based applications which enable users to create and share content or participate in social networking.

Chapter 58
Counseling Chinese Communities in Malaysia:
The Challenges and Needs in Mental Health Service Deliverance

Rachel Sing Kiat Ting
Monash University Malaysia, Malaysia

Pei Lynn Foo
Penang Association of Counselling and Psychology, Malaysia

ABSTRACT

This chapter presents the experiences of Chinese in Malaysia (CIM), in the context of mental health services. As the second largest ethnic group in Malaysia, CIM is diverse in its dialectic subculture, education, generation, geography, and degree of assimilation to the mainstream culture. The chapter introduces the ecological characteristics of CIM and how they shape the unique psychological challenges. Though CIM are known for their multilingual ability, strong work ethics, emphasis on education, and family piety, the clashes between tradition and modern values, the marginalized position in the Malaysian political arena, the stereotype of overachiever in education, and the "brain drain" movement of young elite CIM, have all caused a strain in CIM families as well as individuals. Moreover, they face both external and internal barriers in getting quality mental health care. It is therefore imperative to promote a mental health discipline that is open to serve CIM, as well as being sensitive to its cultural and historical backdrop.

INTRODUCTION

In the recent two decades, the discipline of psychology in Asia is arriving at its golden age of development due to waves of globalization, modernization and westernization. Since the publication of the *Handbook of Chinese Psychology* (Bond, 1996), Chinese psychology is deserving much attention in the arena of cross-cultural psychology and cultural psychology. In 2010, there is an updated edition on the Handbook and the chapters expanded from 32 to 40 (Bond, 2010). Many recent empirical researches

on the Chinese population have been included in the handbook, which demonstrated that psychological research among this population could confirm, verify and be adapted from certain existing theories from Western psychology. Nevertheless, most of the studies cited in those chapters were based on Chinese populations from Hong Kong and Taiwan, as these regions have a longer history in establishing local psychological disciplines. Overall, there is a scarcity of psychology publications and literatures on Chinese immigrants or diasporas in other regions or societies.

The Chinese people have a long history of migrating overseas. Due to acculturation and assimilation, overseas Chinese espouse multiple identities that add to the richness in manifestation of Chinese personalities. The diverse and multidimensional identities among overseas Chinese can be explored through identity conflict and integration in the experiences of acculturative stress and socio-cultural adaptation, cultural competence mediated by coping strategies, personal and situational factors, social support (i.e. in the context of ethnic communities & host cultures), and the roles and interpersonal relationships within the foundation of the Chinese family (i.e. the concepts of family harmony and filial piety) over time and generations (Ward & Lin, 2010). The voices of Chinese immigrants speak of the evolvement of Chinese culture in new lands, as well as their hybridized identities as overseas Chinese. As a pioneering effort, the authors of this paper endeavor to expound upon the experiences of Chinese in Malaysia (CIM), in the context of mental health services. In comparison to Hong Kong and Taiwan, psychology practice is considered to be in its infancy stage in Malaysia. While academic psychology has existed since the late 1970s, applied psychology disciplines have surfaced only in the past 30 years (Ng, Teoh & Haque, 2003).

The Chinese as the second largest ethnic group in Malaysia with a population of 6,650,000 (23.4%) (Department of Statistics, 2016), is also diverse in its dialectic subculture, education background, generation gap, residential areas, and exposure to the amalgamated mainstream Malaysian culture. The aim of this chapter is to introduce the ecological characteristics of CIM and how they shape the unique needs of mental health among CIM. The objective is to empower mental health practitioners to be culturally sensitive and competent in providing services to the CIM community. Due to their unique migration history and settlement in Malaysia, CIM are known for their multilingual ability, strong work ethics, emphasis on education, and family piety. Their relative absence in the political arena, ethnic identity crisis, mistrust towards governmental system, and lack of solidarity have made them vulnerable to psychological stressors. In recent years, there is a rise in awareness of mental health issues among CIM in the public arena through promotional efforts of NGO services, religious groups, para-counselors, and social media. However, there is still stigma towards mental illness that creates barriers for CIM to seek help, especially among the less Westernized and urbanized populations. Since not all lower class CIM could afford private mental health services and deem such services as priority, many CIM rely mainly on family network or strong relational ties as emotional support. From the practitioners' standpoint, many trained counselors or service providers are not fluent in using Mandarin or other Chinese dialects in providing counseling. Moreover, even when there is an ethnic or language match between the counselors and counselees, the former often found that translation of Western psychological concepts a challenge in the counseling room with CIM, and do not necessarily possess multicultural competency. The uncritical transposition of the Euro-American values embedded in Western psychology also contributes to potential cultural clashes in the counseling room with the more traditional CIM (e.g. assigning labels such as "over-enmeshment" to CIM families). This struggle is quite obvious as Malaysia is an ex-colonized country struggling to find its multiracial-multicultural identity after 60 years of claimed independence from British influence. It is therefore imperative to produce a mental health discipline that is open to serve the CIM population, as well as being sensitive to its cultural and historical backdrop. This chapter

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

will end with practical suggestions for CIM mental health trainers, researchers and practitioners in service delivery, education and policy making.

A BRIEF MIGRATION HISTORY OF CIM

Malaysia has a multi-ethnic naturalized population of about 28.4 million that is made up of three major ethnic groups. The largest ethnic group is the Malays at 68.6%. Those of the Chinese descent make up about 23.4% of the total population (about 6.65 million, which is roughly the size of Hong Kong's population). The Indian ethnic group makes up about 7.0% of the population and the remaining 1.0% consists of the aboriginal people as well as mixed ethnicities (Department of Statistics Malaysia, 2016).

Historically, the Chinese have been settling in Malaya since the days of the Malacca Sultanate, when the Straits of Malacca was a major trading route in the 15th century AD. Many Chinese traders settled and integrated into the Malayan culture since then. The second large wave of Chinese entering Malaysia was after Penang was founded in the late 1700s; many of them were planters, traders and tin miners. The influx of Chinese became more established after the founding of Singapore in the early 1800s, expanding their trade to include manufacturing, banking, and timber trading (Tan, Ho & Tan, 2005).

Due to trading and mining, CIM have been instrumental in the economic development of Malaysia as it is now, especially with regards to commerce and industry. A British administrator in Malaya was quoted as saying,

Under present conditions, the Chinese are the bone and sinew of the Malay states. They are the labourers, the miners, the principal shopkeepers, the capitalists, the holders of the revenue farms, the contributors to almost the whole of the revenue; we cannot do without them (Tan, Ho & Tan, 2005).

Reinforced by the British policy to keep the different ethnic groups in separate sectors, CIM had been seen as leading in business and trading, while Malays dominated the politics and government administration, whereas Indians provided blue-collared manpower (Fu, 2007). As a result, CIM tend to be seen as being on a higher scale with regards to socioeconomic status as compared to other ethnic groups (Fu, 2007). In 1971, the New Economic Policy (NEP) was introduced to eradicate poverty as well as to eliminate racial differences in economic function and geographical location. It was also a vehicle to boost Malay entrepreneurship by encouraging Malays to venture into business. In spite of its controversial implementation, which resulted in decreased Chinese participation in economic activities, the CIM still flourished in business ventures (Fu, 2007).

Traditionally, economic strength of the CIM is very much related to its community leadership. Many community leaders were successful merchant-entrepreneurs or *towkays.* Some of these leaders were conferred formal leadership status, and named *Kapitan Cina* (Chinese Captains) by the Malays. These *Kapitan*s were instrumental in building the Chinese community, in the areas of infrastructure and trading, as they were also appointed to State Councils. Apart from that, "secret societies" were also instrumental in leading the Chinese communities, especially during the early British colonial times. By the end of the 1800s, the Kapitanship was abolished by the British and secret societies were banned. Instead, the secret societies resorted to underground activities that still managed to keep the Chinese economy afloat (Pan, 2006). Influenced by the Confucian work ethics, the early Chinese settlers were known to be very hardworking with strong determination that lasted generations until today, leading to the stereotype of

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

CIM being the most entrepreneurial people. Today, many CIM have ventured into and demonstrated success in various contemporary vocational areas. They also make up the bulk of the population in most urban areas of Malaysia today (Carstens, 2005; Heng, 2006).

UNIQUENESS OF CIM

According to the theory of ecological rationality (Todd & Gigerenzer, 2012; Sundararajan, 2015), human cognition and emotion are shaped by the ecological system we are embedded in. Even among the same Chinese tribe, such as the Yi ethnic minority group, there could be differences in semantic expression of emotions, explanation of suffering, and help-seeking behavior due to different religious practices and beliefs (Ting & Sundararajan, 2017). This theory could explain why CIM are different from other racial groups in Malaysia, as well as Chinese from other countries. We would describe four major environmental factors as having decisive influence on CIM in this section—language, cultural practices, education, and political status.

Language

With regards to language and culture, although most are conversant in the Malay language which is also the national language, each ethnic group in Malaysia still retains most of their original traditions and mother tongue. In addition, most Malaysians are familiar with the English language, which can be traced back to the long history of British colonization. Such multilingual ability is a uniqueness of CIM as compared to the Chinese elsewhere such as Taiwan, Hong Kong, Indonesia and Thailand. Tan (2005) estimated that there were approximately 5,365,875 number of Chinese dialect speakers in 2000, comprising of 94.27% of overall CIM (i.e. 24.45% of the total 2000 Malaysian population)[1] (Department of Statistics, 2001). Though not all CIM could read and write Chinese characters, most of them are fluent in one dialect or more at conversational levels, depending on their education, origin, and exposure. There are also significant differences in the way the Chinese language and dialects are spoken among the CIM. Influenced by the Malay and English languages, the CIM develop their own unique Chinese dialects, such as the Penang Hokkien which is unique and distinct to the northern peninsular region (Ong & Tan, 2017).

Cultural Practice

While most CIM retain their Chinese identity and traditions in their acculturation process, there exist some degrees of differences in the CIM cultural practice compared to those of Mainland China, Taiwan, and Hong Kong. Some traditional festivals celebrated by the Chinese community in Malaysia are no longer widely celebrated in Mainland China after the Chinese Cultural Revolution. This is especially true of certain regional rites and rituals that continue to be celebrated by the CIM. For example, for wedding ceremony in the Cantonese community, elaborated rituals and gift-exchanges are observed between the engaged families. The Chinese New Year, especially the reunion dinner on Chinese New Year eve and the 15th day, are still highly emphasized (Tan, 2005).

More importantly, the ability to preserve their language and cultural practice enable CIM in general to preserve their identity as Chinese, unlike their counterparts in Indonesia and Thailand where national

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

identity precedes ethnic identity. In fact, many CIM still identify themselves as "Chinese," even if they are already acculturated Malaysians for more than a generation (Ang, 2013). For this group of CIM, their healing methods for mental health problems would also strongly tie to the folklore beliefs and practices, such as shamanism or traditional Chinese herbal treatment (*Zhong yao*) (Chang, Tam & Mohd Suki, 2017; Edman & Koon, 2000).

Education

Tan (2000) divided CIM into three major categories based on their education: Chinese-educated, English-educated, and Malay-educated, and he predicted that the second group will disappear as its boundary with the third group becomes gradually blurred with increased shared characteristics. He postulated that the internal diversities of CIM by education have implications on their cultural identities and even political orientation. The mass media they are exposed to also differentiates their level of acculturation and worldviews, with the English-educated CIM more susceptible to Western ideologies (such as democracy), whereas those who are Chinese-educated may know more about the historical facts and cultural values of ancient China. Not surprisingly, the English-educated CIM have remained politically prominent. This difference in educational background would also influence their worldview towards mental illness as well as help-seeking methods.

Socio-Political Status

Given economic strength and recognized leadership, CIM do possess some political influence in the ruling parties as well as the opposition, compared to other ethnic minority groups. Case in point is the state of Penang which has been under the governance of DAP (former opposition party prior to GE14) Chinese chief ministers since 2008 (Banyan, 2013). However, the ethnic Malays still hold the dominant political power in the country and the political involvement of CIM is decreasing (Freedman, 2000). The recent Penang floods debacle in which the plight and appeal for federal aid became political fodder and contention underlines the challenges faced by the minority opposition party (FMT Reporters, 2017).

In terms of inter-racial relationship, CIM seem to prefer to remain within their own race, forming racial cliques at schools and at workplaces. Due to the ethnic-based political structure in Malaysia, ethnocentric sentiments remain entrenched within each ethnic group thus discouraging meaningful inter-racial interaction. As evident in the university students' campaign against having different races to share rooms in hostels (Ng, 1999), which shows that there is still a strong pull towards keeping to one's own racial-ethnic group, leading to a lack of inter-racial understanding. This sociopolitical atmosphere is caused by the oversea immigration trend among CIM since 1980s, and those who remained in the country are faced with psychological insecurity as a racial minority. In fact, rising racial tension can be seen in recent years due to some right-winged ethnic Malay groups' rhetoric on "Ketuanan Melayu" ("Malay Supremacy" in English), and delegation of the ethnic Chinese as "Pendatang" (i.e. immigrants) and second-class citizens which further harmed positive inter-racial relations (Han, 2015).

According to Minkov and Bond (2017), the main predictors of national differences in happiness (i.e. subjective well-being, SWB) are closely connected to "national economic development, democratization, and increasing social tolerance" among different ethnic groups of a nation. Hence, taking the current socio-political challenges faced by the CIM into consideration, it is understandable that in comparison

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

to the other ethnic groups in Malaysia, CIM have been found to have the lowest level of happiness and SWB (Minkov & Bond, 2017).

DIVERSITIES AMONG CIM

Despite much shared experience among the CIM, there exists much diversity among the population. Different scholars also have different taxonomy to differentiate CIM depending on their educational backgrounds, history of immigration and acculturation, language/dialect spoken, and geography of residence. Knowing these subcultures will help counselors better engage with their CIM clients as well as conceptualizing their struggles in a cultural-inclusive perspective.

Cultural Identity

According to Tan (2007), the CIM are broadly categorized into two groups. The first group, constituting 85% of CIM, builds their cultural identity around three pillars: the Chinese-medium schools (currently about 95% of Chinese children study in Chinese schools; there are around 1,300 national and independent Chinese schools across the country), the Chinese newspapers (nine in West Malaysia and eight in East Malaysia) and the Chinese ethnic corporations (including more than 7000 registered cultural heritage, industrial and business associations). They are typically independent business people, whose main concern is political stability for good economic returns. The second group, constituting the remaining 15% of CIM, consists of those who speak mainly English and are non-Chinese educated. Many are Christians, Peranakan, and members of Lion's or Rotary Clubs. This group is often stereotyped by the first group as the "banana" (i.e., yellow skin [Chinese race], white core [pro-Western culture]) (Tan, 2007).

The main difference between the two groups is that the second group does not share the three cultural pillars as part of their identity. Even though some are sending their children to Chinese schools now, this is done more for practical rather than cultural reasons. The two groups differ in their choice of media (English / Malay newspapers vs. Chinese newspapers), which indirectly results in very different perspectives and reactions to sociopolitical events within the country. Inevitably, because of different interests and worldviews, the two groups tend to associate minimally with each another, which further reinforce their prejudice and stereotype of the other party.

Nonetheless, despite their differences in cultural beliefs and identification, Tan (2007) suggested that both groups of CIM ultimately share one mutual concern -- fairness and justice for all people in the country. With general economic stability over generations leading to less hunger for survival, there is also increased interest in ancestral identity among the contemporary CIM (Fu, 2007). However, in recent years, the wealth gap has been increasing among the CIM community, yet not much attention has been paid to the marginalized CIM from lower socio-economic background (FMT Reporters, 2017).

Degree of Assimilation and Acculturation

According to Tan (2000), CIM could be divided into two broad categories — the more assimilated "Peranakan Chinese" and the so-called "Pure Chinese." The former group refers to the Malay-speaking Chinese, including the Baba in Malacca, and Malay-acculturated Chinese from the rural areas of Kelantan and Terengganu. The origin of this group could be traced back to the 19th century, where interracial marriage

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

occurred between the early Chinese settlers and Malays in those areas. The second group refers broadly to the Chinese who settled in Malaysia in the later stage, and who kept the kinship among themselves. What differentiates them from the first group is that they would never speak Malay among themselves. Their interaction with Malays is more confined to economic exchange (Tan, 2000).

Earlier research on acculturation also showed that those who were able to reach the "integration stage" in the acculturation process tended to have better mental outlook and subjective well-being than those who were stuck in the "marginalized status". Lin and Ting (2014) studied returning oversea Chinese from Southeast Asia to Mainland China during the 1950s, in terms of their re-entry acculturation experience. Many of them experienced cultural shock and disillusionment after returning to China as they lacked language fluency of Mandarin Chinese and still preferred the customs of their original host country (e.g. Thailand, Indonesia, Myanmar). This experience is likely similar to CIM, who although self-identify as "pure Chinese", have already adopted the host country's values and living practices. That is why CIM call themselves as "hua ren" (華人) rather than "Zhong guo ren" (中國人), where the former connotes overseas born Chinese and the latter entails the political nationality as Mainland Chinese.

Nevertheless, there is much variation in the degree of acculturation among CIM and their self-identified status in the society, which manifests as much nuances and complexities in the CIM's identities. For instance, in a preliminary study on psychotherapists in Malaysia (Ng, 2007), when participants were asked whether they would be considered "a member of a social, cultural or ethnic minority" in Malaysia, more Chinese considered themselves as part of the mainstream (60%) than not – a stark contrast with the Indians (about 75% considered themselves a minority), even though both the Chinese and Indians were historically migrants and generally considered the minorities by census. Yet, what makes the CIM very much distinguished from Chinese in other countries is still their hybridized identity shaped by the pluralistic Malaysian culture with the regional social-cultural experience of being Chinese. Bonn and Tam (2015) supported this premise and found that the CIM group carries its own unique cultural values on happiness overlapping with the values from Malays and Mainland Chinese groups respectively.

Dialect Groups

Early Chinese settlers in Malaya were mainly from the Guangdong and Fujian provinces in China. A report by Heng (2006) categorized these settlers into five major dialect groups, with the largest group being the Hokkien (37%), follow by the Hakka (22%), and then the Cantonese (19%), the Teochew (12%) and the Hainanese (4%). The geographical distribution of these groups was not random due to chain migration. The Hokkiens and Teochews mainly settled on the northern and southern coasts, whereas the Hakka and Cantonese settled in the inland regions. In Sarawak, East Malaysia, the Fuzhou and Hakka dialects are more prevalent in most inland and coastal regions, leaving Kuching to be predominantly Hokkien. In Sabah, the Chinese community is largely Hakka, followed by Cantonese and Hokkien (Tan, 2005; Ghazali, 2012). There is also certain bonding within each dialect group due to similar custom, cuisine and heritage.

Geographical Locations

Due to its political backdrop and geographical distance, Chinese in East Malaysia also forms a unique culture and community that is distinctive and different from the Chinese in West Malaysia (Chin, 1981). Sabah and Sarawak joined Malaysia as a country in 1963, after West Malaysia claimed its independency

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

in 1957. Prior to independence, both were under the ruling of British governors and the Malay Raja (king). Due to the discrepancy in political history, East Malaysians usually do not possess an affiliation with their nationality as strongly as those from West Malaysia ("Civil movement", 2013; "GE 13: Movement", 2013; Rintod, 2013).

The Chinese first came to Sarawak as traders and explorers in the 6th century. Today, they make up 29% of the population of Sarawak and comprise of communities built from the economic migrants of the 19th and early 20th centuries (Hing & Tan, 2000). The first Chinese migrants worked as laborers in the gold mines at Bau or on plantations. Through their clan associations, business acumen (*kongsi)* and work ethics, the Chinese rapidly dominated the commerce sector. There were times of riots with British and Holland colonizers early in the history due to discrimination and oppression. Waves of immigration were agreed upon by the British governor, Charles Brooke, in 1901. Though there was mistrust between the local government and the Chinese immigrants during the communist war in China, the majority of the Chinese abided by the rules of the new Malaysian government, formed in 1963. Today, Chinese are amongst the most prosperous ethnic groups in Sarawak (Chin, 1981).

PSYCHOLOGICAL RESILIENCE OF CIM

After introducing the socio-economic status and ecological system of CIM, this section focuses on the psychological resilience of CIM, as well as resources they inherited from the historical and cultural contexts.

Business Vitality

As illustrated above, CIM has a history of success in entrepreneurship and as a leader in economic development. They have a high visibility in business, both nationwide and internationally. Therefore, though they do not hold much political power, their contribution to the Malaysian economy has been widely acknowledged. This also gave them certain leverage and voice over the mainstream political structures (Gomez, 1999).

Strong Adaptability

CIM has a history of resiliency through immigration and differentiation from China by building a new home and identity in a new land. Within a century, the Chinese have grown into the second largest ethnic group in Malaysia, and its contribution to the nation is undeniable. In spite of all the hardship at the beginning of the 20th century, CIM are able to adapt to the new country and be flexible about their roles in the Malay government.

Family Values

The strong family lineage and concept of filial piety have kept the Chinese families intact. According to the Population and Housing Census 2010 in Malaysia (Department of Statistics Malaysia, 2011), CIM have the lowest divorce rate among all the racial groups. This shows family resilience in facing life challenges, as well as their values of integrity of family as a social unit. Moreover, filial piety is still

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

highly emphasized in the CIM, and it serves as a protective factor for the aging population, as children are expected to take care of the elderly (Simon, Chen, Chang & Dong, 2014). The elder siblings are also expected to take care of the younger siblings. The Confucius hierarchy for the family continues to be passed on through generations. Many researchers have established that the tight networks among blood-tie relationships have served as a buffer against social oppression and marginalization (Ng, Bhugra, Mcmanus & Fennell, 2011; Yeh, Yi, Tsao & Wan, 2013). These networks are even more evident in rural areas, where most of the CIM siblings and relatives stay together in the same neighborhood. In many cases as evidenced in clinical practices, when there is mental illness in the CIM family, all the family members feel obligated to take care of the ill-member, hence decreasing the burden of the social welfare system.

Emphasis on Education

Compared to other ethnic groups, CIM have a reputation of high investment on education for their next generations. Chinese parents usually work very hard to save enough money for their children's post-high school education. In spite of the racial profiling at public education, Chinese parents always try to send their children to foreign countries for better opportunities in education. Private Chinese associations or societies would also sponsor some distinguished students through donations and scholarships. In fact, great pride is bestowed upon young students who excel in academic achievements even at the elementary school levels.

Strong Work Ethics

The strong work ethics among CIM is a continuation of the "survival" mentality since centuries ago, and coined by scholar as high "Confucius dynamism" (Hofstede, 2003). This strong work ethics is not only reflected in the common business sector, but also among mental health professionals in the health care domain as well.

PSYCHOLOGICAL CHALLENGES OF CIM

Despite many strengths and resilience embedded in the CIM community, the clashes between tradition and modern values, the marginalized position in the Malaysian political arena, the stereotype of over-achiever in education, and the "brain drain" movement of young elite CIM, have all caused a strain in CIM families as well as individuals (Sukumaran, 2017). According to the 2015 Malaysia National Health and Morbidity Survey, both CIM adult and children population have seen a significant increasing trend in mental health problems from 1996 to 2015 (Ahmad et al., 2015; Ministry of Health Malaysia, 2015). This section presents more specifically how different age cohorts of CIM face specific external pressures that could add to the mental burden of the individuals. We hope the readers would not generalize or pathologize the problems by stereotyping CIM, but to see their personal responsibilities and solutions in the midst of these social dilemma.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Children: Pressures of Achievement (Overachievement/Perfectionism)

In the past decade, the increase of mental health problems among the child and adolescent population in Malaysia has become a significant concern. According to a study comparing data from the Malaysia National Health and Morbidity Survey (NHMS) from 1996, 2006 and 2011, the prevalence of mental health problems among children and adolescents (between the ages of 5 to 15 years) saw an increase of 49.2% across 1996 to 2011. Mental health challenges among preschool aged children (5 to 6 years old) almost doubled in the decade spanning 1996 to 2006 (Ahmad et al., 2015). The latest 2015 Malaysia NHMS highlighted that Malaysian children struggled especially with emotional, conduct, hyperactivity, peer and social problems (Ministry of Health Malaysia, 2015). From the literature reviewed, depression among Chinese children could be associated with family factors, social factors, age and gender, ethnicity and culture, and physical (or body) factors (Zgambo, Kalembo, He & Wang, 2012).

In general, although Ahmad et al. (2015) found that the prevalence of mental health problems among children of Chinese ethnicity was lowest compared to other ethnic groups from 1996 to 2011, mental health problems among CIM children saw an exponential increase of 366.7% from 1996 to 2006. In 2015, the NHMS placed CIM children group second in the prevalence of mental health problems (Ministry of Health Malaysia, 2015). Many CIM children struggle with psychological distress especially pertaining to anxiety, depression and even suicide (Alphonsus, 2012). For the CIM, the pressure to excel and achieve began at a young age, and is invariably closely tied to the Chinese family's interests. Hence, failure to achieve and meet high standards not only reflected poorly on the individual child but impacted the concept of the Chinese family's face, image, pride and integrity. For CIM, such achievement-oriented upbringing and emphasis on family interests served as a double-aged sword for children – especially in the absence of adequate parental and social support, familial and household stability, and positive coping resources – the pressures and stress early in life precipitate significant challenges with mental health adaptability in young children which are unfortunately carried into the later years in life[2] (Alphonsus, 2012; Bernama, 2016; Zgambo, Kalembo, He & Wang, 2012). In fact, research has shown that academic and achievement-oriented stress could actually be carried until the college stage where CIM have been found to have relatively higher levels of stress but lower coping skills in comparison to other ethnic groups (Mazlan, Bahari & Ardillah, 2012).

2. Adolescents: Addiction Problems and Pressures From Authoritarian Parents

As Malaysia goes through the wave of industrialization and modernization under the 2020 vision[3], college students are widely exposed to the most advanced information and technology globally through internet browsing and video gaming. The younger generation has a subcultural of their own with a myriad of cultural exposure that is very different from their parents. The identity crisis of CIM teenagers surfaces in their choice of friendship, dating relationship and career path, as parental authority is still prevalent among CIM (Chen & Liew, 2015). While the traditional CIM parents expect them to be "obedient and filial" children, not many teenagers today can conform to such social norms and expectations. As a matter of fact, in a survey among 2927 secondary schoolers, CIM students were found to have the highest depression rate among all ethnic groups (55%), which is associated with low academic performance and alcoholism (Latiff, Tajik, Ibrahim, Abubakar & Ali, 2016). Similar results were shown in another research in Sarawak, where CIM adolescents had the highest depressive rate among all ethnic groups

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Ghazali & Azhar, 2015). Suicidal ideation is also higher in CIM adolescents (7.9%) in comparison to their Malay counterparts according to a survey done in Sabah (Ahmad & Cheong, 2014).

In the counseling room, the therapists might see many CIM teenagers who are having trouble with their parents. Behavioral problems and teenage delinquency are rising as substance abuse becomes prevalent in Malaysia (Singh, Yap, Redpath & Allotey, 2017). According to a survey conducted in Penang (Guan & Rahimi, 2015), self-hurt behavior has also become prevalent for CIM teenagers (56.81%), especially among female students (33.72%). For children who come from families with lack of emotional support (e.g. single parents, absent father figures), their need for mentoring and emotional regulation become the goal of therapy. As mentioned before, many CIM families engage in entrepreneurship and business management, and therefore it is quite common among CIM families for many fathers to be travelling frequently between places while the mothers and grandparents are the housemakers. These "migrant worker" families were quite common in the first and second generation of CIM, and thus created a unique family structure where the grandparent figures became prominent in parenting. The gap between the grandparent generation and the teenager world creates difficulty in mentoring and behavioral monitoring, even though the former could serve as supportive figures for the family. Hence the lack of moral guidance and supervision of parents are quite common in the "high work ethic" CIM families. Many teenage clients in therapy complained that the parents provided only their material needs but neglected their emotional needs. The challenges in working with CIM teenagers would be to reconstruct the family system to make it more flexible and reciprocal using their perceived language of love.

3. Adults: Family Differentiation

As briefly introduced before, though familism is a strong protective factor for CIM against psychological distress, it could also serve as a stressor when the family lacks resources to cope with acculturative and assimilation stress from the mainstream culture. As Malaysia is still a commonwealth country, it is constantly being impacted by globalization and Western values. Though CIM have been persistent in keeping their cultural heritage, the hybridized cultural identity could be clashing with traditional social norms. For example, many CIM adult clients complaint about the enmeshment and interference of their parents in their daily life decisions and not respecting their boundaries and privacy. It is quite common for unmarried adults to still stay with their parents until they get married. Some traditional CIM also value multigenerational living under the same roof (三代同堂) as a sign of prosperity for the family clan. With this kind of living structure, one could imagine the possible conflicts that could occur between in-laws, and those who seek individuation from the family of origin. Studies have identified that post-natal depression and suicide among CIM women could be perpetuated by the unsupportive family system such as lack of support from the husband or due to in-law conflicts (Yusuff, Tang, Binns & Lee, 2014). Having to struggle with the patriarchal family system (e.g. in-law problems) makes CIM married women more vulnerable to mental illness especially depression (Arifin, 2015).

From the first author's clinical practice in the past 10 years, many depressed CIM adults found it suffocating for not being able to be recognized as an "individual," and expected at the same time to be loyal to the family. Issues with authority figures are always a challenge the adult CIM have to work through in the therapy room. Finding their own voice in the traditional Chinese household would be a life-long challenge due to the pressure of being the "perfect child". For example, career choice is often a battle seen in the therapy room when CIM parents insist on the career choice for their young adult children especially sons who carry the family names. More often, the top career choice for their children is the

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

medical profession or computer sciences which could guarantee a secure financial income and white-collar class. However not many CIM students could thrive through competitive programs like medical school, but they are "forced" to honor the parental wish for choosing a career path that is "good for them." This observation is confirmed by several studies which found that parental authority still plays a key factor for individuals of Chinese descent in determining their career goal (Chen & Liew, 2015; Tang, 2002).

Moreover, Mak and Chen (2010) expounded that strong Chinese cultural values pertaining to the maintenance of the family's "face" and interpersonal harmony could inversely contribute to ineffective coping and adaptability. Research have shown that Chinese adults who uphold stronger preference for familial "face" concerns were more likely to report higher levels of psychological distress. The effort invested towards interpersonal dynamics within the family can be psychologically taxing and distressing especially in the event of failure to sustain interpersonal harmony among family members (Mak & Chen, 2010). Hence, CIM who carry strong adherence to the concepts of the Chinese family's face, interests and harmony are more susceptible to sociotropic cognitive vulnerabilities and psychological distress which in turn precipitate challenges with mental health problems.

4. Older Adults: Somatic Complaints and Empty-Nest Syndrome

Many less acculturated CIM older generation still believe in Chinese traditional medicines in interpreting mental problems and healing of ailments. The popular belief in "shen jing shuai ruo" (神经衰弱), translation of neurasthenia, is still pervasive among CIM older adult circles[4]. Older generation CIM would rather equate mental problems such as mood disorder or anxiety disorder as "shen jing shuai ruo" as it is thought to be a "neurological condition" of their mental problems. It serves the function of destigmatizing mental illness, as well as matching the traditional philosophy of mind-body unison (Kleinman, 1982). It has been argued that Westerners conceive depression as an intra-psychic, existential experience, whereas in Chinese and many other non-Western societies, it is most frequently experienced somatically and in terms of interpersonal dysfunction (Chan, 1990; Kleinman, 1982; Watters, 2011). In her dissertation, Ting (2008) showed that Chinese individuals, when using Chinese language, tended to use discourse that was interpersonally focused (e.g., feeling critical of others) in projecting depressive feelings rather than abstract emotional discourse that was intrapersonal (e.g., feeling lonely). The challenges for aging adults then become their inability to express their pain through internal affective language but manifested through somatic and concrete descriptions instead. Their losses and grieves might not be understood by the mental health practitioners or taken seriously by their family members if emotions are being expressed rather indirectly with somatic symptoms (Mak & Chen, 2010; Ting, 2008). The somatization and interpersonal projection of emotional dysfunctions often times do not overlap with Western diagnostic categories for mental disorders (Mak & Chen, 2010).

Another unique phenomenon surfacing in the CIM community is the "international family" constellation, where younger elite CIM migrated to other countries as Permanent Residents in the foreign lands while still carrying Malaysian citizenship. These kinds of global families normally happened in the middle upper class CIM families where the parents encouraged their children to pursue higher education in more developed and immigrant-friendly countries (e.g. Australia, New Zealand, Singapore, Taiwan)[5]. Most of their children continue to stay on in those developed countries for better living and stable subsistence as the Malaysian government provides limited chance or promotion for CIM (Ward & Hewstone, 1985). This trend of re-migration is also known as the "second wave diaspora among CIM" (Ling, 2008; Tan, 2005). However, this creates a vacuum in the CIM community where the aging cohort lacks support

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

from the younger cohort. Many older adults might suffer from empty-nest syndrome with loneliness and depression as their children and grandchildren are not around, which conversely goes against the cultural tenets of filial piety and family ethics (Simon, Chen, Chang & Dong, 2014).

BARRIERS IN RECEIVING MENTAL HEALTH SERVICES

Though CIM displays a relative low rate of mental problems (24.2%), compared to other races in Malaysia, the ratio is still quite high among the CIM community (Krishnaswamy et al., 2012). The ratio of seeking mental health services is quite low for CIM, hence we need to explore further the barriers hindering them from seeking and receiving quality mental health services in Malaysia. Some barriers listed below are internally oriented, but the major barriers lie externally in the scarcity of resources in meeting the heterogeneous needs of CIM.

Shame in Psychopathology

Though there is an increased awareness of mental health among CIM, there is still stigma towards mental illness and seeking help from mental health professionals[6]. The belief of "never air your laundry outside the family" is still prevalent among CIM. They would usually cover up the pathology of individuals within the family through social isolation, in order to avoid "face losing" or "shame". The stigma towards mental illness and the implication of personal and familial failure, weakness and shame invariably result in low help-seeking behavior and service utilization (Hwang, 2006; Mak & Chen, 2010). Therefore, the delay in seeking help often times exacerbates the symptoms of targeted patients, and consequently demands a lot of case management and crisis intervention from mental health professionals. Another reason for treatment delay is due to financial reasons. Besides financial concerns and affordability, some CIM are reluctant to pay a professional fee to seek help from "talk therapy." Many still prefer pro bono or low fee service from non-profit organizations. Those cases that are being seen by the counselors in community usually are chronic, psychotic, low-functioning and severely-ill. Yet they expect a "quick fix" or "magic pill" in one session. The concept of an ongoing treatment plan is still foreign.

Cost-Benefit Concern

Unlike other countries, where mental health services are covered through managed care or insurance plans, most mental health providers in Malaysia are not included in the welfare systems. Hence, the clients have to pay out of their own pockets should they seek private or community psychologists. Governmental clinics or hospitals have very limited positions for clinical or counseling psychologists, and instead largely depend on social workers who might not have the relevant training, background or experience to manage serious mental health cases. Psychiatrists mainly adopt a medical and biological model in approaching the patients. Hence, private counseling centers become the major sources of mental health referral. However, many lower class CIM cannot afford a costly long-term treatment plan. They would rather opt for other forms of treatment, such as traditional herbal medicines for symptom relief (Chang, Tam & Mohd Suki, 2017; Chen, 1981).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Preference for Ethnic Match

From our clinical experiences, if they have a choice, CIM tend to seek private and Chinese-based professionals rather than government agencies catering to a Malay majority. Even within the government setting, where services are more affordable to most people, Chinese clients have been known to ask for Chinese service providers. Reasons for this tendency include language and sociocultural familiarity, and underlying mistrust towards "the others". According to multicultural counseling research in the United States (Sue, 1998), ethnicity match does not predict the efficiency of therapeutic outcome, but would reduce the dropout rate and prolong the length of the treatment among ethnic minority clients. Ironically, due to the stigma of mental illness, seldom would Chinese parents encourage the new generations to pursue a career in the mental health profession, which contributes to the enormous gap between the demand and supply of CIM mental health service delivery.

Lack of Mandarin and Dialect Speaking Practitioners

Though CIM are educated in the Malay and English language, most of their mother tongue are still Chinese dialects (e.g. Cantonese, Hokkien). Research found that interventions conducted in clients' native language were two times more effective (Griner & Smith, 2006). In order to facilitate greater emotional congruence in the counseling room, we need more Mandarin and Chinese dialect speaking mental health professionals who are able to serve the non-Malay and non-English speaking CIM population effectively. With regard to Chinese psychologists in Malaysia, to date it is estimated that up to 56.6% (77 out of 136) of known active clinical psychologists in the country are of Chinese descent[7]. Fortunately, compared to the data collected between 2004-2005 by Ng (2005), the ratio of CIM clinical psychologists has actually increased almost doubly (from 37% to 56.6%). However, the Chinese representation in the registry of the Malaysian Counseling Association is only about 12.7% (907 out of 7157) (Lembaga Kaunselor Malaysia, 2016). With such a limited number of CIM psychologists and counselors serving the whole community of CIM (ratio=1:6758), one could imagine the gap of services in the system.

Lack of Developed Inventories Used for Mental Health Screening and Diagnosis

Most psychological instruments are predominantly in English and normed on Western populations (such as in the United States, United Kingdom or Australia). As such, assessment services in Malaysia are still largely culturally and linguistically biased. The lack of Chinese translated and locally normed tools for intelligence and personality testing have been a dilemma, as many competent CIM researchers and psychologists are English speaking and not fluent in Mandarin. This leaves the Chinese-speaking CIM population underserved and unfairly assessed.

Lack of Multicultural Competence

Not all institutions that train mental health professionals emphasize on multicultural competency training and include it as core coursework. Moreover, the multicultural modules that are adopted by current Malaysian postgraduate programs are often times heavily reliant on the Western model of multicultural diversity; hence, adequate understanding and contextualization of the unique history, challenges and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

issues of Malaysia's multicultural setting and communities are invariably overlooked in the training of mental health professionals. As counseling is still a young profession, and not many culturally competent senior CIM counselors or therapists are available, the younger generation of mental health professionals often lack supervision and role models, leaving them to stumble their way in gaining more clinical and educational experience (Ching & Ng, 2010; Haque, 2005).

Lack of Regulation on Mental Health Professions

Many of the "counselors" in the Chinese non-profit counseling centers, who have limited training and experiences as para-counselors or volunteers, are not registered with PERKAMA. This could be risky to the clients, especially CIM who are less exposed to the mental health professions. There is a lack of regulatory boards to govern uncertified "therapists" or "psychologists", which leaves the less educated CIM an easy target for scamming or exploitation[8] (The British Psychological Association, 2006).

Lack of Research Funding in the Area of Chinese Psychology in Malaysia

Our feeble effort might be the first formal document in this aspect. Up till date, there is no registered Chinese journal for psychology in Malaysia. There are some local peer-reviewed journals, but the publishing language is mainly in English or Malay. On the other hand, most of the Chinese-speaking NGOs choose to publish their own books and magazines in Mandarin, which could be disseminated to wider readership among the Chinese community. The gap between scholarly work and popular psychology has also hindered the dissemination of appropriate and updated information about mental health to CIM who are fluent in Mandarin only.

Uneven Distribution of Mental Health Services

Most mental health services are concentrated in big cities, such as the Klang valley and Penang (Ng, 2006). There are hardly any counseling services in rural areas or small cities. It is not convenient for people from suburban settings to seek professional counseling. This has become a problem in terms of availability and accessibility of mental health services, especially to those living outside of the city areas, which understandably have lower awareness and greater stigma on mental health issues. In terms of the mental health profession, East Malaysia is still at the infancy stage of development, due to the uneven distribution of resources in governmental sectors. There is limited literature or research conducted in terms of the mental health prevalence and needs among Chinese in East Malaysia. To the authors' knowledge, there is only one clinical psychologist and less than five psychiatrists in the whole Sarawak state; furthermore, most of them reside in big cities. Moreover, most of these mental health professionals are not Chinese and usually would not be conversant in Mandarin or Chinese dialects either. In practice, the mental health professionals working under the government services will rotate to the smaller towns once a month only and would have a very long waitlist of patients which significantly diminishes the quality of care rendered to patients.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Lack of Family Therapists

According to a survey, the mental health profession in Malaysia is dominated by individual-oriented therapists who practice individual therapy (Mohamed & Rahman, 2011; Ng, 2006). Family therapy or other modes of therapy are not as widely practiced due to a lack of training opportunities grounded in the Malaysian context. However, as we have learned, CIM is thickly embedded in familism as well as how mental problems and solutions are perceived and managed. Through the lens of family systems, one could reframe mental illness or psychological struggles in a more dynamic and sensitive language reflected through a multigenerational and familial structure. Aside from the individualistic approach to counseling, mental health practitioners should receive further training in family systems theory or even community psychology (Ching & Ng, 2010), and adopt it to the CIM context. Otherwise, CIM clients would be blinded to their communal resources and be isolated in the therapy room.

SUGGESTIONS FOR FUTURE MENTAL HEALTH DEVELOPMENT

In this section, a blueprint is delineated with the objective and strategy to advance the mental health profession and practice for CIM. The ultimate goals are twofold: First, CIM would be able to access effective and culturally sensitive mental health services; Second, local practitioners will be empowered to take part in discovering a Chinese psychology that is indigenous for CIM. To achieve these goals, the following are some strategies and plans of action in the near future:

1. Indigenizing Research Epistemology and Methodology

While reviewing and researching empirical studies related to CIM, the authors found that ethnicity was seldom a major factor addressed in the literatures. The CIM group was often used as the "comparison group" to the Malay group, and the findings of those papers were also interpreted from the lens of the dominant group where CIM culture was left invisible or not taken seriously. While many anthropologists and sociologists have studied the diversity of CIM in length, Malaysian psychologists are still behind in building a suitable theoretical framework to explain the ethnic differences and uniqueness in our own country. To date, most of the psychological models employed by Malaysian psychologists are either direct translation or importation from developed Western countries. The discipline of psychology practices occur almost exclusively in the Euro–American tradition. There is little awareness of the need to indigenize psychology to fit into the local CIM culture and needs.

International psychologists like Gulerce, Lock and Misra (as cited in Gergen et al., 1996), wondered whether there should be a universally acceptable conception of psychology. These psychologists noted that the journals in their respective countries (i.e., Turkey, New Zealand, and India) seem to differ little from American psychological publications in the methodologies utilized, the issues addressed, or the paradigms adopted. Failure to appreciate cultural particularity tends to result in local phenomena where minority psychologists imitate American models of psychological research (Sundararajan, Misra & Marsella, 2013). In fact, Mohanty (1988) had referred to the replication of Western psychology by Indian psychologists as "Yankee Doodling."

While indigenous psychology may well include non-local wisdom (e.g. scientific methodology), members of the host culture should decide what is to be imported or contextualized in the local culture.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Indigenous psychology not only should be built on the collaboration between anthropologists, psychologists, historians, and sociologists, it should also be constructed on relationships of mutual respect and empowerment between the researchers and the lay leaders of local communities. In contrast, mainstream psychology is culturally bound in that it serves and benefits the people in a Western context. It exports the products of psychology to minority cultures through the processes of colonization, commercial exchange, globalization, and westernization. Mainstream psychology's failure to recognize the limitations of Western theories, and the fantasy of creating a universal psychology have not only disempowered the recipients in underdeveloped societies, but also destroyed the shelter built by the traditions of those cultures (Dueck, Ting & Cutiongco, 2007).

It is hoped that indigenous research for CIM would address the social phenomena of CIM, study the psychological concepts espoused by CIM, and develop measurement tools or scales to assess the concepts coherent and pertinent to the CIM community. The mixed method research approach would be best utilized to explore and identify the key factors contributing to mental health issues of CIM and to validate the best treatment approaches. Pedagogical efforts are needed to invest in research topics concerning the wellbeing of CIM, as well as establishing reliable funding agencies to support such efforts. More awareness on the importance of indigenous psychology in the Malaysian mental health field could also promote similar cultural sensitivity towards other ethnic groups as well.

2. Enhancing Multicultural Competency in Training and Education

It is highly recommended that higher education institutions mandate multicultural therapy as core coursework in counseling training programs. For counselors who are providing services to CIM community, it would be imperative to have a clear understanding of CIM culture and subcultures through reading and cultural immersion experiences. Since it is not possible to train multilingual staff, it is more realistic to train multiculturally competent therapists in post-graduate programs. Even if there is an ethnic and language match between the CIM counselors and counselees, there might be values differences due to education background and upbringing (Tan, 2007). For example, a Chinese-educated therapist may not readily empathize with the unique experiences of English-educated Chinese. With multicultural competency, a good counselor will first examine his/her own biases and values toward different groups of CIM. Multicultural competency training would not only include close supervision of intern counselors working with CIM, but also help trainees work through their own cultural stereotypes and counter-transference challenges with various clients.

Besides having cultural sensitivity towards different groups of CIM, a competent counselor would also be trained with therapy skills that are specific to dealing with frequently seen problems among CIM. For example, cognitive-behavior therapy was found to be preferred and effective for Chinese American community (Chen & Davenport, 2005), due to its education and didactic elements. For those CIM clients who prefer a more practical approach and quick fix, a solution-focused approach would be essential. For those CIM clients dealing with family conflicts, therapeutic skills in conducting family sessions would be necessary. Furthermore, knowledge about CIM community resources and traditional wisdom would help the counselors to facilitate referrals for more traditional CIM. As many CIM still practice folk religions (e.g. Taoist) and ancestral worship, counselors also need to have some basic knowledge of these local practices, aside from the common spirituality and religions practiced by CIM.

Another unique socio-political atmosphere for the mental health profession in Malaysia is its "thickness" in religion. Considering the Islamic backdrop in Malaysia, some Islamic psychologists have taken

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

on a leading role in integrating Islamic teaching into psychological practice (Haque & Masuan, 2002). It was found that religious-based therapy serves as a catalyst to recovery from anxiety disorders among religious Malay patients (Razali, Aminah & Khan, 2002). Some CIM mental health practitioners have already started integrating their religious faith into their research and practice, such as mindfulness and meditation for Buddhist therapists, and prayers and scriptures for Christian therapists (Ting & Ng, 2012). Counselors are encouraged to talk to different religious leaders in the CIM community for wider exposure. Academicians could also study the effects of such integrated therapeutic approaches for empirical evidence based therapy.

3. Empowering CIM Community to Take the Lead in Mental Health Service Delivery

It is highly encouraged for the next CIM generation to pursue a career in the mental health profession due to the great need among its own community. In the past, many CIM parents insisted for their children to pursue medicine or law as the symbols of achievement and success, which contributed to the current shortage of CIM mental health professionals. Careers in the mental health field are also associated with the stigma of mental illness. However, there is a turn in the last decade, where greater visibility of psychology and mental health practices among CIM can be seen. The establishment of Chinese counseling centers and associations, coupled with the blossoming of counseling seminars and various continued education courses, have led to a wider acceptance and understanding of counseling and mental health within the Chinese society. More CIM are expressing interest in psychology and counseling courses. These demands further stimulate the expansion of psychology departments in some private institutions in Malaysia (EduAdvisor, 2017).

Many textbooks and literature in counseling/psychology have been translated into Mandarin in Taiwan, Hong Kong and China, and CIM counselors could also benefit from such overseas resources by accessing first-hand knowledge from their counterparts in other countries. There is also more interchange with Taiwan counselors to bridge in such developing skills through intensive training and workshops. Some CIM counselors/therapists have started to publish their own works, as well as contribute to newspaper/journal columns (such as Sinchew Daily and Guangming Daily). Online media exposure such as to radio station interviews could also help to destigmatize the mental health field, as well as promoting the social status of counselors.

In addition, CIM counselors/therapists have a privilege which other racial groups might not have. Ng (2006) found that a substantial number of Chinese therapists (though not all) speak at least one Chinese language/dialect – 70% speak Mandarin, 60% speak Cantonese, 47% speak Hokkien, 16% speak Hakka, and 2% speak Hinoi or Teochew. In addition, most, if not all, CIM therapists are able to speak and write in English and Malay (Ng, 2006). This is an advantage for CIM therapists who can also reach out to non-Chinese clientele, without the need for translators. Unlike other racial groups who are usually monolingual or dual-lingual, multilingual CIM therapists have wider access and flexibility to the general Malaysian population.

4. Building a CIM Friendly Society Through Advocacy and Public Policy

In ensuring quality services not only to CIM but to the general public, we need to continue to ensure the presence of regulatory boards and enforcement of clinical ethics in mental health service delivery. All

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Malaysian citizens, including CIM, should have equal access to mental health services in the public arena. The counselor registration requirement stipulated by the *Counsellors Act* in Malaysia has a certain positive influence towards the quality control of counselors in Malaysia. The mass media including magazines, television and radio programs very often interview people in the mental health profession, which gives the profession more exposure to the public. This is certainly a reflection of the mental health need in the society, where people are beginning to seek help in this area. The government sectors should also ensure diversity among employed mental health practitioners (e.g. psychiatrists, counselors, psychologists) to serve the diverse CIM population. Many trained CIM clinical psychologists or counselors were actually "drained" to foreign country such as Australia and Singapore as they found current employment in Malaysian governmental sectors not available. Though there is no overt racial oppression and discrimination towards CIM, the implicit racial quota in the government system could be unfair to CIM mental health practitioners. It is urged that all mental health professionals, regardless of ethnic backgrounds, to come together to share resources in the community and promote inter-racial harmony.

Considering the current trend of racial segregation and tight knit CIM community, mental health professionals could utilize community-based services to promote mental health awareness and services to this population. Instead of practicing from an individualistic model, community psychology could help in destigmatizing and demystifying psychotherapy, building a safety net of preventive measures, and decreasing the prevalence of mental illness among CIM. There is also the advantage of mobilizing peer-mentoring groups—such as parenthood groups, adolescent mentoring programs, support groups for family/caretakers of the severely mentally ill, among the CIM community. In rural areas where mental health resources are scarce, the training of lay counselors and peer counselors who come from diverse backgrounds would be a high priority. It is anticipated that local counselors would be able to reach out to the CIM family units in a more culturally appropriate manner than external consultants.

CONCLUSION

Despite the mushrooming number of studies on the mental health of ethnic minorities in the United States over the past three decades (Sue & Sue, 2003), Chinese diaspora remains a novice population to be studied by psychologists and mental health workers. The public slogan of "Satu Malaysia" (One Malaysia) promoted by the Malaysian government with the intention to unite the nationalities, has not been encouraging towards ethnic comparison studies. Emphasizing national identity over ethnic identity is a political strategy that encourages assimilation and reduces tension between multiple races. Yet, if these efforts are not balanced by celebrating diversity under the umbrella of nationality, cultural heritage would be watered down, and the identity of any ethnic group would be compromised. We advocate for a moderate public policy to embrace the diversity within CIM, as well as a mental health field that fosters more peaceful dialogue between CIM and other racial and ethnic groups. Henceforth, this chapter is a feeble attempt to start tackling the complicated mental health issues faced by a heterogeneous group like the CIM. We adopt a psycho-social approach in understanding the diversity and uniqueness of this group, as well as how mental health needs are shaped by the political atmosphere in Malaysia. We address the barriers faced by CIM in getting quality mental health care and services, as well as methods in overcoming these barriers. It is our belief that the mental health profession could promote the welfare of the CIM community by modeling harmony, modesty, justice and peace within and between the mental health professionals.

KEY TERMS AND DEFINITIONS

Acculturation: The process of social, psychological and identity change resulting from migrating to another culture (i.e. original and host cultures).

Assimilation: The process whereby a minority group gradually adapts to the customs and attitudes of the prevailing culture.

Chinese in Malaysia: Naturalized Malaysians of Chinese descent, mostly descendants of Chinese who arrived in various waves of immigration.

Indigenous Psychology: The scientific study of human behavior and mind that is native, that is not transported from other regions, and that is designed for its people. It involves understanding each culture from its own frame of reference, including its own ecological, historical, philosophical, and religious or spiritual contexts.

Mental Health: A person's condition with regard to their psychological, cognitive, emotional, and social well-being.

Multicultural Competency: The ability to understand, communicate with and effectively interact with people across cultures.

Psychological Challenges: Difficulties or obstacles that affect the individual's mental status.

Resilience: The ability to recover quickly or adjust easily to life difficulties, misfortune or adversities.

[3] Wawasan 2020 was proposed as vision for Malaysia to realize the dream of becoming a developed country.

[4] Neurasthenia is a term that denotes a condition with symptoms of fatigue, anxiety, headache, heart palpitations, high blood pressure, neuralgia, and depressed mood, by early neurologist George Miller Beard in 1869. It is currently a diagnosis in the World Health Organization's International Classification of Diseases (and the Chinese Society of Psychiatry's Chinese Classification of Mental Disorders). However, it is no longer included as a diagnosis in the DSM-5 by the American Psychiatric Association.

[5] Stanford University's Asia Pacific Brain Drain Project highlighted Malaysia as one of the countries most affected by brain drain. The full report can be accessed at https://cs.stanford.edu/people/eroberts/cs181/projects/2010-11/BrainDrain/Malaysia.html

Chapter 59
Recent Trends and Issues in Vocational Rehabilitation of People with ID

Bijoy Kumar Dehuri
Exservicemen Contributory Health Scheme, India

Bhavna Mukund
Gujarat Forensic Sciences University, India

ABSTRACT

Employment has many advantages for people. Besides earning an income, work provides opportunities for social interaction, a means of structuring and occupying time, enjoyable activity and involvement, and a sense of personal achievement. Work is considered therapeutic and essential for both the physiological survival and psychological well-being of people in contemporary societies and hence it's importance in people with intellectual disability. The rights of people with disabilities have been given new attention with the entry into force of the United Nations Convention on the Rights of Persons with Disabilities (CRPD) in May 2008. The various policies, issues and trends in vocational rehabilitation of people with intellectual disabilities in existence in different countries need to be examined along with different models in existence to develop appropriate executable models whereby such rehabilitation services could be made available early in life to such individuals and after training they could be provided with supported employment or integrated employment as the case may be.

INTRODUCTION

Vocation or employment is central to human existence. It enables an individual to possess a valued social position and identity that has a significant influence on self-concept and relationships with others. As an important aspect of life in today's society, work has a substantial effect on our fundamental aspects of personality and is a major contributing factor to our levels of self-esteem. Besides earning an

income, work provides opportunities for social interaction, a means of structuring and occupying time, enjoyable activity and involvement, and a sense of personal achievement. In addition, work provides an opportunity for improving skills while also providing income and financial security. Employment as a basic right of citizenship is often taken for granted. Yet, many people with intellectual disability through the non-availability of evidence-based services are excluded from this basic right. Work is considered therapeutic and essential for both the physiological survival and psychological well-being of people in contemporary societies. Conversely, unemployment can produce high levels of stress, anxiety, and depression; low levels of self-worth; and decrease opportunities for self-development, autonomy, and social contact. The shift from being employed to unemployed is significantly associated with not only an increased risk of depression, alcohol dependence, anxiety states, and psychosomatic reactions, but also stigma, aimlessness, and poverty, which combine to trigger or amplify mental health problems. Recognizing the importance of work, vocational rehabilitation professionals such as rehabilitation counselors, have consistently advocated for work as a fundamental human right of people with disabilities. (Rubin &Roessler, 1995; Wright, 1980).

The rights of people with disabilities have been given new attention with the entry into force of the United Nations Convention on the Rights of Persons with Disabilities (CRPD) in May 2008. The provisions of the CRPD contribute to other international standards concerning persons with disabilities, signaling a dramatic shift in international policy terms. In relation to training and employment, for example, states are called on to provide opportunities for disabled people alongside non-disabled people.

People with intellectual disabilities are entitled to benefit from the provisions of the CRPD and ILO Convention concerning the Vocational Rehabilitation and Employment (Disabled Persons), ACT 159 in 1983 as well as people with other kinds of disabilities. Yet, they are frequently not well placed to gain from this changed emphasis on inclusion. In many developing countries, in particular, they are often excluded from school and deprived of opportunities to acquire relevant vocational skills at all, presenting further disadvantages when it comes to seeking jobs. Yet, experience in many countries shows that, with the right training, support in the workplace as required, and the right opportunities, they can make valued contributions in the workplace and to a country's economy (ILO,2008).

Research has shown that people with intellectual disabilities often have multiple secondary impairments, including complex physical and mental health problems (Beange et al., 1999; Einfeld et al., 2006; Hofer et al., 2009). These co-existing disabilities are particularly likely to be problems of agility, mobility, speech and language; and emotional problems including anger control, anxiety and depression. They are also more likely to experience loneliness and lack of friends (McVilly et al., 2004).

It is acknowledged that people with all categories of disabilities have experienced discrimination and stigmatization throughout the centuries. Yet, an intact intellect has historically been highly valued and often seen as the essential characteristic of being fully human (Parmenter, 2001), and people with intellectual disabilities are often the last within the community of disabled persons to receive attention. In the not-too-distant past a person with an intellectual disability "was viewed not as a second-class citizen, but rather as one who possessed no citizenship" (Stevens, 1967).

In the planning and delivery of educational and vocational programs for people with intellectual disabilities, a support needs approach to classification has significant benefits in contrast to the earlier practice of classification based on IQ levels (mild, moderate, severe and profound). Areas of functioning important to employment, where people with intellectual disabilities may need specific supports, include (ILO,2011)

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Literacy and numeracy;
- Comprehension of instructions and information;
- Interpreting non-verbal language;
- Short-term and long-term memory;
- Attention span and concentration;
- Motivation;
- Problem-solving and decision-making skills;
- Making choices;
- Following instructions;
- Time telling/management and organization;
- Ability to travel and/or live independently;
- Appropriate behaviors and social skills;
- Grooming and self-care.

The degree of difficulty and the extent of support required will vary from person to person.

Undoubtedly the early work of Gold and Tizard was a catalyst for change in promoting a deeper understanding of the learning potential of people with even the highest level of cognitive impairment. Later research focused on a more systems-based approach where emphasis has been placed on adaptations and accommodations in a person's environment, in addition to effective skills training (Parmenter, Trevor R.,2011)

Research helped to lead the development of the "place and train" model of employment support services, in contrast to the more traditional rehabilitation approach of "train and then place". Experience has shown that, to be effective, teaching and training of people with intellectual disabilities should take place using real work in practical situations to the extent possible. Support staff should also be aware that making modifications to the person's environment may be an alternative way to assist individuals in handling the requirements of a job. Therefore, support staff should be encouraged to target both their learning needs and adjustments to the workplace. In addition to a good knowledge of work practices, support staff require training in the basic teaching procedures and principles used by special educators (Parmenter, Trevor R., 2011).

Evidence indicates that, irrespective of the culture or the economic circumstances of a country, the employment circumstances for persons with intellectual disabilities are equally alarming, if not worse (Dempsey and Ford, 2009; Department of Health, 2009). Just as they have been denied education, they have been denied access to jobs. This dismal state of affairs has come about largely through ignorance and superstition (Parmenter, 2001).

In Canada, for example, a survey reported by Staintonet. al. (2006) in a survey found that people with disabilities that are working, work only half as many weeks per year as people who do not have a disability; are unemployed longer; and spend three times as long outside the labour force. People with intellectual disabilities were found to experience even lower rates of employment, with only 27 per cent being employed at the time of the survey, while 40 per cent had never worked. In terms of income, nearly 50 per cent of people with intellectual disabilities had incomes below the Statistics Canada low-income cut-off, a widely used measure of poverty.

In Australia, people with intellectual disabilities made up 41 per cent of those served in government funded employment services in 2010, with more males than females benefitting (64 per cent vs. 36 per cent). They represented 27 per cent of all participants with disabilities n open employment, but 73 per

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

cent of those in segregated business enterprises, formerly called sheltered workshops. There has been a gradual decline in the proportion of people with intellectual disabilities accessing inclusive employment services. And finally, there is evidence of 'creaming'—that is, providing services to people who have relatively low support needs and are easier to place in employment - by providers of both employment options, leading to increasing numbers of people with high support needs being referred to state/territory day option programmes. Parmenter, 2011).

In European Union countries, the unemployment rate for people with intellectual disabilities was found to approach almost 100 per cent (Greve, 2009). The vast majority who do work are found in sheltered workshops and those with high support needs are generally directed to day activity centres. A similar picture was reported by Verdonschot et al. (2009), who found from a systematic review of the literature that people with intellectual disabilities were three to four times less likely to be employed than people without intellectual disabilities. In Northern Finland a follow-up of those born with intellectual disability in 1966 had revealed a similar position (Taanila et al., 2005). As per Strategic Social Report Finland 2015, there are 25 000 people with intellectual disabilities of working age in Finland, 13 000 people with intellectual disabilities are engaged in sheltered work or day activities in activity centers.

Employment options for people with disabilities, and those with intellectual disabilities in particular, can be broadly distinguished as those in which people with disabilities work in a segregated environment of only workers with disabilities; and those in which they work in an integrated or inclusive environment of workers largely without disabilities. Employment models under these headings, currently accessed by people with intellectual disabilities in countries around the world, are described below. (Kregel & Dean, 2002).

EMPLOYMENT MODELS/OPTIONS

- **Day Programmes/Centres:** Traditional day centres were initially based on the principles of occupational therapy and were created as respite for family members caring for their adult children or siblings with disabilities. This is slowly changing, however, as programmes offered become more skills-based and focused on increasing independence. For instance, in New South Wales, Australia, one of the post school options initiatives for school leavers classified as not being ready for open employment, is the "transition to work" programme. Since the programme's inception in 2004, Jobsupport, the most successful agency delivering the programme, placed 60 per cent of the 179 school leavers it supported into paid open employment. This agency specifically targets young people with intellectual disabilities who have been classified as having moderate support needs, referred to under the older classification system as "moderately intellectually disabled"(Trevor R. Parmenter, 2011).

Under a medical model of service delivery, people with intellectual disabilities who were assessed or deemed to be unsuitable for employment were catered for in "activity therapy centre" programmes, where one of the goals was to prepare them for employment options. Typically, only a very small number "graduate" to sheltered employment. In practice, these centres in the past became the life-long option for people assessed as not being suitable for employment. Some of the constraints to moving to other employment options may arise from the reluctance of persons with intellectual disabilities themselves to move from a day centre where they have built up friendships over many years. This reluctance acts

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

as a barrier to change, unless opportunities are open to maintain friendships outside of work. This pattern has been highlighted in the UK context by Beyer et al. (2004), who also found that people with intellectual disabilities in day centres were considered to have had restricted lives, leading to a poor attitude to employment, low desire to work, and little self-confidence, in combination with the lack of the experience to make a judgement about what work they might want to do.

- **Sheltered Workshops:** Sheltered workshops, initially established by parent groups, were essentially segregated facilities established for people considered unable or unlikely to obtain or retain a job in the open labour market. The majority of those employed have tended to have intellectual disabilities. The workshops engage in remunerative work to cover some of their costs. Workers are often paid a training allowance in addition to any welfare payments they might be entitled to, and very minimal or no wages - sometimes in the form of a bonus if production targets are met. In many countries, these facilities are described as rehabilitation and training facilities, but very few workers ever graduate to the general employment market, even when financial incentives are offered. In fact, there was a major disincentive to progress the more skilled workers to real jobs in the open labour market, as their productivity was crucial for the financial viability of the organization (Murphy & Rogan, 1995; Parmenter, 1980).

Given the results of research studies, in combination with the realization that a real job in the community gives people a strong sense of identity, it came to be recognized that segregated settings send a message to people with disabilities, and to the population at large, that they are different from the rest of society, and that alternatives were needed to allow them to have the same conditions of life as everyone else (Nirje, 1985). This gave rise to a debate about sheltered workshops that continues to the present.

Arguments have been put forward in favour of sheltered employment. These include the avoidance of perceived physical risks in the outside world (Dudley and Schatz 1985; Migliore et al. 2008); the high complexity of jobs in outside employment being beyond the skills range and psychological capacity of people with intellectual disabilities (McConkey and Mezza 2001; Visier, 1998); that sheltered workshops provide greater opportunities for the development of friendships than outside jobs (Dudley and Schatz 1985; Weikle 2008); and that sheltered employment tends to provide surety of employment across the person's life span without affecting disability benefits. Sheltered workshops are also seen to provide an option for people who fail to secure or maintain employment in the open labour market.

Yet it is widely recognized that change was and continues to be required. In recent years, for example, high-income countries, such as Australia, have re-badged sheltered workshops as "Australian Disability Enterprises" where a much greater emphasis has been placed on good business practices and productivity. Wages and working conditions for the disabled employees have improved, in some cases as a result of Trade Union support. In New Zealand, legislation has ensured workers receive the minimum wage unless an exemption is granted in individual cases, based on assessed productivity rates. In Australia, wages are linked to assessed productivity of the individual employee, compared to the normal industrial award. (Hedger S., 2012**).**

The rate of successful transition of people with disabilities from sheltered workshops to the open labour market has been minimal, ranging from under one per cent to about five per cent (Beyer et al., 2002; US Government Accountability Office, 2001). However, Cimera (2011) found that two matched cohorts of employees—one in which employees had previously worked in sheltered workshops and the other in which they had not had prior sheltered workshop placement—were equally likely to be employed

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the open labour market. There was a difference in the rates of pay with the non-sheltered workshop cohort earning significantly more than those from the sheltered workshops. The former group also worked more hours per week and cost less to support.

Studies conducted in Northern Ireland, Spain and the US have shown that people working in sheltered workshops would like the opportunity to work in outside employment (McConkey and Mezza, 2001; Migliore et al., 2007; Verdugo et al., 2009).

In the US, a network of 23 state developmental disabilities agencies have developed policies under the umbrella of Employment First which has led states and providers to adopt service delivery strategies for persons with disabilities, including those with the most significant disabilities, that embrace the principle of integrated competitive employment (Kiernan et al., 2011). This initiative is strongly supported by self-advocates (Walker, 2011).

There are increasing signs that many sheltered workshops are transitioning to community employment options. In Australia, Greenacres, a large employment agency for people with intellectual and other disabilities, conducts an open employment programme in parallel with its sheltered workshop. It has a policy of actively seeking to move its employees into the competitive employment labour market7. In the US, Rogan and Rinne (2011) have described the processes followed by ten organizations that have shifted their service delivery from sheltered to community employment.

- **Supported Employment:** Alternatives to sheltered employment and day activity centres emerged in the early 1970s. In the US, in addition to the factors described above, the establishment of the President's Panel on Mental Retardation (now 'The President's Committee for Intellectual Disabilities') in 1961, and the subsequent research agenda under the auspices of the newly created National Institute on Child Health and Human Development (NICHD), saw the development of energetic research teams which targeted the post-school options for this population. These influences led to the establishment of an Employment Initiative for Persons with Developmental Disabilities, which promoted the concept of supported employment (SE) to business leaders, community groups, and journals, and to the enactment of two public laws that provided a mandate for the national development of SE: The Developmental Disabilities Assistance and Bill of Rights Act of 1984 (P.L. 98-527), and the Rehabilitation Amendments of 1986 (P.L. 99-506).

Researchers working with people with very high support needs developed four alternative pathways, all of which were characterized as 'supported employment' (Mank et al., 1986). The first was called the 'supported jobs' model, which later became the SE model described above. Other alternatives were the 'enclave' model, the 'mobile crew' model and the 'benchwork' model. Each of these models specifically targeted people with intellectual disabilities who had high support needs.

- **Supported Jobs Model:** The 'supported jobs' employment model involves a 'place and train' approach, rather than the practice in rehabilitation facilities where the model is 'train and then place'. Therefore, to provide employment, a job is required at the outset of the service, and not at its completion. The 'place, train and support' model for SE usually involves job coaches working with the potential employee to identify interests and skills. This is followed by job seeking, matching and placement. The employer might also be encouraged to make adaptations (i.e. accommodations) to a specific job in order to match it with the abilities and skills of the employee with an intellectual disability. In many cases the job coach might learn to do the job first, in or-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

der to subsequently teach the employee with the disability. In other circumstances, the employer might prefer for a regular staff member to teach the skill. This person may subsequently become a 'mentor' to the person with the disability, thus becoming part of the natural support for the person within the workplace (ILO, 2010).

- **Enclave Model:** The enclave model consists of a group of people with disabilities who are trained and supervised among workers who do not have a disability, usually in an industrial or commercial environment. In its original design, the workers were to be paid at a level commensurate to the non-disabled workers, often adjusted according to their relative productivity. This meant that wages for the person with a disability continued to be paid by the sheltered workshop, at the sheltered workshop rates. Storey and Horner (1991) found that individual and enclave job sites were more likely to involve interactions between disabled and non-disabled workers. However, the authors suggested that it could possibly be the features of specific job sites rather than the employment model in itself that result in positive interactions.
- **Mobile Crew Model:** This model is a combination of service and business. It may consist of a crew of five people with disabilities working from a van, rather than a building, performing service jobs in community settings. Examples of work carried out may include lawn cutting, window cleaning, and general ground maintenance. In its original conception, a mobile crew is set up as a small, single-purpose business, rather than as an extension of a large organization. (Parmenter,2011), (ILO, 2011)

Kregel, Wehman and Banks (1989) reported that group settings such as enclaves and mobile work crews provided significantly fewer opportunities for both physical and social interactions. They also found that people with very high-support needs were more likely to be placed in enclaves than any other supported work placements.

- **Benchwork Model:** This model was developed in the early 1970s by the Specialized Training Programme at the University of Oregon, US, as an alternative to day-activity programmes to provide long-term employment to people previously denied access to any vocational services. This model operates as a small, single purpose, not-for-profit commercial operation providing a range of goods or services. The model requires a number of highly qualified staff skilled in instructional technology with no more than a 1:5 staff-to-worker ratio. The size of the business was limited to 20 workers and they were located in close proximity to stores, restaurants, and other community venues that can provide opportunities for integration and participation into the regular community activities during lunch breaks as well as before and after work. At first the model was faithfully replicated in five states of the US and in Australia. The costs of operating the facilities were no more than those incurred in the day-activity centres, but employees received wages based on their productivity for the first time in their lives. Follow-up studies showed that some opportunities for community participation were realized, especially during meal breaks when employees could access local shopping centers. CNS Precision Assembly is an Australian example of a bench work model. Although designed for people with very high support needs, who would not normally be employed in a sheltered workshop because of their supposed low productivity, the bench work model shares many characteristics and constraints with traditional sheltered workshops. (Fletcher-Janzen,Reynolds,2007)

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

The four models described above have undergone some transformations since their original conception. Supported Employment has expanded and has become the preferred option internationally, particularly as it embraces the core values of the UN Standard Rules on the Equalization of Opportunities for Persons with Disabilities, and the more recent UN CRPD, which advocates employment options in inclusive work settings for all people with disabilities, irrespective of their level of support needs. Even in high-income countries, however, the penetration of SE has not been sufficient to encompass all people with intellectual disabilities wishing to work. This has resulted in an increased emphasis on job matching and making adjustments to jobs, so that all or part of a job can be performed by people with a range of disabilities, including intellectual disabilities. This has led to a modified version of SE developed in US called "Customized employment", a term first defined by the Office of Disability Employment Policy in 2001, (ILO, 2001)

- **Customized Employment (CE):** This model embraces a 'person-centred' approach, beginning with the person's needs, aspirations, talents and skills. This profile serves as a basis for contacting potential employers (Inge, 2006; 2008). It also emphasizes the person's choices, strengths and abilities. It is employed in One-Stop Service Delivery Systems (Blanck et al., 2009; Inge, 2008) where workforce investment, education, and other human service programmes work together to optimize access to services and long-term employment outcomes. Similar principles are used by Jobsupport Inc., one of Australia's most successful SE programmes, in its transition from school to work initiative (Tuckerman, 2008a).

Beyer and Robinson (2009) reported on a 2005 study conducted for the US Department of Labor, which found that CE had been used successfully with people with high support needs. In the first round of the study 345 people had been placed in competitive employment. The majority had found highquality jobs, with 95 per cent earning the minimum wage or above, and over 50 per cent placed in jobs with the potential for career advancement. A second round of data collection on 536 randomly selected individuals yielded similar results. Approximately 42 per cent of the sample disclosed a psychiatric or emotional disability, with 20 per cent reporting an intellectual disability. In essence, the major contribution of the CE model to the SE model has been the recognition that a person's job choices play a crucial role in achieving a successful job match. It is another example of the application of the social model of disability, in that environmental adjustments may be more important than trying to change the person.

- **Self-Employment, Self-Directed Employment, Microenterprises:** Neufeldt and Albright (1998, p. 6) defined self-directed employment as:

Income-generating work where disabled people, to a significant degree, have a prime decision-making role in the kind of work that is done, how time is allocated, what kinds of investment in time and money should be made, and how to allocate revenue generated.

Duce and Biersdorff (2002) suggested that business considerations for people with intellectual disabilities are little different from those for people who do not have a disability. In the case of the former, it is usual for someone to perform duties not dissimilar to the role of a job coach. Sometimes this is a family member. They proposed five major steps in the process of establishing a business: i) developing a business plan; ii) obtaining the required skills; iii) securing start-up capital; iv) implementing the busi-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

ness plan; and v) expanding the business. Again, the skills necessary to support self employment will be very similar to those for SE, and may include job analysis, skills training and on-going provision of support. It is also possible for the support worker to initiate contacts with natural supports such as unpaid volunteers and mentors who have experience as entrepreneurs who can act as an on-going resource.

This model has also been described as a micro-enterprise: a small business created around one person. Beyer and Robinson (2009, p. 65-66) reported that the main strengths of the model for people with intellectual disabilities are that:

- It respects the capacity and the assets of people with intellectual disabilities, by focusing on people's interests and strengths, and can be more flexible than mainstream employment and working conditions;
- It pursues equality by opening up the self-employment sector of the labour market, where people with intellectual disabilities are not represented;
- It reflects aspects of governmental thinking on increasing employment for disadvantaged groups, and on developing services to meet individual needs;
- It is for some people a way of gaining income from a hobby or an interest, with support and funding through person-centered planning, direct payments and individualized budgets; and
- It provides another way for a person with intellectual disability to move from being a client to being a citizen.

A review by Neufeldt and Albright (1998) of over 120 self-employment projects across low-, middle- and high-income countries found that there was considerably more experience in low- to middle-income countries in supporting entrepreneurship for people with disabilities than in high-income countries. In the context of people with intellectual disabilities, the small amount of research conducted on this model has addressed the best practice processes involved, rather than outcomes (Okahashi, 2001).

Despite it being a popular option for people with other disabilities, self employment was not considered a viable option for people with intellectual disabilities during a recent technical cooperation project in Zambia, on the grounds that they lacked business skills (Koistenen, 2008). While family-based businesses were seen as an option suited to those with higher support needs, involving support to the well-being of the family as a whole, they provided only limited opportunities for social integration and, in some cases; the people with intellectual disabilities were not receiving wages for their work efforts.

- **Social Firms:** Social firms are a type of social enterprise initially developed in the European context for people with psychosocial disabilities following the closure of the large 'mental asylums'. The specific social purpose of social firms is to create jobs for people who find it hardest to get them. (Sayce, June 2011).

Sheltered workshops have sometimes established small businesses which are labelled as 'social enterprises'. In Singapore, for example, MINDS (Movement for the Intellectually Disabled of Singapore*)*, an organization which provides sheltered employment for people with intellectual disabilities in Singapore, has established a car-wash business in a regular community setting. In this case, all of the workers are people with intellectual disabilities with limited opportunities to engage in regular work related or social activities within the general community. (Tay Tiong Beng & Aaron, 2003)

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

There is limited research information on the outcomes achieved by social firms for workers with intellectual disabilities. In a comparison of 40 people with intellectual disabilities working in a social enterprise and 40 others attending day centres, Forester-Jones et al. (2010) found that people in the social enterprise scored significantly higher on measures of life experience, self-esteem and satisfaction than those in day centres. They concluded, however, that while social enterprises represented better training settings for future employment compared to the day centres, social inclusion was still inadequate.

EMPLOYMENT MODELS/OPTIONS: DIFFERENT COUNTRIES

Recent decades have seen growing recognition of the working capacity of persons with intellectual disabilities in many countries around the world and a flourishing of initiatives to provide them with opportunities to perform meaningful, productive work in ordinary workplaces. Supported Employment has been the main approach adopted, in a variety of forms reflecting the different levels of support required by different persons with intellectual disabilities.It must be recognized, though, that the SE model was developed in high-income countries with well-established formal services. In low-income countries, the informal economy, especially in rural and less developed areas, is the major source of employment. People with intellectual disabilities are often employed in village-based industries, including farm work, similar to the patter in western countries in the pre-industrial era.(Parmenter, Trevor R.,2011) (ILO, 2011).

- **United States:** A feature of the SE programmes in the US, not always present in other countries, is the legislative base supporting inclusive employment options for people with disabilities in general. This strong legislation supported the initial growth of SE programmes across the country. At the same time, the strong support the US Federal Government gave to research and to research centres specializing in the study of intellectual disability was another significant factor in the growth and support of SE programmes. Legislation and subsequent funding initiatives led to better educational services for this population, including an emphasis on the transition of students with disabilities from school to work and further study.

Despite this enabling environment, there is consistent evidence that there has not been a parallel diminution in the number of people with intellectual disabilities in segregated sheltered employment settings (Braddock et al., 2008). And the latest State of the States in Developmental Disabilities, conducted by David Braddock and associates at the University of Colorado, reported that the proportion of Supported Employment workers among recipients of day/work programmes declined from a high of 24 per cent to 21 per cent in the period 2000 to 2006. The report also indicated that there is approximately a 3:1 ratio of non-competitive to competitive work outcomes for people served in day work, and sheltered employment programmes (Braddock et al., 2008).

Experience in the US indicates that the anti-discrimination provisions in the Americans with Disabilities Act (ADA) of 1990 appear not to have stimulated effective employment outcomes for people with intellectual disabilities. Therefore, it is assumed that there is still a strong belief that a person with cognitive limitations is incapable of gaining an integrated employment outcome, despite evidence that even those with high support needs are capable of learning complex tasks with adequate training and support (Bellamy et al., 1988; Gold, 1972, 1975; Horner et al., 1988).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Australia:** The development of employment services for people with intellectual disabilities in Australia has followed a similar trajectory to that of the US. In the early 1970s, the Australian Association for the Mentally Retarded (now the National Council on Intellectual Disability, or NCID) expressed concern about the high numbers of people with mild intellectual disabilities entering sheltered workshops rather than open employment (Rigby, 1973). The Australian Federal Government, through the Commonwealth Rehabilitation Service subsequently established seven Work Preparation Centres for school leavers with mild intellectual disabilities in a number of state capital cities. After 12 to 18 months of intensive job skills and social skills training, trainees obtained permanent employment in the open labour market, generally in manufacturing industries, which were the major employers in those years in Australia (Parmenter et al., 1977; Ward et al., 1978). During their ten years of programme development, the Work Preparation Centres commenced trials of SE models, based on the research work being conducted in the US.

In order to stimulate the development of paid employment in integrated settings, the Australian Government sponsored several open employment demonstration pilot projects, a number of which concentrated on supporting people with high support needs. One of these, Jobsupport, has continued since its inception in 1986 and has achieved one of the best records in the country for supporting people with intellectual disabilities and high support needs (Tuckerman, 2008a; Tuckerman, et al., 1999).

The overall picture currently for integrated employment in Australia is not dissimilar to that in other countries. There has been no reduction in the numbers of people with disabilities employed in segregated settings. In fact the Commonwealth Government, despite earlier attempts to limit funds to this area of employment, has given way to the strong lobby groups including parents and service organizations by accepting segregated options as a viable employment alternative. This is also in spite of strong anti-discrimination legislation and a formal commitment to the various United Nations Declarations and Conventions.

- **Canada:** Neufeldt et al., (2000) found that the SE model was fairly well established in the four provinces of Nova Scotia, Ontario, Manitoba and Alberta. Canadian SE programmes are funded by the federal government under the Opportunities Fund, some Labour Market Development Agreements and by provincial/territorial governments, or by cost-sharing with the federal government.

In Canada, as in other countries, there is a pattern of SE agencies rejecting applicants with complex needs, such as those with intellectual disabilities. Stainton et al. (2006) have suggested that the increasing market competition in service provision and the emergence of for-profit organizations into the disability 'industry' have increased the 'commodification' of disability (in other words people with intellectual disabilities become commodities from which to make a profit), resulting in competition among agencies for clients who are easier to support. Special incentives may have to be built into the funding systems to counter the trend towards 'creaming' practices.

- **Finland:** With Finland's entry into the European Union (EU) in 1995, the country could access the Community Initiative Programmes of the EU Social Fund (ESF) to start several pilot projects on SE for people with intellectual disabilities. Regular surveys of the state of SE in Finland have been conducted since 1998 (Saloviita and Pirttimaa, 2007).

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is concluded that since the introduction of SE programmes in 1995, no more than 100 people had been supported. Clear changes in the composition of the people being supported changed markedly during the period 2001–2003. There was a major increase in the proportion of people with mental illness and a similar decrease in the proportion of those with intellectual disabilities being supported. The original concept of SE appears to have been distorted to be used to facilitate employment of people from different marginalized groups and, in the process, people with significant intellectual disabilities have found themselves barred, with sheltered employment and day care centres being the main options (Saloviita and Pirttimaa, 2007, p. 233). It clearly indicates that there are differing moral, political and economic value systems operating when the question of how best to support people with intellectual disabilities is considered, in contrast to other marginalized groups in a society.

- **Ireland:** Ireland has also been at the forefront in pilot-testing SE, the first programme being introduced in the late 1980s when a not-for-profit organization, St Michael's House, set up the "Open Road" demonstration project designed to provide job coaches for adults with moderate to severe intellectual disabilities to support them finding regular entry-level jobs. Soon after, several other similar programmes were initiated by other not-for-profit organizations, including St John of God's STEP Enterprises, Sunbeam House's Dargle Employment Centre and KARE's Employment Assist Bureau. At a conference Disability and Employment - What the Research tells Us, sponsored by the National Disability Authority, McCormick and McRae (2005) cited the 1996 RISE evaluation study by Lynch, McCormack, Pierce and Kelly into the status of SE in Ireland which found that 388 individuals in 30 agencies were in part-time employment, using the individual Supported Employment model, increasing to 449 by 1999. By 2005, McCormick and McRae reported that almost all agencies supporting people with intellectual disabilities offered supported employment to at least some of their service users.

In their paper McCormick and McRae (2005) highlighted that many people with intellectual disabilities who were working in Dublin supermarkets did not progress beyond entry-level jobs and did not get opportunities to move onto jobs of their choice. They emphasized the need for job development and career enhancement through additional on-the-job training. They also raised the possibility that low expectations of employers were placing a ceiling on the potential of people with intellectual disabilities. Kelly, Craig and Kelly (2010) reported that in 2009, 951 persons with intellectual disabilities were in some form of SE, whereas a group four-fold in size attended sheltered workshops. Still, questions remain as to whether the extension of the SE model to people with other impairments, such as those with mental health disabilities, has led to discrimination against people with intellectual disabilities who have higher support needs; the very population for which it was originally designed.

- **The Netherlands:** In the Netherlands, in addition to special secondary schools, there are two options for students with intellectual disabilities within the mainstream system - the 'supported learning route' and the 'practical education' route. The former is more appropriate to students who will graduate with a diploma, provided they receive special needs support. The pre-vocational practical education route is for students with higher support needs who would not qualify for a diploma even with additional support as reported in (The Netherlands Monitoring Report, 2005). The situation for people with intellectual disabilities in the Netherlands is not dissimilar to other countries with a history of welfare provisions for people with disabilities. Likewise, its extensive

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

legal and policy framework establishes an approach that supports active independent living and access to employment for this population. The Netherlands is attempting, as are other high-income countries, to rein in burgeoning numbers of people who are in receipt of unemployment and disability welfare payments. This policy is having a negative effect on open employment opportunities for people with intellectual disabilities, as government initiatives to increase the employment participation rate of people with disabilities tend to target people with lower support needs. Despite some strong attempts to increase numbers of people with intellectual disabilities accessing SE, sheltered employment appears the preferred option for this population for the majority of parents and government. (Trevor Parmenter, 2011).

- **New Zealand:** The repeal of the 1960 Disabled Persons Employment Promotion Act and the adoption of the Minimum Wage Amendment Act in 2007 ensured that people with intellectual disabilities are guaranteed the same employment rights as other workers, including the payment of the minimum wage to people employed in sheltered workshops, unless an individual work has an exemption.

A partnership between IHC New Zealand and Tokanui Psychiatric Hospital led to the development in 1990 of the Teawamutu Gracelands Trust to support patients moving out into the community. The Graceland Group of Services has expanded its services across New Zealand, supporting people with disabilities (including intellectual disabilities) in inclusive employment opportunities and helping them to live independently or semi-independently. In the early 1990s a small group of people who had been pioneering SE in New Zealand set up the Association for Supported Employment New Zealand (ASENZ). ASENZ has developed and refined a set of principles of SE which are universally applicable. These are now accepted as the core principles and are central to all aspects of SE in New Zealand. The Association has given significant attention to training and development for people who work in SE. To date, New Zealand has not developed a significant research profile in SE. Thus, data on SE outcomes are unavailable. However, ASENZ has a considerable number of association and individual members, indicating that SE is seen by government and service providers as a strongly viable employment option. (Annual Report, New Zealand Disability Support Network, Annual General Meeting, 25 September 2014).

- **United Kingdom:** Supported Employment had its early beginnings in the United Kingdom (UK) around 1985, about the same time as pilot programmes were being sponsored in Australia and Ireland (Beyer et al., 1999). The term 'supported employment' in the UK at that time was used by the UK Government's Employment Service, responsible for vocational rehabilitation of people with disabilities, to describe sheltered workshops and a wage subsidy scheme that operates largely without job coach support. This is similar to the way the terminology is currently used in Australia.

Three important UK Government initiatives provided a useful framework in which to examine the penetration of SE in improving the life quality of people with intellectual disabilities. The first is the Disability Discrimination Act (UKDDA), which was passed in 1995. The UKDDA defines a person with a disability as someone who has a physical or mental impairment that has a substantial and long-term adverse effect on his or her ability to carry out normal day-to-day activities. The Act seeks to prevent discrimination on the grounds of disability in employment and other areas. The second important initiative was the release in 2001 of "Valuing people: A New Strategy for Learning Disability for the 21st Century", which identified significant difficulties in the coordination and delivery of services to

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

people with intellectual disabilities in the UK (Department of Health, 2001). In recognition of the slow progress being made in achieving objectives in employment for people with intellectual disabilities, the UK Government has recently released Valuing Employment Now – Real Jobs for People with Learning Disabilities (Department of Health, 2009). This strategy sets out an ambitious goal to radically increase the number of people with intellectual disabilities in employment by 2025. The strategy will focus on people with moderate and severe intellectual disabilities, because they have benefited least from previous initiatives. This was a major landmark policy event in the UK, being the first Government White Paper in 30 years dedicated to people with intellectual disabilities (UK,Department of Health, 2009).

REMPLOY, the leading UK provider of specialist employment services for people facing complex barriers to employment, offers a combination of supports to placement in mainstream employment along with work opportunities in businesses which it runs in different parts of the country, catering solely to persons with disabilities. Following a review of its future business options in 2006, to enable it to support more disabled people into open employment in a cost effective manner, REMPLOY has taken steps to expand its network of tailored employment support services ('Interwork'). While people with intellectual disabilities (called 'learning disabilities' in the UK) are acknowledged to have high support requirements when it comes to mainstream employment, Interwork reports considerable success in its placement rates for job-seekers with this type of disability (see: http://www.remploy.co.uk).

- **Other European Countries:** The unemployment rate for people with intellectual disabilities in Eastern European countries was found to approach almost 100 per cent (Open Society, 2006). The vast majority who do work are found in sheltered workshops, and those with high support needs are generally directed to day activity centres. However, there was evidence of attempts to increase the participation of people with intellectual disabilities in SE. In a comparative study of Supported Employment in ten countries of Europe, undertaken in 2006-2007, it was found that over a third of users of SE services (35.3 per cent) were people with intellectual disabilities (Jordan de Urries, Beyer and Verdugo, 2007).

The European Union of Supported Employment (EUSE), established in 1993 and now with 19 national associations for SE, is a driving force in the endeavor to increase employment opportunities for their clients. EUSE conducts regular conferences and training workshops across Europe. It recently received support from the European Union Leonardo Partnership to develop a European Supported Employment Toolkit which was completed in mid-2010. This toolkit consists of a range of position papers and 'How To' guides, and has been designed to increase the knowledge and skills of professionals responsible for the delivery of Supported Employment services. To increase the replication of good models at the national and international levels will require strong government support. (EUSE Toolkit 2010)

- **Singapore:** Educational and employment services for the majority of people with intellectual disabilities are provided by two large voluntary agencies: the Association for Persons with Special Needs (APSN), which conducts schools and employment services for those with 'mild' intellectual disabilities; and the Movement for the Intellectually Disabled of Singapore (MINDS), which conducts schools, employment services, day activity programmes and residential living for those in the 'moderate' to 'severe' range. Both organizations conduct traditional sheltered workshops and programmes known as 'social enterprises'. Examples of social enterprises in Singapore are a car wash 'crew' which works in a regular community setting, and a 'thrift shop' that sells recycled

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

clothing. While in some cases, these enterprises are located in regular community settings, they tend to project a welfare impression, rather than a regular commercial image. (Parmenter, Trevor R., 2011)

- **Japan:** In 1966, Japan adopted a voluntary employment quota policy to benefit workers with disabilities. Since 1976, under amendments to the Law for Employment Promotion for Persons with Disabilities, the quota is now a legal obligation, initially relating to persons with physical disabilities only. In 1998, amendments to the Law extended its provisions to people with intellectual disabilities. Two hundred and forty two such companies existed, employing 7,700 persons with disabilities. Over 40 per cent of these employees were persons with intellectual disabilities. (Parmenter, Trevor R., 2011)

The Japan Association for the Employment of the Elderly and Persons with Disabilities (JEED) plays a major role in implementing the nation's policies for people with disabilities. As part of its role, JEED conducts research into employment support methods for various disability groups, including those with intellectual and other developmental disabilities.Through its network of Local Vocational Centres for Persons with Disabilities, JEED provides support to people with intellectual disabilities in work experience and job coaching in order to facilitate a smooth transition to work opportunities. JEED also provides extensive support services to employers, including general information, counselling services, employment management support and technical advice.

The Japan International Cooperation Agency (JICA) has been active in assisting the development of SE and the training of job coaches in the Asia Pacific region. (Parmenter, Trevor R.,2011)

- **Malaysia:** In July 2008, the Malaysian Government passed the Persons with Disabilities Act, marking a shift from the former charity model to a rights based approach for people with disabilities in Malaysia. This Act stresses the importance of accessibility, equal opportunities and protection and assistance from the government, private sector and NGOs to ensure the full participation of disabled people in society. The National Council for Persons with Disabilities was subsequently established and a National Action Plan for Disabled Persons 2007-12 was developed.

The Joy Workshop in Melaka was founded in 1999 to improve the quality of life of persons with learning disabilities through integration into society through employment opportunities and enhanced community living skills. Its INTOWORK programme supports the transition of workers from the sheltered workshop environment into SE. Inspiration for this initiative was the work of the late Marc Gold and his "Try Another Way" approach to training people with intellectual disabilities. The approach starts from the underlying conviction that everyone can learn. It involves a planning process with the individuals with disabilities, their families and employers; proposed job matches, based on the requirements of jobs and individuals; actual job match based on job analysis; commencement of work, with on-site assistance, fading and transfer; and on-going support where needed (Warner, G. 2010)

- **South America:** Centro Ann Sullivan del Peru (CASP) was inaugurated in 1979 by DrLiliana Mayo with the help of her parents and colleagues, teaching eight children with different abilities in the garage of her parents' home located in the district of La Punta, Callao, Peru. Since 1985, Dr Judith M. LeBlanc, from the Schiefelbusch Institute for Research in Life Span Studies of the University of Kansas, joined the CASP as principal consultant. With Dr LeBlanc's specialist edu-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

cation input, CASP has turned into an international model centre where a series of unique teaching procedures have been developed into what is known as the Functional-Natural Curriculum. (Mayo,LeBlanc,2000).

The CASP SE programme is aimed at youths and adults with different abilities (such as autism, Down syndrome, cerebral palsy or developmental delay) of 16 or more years of age, who have the skills to be included full-time or part-time paid work in a real workplace. For example, student workers of the SE programme started working at the Ministry of Health (MINSA) in February, 2011. Tasks such as putting codes on documents, filing and other clerical duties have been assigned to them. They have become the first young people with different abilities who work for public institutions in Peru. An agreement reached between CASP and MINSA in October 2010 made possible this important hiring. It is part of a plan for promoting inclusion for people with different abilities into the Ministry of Health, a policy the present administration strongly supports. The CASP SE programme follows the principles first established by researchers in the US, including job coaches and on-going support in real jobs in the community. (Parmenter, 2011)

- **India:** The prevalence of intellectual disability is 94 out of 1,000,000 population (NSSO 2002). There is a paradigm shift in the approach to disability rehabilitation from charity mode to right based. However, Persons with intellectual disability have been proving their skills in specific jobs. Department of Adult Independent Living (DAIL) of National Institute for the Mentally Handicapped (NIMH) strives towards improving quality of life of Persons with Intellectual Disability through vocational training and placement services. As part of these services, the Adult persons with intellectual disability are trained to acquire vocational and independent living skills. Independent living means living like anyone else with same limitations and same opportunities. Persons with intellectual disability also observe the same style of living like other individuals of their society. The ability of Persons with intellectual disability to be productive was linked to social behaviour and practice and bore very little relationship to their intelligence (Cornelius D.J.K, 2009).

The Government of India has set up the Vocational Rehabilitation Centre for disabled at Bangalore and the same has been functioning from 1991. The Centre is providing vocational training in Computers, Carpentry, Welding, Fitter, Electrical, Embroidery, Book Binding and Tailoring etc. The Vocational Rehabilitation Centre has provided 100% placement for all the trainees who have undergone training. The Vocational Training Centre also provides counselling services for children/ persons with intellectual disabilities. The Government also has a scheme to provide incentive employers. for providing employment to persons with disabilities in the private sector. The Rehabilitation Council of India (RCI) was set up as a registered society in 1986. On September, 1992 the RCI Act was enacted by Parliament and it became a Statutory Body on 22 June 1993. The Act was amended by Parliament in 2000 to make it more broad based. The mandate given to RCI is to regulate and monitor services given to persons with disability. There is a need to study on the prevalence of employed persons with intellectual disability. Further more studies need to be done involving more number of HR professionals in different locations of the country. These efforts will enhance awareness creation among HR professionals regarding vocational potential of persons with intellectual disability. This in turn boosts inclusive employment of persons with intellectual disability in Govt. and Corporate sectors. HR policies may be developed and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

implemented to recruit the persons with intellectual disability. Data bases of trained persons with intellectual disability potential for employment need to be developed by the Govt. agencies in collaboration with all organizations working for empowerment of persons with intellectual disability. Employment exchanges need to register potential candidates and enable providing suitable employment (Bino S. Berry and K. Ravi Kymar).

- **Low-Income Countries - Examples from Africa:** There is a dearth of examples of SE in Africa for people with disabilities in general, and those with intellectual disabilities in particular. This is not surprising, given the degree to which this section of the community has been discriminated against for a variety of complex reasons; a major factor being general community negative attitudes toward this population (Mung'omba, 2008). Even in countries where SE has been an employment option for several decades, the take-up has been difficult. One of the reasons for this is the lack of government initiatives to ensure the long-term sustainability of programmes for people with high support needs, despite the cost benefits that can be achieved. There also remains a tension between the welfare and human rights approaches to support for people with disabilities.
- **South Africa:** The Living Link, a non-profit organization, founded in 2000 in Johannesburg, South Africa, supports the inclusion of people with intellectual disabilities in society and facilitates their transition from school to work to independent living. Students at the Living Link complete an Adult Integration Programme aimed at integrating them into society and into the community. The programme is life-skills based and focuses on practical components of daily living that are essential. After students have graduated from the programme, the Living Link assists in placing their members in suitable positions in the open labour market using a SE approach. Adults are placed in ordinary working environments, doing regular work where salaries and benefits are realistic and reflect work performance. Supports are provided to the employers and employers, in a mutually beneficially way. (Julia, Ingrid, 2000).

The Ntiro Project for Supported and Inclusive Employment, founded in 2000 in the Tschwane South District of the Guateng province of South Africa, targets the multiple barriers that people with intellectual disabilities face in the areas of education and work. Of particular significance is the Ntiro Project's emphasis on changing attitudes and building integrated community-based support. It gives strong focus to providing information and skills to district officials, NGOs and community organizations, and to building partnerships among them. The inclusive model has proved extremely successful, serving to progressively replace older segregationist models throughout the district. The project gives concrete expression to the new vision of inclusive education in South Africa and to the call for more inter-sectoral approaches. (Permenter, 2011).

- **Zambia:** The concept of Supported Employment for people with intellectual disabilities has been introduced in Zambia through a project funded by the Government of Finland. Implemented by the Finnish Association on Intellectual and Developmental Disabilities (FAIDD), in association with the Zambia Association on Employment for Persons with Disabilities (ZAEPD), the project focused on examining the relative benefits of an SE model in formal and informal economies, small business ventures and self-employment (Koistinen, 2008). Through this project, which ended in 2005, more than a hundred graduates were placed in employment either in the formal economy (as kitchen assistants, agricultural workers, office orderlies, cleaners, tailors and weavers) and in the informal economy (as housemaids, gardeners and poultry workers) which absorbs up to 70 per

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

cent of the Zambian labour force. This project is an excellent example of collaboration between a high income country with experience in SE policies and practices, and a low income country. The issue remaining to be addressed, however, is how to ensure the sustainability of such initiatives, especially job retention, when the foreign aid programme concludes. (Koistinen, 2008).

CHARACTERISTICS OF SUCCESSFUL PROGRAMMES

- **Commitment of Stakeholders:** Programmes in which all the stakeholders, including government, employers, service providers and families, were committed to the principle of equity for people with intellectual disabilities led to successful and sustainable integrated employment outcomes (Mills, 2006; Wehman et al., 2006).
- **Programme Size:** Programme size appears to play a role in the type and range of day and/or employment services offered. In a national survey of rehabilitation agencies in US, Kiernan, Gilmore and Butterworth (1997) reported that smaller agencies, providing support to 50 people or fewer, were found to be more likely to provide integrated employment exclusively than larger organizations. In the current globalized climate of business amalgamations, based on the principle of economies of scale, the loss of a personalized service militates against the delivery of effective outcomes for individual beneficiaries.
- **Support Needs Assessment:** A comprehensive support needs assessment of the person with intellectual disabilities has been shown to be important, not only for the purposes of employment, but also for other life activities, including community living and leisure activities (Riches et al., 2009a, 2009b; Thompson, et al., 2004). It has been shown that work cannot be dealt with in isolation from other life activities (Halpern, et al., 1986). In terms of the sustainability of integrated employment, there is overwhelming evidence that people with intellectual disabilities tend to lose jobs, not because of their inability to perform the job tasks, but because of negative social behaviours (Chadsey et al., 1999; Knox and Parmenter, 1993). On the other hand, Chadsey et al. (1997) warned against too much emphasis being placed on a 'deficit-remedial model', rather than emphasizing the congruence or 'ecological fit' between the person and his/her environment. It may be more efficacious to find the right environment, rather than changing a particular social behaviour. This principle is especially relevant for people with intellectual disabilities and high support needs.
- **Person-Centred Planning:** Person-centred planning puts the person with the disability at the centre of the decision-making processes, taking into account the person's wishes and desires (Coyle and Moloney, 1999; Wiese and Parmenter, 2009). In the employment area, strong motivation on the part of the person seeking a job has been shown to be a significant predictor of a satisfactory outcome. Whilst more work remains to be done on assessing the impact of person-centred planning on client outcomes and satisfaction, research to date has shown promising results (Robertson, et al., 2006). In the pilot SE project in Zambia, Koistinen (2008) found, that good job matches were made when job-seekers' preferences and needs were recognized, leading to better long-term outcomes.
- **On-Job Support:** The 'place, train and support' model for SE usually involves job coaches working with the potential employee to identify interests and skills. This is followed by job seeking, matching and placement. The employer might also be encouraged to make adaptations (i.e. ac-

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

commodations) to a specific job in order to match it with the abilities and skills of the employee with an intellectual disability. In many cases the job coach might learn to do the job first, in order to subsequently teach the employee with the disability. In other circumstances, the employer might prefer for a regular staff member to teach the skill. This person may subsequently become a 'mentor' to the person with the disability. Another role for the job coach is as support to families who may initially have negative attitudes to their son/daughter working in a regular work environment, because of fears that they may be victimized. Parents of children with a disability are frequently over-protective. For others, cultural factors may encourage them to persist in hiding their child with a disability because of negative community prejudices (Mung'omba, 2008).

- **Parental Support:** Griffin et al. (2008) and Lindstrom et al. (2007) stressed the importance of families' attitudes toward their adult children's capabilities as being a critical determinant in their support for community-based employment options. Since the first point of contact in the diagnostic process is the medical and allied health professions, limited expectations are often entrenched in the child's early years. Lack of career choice was highlighted in a study of attitudes of parents and primary caregivers of people with high support needs towards SE (Ford et al., 1995). This study also emphasized the need for greater communication between the service providers and families. Donelly et al. (2010) have shown the importance of family networks to the person with intellectual disabilities achieving satisfactory employment outcomes. Koistinen (2008) concluded that parental support was important, though often lacking in Zambia, especially at the vocational training, job-seeking and placement levels.

CONCLUSION

Since its inception in the 1970s, SE has provided inclusive employment options for people with intellectual disabilities across several continents. The personal stories of what having a job means to people with intellectual disabilities is testimony to how important this issue is in terms of social justice and human dignity. A key factor in the growth of initiatives has been a clear policy commitment by governments to support such initiatives. However, experience from both high- and low-income countries indicates that on-going support is required for these initiatives to be sustainable. Low-income countries, given their rural nature and severe fiscal constraints, may be in a better position to test a number of the alternative models described above. For instance, self-employment, small business enterprises, and, at a regional level, CED, may be viable options, but these have not as yet been critically analysed. The evidence from a study conducted in Zambia questioned the viability of the small business enterprise model for people with intellectual disabilities, as it was suggested they lack the necessary business skills (Koistinen 2008, p. 32). An alternative would be to employ a person with business experience and a strong commitment to assisting people with intellectual disabilities, as the manager. The SE principles, including the important 'place and train' and on-going support features, can be used in each of these approaches. A positive feature is the growth of national SE organizations which provide advocacy and training support to their constituents. As these organizations gain strength, they may be in a position to mentor initiatives in low-income countries.

Two phenomena are emerging in countries where SE has a longer history. First, there is a natural tendency to extend SE to other disability groups; for instance, to people with mental health disabilities. This has had the effect of lessening the take-up for people with intellectual disabilities. The second, and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

related, issue is the tendency for agencies supporting SE to select easier-to-place people for SE programmes. To further complicate the matter, the exponential growth of people receiving welfare benefits has led governments in many parts of the world to tighten the criteria and the assessment processes in an attempt to rein in welfare expenditures. However, a contrary position has been taken by Heath (2010), whose analysis suggest that welfare benefits to people with disabilities reduces poverty, but does not necessarily discourage employment.

Various countries have clear policies concerning employment for people with disabilities in general, which affirm the goal of community integration and support for individual choice. Despite this, however, the reviews highlight the reality that the vast majority of people with intellectual disabilities still do not have access to integrated employment; and in many cases, no access to any meaningful day activities.

At National level, Governments in consultation and collaboration with civil society and social partners bear responsibility for promoting opportunities for people with intellectual disabilities to take part in their communities and the broader society. They have to conduct a systems analysis of current situations, develop a set of goals and objectives to guide the implementation of SE initiatives and develop a national policy on integrated employment for people with intellectual disabilities. They have to develop a national implementation strategy and have in place an effective data collection system designed to track progress. Further they have to communicate the results of programmes to assist the process of attitudinal change among social partners in the community and widely disseminate positive results of pilot projects through all available media, since success stories can stimulate further successes. Also they must involve social partners and community leaders to act as 'champions' who can assist this process.(Parmenter T.,2011)

At Regional level it would be of value to develop a Regional Association of Supported Employment. To assist in the sharing of information and technical assistance, consideration may be given to the establishment of a regional support organization modelled along the lines of the European Union for Supported Employment (EUSE) or the World Association for Supported Employment (WASE), which would have Links with the EUSE and similar national associations for supported employment would give access to training materials and other technical assistance. These would subsequently organize workshops and training programmes at regional and/or national levels.

Despite enormous challenges, including extreme poverty and difficulties faced from attitudinal and policy perspectives in the provision of support to people with disabilities in general, and those with intellectual disabilities in particular, there are some positive trends. Of special significance is that the majority of countries around the world have subscribed to the various contemporary human rights principles relating to people with disabilities. What remains is the need for a genuine commitment to ensuring these principles are not only incorporated into national disability policies, but are put into practice and monitored to the best level possible in terms of the socio-economic conditions prevailing. Most countries have signed and ratified the UN Convention on the Rights of Persons with Disabilities. Article 27 of the Convention states:

States parties recognize the right of persons with disabilities to work on an equal basis with others; this includes the right to the opportunity to gain a living by work freely chosen or accepted in a labour market and work environment that is open, inclusive and accessible to persons with disabilities. States parties shall safeguard and promote the realization of the right to work.

This statement provides a compelling reason to explore how a country, even with limited resources, might embark on a programme to assist one of the most disadvantaged groups in its society to become

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

engaged in work 'that is open, inclusive and accessible'. The fact that countries around the world have enacted specific disability legislation is a positive feature, but as noted throughout this chapter, people with intellectual disabilities are often left until last in the provision of support.

Chapter 60
Effectiveness of Internet Based Psychotherapeutic Intervention in Common Psychiatric Disorders

Shilpa Suresh Bisen
Visvesvaraya National Institute of Technology Nagpur, Nagpur, India

Yogesh M Deshpande
Visvesvaraya National Institute of Technology Nagpur, Nagpur, India

ABSTRACT

The rationale of the article is to describe the use of the Internet for psychological treatment in a clinical setting. Internet-based psychotherapy as a therapeutic tool, that offers an anonymous way for people to search for information and participate in treatment. Research studies on web-based psychotherapy for the major depressive disorder, anxiety disorders and other psychological conditions has grown swiftly in the last decades. Findings revealed that some forms of Internet-based treatments often lead to results similar to those of traditional face to face psychotherapy. The advantages of Internet-based interventions are high-cost effectiveness, greater access to evidence-based treatment, and greater access to patients in remote locations. The deterioration of symptoms, the emergence of new psychological symptoms, a high rate of abandonment and the frustration caused by technical problems are some of the negative effects of Internet interventions. In conclusion, there is now ample evidence that Internet based-interventions work for common mental disorders such as depression, anxiety disorder, alcohol consumption, smoking cessation, eating disorders, headaches and insomnia. Research on interventions on the Internet is advancing at high speed, while the proliferation and prolonged implementation of interventions on the Internet in regular assistance is still in its infancy.

INTRODUCTION

Internet-based psychotherapeutic intervention is mainly a self-directed psychotherapeutic intervention program implemented via a potential website program used by patients seeking mental health assistance. These are categorized into psycho-education intervention on the Internet. Therapeutic intervention on the basis of self-directed Internet-based therapeutic interventions on the Internet with human support. The benefits of Internet-based psychotherapy are highly cost-effectiveness, better access to evidence-based management, and feasible approach to patients in remote locations (Carlbring & Andersson, 2006). The worsening of symptoms, the appearance of new psychosomatic symptoms, elevated rate of abandonment, the lack of positive effect expected in the symptoms of the target and the annoyance caused by technological problems are some of the disadvantages of Internet interventions (Boettcher et al., 2014). The Internet has the potential to have a great impact on society and human behaviour. One of the most promising applications of the Internet is within the psychological and therapeutic fields. There are many potential benefits to providing psychotherapy and assessment on your computer. Internet-based therapy is a form of psychotherapy conducted over the Internet rather than in face-to-face sessions. Therapeutic sessions may be conducted using instant messaging, chat rooms, or e-mail messages. Internet-based therapy is also called online therapy or e-therapy.

There are pros and cons to both sides of the online versus face-to-face therapy issue. First, communicating through e-mail, online chat, or instant messages has the same drawbacks of any written-only communication: The non-verbal cues such as tone of voice, facial expression, and body language are missing, making interpretation of the message more problematic than in a face-to-face situation. On the other hand, the relative anonymity of online interactions makes such therapeutic relationships more attractive to those who would hesitate to go into a therapist's office for fear of being found out by others, fear of embarrassment, or unwillingness or inability to get to the office. In addition, online therapy tends to be less expensive than in-office therapy, a consideration for many clients. As with any service provided over the Internet, one must be an informed consumer not only before choosing an e-therapist but even before deciding to use Internet-based therapy itself. Because Internet-based therapy is an emerging field, there are still many issues to be resolved. Obviously, one must check the professional credentials of a therapist to make sure that he or she is licensed, whether one is choosing a therapist for online or in-office therapy. In addition, it is unclear at this time whether it is legal for a therapist licensed in one state to treat a patient in another state. Choosing a therapist in one's own state makes this issue irrelevant, but requires research.

Client/therapist confidentiality is important in any therapeutic relationship. When choosing an online provider of psychological services, one must be certain not only that the therapist subscribes to a professional code of ethics, but also that any information—including personal data about the client—is kept confidential and not sold to or shared with third parties. Similarly, it is important to check that the Web site used in online therapy is secure and that conversations, instant messages, and e-mail transmissions between client and therapist are not recorded on the site's secured host computer.

Internet-based therapy shows promise for helping people who could not or would not otherwise engage in a therapeutic relationship. This potential is beginning to be tested in research. However, much of this research also recommends that Internet-based therapy is used in conjunction with face-to-face sessions. There are still many technical, logistical, and ethical questions to be answered regarding how the Internet best can be used for therapy.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to these authors, internet-based psychotherapeutic interventions are not a new phenomenon but have been around for at least 15 years. Internet-based psychotherapy has multiple formats:

1. Self-help web-based therapy (web-based therapy without human interactions)
2. Online communication-based therapy, internet therapy (with therapist support)
3. Synchronous delivery, therapy in real-time via the world wide web (chat)
4. Asynchronous delivery, delays between therapeutic exchanges (email, forums)
5. Therapeutic exchanges via instant typed messaging platforms
6. Audio-only therapeutic exchanges (with or without telephone support)
7. Therapeutic exchanges via video/webcam (with or without telephone support)
8. Group therapy
9. Individual therapy
10. Cognitive behaviour therapy
11. Psycho-education
12. Behaviour modification

Challenges of internet-based psychotherapy include confidentiality concerns, licensing laws, legal jurisdictions, professional insurance, special training requirements, and most importantly, lack of face-to-face visibility important for nonverbal communication, which is thought to be essential for the therapeutic exchanges. None of these concerns has stopped numerous professionals from utilizing this new mode of delivering therapy. The limit seems to be a dependency on electricity and access to the World Wide Web.

Advantages of internet-based psychotherapy include better therapist availability, high acceptability by clients, a greater variety of modes of communication, availability of anonymity should it be desired, psycho-education enhancement by video technology, graphics, and interactivity. Evidence suggests that therapeutic bonding or working alliance is still achievable. Evidence also suggests that Internet-based psychotherapy appears to be more or less effective as part of the treatment for a variety of psychological, psychiatric, and physical problems: chronic stress, loneliness, hazardous behavior, body dissatisfaction, eating disorder, over-eating, binge drinking, pre-surgery anxiety, smoking, depression, post-traumatic stress, anxiety, panic, social phobia, agoraphobia, bed-wetting, insomnia, tinnitus, traumatic brain injury, chronic headache, and chronic back pain.

Challenges and Future Directions in Researching Internet Psychotherapy Interventions

Some of the most important issues are:

1. for whom and how Internet treatments work
2. how Internet treatments can and should be disseminated and implemented in regular healthcare
3. how Internet interventions can best be combined with face-to-face treatments

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

Treatment Models for Internet-Based Psychotherapy

Most Internet-based psychotherapy treatments are based on cognitive-behavioural models (Andersson, 2009), but other approaches such as psychodynamic, interpersonal and eclectic (or integrative) treatments have also been evaluated (Andersson et al., 2012).

A recent development is the use of trans-diagnostic and tailored treatments that address the problem of high co-morbidity rates in patients with common mental disorders (Titov et al., 2010). While trans-diagnostic treatments target common elements of several disorders, Internet-based tailored treatments do not use the same protocol for all patients but individually tailor the self-help material to the symptom profile of a patient.

Most of the growing body of evidence comes from studies evaluating guided self-help treatments in which the main component of the intervention is a Web-based self-help program. Such programs are typically arranged into a series of lessons or modules that include exercises and homework assignments.

While patients work through the program, therapists assist and support patients. The amount of contact between patients and therapists and the time therapists spend working with patients varies between studies. However, the majority of interventions only involve minimal guidance via e-mail, which requires considerably less time than face-to-face psychotherapy. Often, minimal guidance consists of a weekly feedback to patients on their behaviour and progress in the self-help program. It is mainly aimed to motivate and reinforce the patients' independent work with the self-help guide and to provide patients with a time structure that corresponds to the weekly scheduling of face-to-face therapy.

Efficacy of Internet-based Guided Self-help Treatments

Independent replications have shown moderate to large effect sizes for Internet treatments in comparison with control groups for the efficacy of Internet-based guided self-help treatments for anxiety disorders and depression (Hedman, Ljótsson, & Lindefors, 2012). Moreover, in some direct experimental comparisons between Internet-based treatments and face-to-face therapy, no differences have been found between the two approaches.

An important limitation of the evidence is that most of the studies were efficacy trials conducted in university-based research settings with participants recruited from the community. However, in a recent review, four controlled trials and eight open studies conducted under clinically representative conditions were identified showing that the promising effects of Internet-based guided self-help treatments can also be observed when the treatment is transferred to regular clinical settings.

Combining Internet-based Psychotherapy Treatment and Face-to-Face Therapy

Blending internet-based treatment with traditional face-to-face therapy has gained in popularity (see e.g., www.ecompared.eu). It is likely that therapists are getting more and more used to providing some interventions online, while still having face-to-face therapy sessions. However, more research is needed on how Internet interventions can best be blended with traditional forms of care.

The Internet has the potential to have as great an impact on society and human behaviour. One of the promising applications of the internet lies within the psychological and therapeutic domains. There are several potential benefits to offering psychological treatment and assessment over the computer.

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. As a therapeutic tool, the computer offers an anonymous way for people to seek information and engage in treatment.
2. Being able to access information and services from the comforts of home or another private location reduces barriers that may significantly hinder a patient from receiving necessary care.
3. Delays in seeking treatment may stem from several concerns: shame/embarrassment, lack of time, and lack of nearby services. Thus, it may be easier for patients to disclose information about themselves.
4. It also is believed that people may be less self-conscious without the pressures of face-to-face interactions. Also, it may reduce social desirability and pressure for a patient to respond in a particular way (Skarderud, 2003).
5. It can be implemented in a cost-efficient manner and can create written records of patient interactions that can be examined and used as treatment progress (Miller &Gergen, 1998). These records may facilitate treatment compliance, as tracking devices can be utilized to determine whether a participant viewed a particular Web page or opened an e-mail (Murphy & Mitchell, 1998).
6. Another important benefit is that they are not time-dependent; in other words, participant-to-participant or participant-to-provider communications can occur asynchronously at any time—electronic bulletin boards are available 24 hours a day, seven days a week, making support accessible on an as-needed basis.

The internet offers many applications for treatment of various psychiatric disorders. The basic types & the principles underlying their use are as follows:

Applications with Minimal or No Therapist Interaction

Applications with minimal or no therapist interaction range in intensity from Web-based self-help treatments with little or no feedback to fully automated applications where the computer "functions" as the psychotherapist. The major advantages to these treatments lie in the ability to widely disseminate them much more inexpensively than traditional therapies.

Applications Involving Asynchronous Computer Contact

Asynchronous computer contact facilitates communication among those with the same disorders (Internet support groups) and for communications between patients and providers (Internet therapy) It is characterized by messages between people that do not take place simultaneously (e.g., e-mail, list servers, and electronic bulletin boards). Messages can be sent or posted by one individual to be read and responded to by others at their leisure. Asynchronous, online social support groups have been studied for a range of disorders including sexual abuse, suicide and depression (Finn, 1995).In general, results have found that online groups provide therapeutic factors and support similar to face-to-face formats. The main advantage of internet therapy is the convenience offered to consumers. The time spent travelling to the treatment centre and actual time spent in psychotherapy can be greatly reduced utilizing e-mail or chatrooms. Behavioural treatments for less sensitive disorders have been delivered via e-mail. Internet behaviour therapy includes structured behavioural lessons posted on the Web site each week, tips and links to other sites, reporting of self-monitoring information via Web-based diaries, opportunities for group support via electronic bulletin boards, and participant–therapist interactions via e-mail.

Applications Involving Synchronous Computer Contact

Synchronous communication is more interactive and better mimics face-to-face interactions, as every sentence typed is immediately displayed on the screen for other participants to respond to in real time. They take place in common areas, or chatrooms, where participants can simultaneously log onto a particular Web location to interact and communicate with each other. It also allows for discussion and practice of particular skills, such as cognitive restructuring or role-playing.

Computer-Based Cognitive Behavioural Therapy for Psychiatric Disorders

The highly structured approach of Cognitive Behavioural Therapy (CBT), with clearly defined processes and concepts, is particularly well suited to an online format and predominates the current pool of online interventions (Carlbring & Andersson, 2006). Computer-assisted CBT typically consists of presenting aspects of CBT via computer, including the rationale for treatment, instruction in various anxiety management techniques, and instruction in exposure. Computers have been shown to be effective in delivering several standard aspects of CBT used mainly in the treatment of depression, post-traumatic stress disorder & panic disorder. An overview of a few studies depicting various interventions are as follows: (Amstadter et al,2009)

Table 1. Table showing Studies related to Internet-based interventions in various psychiatric disorder

Studies	Intervention conditions	Sessions
Depression		
Selmi et al (1990)	Computer CBT v/s Therapist CBT v/s wait list	6 sessions
Patton (2003)	IB-CBT v/s Psycho education	4 modules
Spek et al (2007)	IB CBT v/s Group CBT v/s wait list	8 modules v/s 10 sessions
Christensen et al (2004),Mackinnon et al (2008)	Mood Gym v/s IB Psycho education v/s control	6 CBT sessions
Anxiety & Depression		
Proudfoot et al (2003)	Computer CBT v/s TAU	Weekly sessions
Post-traumatic stress disorder		
Wagner et al (2006)	IB-CBT v/s Waitlist	5 weeks
Litz et al (2007)	IBI-CBT/s Supportive counselling	8 weeks
Panic Disorder		
Newman et al (1997)	Computer CBT v/s Therapist CBT	4 v/s 12 sessions
Carlbring et al (2001)	IB-CBT v/s Waitlist	6 modules
Klein & Richards (2001)	IB-CT v/s self-monitoring	1 week
Carlbring et al (2003)	IB –CBT v/s IB AR	6 V/S 9 Modules
Marks et al (2004)	IB Exposure v/s Clinician Based Exposure v/s IB Relaxation	10 weeks

- Studies have found the internet behavioural interventions to attenuate symptoms of various anxiety disorders when compared to the waitlist group. No significant differences were found between the computer- and therapist-delivered treatment groups.
- In cases of anxiety & depression, Internet-based intervention (IBI) was superior to the treatment-as-usual condition in terms of decreasing depression and anxiety, as well as work and social adjustment (Proudfoot et al, 2004). Generally, IBIs have been found to be highly effective in treating panic disorder, as well as affording a treatment modality that has higher availability and lower cost than traditional face-to-face services.
- Studies utilizing a self-monitoring control group have demonstrated the superiority of the IBI condition to the control condition in amelioration of panic disorder symptoms. Carlbring et al. (2003) compared CBT to relaxation, both administered via the internet and found that both treatments were equally and significantly effective in reducing symptoms.
- The majority of studies identified measures of distress, disability, quality of life, or work force participation as secondary outcome measures. While changes in these secondary outcome measures were not as large as in the primary outcome measures, they were significant and demonstrate that internet treatment has the capacity to change health status not merely reduce specific symptoms (Andrews et al., 2010).

Treatment for Depression

Problem-Solving Technique

The problem-solving technique is used to recover a person's capacity to solve problems whilst treating signs of depression. The series is usually implemented for five weeks with one session per week via e-mail. The main essentials of this method are to resolve the problem by operationalizing the problem, brainstorm, best possible solution, solution implementation plan, solution and evaluation (Warmerdam et al., 2012).

Internet-Based Cognitive Behaviour Therapy

This is a doctor-supported management consisting of 8 online tutorials with a summary of the consequent session that includes a practising one lesson per week using the transcript, aural and video exercises. The wizard will be communicated with the patient by means of e-mail. the specific mechanism is psychoeducation, self-discipline, cognitive restructuring, behaviour activation, structural problem solving, relaxation techniques and social skills training (Warmerdam et al., 2012).

Acceptance and Commitment Therapy

The therapeutic goal of this intervention is psychological flexibility, defined as "contacting the present moment fully as a conscious human being, and based on what the situation affords, changing or persisting in behaviour in the service of chosen values". Hayes et al., 2006 draw on six processes of cognitive diffusions, acceptance, awareness with the present moment, self-as-context, value, and committed effort. The session consists of text, video, and animated images. The patient also has been facilitating with a workbook and a CD (Segal et al., 2002).

Mindfulness-Based Therapy

Is an empirical intervention to instruct clients emotion management skill to diminish residual depressive symptoms and evade relapse triggers which could lead to chronic disease. Is an eight-week module with 10 interactive sessions underneath training. Clients are trained to exercise formal meditation techniques (body scanning, conscious movement, sitting meditation, breathing for three minutes) and informal mindfulness technology (incorporating mindfulness into daily activities) A module is delivered through downloadable videos, sound clip, coursework, and emails (Segal et al., 2012).

Clients are required to finish a module per week and perform mindfulness exercises twice a day for 6 days a week. Participants can access the following module once the previous session has been completed. The most used technique in mindfulness is mindful mood balance over the internet. It has 8 sessions of 60-90 minute programs with each course incorporating mindful meditation and cognitive behavioural therapy (Segal et al., 2014). At present, three online application is most popular for being easily accessible without a penny to consumers: Blue Pages, MoodGYM and ODIN.

Treatment for Anxiety disorder

Internet-based cognitive behavioural therapy has become an increasingly popular treatment based on empirical evidence of various anxiety disorders. Evidence suggests that the Internet-based CBT for panic disorder (Carlbring et al.,2003), social anxiety disorder (Andersson et al., 2012), generalized anxiety disorder (Titov et al., 2010), PTSD (Lange et al., 2003) and Specific phobia (Andersson & cuijpers, 2009).

Internet-based Cognitive Behavioural Therapy

It is a self-help therapy based on a text consisting of ten treatment therapy modules administered over 11 weeks under the supervision of the treating mental health professional and physician. The session aims at cognitive restructuring, exposure prevention, self-focus, social skills and prevention of relapse. Patients receive questionnaires and tasks to finish as a home assignment. The patient is provided with feedback as quick as 24 hours (Heldman et al., 2012).

Treatment for Substance Use Disorder

Alcohol electronic screening and brief intervention proved to eliminate harmful consumption of alcohol in patients with dependence on alcohol. The client is required to finish the online screening questionnaire and is provided with personal comments with short patient intervention via e-mail. Alcohol Anonymous is a type of self-therapy, which is available online as well. Many researchers have analyzed that participation in AA is associated with better outcome for alcohol consumption (Humphrey & Tucker, 2002). The widespread utilization of Internet-based psychotherapy is helpful to quit smoking, very well known (quitnet) showed that the sustainable use of quitnet was associated with better abstinence from smoking. Intervention is provided through interactive websites and personal emails. Smoking interventions can be provided online as well as individual or group counselling or pharmacotherapy (Graham et al., 2007). Cognitive behavioural therapy and motivational enhancement therapy are the main approach used to treat cannabis addiction and are available over the internet also. web-based treatment for Cannabis and

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

other illicit drugs use is at a premature stage, but their effectiveness in reducing cannabis abuse has been supported by some studies (Tait et al., 2013).

Alcohol Consumption

The first randomized trial of alcohol consumption was conducted in 1997 (Hester & Delaney, 1997). Compared to the control group, those who received the intervention over the internet had less alcohol drinking, binge drinking episodes and interpersonal problems followed up for six weeks. Similarly, CBT-IBI found to be more effective in reducing alcohol consumption than psycho-educational control in RCT (Riper et al., 2008).

Smoking

Many smoking cessation programs are available on the Internet but few research has been conducted to scrutinize the effectiveness of these interventions. Schneider et al., 1990 conducted the first RCT of the computer-based cessation program and found online treatment is more effective over healthy controls prominently in terms of abstinence rates. Although most published research has found positive results over the control group, abstinence rates remain very low, underscoring the continuing need for improvement in smoking cessation programs. However, these studies point to the first RCTs for smoking cessation, providing substantial data on the benefit of the Internet in addressing this health-risk behaviour (Amstadter et al., 2009).

Treatment for Insomnia

Insomnia is important for overall wellbeing which is having significant mental, physical and spiritual consequences. accessibility of treatment options for insomnia, cognitive behavioural therapy through the Internet, is severely inadequate. The Internet can be a major channel for this intervention. Online intervention relies on well-established offline cognitive behavioural therapy, which includes the main components of sleep restriction, stimulation control, sleep hygiene, cognitive restructuring and the prevention of relapse. Participants who received Internet-based Intervention, their insomnia significantly improved. Improvements in sleep after the use of "Sleep Healthy Using the Internet" (http://www.shuti.net, SHUTi) are very similar to those of other treatments for the treatment of insomnia. In fact, the proportion of change in sleep efficiency (16%) was almost identical to that of other self-help groups of CBT (15%), telephone (21%) face to face (17%) and pharmacotherapy (13%) (Bastien et al., 2004).

Treatment for the Eating Disorder

Weight gain in teens is a major problem related to dissatisfaction with the body and Eating disorder (ED). Cost-effective methods of early intervention for obesity as well as diabetes prevention are imperative due to the non-compliant nature of both. This multi-site RCT evaluated an online intervention aimed at the loss of weight and eating attitudes/behaviours in adolescents. Because of the magnitude of the impact of obesity on public health and the challenge of treating the population exclusively through face-to-face programs (for example, due to transportation and economic constraints (Newmark-Sztainer et al., 2000), innovative and cost-effective interventions are needed for the hour. Internet interventions are a

EBSCOhost - printed on 2/11/2023 5:46 AM via . All use subject to https://www.ebsco.com/terms-of-use

promising way of providing services because of the possibility Accessibility and convenience (Zabinski et al., 2003) Online weight-loss interventions were tested for adults with moderate success (Gold et al., 2007). A study of African American adolescent girls and their parents showed short-term results for online intervention along with 18 months of follow up (Williamson et al., 2006). The Internet-based interventions have succeeded in reducing risk factors of an eating disorder, as well as the onset of eating disorder risk (Heinicke et al., 2007). So far, the findings indicate that online-delivered intervention showed a slight decrease in weight after four months of treatment and ED attitudes/ behaviours did not improve significantly. Group differences in weight loss were not substantial after 4 months of follow-up due to parallel improvements in groups.

Treatment for Headache

Web-based cognitive-behavioural self-help therapy is a promising novel place to treat recurring headaches. To study the contribution of a therapist-initiated telephone contact in the treatment of frequent headaches over the Internet, the telephone contact initiated by the therapist in a randomized trial in 44 patients with headaches was randomly assigned an online help program with email support or to the group receiving weekly phone calls. additional 8 controls were assigned to receive similar treatment outside the study. The attrition rate was 29% in the telephone support group and 35% in the control group, indicating that telephone calls did not affect attrition. The results showed significant reductions in disability due to headaches, depression, and maladaptive coping strategies and perceived stress, but little to indicate outstanding performance in the Internet group, and a slight improvement in the headache index. In short, the therapist-initiated telephone calls did not affect the results. Internet-based therapy for headaches is not affected by the minimal therapist-initiated telephone contact. Although it's cost-effective, there are indications that this modality may be associated with high dropout rates (Andersson et al., 2003).

CONCLUSION
