Table of Contents

Preface xviii

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
The History of Unreason: Social Construction of Mental Illness 1
Samuel Teague, Swinburne University, Australia
Peter Robinson, Swinburne University, Australia

Chapter 2
Mental Health and Well-Being: Societal Influences 20
Jean Mockry, State University of New York at Plattsburgh, USA
Melissa Martin, State University of New York at Plattsburgh, USA
Alison Puliatte, State University of New York at Plattsburgh, USA
Denise A. Simard, State University of New York at Plattsburgh, USA
Maureen E. Squires, State University of New York at Plattsburgh, USA

Chapter 3
Neurobiology of Well-Being 32
Pamela A. Jackson, Radford University, USA
M. Joseph Sirgy, Virginia Polytechnic Institute and State University, USA
Gabriel D. Medley, Radford University, USA

Chapter 4
Posttraumatic Stress Disorder: Children and Psychological Trauma 53
Veysi Çeri, Marmara University, Turkey

Chapter 5
Technological Issues in Emotional and Mental Health 83
Suresh K., Central University of Tamil Nadu, India
Manimozhi G., Central University of Tamil Nadu, India
Elango M., Central University of Tamil Nadu, India

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
Romantic Relationships, Online Dating, and Mental Health Issues 94
Tejaswini Bhave, Deenanth Mangeshkar Hospital and Research Center, India

Chapter 7
Special Issue: Sexually Transmitted Infections – Diagnoses, Stigma, and Mental Health 103
Sara Bender, Central Washington University, USA
Karlie Hill, Central Washington University, USA

Chapter 8
Muslim Worldviews: Implications for Helping Professionals Providing Culturally Competent Care 121
Anisah Bagasra, Kennesaw State University, USA

Chapter 9
Mental Health: A Global Issue Affecting the Pattern of Life in Kashmir 143
Shazia Ali, Sheri-Kashmir Institute of Medical Sciences, India
Amat Us Samie, Superspeciality Hospital Shireen Bagh, Government Medical College, Srinagar, India
Asma Ali, Independent Researcher, India
Aashiq Hussain Bhat, Cancer diagnosis and research Centre, Sheri-Kashmir Institute of Medical Sciences, India
Tariq Mir, Institute of Hospitality and Management, Srinagar, India
Barre V. Prasad, All India Institute of Medical Science, India

Section 2
Development and Design Methodologies

Chapter 10
Paradigm Shifts in the Theory and Praxis of Mental Health Counseling 154
Moly Kuruvilla, Department of Women's Studies, University of Calicut, India

Chapter 11
Multi-Criteria Decision Making Semantic for Mental Healthcare 178
Chaymae Benfares, System Engineering Laboratory, Ibn Tofail University, Morocco
Ouidad Akhrif, System Engineerin Laboratory, Ibn Tofail University, Morocco
Younès El Bouzekri El Idrissi, System Engineering Laboratory, Ibn Tofail University, Morocco
Karim Hamid, Center for Oncology and Hematology, Morocco

Chapter 12
mHealth as Tools for Development in Mental Health 193
Gloria Ejehiohen Iyawa, Namibia University of Science and Technology, Namibia
Julie Langan-Martin, University of Glasgow, UK
Stephen Sevalie, University of Sierra Leone, Sierra Leone
Wanano Masikara, Nanosoft Designs, Botswana

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 13
Kindness Makes a Difference: Assessing the Efficacy of Addy & Uno, an Off-Broadway Musical, and the Realabilities Educational Comic Book Series Curriculum in Enhancing Children's Kindness, Empathy, and Interest in Their Peers With Disabilities and Mental Health Disorders 216
Nava R. Silton, Marymount Manhattan College, USA
Patrick Riley, Marymount Manhattan College, USA
Amanda Anzovino, Marymount Manhattan College, USA

Chapter 14
Counseling Refugees 247
Ann Nicole Nunis, HELP University, Malaysia

Chapter 15
"More Than Peer Support: Organizational and Relational Intervention Model": First Responder Assistance Program (F.R.A.P.) 269
Mario Jose Gonzalez, Independent Researcher, USA
Marie Guma, Independent Researcher, USA
Bernardo Jose Gonzalez, Boundless Leadership Consulting, USA

Chapter 16
Attitude Training for Police Cadets: Addressing the Problem of Arresting Suspects With a Mental Illness 287
Bruce L. Mann, Memorial University, Canada

Section 3
Tools and Technologies

Chapter 17
Real-Time Mental Health Monitoring: The Indian Scenario 305
Ritika Wason, Bharati Vidyapeeth's Institute of Computer Applications and Management (BVICAM), India
Prashant Singh Rana, Thapar Institute of Engineering and Technology, India
Vishal Jain, Bharati Vidyapeeth's Institute of Computer Applications and Management (BVICAM), India

Chapter 18
Appreciative Inquiry and Mental Health Improvement: A Review on Applicative Potential at Individual Level 315
Malabika Tripathi, Amity University, Kolkata, India

Chapter 19
Digital Heath Interventions in Mental Health 328
Aleksandra Stanimirovic, University of Toronto, Canada

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 20
Mental Health Clinical Decision Support Exploiting Big Data 341
Jan Kalina, The Czech Academy of Sciences, Czech Republic

Chapter 21
Socialization or Social Isolation? Mental Health Community Support in the Digital Age 360
Kim Heyes, Manchester Metropolitan University, UK

Chapter 22
Virtual Communities, Machine Learning and IoT: Opportunities and Challenges in Mental Health Research 381
Christo El Morr, York University, Toronto, Canada

Chapter 23
Efficacy of Telemedicine in Psychiatry and Mental Health Nursing 390
Michael Jones, Marshall University, Huntington, USA
Girmay Berhie, Marshall University, Huntington, USA

Chapter 24
Social Media for Mental Health Initiatives 402
Gemma Richardson, Humber College, Canada

Volume II

Chapter 25
Virtual Reality as a Tool for Mental Health and Conscious Living and Death: Immersive Contemplative Approaches to Existential Anxieties 414
Dorote Weyers-Lucci, Institute of Transpersonal Psychology, Sofia University, USA

Chapter 26
Mental Health and Cognitive Behavioral Therapy: Advanced Issues and Approaches 437
Kijpokin Kasemsap, Suan Sunandha Rajabhat University, Thailand

Chapter 27
The Role of AYUSH in Mental Well-Being 457
Ranjit Kumar Dehury, School of Management Studies, University of Hyderabad, India
Rajeev Kumar, Indian Institute of Technology, Kharagpur, India

Chapter 28
Answering the Call for School-Based Mental Health: Culturally Competent Intervention and Support 469
Maxine Blanche Langdon Starr, Sunflower Therapies, USA

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 29
The Mental Health Interpreter: The "Third Space" Between Transference and Counter-Transference 489
Sarah Parenzo, Bar Ilan University, Israel
Michal Schuster, University of the Free State, South Africa

Chapter 30
Narrative Therapy to Address Trauma for Emergency Medical Services and Firefighters 503
Amanda C. DeDiego, University of Wyoming, USA
Isabel C. Farrell, Wake Forest University, USA
Andrea M. McGrath, University of Wyoming, USA

Section 4
Utilization and Applications

Chapter 31
Individual Funding for People With Mental Health Issues: Opportunities, Tensions, and Outcomes 519
Christina David, RMIT University, Australia
Carmel Laragy, RMIT University, Australia
Elizabeth Hudson, RMIT University, Australia

Chapter 32
Interpreting and the Mental Status Exam 533
Meghan L. Fox, Independent Researcher, Rochester, USA
Robert Q Pollard Jr., National Technical Institute for the Deaf, Rochester Institute of Technology, USA

Chapter 33
Ageing and Mental Health: A Psychological Aspect of Later Life 549
Neelam Verma, Talk to Cure, India

Chapter 34
The Social Mandate to Deal With Mental Health: A Comparison Between Interventions in a Mental Health Center, a School, and a Psychoanalytic Office 573
Alberta Mazzola, Independent Researcher, Italy

Chapter 35
Mental Health Education and Literacy in Schools: The Australian Experience 589
Matthew Dale, Mind Australia, Australia

Chapter 36
Campus-Wide Initiatives 609
Maureen E. Squires, State University of New York at Plattsburgh, USA
Melissa Martin, State University of New York at Plattsburgh, USA
Jean Mockry, State University of New York at Plattsburgh, USA
Alison Puliatte, State University of New York at Plattsburgh, USA
Denise Simard, State University of New York at Plattsburgh, USA

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 37
Activism and College Student Mental Health: A Wellness Perspective 628
Abby L. Bjornsen-Ramig, University of Nebraska – Omaha, USA
Daniel B. Kissinger, University of Nebraska – Omaha, USA

Chapter 38
Interagency Collaboration to Improve School Outcomes for Students With Mental Health Challenges 644
Kristina Bixler, Indiana University, USA
Jeffrey Alvin Anderson, Indiana University, USA

Chapter 39
Providing Primary Prevention and School Mental Health Services to LGBTQ+ Children and Youth: A Resiliency-Based Approach 661
Elizabeth K. Rhoades, Southern Connecticut State University, USA

Chapter 40
Inherent Requirements and Social Work Education: Issues of Access and Equity 681
Steve Boucher, RMIT University, Australia

Chapter 41
Healing Together: The Lid Project 698
Kristine Vuocolo, Human Services Inc., USA

Chapter 42
Healing Alex's Wound: Application of MSJCC in Adlerian Play Therapy 707
Szu-Yu Chen, Palo Alto University, USA

Chapter 43
Culturally Responsive Practices: African American Youth and Mental Health 727
Tricia Crosby-Cooper, National University, USA
Natasha Ferrell, National University, USA

Chapter 44
Mental Health Challenges in Children With Intellectual Disabilities 745
Nisha Elizabeth Mathew, University of New South Wales, Australia
Amelia Walter, University of New South Wales, Australia & South West Sydney Local Health District, Australia
Valsamma Eapen, University of New South Wales, Australia & South West Sydney Local Health District, Australia

Chapter 45
Mental Health Issues, Wellbeing, and Related Issues Among Caregivers of Individuals With Intellectual Disability 772
Tanay Maiti, AIIMS Bhubaneswar, India

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 46
Flying With Eddie: Complicated Grief in the Military..... 781
Emeline Carol Eckart, University of Indianapolis, USA

Chapter 47
Organizational Prevention and Intervention Services: Beyond the Early Intervention System..... 799
Jennifer Kelly, Independent Researcher, Haddonfield, USA
William D. Walsh, Voorhees Police Department, USA

Chapter 48
Application and Integration of Psychological First Aid in First Responder Organizations..... 813
Emily F. Brucia, San Francisco VA Health Care System, USA
Matthew J. Cordova, Palo Alto University, USA
Angelique Finestone, Palo Alto University, USA
Josef I. Ruzek, National Center for PTSD, VA Palo Alto Health Care System, USA & Palo Alto University, USA & Stanford University, USA

Chapter 49
Media, Social Media, and the Securitization of Mental Health Problems in Nepal: Yama Buddha's Case Study 838
Sudeep Uprety, Tribhuvan University, Nepal
Rajesh Ghimire, Tribhuvan University, Nepal

Volume III

Section 5
Organizational and Social Implications

Chapter 50
Barriers to Practitioners' Endorsement of a Recovery Perspective: Considering Attitudes Through a Schema Lens 861
Debra Kram-Fernandez, Empire State College (SUNY), USA

Chapter 51
Fighting Stigma in the Community: Bridging Ties Through Social Innovation Interventions 880
Nicolina Bosco, University of Florence, Italy
Susanna Giaccherini, Public Mental Health Service of Tuscany, Italy
Fausto Petrini, University of Florence, Italy
Stefano Castagnoli, Public Mental Health Service of Tuscany, Italy
Patrizia Meringolo, University of Florence, Italy

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 52
Reducing Stigma in Mental Health Through Digital Storytelling 909
Tatiana Davidson, Medical University of South Carolina, USA
Angela Moreland, Medical University of South Carolina, USA
Brian E. Bunnell, Medical University of South Carolina, USA
Jennifer Winkelmann, Medical University of South Carolina, USA
Jessica L. Hamblen, National Center for PTSD, USA
Kenneth J. Ruggiero, Medical University of South Carolina, USA

Chapter 53
Health Literacy in School 920
S. M. Yasir Arafat, Bangabandhu Sheikh Mujib Medical University, Bangladesh
Md. Anwarul Azim Majumder, The University of the West Indies, Barbados
Russell Kabir, Anglia Ruskin University, UK
Konstantinos Papadopoulos, Middlesex University, UK
Md. Saleh Uddin, Chittagong Medical College Hospital, Bangladesh

Chapter 54
Understanding and Addressing the Stigma in Mental Health Within the Asian and Asian-American Culture 943
Ben Tran, Alliant International University, USA

Chapter 55
Religious Coping Among Muslims With Mental and Medical Health Concerns 971
Seyma N. Saritoprak, Case Western Reserve University, USA
Julie J. Exline, Case Western Reserve University, USA

Chapter 56
Violence: Mental Health, Family, and Media Reporting 991
Samuel Teague, Swinburne University, Australia
Peter Robinson, Swinburne University, Australia

Chapter 57
Finding Strength in the Struggle: Addressing the Mental Health Needs of Children and Families Living in Rural Poverty 1012
Loni Crumb, East Carolina University, USA
Madeline Clark, The University of Toledo, USA
Susan M. Long, The University of Toledo, USA

Chapter 58
Advocating for the Mental Health Needs of Children Living in Rural Poverty 1037
Denise Lenares-Solomon, Augusta University, USA
Christina Conti, Augusta University, USA
Christina George, Augusta University, USA

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 59
Syrian Youth, War, and Community Approach to Stigma Surrounding Psychological Intervention 1060
Adnan Mouhiddin, University of Surrey, UK

Chapter 60
Mental Health Access Issues by People of Refugee Backgrounds in Australia 1076
Ndungi wa Mungai, Charles Sturt University, Australia
Jeanette Ninnis, Service for Treatment and Rehabilitation of Torture and Trauma Survivors, Australia
Ruth (Isobel) Bailey, Charles Sturt University, Australia

Chapter 61
Facebook Depression or Facebook Contentment: The Relation Between Facebook Use and Well-Being 1095
Jessica J. Joseph, Mount Royal University, Canada
Malinda Desjarlais, Mount Royal University, Canada
Lucijana Herceg, Mount Royal University, Canada

Chapter 62
From Medical Student to Medical Resident: Graduate Medical Education and Mental Health in the United States 1117
Warren G. McDonald, Methoodist University, USA

Preface

Mental health has always been a critical issue in society, yet it has not always gotten the proper attention and recognition it deserves. Recent efforts have been employed to reduce negative mental health stigma and better provide education on the different mental illnesses. By better informing society, including those in the medical field and working in mental health, better treatment options and new explorative methods and advancements have been discovered and can continue to improve in the future. Opening the dialogue on mental health, reducing negative stigmas, providing more accurate education, and advanced solutions and treatments will create not only an informed and engaged public but a better quality of life for those living with mental health issues. Examining current research, case studies, and applications can lead to a greater understanding of not only the mental illnesses themselves and the people living with them, but how society and the medical field can better treat and handle mental health for a better future.

Staying informed of the most up-to-date research trends and findings is of the utmost importance. That is why IGI Global is pleased to offer this three-volume reference collection of reprinted IGI Global book chapters and journal articles that have been handpicked by senior editorial staff. This collection will shed light on critical issues related to the trends, techniques, and uses of various applications by providing both broad and detailed perspectives on cutting-edge theories and developments. This collection is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as provide insight into emerging trends and future opportunities within the field.

The *Research Anthology on Mental Health Stigma, Education, and Treatment* is organized into six distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Critical Issues and Challenges.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of mental health both in a historical context and modern times. This reference book opens with the chapter "The History of Unreason: Social Construction of Mental Illness" by Profs. Samuel Teague and Peter Robinson of Swinburne University, Australia. It outlines how health and illness can be understood as socially constructed by illustrating how

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

mental health has been constructed uniquely across cultures and over time. This first section concludes with "Mental Health: A Global Issue Affecting the Pattern of Life in Kashmir" by Prof. Asma Ali, an Independent Researcher, India; Profs. Shazia Ali and Hussain Bhat of Sheri-Kashmir Institute of Medical Sciences, India; Prof. Amat Us Samie of Superspeciality Hospital Shireen Bagh, India; Prof. Aashiq Tariq Mir of Government Medical College, Srinagar, India; and Prof. Barre V. Prasad of All India Institute of Medical Science, India, which explores the patterns of resilience in people surviving war and conflict in Kashmir over the last 60 years with a focus on the young population.

Section 2, "Development and Design Methodologies," presents in-depth coverage of how counseling systems and mental health programs are designed and developed. This section starts with "Paradigm Shifts in the Theory and Praxis of Mental Health Counseling" by Prof. Moly Kuruvilla of the University of Calicut, India. The chapter focuses on the role of gender in clinical psychology, specifically feminist psychology, and how these views have changed over time. This section ends with "Attitude Training for Police Cadets: Addressing the Problem of Arresting Suspects With a Mental Illness" by Prof. Bruce L. Mann of Memorial University, Canada, which describes an approach for attitude-training programs with police cadets to better prepare them for dealing with people with mental illness.

Section 3, "Tools and Technologies," explores the various tools and technologies used to provide mental health services and make them more accessible and acceptable to society. Beginning this section is the chapter "Real-Time Mental Health Monitoring: The Indian Scenario" by Profs. Vishal Jain and Ritika Wason of Bharati Vidyapeeth's Institute of Computer Applications and Management, India and Prof. Prashant of Thapar Institute of Engineering and Technology, India, which analyzes how real-time mental health monitoring has helped improve productivity among the global workforce as well as prevented deterioration of individual mental health across the globe. This section ends with "Narrative Therapy to Address Trauma for Emergency Medical Services and Firefighters" by Profs. Amanda C. DeDiego and Andrea M. McGrath of the University of Wyoming, USA and Prof. Isabel C. Farrell of Wake Forest University, USA, which explores narrative therapy as an ideal option for mental health treatment of first responder trauma, providing a collaborative approach to therapy using the natural coping strategy of storytelling.

Section 4, "Utilization and Applications," describes how programs and services are being developed and offered for mental health along with the trends in how mental health issues are addressed and portrayed. Opening this section is "Individual Funding for People With Mental Health Issues: Opportunities, Tensions, and Outcomes" by Profs. Christina David, Carmel Laragy, and Elizabeth Hudson of RMIT University, Australia, which outlines the key features of individual funding programs and examines their suitability for people with mental illness. The chapter "Media, Social Media, and the Securitization of Mental Health Problems in Nepal: Yama Buddha's Case Study" by Profs. Sudeep Uprety and Rajesh Ghimire of Tribhuvan University, Nepal concludes this section by unfolding the trend and nature of mainstream and social media coverage on mental health issues and providing recommendations for the future.

Section 5, "Organizational and Social Implications," includes chapters discussing the impacts of living as an individual with mental health and the social and organizational impacts of mental illnesses. This section begins with "Barriers to Practitioners' Endorsement of a Recovery Perspective: Considering Attitudes Through a Schema Lens" by Prof. Debra Kram-Fernandez of Empire State College (SUNY), USA, which is concerned with the impact of practitioner biases on the experience of a meaningful life for individuals who live with serious mental illness (SMI). It ends with "Occupational Risk Factors and the Mental Health of Women Firefighters" by Prof. Brittany Sara Hollerbach of the National Develop-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ment and Research Institutes, Inc., USA, which examines relevant literature pertaining to firefighters and mental health with a specific focus on behavioral health aspects that may impact the mental health of women firefighters.

Section 6, "Critical Issues and Challenges," presents coverage of academic and research perspectives on the challenges and issues within mental health and the strategies to mitigate negative impacts and provide affective solutions and therapies for individuals with mental illness. This final section opens with "Adolescent and Adult Mass Shooters: Trauma, Mental Health Problems, and Early Prevention" by Prof. Christopher A. Mallett of Cleveland State University, USA, which takes a broader approach to understanding why mass shootings may have happened by reviewing the empirical literature to identify possible correlations from childhood and adolescent trauma experiences (and subsequent mental health problems) to later adult violence. Concluding this reference work is "Deliberate Self-Harm and Suicide Ideology in Medical Students" by Profs. Vinod Gopalan, Erick Chan, and Debbie Thao Thanh Ho of Griffith University, Australia, which explores assessment, preventative, and management strategies to improve education, awareness, and ultimately reduce the rates of deliberate self-harm (DSH) and suicide risk.

Although the primary organization of the contents in this multi-volume work is based on its six sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to mental health, the *Research Anthology on Mental Health Stigma, Education, and Treatment* provides researchers, administrators, psychologists, psychiatrists, therapists, school counselors, trauma specialists, teachers, mental health professionals, academicians, students, and academicians with a complete understanding of the role mental health has in society along with the new methods for treatment, education, and the reduction of negative stigmas. Given the vast number of individuals living with mental illnesses and the many ways in which mental health impacts society, the *Research Anthology on Mental Health Stigma, Education, and Treatment* encompasses the most pertinent research in the technologies, theories, and methods being employed to better understand mental health and provide effective treatments and services for the impacted individuals.

Chapter 1
The History of Unreason:
Social Construction of Mental Illness

Samuel Teague
Swinburne University, Australia

Peter Robinson
Swinburne University, Australia

ABSTRACT

This chapter reflects on the importance of the historical narrative of mental illness, arguing that Western countries have sought new ways to confine the mentally ill in the post-asylum era, namely through the effects of stigma and medicalization. The walls are invisible, when once they were physical. The chapter outlines how health and illness can be understood as socially constructed illustrating how mental health has been constructed uniquely across cultures and over time. To understand this process more fully, it is necessary to consider the history of madness, a story of numerous social flashpoints. The trajectories of two primary mental health narratives are charted in this chapter. The authors argue that these narratives have played, and continue to play, an important role in the social construction of mental illness. These narratives are "confinement" and "individual responsibility." Drawing on the work of Michel Foucault and Roy Porter, the authors describe how Western culture has come to consider the mentally ill as a distinct, abnormal other.

INTRODUCTION

In the years preceding the seventeenth century, the mentally ill were placed on boats, taken to foreign locations, and dumped there, and for European populations, this was the primary method for dealing with a portion of society considered abnormal (Foucault, 1967). Michel Foucault (1967) described this *Ship of Fools* as a vessel for those who had no real connection to time or place, for "as the madman sets sail for the other world, it is from the other world that he comes when he disembarks" (p. 8). This image of the mad as incongruous and lost on the high seas resonates in the imagination of the twenty-first

century sociologist, because while the *Ship of Fools* no longer exists, the authors suspect that society's perception of the mentally ill as both deviant and abnormal endures.

Even throughout the twentieth century, western civilization continued to perceive and construct mental illness as an abnormality. In the original 1952 edition of the Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association, 1952), patients could be diagnosed under one or more of 106 conditions. In 1994, the DSM-IV contained nearly 300 disorders, an increase of close to 300% in just five decades (American Psychiatric Association, 1994). Peter Conrad (2007) included these statistics in his thesis on the problems inherent in modern medicalization, and used them to outline the modern trend within which human beings are increasingly defined as sick rather than healthy, and as abnormal rather than sane. Certainly, the introduction of Prozac in 1987 as a drug for the treatment of depression has signaled the dawn of a new era where antidepressant medication is used to treat "life problems" as well as serious illness (Conrad, 2007, p. 61). In this chapter, we show that from the *Ship of Fools* to the introduction of Prozac, western civilization has sought to understand and develop ways of controlling those being treated for mental illness.

This chapter details the history of mental illness, as portrayed by Roy Porter (1987; 2002), Michel Foucault (1967), Andrew Scull (2015), Erving Goffman (1959; 1963), and Peter Conrad (2007). The authors trace the trajectory of the principal narratives that have characterised this history, and outline how they persist and operate today. Scholars who have sought to interpret present media portrayals of the mentally ill have neglected an appreciation of the history of mental illness. An account of the history of mental illness is critical in interpreting the present socio-cultural media landscape. In constructing this detailed historical account, the chapter is divided into four parts.

The first introduces the notion that the lived experience of mental illness can be understood as socially constructed. Attention is given to the debate between essentialist and constructionist perspectives, and the authors outline how the two can be considered in unison. The section summarizes the biomedical approach to health for the purpose of detailing how social understandings of health and illness are constructed uniquely across cultures. The second section of this chapter describes the history of madness, and drawing predominantly on the work of Michel Foucault, the authors chart the trajectory of two primary mental health narratives which have played, and continue to play, an important role in the social construction of mental illness. These narratives are "confinement" and "individual responsibility". In part three, this historical account continues, addressing the legacy of Sigmund Freud, the closing of asylums in the 1980s, and an account of the breadth and scope of modern medicalization. The chapter concludes with a focus on Australia's mental health history from 1870 to the present.

BACKGROUND

Mental Illness as Socially Constructed

The experience of mental illness can be understood as socially constructed. By considering mental health from this standpoint, emphasis is placed on the importance of historical accounts, the mental health narratives that underpin these, and print media's role in shaping public attitudes towards the mentally ill. It is the social constructionist standpoint that forms the foundation for this chapter. Questions around how mental illness can be understood have long been characterised by the philosophical debate between "constructionists" and "essentialists". Greider and Garkovich (1994) argue that even the physical en-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

vironment – a wheat field or savannah plain – can be understood as a socially constructed "symbolic landscape" (p. 1). They propose that a real estate developer, a farmer, and a hunter each perceive the environment in distinct ways, making a concrete physical reality a myriad of potentials "grounded in the cultural definitions of those who encounter that place" (p. 2). For these scholars, a rock is not merely a rock, but a sacred stone, a cutting tool, or a wishing pebble, as the world is infinitely constructed and reconstructed.

Latour and Woolgar (1979) expand on this argument, arguing that the scientific study of external phenomena is mostly political and "entirely fabricated out of circumstance" (p. 239). Observing scientists at work in a laboratory, these theorists found that the objective of positivist study was to extend and speed up the credibility cycle for scientists through the creation of work that would grant them a status of higher esteem. In other words, scientists are social creatures first and foremost. Latour and Woolgar (1979) found that the scientists at the center of their research were writers and readers in the business of being convinced and of convincing others, operating within a laboratory that engaged in an organised system of "persuasion through literary inscription" (p. 88). Neurosurgeon and writer Paul Kalanithi (2017) wrote just twelve months before his death in March 2015:

Scientific methodology is the product of human hands and thus cannot reach some permanent truth. We build scientific theories to organise and manipulate the world, to reduce phenomena into manageable units. Science is based on reproducibility and manufactured objectivity (p. 169).

This particular example illustrates the breadth and scope of the constructionist perspective, which suggests that if scientific facts can be understood as socially constructed, then so too can mental illness.

Bury (1986) presents an alternate perspective, arguing that in giving little attention to the existence of a concrete physical reality, constructionists undersell the important role it plays in shaping our understanding of the world. Bury argues that physical reality and human knowledge partake in a fluid relationship, whereby knowledge engages and operates with physical reality, while that physical reality simultaneously imposes itself on human knowledge. He believes that too much emphasis is placed on the human appreciation of a landscape or phenomenon, when the relationship between the two is an interwoven tapestry, and he takes issue with Steven Shapin's (1982) argument that scientific knowledge is routinely constructed to serve the interests of its users. In other words, facts about the origins of a particular disease are "discovered" in the laboratory so as to aid doctors in the treatment of their patients, and Bury argues in response to this that by representing medical knowledge as constructed in the interests of powerful institutions and groups, the sincerity and compassion at the basis of the medical profession is undermined. If facts about illness are constructed, then doctors become mere actors in the constructed play of life.

A balanced view can be a panacea to a philosophical divide. A concrete physical reality can exist, but the construction of attitudes, perceptions, and beliefs around the phenomenon are fluid, malleable, and worthy of study. Barnes (1977) argues that a concrete physical reality and our ideas about it can exist together.

Knowledge is related to activity which consists precisely in men attempting to manipulate, predict and control the real world in which they exist. Hence knowledge is found useful precisely because the world is as it is; and it is to that extent a function of what is real, and not the pure product of thought and imagination. Knowledge rises out of our encounters with reality (p. 110).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

This perspective emphasizes the power of social institutions and the human beings who operate within them to construct external phenomena. As a result, social constructions can be liberating because they remove expectations and allow for reconstructions.

A significant amount of social research supports this argument, that an external social world can be constructed around a distinct organic entity. Julie Hepworth's (1999) account of the social construction of anorexia nervosa suggests that the reality of this illness, for many centuries, has involved three common elements: the starving of oneself, weight loss, and the exhibiting of a common mental dullness. In the twelfth and thirteenth centuries, anorexia nervosa was associated with holiness, as those who chose to subsist on minimal nutritional quantities were considered divine, and subsequently revered (Hepworth, 1999, p. 13). Today, the same individuals are defined as unwell, mentally ill. While the three common elements of the illness have not changed significantly, society's understanding of the phenomenon has, and in a cyclical fashion. This shift in understanding and attitude has transformed the lived experience of anorexia nervosa, which we argue is evidence of the power of human beings to construct and re-shape reality.

Michel Foucault (1967) and Roy Porter (2002) base their respective historical accounts on the assumption that the lived experience of mental illness can be understood as dependent on social forces. Foucault's thesis concerns the power and influence of social institutions.

Whether madness is described as a religious or philosophical phenomenon … or as an objective medical essence … these conceptions are not discoveries but historical constructions of meaning (p. xiv).

While Porter questions some aspects of Foucault's argument, he supports the claim that the history of madness is an account "not of disease and its treatment but of questions of freedom and control, knowledge and power" (Porter, 2002, p. 3). Neither Foucault nor Porter claim that psychological anguish is fictitious, but that the social world around the individual being treated for mental illness is a construction.

Thomas Szasz was a significant figure in the anti-psychiatry movement, which was most prominent in the second half of the twentieth century, and he states in his thesis on "the myth of mental illness" that madness is manufactured to serve the interests of psychiatrists with a view to professional advancement, "endorsed by society because it sanctions easy solutions for problem people" (Porter, 2002, p. 2). Szasz contends that the majority of human suffering originates from life circumstances and stress and that the psychiatric profession routinely medicalises these experiences. This chapter acknowledges this claim, but draws more on the accounts of Foucault and Porter because of the attention they give to the significance of historical narratives.

Biomedical Approach

Western culture's construction of health and illness is apparent in the dominance of the biomedical approach. Biomedicine explains illness as a malfunction of the body's biological mechanisms, and it generally ignores the social origins of health and illness (Engel, 1977). It is a model that places medical professionals such as doctors in positions of power based on their status as experts in the field (Wreford, 2005). Like health and illness more broadly, medical practice has been constructed uniquely across cultures and over time. Engel was one of the first scholars to outline biomedicine's fallibility in its failure to account for the psychological, social, and environmental aspects that are so important in understanding health and illness. Engel's (1977) utopia is one where diabetes and schizophrenia are human experiences

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

as well as disease, and he presents the biopsychosocial model as an alternative to biomedicine. Cooper, Stevenson, and Hale (1996) offer support for this approach.

With the biomedical approach, healthy people become manifestations of healthy, cellular activity; ill people become manifestations of dysfunctional cellular activity. The patient becomes a 'problem' to be solved, and the solution to that problem lies in adopting a scientific, mechanistic approach that precludes any consideration of social, psychological, or behavioural influences.

Cooper, Stevenson, and Hale (1996) draw attention to a subtle irony that underpins western medicine in that while biomedicine is itself a cultural construction, illness is considered almost entirely through the framework of biological function or malfunction.

That biomedicine is a social construct is supported by the differences in treatment and medical beliefs that exist cross-culturally. In African cultures, traditional healers are important in providing spiritual assistance to the sick and dying (Wreford, 2005). South American shamans see illness as a force beyond the confines of physical degradation, instead addressing sickness as "inherently socio-political and cosmological" (Greene, 1998, p. 641). In the remote ethnic communities of Peru, physical affliction is considered the product of spirits, natural forces, and even deceased ancestors. This approach is not considered guesswork in this culture, but a legitimate medical practice broadly termed "shamanism" (Bastien, 1992; Mehl; 1988). A comparison of biomedicine and shamanism emphasizes that where the custodians of legitimate medical knowledge differ, human beings forge unique and contrasting models of health and illness.

Even one's definition of mental illness can be problematic. A sociological definition of mental illness must acknowledge health and wellbeing as constructed distinctly across cultures, environments, and historical epochs, while simultaneously accepting the dominance in Western culture of biomedicine, a medical model which assumes mental illness is a disease. The argument underpinning this chapter, that mental illness can be understood as socially constructed, is derived from the work of both historians and sociologists. Thomas Szasz (2007, p. 3) described mental illness as a "metaphorical disease", invented by psychiatrists to legitimate their authority, while Roy Porter (2002) and Michel Foucault (1967) illustrated the construction of madness across specific socio-historical contexts.

Aneshensel, Phelan, and Bierman (2013) describe mental illness as a concept requiring the insights of several disciplines, and in reviewing the literature from the standpoints of psychiatry, psychology, anthropology and sociology, divided opinion prevails in the search for a universal definition of mental illness. Aneshensel and colleagues (2013) argue that mental illness consists of a vast range of behavioural, cognitive and emotional phenomena, including:

Speaking to a companion whom no one else can see; sitting silently in a room, alone, eating little and sleeping less, contemplating death; becoming suddenly overwhelmed with intense anxiety for no apparent reason; consumption of alcohol to such a degree that it becomes difficult to hold a job or maintain friendships; frequent sickness with no identifiable physiological disease; and feeling no remorse when others are injured by one's actions.

The behavioural, cognitive and emotional phenomena included in this description can form part of the lived experience of mental illness. Feelings of intense and overwhelming anxiety are often characteristic of deeper mental health issues, while the use of alcohol and illicit drugs as a form of self-medication

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to mask underlying mental health concerns is common and can lead to significant upheaval in an individual's life circumstances (Harris & Edlund, 2005).

As a definition, however, the description is inadequate because one could reasonably assume some of these behaviours and emotions are characteristic of the lived experience of the mentally well person. A readiness to associate problematic behaviour with mental illness is at the core of negligent media reporting on mental health topics. And the rush to explain violence through the lens of mental illness offers an explanatory device for every perpetrator of domestic violence.

THE HISTORY OF MENTAL ILLNESS

The history of mental illness is a story of control; a tale of both subtle and transparent confinement. It begins in the early thirteenth century, when according to Michel Foucault (1967), King Louis VIII set in motion the opening of "lazar houses", secure places for the containment of those individuals with leprosy. Such was their effectiveness that by the middle of the thirteenth century, two thousand of these institutions were in operation across France (Foucault, 1967, p. 3). While the mentally ill would not pose a problem requiring state-sanctioned control for at least another three centuries, Foucault argues that the leprosaria are an important institution in the history of madness because they signaled the creation of a specific "fearsome figure" who could be carefully excluded from society "after a sacred circle had been drawn around him" (Foucault, 1967, p. 5). Put simply, madness was leprosy's heir to the throne of otherness.

The lazar houses closed at varying rates across Europe between the fourteenth and eighteenth centuries. In 1348, the leper house at Saint-Alban in France was home to just three inhabitants, and in 1627, the leper house of Saint Bartholomew was closed also. Throughout the decades in which the lazar houses were abandoned, and before the institution of the asylum appeared across Europe, the mentally ill were placed on boats, taken to foreign locations and dumped there (Porter, 2002). This practice was the dominant means for ridding cities of the presence of an undesirable group, and it is in this practice that we find the legacy of the leprosaria. Important are its implications for European attitudes towards abnormality and deviance in the seventeenth and eighteenth centuries. Long after leprosy had vanished along with the fear of its burden, the physical structures, social attitudes, values and images that had been attached to the leper and associated with a fearsome "other", would be attributed to the mad.

In a number of European states, the seventeenth century saw the emergence of a more organised form of social control, what Foucault (1967) calls "The Great Confinement". The year 1656 marks the date, founding in Paris, the first Hôpital-Général. These institutions were not houses created solely for the insane, but for those members of the population that posed a threat to normality and progress. The idle were locked away with the mad; the venereal with the gypsies. Within three years, the Hôpital-Général in Paris became home to more than 6000 people – approximately one per cent of the French population – and just twenty years later, a royal edict decreed that an institution of the sort established in Paris should be built in every city of the Kingdom (Foucault, 1967, p. 54). The rate at which the mad were confined within these institutions differed across most European nations. Britain appears to have followed the trend in Paris. In 1651, the Navigation Act was passed in Britain signaling the formal beginning of a movement which would utilize every member of the 'abnormal' population as part of the broader workforce (Foucault, 1967, p. 67). The structures that formerly housed the lepers became sites for the confinement of vagrants, homeless, gypsies, prostitutes, and the mentally ill.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The process of placing the "abnormal" within structures that had previously been utilized for the leper marks the emergence of two primary mental health narratives, which have contributed to the social construction of mental illness and characterized its history. These narratives are "confinement" and "individual responsibility". Foucault (1967, p. 118) described the practice of confinement as having two important consequences. First, by locking away the debauched, the venereal, the alchemists, the libertines, witches, vagrants, the homeless, the idle, prostitutes, and the insane, the outcome was that all came to be considered as one "undifferentiated mass". Particularly for the mad, European society began to distinguish the mentally ill less clearly, with the "slightly deranged" and the "crazed lunatic" sharing the same label, and subsequently, the same stigma. This is not unlike twenty-first century western countries treating someone diagnosed with paranoid schizophrenia the same as someone diagnosed with an anxiety disorder. The second consequence was that in the depths of these European asylums, madness found its place in opposition to reason and progress. Foucault (1967, p. 28) describes the relationship that developed.

Madness becomes a form related to reason, or more precisely madness and reason enter into a perpetually reversible relationship which implies that all madness has its own reason by which it is judged and mastered, and all reason has its madness in which it finds its own derisory truth. Each is a measure of the other, and in this movement of reciprocal reference, each rejects the other but is logically dependent upon it.

Within the four walls of these institutions, society's so called abnormal became one undifferentiated mass, and this mass was portrayed as opposing reason and progress. Outside lay progress and inside, its threat. As late as 1815, Bethlem Hospital in London showed its insane every Sunday for one penny, with the institution accruing an annual revenue of almost 400 pounds from 96,000 visitors who came to see the mad each year (Foucault, 1967, p. 143). This figure is the equivalent today of a little more than US$44,000. The portrayal of madness as a social spectacle and public scandal emphasizes the place of the mad in the consciousness of European populations. They were the abnormal other, not unlike the lepers centuries before, and it is important to consider this history when evaluating present day attitudes towards the mentally ill.

The second narrative – individual responsibility – is one with firm historical roots cultivated and fostered throughout the seventeenth and eighteenth centuries. The earliest depictions of mental illness, dating back to 650BC, locate madness in the context of an inner devil (Porter, 2002). The seeds of modern Western medicine saw mental illness as originating from an imbalance in the body's basic fluids and juices; or "humours" as they were called (Porter, 2002, p. 37). For a long time, at least until the beginning of the seventeenth century, many behaviours considered mad "remained fixed within the tradition of these four humours", or more pointedly, within the individual (Foucault, 1967, p. 113). Early Greek attitudes towards madness found their place within the tragedy of literary figure *Oedipus*, while Shakespeare transposed his understanding into *King Lear*. In each of these works, madness is depicted as a self-created affliction, which, through introspection of the self, forms a potential road to self-discovery. In both cases, the disease is described as a problem for the individual. Society is an audience.

While the Christian view held reason and sanity were found walking in harmony with God, most early analyses of the origination of madness came from the Socratic belief that self-control held the key to one's living conditions. If one could summon free will and base one's actions on it, then madness could be abated. Western culture, according to Foucault (1967, p. 54), saw madness as "the weakening

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of discipline and the relaxation of morals", an overflowing measure of uncontrolled passion within the individual. Foucault (1967, p. 228) contends that this belief was pervasive among European populations during the seventeenth century.

The possibility of madness is offered in the very fact of passion. It is true that since long before the classical age, and for a series of centuries that has probably not yet come to an end, passion and madness have been kept in close proximity.

The belief that individuals were responsible for their own mental health continued throughout the nineteenth century. Edgar Sheppard (1872) was the Professor of Psychological Medicine at Kings College in London, and in 1872 he wrote that the majority of those he would describe as insane "have made themselves what they are by their own vice and wickedness". We can assume that the views of professionals during and before this time were reflected in the attitudes and perceptions of society as a whole. As Erica Bates (1977) explains, knowledge on the issue of mental health is a two-way process whereby "popular beliefs influence professional thinking, and professional thinking modifies popular beliefs". It is worth considering the extent to which these two narratives persist in the twenty-first century.

Critiques of Foucault's *History of Madness*

Five decades following the publication of Foucault's (1967) *History of Madness*, the French historian's central thesis regarding the confinement of the mentally ill is still subject to critique, revision, and interpretation. As this chapter draws heavily on Foucault's narrative history, it is important to offer a short analysis of his critics' primary appraisals.

The most common critique of Foucault's history is that it is too simplistic and that his account of the confinement of the mentally ill is grossly over-generalized. Yannick Ripa (1990) agrees that madness is a social construction, one that can be interpreted as a product of changing social norms, but believes that his history neglected a "more intimate and fastidious examination of particular [social] groups" that were confined, in particular, to women. According to Ripa (1990), institutionalisation was the ultimate form of feminine repression at a time when women were being held to an absurd expectation of morality, one to which men were immune. Indeed, in his summary of the confinement of the idle, the vagrants, the homeless, and the mentally ill, Foucault (1967) makes little mention of the female asylum experience. There is very little debate on whether the movement to confine the "abnormal" took place, with Lawrence Stone (1982) describing it as "undeniable". But Midelfort (1992) and Porter (2002) both contend that Foucault misread the motivation behind society's institutionalisation of the mad. Porter (2002, p. 95) argues that the rise of the asylum was not an act of state, but a "side effect of commercial and professional society". As the affluent accrued more medical services that had previously been offered in the home, madhouse keepers were in the business of persuading the public that services in the asylum were therapeutic. By 1800, the confined mad in England were largely housed in private asylums. Midelfort (1992, p. 36) extends this argument, stating that the great confinement was aimed "not at madness or even deviance, but at poverty", and instead of a deliberate attempt to segregate the mad, the poor of every kind were locked away.

These critiques suggest that Foucault generalized French confinement and overlooked the unique characteristics of the movement in France's neighbouring countries, yet Foucault's legacy is in his depiction of confinement as a retrogressive step by which the mentally ill became one solid mass, within

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

which variation would go undetected. Andrew Scull's (2015) account of the segregation of the mad offers support for that presented by Michel Foucault in his own description of the history of madness. Scull's (2015, p. 190) account reinforces the importance of the asylum in the history of mental illness, stating that the "presumed need to segregate the mad … remained so notable a feature of the Western response to mental disorder until the last decades of the twentieth century". Scull described this movement to confine and segregate the mad as "a new geography of suffering", and the asylum became the "chosen solution" to the broad set of problems posed by this deviant group (p. 190). As was documented by Michel Foucault (1967), Roy Porter (2002), and Elaine Showalter (1985), conditions in these institutions were as horrendous as those experienced by animals housed in factory farms in the twenty-first century. The following account from French physician Jean-Etienne Dominique Esquirol, who lived from 1772 until 1840, documents the conditions "inmates" encountered inside these institutions.

I have seen them [the mad] naked, clad in rags, having but straw to shield them from the cold humidity of the pavement where they lie. I have seen them coarsely fed, lacking air to breathe, water to quench their thirst, wanting the basic necessities of life. I have seen them at the mercy of veritable jailers, victims of their brutal supervision. I have seen them in narrow, dirty, infested dungeons without air or light, chained in caverns, where one would fear to lock up the wild beasts that luxury-loving governments keep at great expense in their capitals.

Scull (2015) argues that across England, Europe, and North America, it was not uncommon to find in those institutions that specialised in the confinement of the mad, infestations of fleas and rats. Beating and whipping were commonly employed as means for enabling greater control of "inmates", and Scull notes that "female patients were frequently raped" (Scull, 2015, p. 191). The presence of naked women "chained haphazardly to the walls" in these institutions was common, and this treatment was the same for men. At the York Asylum in England, Scull (2015) reports that conditions were the very worst, as filth and neglect were combined with the frequent rape and murder of patients.

By 1860, the asylum revolution was essentially complete. Countries sought to replicate the Western institutional model which began in France, where in 1838 the National Assembly "passed a law directing every department in the country to build an asylum at public expense to house the insane" (Scull, 2015, p. 192). The same took place in England in 1845, while Tsarist Russia embraced the asylum once the Crimean War ended in 1856. Scull (2015) notes that Britain's settler colonies, notably Australia, built their own institutions rapidly and modeled them on those established in Britain. Australia's "inmates", by contrast with those in Europe and England, were mostly men, and many were violent. Even China and Japan would adopt the Western asylum model roughly one century after Europe and North America. An American missionary named John Kerr opened China's first asylum in 1898, in what is now known as Guangzhou. Japan passed the Mental Hospitals Act in 1919. Argentina eventually yielded to the status quo, as supporters of the asylum regime argued that these institutions were the mark of a "civilized society" (Scull, 2015, p. 200). It appears that when confronted with the problem of mental disorder, and the mad, countries looked instinctively to the asylum instead of old modes of family care, and it was a collective movement that fueled the "Great Confinement" Foucault described.

The institutions described by both Foucault (1967) and Scull (2015) developed from madhouses into asylums, where care and proper treatment became paramount. Scull (2015, p. 206) noted that "just as reformed asylums run on moral treatment principles were nothing like the madhouses … so too the new generation of superintendents were necessarily quite unlike their predecessors". He explains that at the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

York Retreat, established by William Tuke in 1792, all forms of physical violence and coercion were forbidden, and chains were dispensed with. This new approach, replicated in all asylums scattered across Western nations, transformed the asylum system into a "moral machine", that Scull and Foucault both argue was no less confining and no more liberating than the conditions characteristic of the madhouse.

Whether or not the motivation of confinement was to round up the mad or the poor is largely irrelevant because too much evidence exists to support the locking away of the mad as part of a broader group that threatened progress and reason. Inheriting the stigma and abnormality that had long been associated with the lepers, even the slightly deranged became synonymous with the dangerous lunatic. The mad were considered as one. Foucault might not have, as Lawrence Stone (1982, p. 26) puts it, "got his history right" in accordance with a strict adherence to facts and moments, but his depiction of the movement of confinement and its transition in varying forms into the twentieth century has been replicated by others of that time and has been undeniably powerful.

What is certainly clear is that Foucault did fail to account for the large number of asylum "inmates" who were women. Elaine Showalter (1985) explains that while Foucault's description of the repressive ideologies of confinement was "brilliantly exposed", he did not explore the possibility that the irrationality and abnormality that the asylum sought to confine was also the feminine (p. 6). It is worth noting that this critique mirrors the views of Midelfort (1992) and Porter (2002). Where these scholars argued that Foucault misread the motivation behind the "great confinement", pinning it on madness instead of poverty, Showalter argues for a similar misinterpretation. Showalter's work, entitled *The Female Malady*, demonstrated how cultural ideas about "proper" feminine behaviour have shaped the definition of female insanity for nearly two centuries, giving mental disorder in women a gender-specific connotation, one which eludes the sick man. Women's madness has historically been tied to the female body, with sickness derived from any one of an unfettered female sexuality that disturbs and threatens the intelligent man (Ussher, 1991); the reproductive functions of menstruation, pregnancy, and menopause; or even a simple tendency towards strong emotion (Russell, 1995). This is significant because if women's madness comes to be associated with the female body, and this is replicated historically, this link presents female suffering as inevitable. On this topic, Showalter (1985) states: "[women] are typically situated on the side of irrationality, silence, nature, and body, while men are situated on the side of reason, discourse, culture, and mind".

As a consequence of this linking of insanity with femininity, society came to seek the same symptoms in the male (Showalter, 1985; Wright & Owen, 2001). Since the beginning of the twentieth century, scholars have sought to revise this association, citing male representations of madness through literature and art which are equally powerful in comparison with the feminine images of suicidal Ophelia, crazy Jane and violent Lucia. Elaine Showalter describes in *The Female Malady* the three major Romantic images of female insanity – suicidal Ophelia, crazy Jane, and violent Lucia. She argues that all three were constructed to establish female sexuality as the primary source of madness. Wright and Owen (2001) state that "images such as the mad genius and the criminal lunatic portray men's madness as a 'malfunction' of masculine rather than feminine traits", suggesting that there has been movement beyond madness as being linked entirely with the female body (p. 145).

That Foucault overlooked the oppression of women within the asylum regime is certainly a shortcoming of his narrative history. But the purpose of his work and its resulting legacy still has important implications. Whether or not the movement to confine those perceived as threatening European reason and progress was aimed at the poor, the feminine, the mad, or all three, is largely irrelevant. The legacy of Foucault's work is in confinement as a deliberate system of control, and that the mentally ill were one

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

part of a large, undifferentiated mass that fell under this oppressive system. This was not a new form of control, as even the institutions used to confine this mass had once been saved for the lepers. And similarly, even after these asylums and the institutions known as madhouses had closed, our modern world has sought new ways to control and confine those who appear as abnormal, undesirable, or threatening. Sometimes this confinement is physical, sometimes more subtle, as is the case through the use of language.

Mad, Bad or Sick

Early asylums across Europe, Great Britain, and North America came in "all shapes and sizes", and according to Porter (2002), many were atrociously run given medical supervision was not a legal requirement until well into the nineteenth century (p. 97). Treatments were basic and mostly ineffective, as was the case with either hot drinks or ice-cold baths that Foucault (1967) describes were a means to return the human flesh to its "natural suppleness" (p. 316).

In the cold shower proper, "the lunatic was tied to a chair and placed under a reservoir filled with cold water, which poured down directly onto his head through a wide pipe". The variant was the surprise bath where "the patient was … tipped backwards into the water". This violence promised the rebirth of a baptism (Foucault, 1967, p. 317).

In the years preceding the seventeenth century, the mad who were placed on foreign-bound boats searched for their reason out on the high seas. Even throughout the eighteenth century, Foucault's quote illustrates how this image persisted, as water remained the dominant purifying method for the treatment of madness. Yet among this prolonged ill-treatment were periods of progress where compassionate ideals were adopted. These began most clearly in 1794 when Philippe Pinel liberated the mad in chains at Bicêtre, an asylum in the south of Paris. It was Pinel who would pioneer moral therapy in revolutionary France, promoting more compassionate ideals that were to be mirrored by physician William Tuke in England (Porter, 2002, p. 106).

Despite the rapid increase in the number and scale of mental hospitals throughout Europe in the nineteenth century, reforms were introduced that minimized restraint and delivered some freedom back to the insane. Roy Porter describes the rate at which non-restraint methods were adopted at the Lincoln Asylum in London. Between the years 1829 and 1838, the total number of patients restrained went from 39 to 0; the total number of instances of restraint went from 1727 to 0; and the total number of hours passed under restraint declined from 29424 to 0 (Porter, 2002, p. 115). This example serves to illustrate the power of human beings to construct the lived experience of mental illness. In the short span of nine years, the asylum experience had changed dramatically, transforming from a life characterised by restraint to one with the possibility of autonomy and freedom. Discarding methods of restraint, the mad were treated with greater levels of compassion throughout the nineteenth century, contributing to a process whereby madness would transition from "badness" to "sickness".

For present day understandings of attitudes towards mental illness, the asylums of Europe, Great Britain and North America would develop into locations and structures for the delivery of psychological treatments, largely on the back of the pioneering work of William Tuke and Philippe Pinel. It was these individuals who devised the first true methods of psychological treatment, ones that would form a platform for the work of Sigmund Freud. It is at this point in the history of unreason that the story of confinement takes a subtle turn. The following section depicts the psychiatric relationship as a modern means of confining the mad.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Legacy of Sigmund Freud

The practice of confining the mad within asylums has formed one part of a broader narrative that has defined, and continues to define, the history of mental illness. As has been established in this chapter, western civilization has used this method for over three centuries, and has done so in both subtle and overt ways. In simplistic terms, the sixteenth century saw the mentally ill placed on boats, taken to foreign locations and dumped there. In the seventeenth and eighteenth centuries, western nations found convenience in segregating the mentally ill within workhouses, a system of confinement that would continue in varying forms until asylums were closed in the 1980s (Barham, 1992). In the nineteenth and twentieth centuries, following the pioneering treatments of William Tuke and Philippe Pinel, the expression and treatment of mental illness were confined within the institution of the psychiatric relationship. In proceeding with this chapter's account of the history of unreason, I argue that Sigmund Freud played a central role in connecting the physical confinement of the seventeenth century with the more subtle segregation of the twenty-first. In this section, I detail the legacy of Freud and place particular emphasis on his role in the birth of modern medicalization.

Born in 1856, Sigmund Freud came to prominence at a time when the legacy and effects of confinement had become two-fold. First, madness had become entwined with unreason. Both metaphorically and physically, the mad posed a threat to enlightened thought and progress, and so justified 'normal' society's sequestering of this group within asylums (Foucault, 1967). Second, within confinement the mad became one undifferentiated mass, with individual insanity distinguished less clearly. It is only with the value of hindsight that one is able to assess the relevance of these consequences for the development of Freud's work. Yet it is clear that these two effects formed a platform from which he could develop his psychoanalytic approach. The mad were guilty of unreason, and so required a treatment that could deliver them back to normality. And with the mad as one unbroken mass, theories and hypotheses could be freely developed for a group that was, during the eighteenth and nineteenth centuries, relatively static. If the mad were not this solid body of despair, threatening civilized society, they would have been too fragmented and fluid for the development of a large-scale therapeutic technique. Ironically, Sigmund Freud could thank confinement for ensuring the inception and ongoing relevance of his talking cure throughout the twentieth century.

Following the publication of his first major thesis, *The Interpretation of Dreams*, Freud began to develop and outline the fundamental tenets of his psychoanalytic approach, a set of theories that would become the dominant therapeutic method of the first half of the twentieth century (Porter, 2002). His work on the unconscious, the symbolic meaning of dreams, hysterical symptoms and infantile sexuality laid the foundations for the work of other prominent European psychologists, notably, Eugen Bleuler (1857-1939), Carl Jung (1875-1961), Pierre Janet (1859-1947), and Alfred Adler (1870-1937). Roy Porter argues that each would extend and reshape Freud's theories.

While asylums were still prominent well into the twentieth century, Freud's work allowed for the flourishing of a more subtle method of control, namely, "the doctor-patient relationship". As Michel Foucault explains, Freud's most powerful legacy was in opening up the possibility of a dialogue between madness and medical thought, and so bringing mental illness back in tandem with unreason (Foucault, 1967, p. 339). He argues that Darwinian-based positivism had reduced the experience of madness to silence because it locked it away inside the walls of the asylum and within the confines of incurability. The development of a therapeutic technique prefaced on conversation reopened the gateway between

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

reason and madness, with the consequence that it concentrated the treatment of mental illness within the doctor-patient relationship, laying the foundations for twenty-first century medicalization.

This transformation was mostly subtle. Freud did not change the nature of the structures put in place by his predecessors, he simply moved them from the madhouses into the psychoanalytic situation. He did not change the nature of madness, but altered its location and so forced others to see it in a new light.

Freud made sure all the structures integrated by Pinel and Tuke into confinement were appropriated by the doctor. He freed the patient from that asylum experience … but he failed to spare him the essential components of that existence. He concentrated its powers … and placed them in the hands of the doctor. He created the psychoanalytic situation, where … alienation became disalienating because, in the doctor, it became a subject (Foucault, 1967, p. 511).

The doctor came to be seen as the sole means by which a patient could be delivered from their suffering, as madness was now a subject for the doctor to decipher. This is a transition of power that remains to this day. Considering the development of this doctor-patient relationship with the growth of medicalization following the second World War (Conrad, 2007), and one would suggest that confinement did not end with the liberation of the mad in chains at Bicêtre, or the birth of psychoanalysis. Rather, the walls remained, but they became invisible.

Medicalization

Medicalization is the process of taking non-medical problems and reframing them as issues that require medical attention (Conrad & Schneider, 1992). It is not the direct work of Sigmund Freud, but there is little doubt that medicalization has benefited greatly from the platform of the doctor-patient relationship, without which its ability to expand in both breadth and scope would be greatly diminished. Medicalization is an important figure in the history of madness for two reasons. First, it represents a continuation of the confinement narrative, albeit in a more subtle form. Second, it is a social process that supports the constructionist view of health and illness, explored in the early stages of this chapter. Peter Conrad (2007) offers a suggestion for how mental health can be understood as socially constructed through a description of medicalization's bidirectional nature.

Medicalization is bidirectional, in the sense that there can be both medicalization and demedicalization … For demedicalization to occur, the problem must no longer be defined in medical terms, and medical treatments can no longer be deemed appropriate interventions. A classic example is masturbation, which in the nineteenth century was considered a disease and worthy of medical intervention (Conrad, 2007, p. 7).

Conrad's thesis on the medicalization of society focuses on balding, erectile dysfunction and adult ADHD as more recent examples of non-medical problems that have been defined and treated under the umbrella of the medical model. This medical imperialism has been aided by major pharmaceutical companies and their development of medication designed to treat what Conrad (2007) argues are not illnesses, but "life problems" (p. 61). These developments became most evident in the second half of the twentieth century.

The introduction of penicillin in the 1940s and chlorpromazine in 1954 became precursors to the pharmacological revolution (Barham, 1992). Chlorpromazine was the first antipsychotic drug designed

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

for the treatment of mental illness, and significantly changed the way the insane were treated in asylums during the twentieth century (Barham, 1992, p. 6). Elizabeth Bott (1976) explains that medication was useful in British institutions because it solidified the distance thought necessary between the insane and their carers. She states that "talking to patients is dangerous because it threatens to puncture the barrier that keeps sanity and madness in their proper places" (Bott, 1976, p. 133). The use of medication to confine and control, evident in Bott's description, represents an overlap in the confinement narrative. While the confinement of the psychiatric institution faced imminent closure towards the end of the twentieth century, the confining effects of medication and its inherent linking with the doctor-patient relationship were rapidly developing in its stead. Barham (1992) argues therefore that the legacy of the asylum is the "abolition of the *person* who suffers from mental illness", replaced by the mental patient, identity permanently spoiled, exiled on the margins of society (p. xi).

In 1987, Prozac was first introduced as a new type of medication to treat depression. Conrad and Schneider (1992) argue that the introduction of Prozac was important because while the 1980s saw the widespread closing of asylums and the end of physical confinement for those defined as needing treatment for mental illness across western countries, the mentally ill would find a new segregation within the doctor-patient relationship, the site at which they remain dependent for their antidepressant and antipsychotic medication. The uptake of prescription medication has been rapid and unrelenting. Between 1990 and 2007, there has been a 2.5-fold increase in the number of visits to a doctor in the United States that resulted in a prescription for a psychotropic medicine, suggesting that "problems that a decade or two ago would not have been deemed appropriate for medication are now managed with psychotropics" (Conrad, 2007, p. 129). Between 2011 and 2012, there were over 23 million prescriptions written for mental health medication alone (DoHA, 2012). According to Conrad, medicalization holds biological factors accountable, and it is here that prescription medication and the physician who prescribes them, present themselves as necessary for complete recovery. In describing the patterns of use for mental health medications in Australia, the Australian Bureau of Statistics (1995) reports:

Almost everyone who used … anti-depressants did so on the advice of a health professional, mostly a General Practitioner or medical specialist … Nearly all people who used medications in these groups obtained them either by prescription of from a doctor or a hospital. Patterns of use differed by the types of medications used … of people who used antidepressants, 94% used them regularly and 91% used them daily. Of people who used antipsychotics, 90% used them regularly and 87% used them daily (ABS, 1995).

Peter Barham argues that this dependency on medication has been one of the major consequences of the closing of asylums in the 1980s. He also believes that it propelled the process of deinstitutionalization forward, arguing that multiple factors originating from the middle of the twentieth century combined to reinforce a focus on deinstitutionalization, namely, "the literature of protest against the indignities of the mental hospital regimes on the one hand, and the new-found psychiatric optimism about the major tranquilizers on the other" (Barham, 1992, p. 12). With inadequate community-based support set up to meet treatment and care needs, the mentally ill were discharged and expected to re-join the broader community outside the mental hospital seamlessly. Evidence suggests that doctors were the most vocal enthusiasts for community-care policies, based on their belief in the effectiveness of new drug treatments. Community care facilities were envisaged as a stepping-stone between a brief stay in a mental hospital and complete reintegration back into society (Barham, 1992, p. 12), and so it appears there was a discrepancy between the commitment to scale down mental institutions and the establishment of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

alternative forms of service. As a consequence, a vast majority of the mentally ill found new forms of confinement within prisons, on the streets as the homeless, and finally, through the confinement of the doctor-patient relationship, an institution that began with the work of Sigmund Freud at the beginning of the twentieth century. In the final section of this chapter, I shift the focus more locally, outlining how twenty-first century confinement is taking place in Australia.

AUSTRALIA

Australia's mental health history mirrors that which has been described throughout this chapter for seventeenth-century Europe, blended with some characteristics unique to Australia's rich Indigenous culture (Martyr, 2010). Brenda Happell (2007) reflects that in the 1800s, Australia's approach followed the British model, tending to "reflect the views of medical superintendents who migrated to the colonies to oversee the asylums" (p. 1440). By the year 1811, at the Castle Hill Lunatic Asylum in New South Wales, mental illness was still referred to as "madness", and its origins remained the product of "bad blood" or character flaws, as opposed to illness (Happell, 2007). This suggests that the "individual responsibility" narrative introduced in part two of this chapter was transposed from the British context into Australia. The mad were managed through methods of physical restraint and isolation, and there appears no evidence of mental treatment, with a far greater emphasis placed on the custodial role (Keane, 1987). The treatment of supposed mentally ill Indigenous Australians between 1870 and 1914 has emerged as a unique characteristic of Australia's mental health history also. Philippa Martyr found that between 1870 and 1914, a total of 30 Indigenous Australians, mostly from Western Australia, were charged and/or diagnosed with lunacy. The incarceration that followed forms part of White Australia's mistreatment of Aboriginal Australians following colonisation. Yet as the moral therapy pioneered by Tuke and Pinel signaled the transformation of European attitudes towards mental ill-health, Australia's approach began to consider mental illness less as a moral failing and more as an issue requiring behavioural treatment and change (Happell, 2007).

In line with broader changes occurring in most western countries at the time, mental illness was shifting from "badness" to "sickness". In 1867, an Act of Parliament ensured that the mentally ill were sent to asylums rather than prisons, and by the middle of the nineteenth century, mental patients were being transferred from jails to newly opened asylums in all major Australian cities (Happell, 2007). Responsibility for mental illness was becoming less individual and more societal. In 1955, the Stoller Report became the first document to outline the consequences of social indifference towards public mental health services, and the effect this lack of attention could have on the mentally ill (Bates, 1977). Erica Bates (1977) described the report as "the first public recognition that the problem of mental illness is a general problem, and not one to be blamed on the individual" (p. 20). The Stoller Report proved prophetic. Following deinstitutionalization, Australia's mental health approach accelerated towards community-based care, ensuring the responsibility for mental illness came to rest on society more broadly. How effective this process has been for the treatment of the mentally ill is debatable, yet community mental health organisations naturally increased in prominence as a result of this trend, with *Reach Out* founded in 1996, *beyondblue* in October 2000, and *Black Dog* in 2002.

Despite this increase in community-based care practices, western medicalization continues its rapid expansion, of what has been described in this chapter as a modern form of mental health confinement. This control, enabled through psychiatric diagnosis and psychotropic medication, has been no less

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

pronounced in Australia. Following the publication of the DSM-V in 2013, the Australian Broadcasting Commission (2014) reported that current definitions of mental illness were so broad that "50% of western populations can be diagnosed with a mental disorder". To an extent, this is exactly what is taking place. The prevalence of mental illness in countries like Australia has become a problem taking on epidemic proportions. According to the World Health Organisation (2013), major depression is the most prevalent psychological disorder in the west, affecting approximately 350 million people, and surpassing heart disease as the world's leading cause of disability. This growth is symptomatic of a society seeking to solidify the boundaries between normality and abnormality, reason and unreason. In clarifying this divide, western civilizations have re-enacted an historically effective method of controlling the mentally ill. This method is confinement.

The process of identifying more and more behaviours as symptomatic of mental illness segregates the mentally ill because it concentrates the site at which mental health issues are treated: within the doctor-patient relationship. It also focuses the problem within the individual at the expense of a thorough exploration of broader social causes. From the leprosaria to *The Ship of Fools*, and from the madhouse to the therapeutic relationship, society has developed the "deep disposition to see madness as essentially Other" (Porter, 1987, p. 35). As a consequence, modern society seeks to segregate and control this deviance, and since the closing of asylums in the 1980s, medicalization has been an effective means of enabling this control. Peter Barham suggests that to some extent, the asylum provided a more certain system of care than the one offered today.

It is clear that people with long-term mental illness in the community may find themselves as structurally isolated as ever they were in the asylums, and in addition their health needs may now be ignored (Barham, 1992, p. 32).

Within the asylum, the mentally ill were neglected as patients. Released into the community, they are now neglected as both patients and citizens, in equal measure. In this way, Western society has developed a subtle continuation of seventeenth century European confinement, representative of a powerful arm in the social construction of mental illness.

CONCLUSION

This chapter charted the history of mental illness as a means for illustrating how it can be understood as socially constructed. Drawing on the work of Roy Porter (2002) and Michel Foucault (1967), we have shown that social norms, attitudes, beliefs, and institutions within which treatments are delivered define the lived experience of mental illness. These phenomena, particularly social institutions, are all dependent on social forces. The individual confined in a Parisian Hôpital-Général in 1656 experienced their illness differently from an American teenager diagnosed with depression in 2018. Their social worlds were different and so also were the understandings of mental illness – madness in the case of the Frenchman – and the treatments they received. The mark of stigma affects the way an individual understands their illness, and we have shown in this chapter that this stigma has distinct historical origins.

Roy Porter's (2002) description of the rate at which non-restraint methods were adopted at the Lincoln Asylum in London between 1829 and 1838 illustrates how quickly human beings can reshape and reconstruct the lived experience of mental illness. The central argument of this chapter is that while methods,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

treatments, and institutions have changed over time, the purpose of these changes has almost exclusively been to exercise a tighter form of social control. Institutions like the Lincoln Asylum eventually discarded their shackles in the mid-late nineteenth century, but Porter (2002) and Foucault (1967) argue that the institution then became a site for moral segregation, moving mental illness from "badness" to "sickness".

The dominant mental health narratives that characterised this history have been "confinement" and "individual responsibility". While the *Ship of Fools* no longer exists, nor the madhouses that were borne out of what Foucault called "The Great Confinement", we argue that this narrative persists in more subtle forms, namely, through the invisible walls of stigma and medicalization, which continue to frame the mentally ill as a distinct, abnormal "other". An appreciation of this history allows for an acknowledgment of our ability to construct and reconstruct the mental health lived experience.

ABSTRACT

In this chapter, the authors provide a brief overview of the distinction between flourishing and non-flourishing mental health and well-being for people not diagnosed with a clinical mental disorder. While recognizing that genetics and personality impact the well-being of people, research supports the profound impact of societal constructs in American life. As part of a team of faculty who work with undergraduate students in Teacher Education, the authors feel this distinction is essential to understand as medical issues require diagnostics by people trained in that area. The book's focus is to examine what the college community can do to promote flourishing mental health in its social construction in classrooms, on campus and beyond. Dominant influences for non-flourishing mental health and well-being for college students rest in ideologies, happiness seeking and digitalization within American life, membership in groups that are underrepresented and well-intentioned but enabling parenting that ill prepares children for adult responses in life.

INTRODUCTION

In this chapter, the authors provide a brief overview of the distinction between flourishing and non-flourishing mental health and well-being for people not diagnosed with a clinical mental disorder. While recognizing that genetics and personality impact the well-being of people, research supports the profound impact of societal constructs.

The chapter then focuses on the non-flourishing mental health of undergraduate students in college and the social constructs that have impacted the development of these anxieties. These include the influence of living in American society with its polarizing politics and obsession with the pursuit of happiness and media views of what this looks like, the influence of being a part of groups that are underrepresented in America, such as race and culture, religious beliefs, classism, sexual orientations, gender, and the influence of over-productive parenting and early educational experiences.

NON-FLOURISHING MENTAL HEALTH AND WELL-BEING

No one is raised in a vacuum and this is true of college students. Genetics and environment influence all, and people seeking higher education are no exception. While this life transition can trigger intense feelings of joy, it can also activate feelings of anxiety and depression. For purposes of this book we are not focusing on those with clinical mental illness but rather as Corie Keyes, full professor of Sociology at Emory University and UVM's Keynote for the 2nd Annual Conference "Mental Health Matters: Building a Resilient Campus" (Oct. 28, 2016), identifies those who are struggling emotionally, but who are not classified as mentally ill. He counters the often-held belief that if one does not carry a mental illness then one is mentally healthy, but this denies a category of people who are neither mentally ill nor mentally thriving or flourishing. According to Keyes, this middle category of "not flourishing" can include over 40% of the population.

This chapter will primarily focus on social constructs that can influence mental health and well-being: 1. membership in America's citizenry that promotes the "pursuit of happiness" and the often superficial representation on social media, along with America's current Nationalistic polarization, 2. membership in American's subcommunities that are underrepresented within the larger whole, and 3. membership in families and educational settings that may over-protect and over-control with good intentions, keeping young adults overly dependent on others and insecure in their own abilities and decision making skills. Later in the book there will be information regarding the role the campus community can play in easing some of these social constructs and in building a more supportive, proactive and safe collegiate society.

Using Keyes' Mental Health Continuum, John Fink (2014) identified and analyzed predictors from students about their college experiences that impacted their mental health favorably as college faculty and staff found entering freshmen to have "all-times highs of emotional disengagement" (Fink, 2011, p. 380). The World Health Organization published a report on Promoting Mental Health (2005) that shored the research that mental wellness is more a societal issue that is less about individual interventions and more about "social structures and processes" (p. 29). British author Ruth Whippman in her 2016 book, *America the Anxious: How our pursuit of happiness is creating a nation of nervous wrecks* analyzes America's obsession with happiness and the resulting failure of our intense multiple pursuits of it. She notes that the American Psychological Association (2012), forewarned that the US was on the precipice of "stress-induced public health crisis" (p. 10).

Many would say that it is the larger college community itself, beyond individuals, that creates the climate of stress. A recent study concludes its research with imagining a "different kind of academy, exploring the practices that produce it can be differently enacted…" (Peake, L., & Mullings, B., 2015, p.253). One of the hopes of Peake's and Mullings' study is to begin to create a space for mental wellness that de-stigmatizes people with mental and emotional stress so that care of self is more emphasized and that the corporate mindset of universities is minimized. (273). Whippman recognizes the impact that

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

social media bring to these stresses in chapter 7 entitled, "I'm not a happy person; I just play one on Facebook". The intense need for a positive public persona on social media can result in the creation of a disingenuous self with exaggerated superlative displays of happiness that can play into readers' insecurities as well. This manic polarizing drive to pursue perfect happiness can also result in disconnections from real life and real people.

Informally and in support of the above, we in Teacher Education have observed more students who self-describe themselves as anxious, depressed and overwhelmed in this program so these findings don't surprise us. However, it does challenge us to better understand so we can provide more effective assistance in a systemic and empowering manner, as we acknowledge student responses to frustration, social status and anxiety often run counter to their paths for college success.

THE AMERICAN WAY OF LIFE, PARENTING, AND BRIBERY

The review of literature indicates many influences for non-flourishing mental health on campuses, reflective of the social constructs of communities in which students' live. Beginning in homes with overprotective parenting and/or from parenting immersed in economic survival to students' reactions to the new institutional community they've joined may or may not scaffold this new acclimation. Living in a culture that advocates for 24/7 perfect (and unattainable) happiness presets disappointment for many. People who are from underrepresented groups and who are away from their first home bases may come to realize unique isolation and stressors that might or might not be present for those in the dominant groups. Parenting contributes to mental health status, ironically and particularly from homes that believe they are protecting their children from the world that they believe is difficult to navigate safely (Lythcott-Haims, J., 2015). It's theorized current college students are struggling to find their place in a world with an expansive generation gap, ranging from digital nativism, economic disparities, interpersonal challenges and isolation in spite of life in the world-wide web and a sense of entitlement (Levine, A. & Dean, D., 2012).

At issue for many young college students can be found in Lythcott-Haims' book *How to raise an adult.* She presents a compelling argument that much parenting, while good intentioned, has handicapped young adults who learned to overly rely on protective adults for any decision making, inadvertently undermining their confidence and willingness to take risks, and creating a false expectation that perfection can someway be attained with interventions by authority figures. She argues that current parenting and formal early schooling do a good job of caring for children but a bad job of preparing them to be adults who are independent thinkers and contributors in their adult communities as most of their youths they've been kept safe and involved in adult-decided and supervised recreation and activities. While there are sane reasons for this parenting approach, given milk cartons with many different pictures of children who've been abducted and Halloween candy penetrated with sharp instruments, she thinks this approach went too far and hovering parenting has become the norm. Children have absorbed their parents' fears and tread lightly into the larger world of unknowns. These children have not had enough experiences making their own decisions, such as setting and applying agreed upon rules for pick-up games, where fairness was negotiated among the players. Children have not often had opportunities to recover from incidents dealing with hurt feelings or conflict resolution among themselves. Too often parents become involved to "save" their child from any hurt be it in schools, with peers, with coaches, the list goes on.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

How do children know they can recover when things don't go the way they'd like? How do they learn to problem solve when there are no problems for them to solve on their own?

Lythcott-Haims says children learn two things from over parenting: they learn they are inept and the world is not safe. This results in passivity, inertia and apprehension. The parent's fears, of which the parent may say is responsibility-taking, turnkeys into insecurity and inaction in the child. An independent, decision making adult has been submerged into a timid, insecure, anxious adult. With good intentions or not.

Jessica Lahey in her book: *The gift of failure: How the best parents learn to let go so their children can succeed* offers a similar sentiment for parents and teachers. She, too, says that over-parenting, of which she concedes complicity from her own parenting, has the potential to undermine children's confidence and undermine their education. Children need many opportunities to have success from their own making or they learn they can't create their successes. Failure is not failure as reputed but rather it is necessary for success to occur. Ms. Lahey learned for herself and now tells others that it is important to embrace children's failures as this is where they learn about life and learn what they can handle on their own.

In this same vein of overprotective parenting, Lukianoff and Hadt perceive colleges campuses and classrooms as over protecting students "from words and ideas students don't like, seeking punishment of those who give even accidental offense" (2015, 42). They build a case showing that guiding students to question their unexamined thinking is challenged with a "new protectiveness" that may encourage pathological thinking and compromised mental health. Reflective of the current culture of polarized politics and hostility and the "self-righteousness fueled by strong partisan emotions" (45), students may feel the pressure to join a side and be true to the "team". The social media used by these true "social-media natives" has shifted the faculty/student balance, putting faculty in fear to offend. Thinking is dominated with strong emotion and defensiveness by both Millennials and Gen Zers, who've received the message from their homes that adults should protect them from the dangers of life, including each other. They further reason, citing psychological theory that people with anxieties need help in facing their fears, not be protected from them.

Many students enter college with the expectations that rewards are attached to everything they do and this could be result of their experiences in K-12 schools and elsewhere. Alfie Kohn espoused the problems with our externally motivated tactics in school operations in his 1993 book, *Punished by rewards: The trouble with gold stars, incentive plans, $, A's, praise and other bribes.* Kohn argues that these "incentives" undermine self-confidence and create a sense that learning is contingent only for the bribe, giving the sense that the learning is secondary. Creative thinking is minimized as getting the bribe becomes the focus and accountability for one's work is greatly diminished as the goal becomes to get through or survive some project, activity, or routine to get to the reward. College students have been well immersed in this world of extrinsic motivation and not enough has been done to develop more fully internal motivation to creatively problem solve and be thoughtfully engaged with the needs of the community in which they live. Rewards become punishments when not received and anxieties can result when the external bribes are not present per expectations.

Daniel Pink in his 2009 book *Drive: The surprising truth about what motivates us* develops this thinking more thoroughly arguing that institutions operate in ways that run counter to science research about what motivates people to engage with full energy in tasks to think deeply and to creatively problem solve. He says the extreme emphasis on rewards and punishment to get work done actually runs counter to learning and problem solving and to the quality of the work. Current young adults have been programmed to do what's minimally expected to get by for a reward or not, but generally not for the joy of the work and/or learning.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Today's college students are living in a world that is very different than their parents, according to Arthur Levine and Diane Dean in *Generation on a tightrope: A portrait of today's college students.* A chart in this book (p. 17, 2012) analyzes four critical areas of difference for today's college students and their parents: technology, globe, economy and demographics. Parents grew up in era where the cold war and two super powered countries thrived. Russia was already dissolved before students were born, and students were babies when the twin towers were attacked by al-Qaeda. They grew up in a world of escalated terrorism and a less powerful nation than the one their parents lived in. Their parents' world was pre-digital (analog) while digital technology is all current students have known. The dominant white middle-aged baby boomer time period in the Northeast and Midwest that parents of current students know has been replaced by many more people from countries other than European heritage, and there's been a shift of living in the NE to the West and South, along with a now aging baby boomer population. Parents' lives began with an economy that was industrial while their children primarily have only known one that is based on information and one that has been in recovery from recession. These social contrasts for students born in the 21st century have been dramatic and realized in a relatively short time period and "give insight into the generational experiences we are experiencing today" (p. 17). In addition, this diverse and different world students inherited "may be far more profound, affecting career choices, economic opportunity and attainment, and the future of the American Dream" (p. 35).

DIVERSITY AND IDENTITY FORMATION

Citing the 1998 study *When Hope and Fear Collide,* Levine and Dean note that the "multicultural divide is less deep; the gap between diverse groups is less wide" (p. 97) and that higher education campuses are not the same as yesteryear. However, they also note that racial, religious and sexual identities are still problematic. And as this digital generation is not strong in interpersonal skills, there is an undercurrent barring good communication and understanding, as does a sense of being political correct. "Diversity problems are one of the topics most frequently left for parents to raise with the dean" (p. 99). Self-segregation by race and lesser by religion is still present on campuses with many students of underrepresented racial and ethnic groups socializing primarily with those in their same groupings. As a result of this inclination there has been a rise in student affinity groups where clubs and organizations are focused on specific populations, such as religious organizations, racial/ethnic and sexual orientation groupings. While these grouping provide assistance to students who are underrepresented in their identity formation, they also can be barrier like to the larger community.

Economic status is a powerful variable in the development of a flourishing mindset. In a December 2015 report from the Pew Research Center entitled. "Parenting in America" it was concluded that there is a notable divide in parenting that is more related to economic circumstances and less for the parenting analysis between the overprotective parenting and the more laid back parental approach for children's life success. Lower income parents have more challenges than higher income families and this shows itself in children's less participation in extracurricular activities, like sports or scouts or the arts and in getting affordable after school care. Social issues like teen pregnancy and legal troubles are higher for those in low SES, and worries about their children being victims of violence are increased too. The heightened propensity for single parenting in the lower SES groups impacts this divide as well. Survivors of those who have lived with poverty have a steeper uphill journey to thrive in colleges.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

College students who come from groups that are underrepresented, including students in the LGBTQ community (Sabato, 2016), students who are female (Liss & Erchull, 2015) (Merianos et al., 2013) or students from races that are neither White nor English speaking have different experiences and challenges in college than those in the dominant groups. This "outside looking in" also extends to those students who are from indigenous communities (Scholl, 2006) (Dellinger et al., 2016), to students with different learning abilities (Carroll, Muller & Pattison, 2016) to students who belong to religions other than Christianity (Abdel-Khalek & Lester, 2017). Extra challenges exist for those who are first generation college attenders (Wheeler, 2016), for those in a lower socio-economic status carry (Brown et al., 2015) and/or for those with different abilities (Piers & Duquette, 2016). The campus climate itself may contribute to mental wellness in terms of available supports and sensitivity to the emerging adults' developmental, physical, social, emotional and learning needs.

Identity formation is an integral component of undergraduates' development and a strong indicator of their well-being. Family background, race, ethnicity, religion, sexual orientation, gender and ability can be components of identity as can genetic inclinations and environment that begins with family of birth. It's been found that people with moral and emotional maturity along with identity integration possess more positive mental health and thus engage in fewer risky behaviors (Hardy, 2013). Erik Erikson theorized that there are life stages of psychosocial development, focusing on the crisis for each human in each stage that can conflict with societal expectations. Adolescents search for personal identity in the midst of efforts to clarify their roles in the world to about 18 years of age, the entry age to college. These emerging young adults throughout their undergraduate years in college then search for intimacy as they balance their own sense of isolation. This is where the pursuit of close relationships outside of family develops (McLeod, 2013), and as in all of Erikson's theoretical stages, it is essential for the person to successfully maneuver the elements of "crisis" within each stage and to integrate the skill sets that are necessary for a healthy personality development for life.

This personal life developmental trajectory provides enough hurdles for those born with privileges of belonging to groups in areas such as class, gender, heterosexuality, race, physical, emotional and learning abilities, and language. Even if students' families are familiar with college rigor, demands and expectations, students still need to navigate the new collegiate territory, and this is much more challenging for those without the membership in dominant groups.

For first-generation college students (FGCSs) there may be a lack of grounding in understanding higher education and its operations. In addition, many FGCSs carry the hopes of their families for success and the responsibility to bring them honor and respect. In addition, there may be some intensity around finding careers to support family and this often requires college degrees (Wheeler, 2016). This extra burden can be substantial enough, but if completion of plans or program shifts and the expected success in the career path is at risk, mental wellness may swing toward non-flourishing and as research shows currently, retention of FGCSs is very low compared to other college peers in the first year of college (p. 112). Guilt, a sense of failure and of disappointing family, a belief that the sacrifices of the family make this "failure" difficult to discuss with them in the midst of confusion for next steps can compromise students' mental strength to stay in college and/or approach another career path (p. 114). Compared to their peers, many FGCSs carry a stronger sense of belonging to their families and culture, but when they feel they've broken their commitment to bring honor and improved economic status for their families, this belonging sense can be broken, making them more vulnerable to poorer mental health (p. 115). It's recommended that career counselors understand the uniqueness surrounding the FGCSs' experience in college, so extra steps can be taken to guide and work with them (p. 114).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

For students in underrepresented groups of race, culture and/or gender, obstacles for college success and flourishing mental health are present. In a study designed to analyze students from these groups in terms of health wellness compared to White peers, it was found that poorer mental health has a propensity to rest in those from the minority communities, regardless that they may attend colleges where their minority grouping was the majority (Smith, Chesim & Jeglic, 2014). While students who are White may experience social issues around money, academics and entrance into new sub-communities, students who are in the minority also experienced these and additional stressors, such as racism, depression, feelings of isolation, suicidal ideation and self-harm (p. 85). Female students in this study of 461 students ranked at risk for depression, isolation and suicidal ideation as well and if the females were also from the minority racial/ethnic community, there was a higher probability for mental health to not flourish more significantly (85). This study shared a limitation that they didn't distinguish between minorities born in the US and those born elsewhere, so Blacks and Hispanics were situated as one group. It was recommended that this distinction be recognized for a future study (p. 87). There have been many studies from which this study built and it is clear that being from an underrepresented race or culture can impact the well-being of mental health.

Class influences perceptions about higher education. One study used the metaphor of a funnel to better explain "there are "cumulative disadvantage results when first-generation and low-income college students are disproportionately filtered out at each stage of the postsecondary education process: (Aronson, 2007, p. 1). If parents don't possess a college degree, there is a higher likelihood that encouragement for their children to attend college is lessened as ambivalence about dropping out is heightened, as that may reflect their family norm. Financial aid is complex and many students begin in community colleges and try to transfer to 4 year institutions, often with a loss of credits at a financial cost. Academic performance is poorer compared to their more advantaged peers who benefited from a stronger K-12 program.

There is much disparity in readiness for college in terms of what is taught in high schools and college expectations as well as great differences between students living in poverty and those living with economic advantages, parental support and expectations to continue with higher education (Venezia & Jaeger, 2013). Discrepancies are found in schools well-funded from higher SES locations as opposed to those centered in inner cities and rural areas reflecting a lower SES. All public schools are not equal per economic structures that fund public education's resources and programming among low SES public schools, either in urban or rural areas, and this disadvantages students preparing for higher education (Klugman, 2012). The growing stratification within higher education precludes most who are not in the higher SES from attending many selective institutions (p. 803).

As a result, too many students are entering colleges ill prepared for the academic rigor. There's a need for reforms that "take a systemic, comprehensive approach to provide students with both academic (like the CCSS) and nonacademic resources and opportunities" (p. 122) to more comprehensively support students' college readiness needs. Students who are from low SES and those who are first generation to attend college may need to compensate for learning advantages denied them. The additional struggles that students from low SES and those who are first generation impact success at colleges of choice as it influences their mental well-being in juggling feelings of inferiority and feelings of frustration and anxiety in trying to keep up with the college work and often with employment to augment college costs.

Keyes, et al (2010) concluded that genetics play a role in influencing social and emotional health, as does environment. Burris, et al analyzed several factors that contributed to students' psychological distress and well-being. Among them they found that the best predictor of positive mental health was a positive disposition (2009). Students who can see the glass half full rather than half empty demonstrate

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

perseverance in their studies and work. This study also found that students who see their health as important (HAV-Health as value) also have better mental health. Exercise, good nutrition and minimizing alcohol intake show a positive indicator for better mental health. More study is needed to connect religiousness, spirituality and sexual behaviors but there are indicators these, too, could be predictors.

Supporting Keyes' research, Fink explored elements that could predict student mental health in college life (2014). Keyes had developed a mental health continuum, describing positive social functioning and the implicit optimism in working with and expectations of individuals and groups to be indicators of mental health from languishing to flourishing. Fink added Astin's I-E-O conceptual framework that identifies input, environment and outcome to project how precollege characteristics along with the college's environments could reflect scores that indicate flourishing mental health. While this study highlighted several predictors of flourishing mental health for college students, such as supportive social arenas, ease into college routine, sense of belonging and self-confidence, this study didn't show relationship with students' college environs and positive mental health.

Levine and Dean have also found that there are differences in thinking and attitude in this generation of Blacks, Whites, Hispanics, Asian Americans, Females and Males in being less polarized with race and gender and having more satisfaction with college. They've expressed a community feeling, having professors who are accessible, experiencing good teaching quality and having comfort with expressing unpopular or controversial positions. There is more positivity regarding race and discrimination and opportunities for women than in their parents' generation. "There is more homogeneity between groups and greater heterogeneity within diverse groups than in the past as well" (p. 107).

However, as social constructs are considered in analyzing non-flourishing mental health for college students, there needs to be mention of the dramatic shift in US leadership this year of 2017. "A culture of war buttressed by the forces of white supremacy and militarization has been unleashed in a series of policies designed to return the United States to a history in which the public sphere was largely white and Christian, and the economy was and the state were governed by a ruling corporate elite" (Giroux 2017, p. 1). We are experiencing a pugilistic attitude at home with Muslims, women and their reproductive rights, immigrants and the poor, along with the sense that war abroad could happen at a tweet's moment. Giroux argues that those with social liberal perspectives need to pay attention to the politics and the causations for this shift in leader shift, this polarization of citizens who are passionate about being ignored, losing good jobs and benefits and who are looking to a hero to save them. Emotions are high and fear is widespread from both polarized positions of those believing the current POTUS can right the ship to those fearful of his capricious, erratic functioning.

Just prior to his election in fall 2016, some of these fears were articulated in a journal that re-constructed his Nationalistic slogan, "Make America great again" to "Make America hate again". Rage was and is widespread in reaction to a slowed economy, terrorism, social and demographic transitions, mass shootings, crime and gun control, in addition to leadership that well knows how to manipulate these emotions for personal benefits. Sasha Abramsky describes hateful behaviors toward Islam, Muslims, immigrants and those not white. She says this "rejection of democratic norms" will be felt for years to come not only in the US but around the world (Abramsky 2016, p. 29). As a land of immigrants and people of diversity in religion, culture, race, language and sexual orientations, those in these groups, at college or not, may have a higher propensity toward non-flourishing mental health and those of us in public and private institutions need to shore each other with support and strategies for coping with this public state of affairs. Polarization in thinking has threatened engaging conversations to understand and compromise with the other.

One study about traits of college students identified several factors that contribute to what the researcher called "the mental health crisis in North America". Based in Canada but inclusive of the United States' populations, Kruisselbrink Flatt (2013) cites a study that determined that depression in Canadian and US institutions found first year students met the criteria for depression with 7% being male and 14% being female. She notes that nearly 100% of campus psychological counseling centers have reported a rise of cases with students seeking mental health interventions. In this paper, she notes several factors that contribute to this "crisis", with academic pressure being first with the high-grade expectations, the reality check for this and millennials difficulty in dealing with failure. The competitive economic environment also creates strain for employment probabilities, along with student loan debt increasing the more years in higher education to prepare for life after. Kruisselbrink found in her research that it wasn't the amount of the debt that was the stressor but rather it was the students' worry about the debt that impacted their academic performance in a negative manner. Another factor cited was the accessibility of higher education for those from lower SES brackets who previously wouldn't have had this option to further their education, speculating that the competitive college environment may trigger for some college students from disadvantaged backgrounds mental health stressors as survivors of less than desirable home environments.

In a March 2014 study, the Pew Research Center focused on "Millennials in Adulthood" and found that "they are relatively unattached to organized politics and religion, linked by social media, burdened by debt, distrustful of people, in no rush to marry and optimistic about the future" (p. 1). They also describe them as "America's most racially diverse generation" (p. 2). In spite of their optimism, they also carry more debt than the previous generations of Gen Xers and Boomers as a result of the convergence of The Great Recession, globalization and rapid technological change on the American workforce. Millennials that are only equipped with a high school degree particularly feel this divide with higher unemployment and lower wages than those in previous generations. It is not a stretch to understand Millennials lack of trust of institutions and their critiquing of those in charge, such as politicians, priests/ministers/rabbis etc. teachers/professors, management personnel and decision makers. According to this report, that while Millennials vote Democratic, more than half choose "not to identify with either political party" (p. 8).

Levine and Dean find that Millennials are very conflicted. They are passionate about desiring social change as Obama promised but find themselves disillusioned with social institutions and they have disengaged from social activism with outspoken liberal leaning but conservative beliefs and the conservative identification but liberal positions. It's as if they refuse to fit in any mold (p. 131). The environment and globe tend to bring them together as a group. They overwhelmingly say they want to make a difference in the world, and it appears global environmental issues and local issues tend to be more on their radars. However, "Their commitment is not large-a median and mode of eleven to twenty hours a year" (p. 146).

Levine and Dean discuss the irony of technology usage for Millennials and Gen Zers that brings social life into the classroom while replacing the need for social life on campus. They discuss the "new tribalism" in which social media contacts can expand to present and past friends, family and any number of people 24/7 in class and out, creating their virtual communities and a lack of need for face to face relationships. The existence of diaphobe which is "the fear of being without a digital device" (p. 75), creates an inherent intense focus on the device in which some would say much time is wasted. With this comes the expectation that everyone else is reading texts and email as soon as they are sent and that the expectation for an instant response creates impatience and a sense that Millennials and Gen Zers are the "I want it now generation" (p. 75). We know fellow college instructors who share both frustration and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

feelings of anxiety around the emails late at night to answer questions re: coursework. Synchronous time overlaps with students with asynchronous time. Many faculty want to help students as much as possible, but maybe not at midnight. Many students expect answers when they ask the questions. And many students obfuscate social media "friends' with genuine ones. The social navigation remains complicated in spite of technological advances.

An Undergraduate Survey 2009 shows that more than a third of undergraduates do not participate in the general social activities on campus like: the gym or fitness center, academic or professional clubs, lectures, debates, or other academic events. The library is one exception. Part of this finding is that more students need to "work longer hours, attend college part time, and extend undergraduate education beyond age twenty-four" (p.57) in at least State schools and community colleges. However, this is not the only causation for less involvement in campus activities. In three studies in response to the question about what they like to do for fun, drinking and partying were number one response. This isn't a new phenomenon but how and what they drink may be. They are not drinking beer in the same way but rather they drink hard alcohol with flavored vodka as a new favorite. They also drink more intensely, not just five or six but often twelve or more (p. 60). And as a result, as always when alcohol is in the mix, good decision making is compromised. Sexual encounters, harassment, stalking, violence, drug use other than alcohol can be advanced and the next day's regret can contribute to non-flourishing mental health.

Boundaries have been blurred for Millennials and Gen Zers as a result of public posting and the needed self-restraint to think before response posting. As a result, stalking has escalated and this is not easy to differentiate from checking out others' posts which might be called voyeuristic but not with carried intent to invade another's space for harm. From the 2009 Undergraduate Survey quoted by Levine and Dean, nearly half of the undergraduates "believe they can trust the people they meet through Facebook" (p. 76). Strong emotions result when they find this isn't always true.

While today's college students are not the people of yesteryear, this has been said of young people by older people for decades, if not centuries. We do, however, have a better profile of who we are teaching when we consider the research. We know we have many more people in our classrooms that come from underrepresented groups; we have people who have always lived with full immersion into technological access; we have people who may need to shore their interpersonal skills, who are more comfortable online communicating than they are in person; we have people who have lived in economic times that are less secure financially than their parents were with less hope to improve their quality of living as had been the expectation of earlier generations; simultaneously, we have people who are more impulsive consumers who want what they want when they want it; we have people who have been over protected and not given enough opportunities to think and act on their own accord and as a result expect life to go their way with minimal effort, on their part.

We also have college students who are more comfortable with diversity than previous generations. They are experienced technologically savvy, networking as they think globally rather than "in a flattened world" (p. 163). They have potential to become genuine multiculturally competent humans with needed digital expertise in this global society.

Our future work on campus centers around the question: How do we help undergraduates manage their anxieties for more flourishing mental health and well-being, so they can access their talents for their own personal developments and that of the communities in which they live? Much of their non-flourishing selves finds causation within the communities in which they have lived. We as faculty are building our own mindfulness as we move forward to address strategies to help our students manage

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

their lives for their own well-being. The following chapters will speak to character trait development, emotional intelligence awareness and campus-wide initiatives, in addition to our thinking about "next steps". We know there is no perfect as we also believe we can do better tomorrow.

Chapter 3
Neurobiology of Well-Being

Pamela A. Jackson
Radford University, USA

M. Joseph Sirgy
Virginia Polytechnic Institute and State University, USA

Gabriel D. Medley
Radford University, USA

ABSTRACT

This chapter is designed to review much of the research on the neurobiology of well-being. A distinction between hedonic well-being and eudaimonic well-being is made. The brain reward center was discussed in relation to well-being, which was followed by an in-depth discussion related to drugs, neurotransmitters, and well-being. Neurochemicals related to hedonia and eudaimonia were then discussed, followed by another discussion on gene expression. Finally, brain structures involved in well-being were the discussed followed by concluding thoughts.

INTRODUCTION

Well-Being: Hedonic and Eudaimonic

There is a plethora of concepts directly related to the psychology of well-being, including but not limited to life satisfaction, domain satisfaction, positive and negative affect, emotional well-being, hedonic well-being, perceived quality of life (QOL), happiness, psychological well-being, eudaimonia, authentic happiness, flourishing, positive mental health, psychological happiness, prudential happiness, perfectionist happiness, the good life, etc. Philosophers and psychologists of well-being have much to say about these concepts and their meaning (Sirgy, 2012).

In a review of the literature on subjective well-being, Diener, Suh, Lucas, and Smith (1999) defined subjective well-being as a broad category of phenomena that includes people's emotional responses, domain satisfaction (satisfaction in important life domains such as satisfaction with family life, health life, work life, leisure life, social life, etc.), and global judgments of life satisfaction. Diener and his col-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

leagues added that each of these concepts should be studied separately, although the constructs often correlate substantially with each other.

Sirgy and Wu (2009) assert that true happiness occurs when an individual experiences satisfaction in terms of their basic needs (based on Maslow's hierarchy of needs), but also in terms of their growth needs (i.e., social, esteem, self-actualization, knowledge, and aesthetic needs). This type of satisfaction is referred to as eudaimonic or psychological well-being. Ryff refers to eudaimonic well-being as human flourishing. Ryff's construct involves six dimensions: self-acceptance, positive relations with others, personal growth, purpose in life, environmental mastery, and autonomy (e.g., Ryff, 1989, 2017; Ryff & Singer, 2008; Ryff et al., 2016). Whereas the hedonic approach to well-being focuses on pleasure attainment and pain avoidance (Kahneman, 1999), the eudaimonic approach focuses on meaning, self-realization, and purposefulness. Throughout this chapter hedonic well-being and eudaimonic well-being will be referred to as two major components that define overall well-being.

In sum, well-being is an umbrella concept that captures hedonic well-being and eudaimonic well-being. Hedonic well-being is the affective dimension that reflects preponderance of positive affect over negative affect. Eudaimonic well-being focuses on experiences related to personal growth and character development.

The Reward Center and Well-Being

What is the mechanism of action that produces pleasant emotions that result in hedonic well-being? The mechanism involves brain centers that reflect what neuroscientists refer to as "the reward system" (Wise, 1996). The seminal study demonstrating the presence of the reward circuit involved rats that pressed a bar to administer a brief burst of electrical stimulation to specific sites in their brains (Olds & Milner, 1954). Said behavior had no value to their survival (i.e., food) or to that of the species (i.e., sex), but resulted in compulsive repetition of bar pressing. This phenomenon has been referred to as "intracranial self-stimulation" or "brain-stimulation reward" (Wise, 1996).

Research investigating intracranial self-stimulation has identified several brain sites that are involved in the reward system. Some regions stand out more than others (e.g., the ventral tegmental area (VTA) and the medial forebrain bundle). Stimulation of these regions activates fibers that form the ascending pathways from dopamine-producing cells of the VTA that project to the nucleus accumbens (NAc), the amygdala, the hippocampus, and the prefrontal cortex (Advokat, Comaty, & Julien, 2014; Kolb & Whishaw, 2014; Rickard & Vella-Brodick, 2014). This system, referred to as the mesolimbic dopamine pathway, plays a crucial role in reward. Drugs of abuse activate this reward system either directly (e.g., cocaine) or indirectly (e.g., opium). Much evidence shows that increases in dopamine (a neurotransmitter) in this pathway are directly involved with positive affect (i.e., feelings of pleasure and even euphoria).

The mesolimbic system shows a marked increase of dopamine when animals are engaged in intracranial self-stimulation (Olds & Milner, 1954). The same system shows a marked increase of dopamine when animals engage in rewarding behaviors (e.g., feeding and copulation). The reward system also shows a marked increase in dopamine with all drugs taken for pleasure, such as amphetamines, opiates, barbiturates, alcohol, THC, PCP, MDMA, nicotine, and even caffeine (Kolb & Wishaw, 2014, p. 438). Other addictions, such as compulsive gambling, pathological overeating, and sexual addiction, have also been strongly correlated with changes in the VTA-NAc dopamine system (Nestler, 2005). Chronic dopamine activation diminishes endogenous dopamine release and causes down-regulation of dopamine receptors which is a major aspect of drug tolerance (Volkow et al., 2005). Fewer dopamine receptors creates a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

"reward deficiency syndrome" that accounts for addicts' lowered responsiveness to natural rewards and predisposes addicts to seek out drugs to experience even normal levels of pleasure.

Other neurons interact with the dopamine-producing neurons in the VTA, and other neurotransmitters are involved in the increase of dopamine in the system as well. The endogenous opioid system (EOS) is one of the principal modulators of the mesolimbic dopaminergic reward circuitry (Mathew & Paulose, 2011). The use of acupuncture has been linked to the enhancement of endogenous opiates, resulting in pain relief from multiple disorders, surgeries, and diseases (Patil et al., 2016). The "runner's high" is an example of intense pleasure following the release of endogenous opiates (endorphins) during prolonged vigorous exercise (Gianoulakis, 2001). When observing individuals with borderline personality disorder (BPD), it is believed these individuals will go to any means to experience pleasure, regardless of the harmful effects that may accompany it, such as using whips to cause heavy bleeding to reach a heightened state of ecstasy (Gratz & Gunderson, 2006). This suggests a dysregulation in the EOS of individuals with BPD.

Heller et al. (2013) examined neural responses to positive stimuli and found links between sustained activity in the reward center (ventral striatum and dorsolateral prefrontal cortex) and higher eudaimonic well-being. In other words, participants with higher levels of eudaimonic well-being experienced sustained activation of the reward center in response to positive stimuli and lower levels of cortisol. Panksepp (2005) has argued that the brain reward center is the motivating force underlying growth needs or higher-order needs *a la* Maslow (cf. Silton et al., 2011). Specific areas of the limbic system (i.e., the reward center) may help actualize a diversity of internal wants and desires, thus motivating the individual to satisfy growth needs that lead to positive affect. On the other hand, the person that seeks to increase hedonic well-being by using drugs regularly will experience lower life satisfaction because of the tolerance that develops. The reasons are threefold and due largely to the changes in the reward center: 1) the reduction in dopamine and dopamine receptors in the VTA means that the person will feel less pleasure in general when the drug is not on board, and 2) they will need greater amounts of the drug to experience the original level of euphoria the drug produced, and 3) to satisfy the craving that results and the need for the euphoric effect, the person will spend greater time and resources engaging in drug seeking behavior, time and resources needed to maintain life quality in various life domains.

In sum, the brain center responsible for hedonic well-being reflects what neuroscientists refer to as "the reward system." The reward system involves several regions in the brain. Stimulation of these regions activates pathways from the VTA that project to the NAc, the amygdala, the hippocampus, and the prefrontal cortex (i.e., the mesolimbic dopamine pathway). Increases in dopamine in this circuit produce feelings of pleasure or positive affect. Sustained activity in the reward center is associated with higher levels of eudaimonic well-being and lower levels of cortisol. The brain reward center seems to be the motivating force underlying growth needs related to eudaimonia. The mesolimbic system is characterized by marked increases in dopamine with all drugs taken for pleasure, such as amphetamines, opiates, barbiturates, alcohol, THC, PCP, MDMA, nicotine, caffeine, and even compulsive gambling, pathological overeating, and sexual addiction. Other systems interact with the mesolimbic system such as the endogenous opioid system. Individuals seeking to increase hedonic well-being through drug use are likely to experience lower levels of life satisfaction because of the adverse effects of drug tolerance.

Drugs, Neurotransmitters, and Well-Being

Throughout the history of humanity, people have used drugs of all types to make them feel happy and numb the pain of life's adversities. Probably the most common drug is alcohol. Other drugs include opium (derivatives of opium include morphine and heroin), cocaine, amphetamines, benzodiazepines, and cannabis (THC). These, and many other drugs, stimulate the reward system and produce euphoria in the user, which makes these drugs key candidates for abuse.

Cocaine (a potent psychostimulant) can dramatically induce the release of dopamine (as well as norepinephrine, epinephrine, and serotonin). The net effect is heightened alertness, euphoria, lowered fatigue, decreased boredom, depressed appetite, and insomnia (Advokat, Comaty, & Julien, 2014). In 1884, Freud recommended using cocaine to alleviate depression and chronic fatigue. However, the rebound symptoms (once the drug leaves the system) are fatigue and depression (McKim & Hancock, 2013) making the therapeutic use of cocaine for depression ill advised.

Looby and Earleywine (2007) compared a large sample of people that had never used methamphetamine to a group that had used it at least once in the past year. They found that methamphetamine use decreased subjective well-being. It was also predictive of feeling more depressed and apathetic, less happy and having lower levels of satisfaction with life. This could mean that unhappy people seek out psychostimulants to self-medicate, or it could indicate that using methamphetamine produces depression, symptoms of which have been shown to be increased in methamphetamine users in other studies (e.g., Dyer & Cruickshank, 2005). While acute use may produce hedonia, it has long-term detrimental effects on well-being.

Opiates (morphine, codeine, and heroin) have euphoric effects. In small doses opiates decrease anxiety and reduce pain; higher doses can produce euphoria. The brain and body make their own opiate-like chemicals, commonly referred to as "endorphins" (endogenous morphine-like peptides). Endorphins control pain by stopping the flow of pain signals to the brain. Engaging in physical activities such as distance running could produce an "endorphin high."

Clearly, drugs that act on the reward system in the brain influence hedonic well-being (i.e., short-term positive and negative affect). However, do drugs affect other forms of hedonic well-being or eudaimonia? The answer is yes, drugs affect life satisfaction in a negative manner. Consider additional evidence:

- Focusing on substance abuse, a longitudinal study conducted by Bogart et al. (2007) clearly showed that the use of cigarettes and hard drugs at age 18 was associated with lower life satisfaction at age 29. In contrast, marijuana use and alcohol consumption at age 18 was not related to life satisfaction at age 29. Low income, poor health, and cigarette consumption in adulthood were determined to be mediators of the link between cigarette smoking and earlier hard drug use and lower satisfaction at age 29 (Bogart et al., 2007).
- A recent study (Khan & Shah, 2014) compared the subjective well-being of two groups of addicts, those who received drug-de-addiction treatment and those who did not. The study found that those who received treatment scored better on certain dimensions of subjective well-being (i.e., confidence in coping and perceived ill health). However, the two groups did not differ significantly on other dimensions such as general well-being, positive affect, expectation achievement congruence, transcendence, family group support, social support, primary group concern, inadequate mental mastery, deficiency in social contact, and negative affect (Khan & Shah, 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Quite a bit of evidence suggests that those with substance use disorder (SUD) and those seeking psychiatric treatment do not score as well on quality-of-life (QOL) measures as participants without a SUD or with no psychiatric condition (e.g., Donovan et al., 2005; Rudolf & Watts, 2002; Smith & Larson, 2003). Laudet, Becker, and White (2009) confirmed the finding but also found that QOL played a critical role in longitudinal remission. Higher QOL correlated with sustained remission. However, if QOL decreased during the measurement period it predicted increased vulnerability to substance use and relapse.
- Zullig et al. (2001) conducted a large study of public high school students and found that several drugs of abuse were correlated with a reduction in global life satisfaction (cigarettes and chewing tobacco, marijuana, cocaine, alcohol use, and steroids). In addition, the earlier the age at which they first used marijuana, alcohol, cocaine, or cigarettes, the stronger the association with reduced life satisfaction.

Research has also shown drugs such as opiates may activate both dopaminergic and nondopaminergic systems (e.g., Spanagel & Weiss, 1999). Such findings led to the development of the incentive-sensitization theory of addiction (Robinson & Berridge, 1993, 2003). This theory asserts that rewards involve two separate dimensions: "wanting" (which may be viewed as an incentive) and "liking" (which can be viewed as evaluation of the pleasant sensation). For example, a person may feel the desire to eat chocolate ("wanting"), and he may experience a pleasant sensation having eaten the chocolate ("liking"). The dopamine system seems to be related to both the "wanting" and "liking" components, whereas the "liking" component may also involve opioid and GABA (an inhibitory neurotransmitter) systems.

Another theory explained the role of dopamine in learning. More specifically, the dopamine system responds to the "unpredictability of rewards" (Berns et al., 2001) or errors in prediction (Schultz, 2002). That is, learning occurs when the reward is better or worse than expected. Learning does not occur when the reward matches expectations. Dopamine release is concomitant with learning. This learning is evidenced in brain plasticity involving significant neuronal changes—increased dendritic length and complexity in the nucleus accumbens and prefrontal cortex, as well as activity increases in areas involved in learning such as the hippocampus (e.g., Robinson & Berridge, 2001). Given the dopamine release in situations when expectations are negatively disconfirmed (worse than expectations), dissatisfaction may follow, and of course dissatisfaction is reflective of negative affect. Negative affect cannot be construed as "reward." Hence, neuroscientists now feel more comfortable using the term "reinforcer" rather than "reward." In other words, dopamine plays a crucial role in the "reinforcement" system (i.e., learning), as well as in the "reward" system.[1] In addition, large and fast increases in dopamine, such as those triggered by drugs, are associated with phasic dopamine firing in the brain, which conveys information about saliency as well as reward (Schultz, 2010). Therefore, when a person expects a certain euphoric high from taking a drug but the euphoria is lower because tolerance has developed, they will experience negative affect. This may contribute to the decreases in life satisfaction observed in those with substance-use disorder.

Based on the research related to drug dependence (e.g., Kalivas & Volkow, 2005; Kalivas et al., 2006; Volkow et al., 2005), the following theoretical notions concerning well-being can be extrapolated:

1. Humans possess a reward circuit that is activated by both drug and non-drug rewards. The most well-known reward circuit involves stimulation of neurons in the ventral tegmental area which project to and cause release of dopamine in the nucleus accumbens, amygdala, and prefrontal cortex. This produces subjective feelings of pleasure.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. Thus, dopamine underlies the reward experience and promotes learning through brain plasticity. The projections, over time, facilitate brain changes (at the neuronal level) promoting learned associations with those behaviors perceived to have led to positive affect or the reduction of negative affect, as well as progressive tolerance to the substance, ultimately resulting in less pleasure. With repeated exposure to the drug, there is a transition such that activation begins to occur more in the dorsal striatum (the caudate nucleus) as opposed to the nucleus accumbens. This is thought to underlie habit learning, in which drug taking switches from a reward-motivated behavior to a behavior that is automatic, habitual, and even compulsive. This results in negative emotionality, but also higher drug craving (see Volkow et al., 2014 on marijuana abusers).
3. Although dopamine release in the nucleus accumbens is important for the association between the behavior and the reward to be established, repeated behaviors (i.e., habits) cause recruitment of the frontal cortex and involves glutaminergic efferents to the nucleus accumbens, amygdala, and hippocampus. Kasanetz et al. (2010) found that rats developing an addiction to cocaine via self-administration showed permanent impairments in long-term-depression in the nucleus accumbens, whereas those rats exhibiting controlled drug intake were able to recover this form of neural plasticity.
4. Habits then persist as a result of enduring cellular changes in glutamate neurons in the frontal cortex. These glutaminergic projections from the frontal cortex to the nucleus accumbens are involved in motivating the individual to maintain his/her habits. Interference with the glutamate pathway impairs the ability of the prefrontal cortex to mediate response inhibition and impulse control (one consequence of chronic drug use). There are increases in prefrontal cortex activity in response to the drug itself or to cues associated with drug use (e.g., Wang et al., 1999). Volkow et al. (2005) showed an increase in metabolic activity in the orbitofrontal cortex, anterior cingulate cortex, and the dorsal striatum with drug craving as well. As a result, the drug-addicted person cannot control the craving, the impulse to take the drug, or even to avoid seeking out the drug.
5. As such, the drug-addicted person cannot control the impulse to take the drug or even to avoid seeking out the drug. Drug-addicted individuals show an enhanced motivation to procure drugs; they will go to extremes to obtain drugs despite the adverse consequences. The drug seeking and drug taking motivational drives consume much time, energy, and resources undermining both hedonic and eudaimonic well-being.

In sum, drugs of abuse provide us with a window to identify neurotransmitters and brain systems involved in hedonic well-being. These drugs stimulate the reward system and produce short-lived positive affect (as well as reduce negative affect). In the long-term, these same drugs undermine feelings of well-being via multiple mechanisms. The neurotransmitters involved with these drugs include dopamine, norepinephrine, epinephrine, serotonin, glutamate, and endorphins, which are discussed next. Furthermore, the research shows that dopamine and glutamate play important roles in the experience of well-being, learning, habit formation, and drug seeking behavior.

Neurochemicals Related to Well-Being

With or without drugs, the preponderance of the evidence from neuroscience shows the major neurotransmitters implicated in positive affect include dopamine, norepinephrine, serotonin, and oxytocin,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

with cortisol being implicated in negative affect (Advokat, Comaty, & Julien, 2014). Discussion of these neurotransmitters in relation to well-being follows.

With respect to dopamine, much evidence from psychopharmacology suggests dopamine has a direct role in the experience of positive affect because it is the primary neurotransmitter for the reward system in the brain. The vast majority of activities people engage in for pleasure (e.g., eating, drinking, having sex, listening to music) influences dopamine neurons, specifically the release of dopamine in the NAc, which then projects up to the frontal lobes (Advokat, Comaty, & Julien, 2014). The net effect is not only feelings of euphoria but also arousal and quick thinking. Wenk (2009) uses the analogy of the gas pedal and race car to explain the adaptive function of dopamine. The brain is like the race car and dopamine is like the gas pedal. The brain feels euphoria when the gas pedal is pushed, one result of which is quick thinking. The forces of evolution have shaped the brain to enjoy working fast; the faster the better. Creatures that work faster and better are likely to survive and pass this trait to the next generation.

Studies focusing on dopamine have shown maternal separation leads to a lower density of neurotransmitter sites for dopamine (e.g., Brake et al., 2004). In actuality, dopamine and norepinephrine work together to allow the individual to experience positive affect. An insufficient amount of norepinephrine will lead to poor concentration, restlessness, and irritability (Mathew & Paulose, 2011). On the other hand, Davis et al. (2015) found an association between low eudaimonic well-being and higher levels of tumor norepinephrine in female patients with ovarian cancer. The authors also found an indirect relationship between eudaimonic well-being and psychological resilience, such that increased eudaimonic well-being appeared to improve physiological as well as psychological resilience in these patients.

Neurons that produce and release serotonin are located in the brainstem but project throughout the brain (Kolb & Whishaw, 2014). Serotonin is involved in wakefulness and modulates many psychological processes including sexual activity, aggression, sleep and body temperature. Serotonin is also implicated in the regulation of mood, anxiety, hostility, and depression. Low levels of serotonin may be the underlying cause of depression and aggressive actions (Coccaro & Kavoussi, 1997). Peirson and Heuchert (2000) found that higher levels of platelet 5-HT_2 receptors, corresponding to lower levels of serotonin (5-HT), were significantly correlated with depressed mood in college students. Although Peirson and Heuchert's participants were not diagnosed as depressed, the authors noted that clinically depressed patients also showed this effect in several other studies. One study (Flory et al., 2004) found that central serotonergic function measured by the peak prolactin response to fenfluramine was significantly related to positive mood averaged across seven days, but was not correlated with negative mood in a nonpatient sample of adults. The authors suggested that reduced serotonin may result in the absence of positive mood. Williams et al. (2006) found that whole-blood levels of serotonin were positively correlated with positive affect using the PANAS scale, but not with negative affect. A two-way interaction between serotonin synthesis and mood is also a possibility. Meaning that while mood may be influenced by serotonin level, it may also be true that the opposite occurs–serotonin level may be influenced by mood (Mathew & Paulose, 2011).

Turning to oxytocin, research has shown this hormone to be associated with childbirth and lactation, mother-infant bonding (Kendrick, 2004), stress, and the regulation of social behavior (i.e., Elkins, 2016). Early life experiences, such as child abuse or any childhood trauma, was negatively correlated with oxytocin levels, suggesting those early experiences can cause social deficits in the future. One study confirmed the use of oxytocin as a buffer against stress in pregnant women and showed it protected women who were of high stress from developing depressive symptoms, which, in turn, may have increased sensitive maternal behavior (Zelkowitz et al., 2014). Oxytocin has also been found to reduce symptoms related to alcohol withdrawal (Pedersen et al., 2013) and cannabis craving. The use of cannabis has been linked

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to stress, and a study involving marijuana-dependent individuals supported this idea. McRae-Clark et al. (2013) assessed a baseline using the Marijuana Craving Questionnaire (MCQ). The individuals were then administered oxytocin or a placebo prior to a psychosocial stress task. Intensity of craving was assessed immediately after the task and also 5-, 35-, and 60-minutes post task. The overall results showed a significant reduction in craving of marijuana in response to the stressor in the group that was administered oxytocin. Another observation from the study was a lower anxiety response in the oxytocin group versus the placebo group (McRae-Clark et al., 2013). Oxytocin is also released during sexual orgasm (Huppert, 2009) and while experiencing feelings of trust (Kosfeld et al., 2005).

With respect to cortisol, studies have shown that exposure to stressors activates the hypothalamic-pituitary adrenal (HPA) axis and results in increased secretion of the stress hormone cortisol. Individual differences in emotional style (positivity versus negativity) modulate stress-induced elevations in cortisol (e.g., Jacobs et al., 2007; Polk et al., 2005; Pruessner, Hellhammer, & Krischbaum, 1999; Smyth et al., 1998). However, it is not only the absence of cortisol that is important, research has shown that it is the pattern of cortisol release and the recovery to baseline following stressors that correlates best with well-being (e.g., Steptoe, Gibson, Hamer, & Wardle, 2007; Ryff et al., 2006). Consider the Ryff, Keyes, and Hughes (2003) study as an example of how cortisol is implicated in eudaimonic well-being. The study compared US Blacks with Whites. Blacks were found to score higher on inventories of purpose in life and personal growth than Whites. Correspondingly, Blacks registered healthier profiles of diurnal cortisol (steeper diurnal decline) compared to their White counterparts.

Pressman and Cohen (2005) conducted a meta-analytic study establishing an association between trait positive affect and reduced release of stress hormones (e.g., cortisol, epinephrine and norepinephrine). In aversive situations, the amygdala sends signals to the HPA axis causing cortisol to be released from the adrenal glands. As such, people with a positive affective disposition tend to have lower basal cortisol levels compared to those with a negative affective disposition.

Several studies have shown that a pattern of cortisol secretion that involves a post-awakening peak and a 20-fold decrease later in the day is associated with high scores on measures of well-being (e.g., positive affect, optimism), but not with scores on measures of ill-being (e.g., negative affect, pessimism, anxiety, fear) (Lai et al., 2005; Ryff et al., 2006; Steptoe et al., 2007; Steptoe & Wardle, 2005). Individuals with a lower score on eudaimonic well-being experience increased activity in the HPA axis, which resulted in greater cortisol release (Heller et al., 2013; Lindfors & Lundberg, 2002). Thus, both positive and negative affect seems to be associated with the cortisol response, but they seem to be independent of each other. Excessive stress may result in wear and tear on the body and brain. This excessive stress can cause the HPA axis to remain activated because it is less able to shut itself off, which leads to an impairment in the immune system. This impairment may decrease well-being by making the individual more susceptible to illnesses, as well as depression and anxiety disorders (McEwen, 1998b; Walker & McGlone, 2013).

Having a social support system can serve as a buffer for this stress reactivity, which can aid in increasing well-being, therefore, decreasing the probability of illness. Studies confirming this theory demonstrated the decrease of cortisol responses when a significant other was giving social support in comparison to when a stranger was providing it (DeVries et al., 2003; Walker & McGlone, 2013).

Another method that may aid in reducing stress, which also inhibits excessive cortisol secretion, is prefrontal transcranial Direct Current Stimulation (tDCS). It involves the placement of two macro-electrodes on the skull in certain brain regions and sending a weak current between them. Austin et al. (2016) used the F3 and F4 brain regions, and applied it to healthy, early adult females to observe if

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

there was a difference in psychological distress after tDCS. Typically, the F3 and F4 regions are used in the treatment of depression. The results yielded significantly less psychological distress from daily stressors in the participants and a decrease in negative mood states (Austin et al., 2016; Siever, 2015). The Petrocchi et al. (2017) study involved only anodal stimulation, which is related to an increase in neuronal excitability and is followed by a decrease in GABA. They sought to find a correlation between heart rate variability and positive emotion in healthy individuals. This study placed an electrode on the left temporal lobe only. Researchers found one session of tDCS increased heart rate variability, and in return, this stimulation triggered soothing positive affect, which was associated with peacefulness, contentment, and well-being. Their study provided support for the effectiveness of tDCS on depression and other psychopathological conditions (Petrocchi et al., 2017; Stagg et al., 2009).

In sum, much of the evidence shows that the major neurotransmitters implicated in positive affect include dopamine, norepinephrine, serotonin, and oxytocin. Cortisol, on the other hand, is implicated in negative affect.

Gene Expression and Well-Being

Chronic stress or a major acute stressor (e.g., divorce) is highly correlated with clinical depression, especially for those genetically susceptible (Kanarik et al., 2011; van Praag, 2004). Kanarik et al. found that the Gsk3b gene (glycogen synthase kinase-3) was significantly down-regulated in the frontal cortex following chronic social stress in rats. This gene, Gsk3b, is inhibited by lithium, a mood stabilizing drug (Gould et al., 2007), as well as other antidepressants and atypical antipsychotics (Beaulieu, 2007). Kanarik et al. concluded that down-regulation of the Gsk3b gene is an adaptive response to severe stress. Kanarik and colleagues also found down-regulation of the Map1b gene in the frontal cortex and the hippocampus due to chronic social stress. The Map1b gene has also been implicated in neural plasticity (e.g., Nozumi et al., 2009; Kuo et al., 2009) and regulation of serotonin and glutamate receptors (e.g., Moritz et al., 2009; Sun et al., 2008).

Genetic susceptibility to stress can be inherited directly or promoted via epigenetics, an interaction between the environment and the genetic makeup. For example, Francis, Diorio, Liu, and Meaney (1999) found that rat litters receiving low maternal attention (specifically lower levels of licking and grooming the pups) were more fearful and showed a higher hypothalamic pituitary adrenal response to stress as adults than those that received high levels of maternal attention. The differences in maternal care caused glucocorticoid receptor (GR) gene expression changes in the hippocampus, which resulted in differences in hippocampal GR levels and glucocorticoid negative feedback sensitivity (Liu et al., 1997). Additionally, Weaver et al. (2004) found that the maternal behavior produced alterations of DNA methylation and chromatin structure. Relatedly, van Hasselt et al. (2012) examined the effect of maternal attention at the level of individual pups using a complicated cross-fostering system to ensure that the experience was translated through an epigenetic mechanism of inheritance. Specifically, the frequency of licking and grooming during the first postnatal week correlated with mRNA expression of the hippocampal GR gene and with the ability to induce long-term-potentiation in the dentate gyrus (associated with cognitive ability). These findings point to the possibility that the glucocorticoid receptor gene NR3C1 may be a key candidate in epigenetic investigations of stress and depression (e.g., Labonte et al., 2012; Perroud et al., 2011).

Research has also documented the effects of hedonic versus eudaimonic well-being in gene expression, specifically the conserved transcriptional response to adversity (CTRA). CTRA is characterized

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

by expression of pro-inflammatory genes and antibody synthesis genes. For example, Fredrickson et al. (2013, 2015) found that hedonic well-being was associated with CTRA up-regulation (i.e., increased expression of pro-inflammatory genes and decreased expression of antibody synthesis genes). In contrast, eudaimonic well-being was associated with CTRA down-regulation (i.e., decreased expression of pro-inflammatory genes and increased expression of antibody synthesis genes). The authors suggested that the immune system of the participants was more sensitive to the source of their happiness than their own conscious experiences. As such, eudaimonic well-being seems to be associated with health benefits related to gene expression not evident for hedonic well-being (cf. Cole et al., 2015). A similar study by Cole et al. (2015) found the same effect when they controlled for loneliness as a factor. However, when eudaimonia was controlled for in the data analysis, CTRA was less correlated with loneliness. Cole and colleagues concluded that social well-being could be compensated for by treatment aimed at increasing a person's sense of purpose in life.

In sum, gene expression seems to also play a role in both hedonic and eudaimonic well-being. Several gene alterations have been found to be correlated with depression and high levels of stress. Hedonic well-being seems to be involved in CTRA up-regulation, whereas eudaimonic well-being was associated with CTRA down-regulation. Mechanisms that may explain some aspect of the role of well-being in immune function.

Brain Structures and Well-Being

Huppert (2009) suggested that the individual differences seen in baseline activation in the prefrontal cortex corresponding to emotional style also correlates with adaptive cognitive and emotional responses in relation to psychological well-being. Several studies by Davidson and his colleagues (Davidson, 2004; Tomarken, Davidson, Wheeler, & Doss, 1992; Urry et al., 2004) have shown that activation in the prefrontal cortex (PFC) is asymmetrical and that higher baseline activation occurs in the left PFC in those with a positive, more resilient, affective style, whereas those with a negative affective style show higher baseline activation in the right PFC. Davidson (2004) states the mood of patients following damage to the left side of the PFC results in a greater incidence of depressive symptoms compared to damage to the right side. Consistent with these findings, Grajny et al. (2016) found that stroke damage in the left dorsolateral prefrontal cortex was associated with greater symptoms of depression. In addition, Turner, Cipolotti, Yousry, and Shallice (2007) found that in human lesion patients, damage to the left lateral PFC was associated with deficits in organization and strategy, whereas damage in the right lateral group caused failure of error detection and the checking system. Taken together this data suggests that the PFC is very much involved in both the emotional and cognitive aspects of well-being.

Stroke patients with damage to the left side PFC tend to experience more anxiety and depression than comparable right lesion patients (e.g., Robinson & Sztela, 1981; Starkstein et al., 1987). Similarly, patients with right PFC lesions tend to experience flat affect, implying that the right hemisphere based PFC is implicated for negative affect. Furthermore, much research using electroencephalographic methods supports the association between frontal asymmetry and positive affect and well-being (see Rickard & Vella-Brodick's literature review, 2014, pp. 443-445). The implication from these findings is the left PFC may be involved in approach-related, goal directed planning of actions, as well as positive affect; and conversely, the right PFC may be related to threat-related vigilance (see meta-analytic studies by Murphy et al., 2003; Wager et al., 2003). Additionally, interventions (such as mindfulness meditation)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

aimed at increasing well-being appear to increase left-sided frontal asymmetry, possibly by promoting emotion regulation (Brefczynski-Lewis et al., 2008; Davidson et al., 2003).

With respect to eudaimonic well-being, Urry et al. (2004) found that those with high eudaimonic well-being show greater left than right superior frontal activation in response to emotional stimuli after adjusting for reported levels of hedonic well-being. Van Reekum et al. (2007) examined amygdala activation in response to negative stimuli. The study showed that those who were faster to evaluate negative information also showed increased amygdala activation. However, the pattern of amygdala activation varied between high and low eudaimonic subjects. High eudaimonics were slower to evaluate negative information (showing reduced amygdala activation) as well as increased ventral anterior cingulate cortex activity—possibly evolved to deal with aversive stimuli (cf. Schaefer et al., 2013). Lewis et al. (2014) found an association between eudaimonia and insular cortex volume—those with higher well-being had greater volume of the right insular cortex gray matter. These data suggest that regulation of emotion via PFC inhibition of the amygdala may correlate with higher eudaimonic function.

Furthermore, research (Boyle et al., 2010, 2012) has shown that eudaimonic well-being is negatively associated with Alzheimer's disease and mild cognitive impairment. Specifically, purpose in life was found to significantly mitigate the effects of Alzheimer's disease pathology (evidenced by a global pathologic score and a measure of neurofibrillary tangles) on cognitive impairment. Additionally, Yu et al. (2015) have shown that greater purpose in life was associated with significant reduction of risk of cerebral infarcts (macroscopic infarcts caused by lacunar infarcts).

In sum, research indicates that expressions of well-being are associated with prefrontal cortex activity. Specifically, activation in the left PFC is associated with positive hedonic well-being, whereas activation in the right PFC is associated with negative hedonic well-being. The pattern is somewhat different in relation to eudaimonic well-being. Although individuals high in eudaimonia experience a similar pattern of activation in the left PFC, they are better in controlling their negative affect via PFC inhibition of amygdala response. Furthermore, high eudaimonic individuals are also less susceptible to cognitive impairment than their low eudaimonic counterparts.

CONCLUSION

Hedonic well-being was defined as an affective dimension that reflects a preponderance of positive affect over negative affect. In contrast, eudaimonic well-being refers to experiences related to personal growth and character development.

Much of the research shows that the brain centers responsible for hedonic well-being involve the VTA and the medial forebrain bundle. Stimulation of these regions activates pathways from the VTA that project to the NAc, the amygdala, the hippocampus, and the prefrontal cortex (i.e., the mesolimbic dopamine pathway) generating a surge of dopamine, which in turn induces positive hedonic well-being. Drugs of abuse and addictive behaviors produce their euphoric effects via the mesolimbic dopamine system. Endogenous and exogenous endorphins (opioids) modulate the reward system. Chronic excitation of the reward system (e.g., by a drug) generally results in a reduction in hedonic well-being, and at the same time, an increase in wanting the drug (resulting in compulsive drug-seeking behaviors). Furthermore, the research indicates that the reward system (the system that produces hedonia) is also involved in eudaimonic well-being, possibly as a motivating force underlying personal growth.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Stress hormones, such as cortisol, are heavily implicated in negative hedonic well-being. Not only does positive affect, and a more positive disposition, correlate with increased well-being, but also with decreased cortisol release. Reduced cortisol release is associated with higher levels of eudaimonic well-being as well. Hedonic well-being has been found to be correlated with a poorer immune system response as measured by CTRA, whereas increased immune function is associated with higher scores on eudaimonia. Healthier profiles of diurnal cortisol are correlated with inventories measuring personal growth and purpose in life.

Hedonic and eudaimonic well-being appear to differ in their neural substrates. Hedonic well-being is more closely associated with the mesolimbic dopamine pathway, whereas eudaimonic well-being is more closely regulated by the prefrontal cortex; although both brain regions are clearly involved in both types of well-being. Individuals high on eudaimonia not only experience a higher pattern of activation in the left PFC but also are better in controlling their negative affect via PFC inhibition of amygdala response. Evidence suggests that the left PFC may be involved in approach-related, goal directed planning of actions, as well as positive affect, whereas the right PFC may be more involved in threat-related vigilance and negative affect. Individuals with high eudaimonia are also less susceptible to cognitive impairment than their low eudaimonic counterparts. Individuals who have a purpose in life, a major characteristic of eudaimonia, have an advantage in this regard as well. Importantly, a person's sense of purpose in life seems to increase resilience, buffer against mild cognitive impairments, and protect against relapse to substance use.

Much progress has been made in neuroscience research related to well-being, and much remains to be done. The hope is that this chapter will provide scholars interested in the neuroscience of well-being with a brief synopsis of this research and possibly inspire and motivate future research on this very important topic.

ENDNOTE

[1] It should be noted that the current level of subjective well-being experienced by an individual is likely to moderate the effects of euphoric drugs, such as pain killers or psychostimulants, as well. This phenomenon is commonly known as the "Law of Initial Value" (Wilder, 1958). Wilder's law states that a change, such as that produced by a drug, cannot affect the person's mood or cognitive state beyond their capability for change. In addition, the effect of the drug depends on the user's initial state. If the person is close to their maximum state for the effect in question, then little change will occur; however, if they are quite distant then the greater the potential effect. For example, a person who is currently in a negative mood state (i.e., experiencing anxiety, pain, or melancholy) may experience euphoria when given small doses of morphine. In contrast, a similar dose of morphine given to a happy person may have little effect or even induce anxiety and fear (Wenk, 2009, p. 20).

Chapter 4
Posttraumatic Stress Disorder:
Children and Psychological Trauma

Veysi Çeri
Marmara University, Turkey

ABSTRACT

We all know that the baby's world is a 10-20 square foot field, which grows steadily over the years. The small world plays a leading role in shaping the child's mind at a rate inversely proportional to its size. In fact, not only stressful pieces of life but all kinds of experience takes part in the psychosocial development of the child, good or bad. Herewith, the conditions that cause chronic stress such as neglect, abuse, poverty, domestic or societal violence, war, and dislocation leave unfavorable traces that are difficult to change in the human mind. Today, while we, the mental health workers, are more focused on the apparent wounds that such adverse experiences have left in our souls, the unseen wounds continue to shape the child, society, and us all.

INTRODUCTION

"Everything is related to how the world is presented to the child," says Donald Winnicott, to state the importance of the environment on the mental development of the child. We all know that the baby's world is a 10-20 square foot field, which grows steadily over the years. The small world plays a leading role in shaping the child's mind at a rate inversely proportional to its size.

The infant mind, which does not host almost any content, in the beginning, gets a position that affects every area of his later life by being shaped with the effect of its close environment. A position where he can see the world as it passes through its lenses.

In fact, not only stressful piece of life but all kinds of experiences take part in the psychosocial development of the child, good or bad. Herewith, the conditions that cause chronic stress such as neglect, abuse, poverty, domestic or societal violence, war and dislocation leave unfavourable traces that are difficult to change in the hu-man mind. Today, while we, the mental health workers, are more focused on the apparent wounds that such adverse experiences have left in our souls, the unseen wounds continue to shape the child, society and the universe (Terr,1990).

Although the neuroimaging technologies in the years that Winnicott pointed out the importance of the environment were far from showing the effects of such experiences on brain development, today, there is growing evidence that shows the structure of the brain is shaped by one's experiences(Teicher,2016). Today, it is also well known that traumatic experiences such as accidents, sexual or physical abuse, surviving war or maltreatment can lead to structural or functional changes in various brain areas, and may cause suicidal behaviours and PTSD or other psychiatric disorders(Dyregrov,2006).

It is becoming clearer every day that chronic stress which arises from traumatic exposure lead to changes in the brain circuits related to working memory, attention, emotion regulation, cognition and threat detection systems(Teicher,2016) which cause significant deterioration in the detection, integration and representation of internal and external stimulus (Van der Kolk,1996). Although traumatic stress may have negative consequences for everyone, the impact of such incidents in early years which is the most critical time for the brain development is more devastating because of the destructive consequence of the chronic fear response on the development of the central nervous system(Kaufman,2001).

Since the effect of chronic stress on the function and volume of related structures of the brain is addressed in the relevant parts of this book, it will be discussed the impact of traumatic stress on the development of a unique psychiatric disorder, PTSD, in the light of literature findings in the present chapter. The epidemiology and the effect of PTSD on the psychosocial wellbeing and functionality of the child will also be addressed.

DEFINITIONS

Although it was not believed that the diagnosis of PTSD is relevant for children and adolescents, studies by Leonore Terr, David Kinzie, William Sack, William Yule, Van Der Kolk and many others who researched whether mental wellbeing of children is adversely affected by traumatic events proved otherwise. Thanks to the authors, today it is, undisputedly accepted that PTSD could develop in children following life-threatening traumatic incidents(Dyregrov,2006).

The traumatic experience is defined as exposing to an incident that threat person's bodily integrity or his life (Karakaya,2007) Many people are exposed to traumatic incidents such as injuries, violence, natural disasters, fire, traffic accidents or sexual and physical assault during childhood. Besides, witnessing the injuring or killing of someone, and learning death or serious injuring of a close relative or parents after a traumatic event could also be traumatic(Ozgen,1999;DSM 5,2013). Besides, some medical interventions, such as various medical procedures and surgery, are similarly traumatic for children (Ari AB et al,2017).

Psychiatric disorders arise as a result of the complex interaction between social, psychological and biological factors (Cuhadaroglu,2008). An accumulation of ad-verse experiences and risk factors cause greater harm to mental health(Sack,1999). Both the type of event and duration of exposure may increase risk by intensifying personal threat (Hodes,2008). It has been showed that the number of exposures to traumatic incidents is associated with increased PTSD probability (Laufer,2009; Thabet,2000).

It must be known that PTSD mean neither ''as a normal response to stressful situations or events'' nor the person with PTSD is ''emotionally weak'' or "mentally ill''. But it could be conceptualized as an "information-processing disorder that interferes with the processing and integration of current life experience"(Vander Kolk,1996).

CHILDHOOD TRAUMATIC EXPERIENCES

Epidemiologic studies have revealed that two-thirds of US population survive at least one traumatic severe incident at one point of their life. However, when it is taken in to account that the most of the community in many countries live in areas under conflict and expose to violence, it is estimated that the global prevalence of experiencing traumatic incidents worldwide might be higher than in the US(Galea,2005)

Many people are exposed to traumatic incidents in their childhood. In a national study conducted in the UK, the prevalence of exposure to a traumatic event was found to be around 8.7% in children 5-10 years of age, and about 12.6% in children aged 10-15 years. (Ford,2003). It is estimated that children in underdeveloped countries are exposed to more traumatic experiences. Given that a considerable part of the world's children's population is gathered in developing or underdeveloped countries, it is estimated that traumatic experiences are more than an exception for children.

Unintentional injuries which increase gradually after the age of five are the leading cause of traumatic experiences and one of the main causes of mortality and morbidity during childhood and adolescence(Minino,Peden 2008). Just traffic accidents, each year, lead death of over a million, and injuring of nearly 50 million people worldwide (WHO,2015), while, every day, 2000 children lose their lives as a result of unintentional injuries (Branche,2008).

The data show that millions of children are treated in emergency services every year due to various accidents. For example in 1997, in England, more than 72 thousand children were treated in emergency services because of a traffic accident, and 16 per cent of these children had fatal injuries. Beyond causing death, injuries are also the leading reason for permanent disabilities in children and adolescents (Peden,2008). Literature shows that the number of children who die from accidents and injuries is higher than the total number of children who die from various infectious diseases (Molnar,2001).

Sexual and physical abuse are also common during childhood. Epidemiological studies indicate that child sexual abuse (CSA) is far from being an exception (Molnar,2001). A review of community–based studies that investigate CSA from various countries reported a range of 7% to 36% for females and 3% to 29% for males (Finkelhor,1994). Another review revealed that 12% to 35% of girls and 4% to 9% of boys were forced to have sexual involvement before age 18 years(Putnam,2003). Nevertheless, the fact that child sexual abuse is largely hidden and never disclosed suggests that childhood sexual abuse might be at the epidemic level. Over 2 million cases of child physical abuse reported in the US in 2008, which estimated to represent only a small part of the actual incident rates(Nooner,2012).

Violence is also one of the significant traumatic experiences of childhood. War by its nature is one of the prominent reason for chronic stress for people who survive it. It has been estimated that more than 160 wars which caused the death of 24 million people have taken place since 1945 (Pedersen,2002). Although fatalities are the worst toll of the wars, the adverse impacts of conflicts are not limited to deaths and physical destruction. It also leads to the displacement of many people and devastated and everlasting psychological wounds. As a consequence of war, conflicts and violence, every minute, 24 people were forced to flee their homes in 2015. Accordingly, the number of displaced people has risen from 37 million to 65 million in the past two decades (UNHCR,2015).

Today, 352 million children are trying to grow up in areas under conflict which are mostly underdeveloped countries. Living in the conflict zone does not just mean exposing violence. It brings with it many negative experiences such as the violation of human rights, maltreatment, the attainment of basic physiological needs, uncertainty, inability to reach educational opportunities. However, children

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in underdeveloped countries expose to many other traumatic incidents. For example, it is also reported that accidents and unintentional injuries are more common among children living in these countries

Refugee and asylum-seeking children also constitute another group of children ex-posed to intense traumatic experiences. Today, children account for more than half of the refugee population, which has reached the highest number of all time, rising to 65 million. Findings of investigations with refugee children indicate that these children have been exposed to a large number of traumatic experiences which are not limited to the pre-migration period and continue after the resettlement. It has been showed that various traumatic and adverse life experiences such as violence, loss, physical, emotional or sexual assaults, uncertainty, poverty, overcrowded and unsafe housing, domestic violence, impaired parenting, limited access to education and health services, discrimination, stigma or social exclusion by new culture are all very common among refugee children (Fazel,2005; Heptinstal,2004; Ibrahim,2017; Ahmad,2008; Kinzie,1986)

As mentioned above, children worldwide expose to various traumatic events which is at the epidemic level. Although the adverse effects of traumatic events on children's mental and psychosocial well-being are better understood day by day, we must accept that we have failed to protect children from such traumatic experiences.

Post-Traumatic Stress Reactions in Children

Following traumatic events, various stress symptoms such as excessive fear, shock, crying, intrusive thoughts, hyperarousal, unable to calm, sleeping problems, impatience, nervousness, abdominal or muscle pain, stomach cramps, irritability, fatigue, dizziness, unwillingness to go out, school refusal, loneliness, social isolation, enuresis, sudden change in preferred games and activities may develop in children and adolescents. Additionally, memory and concentration difficulties and attention problems are also observed frequently. Suicidal thoughts and sense of worthlessness are other significant symptoms that can develop in children and adolescents after traumatic events.

Symptom cluster may vary with age and by gender. And it may manifest with classic attention deficit hyperactivity disorder (ADHD) symptoms such as hyperactivity, restlessness, impulsivity, irritability or distractibility in younger children (De Bellis,2013;De Bellis,1999), and "unless a careful history of traumatic exposure is taken in relation to the timing of the onset or worsening of symptoms, these conditions may be difficult to distinguish"(Cohen,2010).

Although externalizing problems, repetitive plays (and drawing) or behavioral re-enactments could be seen in all ages; younger children more commonly exhibit such behaviors(Dyregrov,2006). Irritability and feeding problems might be seen during infancy. Problems in emotional regulation, irritability, intense fear, regression, sleep and eating problems and are common in the early childhood period. Pre-school children may manifest the overwhelming stress by repeated games, aggression, difficulties in impulse control, separation anxiety, enuresis or encopresis and night fears. Attention and concentration problems, peer problems, separation anxiety, somatic symptom, drop in school achievement, isolation and various fears could be observed in school-age children. Despite the fact that, most of these symptoms disappear within 2-4 weeks, these symptoms may increase rather than diminish, and they can reach dimensions that threaten the child's functioning over time. Although such symptoms could be alarming for children, it could be tough for parents to be aware of these symptoms because of children's unwillingness to talk about these symptoms to not upset their parents.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Physiological and Biochemical Measures

It is suggested that "fight and flight" response to traumatic incidents are less compatible with younger children(Perry,1995). When exposed to a traumatic event, children tend to respond with irritability at the beginning, which is to attract the attention of adults. But if traumatic exposure or threats persist without help, the response might switch immobilizing or freezing and then dissociation or surrendering(Tebbit,1997).

Traumatic exposure triggers physiological and biological changes in traumatized children. These changes can forward to mobilize the child to escape from the traumatic exposure. However, these changes may normalize if the traumatic exposure persists for a period or the child start to dissociate. (McFarlane et al., 1987; Shaw et al., 1995),

Post-Traumatic Stress Disorder

Although the negative outcome of traumatic experiences on mental well-being has been recognized for a long time, systematic research has carried out for the last 50 years. In 1952, post-traumatic reactions conceptualized as the "Great Stress Reaction" in the Diagnostic and Statistical Manual of Mental Disorders (DSM) –I.. It took place in DSM-III, with the name of "Post-traumatic Stress Disorder", especially after the monitoring of soldiers injured in the Vietnam war. The PTSD diagnosis has come up with some minor changes but has remained in all subsequent DSM updates including DSM-V.

In DSM V, post-traumatic stress disorder is defined as a psychological disorder characterized with intrusive (repetitive, involuntary images, memory and emotions associated with the event etc), avoidance (situations associated with the trauma or emotional numbness etc.) and hyperarousal (irritability, anger, sleep and concentration problems etc) and negative alteration in mood and cognitions that occur after encountering one or more traumatic events and persist for at least one month. The diagnostic criteria were separated for children under the age of 6 and people older than six years in DSM-V as shown below:

DSM-V posttraumatic stress disorder diagnostic criteria for people older than 6 years:

1. Exposure to actual or threatened death, serious injury, or sexual violence in one (or more) of the following ways:
    a. Directly experiencing the traumatic event(s).
    b. Witnessing, in person, the event(s) as it occurred to others.
    c. Learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental.
    d. Experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g., first responders collecting human remains: police officers repeatedly exposed to details of child abuse).

Note: Criterion A4 does not apply to exposure through electronic media, television, movies, or pictures, unless this exposure is work related.

2. Presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

a. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s).
b. Note: In children older than 6 years, repetitive play may occur in which themes or aspects of the traumatic event(s) are expressed.
c. Recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s).

Note: In children, there may be frightening dreams without recognizable content. Dissociative reactions (e.g., flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the most extreme expression being a complete loss of awareness of present surroundings.)

Note: In children, trauma-specific reenactment may occur in play. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s). Marked physiological reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

3. Persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by one or both of the following:
   a. Avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).
   b. Avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).
4. Negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following:
   a. Inability to remember an important aspect of the traumatic event(s) (typically due to dissociative amnesia and not to other factors such as head injury, alcohol, or drugs).
   b. Persistent and exaggerated negative beliefs or expectations about oneself, others, or the world (e.g., "I am bad," "No one can be trusted," 'The world is completely dangerous," "My whole nervous system is permanently ruined").
   c. Persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others.
   d. Persistent negative emotional state (e.g., fear, horror, anger, guilt, or shame).
   e. Markedly diminished interest or participation in significant activities.
   f. Feelings of detachment or estrangement from others.
   g. Persistent inability to experience positive emotions (e.g., inability to experience happiness, satisfaction, or loving feelings).
5. Marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following:
   a. Irritable behavior and angry outbursts (with little or no provocation) typically expressed as verbal or physical aggression toward people or objects.
   b. Reckless or self-destructive behavior.
   c. Hypervigilance.
   d. Exaggerated startle response.
   e. Problems with concentration.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

   f. Sleep disturbance (e.g., difficulty falling or staying asleep or restless sleep).
6. Duration of the disturbance (Criteria B, C, D, and E) is more than 1 month.
7. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.
8. The disturbance is not attributable to the physiological effects of a substance (e.g., medication, alcohol) or another medical condition.

DSM-V posttraumatic stress disorder diagnostic criteria for children younger than 6 years:

1. Exposure to actual or threatened death, serious injury, or sexual violence in one (or more) of the following ways:
   a. Directly experiencing the traumatic event(s).
   b. Witnessing, in person, the event(s) as it occurred to others, especially primary care givers.
   c. Learning that the traumatic event(s) occurred to a parent or caregiving figure.

Note: Witnessing does not include events that are witnessed only in electronic media, television, movies, or pictures.

2. Presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:
   a. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s).
   b. Recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s).
   c. Dissociative reactions (e.g., flashbacks) in which the child feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the most extreme expression being a complete loss of awareness of present surroundings.) Such trauma-specific reenactment may occur in play.
   d. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).
   e. Marked physiological reactions to reminders of the traumatic event(s).

Note: Spontaneous and intrusive memories may not necessarily appear distressing and may be expressed as play reenactment.

Note: It may not be possible to ascertain that the frightening content is related to the traumatic event.

3. One (or more) of the following symptoms, representing either persistent avoidance of stimuli associated with the traumatic event(s) or negative alterations in cognitions and mood associated with the traumatic event(s), must be present, beginning after the event(s) or worsening after the event(s):
   a. Persistent Avoidance of Stimuli
   b. Avoidance of or efforts to avoid activities, places, or physical reminders that arouse recollections of the traumatic event(s).
   c. Avoidance of or efforts to avoid people, conversations, or interpersonal situations that arouse recollections of the traumatic event(s).
   d. Negative Alterations in Cognitions

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

   e. Substantially increased frequency of negative emotional states (e.g., fear, guilt, sadness, shame, confusion).
   f. Markedly diminished interest or participation in significant activities, including constriction of play.
   g. Socially withdrawn behavior.
   h. Persistent reduction in expression of positive emotions.
4. Alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following:
   a. Irritable behavior and angry outbursts (with little or no provocation) typically ex pressed as verbal or physical aggression toward people or objects (including extreme temper tantrums).
   b. Hypervigilance.
   c. Exaggerated startle response.
   d. Problems with concentration.
   e. Sleep disturbance (e.g., difficulty falling or staying asleep or restless sleep).
5. The duration of the disturbance is more than 1 month.
6. The disturbance causes clinically significant distress or impairment in relationships with parents, siblings, peers, or other caregivers or with school behavior.
7. The disturbance is not attributable to the physiological effects of a substance (e.g., medication or alcohol) or another medical condition.

The lifetime prevalence of PTSD was estimated in The National Comorbidity Survey (NCS) as 7.8% (Kesssler,1995). However, prevalence rates vary from study to study widely related to, sample selection, the type of trauma and methodology of the survey. For example, it has been reported that higher rates of PTSD are observed following man-made traumatic incidents and sexual abuse, than exposure to natural disasters (Donnelly 2002).

Clinical presentation of post-traumatic stress varies widely. For example, hyper-arousal can be manifest as, concentration problems, irritability, anger outbursts or problems in emotion regulation. Difficulties in sustaining attention may also observe as a consequence of reexperiencing the traumatic event. Thus, children may look like having hyperactivity(Donelly,2002)

Although many children who experienced a traumatic event will develop PTSD, this rate varies considerably from study to study. It has been suggested that the differences between the results may be related to the traumatized person and the nature of the traumatic event (De Bellis,1999). Thus, the nature of the traumatic event, individual's physical or emotional proximity to the incident, person's age, psychological development and previous experiences family characteristics and cultural factors can influence the development of PTSD (Langeland,2008;Kilptrik,2003; Olofsson,2009;Pfefferbaum,1997). The physical proximity is described as physical distance from the traumatic event, while emotional proximity is characterized as emotional involvement with the survivors of the incident(Pynoos,1987).

PTSD has been criticized for being a culturally constructed disorder which does not have validity in other nations (Summerfield,2000). However, high rates of PTSD has been shown in many non-western countries (Fazel,2005;Heptinstal,2004; Ibrahim,2017;Ahmad,2008; Kinzie,1986) which showed that PTSD is not limited to any culture, and it is universal among all cultures which were exposed to traumatic events (Mollica,2001;Yule,2015).

Although PTSD has been reported to have severe negative impacts on self-control, concentration, attention, cognition, emotion regulation, memory and learning that may threat children's school attendance

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and academic achievement, the impact of PTSD on academic functionality has not been adequately studied (Heringa,2017). However, studies which investigated the impact of traumatic experiences on school drop out or academic problems among children have shown the negative outcome of such experiences on the academic life of survivors (Broberg,2005;De Prince,2009).

Complex PTSD

The psychiatry field had ignored the effects of psychological trauma on mental health for long years. However, it was eventually wiped out with the involvement of PTSD in DSM-III. Discussions are not finished after accepting the PTSD diagnosis in the DSM-III. Some authors argue that PTSD symptoms are normal reactions against an abnormal situation, while others say that DSM criteria are from covering the effect of psychological trauma in depth. In addition, studies have shown that there is a significant difference between stress reactions that develop following a single traumatic event and reactions which develop after exposing repetitive and prolonged traumas. However, the trauma literature suffices to focus on PTSD that develops after a single trauma for many years. However, studies in recent years have revealed that the traumatic events are not causing just classical PTSD. In light of these new findings, a new diagnosis, Complex PTSD, has been suggested. Although there have been many studies on the validity of Complex PTSD and serious studies have been undertaken to include it in DSM 5 as a different diagnosis from PTSD, this diagnosis has not been included in DSM 5. However, the diagnosis of Complex PTSD has taken part as a different disorder than TSSB in ICD-11.

Complex post-traumatic stress disorder (Complex PTSD) is conceptualized as a “disorder that may develop following exposure to an event or series of events of an extremely threatening or horrific nature, most commonly prolonged or repetitive events from which escape is difficult or impossible (e.g., torture, slavery, genocide campaigns, prolonged domestic violence, repeated childhood sexual or physical abuse).” And it is characterized by “1) severe and pervasive problems in affect regulation; 2) persistent beliefs about oneself as diminished, defeated or worthless, ac-companied by deep and pervasive feelings of shame, guilt or failure related to the traumatic event; and 3) persistent difficulties in sustaining relationships and in feeling close to others” in addition to all diagnostic requirements for PTSD.

EPIDEMIOLOGY

Almost all children exposed to traumatic events develop some of the post-traumatic reactions mentioned above, most of these symptoms disappear in a couple of weeks. However, a considerable proportion of these children develop PTSD which characterized by re-experiencing, avoidance, hyperarousal and negative alterations in cognition and mood (DSM-5,2013).

PTSD is not a rare or occasional disorder. However, the prevalence of PTSD in the community sample varies considerably from country to country ranging from 7 to 12%(Breslau,2012). The differences in study findings are acknowledged with methodological or sample differences, the nature of the traumatic incident, assessment tool, cultural differences, time of assessment, and demographical characteristics of the investigated population (age, economical or educational situation etc.) (Dyregrov,2006).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Prevalence of PTSD in Community

In a study of 490 adolescents aged 16-22 years evaluated with a semi-structured interview tool, 3% of girls and 1% of boys were found to have PTSD (Olofsson,2009). The results of a study of 287 children in Afghanistan showed that more than one in four men (26%) had PTSD. In the same study, it was found that 14% of the girls had PTSD(Catani,2009). The lifetime prevalence of PTSD which is reported to be as high as 8.7%, is estimated to be higher in the USA than in Europe (dsm-5,2013). It is concluded that 61% of children will experience a potentially traumatic event and PTSD will develop in 4.7% of them by the age of 18(Mc Laughlin,2013).

Although it is reported that PTSD is less prevalent in children and adolescents than adults. This might be because of previous criteria did not fully account for develop-mental differences (DSM-5,2013). In a child and adolescent psychiatric epidemiology study in the UK that assessed 10,438 children aged 5 to 15 years, PTSD was found to be around 0.14% of this age interval (Ford,2003).

It has been reported that adolescents might be at higher risk of experiencing trauma than either adults or children (Nooner,2012). In a study of adolescents aged 12-17 in the United States, the 12-month prevalence of PTSD was determined to be 6.3% in girls and 3.7% in males, and the co-morbidity of depression and substance use with PTSD was also high, Thus, it is noted that PTSD may also be a risk factor for substance use in children and adolescents (Kilpatrick,2003). Nooner et al., by evaluating studies from 2000 to 2011, reported that the prevalence of PTSD among adolescents is 3–57% (Nooner,2012).

The results of a study with 8th Grade students in Denmark show that the lifetime prevalence of PTSD of these kids is around 9%. And, another community study in the United States reported that one out of every ten children had PTSD (Kessler,1995). The results of a comprehensive meta-analytic study examining the development of PTSD in children and assessing a total of more than 2500 children revealed that more than a third of children (36%) developed PTSD after exposure to a traumatic event (Fletcher,1996).

"Traumatization within attachment relationships has profoundly different impacts on affect regulation, self-concept, and management of interpersonal relationships than do disasters and motor vehicle accidents"(Van der Kolk,1996). The incidence of PTSD after different traumatic events vary enormously which explained with differing methodologies, different types of traumatic events or cultures (Dyregrov,2006).

Traffic Accidents

It is known that traffic accidents are the main factors causing PTSD development in adults (Blanchard,1997). In a follow-up study in which adults were evaluated, the incidence of PTSD was 32% one year after the traffic accidents, and the stress symptoms of the person following the accident were more correlated with the development of later PTSD than the severity of the injury by accident (Koren,1999). However, it is not known exactly how much such traumatic experiences lead to the development of PTSD in children (Keppel-Berison,2002). The results of studies conducted with children who were evaluated following traffic accidents indicate that a quarter to one-third of these children suffers from PTSD (Langeland,2008).

The results of a study with children showed that 24% of children who were assessed after 9 months of traffic accident had stress symptoms and 14% had PTSD (Keppel-Benson,2002). An-other important finding in the same study is that the supportive approach of the police or health team after the incident has been effective in preventing the development of PTSD symptomatology in children. This result

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

shows the importance of the supportive attitude of the team that interferes with accidents or injuries when it comes to children.

In another study, 35% of the children reported having PTSD (Stallard,1998), while another study findings revealed that PTSD developed in 50% of the children (Milgram,1988). In a follow-up study in which the children were evaluated immediately after the accident and at 1, 6 and 18 months, symptoms of PTSD in children were observed in 69%, 57%, 59% and 38%, respectively (Schreirer,2005). In a review included twelve studies, it was reported that PTSD was observed around 30% of children over the period of 1-2 months after the event (Qouta,2003).

War and Violence

Another group of children with a very high prevalence of PTSD is the children who live in areas under conflict. The studies which carried out with children exposed to violence, war or terrorism have revealed a high prevalence rate of PTSD among child survivors (Thabet,2008).

In one of the first study which carried out with children from areas under conflict Kinzie et al. revealed that one out of two Cambodian refugee children residing in the US has PTSD (32). The findings of a study of 121 children living near a bombardment area in Palestine revealed severe PTSD symptoms in 51% of the child (Qouta,2003). PTSD was found in 87% of children in a study conducted 5 years later with children in the Halabja region of Kurdistan where the Iraqi Ba'as regime carried out genocide with chemical weapons (Ahmat,2000). Seventy per cent of Kuwaiti children evaluated after the Gulf War was also observed to have significant PTSD symptoms (Nader,1993). The results of a comprehensive community sampling study which carried out in Algeria, Cambodia, Ethiopia and Gaza with people older than16 years revealed that the proportions of PTSD in these places were 37.4%, 28.4%, 15.8% and 17.8%, respectively(De Jong,2001). The results of a study with child survivors of the Bosnian war suggest that 28% of children have PTSD (Papageorgieu,2000). In a research that evaluates children aged 1.5-5 years, there was PTSD in more than one third (37.8%) of children living near a conflict area (Feldman,2011). The results of a study which carried out with 99 Cambodian children aged 18-25 showed that 86% of these children had PTSD or PTSD-NOS (Savin,1996). Another study with Cambodian children also reported high rates of PTSD (%37) among child survivors (Realmuto,1992). Results of Kızılhan et al.'s fascinating investigation with child warriors showed that 48.3% of these children had PTSD. They also revealed that PTSD rates in child soldiers were higher than other child survivors of the war (Kizilian,2018). Ceri et al. also reported high rates of PTSD and Acute Stress Disorders among Yazidi child survivors (Ceri,2016). The finding of a systematic review reported PTSD ranging from 4.5 to 89.3%, with an overall pooled estimate of 47% among children exposed to war (Attanayake,2009).

Displaced Children

Study results with refugee children indicate increased PTSD rates in these children (Bronstein,2011). This increase is reported to be ten times higher than non-refugee children. Studies from various countries such as Uganda (Betancourt,2009), Somalia (Betancourt,2009), Darfur (Morgos,2008), Cambodia(Kinzie,1986), Bosnia(Goldin,2008), Syria (Kandemir,2018) and Iraq (Ahmad,2008) have shown high rates of PTSD among displaced children.

In a review that evaluate 260 refugee children, Fazel and his friends reported the TSSB rate as 11%. Dyregrov and Yule (2006) report that 25% to 70% of refugee children have PTSD in conclusion of their

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

review on PTSD in children (Dyregrov,2006). Another comprehensive review which included 22 studies concerning refugee children from over 40 different countries reported that 19 to 54% of refugee children residing in Western countries had PTSD (Bronstein,2011).

The results of a series of studies with refugee children in Turkey have shown that, even after years of resettlement, PTSD was observed in 9% to 43% of these children (Ceri,2016; Yalin,2017; Nasiroglu,2016). Çeri et al. in their study which carried out with Yazidi children immediately after their arrival to Turkey revealed that 18% of these children had acute stress symptoms, and, PTSD was diagnosed in 10% the children (Ceri,2016). In another study, Nasıroğlu and Çeri reported that 36% of refugee children have PTSD (Nasiroglu,2018). Another study found that more than half (55%) of refugee children had PTSD (Hodes,2008). The results of a study with Bosnian children showed that 65% of these children had PTSD even after one year of their journey to the US (Weine,1995). The result of a follow-up study in Netherland indicated that the psychological distress of refugee children are severe and It has a chronic nature (Bean,2007).

Child Abuse

High rates of PTSD have been reported among victim of CSA (Rowan,1993). A national cohort study revealed increased lifetime PTSD diagnosis for females (39%) and males (29%) who sexually abused during childhood. The lifetime PTSD diagnosis was 5.7% and 3.8% among for females and males who have not childhood sexual abuse (Molnar,2001). Finding of a meta analysis which included thirty-seven studies involving 25,367 people indicated that "there is a 143% increase in the risk of developing PTSD symptoms following CSA among the general population"(Paolucci,2001). Another study which carried out with child survivors of sexual abuse reported one out of two (48%) children suffer from PTSD (McLEER,1988).

Natural Disasters

Post-traumatic stress reactions which develop following disasters is a serious public health problem as millions of children are affected each year (Nooner,2012). In a review which investigates the epidemiology of PTSD after disasters Galea et al. (2005) revealed that PTSD rates are ranging from five to sixty per cent among child survivors(Galea,2005).

A study which carried out with children who survived a hurricane reported that 56% of children have PTSD 3 months after the incident. The PTSD prevalence was found as high as 34% 10 months after the hurricane (LAGRECA,1996). Another study revealed that 20 per cent of children who survive an earthquake have PTSD (Hsu,2002). A meta-analysis which consists of forty-six articles involving 76,101 earthquake survivors indicated a 23.6% prevalence rates for PTSD (Dai,2016). Another study which investigates psychological problems among children after hurricane Katrina reported a 32% of PTS symptoms (Lai,2015). Seventy per cent of the children who live in an area impacted by a tsunami in India also reported suffering posttraumatic stress symptoms two months after the disaster (John,2007).

Various Traumatic Incidents

A study which carried with children who affected by the 11/09 terrorist attacks revealed that 84% of children had experienced moderate or severe posttraumatic stress reactions (Fairbrother,2003). 37% of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

children aged 2 to 15 years who survived the demolition of a dam, were found to have PTSD symptoms two years after the incident (Green,1991). Another study which carried out with children who survive a sniper attack in school revealed that 38% of the children had a significant level of PTSD symptoms (Hinton,2009). Reports have shown that one out of two children exposed to physical abuse also has PTSD (Dubner,1999). Domestic violence is another common kind of traumatic experience for exposed children that associated with high PTSD rates of about 36% (De Bellis,2009).

PTSD AND FUNCTIONALITY

Childhood PTSD does not only lead to psychological difficulties in the child but affects the child's academic life and is associated with increased depression, sub-stance use and suicidal behaviors. (Warshaw,1993) PTSD, which develops after a traumatic experience, can seriously disrupt the developmental process of the child and can negatively affect the social and academic life of the child by causing considerable loss in functionality (Karakaya,2007). It has been reported that survivors were more easily annoyed, had more difficulty controlling their emotions, and were more aggressive towards family members after a traumatic experience (Hinton,2009; Abe,1994). It was found that when people with PTSD are nervous, their heart rate increases more (Beckham,2002). Several studies have also shown that PTSD has a detrimental effect on cognitive functions (Gil,1990;Kocak,2017). It is therefore understood that PTSD has a serious negative impact on children's social and academic functioning (Ainmani,2017). It is stated that early treatment may prevent the later negative out-comes by preventing further functionality loss (Olofsson,2009). However, it is stated that PTSD in children is not well recognized in the society and treatment can be delayed (Ceri,2018; Ceri,2017).

Children's immediate attention may switch on physical safety or survival after ex-posing a life-threatening event and may not turn to the normal function for a while (Pfefferbaum,2016). Even though a traumatic event will not lead the development of PTSD among all of the exposed children, partial symptomatology could be debilitating and should be the target for treatment even in the absence of full syndrome criteria(Pfefferbaum,2016). Several studies have investigated whether traumatic events have an adverse effect on concentration or attention of child survivors. A study which Sprung carried out with children exposed to a hurricane reported lower concentration levels among child survivors (Sprung,2010). Another study also reported attention problems among children who indirectly exposed to 11/09 attacks (Hock,2004). Problems in attention, memory, learning and concentration were reported in several other studies that carried out with children exposed to traumatic incidents (Scrimmin,2009; Vasterling,2009; Chemtob,2008). Another study findings revealed significant deterioration in verbal intelligence scores of children who survive an earthquake (Chetomb,2008). Other studies also reported a decline in school achievement in children exposed to various disasters (Pérez-Pereira,2012; Ward,2008). It is also reported that adolescents with PTSD are under risk to failed a grade or suspended from school (Nooner,2012). Another study revealed a drop in attention and executive functions of children with PTSD (Beers,2002).

A study which conducted with children witnessed domestic violence revealed that those children had diminished executive functioning. Their attention and IQ also tended to be lower (Samuelson,2010). Another study which carried out with the child survivor of sexual abuse showed reduced ability to inhibit automatic responses in the Stroop test (Barrera, 2013). Findings of another study reported diminished cognitive skills or neuropsychological deficits among children with PTSD (De Bellis,2013). A study which assessed executive functions such as automatic response inhibition, self-regulation, monitoring,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and cognitive flexibility, indicated significant difficulties in women who had a history of CSA (Navalta,2006). Worsened performance in the visuospatial domain task also revealed among children with PTSD (De Bellis,1999)

PTSD, Brain Development and Neural Circuitry

The development of the brain and central nervous system which is associated with the progression of cortical myelinization continue during childhood and adolescence (Sowell,2001). Pediatric PTSD causes structural and functional abnormalities in neural circuits that regulate distress and emotion. It is also stated that abnormalities are observed in the development of frontolimbic circuits in these children and that abnormalities in these pathways make emotional control difficult and lead to increased perception. It is also reported that children and adolescents with PTSD have a decreased hippocampal volume and an increase in amygdala reactivity (Herringa,2017).

Neuroimaging studies have revealed an association between PTSD and emotion regulation, dopamine, and norepinephrine activation (Nooner,2012). Reduced grey matter volume in the anterior cingulate cortex, ventromedial prefrontal cortex, and hippocampus have also been showed (O'Doherty,2015). Functional brain imaging studies have revealed hyper-activation in the amygdala, insula and mid Anterior cingulate cortex, whereas hypo-activation is indicated in the medial prefrontal areas and Dorsal Anterior Cingulate Cortex (Hayes,2012). The effect of traumatic exposure on brain might vary according to the age of survivor. In a study conducted with victims of sexual abuse, it was reported that abuse before age 14 effect hippocampus volume, while abuse that exposed between 10-11 years of age is associated with amygdala volume and aged 14-16 years with prefrontal cortex volume (Teicher,2016).

Risk Factors

An accumulation of adverse experiences and risk factors cause elevated harm to mental health (Sack,1999). Both the duration of exposure and proximity to the event may increase risk by intensifying the threat on the survivor (Hodes,2008). The number of exposures to traumatic incidents is reported to be associated with PTSD (Laufer,2009; Thabet,2000),

In a meta-analysis, Cox and colleagues reported that eight factors are associated with higher PTSD rates among traumatised children after traffic accidents such as threat to life, previous psychopathology, younger age, female gender, previous traumatic exposure, severity of injury, involvement of a family member or a close friend in the accident (Cox,2008). Another meta-analysis which involved 32,238 children aged 6-18 years and investigated twenty five possible risk factors for PTSD revealed race, younger age, female gender, low intelligence scores, low SES, pre and post-traumatic adverse events, low social support, peritrauma fear, perceived life threat, social withdrawal, comorbid psychological problem, poor family functioning, distraction, previous psychological problems in the individual or parent, low self-esteem before trauma, post-traumatic parental psychological problems, bereavement, time, trauma severity and exposure to the event by media as risk factors for PTSD (Trickey,2012).

Another research that aims to investigate risk factors for the development of PTSD pointed out the nature and impact of the traumatic event, physical proximity, expo-sure time, children's and parents previous experiences as important factors in the development of PTSD in children and adolescents (Pfefferbaum,1997). Nooner et al. in their review revealed that 4 out of 5 adolescents had been exposed to a serious traumatic event, while PTSD developed in 3 to 57% of them. Gender, type and number of traumatic

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

exposure and age were associated with increased rates of PTSD (Nonner,2012). Gekker et al. suggested that child abuse is leading to more severe PTSD which is associated with more comorbid disorders and resistant to treatment (Gekker,2018). Level of exposure (Pine,2002), age, ethnicity(Meiser,2002), lack of social support, problems in family cohesion, female gen-der, prior exposure to trauma, prior psychiatric problems, and strong peritraumatic reactions (Pine,2002) have also reported to have an association with development of PTSD after various traumatic events in children. Although risk factors vary across studies, previous psychopathology and personal threat to life were found to be significant in all studies (Trickey,2012). The miscognitions or misinterpretation of the event, extreme worry about the safety of family, disruption in parental relationship, relocation, neglect, and avoidance-focused coping methods are also stated as risk factors for the development of PTSD in children following a traumatic event.

Course

It is stated that negative childhood experiences are the main cause of preventable mental disorders and substance use (Teicher,201).

Exposure to traumatic events in early childhood is particularly toxic due to its devastating effects on healthy development. The traumatic experiences in early childhood may prepare the ground for the development of other debilitating conditions. Toxic stress might lead to severe biological changes that cause problems in cognition, emotion and behavioral regulation which are associated with impaired social skills, aggression, violence and impulsivity (Donelly,2002).

It has been showed that childhood onset PTSD could persist for as long as 33 years (Morgan,2003). A follow-up study which carried out with adolescent survivors of a ship sinking revealed that 34% of survivors have PTSD years after the event (Yule,2000). Another study which assessed child survivors of a landslide disaster, 33 years after the incident, found that 29% of children still have PTSD (Morgan,2003). Sack et al. in their follow up study which carried out with refugee children of Cambodia reported that the onset of PTSD was quite variable, with 18% of subjects developing PTSD at least five years after cessation of the traumatic exposure (Sack,1999). They also reported that PTSD persists in one out of every three children even a decade later (Sack,1999). A study which carried out 20 years after an earthquake showed that 30% of children have full PTSD, the prevalence of partial PTSD symptoms were as high as 56% among the survivors (Najarian,2017).

New findings point out that the effects of toxic stress may extend its influence be-yond the survivor into next generations by leading behavioural changes in the ex-posed person or epigenetic changes that transmit directly to the offspring of the survivor (Neigh,2009). Furthermore, when left untreated PTSD may lead the development of affective or anxiety disorders, and substance use and impair their psychosocial and academical functioning in the later time course (Bolton,2000). Psychiatric comorbidity is as common as a norm rather than an exception in people with PTSD (Creamer et al., 2001). Even adult-onset PTSD patients who have a history of child abuse may represent a subgroup with a more severe form of the disorder that is associated with a higher comorbid depression, psychotic symptoms and phobic disorder, severe clinical course, treatment resistance and poorer outcome (Gekker,2018). Findings of National Comorbidity Survey showed that lifelong PTSD is associated with increased mood, anxiety disorders and substance abuse (Kessler et al., 1995, (Jeon et al., 2007). Comorbid psychiatric conditions lead to more functional impairment and treatment resistance and worse quality of life in PTSD patients (Post et al., 2011; Araujo et al., 2014; Pagotto et al., 2015; Gekket 2018).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

It has been shown that lifetime traumatic event exposure increases suicidal thoughts, substance abuse and binge drinking in adults (Forman-Hoffman,2012). It was reported that the history of having traumatic exposure or PTSD might lead a three times increase in suicide attempts in adolescents (Nonner,2012).

Individuals with a history of child abuse, as compared to their counterparts without such history, showed a more severe comorbidity profile in general, characterized by a higher mean number of lifetime and current comorbid disorders and a greater life-time and current prevalence of panic disorder (Gekker,2018).

TREATMENT

Early Interventions

Although prevention is better than treatment, it is a hard task to achieve in most of the disorders which arise as a result of complex interaction of social, psychological and biological factors (Cuhadaroglu,2008). However, the preventing of PTSD may be achieved very easily by ending the happening of traumatic incidents or the exposure of children to such events. Thus making policies and arrangements to decrease accidents, child abuse or maltreatment and exposing violence may have a significant effect on reducing rates of children who suffer from PTSD

In case of exposure to traumatic events, early interventions will also be very useful if its effect on preventing the development of PTSD could be shown. Like the ABC of first aid in medical support, the psychological first aid starts with ensuring that the child feels secure and safe and to make certain that the child knows what is happening around him and provides information and explanation about the status of family members and his/her friends(3). Despite strong evidence have shown that traumatic events increase psychiatric morbidity and the initial distress might be far greater than PTSD, there is no effective way to protect children from developing PTSD after traumatic exposure (Rose,2002).

Various preventing or supportive interventions have been developed to support children to cope with post-traumatic stress (Rose,2002). A program which teaches cognitive behavioral coping strategies to prevent the development of psychopathology following stressful events results indicated a significant decline in depressive and externalising symptoms (Jaycox,1994). Crisis Intervention Program for Children and Adolescents (CIPCA) has been recently developed by Abdulbaghi Ahmad to prevent post-traumatic psychopathology among displaced children and adolescents (Ahmad,2014). The findings of a recent study pointed out that a single session of CIPCA might be effective in preventing and/ or relieving the symptoms of PTSD in displaced kids (Ceri,2108). Debriefing is also a psychological intervention that aims to reduce the psychological morbidity after traumatic exposure (Hodgkinson,1991). It consists of encouraging of the survivor to express his emotion, support to process the traumatic event and increase social connectedness (Rose,2002). However, meta-analysis fails to show the effectiveness of such preventive interventions, and it is recommended to carry out further investigation to evaluate whether preventive intervention programs are efficient (Rose,2002; March,1998). Although the efficacy of these interventions has not been showed systemically, it is important to be aware of that reduction of even one symptom of PTSD might have notable favourable effect on the functionality of children (Donelly,2002).

Partial symptomatology is widespread in kids exposed to traumatic events and may impair the functioning of the individual even if the exact criteria are not met (Giaconia et al., 1995). Thus, it is crucial to recognise all symptoms and to think about treatment even when the full PTSD symptoms have not

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

developed. This is especially critical for children whom PTSD might undermine their development (Tebutt,1997).

Study findings have revealed that psychological interventions might be useful in relieving posttraumatic stress symptoms. Results of a recent meta-analysis have indicated a significant weighted mean effect size in PTSD improvement as a result of psychosocial treatment, which pointed out a 74% reduction in PTSD. Furthermore, kids getting any psychological intervention improved considerably better than those children not get an intervention (Newman,2014).

Treatment of PTSD

Because even partial PTSD symptoms may lead significant impairment in the child's social, emotional or academic functionality, "treatment decisions should take into account functional impairment and symptom severity regardless of whether or not they have an actual PTSD diagnosis" (Cohen,2010).

Treatment of PTSD start with education of parents and the child about PTSD. School teachers also should be involved. PTSD treatment requires trauma-focused approaches such as trauma-focused cognitive-behavioral (CBT), psychodynamic, or family therapy (Cohen,2010).

Trauma-focused CBT which has a sizeable supporting data about its effectiveness in school-age and older children is recommended as the first choice in PTSD (March,1998). Pharmacological interventions are not suggested as an initial treatment option. How-ever, using pharmacological agents as an adjunct (Cohen,2010). Deblinger, Stauffer and Steer (2001) revealed better outcomes among children enrolled in group CBT than children enrolled in a support group (Deblinger,2001). Another study also showed the effectiveness of CBT in PTSD among sexually abused children (King,2000). A study which carried out with 229 children with PTSD reported better outcomes for PTSD and depression symptoms in children assigned to Trauma-Focused CBT, compared to those as-signed to child centered therapy (March,1998). Findings of a (Cohen,2004) meta-analysis revealed that CBT, EMDR, Exposure, and Eclectic with CBT interventions are all effective for children and adolescents (Newman,2104). Another meta-analysis also give some evidence for the effectiveness of psychological therapies in both prevention PTSD and treatment of PTSD in children and adolescents (Deblinger,2010)

Cohen et al stated that a trauma-focused psychotherapy should directly address children's traumatic experiences, include parents in treatment, not focus only relieving PTSD symptoms but also enhancing the child's functionality and resilience capacity, and supporting his/her developmental trajectory(Cohen,2010).

Neither therapies nor medications expected to be useful in settings where traumatic exposure is ongoing in the life of a child (Gillies,2016). The pharmacological interventions should be considered in the early phases of the treatment when severe and debilitating symptoms such as hyperarousal or avoidance are limiting the child's functionality or interfering with therapy (Donelly,2002).In a review that aimed to assess the effectiveness of pharmacotherapy in the treatment of PTSD in 1999, Donelly et al. concluded that there were not enough studies in the Pediatric PTSD literature to confirm treatment recommendations(Donelly,1999). Although there have been two decades passed, we still don't have adequate evidence for pharmacological interventions in PTSD treatment in children and adolescents.

In conclusion of a meta analysis concerning treatment of PTSD in adults Trauma Focused Psychotherapies (TFP) were recommended as first-line interventions. Stress inoculation training and potentially sertraline or venlafaxine, rather than entire classes of selective serotonin reuptake inhibitors (SSRIs) or serotonin-norepinephrine reuptake inhibitors (SNRIs) were suggested as a second-line treatment option (Lee,2016). A meta-analysis on pharmacotherapy of PTSD in adults also reported favourable

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

results with selective serotonin reuptake inhibitors compared to placebo in reduction of PTSD symptoms (Hoskins,2015). Another review which aims to assess medication options for treatment of PTSD in adults concluded that medical treatments could be useful for the treatment of PTSD and to reduce its core symptoms and functionality loss (Stein,2000).

Adrenergic agents such as clonidine and guanfacine and the β-adrenoceptor antagonist propranolol could be useful in the treatment of hyperarousal and impulsivity in PTSD by reducing sympathetic arousal (De Bellis,1994). However, there are not adequate data to recommend such agents in children with PTSD. Similarly there is no evidence about dopamine blocking agents in the treatment of pediatric PTSD. However, these agents could be used for patients with PTSD who exhibit paranoid behaviors, para-hallucinatory phenomena or intense flashbacks, anger, self-destructive behavior, or psychotic symptoms (Donelly,1999).

Psychotherapy and pharmacotherapy is represented as the twin cornerstones of intervention for PTSD (Stein,2009). And, it is stated that "regardless of what type of treatment intervention is preferred for treatment of PTSD, the ultimate goal of the intervention should be symptom reduction, and ideally, resolution, as well as a full return of optimal psychosocial functioning (Stein,2009)

Donelly et al. recommended a stepwise work in selecting pharmacological agents for treatment of PTSD in children and adolescents which start with accurate diagnosis and recognizing even partial PTSD symptoms that lead significant functionality loss in the child's social, emotional or academic life. The second step is focusing comorbid conditions which are very common with PTSD such as depression, anxiety disorders and ADHD etc. Thirdly, target symptoms and reasonable treatment goals must be identified (e.g. reduction in sleep latency, frequency of nightmares, or avoidance behavior). The fourth and final step is selection of therapeutics. However, it must not be forget that psychosocial support, psychoeducation and CBT is the first choice and such interventions must always be in mind before consideration is given to pharmacotherapy (Donelly,2002).

A gradual approach should be followed in pharmacological treatment of PTSD in children which begins with the treatment of the most disabling symptoms first. It also must be taken into account that reduction of even a single symptom, might lead considerable relief and improvement in overall functioning of the child (Donelly,2002).

Summary

Growing amount of evidence showing that traumatic experiences have a devastating impact on the child, by deteriorating their physical, cognitive, emotional, and social development. Beside causing psychiatric disorders such adverse experiences shaping the whole community by leading disruption in traumatized children's way of life, sense of self, other and community. However, the findings of research on effect of traumatic stress on the child could be summarized in five measurable areas stated below

- Leading severe mental, interpersonal and behavioral problems such as PTSD, depression, suicidal ideation, affect regulation, poor judgement, peer and relationship problems and substance use
- Academic and occupational problems, deterioration in language use, literacy and math skills
- Changes in brain structure and neuronal circuits, volume and functional changes in distinct brain structures such as hippocampus, amygdala, dorsal prefrontal cortex and anterior cingulate cortex
- Increased risk for physical health and lowered life expectancy due to various medical conditions

ABSTRACT

In the 21st century, people are connecting with technology, and most of the people are spending time in social networks for sharing information. For the most part, spending time on social media is linked with an increased risk of loneliness and depression. Negative effects of social media and social network are affecting the person's mental, emotional, and physical health. The World Health Organization (WHO) reported that 8,000,000 people are dying due to suicide every year, and especially, every 40 seconds teenagers are dying. Generally, most of the teenagers are emotionally imbalanced; most of the suicide is committed on high depression. Depression is the foremost cause of emotional and mental illness. Emotional health is a state of emotional wellbeing, and it's a hidden and invisible factor as well as a factor for good mental health; mental health is a deep-seated problem for most humans. With this background, this chapter discusses the emotional and mental health with respect to technological issues.

INTRODUCTION

Emotional health is so important of every human's life because no humans can live without emotions such as smile, enjoy, angry and so on. Emotions are innate characteristics, and exposing and realizing of emotions are depends on individuality. Emotions play a crucial role in human life for their happiness and mutual understanding with the society. Emotionally healthy persons can control their emotions, feel-

ings, thoughts, overall behaviour and realize the potential of them. Generally, emotional outburst created by destructive emotions suffers other seriously. An emotionally unstapled administrator always getting angry easily and scolds his/her subordinate is an example for emotional outburst. Emotions cannot be controllable but manageable. Some peoples are not compromise with their negative/destructive emotions that directly suffers others and themselves also. Suicidal activities are the result of uncontrollable destructive emotions. Everyone take care about

Figure 1. 15-29 years ages causes of suicides (WHO, 2017)

World Health Organization (WHO) reported that 8, 00,000 people are dying due to suicide every year and every 40 seconds 15-29 years old people are dying is deployable news. Roving the blue whale game also is one of the best examples of illness of emotional health problems. American Association of Suicidology (AAS), 'Blue Whale Challenge' is a social media game and the teenage people addicted to this game. It purposefully encourages the activity of hold in self-harm and suicidal behaviour to the young people. AAS also insisted that the teenage people directed by the game to do suicidal activities and ending their lives. Because of teenage people are not known to how rightly deal with their own emotions.

Emotionally Healthy person is an individual who knows how can aware of negative emotions, how to manage their negative feelings and they can handle the emotional problems. Maintaining emotional health is one of the skills to improve our lifestyles and travel our life path in positive manner. Emotional healthy persons always manage the destructive emotions and he/she follow some management strategies. They always prefer constructive emotions for maintaining the mental and emotional health. Emotional health is linked with one's mental health and physical health and so on.

Meaning of Mental Health

WHO (2004), Mental Health is a "state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community".

Medical dictionary (2012), mental health is "emotional, behavioural, and social maturity or normality; the absence of a mental or behavioural disorder; a state of psychological well-being in which one has achieved a satisfactory integration of one's instinctual drives acceptable to both oneself and one's social milieu; an appropriate balance of love, work, and leisure pursuits"

Public Health Agency of Canada (PHAC, 2006) states that ——mental health is the capacity of each and all of us to feel, think, and act in ways that enhance our ability to enjoy life and deal with the challenges we face. It is a positive sense of emotional and spiritual well-being that respects the importance of culture, equity, social justice, interconnections and personal dignity.

With the help of above definitions, some of the common things are listed below and they are representing the mentally healthy person.

- One can easily solve the emotional problem and manages the challenges of their stresses.
- Mental health persons comprise the psychological well-being such as oneself and surrounding of others also accepting social integration behaviour.
- Mentally Healthy person having a positive sense of emotions and give respect to the values and the honesty of the rules.
- Mental Health persons also be emotionally healthy, psychologically healthy and socially well-beings.

Factors Affecting Mental Health

Mental health disturbed with internal or external. Internal factors like emotions, feeling and external factors like fevers, different type of aches and diseases may decide the status of one's mental health. Every individual should care with these factors to maintain their mental health and they are briefly explained below,

- *Internal factors:* The factors that relevant to the individual that are also called as psychological factors. The internal factors like self-esteem, emotions, feelings, stress and depression are involving the increase or decrease the level of mental health.
- *External factors:* Other than the internal factors which are not relevant to the psychological factors of an individual and they are indicates the outside of the individual. Physical conditions, different aches, diseases, fever, abuse, ill-health, family breakup, loneliness, bereavement, homelessness and environment are the external factors.

On the other side, mental health may be affected by the environment in which the persons belong. Generally, the learners' mental health affects in two environments, they are briefly explained below,

- *Home environment:* Home is an innate environment to the learners, because the learners were born in a home where they remain in the company their mothers in the formative years of infancy. The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

home is the first community and school to the learners and it is a first place to engage the character and personality development. The parents of the learners always care about their future. Of course, the parents control the learner over to childhood for discipline. The first important requisite condition for learners is affection should feel secure and loved in their home. But, Parents meet the legitimate needs of their child. This legitimate atmosphere cannot be accepted by the learners. The learners always want to be free. But, the home atmosphere made these opportunities ever. Thus, the home environment turned to make metal illness of learners and it affects mental health. The ideal home atmosphere provides proper and conductive environment up to early childhood. Pleasant and satisfaction giving experiences should be provided for harmonious development of the personality of the child. The parents should keep the following things into consideration.

- Provide proper affection and love to the child.
- Provide conductive environment in home.
- Do not criticize the child.
- Do not compare the child with other children.
- Don't ask irritable questions to the child
- Be a friend in time
- Don't use harsh words to the child while they did wrong
- Do not reject or overprotect the child.
- Do not quarrel in present of the child.
- Do not be over anxious about the future of the child.
- Try to be democratic in your dealings.
- Meet legitimate needs of your child.
- Provide guidance where necessary and build self-confidence in the child.

These points will assist the parents to create mental healthy individuals. Otherwise the learners become mental illness which affects the academic performance and other outcomes on the child.

- *School environment:* Schools are the second community or social place. In India, most of the parents are illiterate and ill informed who cannot be charged with the responsibility of providing proper guidance for mental health. The school has the great responsibility in harmonious development of personality of the learners. Normally, the learners spend six to seven hours in schools. Schools are in position to help in the development of children potentialities by catering their needs. In schools, the teacher should maintain the students' mental health when they are learning. The atmosphere of the schools is in the hands of the teachers. The teacher is a second parent of the students. It is one of the responsibility of the teacher who providing proper guidance for developing mental health. Because of the school are in a position to help in the developing of children's potentialities. The following school factors may affects the students' mental health.
  - Bad environment of school leads to make fear tension and frustration of the students.
  - The teacher autocratic style leads the authoritative environment in schools.
  - The undesirable participation of teacher to forget makes the positive attitude.
  - Some time the school rejects proper human relations.
  - Less facility of schools.
  - Irrespective activities of teachers and the head.

Qualities of a Mentally Healthy Person

Like a proverb 'Face is the index of the mind', the face is also the index of the mentally healthy persons. Emotionally disturbed persons never behave with the qualities of a normal person and their qualities are generally different from a normal person. The following qualities are identified and it's mostly fit for the mentally healthy persons. Jha and Bhatt (2010) quoted the following qualities are possessed by the mentally health persons and they are;

- *Adaptability and resilient mind:* The individual, who is adaptable to the changing conditions of his environment receptive and not rigid in his behaviour, can be said mentally healthy.
- *Social adaptable:* A mentally healthy person is socially awakened. He participates in social activities and his personality functions properly under strain ad stress of emotional disturbances.
- *Emotionally satisfied:* The emotions of mentally healthy persons are well trained and controlled. He is free from persistent emotional tensions in his life.
- *Desires are in harmony with socially approved goals:* The mentally healthy person does not indulge in anti social activities. The goals of the person of life are in accordance with social norms. The person's objectives are harmony with other people.
- *Insight into his own conduct:* The mentally healthy person has insight into his own conduct He self evaluates his behaviour. He improves his behaviour on the basic of his self-examination.
- *Enthusiastic and reasonable:* He has enthusiasm in life. He works with curiosity and is devoted to his profession. He is responsible in his actions. He accepts criticism sportingly.
- *Good Habits:* The healthy person has good habits. He is balanced and is not easily annoyed.
- *Philosophy of Life:* The healthy person has his own philosophy of life. He develops definite attributes towards values of life.
- *Provision for sex and moral education:* Most of the problems of adolescents are concerned with sex and moral conflicts which cause mental disturbances. It will be great use if sex and moral education are made an integral part of regular curriculum.
- *Art and craft:* Writing for understanding and release of emotional tensions can also be used in mental hygiene programme.
- *Guidance:* School students should be given guidance through guidance services for their benefit. This is of three types: personal, educational and vocational.

Meaning of Emotional Health

Mental health and emotional health are interrelated but both are slightly different. Ones lack mental health; those persons can be affected mental illness such as depression/ mood disorder, anxiety, personality disorder. National Alliance on Mental Illness quoted in their report that one in five adults in the United State suffers mental illness each year.

According to Peterson (2015), Emotional health is a psychological functioning and it's based on a positive manner. Emotional health is the extension of mental health and its function the inner and outer worlds of human to build one's thoughts, feelings and behaviours.

According to mental health foundation, "Emotional health is a positive sense of well being enables an individual to be able to function in society and meet the demands of everyday life."

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

From the above definitions, Emotional Health comes from several common points that common points are,

- To build up the thoughts, feelings, and behaviour from the ones psychological functioning.
- Emotional health is fully depending on the positive manner and engages with society in optimistically.

Factors Affecting Emotional Health

There are many factors contribute increase or decrease the level of emotional health and it is a key factor in promoting or de-promoting the mental health. So, the before said factors in the topic 'factors affecting mental health' also affects the emotional health. In addition to that the following factor also affects the emotional health and they are;

- *Level of anxiety:* It is a basic emotion that assists an individual from the dangers. Fluctuation in anxiety causes emotional imbalance and it directs less emotional health. Anxiety is a manageable emotion by the interventions and strategies like relaxation and mindfulness.
- *Level of self-confidence:* It is a belief of one's to reach the goal or the task assigned to the individual. Self-confidence makes the person to face the challenging, difficult and complex situations. The poor self-confident individual easily getting fear and anxiety which pushes the imbalance in emotions.
- *Physical illness:* It is also changes the level of emotions. Diabetic persons always feel about the activity of injecting artificial insulin in their body and kept medicine with themselves as well as their eating styles. This may repress the emotions in negative directions. On the other side, fever, diseases may make emotional instability.
- *Undesired events:* Pleasant events makes the desired emotions and opposite are vise versa. An individual getting happy for pleasant events and upsets if the person facing an unpleasant event.
- *Capacity to manage emotions:* Escaping from the emotional issues, the person may have managing capacity or coping capability (Emotional Intelligence) in outburst of destructive emotions. Some persons having balanced emotions that are they maintain the emotions in average level. These types of persons not excited too for pleasant events and vice versa.

Qualities of Emotional Healthy Person

An emotionally healthy person is having high tolerance because those people are easily adopted in a new situation. They are always feeling free with others. The television Programme titled 'Big Boss" has been organized by Star Vijay Television is showing the emotions of the participants. This programme is normally telecasting for 100 days and the participants are insisted to stay with a group in a closed home. There is no mobile phone, entertainment for the participants and they are requested to cook the food themselves with the limitation of vegetables. Their activities are watching through a camera and high emotional participants are

Emotionally healthy people,

- Try to grow up their self-awareness and self-esteem,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Known their boundaries of characteristics,
- End a bad relationship for good things,
- Easily adopt any emotional situation,
- Chooses the best approach to others and them following their passion

Barriers of Mental Health Services

Raguram, Weiss, Channabasavanna and Devins (1996) stated that the most important barriers in looking for mental health is unavailability of professional services, low literacy, socio-cultural barriers, traditional and religious beliefs, and shame. According to WHO (2017), the median number of mental health beds per 100 000 population ranges below 7 in low and lower-middle-income countries to over 50 in high-income countries; from 100,000 people just 0.4 psychiatrists and 0.02 psychologists. Mental disorders are disgustingly underestimated by the community and health system in India and across the world. In the year 2000 estimation of the mental disorder, 12.3% of disability-adjusted life years and 31% of years lived with disability. Projection proposes that the health trouble owed to mental disorders will increase to 15% of disability-adjusted life years by 2020 (Murray and Lopez, 1996).

According to the National Commission on Macroeconomics and Health (2005) shows that at least 6.5% of the Indian population has some form of serious mental disorders. Mental health workforce breakdown per 100,000 populations by WHO region such as noted in the table given below.

Table 1. Mental Health Atlas. (WHO, 2018)

	Psychiatrists	Psychiatric Nurses	Psychologists	Social Workers
2001	0.4	0.04	0.02	0.02
2005	0.2	0.05	0.03	0.03
2017	1.3	3.5	0.9	0.3

Technological Issues and Remedies for Mental and Emotional Health Problems

In the older time, people often used typewriters, cycling, dancing, did puzzle, played board games and played in the ground for entertainment. Nowadays the boom of technology, computers, tablets, and mobile phones has replaced all those things and become very popular. Gaming technology in mobile phones, laptops, tablets and video games like a PUBG and Blue whale, have been as entertainment and hobby of the young students. Many years ago there were not very many forms of technology that stay alive. If an individual is not using technology for some form of entertainment, they are most likely using it for something along the lines of school or work. Technology has gone from being a suitable tool for being a bad impact on society. Not only is it slighting the brainpower and mental health of many people, but it is also taking away from one's social behaviour.

During the past years, the rapid development of technology in human mental health is based on social media such as facebook, twitter, Skype, whatsapp and my space was used to interact and communicate to others.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

American Association of Suicidology stated that social media is a significant impact on mental health towards young people. An exception of vague booking, social media usage may be misplaced (Berryman, Ferguson & Negy). Sometimes technology can also offer new ways to treat mental health disorders. More than mental health apps also available for alternative treatments the apps also available in Smartphone such as,

- What's up: Cognitive Behavioural Therapy (CBT) and Acceptance Commitment Therapy (ACT) Method
- Mood kit: Cognitive Behavioural Therapy and Mood improvement activity
- Twenty-Four Hours a Day: Meditation book for people in recovery from addiction. Companion and Focus on moderation of addiction behaviour
- Quit that: strike their habits or addiction, perfect recovery tool and monitoring the progress.
- Mind shift: It is an anxiety app, this app trying to avoid anxious feelings and changing the negative thing about anxiety
- Self-help for anxiety management: Social Cloud" feature to confidentially connect with other users in an online community for additional support
- Bipolar Disorder Connect: Identify the struggles of people and monitor the people moods
- IMoodJournal: Analyze the daily feelings through the summary charts such as noted the stress level based on rising and falling.
- Talk space Online Therapy: This app is used to support one's through the ones own depression
- Happify: This app is fast-track to a good mood. Try various gratitude prompts, activity suggestions, engaging games and more to train your brain as if it were a muscle, to overcome negative thoughts.
- Recovery Record: Recovering from an eating disorder and inadequate to build up a more optimistic body image and used to stick the meal plan.
- nOCD: nOCD giving mainly two treatments such as mindfulness and Exposure Response Prevention Treatment.
- PTSD Coach: to find and giving an opportunity for Post-Traumatic Stress Disorder from a self-assessment
- UCSF PRIME: This app is used for schizophrenia groups. It also lets people track "challenge goals," belongings they'd like to accomplish or improve about them.
- Headspace: This app is used to make meditation in a simple way, that meditation on the lot from stress and anxiety to sleep and focus.
- Calm: Calm provides people experiencing anxiety and stress with guided meditations, breathing programs, sleep stories and relaxing music.
- MY 3: This app is suicidal prevention app and used to recognize ones warning signs through one's safety plan and listed warning plans.

The above apps are using the people to develop mental health in positive manner, technology impact the humans in both way. Technology can impact society in positive and negative. So human only choose the correct way and tools to grow up the living style, personality and so on.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

In this chapter, the authors discussed various opportunities for all people for maintaining mental health and emotional development. Our focus is that the individuals growing up with good emotional and mental health. For that, the authors briefly discussed technological issues regards to mental and emotional health. Everyone knows that emotions are innate, cannot be controlled but manageable and it is a hidden factor for developing good mental health. Generally, destructive emotions affect an individual's mental health and high on that emotions may throw the individual as a murderer or committing suicide. Constructive emotions ensure stress-free and peace of living, which develops good mental and emotional health. So, emotions play a vital role in maintaining emotional health which is a factor for developing mental health. Notwithstanding this, some technologies also fluctuate emotions and direct emotional and mental health issues. Hence this chapter discussed with technological issues regards to mental and emotional health and providing remedies for emotionally and mentally healthy life.

Chapter 6
Romantic Relationships, Online Dating, and Mental Health Issues

Tejaswini Bhave
Deenanth Mangeshkar Hospital and Research Center, India

ABSTRACT

This chapter attempts to present the overview of mental health issues associated with online dating and online romantic relationships with relevant research background. It briefly cautions about the possible risks involved in the world of online dating platforms and later delves into mental health concerns that can emerge out of experiences while selecting a potential partner online, developing a romantic relationship, and being involved in a romantic relationship online. It also discusses safety measures that need to be taken before and while being active on such online dating sites. The chapter draws attention to the specific role of mental health professionals that is needed while dealing with victims of online scams and abuse.

INTRODUCTION

Love and affection are very basic human needs. Romantic relationships are significant part of our lives and contribute in our physical, social and emotional well-being. A good relationship enhances our overall health. (Cohen, Frank, Doyle, Skoner, Rabin, & Gwaltney, 1998), and even help in speedy recovery from various disorders (Kiecolt-Glaser, Loving, Stowell, Malarkey, Lemeshow, Dickinson, & Glaser, 2005). Most of the people find their partners through their social or professional sphere. However, these circles are limited in number and thus the choices can become narrowing. Consequently due to the advent of new technology, people want to widen the scope of finding a more suitable partner and they find the solution in online dating sites.

Using the internet has not just remained a convenience but has become a necessity. With the advancements in technology, today we have plethora of very diverse social networking platforms which are unique in their own way connecting people together online. Social media has revolutionized and

digitized human interactions and relationships. Rosenfeld and Thomas (2012) found that the Internet has allowed users to find partners more easily, especially homosexuals and middle-aged people who operate in a "thin market.

With the popularity of online dating sites, the stigma of online dating has diminished considerably in the last decade. According to the survey conducted by Smith and Anderson, (2015), overwhelming majority of Americans suggest that online dating is a good way to meet people. Interestingly, more than 15% of adults say that they have used either mobile dating apps or an online dating site at least once in the past. Online dating services are now the second most popular way to meet a partner.

WHAT PERSONALITY CHARACTERISTICS ARE ASSOCIATED WITH THOSE WHO PREFER ONLINE DATING?

1. In a research finding it was concluded that loneliness was found to be one of the major factor that encouraged people to go for online dating. (Lawson & Lake, 2006). The participants reported that they felt less lonely after being a part of the online dating websites.
2. It was observed that individuals scoring higher on the romantic beliefs and especially idealisation of the romantic partner were more vulnerable to being deceived on the online dating sites. These individuals also tended to be more agreeable and more likely to opt for online dating. (Whitty & Buchanan, 2012)

WHAT IS WRONG WITH ONLINE DATING?

In a popular blog post by Ryan Anderson, several warning signals regarding online dating have been put up and they seem to be resonating with reports of Indian newspapers on the same topic (Psychology Today, 2016).

1. People tend to lie about themselves on online dating sites. Out of over 1000 online daters in the USA and UK, 53% confessed that they have lied in their online dating profile; mostly about look, height, financial status. This was an attempt to project an ideal self to attract more partners.
2. It's basically virtual! Smith and Anderson (2015) found out that more than one third of their research participant (online daters) never actually went on a date and those who went found it difficult to connect to the person they had met online.
3. It makes people judgemental. Various online daters confess that they judge the person based on the looks. The apps and websites offer an interface where only the physical aspects of the individual are highlighted so as to make the website more appealing. Naturally the users dismiss the not-so beautiful candidate in just a swipe or a click.

EMERGING MENTAL HEALTH ISSUES RELATED TO ONLINE DATING

However there are some shortcomings of this epidemic of developing romantic relationships. Right from becoming a victim to identity or financial frauds to brief, deceitful and virtual nature of relationships,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

online dating poses a serious danger to the person's sense of self and his or her relationships with others which in turn lead to many mental health-associated issues.

1. Short and unsuccessful relationships. The very virtual nature of the online dating scene itself suggests that it promises a 'fling'; meaning a very casual, non-committal relationship or so the stigma associated with online dating suggests to people. People are attracted to online dating when they feel lonely or are disappointed by the conventional dating experience or "let some steam off". Thus it becomes apparent that these relationships are not looked upon to be serious and following study attest to that.

A recent study by Paul (2014) showed that couples who met on dating sites are less likely to get married and even further he also pointed through surveys that breakups were more common in couples who met online versus those who met in more traditional set ups. This study asserts that this result is consistent with both married and unmarried couples.

We know that short term and less meaningful relationships that lead to breakups do not contribute to our well-being. Frequent or even one incident of breakup leads to bereavement symptoms including intrusive thoughts and attempts to suppress them and insomnia as well as morbidity factors including broken heart syndrome and immune dysfunction (Field, 2011). In this way online dating can really pose a threat to one's well-being.

2. Online dating scams. As discussed above online dating sites are not safe as in the candidates can put up false information about their looks, financial status, marital status and you have no means to crosscheck this information. A huge number of scams including financial frauds, sexual abuse, internet bullying and blackmailing have mushroomed with the increasing use of online dating websites and apps.

Professor Whitty and Professor Buchanan from the University of Leicester and Westminster have conducted comprehensive studies of the victims of online dating scams. They appraised from a nationally representative sample survey that almost 230,000 people may have been tricked by romance fraudsters in UK only. They assessed the 2 sets of such victims i.e.: 1) those who lost money due to frauds done by online romantic partners, and; 2) non-financial victims.

The victims who had lost money reported significantly higher emotional distress than those who did not lose money. Many non-financial victims too reported high levels of emotional effects. Both set of participants reported experiences of depression, guilt, shame, embarrassment, fear, feeling suicidal, extreme emotional distress, emotionally violated, loss of trust in others, feeling stupid, denial, problems in appetite, sleep and sexual functions.

3. Body Image and Self-Esteem. As discussed above the dating apps and websites bank on the good looks of the candidate and hence the individual with more appealing physical appearance are desired by the opposite gender and they get the most right swipes/likes/interest requests. This creates a problem in how one looks at one's own body and how much importance is attached to looking beautiful.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In a study presented at the annual convention of the American psychological association, researchers explored the psychological effects of a certain popular dating application on a group of 1300 college students. These participants were asked questions based on their appraisal of their own body image and how they compare their looks with others. At the end of this questionnaire they were asked if they used that certain application.

The results showed that individuals using that application had lower levels of self-worth than those who did not use the app. They also reported being less satisfied with their facial features and they were ashamed of their bodies. They also constantly compared themselves with the appearance of others and were self-conscious. Surprisingly, this research even showed that all the findings were true for men and women both, because women tend to judge their own looks negatively (Strubel & Petrie, 2016).

Body dissatisfaction appears to be associated with greater impairment in self-esteem and other aspects of psycho-social functioning in males (Furnham, Badmin, & Sneade, 2002; Wardle & Cooke, 2005).

A longitudinal study examined the relationship between low self-esteem and depression and found that low self-esteem is a causal risk factor for the development of depression. (Robins, Widaman, & Conger, 2014)

4. Too much attention is not good for you! In the world of online dating, the *super like, like, comment, right sweep* is like a tiny dose of positive reinforcement and it is highly pleasurable to the receiving candidate. The rampant world of social media has wired our sense of identity to how we look on our social or dating profile online. People either tend to get more arrogant when they are desired by many people or lose their self-worth because they are rejected or ignored.

An online app user confessed to Times of India how using this app first gave her too many feel good emotions and how she became significantly arrogant and narcissistic. However, when her profile was rejected by a good-looking individual and he said that she was too pretentious she fell in the spiral of self-doubt, low confidence and despair. This shattered her self-worth and she spent hours in the late night to see if anybody has liked her profile or not. The rejection stung her too much and she began crash dieting and her work-life and mental health deteriorated (Times News Network, 2017).

5. Online sexual abuse. Women on various dating websites report the experience of receiving rude, disgusting messages, sexual propositions/requests which if entertained go on to develop sexual abuse. As announced by the UK's national crime agency, online dating related rape has increased by more than 450 percent in last 5 years (2016). The report elaborated that online relationships generally progress at higher rate as compared to offline relationships because in the virtual world people tend to feel free and express their emptions readily. This increased trust leads to individuals taking more risks in the relationship and be willing to participate in vulnerable situations. In these cases previous online flirting, messages with sexual content increase the intimacy between the partners and thus they have higher expectations about sexual activity when they meet for the first time. The offenders use the strategies of persuasion, perseverance and coercion to get the victims agree on the early first date.

This can result into serious mental health problems leading to development of disorders like depression, suicide attempts, Post traumatic stress disorder etc. Research consistently identifies the negative consequences of being a victim of cyber abuse. Victims experience loneliness and social isolation. The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

person's consequent social withdrawal is likely to lead to low self-esteem and depression. Those who abuse others too are at risk too. They are more likely than non-abusers to engage in a range of maladaptive and antisocial behaviours and at risk of alcohol and drugs dependence, depression and suicidal ideation (Cowie, 2013).

PROTECTING ONE'S WELL-BEING WHILE DATING ONLINE

Now when we are familiar with what dangers online dating poses to our emotional and physical well-being, it becomes mandatory to go through some safety measures candidates need to take before embarking on the journey of online dating. These tips are compiled from various dating websites and cyber security professionals (eharmony.com, Tinder™, OKcupid.com, National Cyber Security Alliance).

Though these measures cannot make the person absolutely immune to the horrors of online dating scams and abuse they can definitely prevent many unwanted situations. It is ultra-important to stay safe online.

1. Use a trusted online dating site or app which has strong customer support, better privacy and those who approve the candidate profile only after checking the claimed information with valid documents or proofs.
2. Check the privacy policy, required details and permissions by the website so as to safeguard your sensitive information and how they handle cases of abuse or scams, features like blocking a profile or disabling instant messaging/ location tracking or the option of reporting a profile are very much necessary.
3. Do not provide sensitive information about yourself and financial details, do not divulge in sharing private and personal details. Do not respond when request of financial details or sexual content are made, block that person and immediately report his profile to concerned authority. Do not exchange private and personal information.
4. Be careful to not disclose your personal mobile numbers immediately. Do not trust blindly.
5. Use a disposable email id for dating sites.
6. Create an honest profile and be specific in your expectations from prospective partners. Do not upload inappropriate pictures or those containing information about your car number, house location etc.
7. Check the person's identity through Google, Facebook or other platforms. Make sure that the name, face and other details are correct.
8. Do not develop too much intimacy online. First meet the person as soon as possible and when your fact check is complete you can slowly develop the relationship.
9. While going on first dates learn to say a firm "No" to any sexual requests, always confide the location details of your date with a known person (family or friend). Meet in public places and avoid long drivways or lonely places. Do not drink too much on the date and be vigilant to any cues of dangers. Confront and ask question when something looks fishy even online and in person.
10. Confide in your near and dear ones about your dating experience online. Do not choose online dating just because you are too lonely, depressed or recently broke up with someone. Make an informed choice.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ROLE OF MENTAL HEALTH PROFESSIONALS

The increasing number of cases of cyber abuse and scams are leaving the victims stranded in the miserable state of anger and disappointment and in many cases their reaction is that of experiencing a trauma. Mental health professionals need to be aware of unique challenges these victims face and they need to prepare themselves to tailor their interventions in such a way that they meet the needs of victims of such abuse.

The study done by Whitty and Buchanan (2012) proposed the shortcomings of the help given by counsellors to such victims. The professionals were inept to understand the nature of the trauma and were quick to judge the victims for being conned financially and emotionally.

The counsellors also did not understand that the victims could not turn to their family and friend for social support and they felt withdrawn and isolated from others.

Hence the mental health professionals need to take care of following aspects as a reflection of Whitty and Buchanman's study;

1. Increasing awareness about such abuse and scams in their working field and spread word of caution. They also need to be approachable to such victims and come out of traditional therapy/counselling set up to meet these victims.
2. Law enforcement agencies need to have strong tie-ups with mental health professionals to facilitate timely referrals and crisis intervention in earlier stage when the victims are vulnerable to suicidal ideation, substance abuse and other such situations.
3. It is necessary to understand that this trauma reaction is similar to the stages of grieving as explained by Kubler-Ross's (1969): denial, bargaining, anger, depression, and acceptance.

The denial stage when unresolved can lead to re-victimization which is much more dangerous. Appropriate interventions need to be employed to fully resolve the grieving response.

4. The increased mistrust towards other people the victims have developed after the trauma can lead to transference issues.
5. Ways of coping with the distress need to be realistic rather than dreamy and farfetched; the professionals need to understand that empowering the victims for a long term is essential rather than for a temporary basis.
6. The professional need to understand the '*double hit'* victim has suffered- the financial loss as well as the loss of a perceived significant relationship.
7. It is necessary to protect the victim from the second wave of being conned.
8. The victims who go through such trauma are often seen to have history of previous sexual abuse and other mental health problems. These vulnerabilities need to be sensitively handled.
9. The victims need to know that professional help is available and professionals need to standards of uphold highest ethical and moral conduct to safeguard the confidentiality and well-being of the victims.

THE POSITIVES OF ONLINE DATING

It goes without saying that even after enlisting many drawbacks of the world of online dating it also has some uses and that is why it is so popular. Finkel and colleagues (2012) discuss the plus points of online dating:

1. **Access:** Online dating equips the individuals with access to many more potential partners than they could often find in their daily lives. This is especially true for individuals interested in partners of a particular type, orientation, lifestyle, or in isolated areas.
2. **Matching:** Many online dating sites offer various types of personality testing and matching. Such matching can help guide individuals toward dating partners who may be more compatible.
3. **Communication:** Online dating offers a number of ways to get to know a possible date before meeting in person. Such computer-mediated communication allows for safe and convenient interaction, without much risk or time commitment. For the busy professional, or the safety-conscious, such communication is an excellent way to "check" potential partners.
4. **Individuals With Social Stigma Attached to Their Particular Condition or Way of Life:** It is difficult for individuals who have social stigma associated with them like homosexuals, people with disability or people having mental illness to find a romantic partner through conventional methods of dating. But these individuals have found it useful to search for a suitable partner through online dating and they are finding meaningful romantic relationships online.

CONCLUSION

In conclusion, it is necessary to understand that both the traditional and online methods have their own advantages and disadvantages but the key to cultivate online romantic relationship is to be cautious while wading through the virtual world. Online dating is a start but meeting the person as soon as possible leads to trust building and rule out dangers of being conned. Considering internet as way to engagement with real human beings and not mistaking it with actual relationship is of utmost importance to protect own mental health and overall well-being.

Chapter 7
Special Issue:
Sexually Transmitted Infections – Diagnoses, Stigma, and Mental Health

Sara Bender
Central Washington University, USA

Karlie Hill
Central Washington University, USA

ABSTRACT

Misconceptions regarding the cause(s) of sexually transmitted infections (STIs) has led to a number of prejudices against those with such diagnoses. A fear of being the object of prejudicial attitudes and behaviors leaves many individuals concerned about the social stigma of a STI diagnosis. This, in turn, may leave people unwilling to get tested or hesitant to disclose their diagnosis to others, which may fuel the spread of such infections. In addition to the numerous medical concerns associated with STIs, the psychological consequences of STIs are notable as well. Understanding the stigma related to STIs is an important step towards improving the mental health of people with such diagnoses. This chapter provides the reader with an overview of STI diagnoses, and an explanation of their physical and mental health consequences. The chapter continues by examining the three types of stigma as well as their components. Finally, the chapter offers a number of suggestions regarding how to combat STI stigma, which may be extrapolated to combat other forms of stigma affecting mental health.

INTRODUCTION

According to the Center for Disease Control (CDC) (2016), there were 1,526,658 cases of chlamydia, 395,216 cases of gonorrhea, 23,872 cases of primary and secondary syphilis, and 487 cases of congenital syphilis reported in United States in 2015. These figures, which only include a small fraction of potential sexually transmitted infections (STIs), represent a substantial increase in reported diagnoses from the previous reporting period (2014), suggesting that the transmission of sexually transmitted infections (STIs) is on the rise. What is interesting about these figures is that they paint only a part of the picture. The CDC

DOI: 10.4018/978-1-7998-8544-3.ch007

Copyright © 2021, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

relies on the reports of local health authorities and other public reports to gather its data. As such, these figures are estimates, at best, and likely greatly underrepresent the STI epidemic plaguing the country. The fact is that many cases of chlamydia, gonorrhea, and syphilis go undiagnosed and/or unreported. Further, data on other STIs, such as herpes simplex virus, trichomoniasis, and human papillomavirus, are not routinely reported at the national level. As such, information regarding the pervasiveness of the current STI epidemic is based on estimates. In 2016, the CDC estimated that approximately 20 million new cases of sexually transmitted infections occur every year within the United States (CDC, 2016).

While the exact prevalence of STIs are unknown, their impact is evident. Research indicates that STI diagnoses influence people's short-term and long-term physical health and often impacts their mental health statuses as well. Additionally, STIs also contribute to a number of burdens that broadly impact society as a whole, including compromised productivity as well as economic outcomes (CDC, 2016). In 2016, the CDC estimated that the country spends over $16 billion in health care costs related to STIs (CDC). Despite these known effects, trends in the data suggest that many people remain resistant to pursuing adequate testing and/or treatment for possible STIs due to their concerns regarding the stigma of having such diagnoses (Foster & Byers, 2008). This resistance may not only compromise the health of the individual with the STI, but also has the potential to negatively impact his or her current and future sexual partners.

There remain a number of misnomers regarding STIs, including information regarding the manner in which they are contracted as well as their treatability. This misinformation may lead individuals with potential or confirmed STI diagnoses undue stress, which may compromise their overall mental health functioning. It likely also aids in the further perpetuation of inaccurate myths and subsequent stigma regarding sexuality and reproductive health.

The goals of this chapter are to:

1. Introduce the reader to the effects of a STI diagnosis and the consequences of non-disclosure,
2. Explain the types of stigma typically associated with STI diagnoses as well as their components,
3. Explore how STI stigma compares to other forms of stigma affecting wellness, and
4. Review strategies to reduce stigma

By the end of this chapter, readers will better understand the impact of stigma as it relates to sexually transmitted infection diagnoses and associated mental health functioning. Understanding the nature of STI stigma will provide insight into the nature of stigma, as a whole, thus allowing the reader to further deconstruct the stigma of mental health specifically. The ability to more fully understand the nature of stigma will allow advocates an increased capacity to combat it effectively.

BACKGROUND

Physical and Psychological Effects of an STI Diagnosis

There are over 20 different types of viruses known to be transmitted via sexual contact (NICHD, 2017). Of these, the most common include: chlamydia, gonorrhea, syphilis, herpes, HIV/AIDs, human papillomavirus (HPV), bacterial vaginosis, and viral hepatitis. While each variable in the display of its specific symptoms, STIs may have a profound impact on a person's physical health. For example, chlamydia, an

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

infection that may spread via oral, anal, or vaginal sex, may lead to a variety of symptoms. Some with the infection will experience no symptoms while others will experience high fevers, abdominal pain, and unusual genital discharge. Chlamydia may also cause a woman to develop pelvic inflammatory disease (PID), which, if it develops, can lead permanent damage to her reproductive organs and lead to infertility. Further, there is an increased risk to the health of the fetus of women pregnant whom have this infection (NICHD).

Gonorrhea symptoms most typically include genital discharge and/or painful urination. Like chlamydia, this infection is spread via genital, anal, and oral contact and may also result in PID and its associated consequences. Research indicates that gonorrhea can spread to multiple parts of the body and eventually become a life-threatening illness. This diagnosis may also place an individual at an increased risk of contracting other STIs, such as HIV (NICHD, 2017).

Syphilis is also spread via oral, anal, or vaginal sex. Its most recognizable symptom includes painless genital sores. If left untreated, this infection may involve other organs of the body, including skin, blood vessels, the liver, and bones. Over a period of years, the infection may further spread to involve the nerves, eyes, and brain, often leading to death. Mothers carrying the infection may spread it to their fetuses, which could result in miscarriage, stillbirths, or a number of other birth deformities. Additionally, research indicates that those with syphilis are two to five times more likely to contract the HIV virus (NICHD, 2017).

There are two types of herpes, which is caused by the herpes simplex virus (HSV). This virus is typically spread via genital, anal, or oral contact. Herpes leads to the development of painful blisters, which typically appear around the genitals or anus. Fever blisters or cold sores may also develop on the lips as well. While some people with this infection may remain asymptomatic, the virus is incredibly easy to spread. Like many other STIs, herpes poses great risk to the unborn fetuses of women whom are infected (NICHD, 2017).

The human immunodeficiency virus (HIV) may lead to the development of acquired immunodeficiency syndrome) (AIDS). HIV attacks a person's immune system by killing the blood cells that fight infection, leaving those infected with the virus particularly susceptible to further illness. A few decades ago, the presence of the HIV virus would typically mean almost uncertain death, however recent research has led to a number of functional cures for the virus. Further, increased sexual education has helped curb the spread of this virus (NICHD, 2017).

The most common STI at this time is human papillomavirus (HPV). Thus far, research indicates that there are over 40 variations of this virus, which commonly lead to infections throughout the body, the development of genital warts, and the growth of certain cancers. As with HIV, scientists have developed some medical interventions aimed at minimizing the prevention of HPV, including effective screening procedures to identify the presence of the virus as well as an immunization against it (NICHD, 2017).

Women are susceptible to bacterial vaginosis, a vaginal infection that is thought to be sexually transmitted. While the symptoms associated with this particular infection tend to be minimal, its presence is of concern as it puts women at increased risk of contracting other STIs, PID, and suffering from compromised reproductive health (NICHD, 2017).

Viral hepatitis results from one of several viruses that are typically transmitted through sexual contact, exposure to infected needles, exposure during birth, or exposure to infected blood. This infection results in a serious liver disease. There are several forms of the infection. Hepatitis A typically results in a serious, but short-term liver infection. Another form of the virus, Hepatitis B, is a serious liver disease that can result in urgent illness as well as well chronic infection, which can lead to death. Like Hepatitis

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

B, Hepatitis C can result in an immediate illness or a more chronic infection of the liver, which can contribute to one's death. Vaccination is said to help prevent the spread of Hepatitis A and B, but there is no cure or prevention for Hepatitis C (NICHD, 2017).

MAIN FOCUS OF THE CHAPTER

Issues, Controversies, Problems

Collectively, the research pertaining to these STIs indicates that they can lead to acute infection (NICHD, 2017), chronic pain (CDC, 2016), severe reproductive health obstacles, including infertility and pregnancy complications (CDC), or even death (NICHD, 2017). As such the prevalence of and efforts to prevent these infections should not be taken lightly. Luckily, as medical science has expanded so too has our understanding regarding the very nature of these infections. Medical interventions, including a number of immunizations and antibiotics, are now available to help prevent and/or combat the symptoms of these illnesses.

The impacts of STIs are not limited to physical health, however. STI diagnoses may also have a notable impact on one's mental health presentation as well. Past research confirms that those diagnosed with one or more STI diagnoses are likely to experience embarrassment, anxiety, shame, and fear both sexual and social rejection (Darroch, Myers, & Cassell, 2003; Duncan, Hart, Scoular, & Birgrigg, 2001; Osborn, King, & Weir, 2002). STI diagnoses are also correlated with depressive symptoms (Chen, Wu, Yi, Huang, & Wong, 2008; Khan et al., 2009) as well as symptoms of anxiety (Arkell, Osborn, Ivens, & King, 2006) and increased suicidal gestures (Badiee, Moore, Atkinson, Vaida, Gerard, & Duarte, 2012).

Disclosure and Non-Disclosure

There are a number of reasons a person may choose not to disclose his or her STI diagnosis to others. More often than not, the primary reason is to avoid stigma (Lichenstein, Neal, & Brodsky, 2008). Past research confirms that internalized stigma and the potential for treatment stigma often lead people to avoid seeking help for their STI-related symptoms. More specifically, people endorse concern regarding the confidentiality of their diagnosis status as a main treatment-seeking barrier (Clement, Shauman, Graham & Maggioni, 2015). Concerns regarding others' external stigma, which is often rooted in religious and cultural expectations, leads many people to avoid disclosure primarily due to the fear of social judgement, and, in some cases, fear for personal safety (Kingori, Ice, Hassan, Elmi, & Perko, 2016). Non-disclosure has several potential effects. First, it may exacerbate the cognitive and emotional toll of the diagnosis itself, causing increased stress, shame, and discomfort to the individual. Further, the failure to disclose one's symptoms to parents, medical providers, and others affecting one's healthcare may prevent access to effective treatment, which could actually help minimize symptoms and/or prevent the infection from further developing.

The impact of an STI is not limited to the person diagnosed. In addition to the many social consequences of such infections, including high medical costs, compromised productivity in the workplace, and similar circumstances, one's sexual health also affects his or her current or future sexual partners. Individuals who learn of their partners' STI diagnosis may need to reconsider sexual practices, including what activities to engage in and to what extent as to reduce their own chances of infection. Additionally,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

increased protection, such as the use of condoms, may be warranted. Of course, learning of a partner's STI status after exposure may also have psychological consequences as well. Bender and Hill (2017) conducted a phenomenological study, which reveals that partners often wonder about their partners' level of sexual responsibility, commitment to their relationship, and monogamy practices secondary to learning of their partners' STI diagnoses. This, in turn, often creates situations in which the partner of the person infected experiences heightened levels of psychological distress, including anxiety, anger, and depression. Given the potential for conflict with one's partner and/or the prospect of being denied sexual intimacy, it may be tempting for some people to not disclose their STI diagnoses with their partners. Failure to disclose such diagnoses leaves the partner at an increased vulnerability to future infections and associated medical complications.

Defining Stigma

The definition of stigma is inconsistent within the literature. Most explanations of the concept refer back, in some form, to the word's Greek origin of 'a sign or a branding mark' (Sharfestin, 2012). In his seminal book on the topic, sociologist Erving Goffman (1963) defined stigma as an 'attribute that is deeply discrediting" ultimately reducing an individual "from a whole and usual person to a tainted, discounted one" (p.3). Within his explanation, Goffman (1963) highlighted three categories of stigma: tribal identities, body abominations, and blemishes of individual characters. Tribal identity (also referred to as 'group identity') refer to a person's group membership as determined by religion, nationality, sex, race, and similar characteristics. Body abominations refer to physical deformities. Finally, blemishes of individual characters refer to circumstances such as the presence of a mental health diagnosis, unemployment, addiction, etc. Each of the categories, according to Goffman, renders those with them as distinct from those whom do not have them, thus paving the way for prejudicial attitudes and subsequent discriminatory practices to occur. Goffman explained, "By definition, we believe the person with a stigma is not quite human" (p. 5). Within this framework, stigma devalues the individual and excludes him or her from societal acceptance (Goffman).

Jones and colleagues (1984) suggested that there are six stigmatizing dimensions that fuel the separation between a 'usual person' and a 'discounted one' (Goffman, 1963, p. 3). These dimensions include: Whether the stigma is visible vs. concealable, the perceived origin of the condition, the aesthetics of the condition, whether or not the condition is viewed as perilous or not, whether or not the condition is likely to be disruptive to ongoing social interaction, and the projected course of the condition over time.

Explaining Stigma

Social scientists have not only struggled to define stigma, but also to explain it. There are a number of psychological and sociological theories that help describe this phenomenon. Corrigan (2004) suggest that three paradigms exist, which help explain stigma. First, the social cultural perspective suggests that stigmas form to substantiate prevailing social injustices. The paradigm of motivational biases suggest that stigmas develop secondary to meeting basic psychological needs. Finally, social cognitive theories suggest that stigmas result as the consequence of human information processing. Of these three paradigms, the social cognitive theories are most widely accepted. They are said to be the most theoretically rich and best supported empirically out of the three.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social cognitive theories recognize that people engage in a number of heuristics, which allow them to quickly categorize individuals into groups (Dovidio et al, 2011; Kahneman, 2011). While a normative process, this categorization likely organically leads to prejudice and discrimination. Gordon Allport (1954) suggested that this tendency to categorize others an essential element of social life. Assigning those we encounter into categories allows us to process large volumes of information about those we encounter by filtering that data into specific classifications. Categorization also allows us to cluster that information efficiently by relying on previous assessments regarding individuals and situations that we recognize as similar. This, in turn, may also allow us increased access to emotions more easily, as we tend to develop distinct like or dislike for those things we have categorized. Finally, categorizing people also allows us to identify them with speed and efficiency. Prejudice, it is suggested, is an organic consequence of this categorization. Prejudicial beliefs, often lead to discriminatory behaviors associated with stigma.

Stigma Impact

Link and Phelan (2001) suggested that most common definitions of stigma are too simplistic due to the perspectives traditionally held by stigma researchers, which are rooted and limited by their participants' experiences, as well as the individualistic focus of the research dedicated to understanding the phenomenon. They argue that a larger cultural focus must also be considered when operationalizing stigma. Link and Pehan expand the term stigma to refer to "when the elements of labeling, stereotyping, separation, status loss, and discrimination co-occur in a power situation…" (p. 367). They assert that stigma likely serves as a "key determinant of many of the life chances…from psychological well-being to employment, housing and life itself" (382).

There are four commonly accepted manifestations of stigma, including: 1.) public stigma, which refers to people's social and psychological reactions to someone with a perceived stigma, 2.) self-stigma, which refers to how an individual reacts to the possession of a stigma, 3) stigma-by-association, or courtesy stigma, refers to the social and psychological reactions to people associated with a stigmatized person or how people react to their own associations with a stigmatized person, and 4.) institutional stigma, which essentially is the legitimatization and perpetuation of a stigmatized status by society's ideological systems and institutional practices. Each of these manifestations is likely to impact a person's wellness and functioning. Public stigma and stigma-by-association, lead to biases, negative stereotyping, and negative judgment (Kendra et al., 2014). Similarly, institutional stigmatization may lead to increased difficulties securing employment, social status, or housing (Sickel, Seacat, & Nabors, 2014). These factors may serve as barriers to treatment, contribute to increased isolation, and facilitate a variety of negative psychological effects. Further, self-stigma may impact an individual's self-esteem and opportunities (Watson, Corrigan, Larson, & Sells, 2007). All forms of felt and enacted stigma are likely to negatively affect a person's quality of life (Gerrida-Hernansaiz, Helyen, Bharat, Ramakrishna, & Ekstrand, 2016).

STI and Mental Health Stigma

STI-related stigma refers to an individual's awareness that a STI diagnosis is accompanied by a negative social judgement (Foster & Byers, 2008). Historically, the acquisition of an STI has been misattributed to deviant behavior and immorality rather than a consequence of normal sexual activity. Misperceptions regarding the cause(s) of STIs has led to a number of prejudicial attitudes and beliefs against those with such diagnoses. A fear of being the object of prejudicial attitudes and corresponding behaviors leaves

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

many individuals concerned about the social implications and general stigma of such diagnoses. This fear of social stigma secondary to a STI diagnosis leads a high proportion of people unwilling to get tested for STIs and/or to disclose their confirmed diagnoses. This, of course, not only compromises their own health, but also increases the likely transmission of STIs to others, further fueling the STI epidemic.

There are three components of STI stigma, including: shame, sexual anxiety and social desirability. STI-related shame is a "negative affect that an individual experiences as a result of internalizing stigma" (Foster & Byers, 2008, 194). This relates to feelings of immorality and often leads people to think of themselves and themselves as "dirty". Secondary to this label of being 'dirty' due to their diagnosis, those suffering experiencing shame related to the STIs assume that they will be viewed negatively by others (Foster & Byers). Foster and Byers (2008) found that those who reported higher levels of shame were less likely to get tested for STIs and less likely to disclose their diagnosis; again, risking their future health and that of those with whom they are sexually intimate.

While the shame associated with having a STI may affect anyone at any time, research suggests that it is especially prevalent among women. East and colleagues (2011) report that women typically attribute other women's STI diagnoses as a consequence of promiscuity or sexual deviance. This perspective changes, however, when women receive a STI diagnosis themselves. Instead, the literature suggests that women in such scenarios shift their perspectives to internalize new feelings of self-blame and denial, which lead to shame. This shame is often experienced at a deep personal level upon the time of diagnosis and may cause physical and psychological burdens on the individual, which, in turn, places pressure and strain on intimate relationships (East et al., 2011). Research also suggests that there is a positive correlation between sexual conservatism and dissatisfaction with school-based sexual education with high levels of shame due to STI diagnoses (Foster & Byers, 2008).

The second component of STI stigma, sexual anxiety, occurs when a person fears sexual rejection secondary to his or her STI diagnosis. Sexual anxiety is category of sexual dysfunctions, defined as persistent impairment of sexual interest or response cycle. This dysfunction can be physiological or psychological (Adekeye, Sheikh, & Adekeye, 2012). It can create biological and interpersonal conflicts, and can be affected by stress, emotional disorders, ignorance of sexual function, and basic physiology (Adekeye, Sheikh, & Adekeye). Foster and Byers (2008) determined that people with more traditional values are more likely to associate STIs with stigma and shame and are more likely to experience sexual anxiety (Foster & Byers). This sexual anxiety, in turn, may facilitate lower levels of sexual pleasure and satisfaction (Brassard, Dupuy, Bergeron, & Shaver, 2013).

Social Desirability Theory indicates that humans retain an innate desire to please and be accepted by others. Social norms, perceived negative consequences, and fear of rejection all affect social desirability. The desire to remain socially desirable, in combination with fear of rejection, leads many people to resist seeking STI testing as well as disclosing STI diagnoses (Cunningham, 2009). A fear of rejection seems to serve as the common denominator between shame, sexual anxiety, and social desirability in relation to sexuality. This fear of rejection leads many people to avoid seeking STI testing, procuring STI treatment, and disclosing STI diagnoses to their partners. Lichtenstein and colleagues (2005) found that many people reported being embarrassed regarding their STI diagnoses, which contributed to the delay or complete avoidance of treatment for the same. Barth and colleagues (2002) asserted that people sometimes also avoid pursuing initial STI testing due to their own preconceived biases regarding what a STI diagnosis might mean. In their study of undergraduate students, they found that in an effort to avoid negative emotions, deny the possibility of even having a STI, or even a simple preference to not have such a hypothesis confirmed, some individuals would not participate in STI screenings.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

While the stigma associated with STI diagnoses is formidable, research demonstrates that the stigma associated with mental health diagnoses is stronger than that associated with physical health diagnoses (Corrigan, 2004). Further, the stigma associated with various mental health diagnoses seems to be further stratified by the perceived severity of dysfunction commonly allocated to a diagnoses (Stuber, Rocha, Christian, & Link, 2014). For example, those with psychotic diagnoses, such as schizophrenia, are typically evaluated more harshly than those with a more common mental health diagnosis such as depression or anxiety (Corrigan, 2004).

In line with the behaviors of those with suspected STI diagnoses, those experiencing mental health symptoms also often avoid or delay seeking clinical assistance. A systematic review of studies completed from 2008-2011 revealed that stigma was the fourth highest ranked barrier to help-seeking. Within the collection of studies reviewed, the potential to have one's mental health diagnosis revealed was the most notable stigma barrier (Clement, Shauman, Gram, & Maggioni, 2014). Via their study of undergraduate student experiences, Eisenberg, Downs, Golberstein and Zivin (2009) confirmed that perceived stigma or bias affected help-seeking behaviors. Corrigan, Druss, and Perlick (2014) also recognize mental health stigma as a primary barrier to care, but note that the dynamics involved in avoiding such treatment are not that simple. They suggest that one must also consider personal barriers (beliefs about treatment effectiveness, lack of a support network, lack of mental health literacy, etc.) and provider and system-level barriers (lack of insurance, financial constraints, staff incompetence, etc.) affecting the quest for care, too.

THE ROLE OF STIGMA IN PERPETUATING PREJUDICIAL BEHAVIORS AND DISCRIMINATION

Perpetuating Stigma

Stigma, regardless of its focus, is frequently fueled by media's attention on the negative attributes of a situation or diagnosis and via the public's subsequent understanding of the visible minority. For example, one only need to look at the coverage of mass shootings over the past decade to note the media's propensity to focus on whether or not the shooters associated with each horrific incident had some sort of mental health diagnosis. Rarely, did these outlets examine current the offender's stressors, ongoing drug abuse, extreme ideological beliefs, personal victimization, or other factors as potential root causes of their actions. Instead, more often than not, mainstream media often learned of these individuals' diagnoses and dismissed their extreme actions as the result of such diagnoses. Such conclusions fail to portray a comprehensive picture of the various intersecting factors likely propelling these offenders to such acts of horror. The news media's propensity to reduce and oversimplify the dynamics at play in these situations often portrays an inaccurate, or at very least, incomplete depiction of such events, which then leaves the consumers of this media with negative impressions regarding those with mental health issues. Further, due to their own fear of being the victims of such atrocities, those whom consume these media portrayals may feel an increased need to distance themselves from those whom they know or perceive to have a mental health diagnosis as a way to increase their perceived physical safety and in an unconscious effort to protect their own psychological safety (McGinty, Webster, & Barry, 2013). These beliefs trickle down into other areas of society as well. For example, researchers found that most employers report that they are less likely to hire someone with a known mental health diagnosis, as they

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

assume such individuals are more likely to be absent, disengaged, dangerous, or otherwise unpredictable (Overton & Medina, 2008).

The perpetuation of mental health stigma is not the sole responsibility of a misinformed media, however. Research indicates that those within the medical profession also perpetuate stigma related to various physical and mental health diagnoses. In one study, up to 31% of patients surveyed believed that they were discriminated against by medical professionals secondary to their mental health diagnoses (Henderson, Boblett, Parke, Clement, Caffrey, & Gale-Grant, 2014). Crapanzano and Vath (2015) suggest that such discrimination could affect clinical decision making. For example, one's physical symptoms may be dismissed as a manifestation of one's mental health diagnosis, thus compromising a thorough diagnostic process or medical treatment regimen. Closely related to this, the researchers also found that medical providers who stigmatize mental health diagnoses often failed to provide appropriate referrals, were less likely to pursue inpatient hospitalization for their patients with known mental health symptoms, and also maintained the assumption that their patients with mental health diagnoses were less likely to be compliant with treatment recommendations. Corrigan (2005) asserted that the known presence of a mental health disorder may lead providers to provide substandard medical care, even if that is not the providers' intention. His conclusion echoes that of previous researchers whom concluded that those with mental health disorders rarely receive adequate treatment for their medical ailments in general practitioner environments (Wang, Demler, & Kessler, 2002).

Similarly, research indicates that some mental health professionals also maintain prejudicial ideologies pertaining to those they perceive to be 'mentally ill', which further perpetuates mental health stigma (Smith & Cahswell, 2010). Past surveys have found that individuals with mental health disorders often feel as if their mental health providers focus only on their diagnosis while dismissing them as people (Pinfold, Byrne, & Toulman, 2005). Other studies found that mental health professionals sometimes reinforce misnomers regarding the nature of mental health diagnoses by perpetuating the beliefs that the presence of a mental health diagnosis may be correlated with dangerousness or unpredictability (Kingdon, Sharmer, & Hart, 2004) or by insinuating the recovery from one's mental health symptoms is not plausible (Magliano, Fiorillo, De Rosa, Malangone, & Maj, 2004). Smith and Cahswell (2010) suggest that a lack of training and preparedness among mental health professionals sometimes contributes to their negative attitudes regarding some diagnoses. Similarly, Crowe and Averett (2015) indicate that increased educational involvement improved mental health professionals' perspectives regarding likely recovery, effectiveness of treatment, etc. This coincides with research of the general public, which indicates that the more contact one has with those diagnosed with mental health issues, the less dangerous he or she would perceive those with mental health issues to be (Penn et al., 1994).

The patterns and impact of stigma associated with mental health diagnoses is similar to stigma accompanying potential STI diagnoses. For example, via their survey of men who have sex with men, Ross, Larson, Nyoni, and Agardh (2016) found that most patients felt that their health care providers were 'impolite' regarding their symptoms, which served as a barrier to seeking further or comprehensive treatment. Researchers also found that women seeking healthcare from a public health clinic for STI-related issues felt judged by medical staff. This disapproval, it seemed, was compounded in cases in which the patients did not view their symptoms as something to be ashamed of, but rather as a normative consequence of being sexually active (Lichtenstein, 2003). Similarly, a qualitative study conducted by Scheim and Travers (2016) revealed that medical providers' lack of competency regarding gender and sexual identity issues, coupled with lack of trust for those providers, negatively affected individuals' willingness to seek STI testing and subsequent treatment. Even in the instances in which patients desired additional

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

medical intervention for their symptoms despite their perceptions of providers' attitudes regarding their symptoms, these treatments were not always offered or provided.

CHALLENGES AND SUGGESTED SOLUTIONS

The CDC (2017) offers a comprehensive outline that serves as a national response to the current STI epidemic. It suggests that numerous parties must be engaged to effectively treat current STIs and prevent the future spread of such diseases. First, the CDC suggests that all medical providers make screening for STIs a part of their regular medical care protocol. More precisely the CDC calls for physicians to 'integrate STD prevention and treatment into prenatal care and other routine visits' (CDC, 2016, p.3). Next, the public must discuss the topics of gender, sexuality, and reproductive health. There must be an open dialogue regarding the need for those whom are sexually active to receive routine STI tests and to practice mutual monogamy and engage in contraceptive use. Further, parents and medical professional are called upon to proactively discuss the topic of sexual health with younger people to provide them with the information they need to protect themselves and potential sexual partners. Sexual health literacy, in particular, is an important step in the quest to reduce stigma. The CDC calls upon state and local health departments to allocate resources and other support to those impacted by this epidemic. Another important step in reducing stigma is to maintain interpersonal contact with those perceived to be different. Exposure to people of varying backgrounds and statuses allow each individual increased insight into the commonalities held across people making their perceived differences less threatening and more valuable. A final component to reducing stigma includes social activism. Professionals and members of the general public alike are called upon to advocate for increased attention, funding, and care towards sexual and reproductive healthcare issues (Corigan, Morris, Michale, Rafaacz, & Rush, 2012).

CONCLUSION

The aim of this chapter was to introduce the role of stigma in the identification and prevention of STI diagnoses. As the content of the chapter indicates, STIs have the potential to greatly affect one's physical health, mental health, interpersonal relationships, and overall quality of life. As such, it is imperative that individuals are aware of their STI status as not to compromise their own health or that of others. A principal reason many people avoid addressing their STI status is due to the stigma that shrouds such diagnoses. There are a number of interrelated factors that contribute to stigma, including: group identity, perceived blemishes of character, and visible deformations of the body. Collectively, these elements service to differentiate those with a designation or stigma, from those whom do not. STI stigma, specifically, seems to persist due to an intermingling of factors, including shame, sexual anxiety, and social desirability, which are deeply embedded in one's culture. Stigma contributes to the oppression of those diagnosed with STI diagnoses, often resulting in prejudicial beliefs and discriminatory acts against those with them. As with other social justice issues, the most effective advocacy efforts towards STI stigma seem to include a recognition of such circumstances, an active dialogue regarding the same, and a commitment to increased education and funding towards sexual and reproductive issues.

KEY TERMS AND DEFINITIONS

Bias: Prejudice against or in favor of a person, thing, or situation.

Institutionalized Stigma: Stigma that is embedded within organizational culture.

Mental Health Diagnosis: A collection of behaviors meeting the criteria set forth by the DSM-5, typically resulting in distress, dysfunction, or deviance.

Prejudice: A preconceived opinion regarding a person, thing, or situation based primarily on group membership.

Self-Stigma: Beliefs about one's self and one's status based on perceived stigma pertaining to a feature, group membership, or situation maintained by that individual.

Sexual Anxiety: Anxiety regarding the possibility of being sexually rejected.

Sexually Transmitted Infection (STI): An infection transmitted via sexual activity, either via anal contact, oral contact, or vaginal contact.

Shame: A social emotion tied to one's experiences or status.

Social Desirability: The innate desire to please and be accepted by others.

Stigma: Disproval based on perceived group membership.

Stigma by Association: Being the object of actual or perceived stigma secondary to a relationship with a person that maintains a particular group membership.

Chapter 8
Muslim Worldviews:
Implications for Helping Professionals Providing Culturally Competent Care

Anisah Bagasra
https://orcid.org/0000-0002-7057-5278
Kennesaw State University, USA

ABSTRACT

This chapter seeks to provide an overview of traditional and contemporary Muslim worldviews, specifically beliefs and attitudes that may relate to help-seeking and interaction with human services such as counseling, health services, educational systems, and social services. Traditional Islamic beliefs and views, combined with contemporary issues and the experiences of living as a religious minority, can impact successful interaction between members of the Muslim community and service providers. In addition, basic knowledge of Muslim worldviews can aid helping professionals in providing effective, culturally competent care. This chapter focuses on traditional Islamic concepts of health and illness, common lay beliefs that stem from traditional views, attitudes towards treatment, and help-seeking patterns. The interplay of religiosity, acculturation, gender, family dynamics, and other relevant factors on help-seeking and service utilization are also presented to provide the reader with a holistic perspective of prevalent Muslim worldviews.

INTRODUCTION

The area of culturally competent care is one that has been emerging not only for mental health professionals, but for all individuals involved in providing services within a multi-cultural, multi-religious society, including health care providers, mediators, educators, social workers, and providers of other social or community services. Cultural competence is an essential tool for helping professionals to effectively serve all facets of their community. Successful care relies on both the desire of the helping professional to learn about the cultural background and circumstances of the client, and the willingness of the client to share in an honest and open manner his or her perceptions of the situation leading him or her to uti-

lize a service. For Muslims, who have long been viewed as outsiders in non-Muslim majority countries, lack of cultural competency can impact willingness to utilize available services in their community. In addition, a negative encounter with a service or helping professional can significantly reduce the chance that an individual and others in their community will seek out services in the future.

Islam as a global religion provides a distinct cultural narrative that is based upon Islamic doctrine, but is also influenced by the cultures, languages, and countries in which the practice of Islam exists. Islam provides a foundation for those who identify as Muslim and plays a strong role in influencing attitudes and behaviors, as Muslims tend to view Islam as an entire way of life. The Muslim worldview, like other worldviews, consists of sets of beliefs and assumptions that shape reality and therefore influence individual thinking and behavior (Koltko-Rivera, 2004). However, Muslims are not a homogenous group and therefore there is not one definitive Muslim worldview, but rather multiple worldviews that are shaped by both the level of adherence to Islamic theological concepts and other cultural and social factors. Thus, it must be cautioned that there is a great deal of diversity that exists within this unity, just like in any population.

The following chapter provides an overview of key aspects of traditional and contemporary Muslim worldviews as they relate to health and illness, social problems, and help-seeking behaviors, as well as how these worldviews are influenced by the context in which Muslims live in Western society. Topics covered include traditional Islamic views of physical and mental illness, attitudes towards help-seeking, gender and family norms that may impact help-seeking, and traditional Islamic forms of treatment. The chapter describes the usage of both biomedical and psycho-spiritual models of health by contemporary Muslims, and how lay conceptions often differ or co-exist with theological concepts of health and wellness.

Potential factors that influence willingness to use available services and seek help within a country include immigration status, prevailing attitudes towards Muslims in that country, the person's level of religiosity, fear of stigma from both within and outside of their community, language barriers, and the availability of same gender, same culture, or same religion service provider (Vu, Azmat, Radejko & Padela, 2016; Shafi, 1998; Pilkington, Msetfi & Watson, 2012). The cultural, racial, socioeconomic and educational backgrounds of the client must therefore be assessed or taken into consideration by the service provider. Beliefs and attitudes that are shaped by an individual's background can influence Muslims' use of available services to address mental and physical illness, addiction, disability, childhood issues, and trauma. The chapter includes descriptions of common Muslim social norms that may be important to help a professional avoid bias or misunderstanding and increase rapport with Muslim clients.

Traditional Islamic Views of Health and Illness

Traditional Islamic beliefs about health illness can be divided into three categories: (a) theoretical concepts developed by Islamic philosophers, religious leaders, and scholars; (b) theologically derived positions based upon the Quran and prophetic traditions (*Sunnah* and *hadith*); and (c) the lay beliefs of individuals and groups in traditional Muslim societies. Traditional Islamic perspectives on symptoms that correspond to physical and mental illness tend to assume a psycho-spiritual origin for these problems (Athar, 1993; Husain, 2006; Shafii, 1988). These beliefs include definitions of illness, causes and predictors of illness, classification of symptoms, and prescribed treatment methods.

The Qur'anic concept of the self does not adhere to mind-body dualism. A person consists of not just the body but also the mind and soul. These do not exist as separate and distinct units. The Islamic concept of illness echoes these fundamental beliefs about the dimensions of the self and the position

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of human beings within the context of creation. The Islamic conception of illness is that all mental and behavioral dysfunction has a psycho-spiritual root and can be directly tied to an individual's higher spiritual awareness of his or her Creator. An explanation of what constitutes dysfunction is elusive and has changed over time depending upon the cultural and social contexts.

"Sickness of the Heart" or "Diseases of the Heart" (in Arabic *amrad al-qalb*) are terms generally used in Islam to describe illnesses of a psycho-spiritual nature. A diseased heart results from desires and doubts that emerge when an individual fails to utilize knowledge of God, emerging as symptoms such as anger, ignorance, and greed. Within the Islamic mystical tradition, "Sickness of the Heart" refers not to the physical organ, but rather an aspect of the human spirit and personality (Nurbakhsh, 1992). Within traditional Islamic theology, all psychological disturbances are viewed as having a spiritual root. Emotional suffering originates from lack of spiritual consciousness (Shafii, 1988).

Competing ideas about illness arose in medieval times, around the 10th century, as Muslim physicians incorporated the Greek medical model into the diagnosis and treatment of illness in Muslim societies (Al-Issa, 2000). During this period, a combination of medical, psychotherapeutic, and Islamic treatments were utilized, as the conception of illness included humoral theories, the role of fear, grief, and obsessions in symptomology, in addition to spiritual and supernatural causes established in the early Islamic period.

"Mental illness," within the conception of early Islamic philosophers and spiritual figures, stems from desires that are in opposition to the spiritual potential of a human being and can result in behavior that fulfills animal impulses rather than the higher potentials of a human being. "Mental illness," affects emotions, thinking, intention, and behavior, resulting in undesirable actions that go against divine commandments. This mental and spiritual conflict causes deviance and a disintegration of mental health (Alawi, 1992). These traditional Islamic understandings of illness bear little resemblance to modern day problems that are categorized in contemporary Western texts as mental illness, with the exception of melancholia and symptoms such as obsessions, anxiety, depression, delusions, hallucinations, and hypochondria (Alawi, 1992; Al-Issa, 2000b; Husain, 2006; Shafii, 1988). However, they have similar outcomes such as social deviance, distress, and dysfunction for the individual and their social circle.

Islam also acknowledges environmental stresses caused by injury, traumatic events, and outside stressors as causes of illness, particularly anxiety and stress (Al-Munajjid, 2003; Athar, 1993; Husain, 2006). Distress, according to Al-Munajjid (2003), can result from mistreatment by relatives, chronic or serious diseases, and relationship problems.

Islamic tradition recognizes supernatural connections to mental illness. Prophet traditions (the *hadith* and *sunnah*) record various stories and activities that involve *jinn*, evil eye, and black magic. In at least one tradition, the Prophet Muhammad is recorded as treating a young boy for jinn possession, and in several traditions, it is recorded that he recited particular prayers to ward off evil *jinn,* the evil eye, and black magic. In addition, tradition records at least one instance where magic was used against the Prophet Muhammad during his life. The presence of these traditions has been, and continue to be, the legitimizing factor for supernatural causes of illness. In Islamic tradition, when an issue is discussed or acted upon by the Prophet Muhammad, the existence cannot be disputed.

Jinn possession, the use of black magic, and the evil eye (*nazar*, *Al-'Ayn*), are often attributed to severe symptoms of psychopathology, including hallucinations, nightmares, extreme lethargy, and physical symptoms with no known physical causes, as well as physical afflictions (Husain, 1998). The two life forms described in the Quran in addition to human beings are angels and *jinn*. Angels are often described as created from light and possessing no free will. The creation of *jinn* is often described as prior to that of man, with man's creation from mud or clay, and *jinn* created from smokeless fire. Quran and *hadith*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

identify the *jinn* as spirit entities capable of appearing in different forms, and of acting according to their own choice to torment or assist humankind, as well as choose to worship Allah or to deny Him. Islam teaches that the *jinn* can take the form of various life forms including birds, dogs, bees, and humans (Ameen, 2005). *Jinn* possession has been tied to delusions, depression, and anxiety (Ameen, 2005; Bali, 2004). Ameen (2005) describes the symptoms of *jinn* possession which include erratic behavior, seizures, paralysis of a limb with no medical cause, short temper, frequent crying, frequent headaches, nightmares, insomnia, and sleep talking. Speziale (2003) notes that despite the existence of medically grounded interpretations of psychiatric illnesses since the 10th century, supernatural interpretations of mental illness continue to co-exist with physical, environmental, and spiritual explanations within Muslim societies. The attribution of mental illness to possession by *jinn*, evil eye, and magic has been documented in the contemporary Arab Muslim population as well (Al-Adawi et al., 2002; Al-Issa, 2000).

In regards to preservation of life in the face of illness or disability, preservation of life is considered paramount. In the Muslim worldview the paramount purpose or meaning of life is to worship Allah. Within this context, Muslims should do everything possible to maintain their own well-being in order to achieve this purpose. Self-mutilation and self-harm of any form is not allowed. Euthanasia, physician-assisted suicide, and suicide are forbidden within the Islamic context. Providing artificial nutrition or hydration is decided in consultation with religious scholars, based on whether the efforts are causing harm or constitute a futile attempt at lifesaving (Alsolamy, 2014). Suicide is particularly stigmatized within Muslims societies. This may make it difficult for clients to discuss suicidal ideation or suicide attempts with a counselor, health care professional, or social worker, as the topic is still very taboo. In Western countries, as more campaigns seek to address mental health, Muslims have also started to address mental illness and suicide, though not on the same level as seen within other ethnic and religious minority groups. Despite the emphasis on preservation of life and the sacredness of human life within Islam, this has not translated to open discussion of disease prevention among religious leaders or lay Muslims, including public health campaigns for cancer screenings, and dietary or lifestyle changes. Muslims in Western countries have not benefitted in the same way from public health initiatives that have partnered with other faith-based communities. A service provider, working with a religious client, could frame behavioral changes within light of the worldview that life is sacred, the body should be taken care of, and the ultimate purpose of life is worship of the creator. Within this framework, it may be easier to convince a client to comply with treatment, engage in behavior change, or make healthier decisions.

Core Islamic beliefs, such as fasting during the month of Ramadan, can have important implications for health care providers and end of life care for Muslim patients. Devout Muslims fast from sunrise to sunset during the month of Ramadan, abstaining from food, drink, sexual activity, and smoking. Most Muslims would also include abstaining from any other bad behavior or bad speech as part of the fasting requirement. Usually fasting begins once an individual starts puberty. In some families, children will start fasting for a half day, or give up food in order to start preparing for the full fast. Religious Muslims will often adhere to fasting during Ramadan, even though there are religious injunctions freeing a person from this religious obligation if they are pregnant, nursing, menstruating, or ill. A desire to complete the fasts during Ramadan can lead some patients to be non-compliant with medications or timing of medication intake, put off therapy, or risk re-occurrence of symptoms while fasting. This is particularly seen in diabetic patients (Al-Balhan et al., 2018). Understanding the basics of fasting and being knowledgeable about the timing of Ramadan, which changes every year because it is based on the lunar calendar, can help providers discuss the implications of fasting with their clients. Planning treatments around Ramadan, when possible, can make clients feel more in control of their health care planning. Discussions of the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

importance of taking medications on time and consistently may be necessary, as well as emphasizing the potential side effects of non-adherence. Recognizing Ramadan and its importance for Muslim clients can further build trust and rapport.

As Islam clashes with many aspects of modernity, the concept of physical and mental illness and intellectual disability as a state that results from a failure to obey God's commandments through indulgence in forbidden practices, or failure to adhere to Islamic norms, continues to dominate the discussion of health in many Muslim religious circles. However, little is understood regarding how these moral and spiritual illnesses translate into physical or psychological symptoms and are then diagnosed and treated. Illness as divine punishment is not usually the interpretation, but rather illness as a test from God, or the will of God (*qadr*), or resulting in straying from God.

Traditional Islamic concepts of health and illness cannot be ignored, as they often serve as important foundations for an individual's understanding of their own health and wellbeing. The influence of the Quran in Muslim understandings of the role of the human soul and body has and continues to serve as the basis for Muslim interpretations of all forms of illness. In addition, external factors such as *jinn* possession, black magic, and the evil eye are acknowledged aspects of Islamic tradition that are clearly identified in the Prophetic literature as legitimate sources of human suffering. These traditional beliefs play a significant role in understanding both attitudes and behaviors related to health and illness among Muslim populations throughout the world.

Contemporary Beliefs of Health and Illness in Muslim Majority Societies

Islamic theological concepts of health and illness do not necessarily correspond with lay conceptions of the general population in traditional Muslim societies. Of particular interest is the attribution of mental illness to spiritual defects, as widely described by Islamic philosophers and Sufi figures (Alawi, 1992; Al-Munajjid, 2003; Ibn Taymiyyah, 1319-1320/2000) or the attribution of mental illness to supernatural causes, such as those described by traditional faith healers and contemporary religious scholars (Ameen, 2005; Bali, 2004).

Little research has been conducted thus far exploring contemporary conceptions of illness, particularly in traditional Muslim societies. Due to core beliefs in pre-destination and the transcendent and omnipotent nature of God, Muslims also tend to view mental illness as a test from God, God's will, and a form of punishment for sins (Husain, 1998). Contemporary Muslims living in Muslim-majority societies tend to make a distinction between the Islamic views of health and illness and the Western concepts of the origin of illness, though they may integrate both views into their beliefs regarding physical and mental health issues. For example, the parents of a child born with a physical or mental disability may accept the biomedical explanation for that disability, while also adhering to the belief that their child's disability is a test from God. How the problem is interpreted can influence willingness to seek out services for the child. Parents who believe that their child's disability is a test from God or the Will of God may use that notion to seek out the best services for their child. Others may view the child's disability as *qadr* (fate or destiny) and view this as a reason not to seek outside help to improve their child's condition. In addition, conceptualizing of illness, such as terminal illness, as God's will can act as a coping mechanism and a source of comfort for patients and their families (Hamdy, 2009).

Contemporary Muslims living in Muslim-majority societies have been shown to hold tightly to many of the traditional conceptions of mental illness, including attributions of psychotic behavior and physical illness to *jinn* possession, and depressive symptoms to the evil eye (Haque, 2004b; Weatherhead &

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Daiches, 2010; Kobeisy, 2004). Though not directly referred to as "mental illness," words in Arabic, Persian, and Urdu that refer to madness, insanity, possession, and the evil eye are most often used when referring to these specific illnesses. In South Asia, the word *pagal* is used to refer to a person who talks to themselves, has delusions, or exhibits symptoms of mental retardation. The word *junoon*, on the other hand, might be used to describe a person who is exhibiting obsessive thoughts or behavior, most often over another person (Al-Issa, 2000). These supernatural causes of physical or mental illness put the illness outside of the control of the person, absolving them to a certain extent of the stigma associated with deviant behaviors. As such, some researchers have documented better quality of life and outcomes for patients diagnosed with severe mental illness in Muslim countries (Watters, 2010).

Contemporary views of physical and mental illness and disability in predominately Muslim societies is complex with these conditions often interpreted as a combination of both supernatural and social factors. This has been documented by researchers in Malaysia (Azhar & Varma, 2000), Gulf nations (El-Islam, 2000), North Africa (Endrawes, O'Brien, &Wilkes, 2007; Fadlalla, 2005; Stein, 2000), and Pakistan (Mubbashar, 2000; Saeed, Gater, Hussain, & Mubbashar, 2000). Some of these researchers also note the continued presence of belief in illness as a direct result of the evil eye, God's will, or God's punishment (El-Islam, 1982; Fadlalla, 2005; Haque, 2010; Abu-Rabia, 2005). Abu-Rabia (2005) discusses belief in the evil eye amongst the Bedouin tribes and states: "Belief in the evil eye is constantly present in people's lives, alongside beliefs about spirits, *jinns* and other demons, and it has serious implications for how individuals perceive the world and their place in it" (p. 241). *Nazar,* the term for evil eye in South Asia, can be caused by anyone. Black magic (*jadoo*), on the other hand, can be conducted with the help of *jinn* or certain plants according to some faith healers (Ally & Laher, 2008). These beliefs seem to be moderated by factors such as level of education and exposure to Western psychological and psychiatric ideas.

The findings of contemporary research studies dealing with physical and mental illness in predominant Muslim countries continue to support a multidimensional model of understanding of health and illness as having supernatural, social, and biological causes (Arabiat, Al Jabery, Abdelkader, & Mahadeen, 2013). No one model is accepted within the various populations, and in many cases the supernatural model continues to dominate (Graham & White, 2015). For many individuals, interpretations of the cause or reason for an illness cannot be separated from the role of God as creator and ultimate commander.

Perceptions of Health and Illness Among Muslims Living in Western Societies

Though exploration of contemporary lay conceptions of mental illness in predominately Muslim countries has begun, we know little about the translation of these beliefs to Western contexts. Initial research suggests that, at least in the case of refugees and immigrants, conceptions of illness and trauma are preserved, rather than discarded. Beliefs in fate and God's will inform how many refugees view and process their trauma (Eltaiba, 2014). In a study of older Iranian immigrants, Martin (2009) found divergent conceptions of mental health as originating in the spirit (*ruh*) or the mind. The majority of participants referred to an illness of the *ruh*. They also expressed reluctance to seek mental health care, and a reluctance to use psychotropic medications. Martin (2009) concluded that older Iranian immigrants to the United States possess a holistic approach to health that they perceive as not present in the U.S. health care system. Having knowledge regarding religious views of life, death, health, and illness will therefore help health providers to understand the particular frame of view of these individuals. Other research on Muslim refugees residing in Western countries have found that high religiosity acts as a buffer for the trauma suffered during war and displacement (Molsa, Kuittinen, Tiiilikinen, Honkasalo, & Punamaki, 2017).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Religious appraisals of traumatic situations can be both negative and positive and should be taken into account when engaging in trauma work (Bergenzi, et al., 2017).

Religious identity and practice impact how many Muslims perceive of personal illness, providing meaning, context, and coping mechanisms for diagnosis of illness and injury. Religious identity is rarely acknowledged by health practitioners and most Muslim patients also do not feel comfortable discussing the role of religious belief and practice in how they navigate illness (Mir & Sheikh, 2010). Health care providers may assume a patient is being merely non-compliant when it comes to recommended treatment, if issues like fasting, dietary regulations (i.e. use of gel tablets which may contain gelatin), and modesty are not taken into account. Beliefs about illness or disability as the will of God or predestination have also been shown to be prevalent within Muslims living in Western societies (Al-Khateeb, Al-Hadidi, & Al Khatib), which may impact an individual's motivation to proactively seek out care.

Numerous studies have now been conducted among sub-groups of Muslims living in Western countries, especially the United States, focusing on perceptions of mental illness. These studies have used a variety of methodological approaches and theoretical frameworks. Regardless of the particular racial or ethnic sub-group studied, research repeatedly showed that faith and spirituality informed interpretation of mental illness, understandings of symptoms of mental illness often varied in the United States from symptoms described in country or origin, and mental illness was often stigmatized (Pratt, Fadumo, Hang, Osman & Raymond, 2016). Belief in jinn possession, though not as prevalent as in traditional Muslim societies, has carried over and persists in most Muslim communities, especially communities of recent refugees or immigrants (Cheng, 2017; Bagasra & Mackinem, 2014). Beliefs regarding causation of mental illness in Muslim Americans shows a multidimensional understanding, embracing biomedical, environmental, and psycho-spiritual causes of mental illness and distress. All are viewed as equally legitimate explanations for psychological disruption in an individual's life (Bagasra & Mackinem, 2014).

Help-Seeking Beliefs and Behaviors in Diverse Muslim Populations

Little research has been conducted that refers to Muslim attitudes towards seeking professional psychological help. Studies of help-seeking behaviors of Muslims living in Western countries tend to focus on specific ethnic sub-groups within the population. Previous research has shown that perceptions and attitudes toward seeking psychological help were affected by religious, racial, and cultural identities (Haque-Khan, 1997; Aloud, 2004), and stigma played a major role (Raja, 2005) in willingness to see out help. In addition, knowledge about services and providers, length of time in the country, and previous experience with services influence both help-seeking attitudes and behaviors.

Studies have also found that individuals are more likely to choose family doctors before other resources for help with psychological problems. Attitudes amongst the Muslim community toward counseling and counselors range from positive to neutral or negative and counseling was only used when no other options were available (Kobeisy, 2004). Negative attitudes toward counseling tend to be a result of perceptions that are colored by religious and cultural beliefs. These perceptions include the equation of seeking counseling services with the stigma within Muslim society that is associated with a diagnosis of mental illness. Seeking counseling was also attributed as a sign of lack of internal family support. Negative attitudes can also stem from the view that seeking counseling services is a threat to the authority of the family to resolve internal conflicts. Lack of knowledge regarding the purposes and outcomes associated with therapy are another factor (Kobeisy, 2004; Aloud, 2004).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Muslims living in Western countries may vary in their receptivity to formal services, and often continue to show a preference for informal help that comes from family and friends. Barriers to seeking formal services continue to arise from concerns over stigma, lack of knowledge regarding the purpose and process of services, particularly psychotherapies, and a fear of a lack of cultural understanding on the part of the service provider. These findings suggest that basic education of both practitioners and potential clients may serve to ease the reluctance to seek formal mental health services. Direct outreach to communities by service agencies or individual providers can increase knowledge and provide a connection.

Religious Based Treatments and Interventions

The use of alternative methods of treatment in contemporary Muslim societies continues to be prevalent. These include prayers, herbal remedies, dietary changes, and ritualistic practices including seclusion (Al-Subaie, 1994; Al-Subaie & Alhamad, 2000; Deuraseh, 2009; Mehrabi et al., 2000; Saeed et al., 2000). Traditional healing practices sought by those living in South Asia include homeopathy, naturopathy, traditional faith healing conducted by *pirs* and *hakims*, folk healing at Sufi shrines, and sorcery (Farooqi, 2006). Traditional healing practices in Malaysia include herbal medicine, the use of Quranic verses, talismans, and traditional healers called *bomoh* (Haque, 2008). *Al-Ruqyah* (Quran recitation) is a traditional healing method utilized in many Muslim countries. It has been found to be utilized and viewed as an effective method for the treatment of diseases caused by *jinn* (Deuraseh, 2009). Prayer, *dhikr* (remembrance of God), and Quran recitation, are frequently cited by Muslim physicians and psychotherapists as effective forms of treatment for stress (Athar, 1993; Haque, 2004a) and coping with diagnosis of illness. Dietary laws are also cited as a form of Prophetic medicine (Rahman, 1998). Thus, many common practices found within the Muslim community are associated with therapy and utilized as direct responses to physical and psychological illness.

These traditional treatments have been brought by individuals to many Muslim communities in various Western countries. The extent of their use and their incorporation with biomedical treatments, counseling, or other social services have yet to be fully explored. In addition, religious based coping is common. Using religion to cope with serious physical and mental illness in Muslim clients has been found to have a positive impact on health outcomes or the stresses related to simultaneous treatment (Shaheen Al-Ahwal, Al Zaben, Sehlo, Khalifa, Koenig, 2016)

Attempts have been made to develop forms of religious psychotherapy that seek to address the Islamic worldview (Azhar, Varma, & Dharap, 1994; Razali, Hasanah, Aminah, & Subramaniam, 1998; Hamdan, 2007) and include using cognitive techniques from the Quran, making lifestyle changes according to the *sunnah*, and using repentance if clients have developed a sense of guilt. Individuals with strong inclinations towards psycho-spiritual or supernatural causation of mental illness may be more likely to accept Islamically integrated psychotherapy options (Abu-Raiya, 2015). The practice of counseling continues to increase among Muslims (Ahmed & Amer, 2012), with a growth in the number of Muslim clinical psychologists and counselors over the past few decades. Additionally, Muslim counselors have formed their own clinics and professional organizations in acknowledgement of the increase in the practice of counseling that is designed to meet the needs and worldviews of practitioners of Islam. The intersection of Islam and counseling is widely accepted today (Abdullab, 2007)

Islamic-based counseling and Islamically integrated psychotherapy (York Al-Karam, 2018) reflect the growing revival of the application of Islamic psychology and traditional Islamic concepts of mental illness. Attempts to evaluate the effectiveness of incorporating Islamic forms of worship and religious based

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

coping into counseling with practitioners of Islam demonstrate the positive impact in many therapeutic settings (Khalid, 2007; Hanin Hamjah et al., 2017; Zakaria & Mat Akhir, 2017). The contemporary use of religiously based therapy for treatment of mental illness for Muslim clients has been documented in Asian, Middle Eastern, and African countries (Ally & Laher, 2008; Al-Issa, 2000; Campion & Bhugra, 1998). Numerous researchers have proposed a method of religiously integrated psychotherapy for use with Muslim clients (Abu Raiya & Pargament, 2010; Abu-Raiya, 2015; Keshavarzi & Haque, 2013). This approach to the treatment of mental illness directly addresses dimensions of Islam that are relevant to the mental health concepts of Muslims, including Islamic methods of coping. Religious psychotherapy has been found to produce significant improvement in patients in Malaysia (Azhar & Varma, 2000) and has been introduced, to varying results, in other Muslim societies (Al-Issa, 2000). There is also ongoing research testing the effectiveness of adaptation of various therapeutic techniques within Muslim populations in both Muslim majority and Muslim minority countries. This includes cognitive behavioral therapy (Naeem et al., 2015).

Traditional Islamic forms of therapy are therefore dynamic and encompass multiple interpretations of the origin of illness and acknowledge the effectiveness of multi-modal approaches to therapy that include assessment, diagnosis, talking therapy, and specific actions . These practices are tied to evidence that is drawn from religious tradition and perceptions of mental illness within unique cultural contexts. The majority of research and testing of Islamic forms of counseling is occuring in the United States, the Middle East, and most prominently in Malaysia. Further research will determine the effectiveness of these varied techniques and their application to different Muslim communities.

The Impact of Stigma and Perceived Bias on Help-Seeking and Service Utilization

Stigma continues to be a significant factor impacting help-seeking and utilization of services among Muslims. This includes stigma associated with a specific problem (such as depression, marital discord, addiction, learning disabilities, etc.) and the stigma of seeking help from sources outside of the family. Stigma and ideas of shame and honor are attached to help-seeking outside of the family for issues such as child sexual abuse (Haboush & Alyan, 2013), intimate partner violence (Eunha & Hogge, 2015), and suicidal ideation (Heredia Montesinos et al., 2019). Stigma related to members of one's community finding out that has a problem or sought help outside of one's family can also decrease intention and actual help-seeking behaviors (Youssef & Deane, 2006). Stigmatizing attitudes toward mental health services and mental health problems within an individual's social network were found to be a deterrent to seeking help (Kapadia, Brooks, Nazroo, Tranmer, 2017).

Therefore, it is important for service providers to emphasize the confidential nature of services and outline ways that they maintain confidentiality (Hamid & Furnham, 2013). Perceived bias and the rise in Islamophobia are compounding the existing stigma. Anti-Muslim actions, particularly verbal and physical attacks on Muslims, have increased significantly in the United States, Europe, and Australia since 9/11. Latham (2016) outlines cases where mandatory reporting among social workers of perceived radicalization in the UK has led to nearly 80% of individuals referred for perceived radicalization not being deemed actual threats in need of intervention. These false accusations result in increased fear of social service providers among the targeted population.

Muslims are now suffering from increased religious and ethnic-based discrimination in many Western nations, further pushing community members to avoid airing issues or problems with those outside of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

their community, or a fear of being judged by non-Muslims. In the United States, rising Islamophobia has been connected to poor mental health, health behaviors, and low help-seeking behaviors (Samari, Alcala & Sharif, 2018; Samari, 2016). Studies conducted in Europe, Canada, and the United States indicate an increase in negative attitudes towards Muslims and increased experiences of discrimination by Muslims (Abu-Ras, Suarez, & Abu-Bader, 2018; Wilkins, 2018; Kaya, 2015; Giuliani, Tagliabue, & Regalia, 2018). This can further isolate communities from service providers and from the formation of partnerships between religious organizations and agencies that could improve overall public health.

The Impact of Religiosity on Help-Seeking and Compliance: Assessing Level of Religiosity in Clients

Like members of other religious groups, Muslims vary in their level of adherence to religious practice. Research suggests that level of religiosity may impact willingness to utilize services outside of one's religious tradition. More religious Muslims may rely heavily on Islamic-based treatments or utilize religious coping before considering other available resources. In many cases, they may not have considered outside resources at all and may be suspicious or concerned that non-Muslim service providers will not understand them or would be unwilling to meet their needs.

If a service provider is unsure of how religious a client is, or how much of an impact religiosity plays in their lives, there are a number of brief assessments that can be administered. These resources can help service providers/helping professionals determine whether they need to learn more about the cultural or religious background of clients in order to be effective providers, whether they need to engage in a "clergy consult", or whether it would be in the best interest of clients to refer them out to a same-religion or same-culture provider. One of the most well-known tools is the FICA. It has been utilized to assess spiritual beliefs in a variety of settings, including palliative care, nursing, and counseling. The FICA is recommended as a tool to use at the intake interview with clients (Keshavarzi & Haque, 2013). From a social work perspective, there are a variety of spiritual assessment tools that can be utilized, including spiritual histories, spiritual life maps, spiritual genograms, spiritual ecomaps, and spiritual ecograms (Hodge, 2005). Many of these can be applied to other helping professions.

There have been efforts to define religiosity and religious commitment and to formulate measures specific to the Muslim population (AlMarri, Oei, & Al-Adawi, 2009; Abu Raiya, Pargament, Mahoney, & Stein, 2008; Albelaikhi, 1997; Ji & Ibrahim, 2007a; Krauss, Hamzah, & Idris, 2007; Wilde & Joseph, 1997). Several of these scales have been tested in both Muslim-majority and Muslim-minority countries. Most scales focus on measuring adherence to Islamic beliefs and doctrines, the influence of Islamic doctrine on choices such as what to wear, and frequency of religious behaviors including prayer, reading Quran, attending the mosque, fasting, and giving to charity. Most of these measures are in the early stages of development and testing and may be too lengthy for a helping professional to use in their initial assessment interviews with a new client. However, it should be noted that religiosity scales specific to the Muslim population are available as a potential tool for professionals in addition to the FICA and other spiritual assessment tools. Using some form of cultural and spiritual assessment is viewed as essential to developing an appropriate intervention when working with Muslim clients (Ibrahim & Dykeman, 2011).

If you are working with a client who has been assessed as highly religious, and are having difficulty successfully communicating treatment options or navigating stigma around the situation, a clergy or chaplain consult may be an effective way to build rapport with the client, establish the legitimacy of the services, and obtain religious endorsement for treatments or services that the client views as sus-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

pect. An imam is the official title for a religious figure or clergy within the Muslim tradition. This is an individual who is recognized by the community as possessing religious learning, an ability to lead the daily prayers, and apply religious knowledge to addressing community problems. Other names for religious or spiritual leaders in the Muslim community include the title of *sheikh* usually given to a person of high spiritual status or religious learning, and *pir*, a term for a spiritual person that is often used in South Asia and mostly refers to individuals within the Sufi tradition. The role of the *imam*, like that of pastors and other clergy in Western countries, encompasses to some degree counseling, grief and grieving, and family and couples issues (Haddad & Lummus, 1987; Kobeisy, 2004; A.Ali, Milstein, & Marzuk, 2005). Most imams do not have formal training related to counseling or social work but have found themselves called upon to act in this role for community members to address issues mentioned above and increasingly to address the psychological impact of discrimination. Formal relationships with *imams* or chaplains can be established if practicing in an area with a large Muslim population. This type of partnership would encourage imams and Muslim chaplains to make appropriate referrals to service providers and provide a resource regarding religious beliefs and values for helping professionals. Imams can usually be contacted by locating the mosques in the area and calling the direct number for the local mosque or Islamic center. There are also Islamic associations who can help to connect you with a local imam. In addition, many large universities have a designated Muslim chaplain who provides religious knowledge and spiritual leadership to the campus Muslim community. These individuals can be reached through the campus directory.

The Impact of Acculturation on Health Outcomes and Help-Seeking

Many studies have been conducted linking acculturation to health outcomes in minority populations. Many of these studies have focused on the poor mental health of recent immigrants due to the stresses associated with the process of acculturation (Berry & Kim, 1988). Both low assimilation as well as high assimilation have alternately been linked to poor health (Padilla et al., 1985; Oh, Koeske, & Sales, 2002). Strong family ties and social support networks appear to act as a buffer, lowering the risk of mental and behavioral health problems (Eschbach, Pstir, Patel, Markides, & Goodwin, 2004), while lack of acceptance from the dominant or host society can lead to poorer health outcomes, especially for immigrants (Organista et al., 2003; Thomas, 2006). Acculturative stress experienced by Muslim populations has been linked to anxiety, depression, and overall well-being (Amer, 2005; Timazi, 2008; Khuwaja et al., 2007; M. Ali, 2007). Acculturation is often measured by the length of time the individual has lived in the country, and language use. These measures may not be very effective within Muslim populations, as they fail to take into account acculturation experienced by native-born Muslims, converts, and first-generation Muslims, who are often perceived by the society as foreign or other. Measures that look at level of conformity to local norms may be a more accurate measure of acculturation than language usage, length of time, and social interaction (Bagasra & Mackinem, 2019).

The degree of acculturation and assimilation of an individual can have an effect on his or her attitude toward health services and actual behavior in seeking help (Pilkington, Msetfi, & Watson, 2012). This may be influenced by a number of factors including education, rather than length of time within a country, and previous experiences with helping professions may be a larger determinant of help-seeking behaviors. A service provider may want to ask basic questions about length of time in the country if it is apparent that the individual is not native-born. They may also want to know if the individual is a refugee or asylum seeker, as this can impact the level of acculturative stress experienced with the process of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

trying to adapt to a new culture. Depending upon the type of service, other questions may be appropriate. For example, within the education system, a school counselor may need to know more about the family background of a child they have been assigned to work with. A child may quickly assimilate, or want to assimilate to the host culture, but may experience resistance or resentment from parents who are holding on to the culture of origin. This can create family conflicts that may be central to behavioral or mental health needs of a child. A child may also be serving as translator or taking on significant roles due to their acculturation status and language ability. Ability to navigate a new culture can be beneficial and burdensome. Similarly, adolescents trying to establish a personal identity may choose to strengthen their religious identity by wearing hijab or increasing participation in religious activities. This can create distress if family conflict arises, or an adolescent loses social support from family or friends. The bi-directional nature of acculturation, especially for children and adolescents trying to establish personal identity, can result in psychological, social, and physical distress. It is important for a provider to take into account the "story" of each individual client, which may include their journey towards a fuller embrace of the local cultural and social norms, or a careful examination of these norms in the face of their religious values or values of a culture of origin. For Muslim converts, they may choose a specific type of Islam to follow, or to adopt the cultural background of a specific Muslim country, such as wearing the traditional clothing of Pakistan or Morocco. The intersection of culture, religion, self-identity, and societal labeling creates a complex web of factors that a service provider may be able to acknowledge but not address, especially if interaction with a client is short-term.

The Impact of Gender and Family Dynamics on Help-Seeking and Service Utilization

Some Muslims, especially the highly religious or individuals coming from societies where strict gender segregation has been in practice, adhere to gender norms that may prevent a person from seeking health or social services from service providers of the opposite gender. Beliefs regarding being alone in a room with a member of the opposite gender can restrict access to some services, unless accommodation is made that allows a family member to be present during service rendering, or a door left open during the session. In some countries like Saudi Arabia, there are guardianship laws that require women to have permission from a *mahram* (this would be a biological male relative such as a father, brother, uncle, or son) to travel, work, go to school, or go to the doctor; access to services would only come through explicit permission from the male relative. Even though this is not law in many other Muslim countries, variations are in place informally. Though men are not restricted in the same way socially, it is considered inappropriate for men to also be alone with a woman who is not their biological relative or spouse. The presence of a relative during services may be an option but can be especially difficult for social workers and counselors, as confidentiality is a key aspect of their work. Gender segregation and family dynamics that restrict a woman's movement can have significant implications on help-seeking, especially for refugees and recent migrants who have not assimilated to gender mixing and freedom of movement found in most Western countries (Weatherhead & Daiches, 2015).

Modesty in dress for both men and women is an important belief for practitioners of Islam. Some Muslim women engage in various forms of *hijab*, which can range from wearing modest clothing and a head scarf, to wearing free flowing robes called an *abaya* or *jilbab*, to wearing a piece of cloth that covers the face called a *niqab*. Wearing of the hijab may reflect cultural or family norms, a desire to assert one's Islamic identity, strong beliefs in religious injunctions regarding modesty, or a combina-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion of these factors. Many religious Muslim women wear hijab, and many other women who consider themselves religious do not regularly wear the hijab. All Muslim women cover the body and head when engaged in formal daily prayer (*salat)*. Men are expected to be covered from the navel to the knee under all circumstances and to dress modestly. Clothing that features human figures are not to be worn when performing the daily prayers, and a Muslim should not face a human figure or pictures of human figures while in prayer. This can be important if providing a space for meditation or prayer in a practice or clinic.

Muslims will attempt to maintain modesty even in medical situations where it may be difficult such as labor and delivery, physical exams, and surgery. Muslim women consider the gender and cultural background of a health care provider as important, especially for reproductive healthcare (George, Terrion, &Ahmed, 2014). Differences in beliefs about modesty can be a barrier to seeking out health services (Yosef, 2008). Nurses and doctors working with Muslim patients can acknowledge norms of modesty and ask patients to communicate any discomfort. Efforts can be made to keep the patient covered as much as possible during a physical exam. When it comes to labor and delivery, women can bring modest gowns and robes to use to maintain as much sense of modesty throughout the process. Modesty norms and availability of same-gender care providers have been found to influence health behaviors, including mammography (Padela et al., 2016).

Making direct eye contact is also viewed as displaying lack of modesty, as men are admonished to lower their gaze in the Quran. Both men and women may avoid direct eye contact with a member of the opposite gender. Refusing eye contact is therefore not a sign of depression, dishonesty, or lack of respect for the service provider by Muslim clients. In the presence of a same gender service provider, lack of eye contact could indicate respect for an authority figure or alternately indicate a sense of shame or distress regarding the situation at hand. Cultural background can result in varied non-verbal behaviors in a clinical setting.

In addition to these norms, an individual may feel uncomfortable sharing their problems with a member of the opposite gender and a person outside of their family, as it would deviate from standard conduct. If a same gender professional is not available, and the individual is not comfortable disclosing information, considerations for referring out to a same-gender provider should be considered. If a referral is not possible, directly addressing discomfort and ways to address that discomfort in sessions may be useful.

Family dynamics, the presence of intergenerational conflict, and the impact of collectivist and patriarchal structures can all contribute to distress, social and psychological issues, and willingness to seek help for Muslim clients (Graham, Bradshaw, & Trew, 2010). The concepts of honor and shame have been noted as particularly salient for Muslim women who adhere to a collectivist framework (Helms, 2015). Both women and men who are afraid of being viewed as dishonoring or shaming their family by seeking out help for personal and interpersonal problems may be more reluctant to utilize available services, both from Muslim and non-Muslim providers. This is particularly true for domestic violence, victims of sexual assault, psychological distress, and behaviors viewed as socially deviant, including addiction and sexual behavior. (Helms, 2015; Oyewuwo-Gassikia, 2016; Cowburn, Gill & Harrison, 2015; Hamid & Furnham, 2013).

Family dynamics may result in an individual turning to family members for help first, before considering using a professional such as a doctor, counselor, or social worker. Advice from family members may be utilized as a first defense against problems. Once this resource has been exhausted, an individual may consider seeking outside help. Sometimes this is a matter of cost of services, stigma associated with exposing a problem to those outside of the family, and fear of how the problem will look to others (fear of being judged as well as fear of upsetting the image of a model minority).

CONCLUSION

Islamic beliefs and behaviors, mediated by levels of religiosity and acculturation, and impacted by external factors such as culture, status, experiences with discrimination, and previous experiences with services, all play a role in how Muslim clients view health, illness, interpersonal problems and trauma. In turn, perceptions of problems often dictate attitudes towards available care options and help-seeking behaviors. None of these factors exist independent of each other and represent an ongoing and ever-changing dynamic.

This leaves the helping professional in the position of 1) showing dedication to learning the basic values and beliefs of a client in order to engage in culturally-informed care, 2) willingness to engage in communication with individuals who can assist them in gaining religious or cultural information that can inform their care plan and interventions, 3) assessing various aspects of the client including religiosity, acculturation status, and social and cultural norms that may prevent care or adherence to a care plan, and 4) addressing any pre-conceived biases or perceptions that the provider may unknowingly or knowingly harbor as it relates to Muslims. Islamophobia, as well as negative, stereotypical, or inaccurate media coverage of Muslims can contribute to implicit bias of service providers towards Muslim clients. Previous research by the author found some Muslim Americans who had experiences with mental health services reported bias, perceived discrimination, or offensive questions from professionals. These included suggesting that Islam was a source of stress for the individual, viewing the hijab as a sign that a woman is oppressed, and other forms of stereotyping (Bagasra, 2011). Muslims in North America, Europe, and Australia often view helping professions either through the lens of previous experiences with similar services in Muslim-majority countries, which may or may not accurately reflect the nature of the services offered in Western societies, or through the lens of previous experiences by themselves or other community members with such services. Negative experiences or the perception that they will be treated negatively by service providers, have a significant impact on willingness to seek out, utilize, or continue usage of available services.

In sum, culturally competent care requires understanding, willingness to learn and view individuals as distinct from prevailing stereotypes, and open communication. Education and partnerships with religious organizations in the local Muslim community, and communication with and endorsement from Muslim community leaders can help a provider establish a strong relationship built on mutual respect and understanding.

KEY TERMS AND DEFINITIONS

Acculturation: Acculturation is a process that can occur for any individual or group trying to adjust or adapt to the dominant or host culture as a result of contact between cultures.

Evil Eye: Within the Islamic tradition, the evil eye is the belief that a person can cause misfortune, physical or mental illness, by placing a curse on another person as a result of envy. Often referred to as Nazar.

Jinn: Beings within Islamic theology made from "Smokeless fire" and distinct from humans and angels. Jinns can be bad and good and belong to different religions. Traditionally, it is believed that jinn can possess humans and cause symptoms of physical and psychological illness.

Qadr: Often translated as pre-destination or fate, it indicates Divine Will for followers of Islam. Allah (God) is unrestricted by time and knows the final outcome for each individual. The concept does not fully discount the idea of free will.

Religiosity Measures: Psychometric instruments that measure some aspect of religiosity or religious commitment either within a specific religion or measuring religiosity in general.

Religious Identity: The role of religion in personal identity, and the importance of religion in the person's group membership and overall self-concept.

Shame: Shame, honor, or izzat originates in the collectivist notion that an individual's actions reflect in their reputation and the reputation of their family and even larger community. Sinful behaviors, either committed by an individual or against an individual (such as rape, sexual abuse, or domestic violence) may all be viewed as bringing shame on an individual and household.

Spiritual Assessment: Oral or written questions designed to assess a client's spirituality or religiosity, to strengthen communication between a provider and a client, and elicit a better understanding of the role of spiritual or religious belief in the individual's life and decision making.

ABSTRACT

Global health issues are a global burden and are relatively common in industrialized societies. The World Health Organization and researchers have developed and rebuilt tools to report the burden of disease affecting mortality and health of the people. Apart from America and Europe, which are at an average of global burden for mental health disease, in some regions it is a major priority to be addressed globally. In South East Asia, one of the affected regions is Kashmir, Northern Indian. Disasters have manifested in various forms encompassing the natural calamities of earthquake, flood, landslides and manmade calamities of violence. Trauma due to manmade calamities has taken over as a leading cause of morbidity and mortality among the most productive working age group of 12-35 years. The chapter aims to understand the patterns of resilience in people surviving war and conflict in Kashmir over last 60 years. The focus is on the young population of society. Generations in Kashmir have faced the psychosocial impact of ongoing political conflict since the 1980's.

INTRODUCTION

A healthy mental condition is described as a normal standard of life in which a person realises his/her own abilities coping with the hardships of life, working productively and, fruitfully, and is able to contribute to his/or community ("world Health Organization," 2001d). Mental illness is an abnormal affair or health condition that is defined by any change in thinking, mood or behaviour associated with distress and/or impaired functioning ("US Dept. of Health and Human Services," 1999; Kessler et al., 2005). Mental disorders affect people from all countries and societies involving people from all age groups, men and women; poor and rich; urban and the rural populations. People living in conflict zones experience more mental disorders. Recently, the world has received an increased change in terms of warfare and violence to civil society resulting in unstable situations. Introduction of advanced weapons have resulted in grave human concerns. People are disappeared, tortured, forced to migrate, and starved to death. Globally, mental health disorders are among the leading causes of illness and disability. Mental illness leads to decreased productivity and has a negative impact on the quality of life of affected individuals and their families ("World Federation for Mental Health," 2015). Annually, over 450 million people have been reported to be affected by mental disorders, and only a few have access to cure. There are barriers to accessing the treatment created by social stigma and negligence. Mental health is determined by several factors of psychological illness and is influenced by society governed by political instability leading to number of events (Miller et al., 2010; Silove et al., 2014; Steel et al., 2009; Summerfield et al., 2000).

The chapter presents the support that strengthens the patterns of resilience in people who have survived war and conflict in Kashmir (India) over the last 60 years. Peace in Kashmir has been repeatedly interrupted due to conflicts between India and Pakistan. Generations in Kashmir have faced the psychosocial impact of ongoing political conflict from last 60 years. There are reports of human rights violations and their impacts. There has been research, though limited, on losses faced by the community, psychosocial impacts of exposure to violence and impact on mental health, socio-economic functioning and health service usage. In Kashmir, many women have lost their husbands to the conflict. Currently, it is believed that there is no reliable, comprehensive and factual survey about the number of widows and orphans in Kashmir. There are different estimates by different sources. Over the years, people living in Kashmir have been accustomed to the circumstances and have adapted themselves to survive in such situations. Gradually, the role of civil society becomes imperative to increase support systems, especially related to health services, children's needs care and persons with disabilities and women should be protected.

OVERALL POPULATION SCENARIO AND CONFLICTS IN KASHMIR VALLEY

The Kashmir Valley is situated in north region of the Indian state of Jammu and Kashmir between Jammu (to the south) and Ladakh (to the east) with the line of control (border with Pakistan) along its northern and western borders. It covers a geographical area of 15,948 km^2, with a population density of 430/km^2. The total population is 6.9 million, with 73% living in rural areas and 27% living in urban centers (2011 census). The majority (97%) of the population is Muslim, with Hindus, Sikhs, Buddhists and Christians making up the other 3% ("Human Rights Watch," 2006). Since partition of India in 1947, the Kashmir has faced political instability. Following three Indo-Pakistani wars (1947, 1965 and 1971) and one Indo-Chinese war (1962), the wars were consequences of an internal movement for determining freedom. In 1989, an insurgency began, resulting in 27 years of movement of gun-men group (fighting

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

for self-determination) and military activity. By 2012, approximately 70,000 Kashmiris had lost their lives in the conflict and 10,000 people had been reported missing ("History of Kashmir," n.d.).

MENTAL HEALTH: INFLUENCE OF CONFLICT

Conflict influences lives of people and the society by having a negative impact. Irrespective of age, sex, career, residence the emotional and psychological effects of violence are deeply felt by many individuals. The conflict has brought about insecurity and breakdown of social relations, it has destroyed families in Kashmir and forced the youth of Kashmir to switch to drugs and to undertake anti-social activities. Kashmir has been regarded as "heaven on earth" for the nature and beautiful scenery. Over the past three decades, Kashmir has been affected with conflict and violence which has led to mental malfunctioning. Mental well-being is related to physical, social livelihood and economic disability. People who are affected by a conflict environment are burdened under mental and physical stress and suffer from post-traumatic stress problems (Amin et al., 2005; Amin et al 2004). Political instability creates an atmosphere of negativity, with long lasting effects on social, economic and livelihood of common people (Sack et al., 199; Amin et al., 2004; Margoob et al., 2006). A nationwide survey undertaken by the Ministry of Labour and Employment in 2012-2013 reported that Kashmir has the highest rate of unemployed people in India. At state level, the number of job seeking people increased by 190% between 2008 and 2013. Employment-generating sections like private sector, industry, agriculture, horticulture have been reduced due to present instability in region. Tourism was one of the main paths for employment among young people which has reduced in past 27 years. In 2011, a Kashmir-based report by Mercy Corps reported that unemployment leads to stress, social pressure, delay in marriages. The expression and behavior of people in such zones lead to stress, mental illness and tendency to suicide among youth ("Mercy Cops," 2011; Hassan et al., 2013).

For the past decade, a tremendous increase in mental illness has been reported in the Kashmir Valley. IMHANS, Institute of Mental Health and Neuroscience in the valley's capital, Srinagar, has a large number of patients being treated from an average of 100 per week in 1980 to 850 per week in 2016 (Dar et al., 2016). In 2005, in cross sectional study of 548 individuals in the districts of Kupwara and Badgam, researchers reported a prevalence rate of 33% for distress in patients having psychological effect (De Jong et al., 2008) In another study involving 3000 individuals from all districts in 2006, there was a prevalence of 7.3% for PTSD and a lifetime prevalence of 15.2% (Margoob et al., 2006). The year 2009, have shown a prevalence rate of 55.7% for depression in a study of 2728 individuals across all districts of the valley. A retrospective study on suicide demonstrated an increase of over 250% in suicide attempt cases between 1994 and 2012 (Shoib et al., 2012). Another study was reported on behavior of PTSD patients treated in Government Psychiatric Diseases Hospital in Srinagar reportedly having a lag time from symptoms occurred and treatment of such patients of 32 months in women and 48 months in men. The authors also stated that such patients seeking care was highly incongruent with the prevalence of PTSD in the community (Margoob et al., 2006).

As per the Kashmir Mental Health Survey Report 2015, a report prepared by MSF, Medecins Sans Frontieres, 1.8 million (45%) adults in the Valley had mental ill health symptoms. Approximately 1.6 million adults (41%) in the valley are facing depression with 415,000 (10%) susceptible to severe depression. An estimated 1 million adults (26%) in the valley are living with anxiety problems. Nearly 1 in 5 adults (19%) or 771,000 individuals are having PTSD symptoms, with 248,000 (6%) meeting the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

diagnostic criteria for PTSD. There are increased rates of co -morbidity depression, anxiety and PTSD symptoms found in adults in the valley. The districts of Baramulla and Budgam reported increased prevalence rates of mental ill health ("Kashmir Mental Health," 2015).

ARMED CONFLICT AND MENTAL HEALTH STATUS IN KASHMIR

Armed conflict is present in most of the Asian parts (Gates et al., 2012). War has catastrophic effects on health and well-being of human beings. Studies have reported that wars have long lasting effects on mankind, livelihood, households, and hunger. It affects the psychology of people involved, decreasing their working and social ability of a normal life. WHO reflects that 10% of the population are subjected to trauma or war having psychological effect and 10% of those exposed to war have behavioural problems (Laxaminarayna et al., 2006). Studies have shown that the common people including young and adults suffer from trauma and psychological disorders. The common symptoms found were mental disorder, anxiety and PTSD. The children in Gaza have been affected by psychological disturbance and sleeping disorders (Hein et al., 1993). Social supports for such affected people have played an important role but people are affected and destroyed in war zone areas. The social support would have acted as a buffering zone for conflict and psychological disorder if present ("Sustainable Development UNICEF," 2013).

Kashmir has been in conflict for decades now. Deaths, Disappearances, killings, and harassment have been an outcome of conflict in Kashmir. About 8000 persons are reported to be disappeared and more than 70000 persons have been killed, and more than 6000 have been buried in graves ("Alleged Perpetrators JKCCS," 2012). The most affected group is that of the young and children. About 97000 to 100000 children turned orphans. The widows are increasing in number from 16000 in 2000 to 32400 in 2008 (Double) (Rather et al., 2013). This has reportedly increased the number of deaths and mental disorders in Kashmir affecting the young population. As a result, psychiatric admissions to one of the hospital increased from 6 per day in 1990 to 250-300 per day in 2000. The total number of patients rose from 1760 in 1990 to 18000 in 1994, to over 50000 in 2003. In 2006, the number of patients had increased to 82000 (Wani et al., 2006). According to the report documented by MSF, it was shown that about 45% of the adults in Kashmiri have a mental disorder. About 41% in the valley are affected by depression, with 10% having more serious depression. Almost 26% population in the valley have anxiety disorders. About 19% of population is having PTSD (Gates et al., 2012). Exposure to trauma leads to behavioural problems, having psychological and emotional distress to population. However, a different prevalence rate is reported with respect to gender and location. The women are suffering from depression more (60%) as compared to men (51%). Women suffered from increased prevalence of depression in all the age groups, particularly among 26 to 35 years, the reproductive years of their lives. Besides depression, PTSD is common in Kashmir population with symptoms of depression associated with it (Amin Syed et al., 2009). The conflict is one of the main reasons for mental ill heath population (Margoob et al., 1993). In addition to this, suicide rates and drug abuses are on high rate (Yaswi et al., 2008). About 25% of people in Kashmir are having depression (Hassan et al., 2013). Measuring the levels of depression, anxiety among the groups exposed to such conflict is more than non-exposed groups. About 90% of the population who are affected by such psychological disturbance do not intend to return home because of fear of being accepted in society. There are major health issues like gastritis, headache, and weakness (Dilnaz et al., 2014). As a result, the children and youth develop a self-made mind governed by their rules and regulations and react on every small problem (Zahid et al., 2017). It results in children's who

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

do not find their interest in education and normal livelihood, they wander after some self-made life and social set up.

USE OF WEAPONS IN KASHMIR AND IMPACT ON MENTAL HEALTH

The conflict has led to mental disturbance among children and youth. They do not look for jobs or education is not completed. They have psychological disturbances and mental disorders. They react inappropriately to any outbreak or cannot handle critical circumstances and have sleeping disorders. Their social life is affected. They are not able to cope up with normal social life, economically weak. They have lost hope of life, and have difficulty in concentrating on anything (Bilkis et al., 1996). Some of this may be linked to weapons use by law enforcement in Kashmir.

TERRORISM AND THE IMPACT ON MENTAL HEALTH

For the past three decades, 'terrorism' has spread and engulfed the entire world. In the face of escalating tensions created by terrorism and the after-shocks and trauma of violent crime, the psychological aspects of communities who confront terroristic incidents constantly and a terrorizing environment have mental imbalance. While cultures differ, it is amazing how many people are alike. Citizens of all cultures perceive threats to their security and safety in a negative manner. They long for stability and peace in their homelands. Most people want to be able to provide themselves with necessities, rather than fight. There is no dearth of evidences related to the worldwide terrorism. 4220 terroristic incidents were reported by the International Association of Chiefs of Police (IACP) worldwide for 1987. The data plainly indicate that terrorism is increasing and that multiple deaths and destruction are increasing enormously. Terrorism in India still occupies the center-stage in many parts of the country specially Jammu and Kashmir where it has dominated almost every aspect of the life of its citizen for years. Terrorism creates a state of mind where anxiety and fear dominate the people's thinking and behavior. Terrorist succeeded in creating such an effect in Kashmir for the last three decades. Most of the studies have emphasized the post-traumatic stress disorder (PTSD) of the people who have survived the terrorist attacks. Poor Mental health and Depression are highlighted in many related studies along with other related psychological abnormalities. A study was carried to report number of mental health of 58 refugees (18-64 years old) of war who were victimized by trauma. Study reported that 70.7 percent of the people had trauma. While a prevalence of psychiatric disturbance was found in 64.1 percent. Results inferred that age had a major factor related to mental disorder (Hassan et al., 2013). A study on terrorism, trauma and mental health suggests that the effects of violence lead to lack of hope, social ability and support. Another study was on psychology of terror and how this affects the livelihood of common people with lasting effects. One more study was on mental and behavioral problems associated with such outbreak of mental ill-health [39-40-53].

CONCLUSION

Operational Possibilities in Case of Mental Health

It is widely recognized that women and young people are main population who are affected. In most conflict situations, gender plays an important role, women are more vulnerable than other groups including children, they are the primary care, education and home builders and once they are targeted, a family gets affected and which leaves a mark in society. It is evident that very few studies have focused substantially on the life of women in the cultural context of Kashmir, with conflict, and psychosocial interventions, as the primary background. Studies based on Social Work principles and mental health perspectives, hopes to address this gap.

Questions Need to be Addressed

1. What do young women and men from Kashmir have in mind about the current situation there?
2. What are the lifestyle patterns young women and men, from Kashmir, which help them, cope and survive in the conflict zone?
3. What are the similarities and differences in these patterns among young women and men in different age groups say for example 16-21years, and 21-26 years?

Mental Health and Psychosocial Support: Any type of local or outside support that aims to protect or promote psychosocial well-being and/or prevent or treat mental disorder can be incorporated (Ashraf et al., 2008; Haji et al., 2018).

Interviews and Observation: Interviews should be held for these age group populations, observational studies on their behaviour, way of thinking, and pattern of living should be focussed. The data should be kept confidential. Further process of consulting experts, who have relevant experience related to gender and conflict, should be included. The data sheets should be prepared and analysed in the focussed age group. On the basis of these methodologies and data collection, mental health can be studied and evaluated in a conflict zone region. One can take necessary measures in order to prevent such disease affecting mental ill health and how they can be diagnosed by mood, behaviour, and distress. Mental, physical and social health, are vital strands of life that are closely interwoven and deeply interdependent and are important for normal functioning of body and livelihood. This needs to be protected as an important component of life for survival of a population in a region. There has been research, though limited, on losses faced by the community, psychosocial impact of exposure to violence, including impact on mental health, socio-economic functioning and health service usage. Further, the political and economic instability fuelled by unemployment has added to the mental disturbances in the valley. Gradually, the role of civil society groups has also grown in order to increase support systems, especially related to health services, children in need of care and protection, persons with disabilities, and women. Mental health disease is one of the fatal types to be measured and detected at an early stage. Educational set up and working settings need to be reformed to check behavioural parameters collaborated to lifestyle, its affect in community named as a mental illness (Price et al., 2018; Mohan et al., 2018; Soomro et al., 2019).

KEY TERMS AND DEFINITIONS

Disorder: A disorder is a practical irregularity or trouble. Medical disorders can be characterized into mental illnesses, physical disorders, genetic disorders, emotional and behavioural disorders, and functional disorders.

Mental Health: Mental health comprises our expressive, psychosomatic, and communal well-being. It affects how we reflect, sense, and act. It also helps regulate how we handle anxiety, relate to others, and make selections. Mental health is significant at every phase of life, from childhood and adolescence through maturity.

Psychology: Psychology is the discipline of behaviour and awareness. Psychology comprises the study of conscious and unconscious occurrences, as well as sensation and thought. It is a theoretical discipline of immense scope. Psychologists seek an understanding of the developing belongings of brains, and all the variability of phenomena related to those emergent belongings, joining this way the wider neuroscientific group of researchers.

Chapter 10
Paradigm Shifts in the Theory and Praxis of Mental Health Counseling

Moly Kuruvilla
Department of Women's Studies, University of Calicut, India

ABSTRACT

Clinical psychology used to view women's distress as biological and men's distress as externally induced. The psychology of gender relations has progressed to view gender as a principle of the social structure, but counselling practices continue to have an uncritical focus on the unequal gender relations existing in the society. Feminist psychology recognizes that the pattern of women's mental disorders is role related rather than organic/biological and that many gender differences are shaped by differing socialization of males and females. While addressing the mental health needs of the women population, the "subjective distress" in the context of their "subjective realities" is to be explored. Silencing the oppressed is the feudalistic way of resolving issues, but it fails to recognise the storm inside the oppressed minds. From outside, the family may seem to be calm and cool, but the turbulence inside the feminine minds may break out any time either in the form of a suicide attempt or in the form of a complaint to the police or the women's commission.

INTRODUCTION

Despite the fact that stress is a silent killer of the 21st century, the causes and impacts persist and get aggravated in the globalized society. Gender discrimination, gender division of labor, gender role perceptions and gender-based violence prevalent in various forms and extents throughout the globe add to women's stress and negatively implicate their happiness and well-being. Engendering health thus occupies a central point when we talk about women empowerment and gender mainstreaming. The engendering efforts often focus on physical health of women, especially maternal/reproductive health. Mental health of women is an area that is not given serious attention in developing countries like that of

India. To facilitate women's active agency in development, appropriate support mechanisms to ensure their mental health are required. Here comes the relevance of this chapter that calls for paradigm shifts in the theory and praxis of mental health.

Mental Health and holistic wellbeing have received the focused attention of psychologists and those engaged in the study of human nature right from the beginning. The last two decades have witnessed an exponential growth in mental disorders of all types, all over the world. Studies across the world have shown that mental health issues such as depression and anxiety are more common among women. Database generated by many sources, including the WHO, comprises appalling statistics on women's deteriorating mental health. The gender disadvantage and physiological factors might add up to this vulnerability of women. Socio cultural factors varying from discriminatory socialization practices, denial of opportunities for higher education and employment, lack of property rights, decision making power, gender- based violence etc. all add up to the challenges of girls and women. Lack of gender sensitivity of medical practitioners, sociologists and mental health counselors result in overlooking the socio-cultural factors most often. Though the Bio psychosocial model is well accepted by mental health practitioners, its essence does not reflect in the practices.

Mental health is the normal state of wellbeing and defined as conditions and levels of social functioning which are socially acceptable and personally satisfying. There is no single authentic or certified definition of mental health. There are several misconceptions where mental health is equated with lack of mental illness. Cultural differences, subjective assessments, and competing professional theories affect the way mental health is defined. The World Health Organization defines mental health as a state of well-being in which the individual realizes his or her abilities, copes up with the normal stresses of life, works productively and fruitfully, and makes contributions to his/ her community. Different psychologists have emphasized different aspects of mental health in their definitions. According to Hadfield (1950), mental health is the full and harmonious functioning of the whole personality. Bernard (1961) writes (a) mental health involves continuous adjusting rather than a static condition and is, therefore, an ever- shifting progressive goal. It is an ability to cope up with the present and in all likelihood to adjust satisfactorily in the future too. (b) Mental health involves a point of view one takes through all phases of one's living. The White House Conference in its Preliminary Report,1930 defines mental health as "the adjustment of individuals to themselves and the world at large with a maximum of effectiveness, satisfaction, cheerfulness and socially considerate behavior and the ability to face and accept the realities of life".

Positive mental health is not merely an absence of illness or disorder but includes a positive sense of wellbeing; individual resources including self-esteem, optimism, a sense of mastery and coherence; the ability to initiate, develop and sustain mutually satisfying personal relationships and the ability to cope with adversities (Jenkins et al, 2011). It refers to a positive sense of wellbeing and a belief in one's own worth and the dignity and worth of others. Positive mental health includes the capacity to perceive, comprehend and interpret one's surroundings, to adapt to them and to change them if necessary, to think and speak coherently and to communicate with each other. Mental health is often taken as a behavioral process by which humans maintain balance among the various needs or between their needs and obstacles of their environment. Ryff and Keyes (1995) defines mental health as the combination of emotional wellbeing (presence of positive affect, satisfaction with life and absence of negative affect), social wellbeing (incorporating acceptance, actualization, contribution, coherence and integration) and psychological well-being (self-acceptance, personal growth, purpose in life and positive relation with

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

others). Jahoda (1958) has identified categories within which the concept of mental health could be represented and describes it as follows:

- Mental health is indicated by the attitudes of individuals towards themselves.
- Mental health is expressed in the individual's style and degree of growth, development or self-actualization.
- Mental health is based on the individual's relation to reality in terms of autonomy, perception of reality and environmental mastery.
- Mental health is the ability of the individual to integrate developing and differing aspects over time.

GENDER DIFFERENCE IN MENTAL HEALTH

Depression is among the most prevalent and debilitating psychiatric disorders in the world and women are twice as likely to experience depression compared with men (Sloan & Sandt, 2006). Both community-based studies and studies of treatment seekers indicate that women are, on an average, 2–3 times, at greater risk to be affected by common mental health disorders (Thara & Patel, 2001). Gender differences have also been reported in the age of onset of symptoms, clinical features, frequency of psychotic symptoms, course of these disorders, social adjustment, and long-term outcome (Malhotra & Shah, 2015). Weller et al. (2006) analyses the gender differences in depression to determine whether differences in adults are also observed in children and adolescents. Before puberty, major depression occurs at approximately the same rate in both sexes (Birmacher, Brent, & Benson, 1996; Lewinsohn, Clarke, Seeley, & Rhodes, 1994). Once children reach adolescence, however, the rate of depression in females doubles (Weissman, Bland, Canino et al., 1996). Although adolescent males also experience a significant increase in depression at puberty, the rate of depression in females at this age far surpasses that of males. As a result, the female-to-male ratio of depression becomes 2:1 (Lewinsohn et al., 1994; Weissman et al., 1996).

Nolen-Hoeksema (2001) explains how gender differences in stress experiences and stress reactivity may interact to create women's greater vulnerability to depression. This increased prevalence of depression in females has been seen in different countries and ethnic groups (Hankin, Abramson, Moffitt et al., 1998). As young women enter adulthood, they are at a higher risk for early relapse following remission from a clinical episode of depression (Kuehner & Weber, 1999), have more severe depressive episodes, experience greater functional impairments, and develop a more chronic course of illness (Kornstein, 1997; McCauley, Myers, Mitchell, Calderon, Schloredt, & Trede, 1993) than men. Retrospective studies of depressed adults suggest that females more often experience negative life events, such as childhood sexual abuse, or negative social factors, such as poverty, poor education, restricted mobility, reduced employment opportunities, violence and fear of violence etc. (Hankin & Abramson, 1999; Nolen-Hoeksema, Larson, & Grayson, 1999). Cyranowski et al. (2000) report that over 70% of depressed females experienced a negative life event prior to the depressive episode, compared with only 14% of males. Kessler et al. (2003) asserts women to be 70% more likely to experience depression in their lifetimes than are men. According to Nolen-Hoeksema (1987), women experience the onset of depression more frequently than do men, they demonstrate relatively longer durations of depressed moods, and they are relatively more likely to experience a recurrence of depressed mood.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Challenges of Puberty and its Role in Depression

There are dramatic changes in the expression of depression after puberty, but the reasons for these changes are not well understood. Both sexes experience an increase in depressive symptoms with puberty, at a time when they are faced with the pressures of forming an identity, dealing with emerging sexuality, separating from parents, and making important personal, academic, and vocational decisions. Teenagers also have to adapt with the physical, intellectual, and hormonal changes that occur during this period. All these stressors could have a potential role in causing depression (Reinecke & Simons, 2005). According to Parry (2000), hormonal factors related to the reproductive cycle may play a role in women's increased vulnerability to depression.

Females experience additional stressors as they reach puberty, these include biological changes like menarche and breast development and psychosocial stressors like increased concern with body size and image. No one factor may fully account for the observed increase in depression in adolescent females. Whether these stressors contribute to the rise in depression as young girls reach puberty should be determined. Mental health issues like depression in women and girls are often attributed to physiological changes which of course may be one among the various causal factors. Girls who fail to accept and adjust with their hormonal and physical changes are at a higher degree of vulnerability. Girls are expected to be docile, silent and confined both in the private space of home and public spaces like transport system, educational institutions and workplaces. Religious factors such as menstrual-related rituals, practices and restrictions are also reported to create mental stress, among the Hindu adolescent girls (Garg & Anand, 2015; Kirk & Sommer, 2006; NIPCCD, 2014). The religious instructions on dressing style affect Muslim adolescent girls more than their counterparts. Such restrictions on self-expression and mobility are further aggravated by religious dictums.

Numerous socio-cultural factors underline the vulnerability of girls leading to deep frustration and severe depression. In countries like India, noted for the male lineage preference, girls may be sidelined or fail to receive the due concern, or the kind of expectations from them is entirely different compared to boys. So, girls grow up with a sense that they are second-grade citizens in the family. And also, the roles assigned to them are different from that of boys in majority of the families. Girls are also more vulnerable to mental health issues because of violence and fear of violence. The chances of actual sexual abuse and attempts of harassment are much more among young girls compared to young boys. And if a girl tries to disclose or confides an abuse in her family she is not given the uncritical succor she needs; or if she tells someone and she is not believed - that again creates a trauma, which is a double vulnerability. Girls and women who are witnesses of such insensitivities are in turn likely to become vulnerable to frustration and depression (Jijila & Kuruvilla, 2019).

Gender Difference in Symptoms of Depression

Gender differences are reported in the symptom profiles of depression with depressive men more commonly having serious symptoms than depressive women (Poutanen, Koivisto, Mattila, Joukamaa, & Salokangas, 2009). Depressed women are more likely than depressed men to experience changes in appetite, weight gain, carbohydrate craving, sleep disturbances, increased sense of failure or guilt, somatization and increased anger (Carter, Joyce, Mulder, & Luty, 2001; Williams, Spitzer, Linzer et al., 1995). In addition, depressed women have greater rates of internalizing psychiatric disorders, such as anxiety disorders and eating disorders (Frackiewicz, Sramek, & Cutler, 2000). Men more frequently

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

experience psychomotor changes, feelings of worthlessness, decreased concentration, and weight loss (Angst & Dobler-Mikola, 1984; Frank, Carpenter & Kupfer, 1988). Also, depressed men exhibit anti-social personality and substance abuse disorder more frequently (Simon, 2002). Depressed high school females often have anxiety disorders, eating disorders, and adjustment disorders, whereas depressed high school males often have disruptive behaviour disorders and eventually substance abuse disorders (Sloan & Kornstein, 2003). A two-tiered, school-based epidemiologic study of depression in 478 adolescents found that females reported higher levels of depressive symptoms on self-report questionnaires, even when prevalence rates for the two sexes were taken into account. This suggested a gender difference in the expression of depressive symptoms (Cuffe, Waller & Cuccaro, 1995).

Biological Theories of Increased Depression in Females

Several biological theories have been proposed to explain the gender difference in depression but evidence-based research to support these theories is limited. One theory suggests oxytocin (which increases in females with the onset of puberty) causes an increase in affiliative behavior and the need for emotional connectedness. In such a state, a broken bond with a friend, parent, or partner may be perceived as a loss and leads to depression (Frank & Young, 2000). The role of hormones such as progesterone, estrogen, and cortisol in causing gender differences at puberty has been evaluated. To date, there is only limited evidence to prove these hormones as significantly influencing the development of depression in females (Hankin & Abramson, 1999), however, neuroendocrine changes that occur at puberty are presumed to have an effect. These biological changes, combined with socio-cultural factors, may place teenage girls at increased risk for depression. Endicott (1993) reports increased risk of a depressive episode or worsening of existing depressive symptoms during the late luteal (premenstrual) phase of the menstrual cycle.

Stroud et al. (2004) theorized that sex differences in hypothalamic pituitary adrenal axis regulation emerge during puberty and lead to gender differences in depression. Sex differences in cortisol response to a corticotrophin - releasing hormone (CRH) infusion challenge were examined across pubertal stages in normal children 7 to 16 years of age. Tanner stages were determined by physicians for all subjects. Serum cortisol levels were measured at specific intervals throughout an infusion challenge of CRH. Cortisol response to CRH increased with increasing Tanner stages in girls while boys did not show this trend. The authors suggest that small differences in the effect of puberty on cortisol responses and pituitary regulation may play a role in the increased rates of depression in girls during this period (Stroud, Papandonatos, Williamson & Dahl, 2004).

Though some authors report a decrease in the prevalence of depression at menopause (Bebbington, Dunn, Jenkins, et al., 1998), the reason for the same is not fully justified. Women with pre-existing mood disorders, however, may be at increased risk for a depressive episode at menopause (Hay, Bancroft, & Johnson, 1994).

Psychosocial Reasons for Greater Depression in Females

There are many psychosocial theories to explain the gender difference in depression but most are theoretical and therefore difficult to prove by evidence-based research. Cognitive theorist, Beck (1983) suggests that females, who focus on sociotropy (interpersonal dependence) and rely on affiliation and support from others, maybe predisposed to depression. Males rely on autonomy (personal independence) and focus more on self-criticism and achievement expectations. Gender differences in cognitive variables

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

were studied in a community sample of 856 white adolescents (Calvete & Cardenoso, 2005) to determine if they were associated with the development of depression or behavioral symptoms. Male and female adolescents were presented with different cognitive profiles, which could have accounted for gender difference in depression and delinquent behavior. Specifically, adolescent girls tended to doubt themselves, doubt their problem-solving abilities, and view their problems as unsolvable. All of these views correlated with depressive symptoms. Girls also focused on negative cognitions (such as self-blame and negative self-evaluation), expressed less-positive automatic thoughts, and needed a higher degree of approval and success than male counterparts. These factors correlated with internalizing problems and depressive symptoms. Males had higher scores on self-report items involving justification of violence and impulsive/careless styles that were more often associated with delinquent behavior. But why girls tend to have doubts about their abilities and need higher degree of approval than their counterparts is a matter of serious concern pointing to the need of further research with gender perspective.

Frackiewicz, Sramek and Cutler (2000) reviewed the artefact theory, which suggests that women seek help more frequently, visit health services more often, and are inclined to recognize mental illness earlier than do men. This theory also suggests that physicians are more inclined to recognize and treat depression in females and may even over-diagnose depression by 30% to 50% by misinterpreting symptoms of hypothyroidism, rheumatoid arthritis, and systemic lupus erythematosus as symptoms of depression.

Sands and Howard-Hamilton (1995) theorized that the increased sensitivity to societal expectations experienced by adolescent females might lead to negative feedback and feelings of depression. It is also difficult for some adolescent girls to maintain "proper behavior". For example, gifted adolescent females often struggle to maintain a balance between "achievement and sexual attractiveness" (Sands & Howard-Hamilton, 1995) because of conflicting messages from families, teachers, peers, and society. This struggle can be compounded by cultural and socioeconomic factors such as ethnicity, religion, or poverty. Thus, young women face many stressors that predispose them to depression. In the case of married women, broken marriages, indifference and desertion by the partner, lack of ownership of assets, lack of decision-making power etc. place a heavy toll on mental health unlike men. The responsibility of children poses an additional burden to the struggling mothers.

In societies with the practice of women blaming, girls and women are forced to suppress their feelings without even a chance to open up. In countries like India, a girl who is harassed cannot disclose the event fully, even to the judiciary as it may lead to severe blaming of the girl and her family, which most often extend for the lifetime of the girl. Due to the existence of dowry system, there will be several girls ready to marry a harasser but there are only very few men who dare to marry a harassed girl. Since chastity and marriage are overweighed in the lives of girls, the only option before a harassed girl or a survivor is to contain everything to self and suffer in silence. Families prevent any kind of reaction on the part of the girl, whereby the girl and the family are pushed into a trauma of life time guilt and sorrow and the harasser moves about freely without any guilt or contempt on his act. Such socio-cultural factors cannot be ignored while discussing women's mental health issues. As reported by WHO (2001), the morbidity associated with mental illness has received substantially more attention than the gender specific determinants and mechanisms that promote and protect mental health and foster resilience to stress and adversity.

A FEW COUNSELING EXPERIENCES

Three cases that would best represent the grievances of Indian women and also the nature of counseling they receive are given here for facilitating discussion.

Case 1: *Nisha was totally shattered when she approached me. She was 29, a college lecturer and mother of a seven- year -old son. Her husband is employed in a private firm after his college degree. At the time of marriage, Nisha was not employed. Her husband supported her to study further. She passed JRF and got employed in a college within five years of marriage. With the pay revisions of the government, Nisha started getting a much higher salary than her husband. Her husband found it humiliating to earn lesser than his wife. Problems started soon after and their life became so miserable. Her husband wanted Nisha to resign her job which she reckons as a great achievement and the reward for her hard work. They had consulted a counselor earlier where she was advised to resign the job as per her husband's wish. The husband is loving, caring and neither a spendthrift nor with any unsocial behavior. The counselor in presence of her husband made some remarks that as long as the family is rich enough and the husband is ready to take care of all her needs it is not wise on Nisha's part to insist on going out for work against husband's wish. Now the husband is frequently quoting the remarks made by the counselor to blame Nisha. It was at this juncture that Nisha approached me with a broken heart. Nisha's argument is that the present job is the reward for her hard work, she completed her studies along with her pregnancy. She wrote the lectureship examination on the previous day of her delivery. She narrated the pains she had taken for completing the studies and writing the lectureship examination after travelling long hours. Now that she had started enjoying the fruits of her hard work, the better status in the society, the respect from students, she was not ready to give up all these.*

Case 2: *Suja, 42 is a head nurse working in the government sector. Her 50-year-old husband is a retired army man. They have two children, elder son in plus two class and younger daughter in tenth standard. Her husband had taken voluntary retirement from the army at the age of 40 and since then he has not gone out for any work. His only engagement is drinking liquor and finding fault with wife and children. Suja has to hand over her entire salary to husband. She is afraid of taking the night shift since her daughter has grown up and is worried about her safety. Being a staunch Christian, Suja accepts all the harassment of her husband as part of her unfortunate fate. Offering strong prayers and fasts, hoping for a change in her husband's behavior, she is holding on the relationship. Suja is increasingly worried about the elder son's misbehaving tendencies and husband's cruel comments and harassment. When she approached the counselor, she was told that she is doing the right thing in the right direction and was advised to go on stronger fasts whereby things would change for the better. She has become very pale and weak with her fasts and finds it hard to make both ends meet at the home front. The husband was taken to de-addiction centers several times by her relatives but such efforts were of no use as he would start drinking within a week. Nobody has ever thought of getting the man engaged in some or other work and the man himself has a feeling that he is not a person to go for silly jobs. The wife expressed her guilty feelings whenever she considered getting a divorce from him.*

Case 3: *Reena is 35, mother of three children and regularly battered by her alcoholic husband. Though he is employed, the family gets no financial or emotional support from him. Reena is struggling to manage the routine needs of the household with her meager earnings from the agency works she*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

is pursuing at the post office. The husband has gone to the extent of snatching the little money that she earns from the agency work. If she dares to protest, she is cruelly beaten up by him. Thanks to the intervention of some NGOs, the husband and wife approached a counselor. After hearing both of them, Reena was advised to keep silent when her husband comes home drunk. Reena argues that she never sees him without being drunk and how long is she supposed to tolerate his indifference towards the needs of children and family, how long can she subject herself to his merciless battering.

Just three instances of gender insensitive counseling have been narrated above. In the first case, the counselor seems to ignore the emotional and material needs of a woman. The woman is viewed only as a wife and mother. Her role as a career woman, her intellectual satisfaction, need for economic independence and sense of accomplishment are blatantly not taken into consideration. The counselor should have attempted to correct the negative socialization that the husband has received with regard to masculinity and power relations. In the modern world of stiffer competitions, getting a job that you prefer is a matter of chance and luck, and the salary depends on many factors that, one with lesser qualification may sometimes get a higher pay than one with higher qualification. Also, the pay package vary greatly depending upon the changing economic times, work sector and policies of the employer in the private sector. The age-old patriarchal notions, that a husband must earn more than his wife, imbibed by the husband needed correction which was not attempted by the counselor. Instead, the lack of gender perspective made the counselor opt for the usual practice of suggesting adjustments from the woman, to the extent of resignation of her cherished and hard-earned job. The traditional norms regarding gender roles and gender stereotypes are accepted as such while resolving the issue.

In the second case, the wife is considered as someone who is solely responsible for the family integrity and she is entrusted with the duty of clearing the mindset and changing the behavior of the husband. The alcohol addiction of the husband is blindly accepted as a norm and changes are demanded from the wife alone. For this, she is advised to gain strength and courage through prayers and fasts.

In the third case, all the blame for being battered by the husband is put on the wife. Her silence on the face of violence is the remedy advised to solve the issue. The neglect of responsibilities and cruelty by the husband is not addressed. Moreover, the stand of the counselor supports the usual societal attitude of blaming women and according sanction to the drinking habits of men.

None of the above counselors seem to find anything wrong with the attitudes and behaviors of the husbands. The wife is always placed as the culprit and all efforts are made to refine her attitudes and adjustments. This might be comparatively easier in a patriarchal society where the silence and suffering of women is reckoned as a preferred practice for the well-being and integrity of the family.

The present chapter is contextualized in this backdrop. The modern globalized society characterized by its extreme stiffer competitions, materialistic outlook and identity crisis calls for a proactive role for the counselors. The withering familial and interpersonal relationship is a matter of serious concern for the sociologists and psychologists. The need for gender justice and gender equality as a precondition for social health and national development has been highlighted by various state and international machinery. Hence a gender perspective is an essential requisite for those who dedicate themselves for the happiness and well-being, especially in tradition-bound societies like that of India. But there are occasions as mentioned in the three case studies, where women seeking guidance are pushed into further trauma due to lack of gender perspective in the counseling approaches. In this context a redefinition is called forth regarding the concepts of stress, stressors and mental health and a reorientation is required in the counseling practices.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

GENDER PERSPECTIVE IN THE THEORY AND PRAXIS OF COUNSELING

While addressing the mental health needs, especially of women population, the "subjective distress" in the context of their "subjective realities" is to be explored. Counseling practitioners should have a true understanding of the socio-cultural background of the individuals and the society which in turn demands correct perceptions regarding the gender roles and gender relations in a patriarchal society. Moreover, a counselor should be one who has firm conviction that an individual, irrespective of gender, must have a private sphere and public sphere of life and at no cost should one be sacrificed for the sake of another as it will definitely result in imbalances in personal and social spaces. 'Gender perspective' demands looking at the world through a gender lens, transcending both male and female gazes, allowing a better vision of reality. The oppressive and exploitative conditions of half of the human race could be transformed in a constructive manner only if this perspective becomes central to the thoughts and actions of all people, the basis of all policies and all activities. Instead of adopting a superficial approach of treating the symptoms it is high time that we go for a deeper approach of curing the root cause of issues. For instance, in the first case study, the husband considers it as a blow to his masculinity when he earns lesser income compared to wife. This being a clear case of defective socialization, it is the socialization pattern that needs urgent correction to foster a positive attitude towards egalitarian gender relations rather than pressurizing the wife to give up her job.

In the second case study, getting the husband to counseling sessions itself is a difficult task whereas advising the wife to adjust further is an easy solution. Silencing the oppressed is the feudalistic way of resolving issues which fails to recognize the storm inside the oppressed minds. From outside, the family may seem to be calm and composed but the turbulence inside feminine minds may break out any time either in the form of a suicide attempt or in the form of a complaint to the police or the women's commission.

Need for a Paradigm Shift in the Conceptualization of Stressors from Physiology to Socio-cultural Factors

Clinical Psychology views women's distress as biological and men's distress as externally induced. The psychology of gender relations has progressed to view gender as a principle of the social structure and as an inevitable analytical tool, but counseling practices continue to have an uncritical focus on the unequal gender relations existing in the society. Feminist psychology recognizes that the pattern of women's mental disorders is role-related rather than organic/biological and that many gender differences are shaped by differing socialization of males and females. As in the first case study mentioned above, how come the husband developed the notion that it is unfair for a wife to earn higher than the husband. Why do the husband and the counselor think that a wife need not work if the family is rich enough? It is all because of the gender division of labor existing in the society wherein man is considered as the breadwinner and the housewife role is considered as a better option for woman. As per the patriarchal notions, a woman's income is considered only as supplementary income. The right of the woman to work, mental satisfaction and sense of accomplishment of the woman from her employment etc are totally ignored. Ignoring the need for economic independence for woman, especially when the husband's family is rich enough, is a consequence of the incorrect gender role perceptions of the society. The goal of a woman's life is also misconceived as becoming wife and mother. The woman's aspirations to take up careers and leadership roles are underestimated or more often treated as trivial.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the second case study, the wife is expected to survive through the traumatic conditions at home with the help of prayer and fasts alone. Whatever suffering she undergoes, it is not the concern of the society. As the doctrines of most religions emphasize, the husband is to be corrected by wife through unconditional love, sufferings, prayers and fasts. But if the wife happens to err, the husband has societal sanction to correct her through several forms of violence. This is a typical case of double standards of morality for men and women. The husband who remains idle at home while the wife goes out for work is creating a lot of issues in several home fronts. The concept of a house husband is unknown and unacceptable in traditional societies. The trauma of the employed wife to fulfill her responsibilities at home and that of the workplace along with carrying the constant fear of the son being spoiled and the daughter being harassed by her father needs much more concern and understanding.

Role conflict of working mothers requires a detailed analysis in this context. In general, issues related to work- life balance is often conceived as a consequence of lack of proper time management while the need for equal parenting and equal sharing of household chores is ignored. The use of supporting mechanisms like crèches for childcare, household gadgets to reduce drudgery of homely chores or the assistance of a housemaid won't relieve women of their responsibilities regarding childcare, caring of the aged and homemaking. It is the responsibility that is to be shared rather than mere helping with some or other household chores. But such a gender perspective is lacking in the mindsets of people, especially in tradition- bound societies.

Lack of proper relations to confide upon and ventilate personal worries and tensions is also a cultural factor that affects women's mental health. Through her Response Styles Theory (RST), Nolen-Hoeksema has stressed the role of rumination on depression and emphasized that rumination does not have a stronger impact on depressive episodes experienced by women than men, but that because women engage in rumination more frequently, they are more likely to experience depressive episodes in the first place (Nolen-Hoeksema as cited by Lyubomirsky et al., 2015, p.7). More of focused researches are required to test the hypotheses that lack of confiding relations and fear of women blaming contribute to this increased tendency for rumination among women. Women who are confined within homes and those who lack networking facilities at workplaces are equally susceptible to frequent rumination.

The intersection of gender and poverty also influences the mental health of women and is dehumanizing. In the third case study mentioned above, the poverty experienced by the wife and children is not a matter of concern to the husband or the counselor. The luxurious and spendthrift nature of life that the man enjoys is not found problematic. The income earned by the husband is spent as per his whims and fancies. The right of the family over this income and the right of the wife over her hard-earned money are conveniently ignored. The poverty and ill health of the wife is socially accepted as a norm in a similar way as the alcoholism and battering of the husband is sanctioned and justified. This is supported by the patriarchal notion that a woman begets violence because of her "own fault". Here the "fault" is the way the woman questions and protests the husband when he is too indifferent of the family needs. So, the solution is that if she doesn't want to be battered, then she should *keep silent* even when the last penny is taken away. Whatever sufferings she undergoes, it is not the concern of the society. It is always said that 'one can hate liquor and drinks but shouldn't hate a drunkard'. Thus, the rights of the drunkard to get love and concern are well protected while the rights of the wife and children to live a life of peace and happiness are violated and turned a blind eye on.

Physiological reasons like menstruation and associated PMS, pregnancy and associated bodily changes, delivery and associated postpartum depression, menopause and related depression and hormonal changes etc. can have their impacts on women's mental health and stress. But when compared to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the physiological factors, the socio-cultural factors have an overwhelming influence. The socio-cultural factors that induce stress in men and women vary to a great extent. In the case of women, in addition to those factors creating stress in men, the discrimination and bias entrenched in the traditions and culture also serve as stressors. Unlike men, women face poor nutritional status and anemia due to poverty and cultural practices. Women's overwork and undernourishment often go hand in hand in modern society. Lack of basic facilities like toilet and restroom as well as sexual harassment at workplace cause physical discomfort and mental stress to women than their counterparts. Fear of the gender-based violence is also more of a women-specific stressor. Thus, there is an urgent need for a paradigm shift in the focus of discussions and research on women's stress from their physiology to the socio-cultural factors.

FEATURES OF GENDER-SENSITIVE COUNSELING

Gender-sensitive counseling rests on the premise that unequal power relations exist between men and women in society. It necessitates an understanding of the oppression and discrimination that women face in all spheres of life, its underlying reasons and the implications of the patriarchal system on women's lives. The wife who is reluctant to open up in presence of the husband, the adolescent girl silent about the sexual abuse she is facing, the wife sustaining in a battered relationship, a woman attempting suicide after poisoning her kids, all share the common mindset of helplessness and hopelessness. Those who attempt at resolving their issues must keep in mind the underlying reasons for this helplessness. Girls from their birth onwards face discrimination and marginalization; helplessness is induced in them during their upbringing by the family, media and other socialization agencies. At the time they reach adolescence, the dos and don'ts become so intense that girls develop an inferiority complex and low self-esteem. As a consequence, girls fail to discover their true identity and boys fail to accept the individuality of girls. The tendency to view women as mere bodies and to narrow their mental horizons to looks and dressing are further strengthened by the media.

Educated girls have to plea with their brothers, parents, husbands or in-laws to get permission for taking up careers. Political and religious leaderships are still denied to women in most parts of the globe. Marriage and motherhood are considered as inevitable in the lives of women which in the case of their counterparts are not insisted to the same extent. Hence unlike men and boys, these conditions contribute to stress and mental health issues to girls and women. It is such a context that is responsible for the lowest mental health profiles of Keralite women in a country like India. Despite their highest literacy, high educational standards, best physical health indicators comparable to the developed western countries and favorable overall sex ratio, the highest suicidal rates are reported among Keralite women who also are the largest users of antidepressants in the country (National Family Health Survey [NFHS-3], 2006). Socio-cultural reasons like the lack of assets, lack of control over earnings, lack of decision-making power, drinking habits of men, domestic violence and fear of violence as contributing to women's deteriorating mental health are often overlooked.

Gender-sensitive counseling implies looking at things and events through a gender lens that requires an understanding of women's lives in comparison with that of men's lives in the respective age group, class and caste. A woman's life is a journey full of stress from womb to tomb. The disciplining with regard to dressing-walk-talk-smile and laugh during childhood, matters related to menstruation-PMS, dress code, concept regarding beauty –fair skin and body shapes during adolescence, restricted career options, partially /permanently denied aspirations, over-emphasis of marriage, dowry demands and so

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

on during early adulthood are sources of stress specific to girls and women. After marriage, pregnancy, childcare, homemaking and old-age care are some of the women-specific responsibilities entrusted by the culture in patriarchal societies. If she is a working woman the role conflicts related to managing personal and professional roles add up the stress in women (Seema & Kuruvilla, 2016).

Due to the gender division of labor and traditional gender role perceptions rooted in the culture, maintaining family integrity, serving as emotional buffer for all other members of the family, refining the husband when he goes wrong and ensuring happiness of all family members and relatives are all considered as responsibilities of women. But the very same women face the issues of lack of decision-making power, lack of income, lack of employment and economic independence and lack of property rights. The demands placed on women are too high and the entitlements and sanctions given to them are the minimal. In the counseling sessions especially while dealing with couples and families, convincing men and women about the unequal power relations and the social construction of gender pose major challenges to the counselors. The Indian society is undergoing a rapid metamorphosis where the traditional conceptualization of institutions like marriage and family undergo frequent changes and women have started to come out in large numbers to the work front. Nuclear families and living together are rapidly replacing joint families and arranged marriages. The concept of a dominant husband as head of the household is also getting outdated. These are all new challenges that upset the equilibrium of families in the 21st century as the transformation is only halfway, a good number of men and women have adopted progressive attitudes regarding gender roles and men –women relations; while a critical mass still hold on to their traditional beliefs related to gender relations (Seema & Kuruvilla, 2014). In situations where conflicts arise due to the lack of mutual respect or democratic relationship within families, gender-sensitive counseling becomes inevitable. Otherwise, the status quo will be maintained and the conflicts may get temporarily suppressed for an immediate recurrence.

In family counseling, a gender sensitized counselor also has much to do in generating awareness among parents regarding the need for equal socialization of their sons and daughters. Instances where the daughters are denied professional education and treated as liabilities while sons are sent to high fee structured professional colleges are common in patriarchal societies. Sen (2000) highlights seven major inequalities between men and women in South Asian countries with regard to natality, mortality, basic facilities, special opportunities, jobs and professions, ownership of land and assets and in responsibilities related to household chores. When the underlying reasons for these inequalities are analyzed, the role of family and the defective socialization get exposed. Kuruvilla and George (2015) conclude that by the time children reach the school at the age of five years, they might have imbibed all the patriarchal values from the family itself. The girl children are being socialized from the early childhood to be good wives and mothers, at the same time boy children are socialized in the extreme opposite manner, that is, to be independent winners in life (Kuruvilla &Valasseri, 2015). Here comes the need for awareness generation among parents for equal socialization of their wards. When a counselor is confronted with a situation of conflict among family members with a daughter arguing for higher education while parents insist on getting her married and the brother takes a stand of supporting her studies after marriage, the gender perspective of the counselor matters a lot, especially in supporting the girl and convincing the family members.

Girls and women need to be reminded of their inner power while boys and men must be enabled to accept their counterparts as equally capable. Research has proven how girls and women fall easy victims to traps in the cyber world and sex rackets in the real world. The underlying reasons include lack of awareness regarding one's human rights, safety issues in the society and ineffective implementation of the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

protective legislations for women's safety. Women who are unaware of their rights and entitlements need much of consciousness-raising and assertiveness training to enable them survive in a dynamic world. Here also a counselor with gender perspective will be in a better position to support girls and their families.

Gender-based violence is yet another major factor that accounts for the differential stress experienced by women, with a heavy toll on their mental health. Violence against women takes different forms from very subtle ones like discrimination, insult, avoidance etc. to extreme forms such as female feticide and infanticide, wife-beating, mental torture, sexual exploitation, rape, forced pregnancy, dowry deaths and bride burning. Women face harassment and violence within the four walls of home, on the roads, in buses and trains, at workplace and offices, the list is endless. The National Crimes Records Bureau of India (2016) reports an alarming rise in the crimes against women. As long as culture, religion and media support men and blame women for the violence meted out on them, the scope of a violence-free society will remain a distant dream. As a result, a woman is always expected to be cautious and vigilant even while travelling in a bus or a train, as she is blamed for provoking men and inviting harassment. Sexual abuse of the girl child, rape, dowry murder, domestic violence etc. are all causing physical and psychological trauma to women and impede their further development.

Studies from throughout the globe report incidents of domestic violence to be more common among people with mental disorders (Friedman & Loue, 2007; Golding, 1999; Howard et al. 2010; Hughes et al. 2012). In a population- based study in León, Nicaragua, after controlling for other factors, researchers found that abused women were six times more likely to report experiencing mental distress than non-abused women (Ellsberg et al, 1999). Likewise, in the United States, women battered by their partners are between four and five times more likely to require psychiatric treatment than non-abused women (Stark & Flitcraft, 1996). Trevillion, Oram, Feder, and Howard (2012) in their systematic review and meta-analysis on experiences of domestic violence and mental disorders in 41 cases found consistent evidence that both men and women with all types of mental disorders report a high prevalence and increased odds of domestic violence compared to people without mental disorder, with women more likely to experience abuse than men.

Bringing about changes in the mindsets of people is often suggested as the panacea to prevent gender-based violence. A gender-sensitive counselor will have a crucial role to play in bringing about such a change through consciousness raising of the aggrieved. Women blaming happens not only in the context of gender-based violence but also in every aspect of life. If a man becomes a drunkard or a criminal, his wife /mother is blamed for creating a hostile environment at home, when employed mothers face role conflict, they are blamed for the lack of time management, the parenting skills of the mother is questioned when the academic performance of adolescent children becomes poorer. There is cultural support in the form of quotes from great philosophers and writers and also verses from epics and scriptures to the women demeaning/blaming process. As a result, in the tradition-bound societies like that of India, girls and women become voiceless and space less. Gender-sensitive counselors should prevent the tendencies for blaming women and should aim at social changes through women's emancipation.

NEW ISSUES AND CHALLENGES IN COUNSELING

With the technological revolution and the Me Too campaign, counselors are confronted with numerous instances of self-revelation related to sexual abuse. Those feelings hitherto suppressed are being opened up, yet the women fail to adjust with the traumatic experiences.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Issues Related to Sexual Harassment

Case 4: *Lena was abused several times by cousins and uncles while being a child but she realized the gravity of abuse when she grew up into an adult of 22 years and got exposed to the experiences of other women in the Me Too campaign. Both her parents are high professionals and little Lena was most often left alone with grandmother at home. Cousins and uncles used to come and go and the smart and cute baby girl was a doll to be abused by them. The girl didn't tell anybody out of fear since the abusers used to threaten her that she and her parents will be killed if she said this to anybody. At present when parents started seeking marriage proposals for her, she is utterly confused about eligibility for a marriage wherein chastity and purity of the bride are mandatory prerequisites of the tradition-bound society. She is also confused about whether to disclose the matter to boys who come up with proposals and proceed further only when they agree to marry a sexually abused girl. This is the trauma of majority of the Indian girls where the purity of the bride is highly acclaimed while the promiscuity of the bridegroom is not a matter of concern. Ms Lena's parents just like their counterparts cannot imagine of a self-choice marriage and are compelling her for an arranged marriage. When she expressed her wish to speak and get to better know the boy before the "pennukanal ceremony"(literally means seeing the girl), the parents of both sides opposed it.*

In tradition bound societies like India, arranged marriage is a still preferred practice and "Pennukanal" is an inevitable event in it. The boy with parents would visit the girl's family and meet the girl in the presence of her family members. In some families, the parents would let the boy and girl speak in privacy for a stipulated time if both of them like each other from the first looks. In other families parents let children to speak over the phone after the "pennukanal" and let them get to know each other. But in the majority of families, the marriage decision is based on parental choices of compatibility in class, caste, family status and economic background. Even boys and girls with higher education and international exposure, are pressurized to give in to the parental choices and preferences of their partners. This, in several cases, ends up in a divorce when the issue of mutual compatibility between the actual partners spring up, in six months, one year or more. Here the young couples are sent to counselors to seek help for 'adjusted compatibility'. This is a confronting situation for the gender-sensitive counselor, who cannot play the role of a mediator to resolve the issues amidst couples and keep them going for the sake of the children born from the marriage or for their family's prestige and the happiness of the related kith and kin. Keeping aside the peace and happiness of the partners, a life of 'adjusted compatibility' dominates the family scenario.

Managing Postpartum Depression

Postpartum depression is often regarded as a normal consequence of delivery and associated hormonal changes in a woman's body. Cross cultural studies are required to assess the extent of postpartum depression in women in developing and developed countries. In a developing country context with gender division of labor, a mother is bestowed with the nurturing of the baby from the time of birth. Breastfeeding and sleeplessness, caring the baby and taking care of herself, the young mother most often may have to take care of the family responsibilities also in nuclear families. Young fathers are kept outside the room of the mother and baby or are not permitted to be with them during the early days of delivery. In later days, after the 90th day or so, when the father stays with mother and baby, they are conditioned

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to believe that the baby is a mother's responsibility. In such instances, torn between responsibilities of the baby...its father and other family members, the young mother reaches a phase of helplessness- sleeplessness - and hopelessness and it is quite natural for her to lose control over her thoughts and actions and become depressed. Leaving the young mother to her "biologically determined destiny" is actually a great challenge and threat to her mental health. An analysis of the following case studies provides testimonies to this argument.

Case 5: *Lisa was a 24 year old postgraduate when she got married to a rich graduate businessman belonging to a family that had extreme son preference. She delivered a girl baby against the expectations of her husband and in laws. Her life went traumatic with all kinds of violence targeted against her as a punishment for giving birth to a baby girl. She was even denied food and minimum health care. Nobody dared to care for the baby also as it was an unwanted child of the family. The husband started to depend on alcohol to forget the fact that he had fathered a girl. The blames and punishments continued. The telephone was cut off and Lisa was not permitted to speak to friends and relatives in the family and neighborhood. She became thin, pale, depressed, gloomy and finally decided to commit suicide after killing the baby. But on that day, just in between her suicidal efforts she was stopped by an old friend who came there unexpectedly, who reminded her about her strengths and talents and the need to fight a life for herself and the baby. Now both are alive in such positions so as to fulfill their mission of empowering less fortunate girls and women around them.*

Here had Lisa got the usual care, support and warmth from her husband and family, she wouldn't have faced any depression. The unfriendly approach of the people around might be the major factor that resulted in the postpartum depression rather than the physiological factors.

Case 6: *Monica was a career oriented girl who got married at the age of 25 and was not planning to have a baby for the next three years. Pregnancy was a blow to her career as she had to quit the job at a distant place owing to acute morning sickness. In the beginning she used to hate her pregnancy which she had to carry on as per the pleas of her husband and parents. The warmth, care and emotional support from her husband and parents made the pregnancy and delivery a memorable event for her. She often says, "I was treated like a princess and I would always cherish those days". Immediately after delivery by the 60th day she started working, enjoying her mom- life on one side and the career on the other. Lactation and sleeplessness were not issues for her as the baby was well taken care of by the nanny at nights and Monica was left to sleep peacefully as much as she wanted immediately after feeding the baby.*

Had she not received the warmth and care during pregnancy and childbirth and afterwards, Monica would definitely have hated the whole events and succumbed to postpartum depression. The healthiest man or woman if subjected to sleeplessness for three or four consecutive days, will have the chance of developing depression. In the case of pregnancy and delivery, the physiological toll is aggravated by socio-cultural factors of mothering and caring of the infant. Equal parenting of children by both mother and father, is something unimaginable for majority of people in traditional societies like India. The young father can take care of all the baby's needs other than breast feeding, but in the name of traditions, he is denied the opportunity to love and care for the baby. The sole responsibility of the helpless infant along

with other responsibilities of the young mother and lack of sleep and proper health supplements are major reasons for postpartum depression in several cases.

Issues Related to Menopause

Issues of ageing women are yet another domain that poses a confrontation for the 21st century counselors. The menopausal transition is often marked by somatic symptoms such as aches and pains, myalgia, fatigue, etc., physiological symptoms including vasomotor symptoms of hot flashes and night time awakenings, other symptoms like sleep disturbances, sexual arousal disorders, and urino-genital complaints, and psychological symptoms such as irritability, anxiety and low libido (Bungay, Vessey, & McPherson, 1980; Holte & Mikkelsen, 1991). Generally, practitioners attribute such depression to the decreased estrogen and decreasing libido among menopausal women. Life stressors such as marital issues, changes in caretaking (e.g., children departing the home for studies/employment/marriage, aging parents) or career responsibilities, issues related to aging, and feelings of being "overextended" also have been linked to perimenopausal depression (Rasgon, Shelton, & Halbreich, 2005).

As Hunter (1993) reports, the most relevant factors influencing a woman's quality of life during the menopausal transition are her previous emotional and physical health, her social situation, her experience of stressful life events (particularly bereavements and separations), as well as her beliefs about the menopause. Here except previous physical health all other factors are related to psychosocial aspects which in turn are either culturally defined and/or socially conditioned. Women are conditioned to believe and develop pessimistic attitudes about menopause and their families take it up as natural events in women's lives. Definitely the estrogen reduction has a toll on woman's health for which remedies are readily available, but the attitude of the woman herself and her family members need a reshaping. This is not properly addressed by the medical as well as counseling world. The overburden of providing caring and nurturing never ceases in the lifetime of most women, especially in the traditional societies noted for gender division of labor. This needs to be changed and if women start to get care and nurturing at least by the time they approach menopause and if it is continued, majority of menopausal depression could be easily addressed. Unfortunately, women are treated as lifetime health care givers and not as takers. Even the retired hands among baby boomer women turn out to be baby sitters of grandchildren and supporters and care givers of their adult children. Here comes the interventionist role of counselors in spreading the message on healthy transition during menopause among women themselves, their families and the society at large.

Grey Divorce Among Menopausal Women

With advanced health care services and health-seeking behaviors, the life expectancy of men and women is showing a positive trend. But the number of divorce seeking among women after menopause is also increasing. According to Brown and Lin (2012) regardless of educational attainment, the divorce rate for couples aged 50 and older (grey divorce) has doubled since 1990, and it has more than doubled for married individuals aged 65 and older. Also, more than 55 percent of grey divorces involve couples who were married for more than 20 years. Though reported in the U.S context, such a phenomenon is becoming more and more visible in the developing country context of India, which is noted for its low divorce rates. The impact of menopause on Quality of Life (QOL) is a consequence of social, physical and mental changes. It is highly visible that socio-economic and cultural factors influence the menopausal

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

transition. But it varies from region to region, country to country according to the prevailing culture. Menopausal depression among women is highlighted by practitioners as a major reason for grey divorce. But the counseling experiences of the author with menopausal women reveal the uncompromising demands from the husband, children and in-laws for caring and nurturing, in the form of timely food and other services that have been strictly followed over the years hitherto, and the inability of ageing women to meet them as major reasons for dissatisfaction among the menopausal women which prompt them to seek divorce from the partner.

Case 7: *Aruna, aged 62 is worried about the indifference and inconsiderate attitudes of her daughter as a serious blow over her mental health and well-being. Sleeplessness is a major problem for her, and her health in general is deteriorating that doctors fail to diagnose but she is assured of her tensions and depression owing to the frustrations thrown upon her by the grown up, unmarried and unemployed daughter. Mother of the family often serves as an emotional buffer to husband and children. But at a time when her own health shows a declining trend, especially after menopause, she needs love and concern from family members or at the least other members must stop throwing over their emotional outbursts upon her.*

As suggested by Clayton and Ninan (2010), recognition of menopausal symptoms, with or without depression, and effective management are important, given their potential impact on quality of life. Majority of menopausal women complain about the unmet socio-cultural and familial demands as putting much pressure on their physical and mental well-being. A gender perspective is needed in such contexts to make positive interventions and affirmative mindset changes during counseling. In countries like India, massive awareness is to be generated on the aspects of menopause so as to facilitate happy aging especially of the women baby boomers.

LIMITATIONS AND FUTURE DIRECTIONS

This chapter is based on the counseling experiences of the author in the socio cultural and politico legal context of India, especially the state of Kerala. The seven case studies are taken from Kerala only. Also, case studies of transgender and other sexual minorities are not included in this chapter as they are discussed in detail in yet another chapter. But the literature review was undertaken on studies throughout the globe. The real-life experiences related to sufferings of women, share more commonalities than differences, irrespective of their class, caste, ethnicity, locale and similar factors. The purpose of this chapter is to highlight the gender insensitivity of the mental health practitioners and the overwhelming need of having a gender perspective in all- health practitioners, development scholars and policy makers. It is high time researches in the area of mental health need to focus more on the socio-cultural factors than the physiological factors. Stressors that affect men are equally applicable in the case of women also as both genders are coming up to share responsibilities in the public sphere with the private –public dichotomy getting narrowed each day. At the same time factors that cause additional stress to women need to be more exposed. The impact of gender-based violence on mental health of women though well studied in western countries, are few in the Indian context. More attention of the development scholars are inevitable in the mental health area.

CONCLUSION

Stress is part of life in the 21st century and the counselors have an overwhelming role to play to enhance individual and societal health and ensure harmonious and peaceful coexistence in the society. Women's stress and low mental health are often associated with their anatomy and physiology in the world of counseling psychology. Hence a gender perspective is need of the day to redefine and restructure the knowledge constructed about women's psychology which in turn would have its corresponding changes in the counseling practices for a gender just society. A paradigm shift is inevitable in the theory of conceiving women's stress as induced by psychosocial factors rather than by biological reasons alone. The delay in such a conception has led to the wastage of much time and effort in stress research focusing on women's physiology. Women's issues take new dimensions and new forms with the changing trends of society. For instance, the new economic policy and the associated phenomena of liberalization, privatization and globalization have had multifaceted impacts on the lives of women, in quite different dimensions than that of men's lives. It also has differential effects on women belonging to different classes, castes and races. Positive impacts of digital era such as the internet and smart phones have been overshadowed by the negative impacts due to their misuse in the form of pornography, voyeurism, stalking, morphing and subsequent cybercrimes and have differential impacts on men and women.

Thus while considering women's mental health, the focus needs to be shifted from individual and "lifestyle" risk factors to the recognition of the broader, social, economic, and legal factors that affect women's lives. Hence there is an urgent need to evolve women-centered counseling practices using gender-sensitive guidelines and standards rooted in the socio-cultural, economic and politico-legal realities of the respective societies. It is high time that gender perspective be central to the conceptualisation of stressors and counselling practices. Gender sensitisation of counsellors is essential to develop proper gender role perceptions which in turn would facilitate gender sensitive counselling approaches also. Gender perspective must also be made a mandatory component in counselling courses.

To treat the root cause of women's mental health issues, quality education, employment and economic independence, active role in decision making, respect from the opposite sex, egalitarian gender relations, violence free society, adequate health care and above all elimination of gender disparities in every sphere of life, need to be ensured. While lack of gender equality forms a major cause for women's poor mental health, ensuring better mental health of women facilitate improved contribution of women towards sustainable development. Thus, engendering the theory and practices of mental health forms an inevitable strategy of women empowerment for sustainable development.

ACKNOWLEDGMENT

The chapter has taken excerpts from the publication titled "Gender Sensitive Counseling: Implications for a Gender Just Society", co-authored by the editors in the Eastern Journal of Dialogue and Culture (2018), 10 (2), 7- 24. The names of cases mentioned in counseling experiences are changed to ensure anonymity.

KEY TERMS AND DEFINITIONS

Dowry: The money handed over to the bride by her parents at the time of marriage.

Grey Divorce: It is the split or separation of couples above 50 years, who have been married for a long time.

Menopause: It is the time in women's lives when menstrual periods stop permanently.

Morphing: It is a form of cybercrime in which the face of a girl or woman is adjusted with someone else's body.

Natality: Related to birth, where female fetus is prevented birth right through sex selective abortion.

Postpartum Depression: A form of clinical depression related to pregnancy and childbirth. It manifests as mood disorders with feelings of intense sadness, worry and exhaustion following childbirth.

Stalking: Refers to repeated harassing or threatening behavior by an individual, such as following a person, appearing at a person's home or place of business, making harassing phone calls, leaving written messages or objects, etc. It is a criminal offense in India.

Chapter 11
Multi-Criteria Decision Making Semantic for Mental Healthcare

ABSTRACT

Healthcare systems play an important role in the well-being of patients; however, the diagnostic process generates a very large and varied types of data which makes the process of analyzing this data very complicated. More precisely, depression, which is one of the most common psychological disorders, contains a taxonomy of different symptoms, heterogeneous, and varied by data criteria, as confronted by clinicians to predict the degree of the disorder in patients with the aim of selecting the best treatment. To this end, the authors propose a decision architecture based on an approach that combines method ontologies, the Analytic Hierarchy Process, in the context of the prevention and monitoring of depression trends in patients.

INTRODUCTION

In the health sector, the volume of data collected for each patient is very varied and important ; however, clinicians usually face problems with analyzing this data and extracting the criteria relevant for a diagnosis. On the one hand, and more specifically, in the field of mental health, depression is one of the main causes of mental illness (American Psychiatric Association, 2015); indeed, it is one of the most common psychological disorders. In fact, the World Health Organization (WHO) (2018) predicts

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that depression will become the main cause of mental illness in the next 15 years. According to WHO, depression is one of the priority pathologies targeted by the Mental Health Gap Action Program (mhGAP) (WHO, 2018). The purpose of this program is to help countries expand services for people with mental disorders. On the other hand, at public health institutions, like the University Hospital Center Mohammed VI in Marrakech "(CHU)," cancer patients require permanent support and follow up during their oncology care, because they face major constraints while suffering and undergoing treatment, and other psychopathological reactions and symptoms that are identical to depression. Indeed the problem is defined: how can clinicians decide and select in a solid and automatic way the symptoms of depression, compared to other psychopathological reactions of the cancer disease? Due to the large number of patients, it is difficult to consider all these parameters to develop a relevant prevention system. In addition, the constraint of missing, unstructured, and noisy data adds more challenges ; therefore, the selection of relevant and personalized criteria (symptoms) for each patient remains an arduous task. Indeed, the major challenge facing clinicians is the problem of analysis of knowledge at the patient level. Moreover, to the multitude of diagnostic protocols, because they are diverse criteria, therefore the degree of uncertainty among clinicians increases.

In recent years, decision-making in medicine has taken a very important place in the science of medical informatics; indeed many approaches and methods stemming from Artificial Intelligence, assistance systems to decision-making, and mathematical modeling techniques, are gradually being introduced into mental health (Brunelli, 2014), in order to help decision-makers and health professionals make informed decisions based on solid foundations (Aoki, Uehara, Kato, & Hirahara, 2016). It is in this context we adopted the multi-criteria decision method of the Analytic Hierarchy Process (AHP), which is an analytical approach to support decision-making according to a multi-criteria approach. Developed by Thomas Saaty, it is basically based on complex calculations (Aoki et al., 2016), in order to extract the relevant diagnostic criteria. In addition, we proposed a hierarchical ontological model based on domain ontology, in order to exploit the preferences of each user (extracted by the diagnostic sheet and the test), and to be able to promote the integration of heterogeneous knowledge. The ontologies represent a very reliable and structured source of knowledge, and are robust means to represent and exploit the data and the knowledge of a field, and, more particularly, that of the medical field. Our case study is the modeling of the pathologies of depression based on the opinions of clinical experts and the DSM (American Psychiatric Association, 2015). In this context, this paper presents the intelligent decision framework to automatically monitor and predict the level of depression in cancer patients, so that clinicians can make the best decision to ensure better patient monitoring and reduce the impact of their suffering from the disease on their psychology.

This document is organized as follows: Section 2 describes some related work; Section 3 describes the methods used in this study. In Section 4, we present in detail the proposed system, the experimentation, and the results obtained.

RELATED WORK

In a world whose complexity is rapidly growing, making the best decisions becomes an increasingly demanding task (Brunelli, 2014). Indeed, optimal and relevant decision-making is a difficult task in all areas, especially in the health field. Physicians face several challenges ; however, many intelligent

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

methods from artificial intelligence, applied mathematics, and operational research is useful for helping decision makers make relevant decisions.

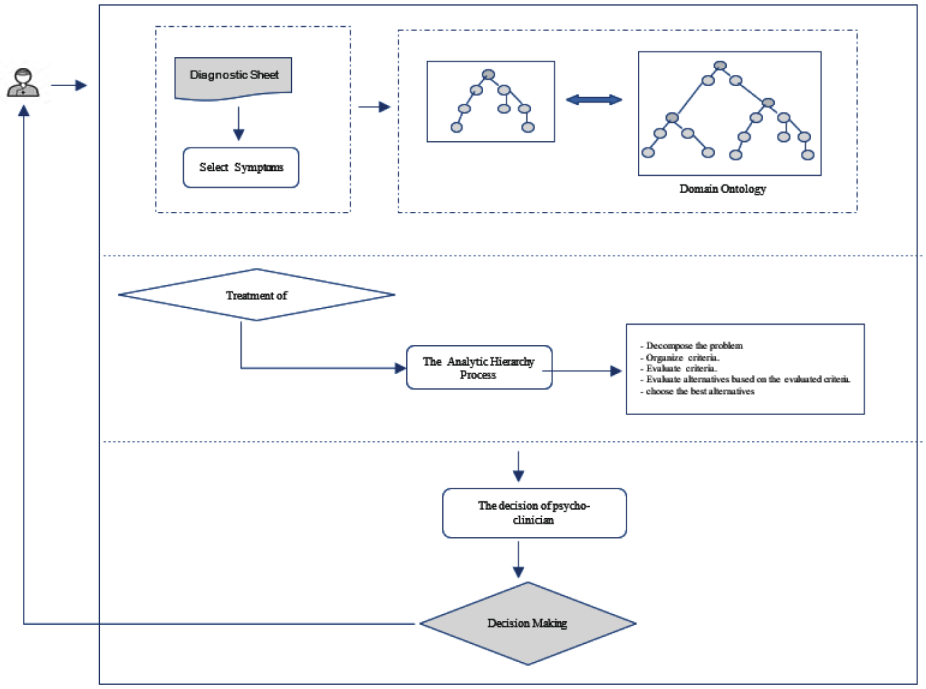
The ontologies are widely used in medical informatics and health care to standardize the vocabulary and share knowledge on a particular domain.

Therefore, in recent years, many researchers have proposed work and research in the field of health, especially mental health, to help doctors make the most relevant and accurate decision. For example, a recent study described a new approach for diagnosing anxiety and depression in young children (Mcginnis et al., 2018). Furthermore Aoki, Uehara, Kato, and Hirahara (2016) presented a study that sought to develop an evaluation index of rugby players' psychological competitive ability as their mental aspects. Moreover, other authors treat the noises depression based on statistic analysis algorithm for kerma area product meter design (Hsieh & Chen, 2018).

Besides, in recent years, much research has been based on systems of decision support, using the Analytic Hierarchy Process (AHP). On the one hand, Ran's (2011) paper applied the AHP for evaluating the energy-indicators system for sustainable development. On the other hand, Ouyang's (2017) paper presented an adaptive, vertical handover algorithm based on the Fuzzy Analytic Hierarchy Process (FAHP). And Hong and Yongsai's (2017) paper put forward a method for evaluating the rescue-priority level of power lines post-disaster based on the AHP. Jaglarz's (2018) study presented the bathroom as a place for health care by applying intelligent technology systems, including Internet of Things (IoT) technologies, in a bathroom space, and Carroll, Richardson, Moloney, Reilly, and Carroll (2017) described how to bridge health care education and technology solution development through experiential innovation.

This paper presents the intelligent decision framework for automatically predicting the level of depression in cancer patients. The added value of this work relies on the selection, in a robust and automatic way, the symptoms of depression, compared to other psychopathological reactions of cancer disease. It is based on the multi-criteria, decision-making AHP approach, so that clinicians can select the best decision, to ensure a better follow up of patients.

SYSTEM OVERVIEW



A medical-decision support system is an organized set of information, designed to assist the practitioner in his reasoning, with a view to identifying a diagnosis and choosing the appropriate therapy, by operating a dialogue between man and machine (Cléret, Le Beux, & Le Duff, 2001). However, the situation becomes complex when the decision maker faces choosing the best decision that best fits the patient context based on several criteria and alternatives.

On the other hand, in practice in public health—more specifically in oncology—clinicians and psycho-oncology practitioners face a constraint of automatically and rigorously distinguishing between the symptoms of depression and psychopathological symptoms that are identical to depression (which are reactions in the normal process of adaptation to cancerous disease). In this regard, this paper presents a decision support system. We opted for the AHP approach to help clinicians choose the best decision regarding the level of depression in order to ensure ubiquitous follow up of patients. We used the domain ontology in our case study, in order to standardize the vocabulary of the system and in order to improve and respond to the problems of heterogeneity and personalization of a diagnosis, adapted to the patient's symptoms.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1 presents the proposed system steps for the purpose; we try to answer the problems encountered in practice within the "(CHU)" oncology and hematology center. On the one hand, regarding the data, the alternatives, and the criteria, we processed relevant data from the CHU diagnostic card to extract the main diagnostic criteria (we will detail them in Section 5); on the other hand, we used the AHP approach to choose the best alternative.

Figure 1. Architecture of the system

In this present work, we propose the architecture of the system, which is divided into three main steps:

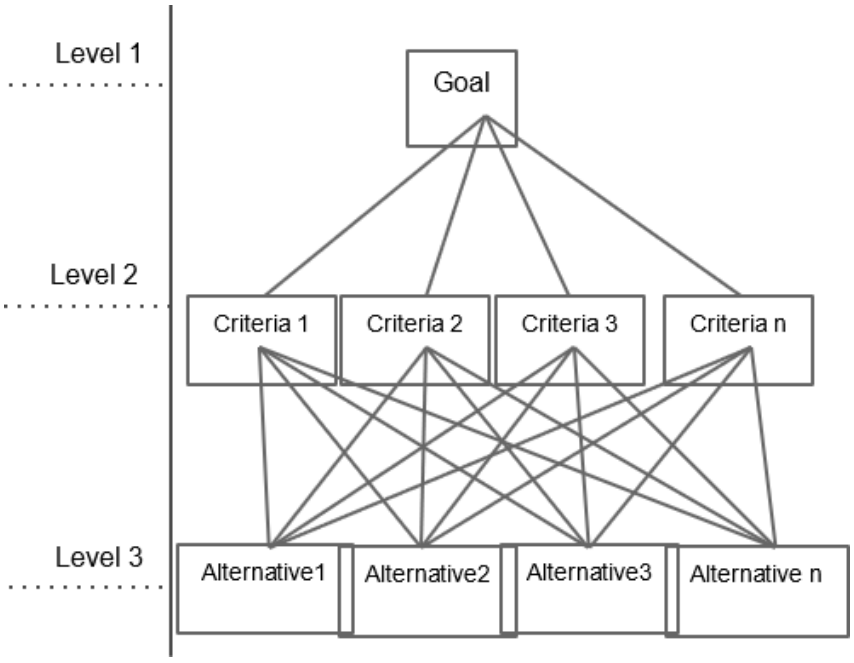
Step 1: The collection of diagnostic criteria (symptoms) from a diagnostic CHU sheet.
Step 2: The representation of knowledge based on domain ontology.
Step 3: The treatment of symptoms based on the analytical approach AHP multiple criteria.
Step 4: Decision-making based on evaluation alternatives.

THEORETICAL BACKGROUND

Introduction to Analytic Hierarchy

At first, decision-making can be defined as a series of cognitive processes including evaluation, comparison, reasoning, and selection of possible alternatives (Jaglarz, 2018), based on relevant information, and optimized by maximizing utility Marwala (2014). Moreover, the AHP is a decision-support model

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use



developed by Thomas L. Saaty of the University of Pittsburgh (Hong & Yongsai, 2017), which supports decision-making with a multi-criteria approach. The selection of a solution among alternatives, according to a certain number of criteria, when the decision maker has many evaluation criteria (Ran, 2011), is fundamentally based on complex calculations.

This method has been used in several areas, such as transport planning, energy rationing, risk management projects, comparative analysis of logistics operations, and quality management of services in hospitals, allowing users to decompose a complex problem in a hierarchical system (Brunelli, 2014). The hierarchical ranking of alternatives and criteria is defined by the decision maker.

The execution of the AHP method is based on the following main steps (Brunelli, 2014; Saaty, 1980):

1. Decompose down the problem by building a next hierarchy (see Figure 2). Determine the goal, criteria, and alternatives;
2. Define the weight of each criterion according to its priority, based on the Saaty scale (Saaty, 1980) (see Table 1), comparing in pairs each criterion; the second comparison is between the alternatives with respect to each criterion. Table 1 shows the different weights of the Saaty scale and their linguistic significance;
3. Determine an overall ranking of the alternatives related to the main objective of the decision, by calculating the weight of each alternative in relation to the criteria.

Figure 2. Structure of analytic hierarchy process

We present, in the following section, the experimental study of the AHP approach in our decision framework, related to the decision of degree of depression in cancer patients, in the oncology and hematology center of the University Hospital of Marrakech.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Linguistic variable scales

Saaty's Scale	Linguistic Meaning
1	Equal important
3	Moderately more important
5	Strongly more important
7	Very strongly important
9	Extremely more important
2, 4, 6, 8	Intermediate values of importance
Inverse	If, for activity "i" gets one number over activity "j," then "j" has its opposite value than "i"

Ontology

Ontology is a central concept of the semantic Web (Benfares, Idrissi, & Hamid, 2019). An ontology formally defines a common set of terms and concepts that are used to describe and represent a domain. An ontology is domain specific and is used to describe and represent an area of knowledge. There is another level of relationship expressed using a special group of terms: properties. An ontology is a representation of general properties of what exists in a formalism allowing automatic processing Kouame, A. (2018).

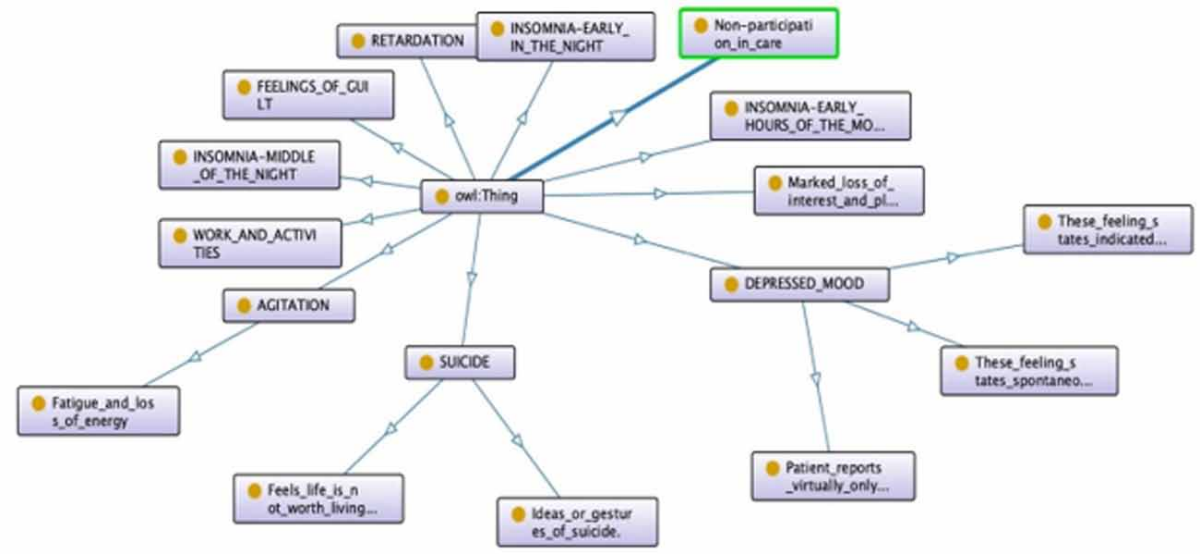
A domain ontology describes the terminology and relationships between terms in a specific domain. The ontologies can be written in different programming languages, to provide a formal description of concepts, terms, or relationships of any domain (Benfares et al., 2019). These languages are RDFS (Resource Description Framework Schema) and OWL (Web Ontology Language) (Benfares, Bouzekri, Idrissi, & Abouabdellah, 2017).

We used the ontology in our system to normalize the vocabulary of the system in order to improve and respond to the problems of heterogeneity and personalization of a diagnosis adapted to the patient's symptoms.

EXPERIMENTAL STUDY: DECISION-MAKING SEMANTICS FOR DETERMINE THE LEVEL OF DEPRESSION

In the present work, we present a model for smart decision-making, one side was based on relevant data from the Oncology and Hematology Center Hospital, and on the other side, we opted the AHP approach to help clinicians make a better decision. As we showed in the preceding section (system overview), to determine the criteria and alternatives forthe implementation of the approach in our case study, we used a diagnostic CHU sheet.

Ontology-Based Approach



In this section, we present the ontology-based case study model. Knowledge modeling and representation is based on domain ontology, with the aim of facilitating and guaranteeing cooperation between clinicians and the diagnostic system. We used the ontology language OWL (Web Ontology Language) (a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

language used to define and instantiate Web Ontologies), because it allowed us to represent and exploit the knowledge of a domain in a very robust way.

In this work, we used Protégé (an open-source ontology editor and knowledge management system that provides a graphic user interface to define ontologies) ; we use a simplified ontology of symptoms of depression as shown in Figure 3.

Figure 3. Concept description from an "Ontology model of symptom"

The patient profile contains all the information necessary to design a relevant diagnosis, in order to personalize it. The patient profile contains personal data and the test information.

Decision-Making-Based on the AHP

In this section we describe all the steps involved in executing the Analytic Hierarchy Process approach in our decision framework as defined in the previous section:

1. Figure 3 presents the problem of hierarchy in our case study on the best alternatives in decision-making regarding the degree of depression in cancer patients:
   a. **The Goal:** Predict the degree of depression most appropriate for a certain patient;
   b. **Criteria:** Extract all the relevant criteria, based on the diagnostic sheet; they present the symptoms of depression. Table 2 shows the different criteria used in our case study;
   c. **Alternative:** Present the possible alternatives related to the degree of depression. Table 3 shows all the alternatives used in our case study.

The steps we followed from the AHP method (Brunelli, 2014) are as follows:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 1: Decompose the problem and define the hierarchy.
Step 2: Establish the comparison judgment matrices.
Step 3: Determine the priority of each matrix.
Step 4: Calculate the 'Consistency Ratio' of each matrix.
Step 5: Derive 'Consistency' from judgments.

Tables 2 and 3 show the code for each criterion, and each alternative.

Table 2. Table code of criteria

Criteria	Code
Recurrent thoughts of death/suicide	S 1
Non-participation in care	S 2
Insomnia almost every day	S 3
Fatigue and loss of energy	S 4
Marked loss of interest and pleasure	S 5

Table 3. Table code of alternative

Alternative	Code
Mild depression	A 1
Moderate depression	A 2
Severe-moderate-depression	A 3
Severe depression	A 4

Comparisons Between Criteria

The first comparison matrix (see Table 4) between the criteria and the clinician (expert in psychology) evaluates each criterion based on its importance, using linguistic terms, which are then associated with real numbers; we based these on the scale of Saaty (see Table 1).

Table 4. Table comparison matrix between criteria

	S1	S2	S3	S4	S5
S 1	**1**	1/3	2	2	5
S 2	3	**1**	1	3	3
S 3	1/2	1	**1**	2	3
S 4	1/2	1/3	1/3	**1**	**2**
S 5	1/5	1/3	1/3	**1/2**	**1**

Eigenvector Calculation

After the establishment of the judgment matrices, the crucial step of the AHP is to derive a priority vector (see Table 5) for each pairwise comparison matrix. The most popular method for estimating a priority vector is that proposed by Saaty (Brunelli, 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Table priority between criteria

	S1	S2	S3	S4	S5	Priority
S1	1	1 /3	2	2	5	0.264
S2	3	1	1	3	3	0.337
S3	1 /2	1	1	2	3	0.218
S4	1 /2	1 /3	1 /3	1	2	0.107
S5	1 /5	1 /3	1 /3	1 /2	1	0.069

Calculate Consistency Ratio

The consistency ratio (CR), is the rescaled version of consistency index (CI), given a matrix of order n. CR can be obtained by dividing CI by a real number (random index) (Brunelli, 2014):

$CR = \frac{CI}{RI_n}$; CI is Consistency Index

RI_n; Random index was developed by Saaty (see Table 6)

The calculation of the value of consistency ratio is more important, to show the coherence of the judgments of the calculated matrix. For this purpose, the value of (CR) must be less than 0.1 (10%) for the matrix to be consistent (Brunelli, 2014).

Calculate Consistency Index

CI is obtained from a large enough set of randomly generated matrices of size n. The values estimated for are shown in Table 5. The coherence index is calculated by the equation below:

$$CI = \frac{\lambda_{\max} - n}{n - 1}$$

n = number of criteria

Calculate Eigenvalue λ_{max}

The next step is to calculate the eigenvalue λ_{max} of each matrix. The elements of the vector of the weighted sum are divided by the corresponding priority for each criterion.

The λ_{max} value of the comparison matrix between the criteria of our case study is as follows:

$\lambda_{max} = 5.434$

In our case study, the calculation of the consistency of judgment between the criteria is as follows.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Random coherence index of Saaty

Number of Criteria	1	2	3	4	5	6	7	8
RI_n	0	0	0.58	0.90	1.12	1.24	1.32	1.41

The value of the eigenvalue is:

$\lambda_{max} = 5.434$

Consistency Index:

$$CI = \frac{\lambda_{\max} - N}{N-1} = \frac{5.434 - 5}{5-1} = 0.108$$

$RI_n = 1.12$

We have five criteria, so:

$$CR = \frac{0.108}{1.12} = 0.096$$

Regarding the consistency ratio, we conclude that the value of CR = 0.096, so CR ≤ 0.1 or (CR ≤ 10%). So the degree of consistency of comparison is consistent (acceptable).

The following section presents the matrices of judgment, comparisons between the alternatives and each criterion, and the results of the priority and the consistency of each comparison matrix.

Comparisons Between Alternatives With Report to Each Criterion

We established the comparison judgment matrix between the alternatives, with respect to each criterion, by calculating the priority vectors, the coherence index, and the coherence ratio in order to check the consistency of the judgment.

The first comparison matrix between alternatives relative to the symptom 4 criterion is shown in Table 7.

We conclude that the value of CR = 0.055, so CR ≤ 0.1 or (CR ≤ 10%). So the degree of consistency of comparison is consistent (acceptable).

The second matrix presents the comparison between the alternatives versus the symptom 5 (marked loss of interest and pleasure), as shown in Table 8.

We conclude that the value of CR = 0.056, so CR ≤ 0.1 or (CR ≤ 10%). So the degree of consistency of comparison is consistent (acceptable).

The third matrix presents the comparison between the alternatives versus the symptom 2 (non-participation in care), as shown in Table 9.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Comparison matrix between alternatives according to symptom 4 (fatigue and loss of energy)

Symptom 4	Severe-Depression	Severe-Moderate-Depresion	Moderate-Depression	Mild Depression	Priority
Severe-Depression	1	2	2	2	0.379
Severe-moderate-depression	1 /2	1	2	3	0.292
Moderate-depression	1 /2	1 /2	1	3	0.212
Mild-depression	1 /2	1 /3	1 /3	1	0.114
λ_{max}= 4.15		RI_n=0.90	$CR = \frac{CI}{RI_n} = \frac{0.05}{0.90} = 0.055$		CR= 0.055

Table 8. Comparison matrix between alternatives according to symptom 5 (marked loss of interest and pleasure)

Symptom 5	Severe-Depression	Severe-Moderate-Depresion	Moderate-Depression	Mild Depression	Priority
Severe-Depression	1	3	4	4	0.519
Severe-moderate-depression	1 /3	1	3	2	0.240
Moderate-depression	1 /4	1 /3	1	2	0.135
Mild-depression	1 /4	1 /2	1 /2	1	0.102
λ_{max}= 4.153	$CI = \frac{\lambda_{max} - n}{n-1} = 0.051$	RI_n=0.90	$CR = \frac{CI}{RI_n} = \frac{0.051}{0.90} = 0.055$		CR = 0.056

Table 9. Comparison matrix between alternatives according to symptom 2 (non-participation in care)

Symptom 2	Severe-Depression	Severe-Moderate-Depresion	Moderate-Depression	Mild Depression	Priority
Severe-Depression	1	2	3	5	0.458
Severe-moderate-depression	1 /2	1	3	3	0.29
Moderate-depression	1 /3	1 /3	1	4	0.174
Mild-depression	1 /5	1 /3	1 /4	1	0.074
λ_{max}=4.200	$CI = \frac{\lambda_{max} - 4}{n-1} = 0.066$	RI_n=0.90	$CR = \frac{CI}{RI_n} = \frac{0.066}{0.90} = 0.074$		CR= 0.074

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

We conclude that the value of CR = 0.074, so CR ≤ 0.1 or (CR ≤ 10%). So the degree of consistency of comparison is consistent (acceptable).

The fourth matrix presents the comparison between the alternatives versus the symptom 3 (insomnia almost every day), as shown in Table 10.

We conclude that the value of CR = 0.033, so CR ≤ 0.1 or (CR ≤ 10%). So the degree of consistency of comparison is consistent (acceptable).

The fifth matrix presents the comparison between the alternatives versus the symptom 1 (recurrent thoughts of death/suicide), as shown in Table 11.

Table 10. Comparison matrix between alternatives according to symptom 3 (insomnia almost every day)

Symptom 3	Severe-Depression	Severe-Moderate-Depresion	Moderate-Depression	Mild Depression	Priority
Severe-Depression	1	1	3	2	0.331
Severe-moderate-depression	1	1	4	5	0.429
Moderate-depression	1 /3	1 /4	1	3	0.154
Mild-depression	1 /2	1 /5	1 /3	1	0.083
λ_{max}= 4.09	$CI = \frac{\lambda_{max} - 4}{n-1} = 0.03$	RI_n=0.90	$CR = \frac{CI}{RI_n} = 0.0333$		CR = 0.033

Table 11. Comparison matrix between alternatives according to symptom 1 (recurrent thoughts of death/suicide)

Symptom 1	Severe-Depression	Severe-Moderate-Depresion	Moderate-Depression	Mild Depression	Priority
Severe-Depression	1	1	5	7	0.440
Severe-moderate-depression	1	1	3	5	0.333
Moderate-depression	1 /5	1 /3	1	3	0.126
Mild-depression	1 /7	1 /5	1 /3	1	0.057
λ_{max}= 4.07	$CI = \frac{\lambda_{max} - 4}{n-1} = 0.023$	RI_n=0.90	$CR = \frac{CI}{RI_n} = 0.025$		CR = 0.025

We conclude that the value of CR = 0.025, so CR ≤ 0.1 or (CR ≤ 10%). So the degree of consistency of comparison is consistent (acceptable).

After establishing the criteria comparison matrix and calculating the weights, the last step is to calculate the weight of the alternatives. We used the following formula to determine a global ranking of the alternatives (the final weight for a given alternative is calculated as follows). Therefore, the goal is yielded by the best alternative score (Priority):

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$S_i = \sum_{i=1}^{N} w_j \times e_{ij}$$

N is the number of criterion.

Table 12. Ranking of the alternatives

	Severe-Depression	Severe-Moderate-Depresion	Moderate-Depression	Mild Depression	Priority
Symptom 1	0.44	0.33	0.126	0.057	0.264
Symptom 2	0.458	0.29	0.174	0.074	0.218
Symptom 3	0.331	0.429	0.154	0.083	**0.337**
Symptom 4	0.379	0.292	0.212	0.114	0.107
Symptom 5	0.519	0.24	0.135	0.102	0.069

In this case study, we have relied on the techniques of the AHP method to provide a solution that exactly fits our problem of uncertainty about the choice of the best and relevant alternative. For this purpose, we have established the problem hierarchy of decision-making on the degree of depression, precisely in patients with "(CHU)" cancer at the Marrakech Oncology and Hematology Center. We applied the AHP multi-criteria analysis method, so that clinicians can make the best decision, in other words, choose the best alternative, to address the problem of distinguishing between the criteria of depression and other psychopathological reactions of cancer. In this study, we have studied five criteria and four alternatives, we have calculated the priority and the consistency ratio for each comparison matrix, and the results have agreed and are consistent, and all the judgments are logical and consistent, since the AHP relies fundamentally on complex calculations (Table 12).

CONCLUSION

The goal of the health systems is to ensure patients are followed up with in an intelligent way and to improve the diagnostic care to minimize the risks of the patients in terms of follow up and prevention. In this regard, in this work, we proposed a decision support system in the context of the prevention and prediction of the degree of depression in cancer patients in the oncology and hematology center of the University Hospital Center. An analytic hierarchy process analysis was used to evaluate the criteria and alternatives, and we used five criteria in this case study. In addition, we developed an ontology model to represent knowledge in order to capture the symptoms of each patient in a relevant way. The results of the simulation show that the model is weak and has provided satisfactory results.

ABSTRACT

This chapter provides an assessment of studies on mobile health (mHealth) tools for development in addressing diseases relating to mental health, informs the current publications trends, identifies research gaps in the existing literature, and suggests a future research agenda that can help address these gaps. We, therefore, assessed empirical studies using a Systematic Mapping Study approach. We searched five academic databases as well as Google Search Engine and Google Scholar. Based on the inclusion and exclusion criteria, 54 full-text papers were included in this chapter. The findings suggest a growing trend in the use of various mHealth tools for mental health, such as mobile apps and text messaging. The findings also suggest that the responsibility of health monitoring and management can be shared between the medical practitioner and the patient in mental healthcare. Research gaps were identified and areas for future research are proposed.

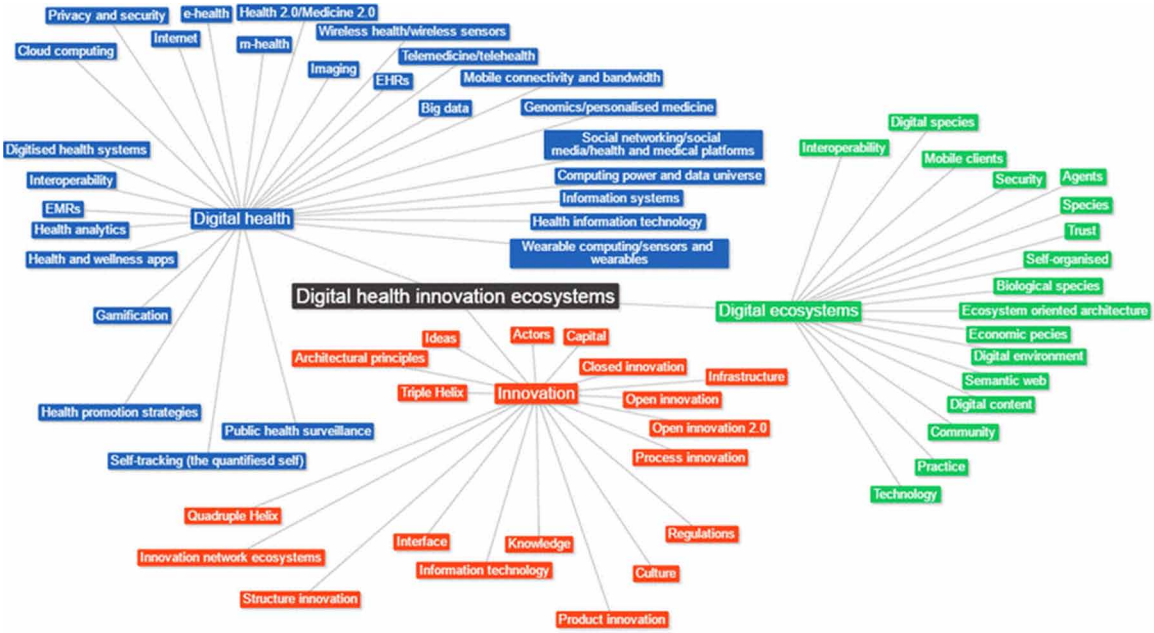
INTRODUCTION AND BACKGROUND

Mental Health

The World Health Organization (WHO) (2014) defines mental health as a "state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community." However, several conditions can greatly impact on the mental health of a person, including mental illnesses such as depression (Hellman, 2018), post-traumatic stress disorder (PTSD) (Bisson et al., 2015), schizophrenia (Rasool et al., 2018) and psychosis (Chan, 2017). Mental health is a serious health issue; however, countries have paid little attention to the burden of mental health (Tomlinson & Lund, 2012). Russell and Patrick (2018) emphasize the importance of addressing mental health issues as these cause a financial strain on health systems.



One of the United Nations' Sustainable Development Goals (SDGs) is to ensure that populations of the world live a healthy life as stated in the SDG 3, to maintain "good health and well-being" (United Nations Development Programme, 2016). To achieve these goals, countries have taken innovative approaches. Some efforts include the use of technologies in diagnosing, managing and aiding the treatment of diseases (Hoffmann & Svenaeus, 2018). Iyawa, Herselman and Botha (2017a) propose Digital Health Innovation Ecosystems as a practical approach for meeting these goals. Digital Health Innovation Ecosystems emphasize the use of digital health technologies in the delivery of healthcare services where both patients and key healthcare stakeholders interact in a digital platform with evidence of the "principles of innovation" (Iyawa et al., 2016a; 2017d, p. 433).

Iyawa et al. (2016a, p.249) define Digital Health Innovation Ecosystems as a "a network of digital health communities consisting of interconnected, interrelated and interdependent digital health species, including healthcare stakeholders, healthcare institutions and digital healthcare devices situated in a digital health environment, who adopt the best-demonstrated practices that have been proven to be successful, and implementation of those practices through the use of information and communication technologies to monitor and improve the wellbeing and health of patients, to empower patients in the management of their health and that of their families." This definition suggests that all healthcare stakeholders are involved in the healthcare process which includes both medical practitioners and patients. Involving patients in healthcare delivery processes have shown to improve health outcomes (Vahdat et al., 2014). While Herselman et al. (2016) advocate for a Digital Health Innovation Ecosystem for South Africa, Iyawa et al. (2017b) validate the components of a Digital Health Innovation Ecosystem in Namibia and present a framework for implementing such an ecosystem in the Namibian context (Iyawa, 2017c). Other studies on Digital Health Innovation Ecosystems highlight the benefits of implementing such an ecosystem. Some of the benefits include the sharing of information between healthcare stakeholders such as patients and doctors and improved healthcare services (Iyawa et al., 2017b; Iyawa et al., 2019).

Digital Health Innovation Ecosystems are important in ensuring that patients are involved in the healthcare process through digital health technologies with innovative approaches. Iyawa et al. (2016b) present the components of a digital health innovation ecosystem which includes digital health, innovation and digital ecosystems as shown in Figure 1. An example of digital health technologies is the use of mobile technologies for healthcare purposes (mHealth) as shown in Figure 1 (Iyawa et al., 2016b). The focus of this chapter is on applying a component of Digital Health Innovation Ecosystems, mHealth, for mental healthcare and explore how different healthcare stakeholders such as patients and medical practitioners make use of mHealth as tools for development in mental health.

Figure 1. Components of a digital health innovation ecosystem (Iyawa et al., 2016b)

mHealth

mHealth is an element of digital health and Digital Health Innovation Ecosystems, which leverages mobile technologies in the provision of healthcare services (Botha & Booi, 2016; Vesel et al., 2015). While other definitions of mHealth suggest that mobile technologies and devices are included in the provision of healthcare services (WHO's Global Observatory for eHealth (GOe), Istephanian, Jovanov and Zhang (2004) explain that mHealth is not just about the application of mobile devices for health care but the application of sensor technologies as well. Sensors in mobile devices have provided a new dimension in improving the health and well-being of patients. Application of mobile technologies in improving the health of patients include the use of mobile phones for educating pregnant and postpartum women (Su et al., 2016; Alam et al., 2017; Iyawa & Hamunyela, 2019), the use of mobile phones for health promotion (Kaplan and Stone, 2013) and apps that aid identification of diseases (Jutel & Lupton, 2015). mHealth encompasses a wide range of mobile technologies including low-end tablets (O'Donovan et al., 2018), mobile phones (Zimic et al., 2009) especially in developing countries where the majority of the population may not have access to sophisticated mobile technologies. For the purpose of this study, mHealth is defined as the use of any mobile device including mobile phones, smartphones, mobile or phone-based sensors for providing and receiving healthcare services such as healthcare monitoring, diagnosis, management and prediction of diseases. One of the reasons why mobile technologies have been adopted for healthcare is the rapid expansion of mobile phone access worldwide, including in low-income countries (Davey & Davey, 2014). With this growing potential, mobile technologies have been adopted in the healthcare sector for health care purposes.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

mHealth and Mental Health

mHealth has been used to monitor and support mental health and mental illnesses. For example, managing mental disorders such as depression (Carswell et al., 2018), psychosis (Stamate et al., 2017), and schizophrenia (Ben-Zeev et al., 2016). Recently, there has been an increase in the use of mobile technologies in providing care to patients. From healthcare service delivery (DeSouza et al., 2015) to diagnosis and monitoring of diseases (Alepsis & Lambrinidis, 2013), mobile technologies have been incorporated in healthcare. One reason for the adoption of this technology is the accessibility of mobile technologies by a considerable proportion of the population, especially in rural and medically underserved communities (Sylvester, 2016; Afolayan et al. 2015). Campbell et al. (2015) also found that mobile phone usage among people with mental health issues was high and also recommended the use of text messaging as a technique to support patients with mental health problems. Despite reviews summarizing and evaluating these technologies in mental healthcare (Sedrati et al., 2016; Chandrashekar, 2018), there is still no study focusing on the current trends in publications of mHealth tools for mental health. This mapping study is useful in identifying research gaps in the literature regarding the use of mobile technologies in mental health and developing a future research agenda. This chapter provides an assessment of studies of mHealth tools for mental health conditions, assesses the current publications trends, researches gaps in the existing literature and identifies future research agenda that can help address the gaps identified.

RESEARCH QUESTIONS

For the main objectives to be achieved, the following research questions were posed:

- What are the publication trends in mental health mHealth research over the last decade?
  - This question aimed to investigate how many papers have been published on the application of mHealth tools for mental health purposes within the last ten years.
- In what ways are mHealth tools being used to address mental health issues?
  - This question aimed to investigate the different mental illnesses in which mHealth tools have been applied and how these technologies are being applied.
- What are the different types of mHealth technologies and applications that have been employed in mental health interventions?
  - This question aimed to investigate various mobile technologies and tools that are being used for mental health interventions.
- In what settings have mobile technologies been used in mental healthcare interventions?
  - This question aimed to identify the different settings in which mHealth has been applied in mental health.
- What are the main publication outlets for publishing research on mHealth for mental health?
  - This question aimed to identify the main publication outlets for publishing research on mHealth for mental health

A systematic mapping study approach was used to achieve the main aim of this chapter. Hence, this chapter contributes to the literature on mHealth for mental health by mapping out current trends of published research on the subject.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

This chapter is structured as follows: the research methodology is presented in the next section. Then, results and discussion of the findings are presented. Finally, this chapter concludes with recommendations and future work.

RESEARCH METHODOLOGY

The systematic mapping study review method was applied to assess mHealth studies in mental health. Other review methods have been used to assess empirical studies in mental health. Examples include, systematic literature reviews of mHealth for mental health services (Aldridge & McChesney, 2018; Karasouli & Adams, 2014), scoping review of the mental health of immigrants (Guruge & Butt, 2015; Goldner et al., 2015) and critical review of mental health policies (Wong et al., 2014). A systematic mapping study aims to "map out and categorize existing literature on a particular topic, identifying gaps in research literature from which to commission further reviews and/or primary research" (Grant & Booth, 2009, p. 97). Systematic mapping reviews have been conducted in different fields including wearable technologies (Iyawa, Velusamy, & Palanisamy, 2019) and software engineering (Petersen et al., 2008). The concept of systematic mapping reviews is to explain the trends of particular research (Grant and Booth, 2009) and is in line with the objective of this chapter. As such, the systematic mapping review was the appropriate methodology to apply in this context.

This systematic mapping review adopted guidelines for conducting systematic mapping studies as outlined by Petersen et al. (2008). This will be detailed in the subsequent sections.

SEARCH FOR RELEVANT PAPERS

Data Sources

We searched five academic databases, namely, IEEE Xplore, ScienceDirect, PyschINFO, Scopus and ACM. We also searched Google Scholar and Google Search engine. A total of 3887 papers were retrieved. After the removal of duplicate records, 3252 papers were identified. We conducted the search in three phases, title, abstract and full-text. We first searched for relevant titles and removed papers with an irrelevant title. In this process, 1822 papers were excluded. 1430 papers remained. These abstracts were read for relevance. In this process, 803 papers were removed. 627 full-text articles were analysed and based on inclusion and exclusion criteria, 54 relevant papers were included in this study. We conducted the search from February 2019 to April 2019.

Inclusion and Exclusion Criteria

- We included papers on mHealth specifically focusing on mental health
- We included articles published between 2009 and 2019
- We included journal articles and conference papers

Our exclusion criteria are listed as follows:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- We excluded papers not written in English
- We excluded papers with mental health focus outside the context of mHealth
- We excluded papers which are not explicitly focused on the mental health of patients
- We excluded Masters and PhD theses

RESULTS

RQ 1: What are the Publication Trends in Mental Health mHealth Research over the Last Decade?

The findings show, in general, an increase in publications in mHealth for mental health research over the past decade. For example, in the first 5 years (2010-2015 inclusive), we retrieved 18 papers relevant to our study and in the second 4 years (2016-2019 inclusive), we retrieved 36 papers relevant to our study. For 2019, we retrieved data published till April 2019. The publication trends of mHealth studies on mental health are illustrated in Figure 2.

Figure 2. Publication trends in the last decade

RQ2: In What Ways are mHealth Being Used to Address Mental Health Issues?

The literature suggests that mHealth tools and technologies including mobile phones, smartphones, and mobile apps have been used to provide a variety of mental health services. The subsequent sections of this chapter explain the different ways mHealth is being applied to address mental health issues.

Determining the Mental State of a Patient

Mankodiya et al. (2013) assessed the feasibility of assessing emotions and the mental state of patients through the use of a smartphone camera to determine the presence of mental illnesses as early as possible. Chow et al. (2019) piloted the use of mobile apps to support the mental health of patients with breast cancer. Epp et al. (2011) developed a mobile app to support nursing trainees in understanding the processes of assessing the mental state of a patient. An evaluation of the app revealed that it improved nursing students' learning.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Treatment of Patients With Dementia

Laird et al. (2018) evaluated the use of a mobile app to support patients living with dementia and the study found that it improved the mental health of these patients.

Early Prediction, Prevention, and Treatment of Depression

mHealth tools such as mobile apps have been used for treating depression (Osma & Plasma, 2014). Mobile apps have also been used to facilitate healthy living in patients with depression and diabetes (Hartzler et al., 2016) as well as support postnatal mothers suffering from depression (Sawyer et al., 2018). Apart from mobile apps, other techniques such as short message service (SMS) and text messaging have been used for the early prevention of depression and violence in young people (Chu et al., 2018; Ranney et al., 2018). A study by Lipschitz et al. (2019) shows that mobile apps can be easily adopted for the treatment of depression. Burns et al. (2011) developed a mobile app based on machine learning algorithms to predict the mood of patients, as such, predict depression in patients.

Suicide Prevention and Monitoring

Indigenous mobile apps have been designed and developed for specific communities in Australia, such as the Aboriginals for suicide prevention (Larsen et al., 2015). Nuij et al. (2018) investigated the possibility of using mobile phones to monitor patients that are at risk of suicide.

Treatment of Bipolar Disorder

Torri et al. (2015) explored the requirements of a mobile app to support the treatment of bipolar disorder. Sensor-based mHealth approaches have been used to monitor diseases such as bipolar disorder and depression (Seppala et al., 2019). Menon et al. (2018) evaluated the use of text messaging to ensure patients with bipolar I disorder take their medication. Prociow and Crowe (2010) utilized a mobile app to facilitate self-monitoring of patients with bipolar disorder.

Detection, Prediction, and Management of Psychosis

Smartphones (Stamate et al., 2017) and smartphone apps (Niendam et al., 2018) have been used to detect psychosis and report mental health symptoms of young patients with psychosis. Niendam et al. (2018) evaluated the use of smartphone apps to report health symptoms of young patients with psychosis. Välimäki et al. (2012) evaluated the Mobile.Net short message service (SMS) as an intervention to improve treatment for people with schizophrenia. The impact of the intervention is that it allowed customized messages to facilitate medication adherence and follow-up.

Maintaining Mindfulness

Maintaining mindfulness is one of the goals of researchers working on technology to support mental disorder. For example, Sanchez et al. (2015) developed a mobile app to help older people maintain mindfulness, while Wolf et al. (2016) investigated user actions on their phones to determine mindful-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ness in depressed patients. Garcia et al. (2017) also developed an app to train people on mindfulness and improve their mental health. Lee and Jung (2018) evaluated the effectiveness of a mindfulness-based app ("DeStressify") to support university students with mental health challenges.

Monitoring and Management of Patients with Schizophrenia

Ben-Zeev et al. (2016) found that mobile phones can be used by clinicians to engage patients in the management of schizophrenia in distant locations. Wang et al. (2016) evaluated crosscheck, a mobile app for the early detection of schizophrenia.

Monitoring Patients with Parkinson's Disease

Cancela et al. (2016) proposed the development of a mobile app to support different specialists in monitoring patients with Parkinson's disease.

Monitoring of Anxiety

Lipschitz et al. (2019) indicate that patients are willing to use mobile apps for monitoring of anxiety. mHealth tools have also supported patients suffering from anxiety. For example, Firth et al. (2017) presented the use of smartphones to alleviate anxiety. Some mobile apps have been developed to support patients with anxiety, for instance, Stoll et al. (2017) and Almadovar et al. (2018) used a mobile app to manage anxiety in young people. Harrison et al. (2011) assessed the efficacy of mobile apps to improve anxiety and low mood, which contains an SMS reminder. Using a mobile app, Teng et al. (2018) enforced an attention training mechanism to improve anxiety symptoms among people between the ages of 20 and 35 years old.

Borderline Personality Disorder and Self-Injury

Lederer et al. (2014) developed a prototype for developing a mobile app for borderline personality disorder and self-injury. Stallard et al. (2018) evaluated BlueIce, a mobile app to encourage activities that boost young people's mood and as such discourage them from engaging in self-harm behaviours.

Cognitive Behavourial Therapy Sessions

A mobile app was developed to facilitate cognitive behavioral therapy sessions between patients and their therapists (Michelle, Jarzabek, & Wadhwa, 2014).

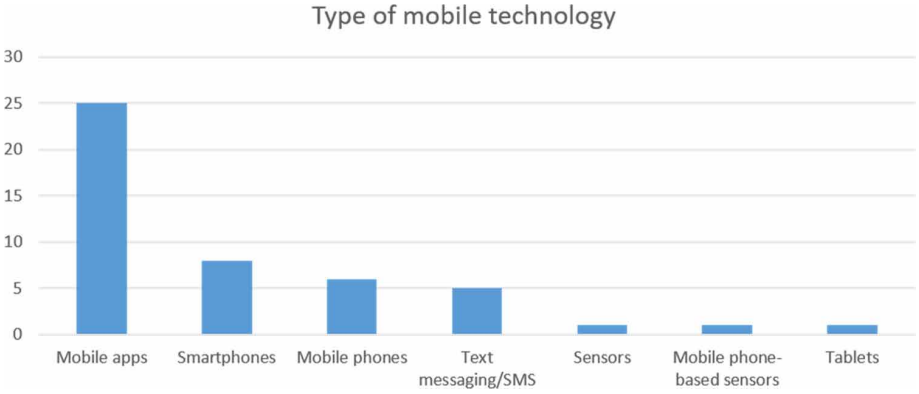
Rehabilitation

Rizia et al. (2014) developed a mobile peering app, iPeer, to aid in the rehabilitation of veterans to facilitate mental help.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Improving the Quality of Care in Child Mental Health Treatment

mHealth tools have also been applied to the care of children with mental health problems. An example is the use of tablet technology to provide trauma–focused cognitive-behavioral therapy for children (Davidson et al., 2019).



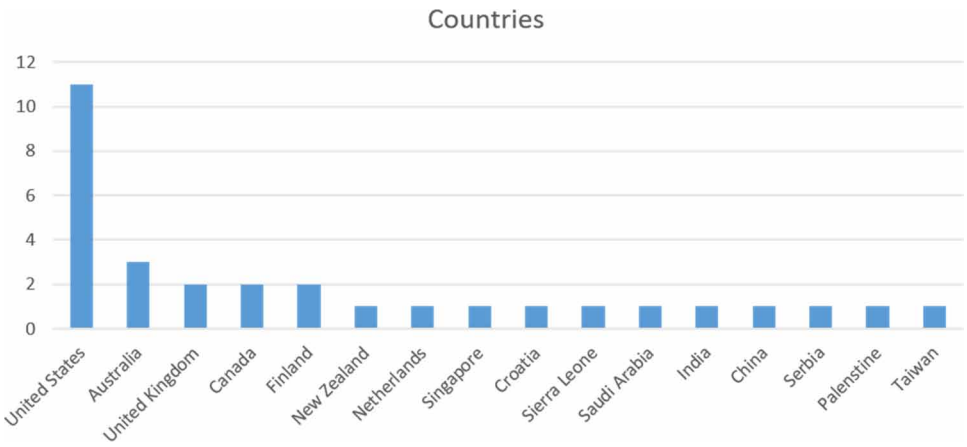
General Mental Health

Mobile apps have been used generally to support and monitor patients with mental illnesses (Tuli et al., 2016). Such apps include recording of disabilities caused as a result of mental health issues (Hebert et al., 2016). Washington et al. (2015) further suggest a method for conducting mHealth trials with mobile apps. Studies have evaluated how patients with mental health issues use mobile apps (Torous et al., 2018; Atallah et al., 2018) and it was identified that the use of mobile apps for mental health is low when patients are out of the hospital. The benefits and challenges of using mobile apps for mental health have also been discussed (Brian & Ben-Zeev, 2014; Jain et al., 2015). Feasibility studies on the use of mHealth apps for mental health in countries such as Finland and Palestine have been conducted (Simila et al., 2018; Ben-Zeev et al., 2017). A mobile app was community co-designed to assist the youth in addressing their mental health issues (Waterman et al., 2018). Other areas of study include the development of a mobile app to monitor side effects of psychotropic medications (Rojnic et al., 2018) and the use of a mobile app to aid the collection of research data for mental health research. Mobile phones have also been used to aid the treatment of patients with serious mental illness to support their full recovery (Noel et al., 2019), to reduce stress (Mak et al., 2019) and for mood reporting (Morris et al., 2010).

RQ 3: What are the Different Types of mHealth Technologies and Applications That Have Been Employed in Mental Healthcare Intervention?

To answer this research question, we grouped the technology types we identified in the literature. However, some articles we identified in the search did not state explicitly the type of technology used (Torri et al., 2015; Cancela et al., 2015). The mobile technologies which have been used to support mental health include mobile apps, smartphones, text messaging/SMS, mobile phones, sensors and mobile phone-based sensors. mHealth technologies and applications for mental health intervention are presented in Figure 3.

Figure 3. mHealth tools and technologies used for mental health intervention



EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

RQ 4: In What Settings Have Mobile Technologies Been Applied in Mental Healthcare Intervention?

Several articles did not indicate the settings where the studies were conducted. However, some studies mentioned the United States (n=11), Australia (n=3), or the United Kingdom, Canada and Finland (n=2 for each). Other countries such as Taiwan, Singapore, Sierra Leone, New Zealand, Saudi Arabia, India, Croatia, China, Serbia, Palestine, and Netherlands were the settings for single studies exploring mHealth for mental health. The number of countries in which mHealth for mental health intervention have been discussed is illustrated in Figure 4.

Figure 4. Countries in which mHealth for mental health have been discussed

RQ 5: What are the Main Publication Outlets for Publishing Research on mHealth for Mental Health?

The majority of studies on mHealth for mental health have been published in journals (n=36), while other studies have been presented at conferences which are depicted in Table 1.

DISCUSSION

This chapter assessed literature on the use of mHealth tools for mental health conditions, to inform the current publications trends, research gaps in the existing literature and identify future research agenda that can help address the research gaps identified. This chapter, thus, contributes to the literature on mHealth for mental health by mapping out the current trends of published research on the subject.

This chapter found that research on mHealth for mental health has evolved over the last decade. The findings suggest there is a progressive growth in the mobile mental health research domain (Torous et al., 2018; Ranney et al., 2018; Chu et al., 2018; Niendam et al., 2018; Atallah et al., 2018). The findings on the publication trends in the last decade suggest a slight decline in 2012 and 2013. This could be as a result of our inclusion and exclusion criteria; as such, the authors could not find relevant papers for that period. This shows that research on mHealth for mental health is emerging. The findings also show that mHealth has been used to monitor and manage different mental health disorders such as depression (Osma & Plasma, 2014), schizophrenia (Ben-Zeev et al., 2016), anxiety disorder (Firth et al., 2017), psychosis (Niendam et al., 2018) and bipolar disorder (Torri et al., 2015).

Mobile technologies have also been used for prediction of mental disorders as well as tracking compliance to medications as well as to identify the side effects of certain medications (Menon et al., 2018; Burns et al., 2011). However, there was a lack of studies on the use of mHealth for a variety of mental disorders, such as eating disorders, obsessive-compulsive disorder, post-traumatic stress disorder and seasonal affective disorder. These areas of mental health disorders represent some of the mental health disorders where mHealth research is lacking. However, mHealth may be of potential value in monitoring and treatment of these mental disorders. Furthermore, there was a lack of research on using mHealth as a strategy for addressing the mental health and well-being of patients in displaced communities, victims of sexual and gender-based violence, especially in low-resource settings.

Various mHealth technologies and tools have been used to support mental health. Examples include text messaging/SMS (Harrison et al., 2011). This represents the easiest way of providing mental health service. Text messaging/SMS is often used to inform and remind patients of appointments or to improve drug adherence (Menon et al., 2018). mHealth can thus be used to facilitate medication adherence among patients, thereby improving the efficiency of mental health care. Mobile applications have also been heavily used for mental health care as evidenced by the findings. Mobile apps, thus, show great potential for development in mental health care. Mobile apps facilitate a wide range of activities such as tracking and early detection of mental illnesses. The difference between mobile apps and other forms of mHealth tools and technologies is that mobile apps are often programmed, to perform specific functions, using algorithms and models, such as machine learning and deep learning. The importance of such algorithms is that they are useful for diagnosis, prediction and prescriptive analysis, offering more capabilities for mHealth in mental health. However, such technologies can mostly be used in urban areas, where people have access to smartphones. Hence, more research should focus on improving the capability of basic mobile phones to perform specific functions to support mental health care.

Mobile phone-based sensors show great potential for mental health. However, the literature suggests that they are seldom used probably because it is a new and emerging area. Researchers can make use of mobile phone-based sensors to optimize mental health care as these sensors can be used to collect relevant data which can be helpful in the early diagnosis and detection of mental health problems (Wang et al., 2016).

Studies on mHealth for mental health has been conducted in various contexts, although the contexts were not mentioned in the majority of the studies. Countries, where mHealth for mental health have been discussed included the United States, United Kingdom, Singapore, Australia, Netherlands, New Zealand, Canada, Finland, Croatia, Sierra Leone, Saudi Arabia, China, India, Taiwan, Serbia, and Palestine. Nine of these countries represent high-income countries. Low-income countries should endeavor to carry out and publish research on mHealth tools for mental health care, as mobile phone penetration is high in these countries (James, 2010), and there is a great need for mental health support as the majority of developing countries often lack mental health resources such as skilled staff, health information systems and ability to capture data for research and mental health service improvement (Bruckner et al., 2011).

The findings of the study show that more papers on mHealth for mental health have been published in journals than conferences, which is similar to other fields where publications rates in journals are much higher than publications in conferences (Iyawa et al., 2019).

The application of mHealth for mental health shows that patients can be empowered to manage their health. This provides a different perspective on how the responsibility of healthcare can be shared between the healthcare practitioner and the patient. mHealth tools can significantly improve the healthcare

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

process as patients are given the opportunity to take part in the diagnosis and monitoring of their health and provide early diagnosis and monitoring of mental health related diseases.

CONCLUSION

In conclusion, this chapter assessed the publication trends of studies exploring mHealth for mental health. The chapter also highlighted the years of active publications, countries in which active research on mHealth for mental health was conducted in the last ten years, areas of research on mHealth tools for addressing mental health disorders, specific mHealth tools and technologies, and publication outlets for disseminating the findings on the subject. This chapter, therefore, suggests that mHealth tools and technologies have indeed, been used for development in mental health as these tools have facilitated treatment and management of mental health conditions.

This study was, however, limited in some ways. First, our findings were based on a search from 2009 to 2019; as such, this might have put a constraint on the publications included in this study. We might have excluded relevant papers as we used only five academic databases. We might have excluded some essential findings from Masters and PhD theses as our inclusion and exclusion criteria did not permit these studies. The keywords we used might have also put a constraint on the papers retrieved.

The authors, therefore, based on the gaps and challenges identified in the current research, recommend mHealth research in other areas of mental health such as obsessive-compulsive disorder, post-traumatic stress disorder and seasonal affective disorder.

The findings from the literature search suggest that text messaging and SMS have been used for mental health intervention. Although mobile apps seemed to be more popular, text messaging and SMS could be a cost-effective approach and relevant in rural areas where the majority of the population do not have access to smartphones.

The findings of this chapter indicate that there is less research in the application of mHealth tools and technologies for mental health intervention in developing countries, and as such, researchers should focus on conducting research in these countries, owing to the huge potential benefits in reducing treatment gap in low-resource settings.

KEY TERMS AND DEFINITIONS

Digital Health: Digital health is an "improvement in the way healthcare provision is conceived and delivered by healthcare providers through the use of information and communication technologies to monitor and improve the wellbeing and health of patients and to empower patients in the management of their health and that of their families" (Iyawa et al., 2016a, p.246).

Digital Health Innovation Ecosystems: Digital health is a "network of digital health communities consisting of interconnected, interrelated and interdependent digital health species, including healthcare stakeholders, healthcare institutions and digital healthcare devices situated in a digital health environment, who adopt the best-demonstrated practices that have been proven to be successful, and implementation of those practices through the use of information and communication technologies to monitor and improve the wellbeing and health of patients, to empower patients in the management of their health and that of their families" (Iyawa et al., 2016a, p.249).

Mental Disorder: A mental disorder is a "syndrome characterized by clinically significant disturbance in an individual's cognition, emotion regulation, or behavior that reflects a dysfunction in the psychological, biological, or developmental processes underlying mental functioning" (American Psychiatric Association, 2013, p. 20).

Mental Health: Mental health is "the state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community" (WHO, 2014).

Mobile Apps: Mobile apps refer to a software program designed to run on mobile devices.

Mobile Health (mHealth): mHealth is the use of any mobile device including mobile phones, smartphones, mobile or phone-based sensors for providing and receiving healthcare services such as healthcare monitoring, diagnosis, management and prediction of diseases.

Mobile Technologies: Mobile technologies refer to portable hand-held devices used for communication purposes.

Psychosis: Psychosis is the "presence of delusions, hallucinations without insight, or both" (Arciniegas, 2015, p. 717).

Systematic Mapping Study: A systematic literature review aims to "map out and categorize existing literature on a particular topic, identifying gaps in research literature from which to commission further reviews and/or primary research" (Grant and Booth, 2009, p. 97).

Text Messaging: Text messaging refers to the use of mobile devices to compose messages which can be sent to another party through a telecommunication channel.

Chapter 13
Kindness Makes a Difference: Assessing the Efficacy of Addy & Uno, an Off-Broadway Musical, and the Realabilities Educational Comic Book Series Curriculum in Enhancing Children's Kindness, Empathy, and Interest in Their Peers With Disabilities and Mental Health Disorders

Nava R. Silton
Marymount Manhattan College, USA

Patrick Riley
Marymount Manhattan College, USA

Amanda Anzovino
Marymount Manhattan College, USA

ABSTRACT

High quality interventions, which employ an extended contact model, wherein stories, roleplaying, and other appealing informational media are used to promote more positive intergroup attitudes, tend to be effective at enhancing the attitudes, intentions, and interests of typical children toward their peers with differences. The following four studies assess the efficacy of The Realabilities comic book series and the Addy & Uno off-Broadway musical, which promote kindness, empathy, and a stop-bullying platform while teaching about disabilities and/or mental health disorders. The studies include 1) a qualitative study of 19 fourth grade students from an elementary school in Paramus, NJ, who viewed the Addy & Uno off-Broadway musical and participated in the full Realabilities educational comic book series intervention; 2) a qualitative study of 20 high school students with diverse disabilities, who participated in the full Realabilities comic book series intervention; 3) a quantitative study of 76 students from a high

school in Long Island City, NY, who read the first mental health-based Realabilities comic book; and finally, 4) a quantitative study of 66 students from a high school in Long Island City, NY, who read the first and second mental-health based Realabilities comics. The researchers used a coding system to find principal themes in the qualitative data and used modified versions of the adjective checklist (ACL) and shared activities questionnaire (SAQ), along with a knowledge measure, to assess quantitative changes from pre to post-testing of the comic book series. Study findings help support the efficacy of an extended contact model and suggest that programs like these may serve as useful antidotes to counter negative attitudes of children and adolescents towards disabilities and mental health disorders, respectively.

INTRODUCTION

According to the Centers for Disease Control and Prevention (CDC) (Okoro, Hollis, Cyrus, & Griffin-Blake, 2018), 1 in 4 adults in the United States is currently living with a disability. Despite the fact that twenty-five percent of American adults have a disability, disabilities are rarely showcased favorably on TV and in the media. Unfortunately, when individuals with disabilities are depicted in the media, they are often being portrayed in an odd, pathetic or poor fashion. It is critical to change the landscape and to focus less on a deficit-based model of disability and more on the refined and unique abilities and strengths individuals with disabilities possess, since they are continuously seeking creative solutions and "work-arounds" to succeed in life (Respectability, 2018).

Children and Disabilities

Recent statistics suggest that from 2013-2014, 95% of all children and youth between the ages of 6 and 21, who were accommodated by IDEA, were enrolled in typical schools (National Center for Education Statistics, 2016). Moreover, the number of students who spent the lion's share of their school day (80% or more time) in regular education classrooms increased from 33% from 1990-1991 to 62% from 2013-2014 (NCES, 2016). This significant rise in just over a decade, suggests that regular education schools will need to be increasingly well-equipped to accommodate students with disabilities in the typical classroom. Research suggests that simply including children with disabilities in the classroom does not ensure that typical children will increase their interest, positive attitudes, intentions and socialization with individuals with disabilities. In contrast, high quality interventions that effectively educate typical children about disabilities and encourage children to befriend individuals with disabilities are critical towards fostering attitudes, intentions and promoting the socialization of typical children toward their peers with disabilities (Silton, 2015; Vignes et al., 2009). Moreover, if programs are not created to promote acceptance and social integration, then children with disabilities will be less accepted by their typically developing peers in the classroom (Favazza, Phillepson, & Kumar, 2000). Research consistently reveals that students with disabilities are not only more vulnerable to negative attitudes (Nowicki & Sandieson, 2002), but are less accepted, have fewer peers, socialize less frequently, and report more loneliness than their typical peers (Bossaert, Colpin, Pijl & Petry, 2011). Various research studies note the importance of establishing learning standards which focus on the development of social skills and social competence skills, rather than focusing exclusively on the acquisition of academic competencies like literacy and mathematics (Scott, Little, Kagan & Freelow, 2006; National Research Council, 2001)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in the classroom. Asher and Coie (1990) reveal that peer interactions are key ingredients towards developing social skills during childhood.

Already by preschool, children can form and enhance their repertoire of peer-related social skills (Odom et al., 2006). Unfortunately, even in high quality inclusion programs, children with disabilities appear less likely to get selected when children's play partner preferences are not predetermined by the instructors' planned activities or by the program structure (Guralnick, 1999). This aligns closely with research suggesting that typical children are more likely to select a typical doll as a play partner than a doll with a disability (Odom et al., 2006). Since preschool-aged children are already capable of identifying a child with a physical disability compared to a typically-developing peer (Diamond, 1994) and since children's experiences in preschool are likely to inform their reasoning about inclusion (Diamond & Stacey, 2000), it is critical that interventions enhance children's attitudes, intentions and knowledge of disabilities as early and as effectively as possible.

Stigma Towards Mental Illness (Anxiety and Depression)

Current statistics indicate that anxiety disorders occur in 32% of adolescents between the ages of 13 to 18 and depression occurs in approximately 13% of adolescents between the ages of 12 to 17 (NIMH, 2017; SAMHSA, 2017). Similar to disabilities, individuals who present with a mental illness often experience stigmatization, in the form of negative attitudes, which can have adverse effects on their health, social identity, and overall quality of life (Silton, Flannelly, Milestein, & Vaaler, 2011). Stigmatization directed at individuals with mental health disorders can be communicated in numerous ways and can result in the stigmatized individual being socially isolated and labeled with unwelcome attributes that separate them (Goffman, 1963). Social discrimination and stigma towards mental illness remains an issue among adolescents (Corrigan, 2004; Corrigan, Dremming, Goldman, Slopen, Medansani, & Phelan, 2004). In fact, a common barrier for adolescents seeking treatment is the stigma associated with mental illness (Clement, Schauman, Gram et al., 2015).

Mental health literacy is defined as having knowledge and an understanding of mental illnesses which assist in preventing or managing disorders (Jorm, Korten, Jacomb, Christensen, Rodgers, & Pollitt, 1997). Mental health literacy has five major components: 1) knowing how to prevent mental illness, 2) recognizing the development of a mental illness, 3) knowledge of treatment opportunities, 4) knowledge of self-coping mechanisms, and 5) first aid skills to support others with mental illness (Jorm, 2012). Jorm (2012) notes that an integral part of mental health literacy, is to connect knowledge to action in order to benefit oneself or others. This relates to adolescents since research has found that adolescents who recognize mental illness tend to be more successful at seeking help and finding treatment (Wright, Jorm, Harris, & McGorry, 2007). The present authors have used the theory of mental health literacy to expand the goals and content of *The Realabilities Comic Book Curriculum Series* by including new comics on mental health disorders for adolescents, rather than solely developing comics featuring disabilities for children. The researchers added *Got Talent* (which teaches about Anxiety and Depression) and *The Carnival* (which teaches about Generalized Anxiety Disorder, Obsessive Compulsive Disorder, and Specific Phobias) to *The Realabilities Comic Book Series* and to the adjoining companion manuals.

The Importance of Teaching Social Emotional Skills and Kindness to Children

Researchers have discovered that programming which aims to foster students' social-emotional skills can positively impact their academic, health and social outcomes. It is for this reason that school settings are now shifting towards teaching social and emotional and prosocial learning skills alongside traditional academics. Social Emotional Learning (SEL) involves identifying and managing emotions, caring about others, making good decisions, behaving ethically and responsibly, developing positive relationships and avoiding negative behaviors (Binfet & Schonert-Reichl, 2015). Similarly, prosocial behavior is important within school contexts, since schools are settings where frequent interpersonal interactions occur among individuals from diverse socioeconomic, social, and ethnic backgrounds and where interpersonal conflict can be prevalent (Binfet & Passmore, 2017).

More specifically, there appears to be an increased interest in examining the construct of kindness, since it is now deemed to be a "valuable socio-emotional skill" (Kaplan, DeBlois, Dominguez, & Walsh, 2016). For this reason, a variety of programs are now being developed to emphasize the importance of teaching kindness lessons in the school system. For instance, all of the following programs attempt to implement Kindness Education Programs: The Random Acts of Kindness in the Classroom Program (The Random Acts of Kindness Foundation, 2015), The Center for Investigating Healthy Minds' Mindfulness-based Kindness Curriculum (Flook, Goldberg, Pinger & Davidson, 2015) Think Kindness (Think Kindness, 2015), and The Ben's Bells Kindness Campus Program (Ben's Bells Project, 2015). More specifically, The Kind Campus Program, a widely-implemented school-based kindness education program that employs a bottom-up program framework, attempts to educate the full school community (students, families, faculty and staff) about the positive effects of kindness and to empower the community to cultivate kindness within and beyond the school walls. Using the Kind Campus Model, a study was conducted with a large number of school professionals and students from 50 schools in Tucson, Arizona to help develop school-based models to help teach kindness in schools. The research suggests that effective kindness education programs would afford students, faculty and staff a common language to discuss kindness and offer a framework that would encourage members of the school community to recognize acts of kindness occurring around the school and to practice kindness towards themselves and towards others (Kaplan et al., 2016).

An additional study specifically looked at the school kindness perceptions of 257 Kindergarten through twelfth grade teachers. Teachers were challenged to define kindness, to offer examples of kindness they had performed and received, to pinpoint key agents of kindness and to rate the quality of kind acts in their schools. Overall the findings revealed that teachers contend that they have a strong to moderate impact on shaping students' kindness and teachers' perceptions of school kindness tend to vary based on the grade they are teaching. Moreover, the research suggested that teachers' beliefs about prosocial behaviors, such as kindness, as well as practicing kindness as part of their professional role, may have far-reaching implications for teacher job satisfaction, and for teacher-student rapport, which could affect learning and the overall school climate (Binfet & Passamore, 2017)

Another study examined the psychometric properties of The School Kindness Scale (SKS) in a sample of 1,753 students from fourth through eighth grade, who were attending public schools in the large school district of Southern British Columbia, Canada. The researchers discovered that the School Kindness Scale (SKS) was significantly and positively associated with teacher reports on students' empathy, social skills and peer acceptance. With respect to gender and grade findings, girls perceived higher levels of kindness in school than boys and students' perceptions of kindness in school diminished from

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

fourth to eighth grade, wherein fourth-grade students reported the highest perceptions of kindness in school compared to eighth graders, who reported the lowest levels of kindness. Moreover, the research revealed that the extent to which students perceive kindness as a commonly occurring aspect of school is a reflection of a broader learning context; wherein students' perceptions of kindness may indicate the level to which the school context fosters underlying conditions that support student development and learning (Binfet & Schonert-Reichl, 2015).

Moreover, a later study (Retnowati, Agoes Salim, & Saleh, 2017) examined whether or not picture books could help teach kindness to 31 five and six year old children from a Kindergarten in Bandung, Indonesia. The intervention was conducted by reading eight picture books to the 31 children over an eight day time frame. The storybooks helped describe kindness behaviors, including helping behaviors and cheering up friends. The storylines were simple, sequential, predictable, and offered clear examples of kind behaviors that could be performed every day. Kindness was measured by utilizing an instrument the researcher created, which involved showing nine colorful cards that described the kindness behaviors to children. Kindness was additionally assessed by reviewing the kindness tree and observation sheets the teachers filled out. Data analysis, employing the Wilcoxon Signed-Rank Test, revealed a significant positive change in the average score of kindness at the $p < .05$ level after the stories were read. Two weeks following the intervention, there were significant improvements on both the card test and on the kindness tree and observational sheets following the intervention (Retnowati et. al, 2017).

Similar to the success of the children's picture books in the aforementioned Retnowati et al. (2017) study, the present authors created the prosocial *Realabilities Comic Book Series Curriculum* to teach kindness and empathy to typical children and adolescents towards children with disabilities and towards individuals with mental health disorders, respectively. Pre and post-test assessments have been utilized at each stage of development to assess the efficacy of these literary interventions.

Key Ways to Enhance Kindness in Children

In addition to the benefits of literary resources, recent work by Harvard psychologist, Richard Weissbourd, who runs the *Making Caring Common Project*, suggests five key ways to raise kind children. A recent *Washington Post* article reviewed Weissbourd's work and shared his five essential ingredients for raising kind children, 1) Make caring for others a priority, 2) Provide opportunities for children to practice caring and gratitude, 3) Expand your child's circle of concern, 4) Be a strong moral role model and mentor, and 5) Guide children in managing destructive feelings.

With respect to the first ingredient, the research suggests that parents need to teach their children about the balance of their own desires and the desires of others. Parents should directly reinforce the importance of being kind and should ensure their children are acting respectfully, even when their children may be in angry or in upset moods. Parents can also visually express how to care for others by introducing children to additional adult figures in their lives.

In terms of the second ingredient of offering opportunities for children to practice caring and gratitude, the author suggests that children should practice being caring to others and showing others gratitude. A plethora of studies reveal that those who express gratitude are often more likely to be happier in life. Rather than rewarding children each time they do something positive, try to make "doing good" a daily activity and habit for children. Parents can also highlight expressions of kindness and caring on TV, in the movies and in books for their children.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

With regard to the third ingredient of expanding your child's circle of concern, the author stresses how important it is for children to care about individuals beyond those in their immediate peer group. Encouraging children to look outside of their inner circle will afford them a better perspective of caring for others in the world around them. It is especially beneficial to encourage children to be helpful to those who are most vulnerable (Joyce, 2019). In fact, a renowned twentieth century philosopher, Emmanuel Levinas (1905-1995) suggests that individuals can reach their highest ethical authority when they help those who are most vulnerable, "the widow, the orphan, the stranger," or those with other vulnerabilities. Showing children TV news, periodicals or other stories can teach them about the diverse problems children may encounter around the world (Joyce, 2019). *The Realabilities Educational Comic Book Series Curriculum* seeks to employ an extended contact model through which to increase positive intergroup attitudes by teaching typical children and adolescents about disabilities and mental health disorders to enhance their knowledge, attitudes and behaviors towards those who may not initially be in their inner circle.

The fourth ingredient of encouraging parents to be strong moral role models and mentors for their children suggests the importance of observational learning and Social Learning Theory. Children learn a number of diverse behaviors and attitudes from observing adults, especially their parents. Parents have an opportunity to showcase honesty and fairness to their children and to model how to volunteer and give back to the community (Joyce, 2019).

Finally, the author suggests that parents should guide children in managing their destructive feelings. For instance, children may become overwhelmed by negative emotions like anger or envy and parents have an opportunity to teach their children helpful coping skills to best address these emotions (Joyce, 2019). One coping skill might be to teach children how to breathe and remain calm, for instance to tell children to "breathe in the roses and blow out the candles" to better help children relax and address head-on the struggles of the day.

Empathy

In addition to kindness, empathy, another critical social-emotional construct, relates to stepping into the shoes of another person and to perceiving and understanding the emotions that other individuals are experiencing (Dziobek, Rogers, Fleck, Bahnemann, Heekeren, Wolf, & Convit, 2008). Empathy involves both cognitive and affective components. *Cognitive Empathy* refers to how well one can *comprehend* another's emotions and *Affective Empathy* relates to how well one can *experience* another's emotions (Van Noorden, Haselager, Cillessen, and Bukowski, 2014). Empathy enables individuals to perceive the world through their peers' lenses. The ability to understand the attitudes and feelings of others is paramount toward establishing meaningful relationships and successful, prosocial behaviors with others (Dziobek et al., 2008). Individuals with higher levels of empathy are often more likely to help others or to pursue prosocial acts (Eisenberg, Eggum, & Di Giunta, 2010). It is therefore critical to cultivate empathy during childhood, since this critical period of development can lead to life-long behaviors.

However, empathy is a fundamental human characteristic that can impact both prosocial and antisocial behavior. Unfortunately, bullying has become one of the most common antisocial behaviors in children. It is thought that the principal motivation behind bullying is the power imbalance that exists between the bully and victim. Bullying can be manifested through verbal, physical or relational means or through cyberbullying. Many believe that those who bully, struggle with lower levels of empathy and therefore, many bullying prevention and intervention efforts have sought to include empathy training.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

For instance, individuals with disabilities are unfortunately two to three times more likely to be victimized by bullying behaviors than their typical peers. This increased vulnerability may be due to a lack of empathy and understanding of the differences associated with disabilities or of what causes these differences. When children glean a clearer awareness and understanding of differences, they are able to enhance their knowledge and sensitivity and to improve their attitudes and intentions towards individuals with disabilities, mental health disorders or other differences.

Aligned with this notion, Van Noorden, Haselager, Cillessen, and Bukowski (2014) conducted a study to determine the relationship between cognitive (mental) and affective (emotional) forms of empathy and bullying behaviors. After a search of 40 empathy studies (24 cognitive and 38 affective) associated with four forms of bullying (bullying, victimization, defending, and bystanding), there appeared to be a negative correlation between empathy and bullying (the higher the empathy, the lower the bullying behaviors). *Bullying* was found to be negatively correlated with both cognitive and affective forms of empathy. More specifically, *defending* was positively correlated with both cognitive and affective empathy, *victimization* was negatively correlated with cognitive empathy and *bystanding* had mixed results. While future studies in this field would be helpful, the current study offered a foundation for improving bullying prevention and intervention programs (Van Noorden et al., 2014).

As an intervention, *The Realabilities Comic Book Series* and the *Addy & Uno Off-Broadway Musical* were created to enhance children's knowledge and empathy towards the unique life circumstances of individuals with disabilities and now mental health disorders, as well. The *Realabilities Curriculum* attempts to increase a child's level of empathy through the engaging lessons incorporated into each storyline that accentuate prosocial values through each character's inner strengths and abilities. Children, as readers and as musical audience members, are able to empathize, since they can envision themselves within the characters and within the rich character experiences. These immersive, empathic opportunities are achieved through the creative media of musicals and graphic storytelling, which align closely with the strength and efficacy of the extended contact model.

Extended Contact Model

Since even high-quality inclusion may cause segregation among typical children and children with disabilities or children with mental health disorders in a classroom, it is useful to consider additional forms of instruction to enhance typical children's understanding, attitudes and intentions towards their peers with disabilities or mental health disorders.

The extended contact hypothesis posits that knowledge that an in-group member has established a close relationship with an out-group member may promote more positive intergroup attitudes (Wright, Aron, McLaughlin-Volpe, & Ropp, 1997). Typical children can benefit strongly from extended contact, since it offers them knowledge of individuals with disabilities or mental health disorders (the out-group) without the anxiety that initial, direct contact may introduce (Pettigrew & Tropp, 2000; Stephan & Stephan, 1985, as cited by Cameron & Rutland, 2006). Stated differently, extended contact can enhance typical children's ("the ingroup's") positive attitudes and knowledge of individuals with disabilities or mental health disorders ("the outgroup"), before children with differences enter the mainstream classroom. In fact, Favazza and Odom (1997) discovered that extended contact had a significant, positive effect on outgroup attitudes (improved attitudes of typical children towards children with disabilities) but not on in-group attitudes (typical children towards typical children). Therefore, learning about differences before students directly interact with their peers with special needs or mental health issues can be more

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

beneficial than actual contact since it reduces the potential for a "backlash effect," if typical children experience anxiety when they first meet their new peers with differences (Paoloni et al., 2004).

Similarly, in England, Cameron and Rutland (2006) explored the efficacy of an extended contact prejudice-reduction intervention in enhancing typical children's attitudes towards children with disabilities. The researchers learned that when group boundaries are maintained and typicality or similarity is emphasized, the extended contact model was more effective and led to the most robust change in typical participants' attitudes towards children with disabilities (Cameron & Rutland, 2006). Therefore it appears that an Intergroup Extended Contact Model, wherein typical children are taught about the realities of disability through story-telling, role-playing or drama (Campbell et al., 2003) that emphasize the similarities and strengths of their peers with disabilities (Cameron & Rutland, 2006) may be a critical antidote to the increasingly negative relationship between age and attitudes towards children with disabilities (Campbell, Ferguson, Herzinger, Jackson, & Marino, 2004; Bell & Morgan, 2000; Morgan & Wisely, 1996). This aligns with research that reveals that story-time is a naturalistic strategy for providing information about individuals with disabilities since it is a typical feature of the kindergarten class routine (Favazaa & Odom, 1997). In addition, activities like roleplays, drama and storytelling help students empathize with the "outgroup" and makes them more likely to disapprove of bullying (Silton, Arucevic, Ruchlin, & Norkus, 2013; Pepler et al., 1993).

The Benefits of the *Realabilities* Comic Book Series Medium for Effective Storytelling

It is instructive to consider the appealing and creative medium of comic books for relaying critical messages related to disability awareness, mental health awareness, and a stop bullying platform in and out of the school environment. Comic books have differentiated themselves from traditional books due to their appealing and creative characteristics. Children may struggle with motivation or may experience difficulty focusing on reading, which can challenge their retention of information from the text (Versaci, 2001). This can often cause the child to feel defeated and frustrated about reading. Comic books offer an engaging alternative to traditional books, since they capitalize on visual aids to enhance the accompanying text. The combination of text and images within comic books provide the dual processing of images and words for the reader, which helps the reader to gain the valuable skill of formulating an inference to follow the storyline (Versaci, 2001).

Comic books are valuable tools in and outside of the classroom, since they help children establish a foundation on which to build their literacy and critical thinking skills (Versaci, 2001). In addition, comic books enable creators to channel their boundless creativity throughout the design and layout of the comic (Silton, 2016). The immersive and creative nature of comic books coupled with their storytelling capacity and literary appeal, prompted the creation of *The Realabilities Comic Book Series Educational Curriculum*. Sharing the adventures of the *Realabilities* characters through the visual form of comic books encourages children to empathize or to immerse themselves in the characters' experiences and enhances their disability and mental health knowledge. This nuanced understanding of disabilities and most recently mental health disorders ultimately leads to more positive cognitive attitudes and behavioral intentions towards the protagonists with disabilities and mental health disorders in the series. *The Comic Book Companion* and *Disability in Depth Manual,* the teaching manuals that supplement the *Realabilities Comic Book Series Curriculum*, further extend these important lessons about disabilities

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and mental health disorders in the classroom and offer richer learning experiences and positive outcomes for typical students and students with disabilities and mental health disorders, alike.

Previous Peer Education Programs

Beyond literary works, a variety of creative peer education programs have been developed over the years in order to enhance typical children's knowledge and positive attitudes towards children with disabilities through direct or indirect exposure using storytelling, role-playing or other techniques. Another form of storytelling, puppetry, has been identified as a potential promising approach toward improving attitudes and knowledge towards disabilities due to its capacity to inspire a large number of students and to be relatively cost-effective (Bernier, & O'Hare, 2005). Additionally, Trimingham (2010) suggests that puppetry also has a host of other benefits. She intimates that puppetry has been exceptionally useful in explaining the etiology of maladjustment in childhood and serves as a significant therapeutic technique through which children can learn to comprehend the complexities of deviating behaviors and to discover more successful solutions. The researchers also note that puppets can help children confront an externalization of themselves, wherein their focus can shift away from their closed, inner worlds and can accommodate another to share in their perception of the world (Trimingham, 2010; Woltmann, 1951). Additionally, Felisa Weiss (as cited in Trimingham, 2010) suggests that "The puppet acts as an intermediary, the projective object that absorbs both the interviewer and interviewee's vectors." (Trimingham, 2010; Weiss, 1998) Finally, Schummann suggests that the material nature of his puppets makes the puppets speak for themselves. Thus the object of the puppet speaks and there is no distortion by the intruding ego of the performer (Trimingham, 2010).

Limited Efficacy of Previous Puppet Show Interventions

Despite the unique strengths of puppetry, previous puppet show interventions have either shown no or minimal effects in transforming typical children's attitudes towards children with disabilities. Rosenbaum, Armstrong and King (1986) conducted a randomized-factorial-design study to evaluate the impact of two interventions, 1) *A Buddy Program*- offering direct exposure to children with disabilities, and 2) *The Kids-on-the-Block (KOB) Puppet Show Program*-wherein puppets are utilized to discuss disabilities to foster positive attitudes and intentions of typical children towards children with special needs. The researchers revealed that while the Buddy Program appeared efficacious, the KOB Program had no significant effect on any outcomes and actually appeared to reduce the impact of the Buddy Program when used in concert. The researchers noted that this might be a result of the dissonance between the puppets in the KOB intervention and the real-life children with disabilities in the Buddy program. In a later study, Baker (1991) discovered a short-term positive impact of the KOB intervention on elementary school children's attitudes in third through sixth grades, but there appeared to be only minimal long-term effects.

That same year, Thios and Foster (1991) assessed the efficacy of *The New Friends Program,* which utilized life-sized dolls with disabilities to relay important information about disabilities three times per week (25 minutes per session) over a three-week period. The intervention presented four units, including, an introductory unit on differences and similarities, and units on hearing impairment, physical impairment (cerebral palsy) and learning impairment. The researchers discovered that that the New Friends' Program enhanced attitudes and knowledge of disabilities but failed to show robust changes in social interaction patterns towards children with disabilities (Thios & Foster, 1991).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In 2014, Dunst conducted a metanalysis of 26 studies which explored the effects of the Kids on the Block (KOB) and/or *Count Me In Puppet Shows* on elementary school students' attitudes and knowledge of individuals with disabilities. The Kids on the Block (KOB) Puppet Troupe and Count Me In Puppet Troupes introduce puppets representing children with physical disabilities, intellectual disabilities, visual impairments, and hearing impairments. The forty-five-minute puppet shows included scripts to introduce each puppet in order to offer awareness of diverse disabilities and to correct common misconceptions of disability. The show also offered a fifteen-minute question-and-answer session after the show.

Dunst (2014) reviewed studies which included 5,302 participants in the intervention group and 2,642 student participants in the comparison group. The results suggested that the puppet shows had only a mild to medium impact on participants' knowledge and attitudes towards individuals with disabilities. More specifically, first and second grade students showed more robust changes in attitudes towards children with disabilities following the puppet show than their third through sixth grade peers and the effects of the puppet show were somewhat reduced over time. Moreover, students showed greater gains in their knowledge of disabilities than in their attitudes towards children with disabilities (Dunst, 2014). Finally, the researcher delineated the following study limitations, 1) There was a dearth of information pertaining to adherence or fidelity to the puppet show scripts, 2) There was minimal to no information regarding the schools or districts where the puppet show was performed, and 3) There was little description regarding the backgrounds of and manner in which the puppeteers performed the shows. Despite these limitations, similar to the notion of the extended contact model, Dunst (2014) intimated that puppet shows could be useful for transforming elementary students' knowledge of and attitudes towards individuals with disabilities, at least in terms of their initial exposure to individuals with disabilities before misconceptions and misunderstandings arise. Moreover, he recommended combining puppet shows with in-vivo or real-life, situated interactional opportunities with individuals with disabilities to offer an additive positive effect on typical students' knowledge and attitudes towards their peers with special needs.

The *Addy & Uno Musical* seeks to improve upon the Kids on the Block (KOB) and Count Me In Puppet Show Programs and research by offering real-life, situated interactional opportunities, information about adherence to the puppet show scripts, specific information pertaining to the location of the show performances, and a brief description of the puppeteers. *The Addy & Uno Musical* presents innovative, kid-friendly puppets with disabilities that are openly operated by the in-vivo, visible puppeteers, who are assuming the roles of individuals with disabilities. The *Addy & Uno Musical* also utilizes original music to foster children's understanding, recall and appreciation of their peers with disabilities. The puppeteers are also available after each show to answer a plethora of questions from audience members.

Moreover, researchers assessing the *Addy & Uno Musical* intervention and the *Realabilities Educational Comic Book Series Curriculum* are employing key valid, reliable and objective quantitative behavioral intention (The Shared Activities Questionnaire (SAQ); Morgan et al., 1996) and cognitive attitudinal (The Adjective Checklist (ACL); Siperstein & Bak, 1980) measures to evaluate the change in participants' perceptions from before and following the musical intervention and comic book series curriculum. They are also utilizing coding and other qualitative approaches to develop themes in order to attain a richer understanding of the program's impact on disability and mental health knowledge and sensitivity.

The four most recent *Realabilities* studies below include, 1) A qualitative study of 19 fourth grade students from an elementary school in Paramus, NJ, who viewed the *Addy & Uno Off Broadway Musical* and participated in the full *Realabilities Educational Comic Book Series Intervention*, 2) A qualitative study of 20 high school students with diverse disabilities, who participated in the full *Realabilities*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Comic Book Series Intervention, 3) A quantitative study of 76 students from a high school in Long Island City, NY, who read the first mental health-based *Realabilities* comic book and finally, 4) a quantitative study of 66 students from a high school in Long Island City, NY, who read the first and second mental health-based *Realabilities Comics.*

STUDY 1: ASSESSING THE EFFICACY OF *ADDY & UNO*, AN OFF-BROADWAY MUSICAL AND THE *REALABILITIES* EDUCATIONAL COMIC BOOK CURRICULUM IN ENHANCING CHILDREN'S SENSITIVITY AND INTEREST IN THEIR PEERS WITH DISABILITIES USING A QUALITATIVE METHODS APPROACH

Participants

Nineteen fourth grade students, 9 males and 10 females from a Jewish Day School in Paramus, New Jersey participated in the two-part disabilities intervention of *The Addy & Uno Musical* and *The Realabilities Educational Comic Book Curriculum*. All of the students self-reported that they were White and Jewish.

Procedure

The fourth grade students viewed the *Addy & Uno Musical* and participated in *The Realabilities Educational Comic Book Series*. Following the Musical, the students penned qualitative letters to the creators of the musical and reflected on the following: 1) What they enjoyed most about the Musical, 2) What they learned, 3) Whether they felt differently about disabilities and bullying following the Musical, 4) Whether they enjoyed the Musical and 5) Whether or not they would see the show again. Additionally, after reading the 11 *Realabilities Comics,* the students were asked to respond to the following questions: 1) Do you believe it's important for kids to stop bullying? 2) Who was your favorite character in the comic series and why? 3) Which comic book was your favorite and why? 4) What would you like the characters to do in the next *Realabilities Comic book* and finally, 5) Would you buy a Realabilities comic? The students responded to all of the aforementioned questions and the responses were collected, stored in a secure database, coded and analyzed (Please see APPENDIX A for images of the *Addy & Uno Musical* and APPENDIX B for images of *The Realabilities Comic Book Series*).

Results

With respect to appeal, the fourth grade students shared that they most enjoyed "the puppets and thought they were very interesting," "they liked when the bullies decided not to be mean," and "liked when (they) learned a sentence in sign language (during the show)." Moreover, the students "liked when Uno's friends helped him not be nervous" and "enjoyed the songs in the play." Following the Musical, the students noted that they learned "not to treat people differently just because they are different" and that "people aren't as different as we think they are." A large majority of students remarked that they would love to see the show again because it was "AMAZING!" Students also wondered if a second show would be made or if all of the comic books would be incorporated into the show. Finally, the students shared whether or not they enjoyed the Musical and whether or not they would like to view a TV show version of the show

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

again. The lion's share of students said they enjoyed the Musical because it was "funny," "interesting," and "it was fun to watch the songs." Furthermore, students added that the Musical "taught me not to bully" and "helped me to be nice to be people who are different." When asked if they would watch an *Addy & Uno TV show*, the majority of students responded "yes" because they "love the play and (comic) books," they "like Addy and Uno," and "because you can learn a lot from it." One student mentioned that he/she would watch the TV show because "it teaches people to stop bullying" and another student said that the TV show "would make people who have disabilities happy."

Following the comic book series, the majority of students shared why they believe it is important to stop bullying. For instance, some students noted that "bullying can really hurt someone, even if it's not physical," "it affects how the kid being bullied feels about himself," and "because it can hurt people's feelings and (make) it like they're not important to the world." The students also discussed which characters from *The Realabilities Series* were their favorite characters and why. The majority of people liked Addy since she is "energetic and happy" and "she is really nice to people and her friends." Uno was the next highly-rated character since he is "smart" and "likes math." "Math Mania," the comic portraying Uno's preparation for a math competition and the comic that most closely relates to the Musical, was the most popular comic among the students. Students also enjoyed "Math Mania" because "it's about math," "Uno overcomes his fear," and "Uno's friends are helpful and supportive." The next most popular comic the students endorsed was "The Real Goal" because the characters are "kind" and "it involved sports." When asked what the students would like to see the characters do in a subsequent comic book, the students discussed a number of possibilities including "have a pool party and enjoy life," "go to Mars in a real rocket that RJ moves," and participate in more sports like baseball, snowboarding, and basketball." One student also wanted the characters to "tell us how they got their disabilities." Finally, when asked if the students would purchase a *Realabilities Comic Book*, the majority of student participants said they would, while a smaller minority said they would not. A reason for not wanting to purchase a comic was because they "don't like comics." Whereas reasons for wanting to purchase a comic book included "because they are funny," "it teaches kids to stop bullying," and "it could teach you to be nice to people who are different."

Principal Conclusions

Thus, the researchers found that the combination of *The Addy & Uno Off- Broadway Musical* and *The Realabilities Comic Book Series Curriculum* significantly enhanced typical students' nuanced knowledge, interest and understanding of disabilities as well as the importance of promoting a stop bullying platform in their schools. Overall, the study results confirm that an extended contact model, wherein appealing storylines, role-plays and other engaging media can be highly advantageous towards teaching about an outgroup (in this case disability), prior to or in addition to successfully interacting with children with disabilities in and outside of the classroom.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

STUDY 2: THE IMPACT OF THE REALABILITIES COMIC BOOK SERIES CURRICULUM ON A SAMPLE OF STUDENTS WITH DIVERSE DISABILITIES

Participants

Twenty high school students with disabilities (fourteen males [70%] and six females [30%] from Manchester, New Jersey participated in *The Realabilities Educational Comic Book Intervention*. The majority of students identified as White (14; 70%), three (15%) as Other, two (10%) as Latino, and one (5%) as African American. Students presented with diverse disabilities, including autism, visual impairment, obsessive compulsive disorder (OCD), physical impairment, seizure disorders, intellectual disabilities, and/or with behavioral limitations.

Procedure

The students participated in the full *Realabilities Comic Book Series Curriculum* (11 comics featuring 11 disabilities, discussion questions and activities) and then responded to the following questions: 1) What did you learn from *The Realabilities Comic Book Series*? 2) Who was your favorite character in the comics and why? 3) Which comic was your favorite and why? 4) What would you like the characters to do in the next comic? and 5) Would you buy a *Realabilities Comic*? The students responded to all of the aforementioned questions and the responses were collected, stored in a secure database, coded and analyzed (Please see APPENDIX B for images of the comic series).

Results

Following the comic series, the students noted that they learned, "to never give up and to keep trying," "to not bully people," "to not judge people" and "that people have different strengths and weaknesses." In identifying their favorite characters, the majority of participants selected Beat, the African American character who stutters and dances, since she "resembles me," "is a good dancer," and is a "great singer." Uno, who presents with autism, was the next highly-rated character since he is "funny," "cool," and "smart." "Food Fight," the comic introducing Lexxy, a character with Down syndrome, and the comic that teaches about food allergies was rated the highest, because it "looks fun" and "teaches about allergies and shows there are ways to help." The next most popular comic the students endorsed was "Math Mania" because it was "funny," "cool," and "awesome." In a subsequent comic, the participants recommended that the characters "work on computers," "teach about the weather," "build a spaceship and go to the moon" "participate in basketball and football games" and do "more stuff that I can learn from." Finally, with respect to purchasing *Realabilities Comics*, the majority of students noted they would purchase them "because they were fun to read" and "are educational," while one participant remarked he wouldn't because he doesn't "read comics."

Principal Conclusions

Thus, the researchers found that *The Realabilities Comic Book Series* enhanced students' with disabilities nuanced knowledge of disabilities as well as the importance of promoting a stop bullying platform in their schools. Overall, the study results confirm that an extended contact model with appealing storylines

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and other engaging media can be highly advantageous towards teaching about diverse disabilities and that individuals with disabilities found the series both helpful and appealing.

STUDY 3: ASSESSING THE EFFICACY OF THE FIRST MENTAL HEALTH-BASED REALABILITIES COMIC AMONG A HIGH SCHOOL SAMPLE

Participants

Seventy-six students (44 males [61.1%] and 28 females [38.9%]) from an Information Technology High School in Long Island City, NY took pre and post-tests prior to and following the reading of the first comic book on mental health disorders in the *Realabilities Comic Book Series Curriculum*. In terms of grade, 71 (93.4%) of the students were enrolled in eleventh grade and five (6.6%) were enrolled in twelfth grade. The majority of students identified as Latino (50; 66.7%), nine (12.0%) identified as African American, five (6.7%) as Asian American, four (5.3%) as White and six (8.0%) as Other.

Procedure

The teachers administered brief Knowledge and Bullying Measures and Modified Pre and Post-Test Assessments of the Shared Activities Questionnaire (SAQ; Morgan et al., 1996), a behavioral intention measure, and The Adjective Checklist (ACL; Siperstein & Bak, 1980), a cognitive attitudinal measure, to students one day before and one day following the students reading through "Got Talent," the first mental health-focused comic of *The Realabilities Comic Book Series.* "Got Talent" introduces Celia with Anxiety and Kari with Depression. The students also noted whether they would view an episode of *Realabilities* or would purchase a comic. (Please see APPENDIX C for images of the new Mental Health-based comics).

Results

In terms of descriptive statistics, more than half of the participants (42; 56.8%) stated that they would purchase a *Realabilities Comic* and would watch an episode of the comic series (39; 50.6%) following the intervention.

Regarding principal study results, Paired Sample T-tests revealed that participants showed significantly more bullying knowledge, $t(76) = -2.296$, $p < .05$ and more stop bullying attitudes, $t(76) = -2.173$, $p < .05$ following the comic book intervention. The participants also showed more positive behavioral intentions (as measured via the Shared Activities Questionnaire [SAQ]) toward hypothetical peers with Anxiety on the SAQ Total, $t(76) = -2.514$, $p < .05$, on the SAQ Academic, $t(76) = -3.103$, $p < .01$ and on the SAQ Recreational, $t(76) = -2.164$, $p < .05$. Moreover, they showed more positive cognitive attitudes, as measured via The Adjective Checklist (ACL), towards hypothetical peers with Anxiety, $t(76) = -2.992$, $p < .01$ following the comic book intervention. Please see Tables 1 and 2 for Means, Standard Deviations and significance levels.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Principal Conclusions

Thus, the researchers discovered that students who read the "Got Talent" Comic, which discusses Anxiety and Depression and is the first comic to focus on Mental Health Disorders in the *Realabilities Series*, appeared to show more bullying knowledge and more positive stop bullying attitudes following the intervention. Additionally, the participants displayed more positive intentions and cognitive attitudes towards a hypothetical peer with Anxiety following the comic book intervention. This study was novel in not only showing the efficacy of a comic in enhancing attitudes toward Anxiety, but in successfully employing a high school population for this subject matter.

STUDY 4: EVALUATING THE EFFICACY OF THE FIRST AND SECOND MENTAL HEALTH-BASED REALABILITIES COMIC BOOKS AMONG A HIGH SCHOOL SAMPLE

Participants

Sixty-six students (45 males [68.2%], 20 females [30.3%], 1 Non-binary [1.5%]) from a High School in Long Island City, NY took pre and post-tests prior to and following the reading of the first two comic books on mental health disorders from the *Realabilities Comic Book Series*. The majority of students were in eleventh grade (59; 34.7%), one (1.6%) was in ninth grade, two (3.1%) in tenth grade, and two (3.1%) were in twelfth grade. Most students identified as Latino (43, 68.3%), seven as African American (11.1%) and as Asian American (11.1%), five (7.9%) as White, and one (1.6%) as Other.

Procedure

The high school teachers administered brief Knowledge Measures, Modified Pre and Post-Test Assessments of the Shared Activities Questionnaire (SAQ; Morgan et al., 1996), a behavioral intention measure, and The Adjective Checklist (ACL; Siperstein & Bak, 1980), a cognitive attitudinal measure both before and after students read the two Realabilities Mental Literacy-based comics.

Results

With regard to principal study results, Paired Sample T-tests revealed that participants showed significantly more knowledge about obsessive compulsive disorder (OCD), $t(65) = -2.169$, $p < .05$ and Phobias, $t(64) = -2.408$, $p < .05$ following the comic book intervention. After the comic book intervention, participants also displayed more positive behavioral intentions towards hypothetical peers with Anxiety on the SAQ Total, $t(65) = -2.294$, $p < .05$, SAQ Academic, $t(65) = -2.288$, $p < .05$, and on the SAQ Recreational, $t(65) = -2.462$, $p < .05$. Additionally, participants demonstrated improved intentions towards hypothetical peers with OCD on the SAQ Total, $t(62) = -2.810$, $p < .01$, SAQ Academic, $t(65) = -2.558$, $p < .05$, on the SAQ Social, $t(63) = -2.149$, $p < .05$, and on the SAQ Recreational, $t(64) = -2.177$, $p < .05$. Moreover, the participants showed more positive behavioral intentions towards hypothetical peers with Phobias on the SAQ Total, $t(65) = -3.317$, $p < .001$, and on the SAQ Social, $t(65) = -3.753$, $p < .001$. Finally, Participants showed significantly improved cognitive attitudes (via The ACL) towards hypo-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

thetical peers with Anxiety, t (64) = -6.527, p <.001, Depression, *t* (64) = -2.802, p < .01, and OCD, t (64) = - 3.648, p <.001 following the comic book intervention. Please see Table 3 for Means, Standard Deviations and significance levels.

Conclusions and Discussions

Thus, the researchers found that students who read the "Got Talent" and "Carnival" Comics, which discuss Anxiety, Depression, OCD, and Phobias, respectively, enhanced participants' knowledge of mental health literacy and improved participants' cognitive attitudes and behavioral intentions towards hypothetical peers with mental health disorders. Additionally, similar to the aforementioned study, the research revealed that the *Realabilities Mental Health Literacy Comics* could be effectively used with a high school population.

General Discussion

In summary, the first study found that a combination of the *Addy & Uno Off- Broadway Musical* and *The Realabilities Educational Comic Book Series Curriculum* significantly enhanced typical students' knowledge, interest and understanding of disabilities as well as the importance of promoting a stop bullying platform in school. The second study found that *The Realabilities Educational Comic Book Series* enhanced students with disabilities' nuanced knowledge of disabilities as well as the importance of promoting a stop bullying platform in their schools. The third study found that typical students who read the "Got Talent" Comic, which teaches about Anxiety and Depression, appeared to show more bullying knowledge and more positive stop bullying attitudes following the intervention. Furthermore, students displayed more positive behavioral intentions and cognitive attitudes towards a hypothetical peer with Anxiety after reading the "Got Talent" comic. Finally, the fourth study highlighted how participants increased their knowledge of mental health literacy and improved their cognitive attitudes and behavioral intentions towards hypothetical peers with mental health disorders after reading the "Got Talent" and "Carnival" Comics, which discuss Anxiety, Depression, OCD, and Phobias, respectively. Moreover, the research revealed that *The Realabilities Mental Health Literacy Comics* could be effectively utilized with a high school population. Overall, all four studies confirmed that an extended contact model with appealing storylines and other engaging media can be highly beneficial when teaching about diverse disabilities and mental health disorders.

With respect to study limitations, the aforementioned studies would benefit from even larger, diverse student samples in order to enhance the study's generalizability and external validity. Future studies would also benefit from observable behavioral data, to examine how student participants might actually act, behave or respond to students with disabilities following the research interventions, rather than solely relying on self-report measures of behavioral intentions and cognitive attitudes. While a limitation of earlier studies related to a failure to include participants with disabilities in the research intervention, our second study sought to rectify this earlier limitation, by recruiting students with diverse disabilities to participate in *The Full Realabilities Educational Comic Book Series Intervention*.

Finally with regard to future directions, the researchers hope to expand upon the Musical and Comic Book Series in multiple ways. Currently, a sequel to the *Addy & Uno Musical* is being created and the research team is in the process of developing two more comic books focusing on mental health disorders and an additional comic book featuring additional disabilities (facial deformities and differences).

The research team is also currently designing a research-based, isometric, first-person adventure video game to offer typical junior high school viewers an opportunity to better empathize and comprehend the strengths and limitations associated with the everyday life experiences of individuals with disabilities (please see APPENDIX D for images of the video game).

Taken together, all of these interventions seek to enhance typical children and adolescents' knowledge, attitudes, behavioral intentions, empathy and kindness towards individuals with disabilities and mental health disorders. With more knowledge, understanding and recognition of the strengths and realities of these differences, rather than solely a focus on limitations, *The Addy & Uno Musical, The Realabilities Educational Comic Book Series Curriculum* and *The Realabilities First-Person Adventure Video Game* seek to enhance the positive intergroup attitudes towards individuals with disabilities and mental health disorders to reduce stigma and promote the socialization and success of individuals with disabilities, mental health disorders and typical individuals, alike.

KEY TERMS AND DEFINITIONS

Behavioral Intentions: A person's perceived likelihood or subjective probability that he/she will engage in a given behavior.

Bullying: Seeking to harm, intimidate, or coerce (someone perceived as vulnerable).

Cognitive Attitudes: The beliefs, thoughts, and attributes that we would associate with a person or object.

Empathy: Stepping into the shoes of another person and perceiving and understanding the emotions that other individuals are experiencing.

Extended Contact Hypothesis: Coined by Wright and colleagues in 1997, postulates that knowledge that an in-group member has established a close relationship with an out-group member may promote more positive intergroup attitudes.

Kindness: The quality of being friendly, generous, and considerate.

Mental Health Literacy: The ability to identify specific disorders; knowing how to seek mental health information; knowledge of risk factors and causes, of self-treatments, and of access to professional assistance; and attitudes that promote recognition and appropriate help-seeking.

Social and Emotional Learning (SEL): Identifying and managing emotions, caring about others, making good decisions, behaving ethically and responsibly, developing positive relationships and avoiding negative behaviors.

Chapter 14
Counseling Refugees

Ann Nicole Nunis
HELP University, Malaysia

ABSTRACT

This chapter discusses the plight of refugees, the challenges faced, and the psychosocial impact of said challenges. It further provides practitioners with a review of coping methods utilized by refugees throughout the refugee journey in order to highlight possible protective factors practitioners may build on in the provision of mental health services. Lastly, the chapter provides an overview of current therapeutic frameworks that are culturally sensitive for counselling refugees, the challenges in the provision of mental health services, and techniques utilized by practitioners in the delivery of mental health services through evidence of research and case-based examples.

INTRODUCTION

Being a refugee is usually considered a temporary situation (El-Sharaawi, 2015). Yet, due to political and environmental situations that impact the flow of migration around the world, being or living as a refugee is met with persistent instability and the consistent need to re-conceptualize a situation of exile and transit in an environment that places little within the direct control of refugees themselves. This also includes a suspension of future plans for education, financial security and building a family with no way of knowing when a durable solution will be reached. Currently, the United Nations High Commissioner of Refugees (UNHCR) has recorded the highest amount of displaced persons across the world since World War II (UNHCR, 2016). The rise of displaced persons and persons seeking asylum across the world has led to increased efforts to alleviate this growing crisis. However, although the crisis of refugees is not new, knowledge is still emerging on evidence based therapeutic frameworks and techniques in providing mental health and even social work services to this group of persons.

This chapter aims to provide a background understanding for mental health practitioners on the plight of refugees, the challenges faced and the psychosocial impact of said challenges. It further aims to provide practitioners with a review of coping methods utilized by refugees throughout the refugee journey in order to highlight possible protective factors practitioners may build on in the provision of

mental health services. Lastly, the chapter provides an overview of current therapeutic frameworks that are culturally sensitive for counselling refugees, the challenges in provision of mental health services and implications for practice.

BACKGROUND

To date, there are 67.75 million displaced persons in the world, the largest number since the end of World War II (UNHCR, 2018a). A majority of this number is made up of refugees. Refugees are one of the biggest crises amongst modern day issues. Each day, masses of individuals and families seeking asylum are forced to leave their homes in search for safety. Some make a long journey on foot or are smuggled into vehicles across country borders. Others even brave the journey by sea in the hopes of landing on more welcoming shores. Many risk their lives and are separated from family and friends in the process.

The term "asylum seeker" and "refugee", although used interchangeably, have different operational definitions. An asylum seeker is an individual who is seeking international protection but whose claim has not been confirmed by the UNHCR (Phillips, 2011). For example, an individual escaping armed conflict in Myanmar may cross the border into Thailand or Malaysia seeking asylum and protection, however is not referred to as a refugee until he or she has completed a refugee status determination process by the UNHCR. On the other hand a refugee as defined by the United Nations 1951 Convention Relating to the Status of Refugees and the 1967 Protocol, is a person who

owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable to, or owing to such fear is unwilling to avail himself to the protection of that country...or is unwilling to return to it. (UNHCR, 2010, p14).

Examples of these reasons include evidence of discrimination and violence towards ethnic minorities, LGBT community or even arrest and detention of individuals who voice opinions opposing that of the government in their home country. The convention also states that refugees should at the minimum be accorded the same rights given to foreign nationals living legally in a country (Arshad, 2005). However, in implementation, the likelihood that refugees have access to the same rights as foreign nationals is not only dependent on the migrant laws of a country but also each country's adherence to international humanitarian treaties and declarations.

The experiences that comprise the asylum seeker and refugee journey can be complex to understand. This journey involves the forceful uprooting of an individual or group of persons from their home country to begin an uncertain journey in the search for safety (Vogel, 2016). The journey of a refugee often involves a lack of certainty of a foreseeable future for a protracted period of time. Refugees can live for several years without recognized documentation, stable financial income and the ability to plan a secure future.

The refugee journey has been conceptualized by researchers in three stages; preflight, flight or asylum and resettlement (Gonslaves, 1992). Preflight is defined as the stage where refugees or asylum seekers are still living in their home country (Wessels, 2014). The flight period, on the other hand, is characterized by a physical relocation to a country of asylum where refugees await a long term solution (Bhugra & Jones, 2001; Wessels, 2014). Lastly, resettlement is the stage where refugees are relocated to a host country where they will be able to live in the long term (Wessels, 2014). However, resettlement is not

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the only option. There are three potential durable solutions for refugees; voluntary repatriation back to their home country, local integration into the country of asylum, or resettlement (Horyniak, Melo, Farrell, Ojeda, Strathdee, 2015). At the same time, only 1% of the world's refugees are resettled to third countries (Phillips, 2011). The question then remains, what is the fate of the remaining 99% who do not attain resettlement is an area of concern for both humanitarian and mental health groups? These individuals usually are faced with continued ambiguity and instability on the result of their status with no possibility of knowing when they will have a conclusion to their living their life in asylum.

Refugees are also at risk of developing mental health issues due to trauma and stress experienced throughout the journey. Research has suggested that 9% of adult refugees and 11% of child refugees have symptoms consistent with post-traumatic stress disorder, otherwise known as PTSD (Schweitzer, Brough, Vromans & Asic-Kobe, 2011). A meta-analysis of psychiatric surveys has shown that adult refugees living in Western countries are ten times more likely to develop PTSD, placing them at a higher vulnerability to substance abuse and suicide (Fazel, Wheeler, & Danesh, 2005). At the same time, the provision of mental health treatment for refugees across the world is met with various challenges due to the lack of interpreters and psychometric assessments that are available in relevant languages (Ullmann, Barthel, Tache, Bornstein, Licino, & Bornstein, 2015). The shortage in availability of a comprehensive and multicultural approach to providing mental health for refugees is also part of the issue that magnifies the challenges in ensuring refugees are able to access mental health services.

Psychosocial Impact

Throughout the journey of a refugee, refugees face various complexities. The constant state of limbo and lack of stability causes the experience of time to become an altered state where the future is uncertain and day to day living becomes unstable due to this experienced sense of limbo (El-Shaarawi, 2015). Refugees and asylum seekers alike face various issues of harassment, threat of arrest and detention, exploitation, discrimination and vulnerabilities to gender based violence and development of illnesses. Communicable illnesses, such as tuberculosis, have an increased likelihood of spreading due to overcrowded living spaces. Furthermore, refugees and asylum seekers typically have preexisting mental health conditions due to pre-flight trauma and experiences such as extortion by traffickers, abuse and harsh physical conditions during the long journey to safety (Mann & Fazil, 2006).

Protection Issues

What can further compound the stressors refugees face is that not all countries recognize refugees and asylum seekers. Although many countries are signatories of the 1951 Convention and the 1967 Protocol, there are still other countries who are not members to these conventions. In Southeast Asia, UNHCR works alongside various governments to address the issues of migration flows across sea and land. Unfortunately, most countries in Southeast Asia have are not signatories to the 1951 Refugee Convention and its 1967 Protocol. Countries who are not signatories include Thailand, Malaysia and Indonesia. This means that thousands of refugees in these countries live without the right to work and without the guarantee of protection and safety. Therefore, it leaves hundreds and even thousands of refugees and asylum seekers with a legal system that lacks the protection structure to ensure basic rights and safety for them. As part of providing a framework that all governments can use as a baseline governments have adopted and signed various international treaties The Bali Process on People Smuggling, Trafficking in Persons

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and Related Transnational Crimes as well as adaptation of the Child Rights Convention, Convention on the Elimination of all Forms of Discrimination Against Women (CEDAW) and the Universal Declaration of Human Rights are some of the international treaties adopted by some Southeast Asian governments. However, countries as these are international treaties that do not carry legal consequences if not met, the majority of these countries often ignore the application of these treaties on migrants, particularly migrants who are undocumented or are considered illegal; a category that many refugees unfortunately fall into.

Although refugees living in asylum are removed from the immediate danger and violence of war in their home country, persistent challenges are faced as refugees experience restricted movement in camps and an uncertain future without work or the provision of education for their children (Farzana, 2016). At the same time, the experience of refugees in different asylum seeking environments may present refugees with varied concerns for safety and mental health. For example, refugee camps offer the possibility of greater safety and higher access to basic needs of food and shelter (Shakespeare-Finch, Schweitzer, King & Brough, 2014). Also, there may be other challenges refugees face in these environments. Asylum centres, for example, may increase the risk of ethnic conflict and the development of mental health issues due to the isolation and segregation within the centre (Lauritzen & Sivertsen, 2012) Additionally, the increased time spent waiting for a result at asylum centres made it challenging for asylum seeking children to develop positively in a space where safety and health are compromised. Furthermore, refugees in Southeast Asia typically live as urban refugees in cities and towns allowing them to blend into daily life amongst locals but without the same rights, access to services and protection as locals. Typically urban refugees were made up of single, young, male refugees (Crisp, 2017). However, urban refugees are increasingly made up of refugee community demographics including elderly, unaccompanied minors, single females and young families. This implies that there is an added risk posed not only in safety, but also in susceptibility to raids, arrest, extortion, gender based violence, and family cohesion.

Other protection issues can impact the mental health of refugees and asylum seekers. Isolation, fear of deportation and the possibility of being separated from family members caused the highest distress for refugees asylum centres (Sourander, 2002). Other mental health stress reactions such as depression, despair, anxiety, shame at surviving, anger were reported to be experienced during the asylum seeking period due to living with the constant threat of death and violence (Knezevic, Olson, 2014). The culmination of detention, ongoing discrimination and economic hardships can generate stress and a sense of hopelessness in refugees, which can lead to suicide (Vijayakumar, 2016).

Generating a Stable Livelihood

Creating a stable livelihood is another challenge faced by refugees in asylum that can contribute to mental health issues. Refugees tend to face difficulties in gaining employment whilst seeking asylum which may induce further psychological issues such as disturbed sleep patterns, low self-esteem, anxiety, depression and family violence (Mann & Fazil, 2006). Refugees living in a camp tend to find it difficult to gain sustainable methods in providing food and amenities due to an unemployment crisis experienced by refugees (Sarfo-Mensah, 2009). Refugees in camps usually have limited equal access to resources as compared to citizens of a country. Local organisations, including international and regional organisations, may be unable to provide sufficient support through provision of food and other basic necessities. Thus, providing a livelihood is not only an issue due to an individual holding a refugee status but also due to resource restraints of intervening organisations and the political climate of the relevant host country.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Language Barriers

Language is one of the most common challenges refugees face once they have left their home country. Refugees who experienced more language difficulties report higher anxiety symptoms, indicating that issues with acculturation is one of the most salient factors in post-migration well-being (Kartal & Kiropoulos, 2015). This can happen at any point of the refugee journey once an individual has left his or her home country. With the lack of English communication skills to assist them in integration to a host country, many refugee parents instead rely on their children to provide translation for them when accessing services (Francis & Yan, 2016). Consequently, youths who had resettled with their families experienced a reversal of roles when it came to language and skills as the youths now had to provide communication support to their parents who had lower proficiency of the English language. This reversal of roles also meant that adult refugees lose the important social roles once resettled to a new country. This may include loss of roles such as a spouse, parent or child through separation or death or even occupational roles and cultural peacemakers or teachers (Goodkind, Hess, Isakson, LaNoue, Githinji, Roche, Vadnais, & Parker, 2014). As you can see, being a refugee can not only impact an individual's livelihood and protection but also the cohesion and wellness of the family unit, an area of life that could act as a protective factor but could serve as a perpetuating factor to stress or mental health issues.

Survivor Guilt

News of increasing conflict in their home country may also lead refugees to experience survivor's guilt as refugees may compare the dangerous circumstances loved ones in their home country may face to their own relative safety (Bemak & Chung, 2017). Many refugees naturally continue to be anxious about the safety of their loved ones who have remained in their home country. They may even feel guilty for not doing more to take their loved ones with them. Others may remember the experiences of violence they witnessed or have known to happen to their own loved ones. Still others may have the shock of finding out that a loved one has been arrested or killed by news on social media. These are issues that can complicate the process of grief, trauma and ultimately the mental health of refugees who have left their home country.

Coping Methods

However, despite the unstable circumstances surrounding refugees that continue for an unpredictable period of time, some refugees have found ways to cope with these difficulties. Being future oriented (Borwick, Schweitzer, Brough, Vromans, & Shakespeare-Finch, 2013; Mann, 2010), being able to utilize cultural traditions and community networks (Knezevic & Olson, 2014; Akinsulure-Smith, Dachos & Jones, 2013), and religious practice (Earnest, Mansi, Bayati, Earnest, & Thompson, 2015; Shakespeare-Finch, Schweitzer, King & Brough, 2014) are some of the factors that have helped refugees to cope with new environments. Although most of these coping methods are common amongst resettled refugees, similar findings were also found by the author amongst refugees in asylum, who also relied on community support, religion, self-directed coping and focusing on their future in order to cope with the long and dangerous type living in asylum (Nunis, 2017).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although the utilization of positive coping methods is widely reported, there also exist reports of negative coping methods amongst refugees. For example, Rohingya refugee youth living in a refugee camp in Bangladesh frequently became involved in drug usage, alcohol consumption and gambling (Farzana, 2016). Higher alcohol prevalence amongst male Middle-Eastern government assisted refugees than female government assisted refugees in British Columbia (Miremadi, Ganesan & McKenna, 2011). The impact of an unstable livelihood on mental health was also seen amongst female Iraqi refugees who were vulnerable to experiencing domestic violence if they had no finances upon arrival in a country of asylum and had borrowed money in Syria (Tappis, Biermann, Glass, Tileva & Doocy, 2012). Similarly, urban refugees working in a factory in Mizoram resorted to alcohol usage and family violence when male family members were unable to protect their families or provide basic necessities whilst seeking asylum (James, 2010).

The Situation in Malaysia

As of February 2018, the number of registered refugees and asylum seekers under the UNHCR mandate in Malaysia was at a total of 154, 400 (UNHCR, 2018b). However, it would be important for readers to bear in mind that this number is not inclusive of asylum seekers who are yet to receive recognition by the UNHCR as a person of concern to their mandate. A majority of registered refugees and asylum seekers are of Myanmar nationality, however, refugees and asylum seekers from Yemen, Somalia, Sri Lanka, Iraq, Afghanistan, Palestine and other countries also make up the total number. Additionally 40, 540 children of the total number are below 18 years old (UNHCR, 2018).

The phenomenon of refugees in Malaysia paints a different set of challenges for asylum seekers and refugees as Malaysia is not a signatory to the 1951 Convention Relating to the Status of Refugees or the 1967 Protocol Relating to the Status of Refugees (UNHCR, 2017a). Malaysia further lacks domestic law that details the rights and protection for an individual of an asylum seeker or refugee status. Instead this group of individuals is classified as illegal immigrants under the Immigration Act thus making them vulnerable to arrest, detention and possible deportation (SUARAM, 2014). Although holding a UNHCR card provides a measure of protection and the hopes of being resettled to a third country, it does not guarantee absolute protection or access to benefits in Malaysia (Alexander, 2008). Due to this, refugees in Malaysia determine the likelihood for safety and protection by negotiating their place of living, typically in either remote jungle areas such as plantations or pockets of the úrban sites' made up of low cost apartments (Nah, 2010). A country that faces a similar situation is Indonesia. Some of the major challenges faced by asylum seekers and refugees include financial difficulty, health issues, lack of security, gaps in continuing education for their children as well as mental health problems (Ali, Briskman, & Fiske, 2016). This then produces a domino effect of being exploited in and out of the workplace including exploitation by authorities and lack of access to education, medical attention and equal and fair work environment.

As Malaysia is not a signatory to the Refugee Convention or the 1967 Protocol, refugees in Malaysia are subject to being arrested and detained by authorities. Refugees are frequently subjected to raids at their workplace or residence, even in public areas, on a daily basis (Alexander, 2008). Rohingya asylum seekers and refugees in Kuala Lumpur have reported being stopped by authorities and having to pay bribes to avoid being arrested, with men being stopped to a higher frequency than those deemed vulnerable such as women, children and the elderly (Wake & Cheung, 2016). The lack of legal status also compounds the ability of refugees to earn a living whilst awaiting a long term durable outcome. Refugees frequently

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

work in informal work areas in what the United Nations High Commissioner of Refugees has classified as 3D jobs – dirty, dangerous, difficult (UNHCR, 2011). Working in these fields further compromises the safety of refugees, in particular female refugees who are frequently sexually harassed and exploited by their employers (Buscher & Heller, 2010).

Furthermore, as refugees legally fall under the broad category of migrants, they are not privy to the right to health access (Health Equity Initiatives, 2010). Issues with communication due to language barriers at health facilities impede access to medical care. It was further reported that a number of refugees displayed PTSD symptoms such as flashbacks, difficulty sleeping and anger outbursts. Additionally, refugee children are not entitled to education in government schools in Malaysia due to their status as an undocumented child and as a refugee (SUARAM, 2015). Refugee children are however able to receive alternative education through community schools run by local NGOs or the refugee community that usually operate out of flats or shop houses (UNHCR, 2017b). However, these alternate routes of education frequently face resource constraints such as qualified teachers, salaries to pay teachers and materials to teach (Health Equity Initiatives, 2010).

Issues such as this can impede the emotional well-being of refugees as this places barriers in other social domains. A research by the author on refugees in Malaysia revealed that refugees face protection and psychosocial issues which impact their mental health well-being (Nunis, 2017). These issues include difficulties in ensuring safety for themselves, ensuring a sustainable livelihood and coping with the psychological impact of pre-migration factors and current living factors. The status as an undocumented person left urban refugees in Malaysia vulnerable to extortion, arrest, and to be taken advantage of by locals. The loss of education opportunities, high medical fees and low salaries were factors that made it difficult for refugees to provide a sustainable livelihood for themselves and their families. This led refugees within the sample to have a decreased sense of self and symptoms similar to post traumatic stress disorder and depression. While some refugees were able to depend on religion, family and community support as well as future oriented thinking to cope with the persistent instability and challenges, some instead turned to alcohol to numb their difficulties. Other families who are unable to gain a sufficient income to look after their families may give their children, particularly female children, to others either in marriage or for labor in order to better provide for the child who leaves and for those who remain.

Working With Refugees

While there have been increased efforts to study and produce evidence based practice for working with refugee clients, research is still in its emerging stages. Most research on the refugee journey and interventions highlight the experiential journey of refugees, particularly during the resettlement stage of the journey. Research has further focused on refugees based in Western countries. Few research efforts have focused on highlighting the delivery of mental health services and interventions through a multicultural lens. Thus, there is less emphasis on a coherent framework to interpret and apply multicultural sensitivity to the provision of mental health services for refugees.

There is no specific model applicable to all refugee cases. This is a group that is diverse, not only in sociodemographics but also in the type of migration experiences and reaction to these experiences, therefore being able to understand the nuances of each individual's journey is imperative in working with refugees. It would be first beneficial to conceptualize the social, legal, and psychological issues surrounding refugees. An example of an approach that would assist is the humanistic approach. Maslow offers a theory to understand this through the motivational theory of the hierarchy of needs (Corey, 2013).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Humans would need to first adequately satisfy the basic needs of food, water and security in order to attempt to meet other psychological and self-fulfillment needs. the case of refugees, basic needs are consistently not adequately met, causing these individuals to cycle back and forth in an attempt to meet basic needs for their families and selves whilst also trying to maintain psychological needs. In the case of refugees, it is a daily struggle to meet their basic needs which are rarely consistently adequately met. Due to this, it may make it challenging for practitioners to work on addressing the emotional and cognitive impact of migration experiences as they may need to first address the stress and anxiety of dealing with current environment challenges within the host country. In fact, this may even deter refugees from seeking out mental health services as it is not deemed high on the list of priorities or needs.

Practitioner Self-Reflection

One of the first questions practitioners should ask themselves before working with a client from a refugee background is "How do I feel about migrants and refugees in my country?" and subsequently "What do I believe the government should do about unauthorized immigrants in my country?" (Villalbla, 2009). Without reflecting on their personal opinions and beliefs of these issues, practitioners may be in danger of being bias, hostile or insensitive to a refugee client which will impact the therapeutic alliance and wellbeing of the client. Practitioners would also need to prepare themselves by reading news articles on the developments specific to the country of origin before beginning an intervention. It would be useful to watch videos or read other resources on the cultural practice of a country, ethnic or religious group.

In today's fast paced virtual world, global news is readily available to the public through both print and social media platforms. These platforms make available both overt and covert political messages around the clock. (Bemak & Chung, 2017). Therefore, it may be possible for mental health practitioners to experience political countertransference which is a negative reaction towards migrants or refugee populations (Chung, Bemak, & Grabosky, 2011). Furthermore, heated debate usually surrounds the issues concerning migration and refugees which can give rise to a culture of fear of foreigners and the possibility that they may be terrorists (Bemak & Chung, 2017). This may affect mental health practitioners on a conscious or subliminal level thus inhibiting their work with refugee clients. Practitioners working with refugees must be keenly aware of their own political knowledge and value system in order to prevent buying into xenophobia and intolerance (Chung, Bemak, & Grabosky, 2011).

Adopting a Culturally Sensitive Lens

Therapy frameworks have long been criticized for being coined from a primarily Western and Caucasian perspective. While the core principles of these frameworks are important to understand in the application of techniques, it is also important to adapt strategies to fit multiple cultural backgrounds and issues. Over recent years, research has increasingly focused on identification of cultural variation in trauma and recovery models in order to make informed treatment approaches.

Cultural Formulation Interview

One of the results of this is the Cultural Formulation Interview (CFI) which has been included in the DSM 5. The CFI offers an assessment tool to assist practitioners during initial assessments in exploring cultural and social issues relevant to the client's cultural background (Crock, 2015). Although not

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

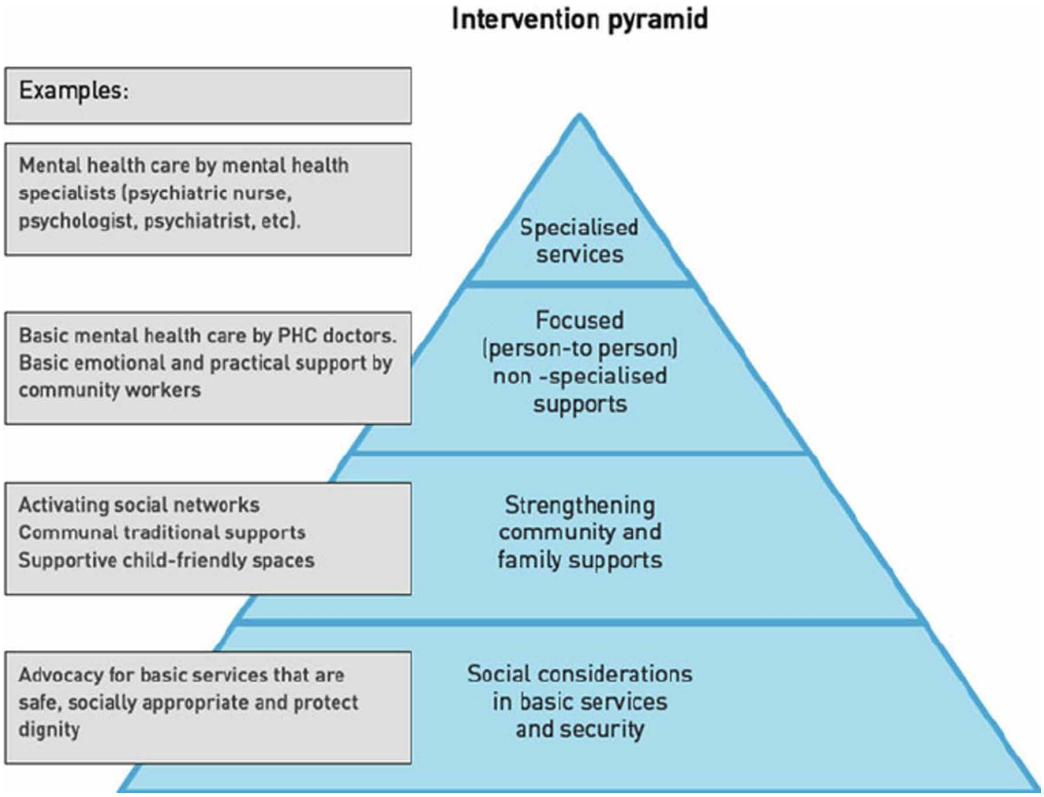
all practitioners would utilize this but an understanding of the categories covered in understanding a person's cultural background would assist providing an example of factors to consider not only during the initial assessment but also throughout the therapeutic process.

Multiphase Model of Psychotherapy, Counseling, Social Justice, and Human Rights

The Multiphase Model of Psychotherapy, Counseling, Social Justice and Human Rights coined by Bemak and Chung (2017) is a framework that allows mental health practitioners to take into account various factors when working with refugee clients. This framework is made up of five phases; 1) the mental health education, 2) individual, group and/ or family psychotherapy, 3) cultural empowerment, 4) indigenous healing as well as 5) social justice and human rights. These phases may be used concurrently or sequentially. The MPM emphasizes the importance of core therapeutic principles including the introduction and education on basic therapeutic practice such as confidentiality, intake assessments, interpreter role and the counseling process. Although explained in the initial phase, these concepts may be reintroduced continually throughout the therapeutic process. The MPM further highlights the importance of practitioners being familiar with the difficulties in acculturation and to adopt a more case management approach in ensuring refugee clients are able to manage their practical problems such as transportation, medical care and housing. At the same time, practitioners need to be cautious of being totally absorbed in becoming a case manager but rather an information guide to support adjustment.

Mental Health Psychosocial Support Model

Humanitarian agencies have also recognized the importance of mental health interventions and psychosocial support, especially in emergency setting. The Inter-Agency Standing Committee (IASC) has created the Mental Health Psychosocial Support model which captures the importance of inter-agency collaboration in humanitarian emergencies. In this context, emergencies are not constricted to preflight but also the disruption of livelihood, family and community structures which plague the life of a refugee. An important point highlighted is the need to focus on local supportive resources and access to said resources instead of focusing solely on the pathology of an impacted group. Bridging a partnership alliance with community organisations and refugee communities can help to reduce isolation and increase social integration (Rousseau, Pottie, Thombs, Munoz, & Jurcik, 2011). Although geared towards humanitarian health workers, it is applicable for other agencies and persons working with refugees to have an understanding of the importance of engaging various organisations and most importantly communities in supporting mental health and psychosocial well-being during emergencies. Figure 1 shows the mental health and psychosocial support (MHPSS) intervention model recommended by the IASC.



The IASC guideline has been found to be particularly useful in practice especially in areas where refugees live as urban refugees.

The Translator as Part of the Therapeutic Process

Working with a translator in delivery of mental health services will require more time allocation. Practitioners cannot ignore the importance the translator plays in building a therapeutic alliance with the client. In fact, research has shown that a good working alliance where all parties establish trust and team support built the foundation for successful therapeutic outcomes (Mirdal, Ryding, & Sondej, 2012).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Mental Health Psychosocial Support (MHPSS) Model

Practitioners will need to take into consideration time constraints when planning each therapy session. It would be useful for practitioners to utilize an extra ten minutes at the beginning and end of each session to develop a working alliance with the translator. The pre-therapy session should be used to review the aim of the session, as well as to clarify technical terminology and cultural factors (Tribe, 2002). Furthermore, practitioners should remember that some translators may hold a refugee status themselves and can thus be vulnerable to vicarious trauma from listening to the client's story in therapy. Thus, it would be recommended to treat the post-therapy session as a debrief session for the translator and practitioner.

If practitioners are working with translators who also hold a refugee status, there is a possibility that practitioners may be able to enhance their knowledge on the current contextual issues and cultural beliefs that may be pertinent to a client. Maintaining openness to feedback from the translator and being curious about the client worldview can help to build a working relationship with the translator while also deepening knowledge of the refugee world. This can be done by utilizing extra time before and after a session for discussion. At the same time, some clients may not be comfortable working with translators who are from the same community as they may share the same living or community spaces which can cause clients to be unsure if information from the session will be divulged to other community members. Practitioners would need to be alert to any discomfort or less forthcoming clients for issues such as this.

It is important to bear in mind that the constructions of psychological health may be culturally different to those entrenched in psychological theories and modalities that are rooted in Western ideologies. For example, words such as "depression" or "self-awareness" may not have an equivalent in some Myanmar

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

dialects. Often times, words such as this will need to be explained by the emotive content of the word or by using an analogy in order to be understood by the client. Therefore, attempt to use simple words in session. Instead of saying "That must be very depressing." You could choose instead to say "That must have made you very sad/ hurt you a lot." This will greatly assist the interpreter in explaining psychological constructs and the different levels of emotion to the client. Complicated words may confuse the client and could increase the power distance felt between a client and a practitioner who have varying levels of English fluency. Hence, it will also assist the client in understanding and explaining their concerns, thoughts and feelings and can contribute to a stronger therapeutic alliance.

As practitioners we are used to speaking seamlessly with our clients in a language exchange both practitioner and client are fluent in. Translators, however, are not necessarily as fluent in English or other mainstream languages a practitioner would be familiar with. Therefore, translators may not be able to remember all of what the practitioner says, especially if it has been said in long sentences with complicated jargon. Attempt to pause after two to three sentences. Translators need time to translate your thoughts and words to the client. It would also be helpful to keep sentences as short as possible in order to increase ease and efficiency of translation during the session.

Interventions and Techniques

In working with refugees, it would be difficult to ignore the external events and living conditions that take place in the everyday lives of refugee clients (Mirdal, Ryding & Sondej, 2012). The issues in gaining an income, acknowledged refugee status, and accessing health and education, as well as the possible experience of exploitation, discrimination and violence perpetrated by local citizens or within the community all contribute to the progress refugee clients can make within the limited therapeutic sessions we have with them. Hence, it is important to consider taking an integrated approach in order to meet the layered experiences and challenges faced by refugee clients. Commonly used approaches include cognitive behavioral, humanistic and psychodynamic approach (Schweitzer, van Wyk,& Murray, 2015). Additionally, cognitive behavioral therapy (CBT), narrative exposure therapy (NET), eye movement desensitization and reprocessing (EMDR) and testimonial psychotherapy have been recommended therapies for working with refugees (Ehnholt & Yule, 2006). However, though refugees come from a homogenous experience of fleeing persecution, each individual may have a very different experience and response to the experiences they have had. These techniques could also include expressive work such as imagery, metaphors, storytelling and psychodrama. An overview will be given for several of these approaches, however, practitioners should bear in mind that research is still emerging in this arena and that the following approaches are not the only ones that may be applicable for working with all refugee clients.

Humanistic Approach

As mentioned before, the therapist ability to connect with the client plays a major role in successful therapeutic outcome. Reflecting the core Rogerian conditions of congruence, unconditional positive regard and empathic understanding would be a basic foundation in working with refugees which need to be done in alliance with the interpreter. Being genuine and authentic have been shown to be the main underlying component in working with refugees which can be the foundations in providing a sense of safety to refugee clients who have had complicated experiences of loss, violence and trauma (Schweitzer, van Wyk, & Murray, 2015). Further, implementing equality between client and practitioner is impera-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tive, particularly in working with refugees. A power distance would keenly be felt in this context where the practitioner is not only deemed more knowledgeable but is also an individual with more rights in the host country. Refugees may be more inclined to feel indebted or the need to comply or withhold information for fear of either not receiving further assistance or incurring other protection issues. Whilst implementing these core principles can assist in building a therapeutic environment favourable to a successful outcome, it would be important to note that practitioners may at times need to take on a more directional approach with refugees, particularly in crisis situations or in advocating on a larger sphere for refugee rights or access to basic needs.

Person Centered Therapy has also been expanded to include person centered expressive art therapy (Corey, 2013). This technique builds on the creative process as a way to transform and heal and ultimately personal growth by integrating the cognition, emotion, bodily and spiritual factors of an individual. Integrating expressive techniques with other therapeutic frameworks may be necessary especially if working with clients who find it difficult to verbalize thoughts and emotions. An overview of expressive techniques will be provided later in the chapter.

Behaviorism Approach

There are concerns that exposure techniques may not be best suited to treatment of trauma in refugees. Exposure techniques often focus on one traumatic event which is not applicable to refugees who have intersecting and complex trauma histories. Additionally, refugees typically receive treatment whilst still in unstable situations in new host countries which further complicate the ability to treat one issue whilst the client is facing a myriad of other threats. However, EMDR has shown improvements in PTSD rates amongst Syrian refugees who showed improvements on the Impact of Events Scale -Revised (IES-R) and Beck's Depression Inventory (BDI) (Lehnung, Shapiro, Schreiber, & Hofmann, 2017). At the same time, bear in mind that refugee clients come from different cultural background and may have difficulty in verbalizing their experience and emotions surrounding a traumatic event. Adopting a trauma-focused psychotherapy approach combined with art therapy has been shown to be more effective in reducing trauma symptoms than only relying on trauma-focused psychotherapy (Schouten, de Niet, Knipscheer, Kleber, & Hutschemaekers, 2014). Furthermore, it would be important to implement a phased method of treating PTSD. Phase one would first require a removal or minimising of risk of trauma, providing coping methods to reduce symptoms and skills training. Only then can the second phase of processing traumatic memories and third phase that focuses on social and psychological reintegration take place (Heide, Mooren, & Kleber, 2015). Whilst it may be challenging to totally remove the risk of trauma, practitioners can work on assisting clients to source for other networks that can provide some support for their basic needs. Examples include safer living spaces, supportive community organisations or members or medical assistance.

Cognitive Behavior Therapy

Culturally adaptive CBT model, or CA-CBT, may be more effective in working with refugee clients (Hinton, Rivera, Hofmann, Barlow, & Otto, 2012). This model highlights the role of arousal and somatic symptoms using an arousal triad to explain how physical symptoms are produced as well as a multisystem model to show how therapeutic techniques can improve physical symptoms. It may also be particularly useful in addressing PTSD amongst Southeast Asian refugees by explaining catastrophic

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

thinking of physical sensations and the spiral of panic (Hinton, Chhean, Pich, Safren, Hofmann, & Pollack, 2005). Many refugee clients may not understand the physical distress and its link to other internal emotional and cognitive distress. This could be due to lack of mental health knowledge, literacy rate, access to education or cultural beliefs. An example of this is a young woman living as a refugee who was diagnosed with depression and generalized anxiety but who also experienced seizure like symptoms and tremors for many years. It was only after several sessions did she reveal that she had deep fear of being abandoned by her partner due to previous issues of infidelity. This also led to issues of not feeling worthy enough for her partner. Coupled with the unstable and harsh realities of living as an urban refugee and coping with separation from family, it had led to other relationship discord. This had a profound effect by manifesting as conversion disorder in order to gain affirmation in the form of care and attention from her partner. By working through the emotional and thought pattern she had and providing relaxation techniques, symptoms of seizure and tremors gradually decreased.

Mindfulness Therapy

The practice of mindfulness training has been shown to be effective in reducing PTSD rates (Marzabadi & Hashemi, 2014). By addressing health from a biopsychosocial approach by assisting an individual to understand their emotions, to accept experiences as it is and to focus their attention it assists refugee clients in building a holistic understanding of the experiences they have had. It also assists in better understanding physical symptoms and therefore a more coherent mindset towards leading a more efficient life outside of therapy. This may be a more appropriate technique in working with refugee communities who experience panic attacks, anxiety and to combat some PTSD symptoms as it introduces the concept of mental health and its effect on the body thereby affirming the manifestation of psychosomatic symptoms.

Narrative Therapy

As previously mentioned, exposure techniques may not necessarily be applicable to refugee clients as these techniques usually address one traumatic experience at a time. However, the creation of an exposure technique that combines individual narratives coined as Narrative Exposure Therapy (NET) has shown to be effective with refugees and asylum seekers. NET was originally designed to provide intervention for survivors of organized violence when faced with limited professional resources to address their needs (Hijazi, Lumley, Ziadni, Haddad, Rapport & Arnetz, 2014; Schaur, Neuner & Elbert, 2005). It is a short term therapy meant for individuals suffering from PTSD through emotional exposure to traumatic memories, and reorganizing said memories into a coherent and chronological narrative (Robjant & Fazel, 2010). Techniques include fusing emotional processing with expressive writing which may imply that clients whose cultural background value history telling may find this approach more socially acceptable (Hijazi et al., 2014). It has been found to be effective when used with both adults and children. At the same time, practitioners who are interested in employing this methodology may need to practice caution when working with refugee clients who live in a country that may not be socially or economically supportive of refugees as this may lead refugee clients to experience increased and consistent victimization and thus aggravate the original trauma experienced. The lack of medical attention, poverty, and malnutrition may restrict impact of any psychosocial intervention (Neuner, Schauer, Klaschik, Karunakara, & Elbert, 2004).

Expressive Techniques

Techniques utilizing art may be especially useful for clients who are less verbal and particularly for survivors of gender based violence and children. Providing clients with the space to express their emotions and thoughts in a non-verbal way will be useful. It can also provide clients a space to assert control of how they express themselves and a way to assert themselves. Art techniques utilized in therapy can also be a way for bridging the gap between refugee parents and their children communication especially when a family has newly arrived in a host country. Combining hope based theoretical framework together with art based techniques (producing a hope quilt, allowing children to take photographs of their lives) and then discussing these elements with the child and later their parents have helped refugee children and parents to be more aligned in hope and strength in order to assimilate better into a host country (Yohani, 2008). At the same time, art based techniques may need to be paired with other frameworks in order to facilitate the journey towards healing. There are several frameworks that have been found to be useful in combination with art techniques. One of them is solution focused art therapy (Moosa, & Koonrankot, 2017). Another is the usage of mandala art therapy in assisting refugees to find safety in a new host country by finding safety and reclaiming their identity and empowerment despite having traumatic migration experiences (Ely, Koury, Bennett, Hartinger, Green, & Nochajski, 2017).

Finding safety is a core issue for refugees living in asylum, particularly urban refugees who do not have the relative safety of a refugee camp to depend on. Previous group work utilizing art based techniques conducted by the author and a group of community health workers with a group of refugee women is an example of this. This group women lived in a high risk urban area that was known for high crime rate and densely populated with drug users. They spent most of the day alone at home with their children whilst their husbands were at work. Many had experienced assault and robbery. It was difficult for many of the group members to acknowledge difficult emotions including fear and even anger. One of the sessions included using plasticine to model their experience of being robbed or assaulted. Some art products included abstract forms and even prison bars. The emotions evoked during and after the activity were discussed and group members were then invited to do whatever they liked with it before collecting it into a basket. Some gently set it aside, others split it into two pieces thus showing the varying reactions each member had to their current situation. This was also processed. The activity allowed group members to acknowledge the emotions and stress they were experiencing towards their current context in a non-threatening and overly verbal way which is the beginning of finding emotional release and coping methods in the situation they were placed.

Implications for Practice

One of the first ideas you may have as a therapist working with refugees is to contact the respective embassy of your client. This is the least helpful approach to take. Many refugees have fled their home country for fear of their lives due to persecution at the hands of their government or fellow citizens. Thus, refugees are usually in fear that their embassy may locate them and taking action against them and their families (Tribe, 2002). Proceeding with this approach, especially without a client's consent, may impact the formation of therapeutic alliance and further deter the client from continuing to further sessions. Instead, consider contacting organisations such as United Nations High Commissioner for Refugees, and a range of local non-governmental organisations that cater to assisting migrants and refugees.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

A main point highlighted by many researchers and practitioners in the medical and psychology field is the importance of psychoeducation for refugee clients and community members (Giacco, Laxhman, & Priebe, 2017; Dotevall, Winberg, & Rosengren, 2017). Providing psychoeducation may increase the likelihood that refugees will access mental health services during asylum or resettlement. This is inclusive of providing brief information on psychological issues refugees may experience and how to seek help. It is particularly important to provide psychoeducation when it comes to treatment adherence of psychotropic medication. This may include the need to include family or community members who can assist the client in adhering to treatment. For instance, a client who is experiencing psychosis will not be oriented to time, date or place and will need assistance from family, friends or community member in adhering to psychotropic treatment in order to reduce psychotic symptoms. Similarly, a client who is elderly and experiencing depression may not only need assistance in taking the right dosage at the right time but also physical assistance and increased emotional support.

Practitioners may be inclined to place clients from the same country in the same therapy group when conducting group therapy. This may be a risky strategy as refugees may have been forced to flee due to reports on their religious, political and ethnic views thus leading refugees to have mistrust towards members of the same national background. Refugees may also be anxious that their personal information may fall into the wrong hands and thus endanger them or the lives of their family in their home country (Tribe, 2002). However, it is not impossible for group therapy or support groups to succeed. For example, due to the nature of political unrest in Sri Lanka, Sri Lankan refugees may have more challenges building a supportive environment even within a support group. One of the key elements that assisted members of this group to move beyond initial prejudices and fears was the sensitive practitioner who understood the nuances of the political situation in Sri Lanka and chose instead to build on commonalities within the group. Building on common experiences of loss, violence and challenges experienced living as a refugee helped the members of this group to extend emotional support to one another.

Additionally, practitioners need to be alert to the impact of cultural patterns, both positive and negative, on a client (Bala & Kramer, 2010). Whilst practitioners should be aware of cultural practices and differences of a client's background, it should not necessarily stop practitioners from addressing and even challenging the negative impact of cultural practices and beliefs. In order to do so, practitioners may need to consult with members of the same ethnic community, including trusted family members or friends of a client in understanding and possibly challenging certain beliefs and behaviors. For example, while some cultures may be more open to a husband physically reprimanding his wife, in many countries this is defined as domestic violence. Most Southeast Asian countries view this as a crime and have legal ramifications. Practitioners may need to confront the seriousness of these actions and its legal and practical implications in the host country. Likewise, some countries may be more open to indulging recreational use of drugs. Again, these are behaviors which can not only negatively implicate a client in the eyes of the law but can also induce negative coping methods which can lead to other mental health challenges such as addiction and drug induced psychosis. As a consequence of this, it can add issues in maintaining a job, income and also decrease the cognitive functioning of an individual. Additionally, it may affect the likelihood of resettlement as a durable solution for the client as countries of resettlement have strict criteria on the sociodemographic and health background of refugees accepted.

Furthermore, services and interventions for refugees are usually clustered within certain geographical areas. Most organizations offering medical, legal and protection services for refugees are clustered around major city centres. This is inclusive of UNHCR that may only have one branch office in some countries. This can leave many refugees with limited knowledge and access to much needed services.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

As an illustration, refugees who work in plantations or on fishing boats may have the tendency to have drug misuse issues as a result of working in lonely spaces for long hours. However, due to their far out location, they would have low knowledge on the signs on addiction and withdrawal and how to intervene in such cases. Besides this, refugees needing assistance would need to travel to these areas in order to access much needed service. This can cause many issues for refugees as their safety may not always be guaranteed when travelling, particularly if they are undocumented or living in a country that does not recognize refugees. It would also impact their finances as they would need to utilize their meagre salary in order to take leave from work for several days to conclude their appointment. Complications such as this can result in many refugees choosing to ignore health or mental health ailments until it has become too serious to ignore often times to the detriment of the individual.

In spite of the various experiences and challenges refugees face throughout their journey it is imperative to highlight that not all refugees, though having experienced major loss and even violence, will need therapeutic intervention. Although most refugees share similar experiences, not all experience significant mental distress as a consequence. It would be practical to first consider the individual's journey, current contextual factors and personality traits before concluding the existence of mental health issues. Drawing from the IASC's MHPSS system, it would be then important to draw on protective factors and preventive measures within the community and individual's life that can assist the client in coping with current challenges.

As mentioned earlier in this chapter, refugees themselves do endeavor to find ways to cope. Some of the factors practitioners may consider are community networks and religion (Nunis, 2017). Refugees typically have a network of contacts and even ethnic and religious organisations specific to their background. It would be beneficial to understand the network of refugee communities and build liaisons with them in order to work together on outreach and support in challenging cases. Local religious organisations are another resource a practitioner can tap into for both community and development support. Further, some refugees may have strong religious or spiritual beliefs. Having a firm belief and faith in God's plan has helped refugees, particularly refugees living in asylum, feel comforted and maintain a sense of hope (Nunis, 2017). These are examples of support systems and coping methods that may exist that can further assist refugee clients. At the same time, not all refugee clients may find these options helpful. Exploring a client's networks and coping mechanisms whilst being aware of cultural differences would be most important in order to help build preventive and supportive measures.

Practitioners would also need to take on a more assertive role in advocating for multi-lingual instrument measures, mitigating social and institutional discrimination, conducting culturally appropriate outreach and placing the client as the cultural expert (Villalbla, 2009). It would be difficult for practitioners to ignore the contextual issues that exacerbate the mental health of refugee clients whilst also attempting to provide services without first understanding the complexity of the social, health and community issues of the refugee client. Practitioners should be prepared to take on a more assertive in advocating for change whilst maintaining the confidentiality of the refugee clients they work with. This includes building networks with both local and international organisations, local refugee communities as well as promoting for the availability and access of services and safe spaces.

FUTURE TRENDS AND CONCLUSION

Moving forward, practitioners would need to take on more assertive roles in ensuring that culturally appropriate interventions for working with refugees and migrants continue to reflect the diversity of the population they work with. More services and information on services should be disseminated to refugee communities and agencies. However, practitioners should keep in mind that not all refugees are fully literate therefore practitioners would have to find different ways of communicating this information, such as pictorial pamphlets or videos (Giacco, Laxhman, & Priebe, 2017). More importantly, practitioners should also be aware of culturally appropriate ways emotions are exhibited before being too quick to diagnose a refugee client.

In the current climate of heated political debate around the refugee crisis and migration policies, practitioners must endeavor to focus instead on the human behind the label of a refugee. Understanding the human aspect of various pre and post migration experiences and current contextual issues should be one of the main aims of practitioners. Practitioners would need to make consistent effort towards understanding patterns of migration, political background of refugee home countries and being adaptable when working with refugee clients. Further, increased efforts should be made in publishing culturally appropriate evidence based strategies in working with refugee clients in order for practitioners to be able to assist clients to cope and heal better throughout the migration journey.

Chapter 15
"More Than Peer Support: Organizational and Relational Intervention Model": First Responder Assistance Program (F.R.A.P.)

Mario Jose Gonzalez
Independent Researcher, USA

Boundless Leadership Consulting, USA

ABSTRACT

The chapter describes a replicable and innovative approach designed to assist first responder communities through the mental health challenges they face in their personal and professional lives. The First Responder Assistance Program (FRAP) strives to create a healthy environment, through a unified structure, three tiered organizational and relational intervention approach, inclusive of peer support, peer chaplaincy support, and clinician involvement. The FRAP Model establishes a direct correlation between organizational wellness, and the individual health of its members. It emphasizes a "top to bottom" organizational intervention, with the understanding that no matter how much help is provided to the individual, the environment must be addressed in order to obtain sustainable results. It stresses a "holistic" approach to healing with a focus on post traumatic growth and the systematic building of individual and organizational resilience.

THE QUESTION

I was sitting in the Fire Chief's Office making a presentation about the needed expansion of our Peer Chaplaincy Program, when he asked a question for which I had no comprehensive answer, at least none that was satisfying to my own mind. "Why are we having more problems with first responder mental health now than we have ever had in the past?" The Chief continued with his line of questioning, not necessarily seeking an answer from me, but more in a rhetorical fashion, externally processing something that obviously he had been wondering for quite some time. He said, "The calls haven't changed. We used to run difficult trauma calls back in the day." As the conversation continued, some obvious possibilities, all with some merit, were posed as reasonable answers:

- Awareness has been heightened, so perhaps what was once hidden, now has come to light
- Maybe the stigma has lessened because we are talking more openly about mental health
- The advent of social media may not allow for a space to disconnect
- Perhaps it is the increase in the sheer volume and intensity of calls
- Or maybe the pace of present-day living is affecting our ability to cope

Now it is here that I must interject that neither the Fire Chief nor I (Chaplain Mario Gonzalez) are sociologists or researchers, but with over 60 years of combined experience as first responders, I think there is some merit and validity to our suppositions.

As we moved on to the task at hand, deciding we were not going to find a definitive answer in the time allotted for our meeting, the question continued to roam in my mind. Are traumatic calls truly adversely affecting and wounding first responders more today than they did in the past? Were former generations of first responders just tougher and more resilient than us, or were they just better at hiding their emotional pain and woundedness? The more I thought, meditated, and prayed about this, the more convinced I became that the answer to both questions is "yes". Perhaps first responders of yester-year, were both tougher and better at hiding their emotional pain than their contemporary brothers and sisters.

Now before I'm taken out to the woodshed by my fellow first responders for having made such a statement, let me just say that I believe we are plenty tough. A lot of what came out of my short impromptu brain storming session with the Fire Chief raised more questions than provided answers. I happen to believe that this is actually good. It is always in the space where hard questions are asked with integrity, that good answers are birthed. Yes, some good work is being done in the area of breaking down the ingrained culture of invincibility and stigma associated with seeking assistance in our first responder community. But are we being shortsighted in what we mean by changing the culture?

Yes, in most Departments, peer support is now considered as an important component in the battle for first responder mental health. But do we have measurable outcomes that our inventions are effective? Although PTSD and other anxiety driven mental health challenges are now topics of conversation in most first responder communities, are we looking at these topics from the most appropriate and helpful perspectives? Are Department administrations "being forced" to take reactionary measures due to new laws and incidents within their organizations? Are they willing to take the necessary steps to not only implement but institutionalize well thought-out support programs? Is their willingness to intervene, truly motivated by a desire to improve the lives of their most precious asset…their people?

In this chapter we will attempt to address some of these questions and provide the best answers from our optic, based on the many years of experience helping the public as well as then pivoting to help

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

our own. In doing this, we believe that a replicable model of organizational and individual relational assistance will begin to appear as the best "wholistic" approach to helping our own.

THE CULTURE

Whenever the topic of changing the first responder community culture arises, the conversation inevitably defaults to the ingrained mindset of invincibility that comes with the uniform, and the stigma attached to seeking assistance. The firefighter, the police officer, and the alarm office call taker are at the receiving end of the most recognizable number in our country…"911". When that number is dialed, the expectation is that the cavalry is coming and help is on the way. But not only help--whatever the emergency at hand--that help had better be prepared to show up ready to have all the answers and provide appropriate assistance in a timely and professional manner. It is expected that the help is strong, courageous, and ready-to-respond at any hour of the day; immutable in the face danger; infallible in split second decisions, and lest we forget, courteous and level headed when faced with individuals who might be unruly because they are quite possibly going through the worst day of their life. Repeat that countlessly over a 25-30 year career, and is it any wonder that most first responders carry an imaginary "S" tattooed on their chest underneath the uniform? Expect Superman or Wonder Woman--that is who had better be showing up. For most of us, it doesn't take long to realize that these expectations are unattainable. However illusory avatars don't die easily, because the ingrained stigma attached to seeking help as mere mortals persists.

There is no denying that addressing this mindset needs to be a component of changing first responder culture, but to stop there would not only be short-sighted but ineffective. First Responder culture is a subculture of two other parent cultures; the organizational culture fostered in each individual Department, and the culture at large from which it draws its members. Together, these shape First Responder culture.

In addressing organizational culture, we must first asses from a management and training perspective, whether the organization is fostering a culture of authority and power or a culture of service. Foundationally at its core, first responder work is about service. The purpose of our profession is service. Service is what we are paid to do, and an attitude of service is what is expected of us. This being the case, it would stand to reason that internally we should be fostering and modeling a culture of service and self-care, for, and by each other. This congruence of expected external behavior and internal culture could be described as "Organizational Wellness". We consider this to be an integral and necessary function in the pursuit of the well-being of the individuals that make up the whole. We are indeed "our brother's keeper", and this attitude should permeate the entire culture of the organization from its highest levels and across all ranks.

This can only be accomplished by an absolute commitment from the administrative and training hierarchy, to implement and adhere to policies that foster this culture of care and service. It is also imperative to hold all positions of authority within the organization accountable to this higher calling of leadership. Sadly, in most organizations, this is not the case. In the day to day "battle" of running a para-military organization, too often pride, ego, and undisciplined behavior in need of adjustment, get in the way of the best intended efforts of creating and maintaining an internal organizational culture of service and care.

In an authority and power-driven culture, management tends to look at its members as unruly children who only respond to the hard line of punishment. Conversely, the rank and file look at management as uncaring parents. This antagonistic mentality leads to a mutual lack of trust and a feeling of administrative betrayal from the rank and file. This will always stand in the way and damage any attempt to create

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

a healthy culture of internal service. The very real and valid administrative challenge of holding its members accountable to appropriate discipline when needed, should never offer up as collateral damage its attempt to create an internal culture of care and service.

On the other hand, a culture of administrative service and care looks at discipline as a constructive tool for improvement. It understands that the well-being of the one leads to the betterment of the whole. It stands by the principle of assistance before discipline and it holds all of its members accountable on an individual basis without using a shotgun approach to disciplinary policy. Organizationally, this is by far not only the harder road, but also the road less traveled. Nevertheless, if we are to truly address the needed change of culture within our industry, we must first endeavor to honestly asses, and then be willing to take the hard steps to improve this aspect of our organizational culture.

Turning our focus to the influence the culture at large is having on first responder culture, it doesn't take long to identify the advent of social media and the rapid growth of portable technology as a major contributor to decreasing interpersonal and relational connection. Fire Station dining rooms and day rooms are not the bevy of relational interaction that they used to be. In fire stations, breaking bread as a family used to be commonplace. Although you can still find pockets of this important tradition in many of our houses, we are slowly experiencing its demise, much in the same way we have witnessed it in the American home. Even when we manage to get together for meals, the unwelcomed presence of technology alarmingly interferes with and disconnects us from being present with each other.

Increasingly, the conversations--when they do happen--are not about our personal lives, so much as they are about the popular entertainment choices of the day. We are becoming so comfortable with the imaginary worlds presented to us by our own inventions, that connecting to the reality of being present is becoming increasingly difficult. From a completely non-clinical and anecdotal evidential perspective, this to me cannot be conducive to the well-being of our mental health, especially when it is challenged by the harsh realities of our profession. I am not saying that technology and entertainment are the root of all our mental health challenges, but we ignore this topic to our own detriment.

Another area where cultural thinking seems to have shifted, and is also affecting the first responder sub-culture, is the notion that life should be easy, and that problems when they come should be resolved at the drop of a hat. Hardship somehow has become an interruption, rather than a normal possibility. The ease and rapid access to all things comfortable inclusive of service, information, and climate control, to name just a few, have made us an extremely impatient society when it comes to dealing with hardship or discomfort.

In our chosen profession, the first responder is regularly confronted with the disruption of these expectations in the life of those he or she is sworn to protect. The constant exposure to these events can begin to intrude into an idyllic expectation of life, especially when it touches too close to home. For example, the death of a child, ran by a paramedic who is a new parent himself; a deadly assault on an elderly couple handled by a police officer dealing with the death of his or her parents; or a nursing home call handled by a rescue crew in which one of its members just placed their mom in an assisted living facility.

This collision of worlds accentuates and opens our eyes to the reality that we have little to no control over the outcome of most things happening around us. This "reality check" to someone who has been living under the illusion that their life journey should always go as they expect or have planned can be terrifying. Again, I am not saying that first responders live in some sort of unrealistic panacea, but the fact is that the culture we live in tends to expect and almost demands quick solutions to problems and ease of life. Accept it or not, our personnel are made up of a microcosm of the society surrounding us. We must do a better job educating our internal culture as to the normalcy of pain and hardship, and the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

opportunity for growth when confronted with both of these challenges in our everyday life. If we fail to understand what changing first responder culture should look like and miss the mark in truly making a difference in this important task, we will constantly be in a reactionary mode when it comes to the mental health of our people.

With respect to changing the culture, in an organization, education and awareness can become the fertile ground where culture change is plausible. But for this to happen, it must occur in the context of Departmental support and participation across all ranks. Any educational intervention must be accompanied by an administrative/leadership modeling of the behavior being promoted. The educational focus should also address the wider topic of how the culture at large is affecting the internal first responder community as just described.

THE SPIRITUALITY OF HEALING

It has been said that we are all recovering from something. The wisdom of this statement is at once both humbling and sobering. No one goes through this life without experiencing pain, disappointment, or heartache in some way. Our journey to healing and wholeness invariably has its starting place from a realization that we have been broken. Like participants in a high-speed game of bumper cars, we are constantly in need of forgiveness either given or received. Acceptance of brokenness, gratitude for where we are in the journey, and our need of forgiveness are prerequisites for healing.

This involves two important linchpins needed on the road to healing; humility and vulnerability. If humility and vulnerability start us on the road, the unflinching search for truth, in our need for love, is where the hard work is done. We are all relational beings. We are in a relationship with ourselves, our present situation, our past events, the world around us, each other, and if we are open to it, the existence of the spiritual and the source of all things created…God. We share the same world, but with each of us experiencing different and unique realities. Our experiences color and filter the way we see the world, but the one constant, whether we are able or willing to see it, is truth.

The addict trapped by his or her addiction, experiences the reality of transient relief through their substance or behavior of choice, but the truth is that they are on the road to deepening their pain. In the mind of a person feeling the paralyzing anxiety which connects a past event to a possible future, nothing could be more real, but is it truth? Recorded in the eighteen chapter of the Book of James, a 1st Century Roman Precept in Judea asked a very important question, but his pride and impatience did not let him wait for the answer…What is truth? It is in the answer to this question, and our alignment with this most elusive concept, where the proverbial rubber meets the very real road in our journey to wholeness.

Indeed, whether you ascribe to his claims of divinity, are a follower of his way, or think he was just a historical anomaly, that most famous of all Galilean carpenters truly put His finger on the pulse of the question of healing and wholeness when he made the following statement. "And you shall know the truth and the truth shall set you free." In meditating on the intersection between spirituality and healing, I decided to pose the question to a trusted friend with a long career of helping people on their road to healing as a successful therapist. I am grateful to my friend, Flora del Cueto LMHC, for her thoughtful and insightful answer to this question. How then do healing and spirituality relate to each other?

"My experience as a clinician has revealed that those who have a relationship with God, a spiritual leaning, are more likely to surrender in the process of recovery and healing particularly from significant traumatic events. That is, those people with a spiritual leaning, or close relationship with God, are less

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

likely to have emotional resistance as they explore the thoughts and memories associated with trauma and or abuse. In contrast, persons who have animosity towards God and or no spiritual leanings, tend to have a greater resistance to emotional healing and the exploration of those events that are emotionally painful" - Marie Guma MS. PsyD (ABD)

THE NEED

In order to try to answer the chief's rhetorical question that spontaneously created quite a conversation between him and Mario, I (Marie Guma MS. PsyD (ABD)) must dive a bit into the history of behavioral health or synonymously coined, mental health. According to the World Health Organization, mental health is:

... a state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community.1

Mental health is no longer solely defined as the absence of mental illness. Neither of these concepts are new to modern society. As early as 1500 BC the Egyptians depicted emotional turmoil in their drawings. They believed that mental illness was due to spirit possessions. The Greeks attributed mental illnesses as rage inflicted by the gods. During the Dark Ages, the cause of mental illness was ties to being possessed by the devil. During these times, a person who did not get better was thought to have weakness in their faith.

Witchcraft was thought to be the cause of mental abnormalities during the 15th and 16th centuries. The chosen treatments during this era were purging, bloodletting and removal of organs that the doctors believed could get infected. Mentally ill citizens were placed in mental hospitals that were primitive and the care was brutal. The patients were mixed with criminals and given the same treatments, where punishment was meant to sway their behaviors. They did not have adequate food, beds or toilets. The patients were placed in isolation or chained. They were not cared for by doctors or nurses but by warders.

During the 18th century, Philippe Pinel reformed the care for the mentally ill. Asylums were directed by doctors and nurses. Kindness replaced the penalizations administered in caring for this community. By the 19th century sedatives came into the picture as did Freud with concepts of mental processes and development. In the 1920's shock therapy and insulin comas were being administered in asylums. In the mid 1940's Moniz began the practice of lobotomies in treating mental illness. By the time Moniz passed in 1972, lobotomies were still in practice.

As is evidenced, the concept of mental health is not new but understanding it as another physiological system in our body and how to treat it, is. In fact, in 1949 the lobotomy won the medical Nobel Prize for treating mental health. This is significant because it explains the current attached stigma on anything related to mental health and mental health treatment in society. If we add to this stigma Mario's perspective on the first responder's personality, culture, and the stress levels inherent to the career, one can clearly understand why these ingredients have been a recipe for disaster. The disaster we are seeing today, where every 18 hours a firefighter is completing suicide in the United States. First responders are signing up and accepting the fact that these careers are dangerous and have high probabilities of death;

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

but first responders' suicide rates are doubling and even tripling line of duty deaths. This is a disaster and an injustice for these men and women.

RESILIENCE AND POST TRAUMATIC GROWTH

Recently, I asked a group of firefighters who have been retired a minimum of 18 years, to define *resilience* in the fire service. They were all in agreement that resilience was synonymous with being tough, not allowing things to affect you, being able to suck it up and do your job and do it well. I poised the rhetorical question, "So if you feel that you need to suck it up and not allow things to affect you, are you also admitting that the possibility of things affecting you are part of the job?" They all smiled as if I had caught them with their hand in the cookie jar and finally one said, "We saw things no one should ever have to see. Letting it affect us, or letting others know it affected us made us weak."

I explained to the group that what they were calling "weak" was being human. They understood that being human was equivalent to having feelings, both negative and positive feelings. They understood that asking firemen, police officers, EMT, correctional officers, dispatchers or soldiers to not let things affect them was also asking them to not be human, to go against their nature. I went a bit further, I wanted them to fully grasp the understanding that being human is not just a pretty concept to excuse a crying grown man but an actual physiological process in their body over which they have absolutely no control.

I began by explaining our command center: the brain, how it controls both physical movements and emotional responses. I described how the brain gets information from the external world and how it reacts with neurochemicals. I described feelings in terms of some of these neurochemicals for them to understand that feelings are not an abstract concept but an actual neurobiological reaction in our bodies. They finally understood that creating a culture in an entire industry where you are deemed "successful" if you go against your nature, over which you have no control, was asking for more than anyone could truly handle.

One of these great men said, Marie, we did not tolerate the ones perceived as weak and teased them because sometimes it was all we could do to keep from being weak ourselves. Keeping the attention on others kept it off me. We did do somethings right though. We weren't lazy. We shared as a family at the kitchen table. Now a day's guys at the station are on their phones and barely know their brothers' names. They all have separate rooms and only see each other during a call. Pardon my French but I knew who had farted just by the smell.

After this group understood what is meant by being human as a physical concept, I went on to correct their definition of resilience. I validated some of their definitions in order to avoid having them leave the conversation. I confirmed that it was definitely about mental toughness, but not by denying what they felt but instead by accepting it and being able to recover or bounce back from it. Resilience is the ability to recuperate functioning after setbacks, barriers, trauma, or difficulties. They were able to understand that if a first responder is spending his or her energy on hiding their human nature, fighting their normal reactions, or not accepting that it is ok not to be ok, than they are wasting time in which they could be getting the assistance they need to be able to bounce back in the arena they love so much.

It's like a pulled muscle or broken leg injury of a football player during a game. What if for years football players traditionally had "sucked it up" and continued playing injured? What if they did not get the rest, physical therapy and assistance they needed to be able to make a full recovery? They would be playing in pain, their careers would be shortened dramatically, their injuries would progressively

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

get worse, their self-confidence and abilities would suffer, and they would begin to cope with numbing agents to be able to get through a day.

Today first responders are numbing their expected reactions to what they see and do every day with alcohol, drugs, sex, gambling just to name a few. When we are fighting something we have no control over and is a normal process within our bodies, we are setting ourselves up for failure. Accepting these processes in and of itself is a sign of resilience as well as the first step in being resilient or recovering from misfortune.

Post traumatic growth (PTG) is the next step above resiliency. PTG is the ability to bounce back from a traumatic event but land in a higher, happier, and more appreciative state then previously in. It is becoming more self-actualized. According to Abraham Maslow, self-actualization represents growth of an individual toward fulfillment of the highest needs. The needs that give meaning to life. Thankfully, after a traumatic event, it has been found that most people are resilient and bounce back to their prior state. It is a small subset that never recovers or grows to a higher level of resiliency or PTG.

What if I were to say to you that first responders have the highest ability to be the most self-actualized humans on earth? It is said that an average person experiences 5 traumatic events in their entire life. First responders, depending what areas you serve, at the very minimum experience at least 5 traumatic events a week, thus giving these industries the experiences needed to find more meaning and more happiness in one's life.

When two holocaust survivors were interviewed together, one stated, *"It is indecent to ever be happy again after going through what I went through and watching the suffering of those in concentration camps." The other replied, "I feel it is indecent to never be happy again. To appreciate that we are still alive and have the ability to keep living."* Post traumatic growth has been found to increase maturity, meaning in life and happiness in individuals that achieve it. So why is the opinion of these two survivors so different? An underlying characteristic in PTG is the ability to recalibrate the experience and your perception of it. For example, being able to change a first responder's opinion of their job from being a thankless, tiresome, traumatic filled, bureaucratic, soul crushing experience to the luckiest job in the world where you have the ability to experience things that are the paths to more fulfilling and happier lives, it recalibrates their perception of the inherent trauma surrounding their careers.

Factors that have been found to affect the possibility of experiencing post traumatic growth include the person's personality pre-trauma. Costa and McCrae's five factor model of personality (FFM;1992) consists of extraversion, neuroticism, openness, agreeableness and conscientiousness dimensions. In 2015, a study found that neuroticism is correlated to a pathogenic outcome after a traumatic event, whereas extraversion was highly associated to positive post-traumatic outcomes.

Those who exhibit openness use cognitive strategies that correlate to PTG. Individuals who were agreeable were more likely to perceive positive changes after a traumatic event and conscientious individuals were characterized with more self-control, more meticulous and pursued goals with tenacity thus facilitating PTG. Another factor that influences PTG is the levels of psychological resilience of the individual as well as the amount of psychological damage caused by the event.

People who have attained PTG have reported that being in relationships where they felt nurtured and validated were essential to their growth. Being able to connect with people who can give them professional assistance during this time and feel genuinely accepted by them were two other factors that highly contributed to PTG. It is important to mention here that post traumatic growth is not only an outcome but also a process. One can experience distress as well as growth simultaneously. A professional placing emphasis on PTG too soon may cause the individual to feel like their trauma is being minimized.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Professionals dealing with individuals who have experienced trauma need to understand that PTG is not always an outcome and need the mention of growth to initially come from the person struggling.

Post traumatic growth comes at a big price. Following a traumatic event, one must experience high levels of distress, vulnerability, and an increased awareness of one's mortality. The price is counterbalanced with the rewards. A firefighter from San Diego Fire Rescue experienced multiple stabbings from a homeless man while he was trying to assist the homeless man's friend on a call. This firefighter states that what shocked him the most was the speed in which the attacker took his knife out and stabbed him multiple times. This firefighter now knows how fast he can be attacked and feels much better prepared where and how he places himself in relation to others on a call. Another reward of gaining PTG is an increase in self-confidence. Individuals who bounce back or attain growth after a traumatic event gain insight into their strength, become proud of themselves and what they have been able to overcome, and become confident in being able to prosper against any obstacle.

Those who attain post traumatic growth also experience more fulfillment in their relationships, clarity in their purpose and meaning, and are grateful for what they have. It has been reported that growth creates a new resistance or resilience, individuals are more prepared for future traumas, they bounce back quicker, feel they have stronger minds, can assess current situations better by using their past. Many who attained post traumatic growth have reported they worry less because they know things can be a lot worse.

Going back to the conversation between Mario and his chief and the big question as to why mental health issues seem to be more prominent in today's first responder industry, I am reminded of my conversation with the retired firefighters. I agree with the driver engineer who boasted, they did some things better back then. He admitted they did not understand mental health nor give it any creditability. He admitted that the culture accepted and even required the men to remain silent and suffer alone, but he says confidently, *"We knew each other. We talked. We connected. The kitchen table was our family, therapist, judge and jury."*

The word "connected" brought me back to my doctoral education, where we are taught that social connection can strengthen one's immune system, helps you recover from disease faster and may even lengthen one's life. Connectedness reduces depression and anxiety, increases self-esteem, increases empathy, trust, and cooperation with others which in turn causes others to cooperate and trust, generating a positive feedback loop of social, emotional and physical well-being.

The lack of connection has shown to be a greater detriment to our health than obesity, smoking, and high blood pressure. The lack of connection leaves us more vulnerable to anxiety, depression, antisocial behaviors and suicidal behaviors which create a further negative loop of isolation. Reports of connectedness in the United States are dropping in alarming rates. In 1985, Americans were asked how many people in their lives they felt they could turn to or feel comfortable sharing a personal problem. At that time, Americans claimed an average of three people they could confide in. The same study was repeated in 2004 and this time Americans reported having an average of zero people they could confide in.

One could be bewildered by these numbers and question how this could be in our current society where our ability to reach someone is the easiest it has ever been. It does not matter where you are, you can reach someone by pressing one button. We are in an era where you don't just talk to someone by pressing one button, but you can see them as well—a technology easily accessible to most in the world.

The issue with these devices is they have created delusion of connection. When we send text messages that include an emoji to replace an entire paragraph, not only are we allowing for misinterpretation, but we are going back to an era of communicating through pictures. We are also excluding the ability to express ourselves, read body language, listen to tone. What we see of our outside world are the fake

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

superficial lives on our devices of those around us. The worlds they have created through pictures that are cropped and filtered to make us look the way we wished we looked. Notifications on our phones have conditioned our brains to abnormal amounts of increased dopamine, thus creating the need for constant hits which you try to attain by constantly checking your phone while you are in the outside world where you would've been connecting to someone, but instead looking at your phone for a dopamine fix.

Recently, Microsoft admitted that our attention span in the digital world has dropped to less than 8 seconds. That is less than a goldfish. We no longer analyze and interpret information giving depth and meaning to our lives, instead we have opted for practicality in our devices that also cause shallow thinking.

In the fire industry, the inclusion of personal smart devices is not the only cause of the decreased sense of connectedness within the fire houses. Fire stations' layouts have changed. Private rooms with TVs have replaced the large room with cots. Kitchen tables are used just for meals, they are no longer the safe base after a tough call or a good cry in your brother or sister's arms. The private rooms give firefighters the ability to suffer alone while social media helps them escape their reality or numb their pain. The layouts, lack of kitchen table talks and the use of smart phones all attribute to the lack of connection in the fire industry.

They are also responsible for the increase of post-traumatic stress disorder (PTSD) in this service. PTSD is simply defined by the treatable malfunction of certain biological, specifically neurobiological, mechanisms. To simplify this even more, without minimizing the disorder's ability to absolutely render someone to the point of being debilitated, it is a glitch in your brain. In order to be functioning first responders, the stress reaction of fight, flight or freeze must be automatically triggered while doing your job. This reaction is what allows first responders to be cool, calm and collected to do their jobs in crisis situations.

Physically what this reaction looks like is: the primal part of the first responder's brain is revved up to 100%, specifically the hypothalamic, pituitary and adrenal systems (HPA). This signals the first responder's body to be in survival mode, focused and ready to go, thus heart rate increases, breathing increases and glucose increases through the release of norepinephrine, adrenaline and cortisol. As the HPA is ignited, the prefrontal cortex area of your brain shuts down for efficiency and survival. The prefrontal cortex of your brain is the last to develop (between the ages of 23-25 years old) and is responsible for all our executive functions like planning, judgement and impulse control. Since this area of the brain shuts off, first responders train extensively in order to make all their procedures instinctual.

The glitch that occurs in PTSD is when that trauma, event or call is not processed into the thinking part of our brains and it remains stuck in the primal brain, which is why someone with PTSD reacts to triggers as if the event is occurring at that very moment because the brain has not processed it or brought it to the part of the brain where it can rationalize it. It is why virtual reality therapy, EMDR and exposure therapy have been so successful in treating PTSD, because these treatments eliminate the firewall or glitch not allowing the event to be processed in your cortex. Going on a traumatic call, not sitting at the kitchen table to allow the call to be processed, isolating oneself in a private room, escaping into social media, and lack of connectedness have contributed to PTSD.

Although the battle against the stigma of mental health is in full force and the culture is changing through education and awareness, the lack of connection needs to be addressed further within the first responder industries. Peer support has played a monumental role in connection but usually it is with first responders that are already suffering. Listening to the retired first responders, getting back to some of the roots of connection in the firehouse, incorporating the systems they were using to keep each other healthy may be a great start.

ORGANIZATIONAL AND RELATIONAL INTERVENTION MODEL

First Responder Assistance Program (FRAP)

I (Dr. Bernardo Gonzalez) believe the failure to address systemic conditions within a First Responder's organizational culture can have substantial negative effects within the First Responder community (First Responder personnel and family). Equally important is the fact that the negative impact created also directly influences and shapes a First Responder's on the job behavior and level of service. More specifically, how First Responders connect and relate to the people and communities they serve.

The heartbreaking reality is that First Responders are not only impacted by on the job stressors, but also the scars, experiences, and in cases deep unresolved trauma carried from their past. With this in mind, most First Responder Departments address these issues in a reactive manner, sending employees to Employee Assistance Programs (EAP) for help, only when the situation or behavior is flagged by someone (usually a supervisor), or when the employee acts out in a manner that puts in question their mental wellness.

In most situations, whether medical or when dealing with mental wellness, the earlier we address a situation the greater the chance for healing. Using a simple analogy, one does not wait to treat an injury from a fall until there is an acute infection in the body. If one does, this delay in treatment severely impacts the healing process and also increases the level of pain and suffering for the person. In the same manner, a reactionary position when treating the mind can produce the same level of increased pain and suffering for the individual who is left untreated.

Equally important, the organization's response to these situations can set in motion a negative cause and effect scenario, as it relates to employee and management relationships. The employee perceives that they are not being valued by the organization and commences to isolate themselves and mistrusts the administration. From my professional experience, this reactionary response and delay in providing assistance can obstruct constructive growth and healing for the organization and individual.

Organizational Intervention

As we examine the existing organizational culture, we can see the incredible impact stress (both on the job and personal) has on the First Responder Community. Anyone having any experience in the field (First Responders) can also attest to the fact that First Responders are already coming with, and are significantly affected by, trauma and stressors caused by Adverse Childhood Experiences (ACE). Unfortunately, as noted, most First Responder Departments fail to proactively engage with this reality and for the most part are solely connecting with on the job stressors relating to Post Traumatic Stress Disorders (PTSD). Interestingly enough some of the work and research accomplished in the military (Ken Falke and others) point to a significant connection existing with Adverse Childhood Experiences and PTSD.

This is an important point to understand due to the reactionary response and focus of most First Responder Departments. Although not a clinician myself, I can attest from my academic, personal, and professional experiences, that First Responders create mental frameworks or elaborations that screen out rational cognition. These elaborations if not properly processed internally, can create negative projections of the future. When these negative projections are left unchecked, the First Responder utilizes these self-created elaborations, that are now separated from facts and the original situation, to shape their values, plans, and actions. If organizations fail to address the negative elaborations being created,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the behavior generated from these unhealthy mental constructs can commence to erode and poison the health of an organization.

Moreover, the organizational culture in directly dependent and is built on the thoughts, mental framework, and behavior of its employees. Further, if left unrestrained these unhealthy thoughts and elaborations in time are passed on as unhealthy values and behavior, becoming fused and part of the informal and at times formal organizational culture. This is why, in my professional opinion, it is important for First Responder Departments to be proactive regarding the mental health and wellbeing of their personnel.

As an example, a First Responder Department may very well have a formal culture that has respect and fairness as two of their organizational values, while unfortunately at the same time the informal culture is living and breathing values of unhealthy competition, unfairness, and ruthlessness. It is imperative for First Responder Departments to assess the health and overall wellness of their formal and informal cultures, as well as their people. How are our employees shaping their internal values, plans, and actions? What thinking process is influencing their decision-making practices? The root of an action is directly connected to one's thinking process.

That being said, all professional behavior (healthy or unhealthy) is also connected to this process. For First Responder Departments to proactively engage and positively influence this thinking process would not only help to modify and enhance employee behavior but also heal the organizational culture, and in the process help to preserve its future. In my professional opinion organizations make a grave mistake if their main attention to wellness is centered around PTSD, solely focused as it relates to on the job stressors.

The following example demonstrates my assertion. A Fire Rescue personnel commences his/her career with a past history of family abuse and alcoholism. Unknown to himself/herself and the organization, the scars from his/her childhood experiences commence to affect personal and on the job relationships, as well as negatively impact his/her behavior on the field. Additionally, the barrier and self-defense mechanism created is so ingrained that he/she fails to see the erosion occurring inside. For years his supervisors have counseled him/her as to his discourteous comments and lack of empathy while servicing the community.

However, being a good test taker, he/she makes rank and progresses through the ranks encouraging unhealthy behavior. His/her behavior, now as a supervisor and leader, commence to advance and advocate a dysfunctional and unhealthy informal organizational culture. One can see how ignoring these types of situations can produce negative outcomes for the health of an organization. Equally important, the negative impact for the organization is dependent on how many individuals are affected by significant past experiences that are left untreated. If that number is high, and these types of situations are left untreated, then the impact on the organization, especially the informal culture, will be serious. From my optic, organizations pay a heavy price ignoring this reality.

FRAP Model

The First Responder Assistance Program/Model (FRAP) encompasses the following three Foundational Pillars:

1. Organizational and Individual Inner Healing
2. Positive and Constructive Organizational and Individual Growth
3. Fostering of Organizational and Individual Relationships and Resiliency

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

With this in mind, FRAP's mission is to help transform First Responder Communities (Organizations and Individuals) from a culture of isolation, distrust, fear, and unhealthy behavior, to a culture of organizational and individual healing, positive and constructive growth, and fostering of healthy relationships and resiliency.

Methodology

- In order to change a resistant culture, one must transform and modify the system from within (Organizational Intervention)
- The FRAP will first help identify unhealthy institutional and behavioral patterns hampering positive growth within First Responder Communities (Assessment of Formal and Informal Cultures)
- The FRAP will work hand in hand with First Responder Communities to implement and institutionalize a systemic progression of care that focuses on Pre-Situational, Situational, and Post-Situational responses, structured within a unified framework and system:
    - Peer Response and Follow-Through
    - Faith-Based Chaplaincy Support
    - Integration of Mental Health and Substance Abuse (Clinicians)

FRAP Modules

The FRAP Modules were created to ensure that First Responder Departments implementing the model understand the necessity to utilize the modules in support of enhancing the formal and informal organizational culture. The FRAP believes that an organizational intervention is not only the best manner in which to change the organizational culture, but also to provide the assistance and support needed to First Responders on the field. The FRAP Modules is comprised of the following:

1. Educational Module

The Educational Model facilitates awareness, understanding, and learning to the following stakeholders:

1. Executive Level Personnel
2. Operational Personnel
3. Support Personnel
4. Families and other Support Groups

The Awareness and Understanding Component of the Educational Module is composed of drills and interactive learning, utilized to retain knowledge and develop pertinent skills and good habits, as it relates to Peer Response, Chaplaincy, and Mental Health Clinicians participating in the FRAP.

The Informational Component of the Educational Module focuses on the importance of communication. The FRAP will work with First Responder Departments to create newsletters, videos, and online communication aimed to facilitate learning and reinforce skills related to Peer Response, Chaplaincy, and Mental Health Clinicians working within FRAP. The most critical element of the Educational Module is to enhance the existing organizational culture (both formal and informal).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. Training Module

The Training Module facilitates organizational efforts to develop or enhance skills, improve performance, and inculcate individual self-fulfillment for the following stakeholders:

1. Executive Level Personnel
2. Operational Personnel
3. Support Personnel

The Formal Training Module utilizes best practices in the field to provide quality training at the Basic Level (all Departmental personnel), Intermediate Level (Peer Response Personnel), and Advance Level (Chaplaincy Personnel and Mental Health Clinicians). Chaplains and Mental Health Clinicians participating in the FRAP are required to also attend the Basic and Intermediate Levels of training to have a thorough understanding of the mindset and training received by Departmental personnel and peers.

3. Process Module

The Process Module examines the formal and informal organizational culture to determine systemic areas needing enhancement. The Process Module focuses on the following organizational and systemic areas:

- Assessment of Organizational Culture
  - Formal and Informal Culture
- Enhancement of Organizational Culture
  - Formal Culture
    - Enhancement of Policies, Procedures, Guidelines, Strategic Plans, Selection Process, Evaluation Process, Discipline Structure, and Promotional Process
  - Informal Culture
    - Fostering a healthy thinking process and modification of employee behavior
- Implementation and Institutionalization of FRAP
  - Critical Incident Peer Response and Follow-Through
  - Faith-Based Chaplaincy Support
  - Integration of Mental Health and Substance Abuse (Clinicians)

4. Mental Health Module

The Mental Health Module provides oversight and a sense of security and confidence to ensure that internal and external Clinicians are adhering to clinical best practices. Equally important the FRAP utilizes clinical oversight to seamlessly integrate the work being done by peers and chaplains. With this in mind, Clinical Oversight focuses on the following two areas:

- Clinician integration to Peers and Chaplains
- Check and balance related to therapeutic practices
- Clinician awareness training of First Responder culture

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

FRAP Step by Step Process and Methodology

FRAP personnel will work hand in hand with First Responder Departments to fully implement and institutionalize the FRAP Model within their internal organizational framework. FRAP personnel will also assist the Departments to fully implement **the four** FRAP modules (Educational, Training, Process, and Mental Health Oversight). The following depicts the implementation methodology utilized by the FRAP:

1. Assessment of organizational formal and informal culture
2. Work with stakeholder community (First Responder Department) to individualize the FRAP Model and reach a final consensus of the areas to be implemented and institutionalized
3. If desired by First Responder Department, selection of Pilot Project (Organizational Department, Section, or Entity)
4. Commence to work with selected department/organization to set up their own internal model integrated with best practices, as it relates to the progression of care (Chaplaincy Program, Critical Incident Peer Response System, Chaplaincy support, and Mental Health and Substance Abuse Clinician integration
5. Ensure selected department, section, or entity is incorporating Post Traumatic Growth (PTG) components within Pre-Crisis, Crisis Response, and Post-Crisis First Responder progression of care
6. Fully implement the FRAP Model in Pilot Project (organizational department, section, or entity)
7. Evaluate model as well as the Pre-Crisis, Crisis Response, and Post-Crisis Follow-up system of care (Pilot Project)
8. Fine tune any areas needing enhancement
9. Implement the model Department-wide
10. Fully institutionalize the model
11. Replicate model and implementation within other First Responder Departments and communities

FRAP Organizational Pillars

Foundational Pillar:

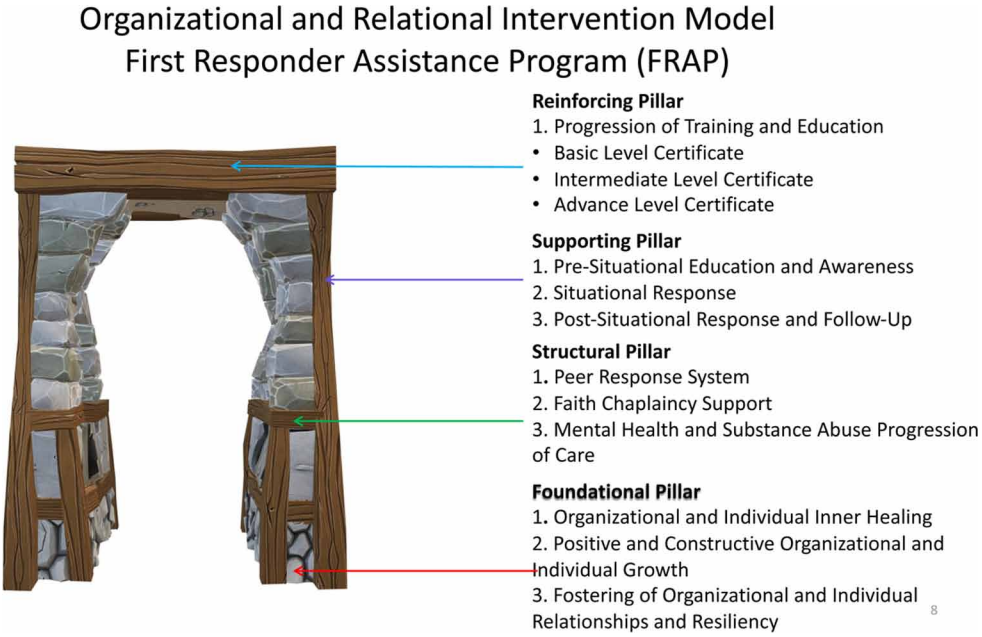
- Organizational and Individual Inner Healing
- Positive and Constructive Organizational and Individual Growth
- Fostering of Organizational and Individual Relationships and Resiliency

Structural Pillar:

- Peer Response System, Faith-Based Chaplaincy Support, and Mental Health and Substance Abuse Progression of Care fused within FRAP's Foundational Pillars (Organizational and Individual Inner Healing, Positive and Constructive Organizational and Individual Growth, and Fostering of Organizational and Individual Relationships and Resiliency)

Supporting Pillar of FRAP:

- Pre-Situational
    - Building Resiliency through Education, Communication, and Awareness aimed at enhancing organizational formal and informal cultures



EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Situational Response
  - A response that is Timely, Appropriate and accomplished by Trained personnel
- Post Situational Response
  - Continuum of Care and Follow-Through at the Organizational and Individual Levels inclusive of possible clinician participation when needed or requested

Reinforcing Pillar:

- FRAP's Peer Response, Faith-Based Chaplaincy, and Mental Health and Substance Abuse Clinicians provide a continuum of care encompassing:
  - Education
  - Training
  - Experiential Involvement
  - Support Groups
  - Processes (Policies, Procedures, Guidelines, Strategic Plans)

Figure 1. Organizational and relational intervention model First Responder Assistance Program (FRAP)

SUMMARY

As has been shown, the organizational culture, both formal and informal, can produce both positive and negative effects on First Responders. In part, a First Responder's inner healing and growth is directly impacted by their organizational reality. If a First Responder's organizational reality demonstrates a culture of isolation, distrust, fear, and unbalanced behavior, it would be logical and expected for the First Responder's inner healing and growth to be severely impacted.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

If one compounds this reality with a First Responder's past experiences and childhood significant events, as well as on the job meaningful stressors, it should not surprise anyone to see the data reflect a high percentage of suicides, substance abuse, domestic violence, and divorce from the First Responder Community. It is also prudent to deduce that if a First Responder's behavior reflects this type of pain and suffering (based on the data) in their personal life, one should not be surprised to find their quality of service as it relates to their profession also diminishing in return. The FRAP focuses on the organization, with its overall mission to:

1. Foster Organizational and Individual Inner Healing
2. Foster Positive and Constructive Organizational and Individual Growth
3. Foster Organizational and Individual Relationships and Resiliency

The FRAP Model if properly implemented and institutionalized can greatly enhance an organization's formal and informal culture. Additionally, by integrating a unified structure and progression of care encompassing Peer Response, Chaplaincy, and mental health clinicians within the formal organizational culture of First Responder Departments, the FRAP can go a long way in bridging the gap that exists among management and First Responders. The implementation and institutionalization of FRAP clearly display an organizational culture that values its First Responders. FRAP's overall mission is to enhance the organizational culture of First Responders as well as to validate the values associated with the First Responder profession.

Chapter 16
Attitude Training for Police Cadets:
Addressing the Problem of Arresting Suspects With a Mental Illness

Bruce L. Mann
Memorial University, Canada

ABSTRACT

The news has not been good for mental health training programs for police in Australia, Canada, the U.S., and the UK. Police training is seen as inadequate to prepare police officers to identify and deal with persons with a mental illness. This chapter describes one approach of writing a proposal to conduct a comparison of attitude-training programs with police cadets. The main aspects of writing a proposal are covered: the background, problem statement, hypothesis, and the design of the treatments for comparison. Isolating the main features of each treatment requires designing some instruction based on factors that can influence police attitude toward suspects with a mental illness. Contemporary design guidelines are recommended, which should be informed by the designer's personal assumptions about how people learn from multimedia.

BACKGROUND AND CONTEXT OF THE PROBLEM

Defining a critical problem in law enforcement begins with describing the background and context. Thirty-two years ago, police in the U.S. were *more likely* to arrest suspects if they knew they had a mental illness (Teplin, 1984). Seventeen years later police officers were *less likely* to arrest suspects if they knew about their mental illness (Engel & Silver, 2001). Three years after that, a prediction that information about a subject's mental illness would have a significant effect on officers' responses, was in fact, *not supported* (Watson, Corrigan & Ottati, 2004). Among the possible reasons for inconsistencies in findings among these studies include: a disconfirmatory response pattern, an expertise reversal effect, or Type III error.

Among the possible reasons for inconsistencies in findings among these studies include a *disconfirmatory response patterns* among learning objectives, or even prerequisite relationships on a hierarchical instructional analysis flowchart (Bart & Airasian, 1972). A disconfirmatory response pattern is one in which an individual achieves mastery of a high level task but fails to master a lower level task. This requires revisions of the instructional analysis flowchart.

A second possible reason for inconsistent findings is *expertise reversal effect.* An expertise reversal effect is a result indicating that an instructional technique that was effective with below-average police cadets loses some of its effectiveness and even becomes ineffective with average and above-average cadets. If, for example, the experimental materials are not difficult enough to split attention, the reason may be due to expertise reversal (Kalyuga, Chandler & Sweller, 1999; Witteman & Segers, 2010). Whereas novices' dominant cognitive activity require appropriate instructional supports, experts tend to retrieve and apply available long-term memory knowledge structures to handle situations and tasks within their area of expertise.

A third possible reason for inconsistent findings is *Type III error*. Type III error, consistent with Gary Henry's formative evaluation of rival explanations, point to erroneous inferences about program outcomes due to implementation flaws (Henry, Smith, Kershaw & Zulli, 2013, p.467). Michael Dawes offers two definitions for a Type III error (Dawes, 2010): When a study provides the right answer but for the wrong question or research hypothesis. For example, when the results support a different question; or when a possible explanation of the failure to demonstrate an effect might be the failure to consider interactive effects of the interventions.

General or Specialized?

Whereas the majority of police academies already provide some kind of specialized training for police cadets, not only in lecture form, but also through scenarios and simulations, there are still notable gaps, including the common failure of neglecting people with mental illnesses in the development and delivery of the instruction. Some jurisdictions have only basic recruit training (e.g., Saskatchewan Police College). Others offer extensive recruit training (e.g., Edmonton Police Service) with online courses, hands-on practice with mental health professionals, and a 5-week Police and Crisis Team Training (e.g., Calgary) (Yasmeen, Krameddine, DeMarco, Hassel & Silverstone, 2013). A report of Police Sector Council determined that not all police applicants perceive 'policing' as an 'honourable profession', nor as 'employers of choice', nor even as 'progressive' (Police Sector Council, 2007). "Specialized training and education in mental health is important… Sensitivity, empathy, and communication, are key" (CBC News, 2018).

Two attitude training treatments (i.e., TEMPO and CIT programs) will be considered for use with a sampling of police cadets, and; a prediction on the probability of similar effects occurring with different samples of police cadets under similar conditions. Could these methods become a template for replicating this research with different samples of police cadets? Replication of the research is the main criterion for a good methodology.

Mental Health Training Programs

Grant Edwin McLeod died in 2008 during the arrest by the Defendants RCMP members due to excessive and deadly force applied and failure of the said defendants to provide first aid care to McLeod after applying excessive and deadly force to him (*Carlick v. Canada (Attorney General), 2013)*. Justice Veale

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

concluded that there was no evidence from the plaintiff to raise a *bona fide* issue that the RCMP officers knew they were acting unlawfully and that such conduct would harm Mr. McLeod or Ms. Carlick. The evidence could support a claim in negligence and wrongful death but that claim was filed after the expiry of the limitation period and dismissed as previously discussed. So a procedural error had the case against the RCMP dismissed.

The *attitude* of a police officer can affect their performance. Attitudes, in this context, can be described as a person's likes and dislikes, with roots in social, emotional, behavioral, and cognitive experience. Attitudes can also be value-laden (e.g., moral or religious beliefs, pride, or a strong work-ethic), self-concept (e.g., academic, personal, professional), or motivational (e.g., goals, interests, perseverance). A positive attitude change by police toward persons living with a mental illness would be a spoken or written statement saying that *they want* to know how to recognize mental illness, how to deal with psychotic behavior in police suspects who are coping with a mental illness, how to handle violence or potential violence among persons living with a mental illness, and what to do when a mentally ill person is threatening suicide.

Krameddine and Silverstone take a different view; that training programs should focus on behavioural changes, not attitude change. The authors admit however, that *some studies show improvements in police attitudes and stigma toward mentally ill individuals and positive behavioral changes after training* (Krameddine & Silverstone, 2015, p.3).

The predominant view in this research therefore, and in current police training, is that if police attitudes toward mental illness can be made more positive, then behaviours will change accordingly. Changing attitudes is the challenge, because once attitudes, stereotypes, or biases are established, they are difficult to change. For this reason, current training programs are focusing on changing attitudes through educational technology.

Preliminary evidence shows that focusing on attitudes and assumptions might maximize the likelihood that police will use their pre-existing factual knowledge appropriately (Coleman & Cotton, 2014, p. 72).

It is clear from the literature that contemporary training programs for police personnel in Canada must adequately address the attitude of police personnel toward persons living with a mental illness.

Having the officers trained allows them to appropriately respond to individuals with a severe and persistent mental illness. The training helps with public safety and gives the officers additional insight when responding. When they are called to the scene, they are able to de-escalate the situation (Herbst, 2018).

Statement of the Problem

Problem statements (about police training methods) should be concise and identify only the key factors in the proposed study (Wiersma & Jurs, 2008, p.34). The problem in this proposal has been previously documented, namely: some facets of police training related to interactions with suspects living with a mental illness can be improved. Whereas the majority of police academies already provide a kind of education, not only in lecture form, but also through scenarios and simulations, there are still notable gaps, including the common failure of neglecting people with mental illnesses in the development and delivery of the instruction.

LITERATURE REVIEW

A good literature review about the attitude of police toward suspects living with a mental illness includes influential theories and previous experiments of the variables proposed in the new study (Wiersma & Jurs, 2008, p.56). There are a few cautions on reviewing the literature in educational technology when comparing contemporary online attitude-training programs for police cadets. Experimentally, a classroom lecture, for example, is another treatment, not the control group. Classroom work should be integrated into all experiential treatments to avoid bias, namely: the de-motivating effect of one group using a computer while another uses a pencil and paper. Finally, although tempting, experiments of training programs that require using a computer should not compare it to a classroom method.

Police Attitude Training

Police officers face significant challenges when responding to a person with a mental illness. Police and clinicians (e.g., counselors, therapists) see these challenges from different perspectives, particularly in situations involving noncriminal behavior that is symptomatic of the mental illness (Schulenberg, 2016). Schulenberg's study also suggests that an indirect procedural bias exists due to situational constraints, a disjuncture between policy and police culture, and limited mental health resources that lead to response strategies that contribute to criminalization of the mentally ill. Hoffman's Ph.D. research determined a disconnect between research and practice, namely: that whereas police officers tend to focus on dangerousness and public safety, clinicians are concerned with indicators of disordered thought (Hoffman, 2013).

Boyd and Kerr conducted a document analysis of four Vancouver Police Department policy reports on 'Vancouver's mental health crisis' from 2008 to 2013 (Boyd & Kerr, 2015). The value of their report lies in the exposure of challenges that Vancouver Law Enforcement face every day that are significant for policy-makers and public health professionals in and outside of Canada. The report highlights some of the negative discourse about deinstitutionalization, mental illness, and violent behaviour that can contribute to further stigma and discrimination of persons with mental illness.

This issue is not new to police. As the population grows and ages, so will the number of persons with mental illnesses. A growing challenge for law enforcement will be dealing appropriately and effectively with persons with mental illness. Most noteworthy in their research perhaps, is their belief that individuals experiencing acute symptoms of mental illness may respond differently than what front-line officers expect. Thus, persons with mental illness raise risk issues regarding intervention, strategy, and program framing.

Moreover, media reports from Vancouver Police Department between 2008 and 2013 linked the challenges of working with persons with mental illness with lack of policing resources and presence, and failure of the mental health care system. This kind of reporting has contributed to a widening net of social control, rather than to the betterment of the lives of people living with mental illness (Boyd & Kerr, 2015).

The reality is that these things unfold very quickly. This is one of the reasons I have tended to go more for training. The reality is that it's going to be the uniformed officer in the vast majority of the time dealing with the person in crisis (Chambers, 2016).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The CIT Approach

The essential goal of the Crisis Intervention Teams (CITs) approach is improving partnerships between police and community mental health resources (Coleman & Cotton, 2010; Watson, Corrigan & Ottati, 2004). The CIT includes instruction about:

- The causes, signs, symptoms, and treatment of mental illness
- Substance abuse
- Psychotropic medication
- Information on commitment criteria and procedures
- Consumer rights
- Personal stories from "consumers" and family members
- Visits to mental health treatment providers
- Information about treatment modalities
- Training in communication and de-escalation skills.

The CIT program has been widely studied (Compton, Bahora, Watson, & Oliva, 2008), which is an indication that the CIT has high *face validity* among police departments in Canada. CIT training includes information on signs and symptoms of mental illnesses, mental health treatment, co-occurring disorders, legal issues, and de-escalation techniques. The CIT curriculum may also include content on developmental disabilities, older adult issues, trauma, and excited delirium. Police officers can volunteer to receive forty hours of training provided by mental health clinicians, client and family advocates, and police trainers (Watson & Fulambarker, 2012). Moreover the CIT has been applied variously in multiple police settings to good effect, also accounts for high, or at least good, *reliability*.

CIT's positive outcomes are described as improved knowledge about mental illness, awareness of community resources, and improved identification of mental health calls. Nonetheless, "there is little outcome research or data-based evidence to inform the exact nature of an effective program, and research that does exist *does not provide guidance as to which components of a learning program are most effective"* (Coleman & Cotton, 2014). Furthermore, it was found that *the majority of all training programs only train specific members,* thus not the whole service is getting the knowledge and skills necessary to deal with mental health calls on a daily basis. CIT has been broadly used by police forces in the United States, but it is clear that more research of this program's potential effectiveness is needed (Compton et al., 2008).

The TEMPO Approach

Training & Education About Mental Illness for Police Organizations (TEMPO) is not a training method *per se,* but an umbrella approach that police organizations can use as a framework to assess their own progress to identify gaps in their existing training (Coleman & Cotton, 2014, p. 10). In 2008 the Mental Health Commission of Canada (MHCC) conducted a review of recruit training at Canadian police colleges concerning police interactions with people with mental illnesses. In 2010, the MHCC conducted a follow-up review of police training at the in-service or continuing education level within Canadian police organizations. Based on these reviews, an aspirational model of police education and training

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

was developed, described, and disseminated, called "Training and Education about Mental Illness for Police Organizations" or TEMPO.

Seven years after the initial report from the Mental Health Commission of Canada, the decision was made to focus only on police education and training to the exclusion of policies and community supports (Coleman & Cotton, 2014). The recent report covers two of the three challenges at once namely: training programs, and policy, and practice. Police learning materials are to be designed and delivered by a combination of police personnel, adult educators, mental health professionals, mental health advocacy organizations and people living with mental illness. People living with mental illness will be involved in the delivery of training.

Required Tasks

The procedure for determining required tasks is called a task analysis that is either displayed on a flowchart or in a decision table showing the *inputs* (goals), *processes*, and *outputs* specifying how an expert (not the cadets) would carry out the tasks. When confronted with a suspect with a mental illness, what tasks would an expert law enforcement officer complete to initiate the correct attitude? It's best to consider everything possible, such as basic skills, any gender or cultural concerns, vocational aspects, and personal skills such as time management or goal setting.

Task Sequence

Once the task analysis has been determined, an instructional analysis is developed showing the learning objectives displayed on a hierarchical flowchart (Gagné, Briggs & Wager, 1992). The flowchart serves as a stepwise arrangement of learning objectives and prerequisite requirements for police cadets to follow. Prerequisite knowledge and skills are critical to behavioural scientists, especially in their quest to determine the causal relationships between learning objectives.

Hypotheses

A hypothesis is a conjecture or proposition about the solution to a problem, a relationship of two more variables (Wiersma & Jurs, 2008, p.42). In this study of police training programs, two hypotheses are written about possible solution to the problem, a null hypotheses (H_0), and an alternative (aka alternate) hypotheses (H_1).

H_0: There is *no difference* between the attitude of police recruits toward offenders with a mental illness after completing the TEMPO training, and of police recruits who complete the CIT training. "Attitude difference" can be operationally defined as a change on the *Police and Community Attitudes Toward Offenders With Mental Illness Scale* (PACAMI-O) before and after training (Glendinning & O'Keeffe, 2015). This *null hypothesis* is based on the published opinion of Coleman and Cotton's review of police training programs in 2010 that focused on changing attitudes, and showed questionable effectiveness due in part to the poor quality of the research design testing their effectiveness (Yasmeen *et al,* 2013). The authors also noted differences in the existing training programs across Australia, Canada, the United States, and the United Kingdom.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

H_1: The attitude of police recruits toward offenders with a mental illness *will perform significantly* better after completing the TEMPO training, than that of police recruits toward offenders with mental illness who complete the CIT training. "Attitude difference" can be operationally defined as a change on the *Police and Community Attitudes Toward Offenders With Mental Illness Scale* (PACAMI-O) before and after training. This is an *alternate hypothesis,* based on the published opinion of Coleman and Cotton's review of police training (Morgan, 2011).

Design Guidelines

Online course development means different things to different people. Whether active teaching staff (i.e., the Lone Rangers) or the university support staff (i.e., the Posse) will develop an online course based on a preferred design guideline. The design guideline can be associated with a supporting assumption about learning from multimedia (Mann, 2009). There appear to be at least eight different design guidelines for designing a course for learning from multimedia.

Table 1. Summary of design guidelines and supporting assumptions about learning from multimedia

Design Guideline	Supporting Assumptions
• Whatever works	Þ Intuition of the developer
• Design-by-type	Þ Role in the software taxonomy
• Favourite feature	Þ Technology preference
• Favourite method	Þ Teaching method preference
• Balance-the-input	Þ *Logogen* & *imagen* connections
• Maximum impact	Þ Auditory-visual sensations
• Cognitive load, first	Þ Intrinsic & extrinsic load
• Structured sound function	Þ Three attentional networks

(Mann, 2009, p.3).

The choice of one of eight guidelines for designing the experimental treatments should be informed by the assumption behind the guideline. Then, learning objectives and instruction can be written consistent the different approaches in each treatment, opportunities provided to practice, feedback on the practice, and a method of assessing learning. A central feature of this part of the study resides in finding the main features in each treatment (i.e., CIT and TEMPO) that are likely to influence police attitude toward suspects with a mental illness.

METHODOLOGY

The problem in this proposal has been previously documented, namely: some facets of police training related to interactions with suspects living with a mental illness can be improved. Whereas the majority of police academies already provide a kind of education, not only in lecture form, but also through sce-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

narios and simulations, there are still notable gaps, including the common failure of neglecting people with mental illnesses in the development and delivery of the instruction.

Participants

In a comparison of attitude-training programs, the participants being studied are police cadets, most critical of all, their *attitude* – critical, because it is the *dependent variable* under investigation in this research. Experienced officers might possibly produce a different outcome. Attitudes can reveal a person's likes and dislikes, might reflect their goals, religious beliefs, and their work ethic. Under ideal experimental conditions, the police cadets would have similar experiential backgrounds (e.g., a family life, leisure time, a social and educational background), and the attitude of every police cadet *before training* would be uniformly neutral toward persons with a mental illness. Moreover, the *attitude* of every instructor would also be uniformly neutral toward persons with a mental illness. This is, in fact, possible in the study, because every cadet and instructor would have been screened for any bias before being admitted to the police.

The *capacity* of the learners (e.g., police cadets) concerns their innate abilities (as opposed to achievement). The definition of 'capacity' includes intellectual abilities (e.g., verbal, mathematical, artistic, and social capabilities), as well as cognitive (e.g., perceiving, remembering, thinking, apprehending, sorting, and utilizing information) and physiological (e.g., perceptual development and motor dexterity) development.

The *competence* of each police cadet is defined by his or her prerequisite skills (e.g., information processing skills, basic skills, and content prerequisites) as well as experiential background (e.g., family, leisure time, social, vocational and educational background). Competence is the result of conscious activity, either a learning experience or another life event. Although competence is limited by an individual's natural capacities, it is influenced by their attitudes and general profile characteristics.

Most researchers also like to collect *demographic data* to apply to their analysis. Data can show differences among the learner performances when they are categorized on the basis of such variables as age, sex, and cultural background.

Practical limitations to the comparison of attitude-training programs, would dictate that the population would need to be limited to local population of police cadets (i.e., males and females in their mid- to late-20's), randomly assigned to one of two treatment conditions. Notably, the cadets would be brand new recruits. Access to personal information about the cadets in the study would be confidential and would therefore require permission from several authorities as well as from the cadets themselves.

Research Ethics

Ethical standards are critical to experimental research, not only to prevent harm to the participant's health (e.g., by negligence), their career, reputation or income, but also to avoid violations of their basic human rights (e.g., confidentiality) and ethical.

Research that requires ethics review includes studies involving living human participants. Human participants are those individuals whose… responses to interventions… are relevant to answering a research question.[1]

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Prior to the start of the study, *ethics approval* would be required of the participants themselves to conduct experimental research on the attitudes of these police cadets, followed by approval from the Interdisciplinary Committee on Ethics in Human Research. Cadets would be informed that they could withdraw from the proposal without penalty at any time.

Sampling and Random Assignment

The sampling method for this proposal, under ideal experimental conditions, should comprise the population of *all* police cadets from *all* of the police training colleges across Canada. Ideally, the training programs would be exactly the same - same facilities, same instructional materials, administered in the same, strictly controlled. However, time, budget, logistics, and local organization constraints being what they are, would nevertheless be difficult to obtain an ideal experimental condition.

Since time and budget would be limited, the study would have to be restricted to a sample of convenience or *"haphazard sample"* of police recruits from the 2016 graduating class. Convenience sampling is the least desirable of all sampling methods, yet probably the most common, especially in training adults where whole classes of individuals are readily available cadets.

If time and budget permitted, the much preferred option to determine the better training program would have been to select participants for the study from *all* police cadets at *all* of the police training colleges across Canada by either a *simple random selection, quota random*, or *stratified random sample selection. Simple random sampling* from *all* police cadets at *all* of the police training colleges across Canada would mean there was an equal probability that any cadet at any police training college could be selected to participate in the study, without consideration of their gender, ethnicity, or prior background. Simple random sampling is the easiest to understand.

If instead, *quota random sampling* was used to select police cadets from *all* of the police training colleges across Canada, the cadets would be categorized based on, for example, police cadets who had personally experienced family members living with a mental illness vs. those who had not. Other categories could be gender, or ethnicity. These categories are then treated as samples of convenience.

Finally, if *stratified random sampling* were used to select police cadets from *all* of the police training colleges across Canada, a ratio of the population of the many thousands of police cadets would be selected within each of the police training colleges, subdivided into subpopulations on the basis of supplementary information. The criterion for stratifying the subdivisions could be, again, say, police cadets who had experienced first-hand, family members who were living with mental illness vs. those who had not had that experience. Other subpopulations could be gender, or ethnicity. Any of these sampling choices would have the excellent benefit of being able to speak with authority about the better training option for all police cadets in Canada.

Random assignment takes place following the selection of participants for the study. Random assignment is a method of assigning cases to groups for the purpose of making comparisons. All participants in the sample are randomly assigned to either the TEMPO or CIT training programs. Random assignment is a simple procedure of assigning even numbers from the unique number code issued to each police cadet (to ensure their anonymity) to one treatment and odd numbers from the number code to the other treatment.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Design of the Proposed Research

The design of this program comparison is a quasi-experimental pretest-posttest design, adapted from a controlled study on the effectiveness of an anti-stigma intervention in a basic police officer training programme at Umeå University in Sweden (Hansson & Markström, 2014). Quasi-experimental research involves the use of intact groups of participants, rather than a random selection and assignment of participants to experimental treatments. The design of the proposed comparison of two police training programs (i.e., CIT vs. TEMPO) will require one or more hypotheses, sampling method information, and the variables under consideration (dependent, independent).

The *unit of analysis* in this study would be the individual police cadet. The unit of analysis refers to the major entity that is being analyzed in a study, the particular type of unit a researcher uses when measuring. The *independent variables* would be the police training program (i.e., TEMPO and CIT) *operationally defined* as classroom instruction, scenario training, and simulations that include people with mental illnesses. The *dependent variable* is "attitude difference" operationally defined as a change on the *Police and Community Attitudes Toward Offenders With Mental Illness Scale* (PACAMI-O) before and after training (Glendinning & O'Keeffe, 2015).

Instrumentation

Instrumentation refers to the methods used in measuring cadet attitude (e.g. written test, time stamps, dribble files, interview questions, written work, segmented verbal protocols, etc.). In this comparison, data is collected from both experimental conditions (CIT and TEMPO) using the PACAMI-O instrument shown in Table 1 (see Appendix). The PACAMI-O scale is adequate for measuring attitudes towards its targeted sample, and has shown utility with a professional group (police officers and custody sergeants) who potentially face such offenders. It therefore has practical implications in assessing attitudes with other groups within forensic mental health.

Materials in the Study

The materials in the comparison can comprise any online tools, software utilities, workbooks, writing materials, verbal instructions, etc. In this proposal, the materials from the training programs are different from one another: the *Crisis Intervention Training* (CIT) program originated in 1988 in the U.S. and has been widely studied (Compton et al, 2008), the newly-developed *Training and Education about Mental Health for Police Organizations* (TEMPO) is untested.

The CIT Approach: "Intervention Training"

In the CIT program, selected officers undergo 40 hours of specialized training in mental health issues. At least two CIT officers are on duty each shift so that at least one is available 24 hours a day, 7 days a week. In collaboration with local mental-health authorities, emergency psychiatric services include a no-refusal drop-off facility and/or a mental health mobile crisis team that can assist officers during CIT calls (Lord, 2008).

The preference is to focus more on police training instead of the broader systems and policies that affect interactions between police and people with mental illnesses, such as the ride-along nurse or

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

counselor. The police themselves think that they lack adequate training to manage this segment of the population. They want to know how to recognize mental illness, how to deal with psychotic behavior, how to handle violence or potential violence among these persons, what to do when a person is threatening suicide, and when to call the specialized mobile crisis team. They also want to know what community resources are available and how to gain access to them.

Mental health training is needed for all police officers, not just for those who are part of the specialized mobile crisis teams. Psychologist Dorothy Cotton and retired police chief Terry Coleman examined how police basic-training programs across Canada prepare future police officers to respond to people with mental health problems. They found a range of approaches.

The TEMPO Approach: "An Umbrella"

TEMPO places particular emphasis on nine course goals:

1. Understanding symptoms such as hallucinations, delusions, paranoia, thought disorder, mood disturbances, intellectual impairments, memory problems, dis-inhibition, behavioral disturbances and other signs and symptoms that may accompany major mental illnesses and related problems
2. Knowing about mental illnesses, sufficient to make an assessment about how much control the subject is likely to have of their behavior
3. Communication skills and de-escalation techniques for defusing and calming volatile situations involving a person with a mental illness
4. Deciding whether a person with a mental illness is capable of understanding and responding to the directions given by police
5. Knowing that the standard police procedures that would typically disarm a non-mentally ill person, stabilize the situation, and lead to co-operation, might have the opposite effect with a person experiencing a mental health crisis
6. Having an understanding of the relationship between mental illness and likelihood of causing physical harm
7. Being able to accurately assess risk of suicide, know how to contain the situation, and when to intervene
8. Knowing how to apply problem-solving methods in the police/mental health environment
9. Knowing how to apply ethical decision-making and to exercise of police discretion

Under ideal experimental conditions, the materials from the two training programs (TEMPO, CIT) would be identical except for the variables under investigation. The *scope* of both programs would be the same, which means to say the type and timing of the training materials would be the same. The *sequence* of the training would also be the same in both programs, the instructors would be the same, or at least have the same preparation, and the presentation of the learning experiences would be the same. Furthermore, the content itself would need to be of the same level of difficulty.

Procedure

Readers of an experimental comparison should be made aware of the step-by-step procedure, in this case adapted from a controlled study by Hansson and Markström (2014, p.3). In the first step the course

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

administrator would approach the police cadets, inform them of the purpose of the proposal and ask for their informed consent. No data would be collected from cadets who chose not to participate. The cadets would be given written information about the proposal and informed about anonymity and procedures of the data collection. No monetary compensation would be offered. Once written authorization was granted by a Research Ethics Board, participating cadets would be issued a unique code, to ensure their anonymity, to be used during data collection and analysis.

Next, the attitude instrument (Glendinning & O'Keeffe, 2015) would be administered as a *pretest,* in advance of mental illness training interventions. This would be followed by the mental illness training interventions delivered separately in the *treatment groups* (i.e., CIT and TEMPO). Finally, the same attitude instrument would again be administered as a *post-test,* after the mental illness training interventions. Under ideal experimental conditions, the procedure in both groups (i.e., CIT and TEMPO) would be exactly the same. More likely however, the procedure in this proposal would be developed in conjunction with, and in consideration of the instructors' course schedules.

Expected Results

The expected results section is a report on whether the *null hypothesis* will be supported or rejected. In this proposal, it is expected that the null hypothesis would be rejected. By implication, this means that the alternate hypothesis would be supported; that the differences in *post-test attitude data* collected from the TEMPO and CIT groups would be statistically significant from chance, and from one another. A further test of the experimental data called a *post hoc analysis* would then be conducted on these data to determine the direction of the cadets' attitude toward persons with a mental illness. Summaries of the statistical testing would relate directly to these research hypotheses. The Scheffé test (Scheffé, 1959) is a common method of comparing significance levels that can be used for test any number of post hoc comparisons, not just pairwise differences.

The convention is to report *descriptive statistics* first. Descriptive statistics typically include the mean or arithmetic average that can be strongly affected by extreme changes in values, and the standard deviation from the mean, or the average difference of between all the scores and the mean. It is expected that the mean (M) would be higher the TEMPO data than in the CIT data, and the standard deviation (SD) in both groups would tend to cluster around the respective means because the population of cadets would be a homogeneous grouping of mostly Caucasian males and females in their mid- to late-20's.

Inferential statistical testing usually follows a brief summary and table of the descriptive statistics, to determine the probability, beyond chance, of making a correct inference about the degree of difference between the two training programs. Inferential statistics rely on probability theory to test a hypothesis formally, permit inferences from a sample to the greater population, and test whether the descriptive results are likely due to random factors or to a real relationship. Under ideal experimental conditions, inferential statistics would be used to interpret (i.e., generalize) the results from an analysis of the attitude data from the cadet sample to the greater population of *all* police cadets from *all* of the police training colleges across Canada. Conditional statements could be quite telling, conditional because the statements would have to depend on the sampling method that was implemented.

In this comparison, it is expected that inferential statistics would reveal first of all, that *differences on pretest attitude data* would be statistically non-significant beyond the 0.05 level of probability; that is to say, that all the police cadets would state a neutral attitude toward persons living with a mental illness. Second, it is expected that inferential statistics would reveal that *differences on post-test attitude data*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

would be statistically significant beyond the 0.05 level of probability. It is expected that further analysis of the significance levels using Scheffé's post hoc comparisons would reveal that cadets in TEMPO training would show more improvement in their attitudes and stigma toward mentally ill individuals, than those learning from the CIT curriculum.

Discussion

The *discussion* is the section where the findings are interpreted and tied back to previous studies. If the results of the *analysis of variance* reported statistical significance between the two conditions, then it is reasonable to expect, beyond chance, that police cadets would indeed show more improvement in their attitudes and stigma toward mentally ill individuals after TEMPO training than if they had learned from the CIT curriculum. If the null hypothesis is rejected and the alternate hypothesis supported, then this result could bode well for phasing-out CIT training in favour of more support for the TEMPO program. If however, in the event that the null hypothesis is supported and the alternate hypothesis rejected, this result may still be important information for policy makers about whether to spend more money on the TEMPO program.

Limitations

There should be a word about the limitations of the study to avoid *Type I* or *Type II errors*. *Type I error* occurs when a significant relationship is reported when none exists, that is to say the null hypothesis was falsely rejected. Experimental research is constantly susceptible to Type I error. *Type II error* occurs when no significant relationship is reported when in fact one does exist, which means the null hypothesis was falsely accepted. It is quite likely for example, that the grand statement made above, namely that inferential statistics would reveal that differences on *pretest attitude data* would be statistically non-significant beyond the 0.05 level of probability, may in truth, be a false assumption because the PACAMI-O *instrument* used to measure attitude of the comparison, even if the study comprised the entire population of all police cadets across the U.S. or Canada, may, in fact, be too blunt to get at the underlying likes and dislikes of the police cadets.

Then why use it? The answer is that while it may not be a therapist's standardized inventory of patient attitude, the PACAMI-O was nevertheless used, tested, and published in a similar study to this one, and could therefore be used to good effect, ensuring good *validity* (i.e., has a similar purpose) and good *reliability* (i.e., has similar participants) – not *the* ever-evolving truth perhaps, but valid and reliable nonetheless.

Philosophically speaking, statistical tests should not be seen as the truth of the premises in an argument, but rather as the conclusion of an argument in a research hypothesis located at the beginning of a study. The truth of each premise in an argument may be difficult to isolate and therefore difficult to control experimentally, due in part perhaps to the dynamic nature of police work, changing environmental factors, cultural or religious factors and so on. Add to these uncontrolled variables, learner factors, training delivery factors, parts of which may be omitted in some training colleges, as reported earlier, or run at different times in the training program. What of missing data - those cadets who dropout, or instructors who retire or quit (aka *mortality)* affecting the truth of the premises? These are all possible threats to the internal validity of the comparison.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

As for the police cadets themselves, what of *maturation,* their changing goals and beliefs over time, of police cadets in all of the police training colleges across Canada? Experimental comparison by its design seeks to corroborate its own methods and measures with outside sources, to justify its own – not seek the dynamic and multi-faceted truths about changing cadet attitudes toward suspects living with a mental illness.

Summary

It should now be clear why the proposal was limited to police cadets at a local college, and *not* police cadets from all of the police training colleges across Canada – because the variables would be too difficult to control, and because experimental study by design aims to take a valid and reliable snapshot of cadet attitudes in a controlled environment. Conditional statements may be all that are left, and great care when interpreting statistical data into generalizations about police cadet attitudes toward persons living with a mental illness. The writing of this proposal has opened many questions that could, and perhaps should, some day, be elaborated by qualitative research. What follows (Table 2) is a summary of criteria for designing a proposal to compare police attitude-training programs.

Table 2. Criteria for designing a proposal to compare police attitude-training programs

1. Describe the research question or problem in the introduction - the dependent variable(s) – E.g.: Finding a problem in law enforcement to study begins with describing the background and context.
2. Summarize in your own words orally or in writing the gist of the literature review, including the theoretical framework to support the questions, problem, or need.
3. Describe the gist of the methodology, including:
a. The participants [e.g., level, prerequisites, prior knowledge of the dependent variable under consideration, motivation to learn (intrinsic better job, etc.)]. Know your participants. Know what they will do - are they sent the materials or do they need to access the materials? Are they all text or i there speech (cues or narration)
b. The materials in depth [e.g., online, tools, software utilities, workbooks, writing materials, verbal instructions, etc.]
c. The research design [e.g., hypotheses, sampling method] variables [e.g., dependent, independent]
d. The instrumentation [e.g., written test, time stamping, dribble files, interview questions, written work, method of segmenting protocols, etc.]
e. The procedure [e.g., "the procedure in this study followed those suggested in previous studies of this kind (reference)," and summary]
4. Describe the gist of the expected results, including:
a. The methods to be used in collecting the data
b. The methods to be used in analyzing the data
c. Expected results
5. Write a brief Discussion:
a. Linking previous research to the results arising from the analyses of the data
b. Expected conclusions of the study
c. Implications of the study
6. State whether or not the references in text and in the list follow the current APA standard.

(Mann, 2006).

APPENDIX

Table 3. Police and Community Attitudes Toward Offenders With Mental Illness Likert Scale (PACAMI-O) measures "attitude differences"

1. As soon as an offender shows signs of mental disturbance, he should be hospitalized.
2. More tax money should be spent on the care and treatment of offenders with mental illness.
3. An offender with mental illness should be isolated from the rest of the community.
4. The best therapy for many offenders with mental illness is to be part of a normal community.
5. Mental illness is an illness like any other.
6. Offenders with a mental illness are a burden on society.
7. Offenders with a mental illness are far less of a danger than people suppose.
8. Locating forensic mental health facilities in a residential area downgrades the neighbourhood.
9. There is something about offenders with mental illness that makes it easier to tell them from normal people.
10. Offenders with a mental illness have, for too long, been the subject of ridicule.
11. A woman would be foolish to marry an offender who suffered from a mental illness, even though he seems fully recovered.
12. As far as possible forensic mental health services should be provided through community-based facilities.
13. Less emphasis should be placed on protecting the public from offenders with mental illness.
14. Increased spending on forensic mental health services is a waste of tax money.
15. No one has the right to exclude offenders with mental illness from their neighborhood.
16. Having offenders with mental illness living in residential neighborhoods might be good therapy, but the risk to residents is too great.
17. Offenders with mental illness need the same kind of control and discipline as a young child.
18. We need to adopt a far more tolerant attitude towards offenders with mental illness in society.
19. I would not want to live next door to an offender who has been mentally ill.
20. Residents should accept the location of forensic mental health facilities in their neighborhood to service the needs of the community.

ABSTRACT

Mental disorders have been identified as one among the leading causes of the global disease burden. Despite being one of the first nations in the world to identify mental health as an important indicator of personal well-being and having adequate plans and policies for ensuring the same, one in every seven Indians is affected by mental disorders of varying severity. Through this manuscript we try to analyze how real-time mental health monitoring has helped improve productivity among the global workforce as well as prevented deterioration of individual mental health across the globe. Our main plan of this study is to identify the significant efforts in mental health monitoring across the globe and then chalk out a real-time mental health monitoring framework for India. We also propose a real-time mental health monitoring smartphone-based framework for India we name as SmartMHealth. We describe the basic components of this framework in this study itself.

INTRODUCTION

As per the World Health Organization estimations varied mental health issues cost the world economy approximately an annual $1 trillion loss in global productivity ("India is the most depressed country

DOI: 10.4018/978-1-7998-8544-3.ch017

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in the world," 2018; James, 2019). About 450 million people globally experience some form of mental health disorders ("Augmented Mental Health," n.d.). $467 billion is the burden of mental disorders on the US economy annually. Given these startling estimates it is important to realize that a mentally healthy population is a key contributor in the success of any nation. Mental health is a key marker of the emotional, psychological and social well-being of an individual. As per World Health Organization (WHO) estimates, at least 6.5 per cent of the Indian inhabitants experiences some type of severe mental disorder, with no distinctive rural-urban discrepancy (World Health Organization, 2007). Positive mental health is a significant indicator of an individual's well-being at each stage of life (Vihan Sanyal, 2018). In fact, it is a fact that good mental health is one the underlying facets to prolonged and fruitful human life. Varied factors like stress, depression, social anxiety, drug addiction, obsessive compulsive disorder and other personality disorders may add to mental health issues leading to mental illness ("Mental health in India," 2017).

Hence, in the current times when competitive, technologically-driven social life is governing most people it has become imperative to verify the inception of mental illness to retain normal life balance. In an era when augmented mental health is emerging as the new paradigm in mental healthcare through data and digital therapeutics. Achieve early detection and prediction of human mental health is no longer a distant dream. Several machine learning algorithms and artificial intelligence have and can be applied for this realisation (Gurjit & Neena, 2006; Hillestad et al., 2005; Kumar & Hancke, 2015; Paul et al., 2018; Price et al., 2014). Such application when applied in real time shall profit the society at large by serving as a monitoring and control tool to identify onset of deviant or malicious behaviour among otherwise healthy and productive individuals.

The rest of the manuscript is structured as follows: Section I discusses the current scenario of world mental health. Section II highlights the need of effective mental health monitoring solutions. Section III stresses and analyzes the varied available mental health monitoring mechanisms. Section IV details the Indian state of affairs in mental health monitoring. Section V proposes SmartMHealth framework for real-time mental health monitoring. Section VI concludes the discussion.

Need of Mental Health Monitoring

As per global statistics (Kamdar & Wu, 2017), Neuropsychiatric or mental disorders along with cardiovascular diseases, cancer and other communicable diseases are a major contributor to the global burden of diseases and disease-related mortality. Table 1 below lists certain major neuropsychiatric disorders that are currently daunting the human race.

Though these disorder types contribute more than 10% to the prevalent disorders and diseases, however, research in monitoring or control of these disorders is still lagging behind (Kamdar & Wu, 2017). As per WHO estimates many developing and developed nations across the world are bearing the burden of mental disorders. Outcome based monitoring and feedback systems on therapeutic mechanisms have become popular in recent times and have been implemented by several health care providers all over the world. However, these don't seem to be implemented widely in mental health care ("India is the most depressed country in the world," 2018) (Birla, 2019). Mental healthcare as opposed to other non-communicable diseases requires continuous monitoring on a regular basis. Patients with psychiatric disorders may suffer behavioral symptom on a relapsing basis. Hence, to provide optimal care to such patients it is important to have some low-cost, widely available, real-time monitoring mechanisms in

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

place. Table 1 above establishes that there are direct relations between physiological/behavioral and mood states. Wearable sensors are hence, suitable mechanisms to continuously monitor mental conditions in an unassuming mode (Garcia-Ceja et al., 2018).

Table 1. Classification of Neuropsychiatric Disorders(Garcia-Ceja et al., 2018).

S. No.	Disorder Class	Signs & Symptoms
1	Mood Disorders like depression, unipolar and bipolar disorders	Hypoactive Electrodermal Response, Reduced Motor Activity (Chang et al., 2014; Sarchiapone et al., 2018; Todder, Caliskan, & Baune, 2007; Volkers et al., 2003), Cardiac Autonomy Disregulation (Chang et al., 2014)
2	Anxiety-Related Disorder (Anorexia, Eating Disorders, OCD (Obsessive Compulsive Disorder), Panic Disorder, Post-Traumatic Stress Syndrome)	Sleep Problems, Heart Palpitations, Unable to stay calm and still
3	Schizophrenia	Reduced Motor Activity (Winograd-Gurvich, Fitzgerald, Georgiou-Karistianis, Bradshaw, & White, 2006)
4	Dementia	Memory Problems, Depression, loss of ability to do everyday tasks
5	Substance Use Disorder	Disorientations

As clear from table1 there are multiple neuropsychiatric disorders plaguing humans. However, detection and monitoring of these disorders majorly rely on descriptive criteria. Limited clinical tests or medical devices are available for mental health monitoring (Kamdar & Wu, 2017). Information used by physicians in treating such patients is episodic relying on patient's visit. Tools and mechanisms for continuous, real-time data collection are desirable for such patients. EEG and video monitoring-based mechanisms though effective are insidious and do not allow incessant data collection. Further, output of these methods may not always be easy to interpret. Hence, more robust and patient-friendly mechanisms are desirable to improve the state of mental health monitoring as well as care.

Mental Health Monitoring Mechanisms

Globally current mechanisms to supervise mental health engage the prolific use of wearable technologies (Kamdar & Wu, 2017). Advances in EEG and video monitoring have lagged far behind due to the difficulty involved in their widespread use (Pantelopoulos & Bourbakis, 2009). Wearable technologies have surfaced as an emerging, omnipresent mechanism for providing uninterrupted, quantitative data about an individual (Pantelopoulos & Bourbakis, 2009). These mechanisms allow for easy, passive accumulation of quantitative data enabling proactive mental health management and better treatment. The wearable devices market has grown exceptionally in the last few years. As per Transparency Market Research, "the global wearable technology market is expected to grow from US$750 million in 2012 to US$5.8 billion in 2018" (Wei, 2014). This expansion and growth in the hardware device market forecasts creation and implementation of efficient mechanisms for wearable devices-based mechanisms for real-time mental health monitoring. It is important to note that these products can be easily empowered to measure varied attributes related to the surrounding environment, human physiology and activity. Hence, data can be easily collected passively without interfering the day-to-day activities of the user. Sentiment analysis on such data streams provides more accurate results as compared to surveys. Development and imple-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

mentation of wearable-device based mental health monitoring frameworks shall enable early diagnosis of unidentified users providing chances for preventive care as well as better diagnosis and treatment for diagnosed patients. Table 2 below details some notable mental health monitoring mechanisms applied in different perspectives.

Table 2. Notable Mental Health Monitoring Mechanisms

S. No.	Title	Ref.	Description	Achievements
1.	PRISM: A Data-Driven Platform for Monitoring Mental Health	(Kamdar & Wu, 2017)	Recapitulates user-reported ratings of their emotional state through applying supervised and unsupervised learning to PRISM — Passive, Real-time Information for Sensing Mental Health. Integrates motion, light and heart rate data obtained from smart watch application along with user interactions and text obtained from a web application.	Platform enables collection of incessant streams of passive data for near the beginning diagnosis or regular monitoring of patients with mental disorders.
2.	A Zigbee-Based Animal Health Monitoring System	(Kumar & Hancke, 2015)	An animal health monitoring system (AHMS) for checking the physiological parameters like rumination, body temperature, and heart rate with neighboring temperature and humidity has been developed. The system can also analyze the stress level corresponding to the thermal humidity index (THI).	The device has proved to be helpful in low-cost health care of livestock.
3.	Consume: A Privacy-preserving authorization and authentication service for connecting with health and wellbeing APIs	(Wetzels et al., 2018)	Current proliferation of Internet of things (IoT) enabled devices in health and well-being domain empowers individuals to monitor their health. However, the variety of devices leads to complexity of data aggregation and scattered overviews. Consume facilitates the integration of these APIs and data aggregation over a common platform.	Consume promises to aid researchers in development of personalized healthcare systems. It has provided the base for a universal data aggregation system for varied APIs. Thus, it shall accelerate development of new health monitoring as well data collection devices.
4.	Mental Health Monitoring with multimodal sensing and machine learning: A survey	(Garcia-Ceja et al., 2018)	Surveys research work in mental health monitoring systems through the use of ubiquitous sensing technologies for data collection and machine learning to predict the related user contextual information.	The papers surveys all research works on mental state monitoring through sensors that gather wearable data. The classification given is helpful in understanding the basics.
5.	Complexity Index from a Personalized Wearable Monitoring System for Assessing Remission in Mental Health	(Lanata, Valenza, Nardelli, Gentili, & Scilingo, 2015)	Introduces PSYCHE, a t-shirt with embedded sensors for monitoring electrocardiogram heart rate variability (HRV) series, respiration activity and activity recognition for patients suffering with mental disorders.	Continuous interface between clinicians and patients advances the quality of life of patients aiding the clinicians in the analysis and preventing relapses.
6.	Ginger.io Commercial app (The Ginger App)	(Matheson, 2014)	The app passively analyzes mobile data to detect if a patient with mental illness is acting symptomatic. The symptoms may vary from lethargy to infrequent texts. On detecting an unusual pattern the app sends messages to the patient as well as their health care provider.	The app is currently being used by thousands of patients at more than 25 health care institutions and academic centers across the United States. The app has also been applied for research at a number of universities across the globe.

Real-Time Mental Health Monitoring for India

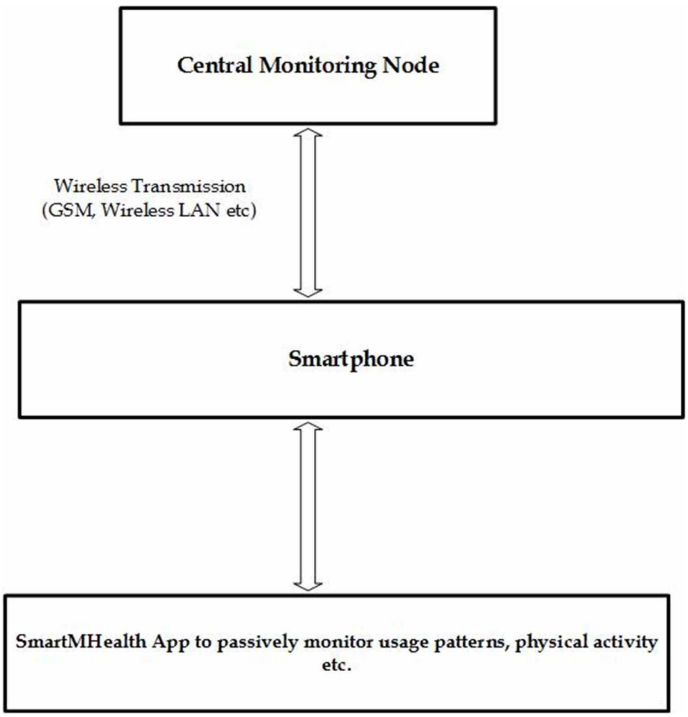
As per WHO estimates, India was the initial nation globally, to identify the need for incorporation of separate mental health services along with general health services at the primary level (Agarwal, Goel, Ichhpujani, Salhan, & Shrivastava, 1946). The National Mental Health Programme (NMHP) was launched as early as 1982, to treat mental disorders among the community with the available care services. However, as a nation we somehow lagged behind in proper mental health monitoring and treatment of our mental disorder affected population. These mentally ill patients are seen more as a social stigma and are abandoned by their family and community. Our policy and community failure was highlighted in 2001, when an asylum fire in Ramanathapuram district of Tamil Nadu killed 26 mentally ill patients residents of this asylum (Agarwal et al., 1946). Following this incident, the Directorate General of Health Services in May 2001 undertook a Current Situation Analysis (CSA) survey in order to evolve a inclusive plan of action to reenergize the NMHP. As a result, the NMHP was re-reviewed and reoriented at district level also known as District Mental health Programme (DMHP) with an outlay of approximately 190crore in the 10th Five Year plan. The DMHP plan now aims to cover every district across the country to reorient mental colleges and hospitals to establish high standards of care and treatment. The plan receives a huge grant in each of the five year plans and is to be re-reviewed in 2020, as NMHP 2020 (Agarwal et al., 1946). However, despite the long presence of this national policy framework, India as a nation has failed to eliminate the stigma of mental disorders from its society. As per records, Kerala one of the most literate and high life quality states in the country reports rising incidence of suicide cases amongst its population (Agarwal et al., 1946; Bachani & Srivastava, 2012; Manoranjitham et al., 2010). Such is the state of affairs despite the fact that India has a well-laid policy framework for mental health in the form of NMHP and the plan is well-aided financially. It is notable to mention here that it costs Rs. 500/ day to maintain a patient in a mental hospital whereas the per capita national expenditure on health is only Rs. 200/year. Gujarat spends more than Rs. 37.2 million on its 4 mental hospitals with a total bed strength of only 680(Agarwal et al., 1946). These facts bring to light certain important observations, which we list below:

- Mental disorders in India are associated with unwarranted social stigmas and superstitions resulting in abandonment of mentally ill patients by immediate family and community. As a result, cost of maintenance of such patients goes up. Destigmatisation of mental disorders is important.
- India should realize that mental health is not related to the purse but to the mind.
- It's time to call for a spirit of invention of practical solutions empowered with available technical skills to accomplish real-time mental health monitoring and care. IoT enabled services and smart devices can be used as a basis to design a framework for continuous mental health monitoring of our able population as well as mentally-ill patients to enable early identification of disorders and ensure their proper prevention and treatment.

Globally lot of notable work has already been conducted in smart health monitoring through m-Health applications as well as through wearable biosensors (Berrouiguet et al., 2018; Chandrashekar, 2018; Chen, Ma, Song, Lai, & Hu, 2016; Pantelopoulos & Bourbakis, 2009)

Some of these applications also monitor the varied mental disorders of patients providing them a close loop monitoring and interaction with their physicians. However, recognizable volume of this work especially in general mental health assessment and analysis of seemingly normal population but on

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use



risk of mental health disorders is missing especially in India ("Mental health in India," 2017). As per WHO, "Vigilant monitoring and assessment of a nation's mental health policy and plan are essential for improving services, healing and care and for guiding future policy directions"(World Health Organization, 2007).WHO under its Mental Health Policy and Service Guidance Package has laid down clear guidelines to assist nation's in laying down policies and plans to assist nation's in improving the mental health of their populations. Mental health remains the elephant in the room in the formidable corridors of corporate India. Of the country's 1.1 million active registered companies, only 1,000 are estimated to have a structured employee assistance programme (EAP) for mental health (James, 2019). Notable studies have already been conducted on varied aspects related to mental well-being of Indian population (Hasumi, Ahsan, Couper, Aguayo, & Jacobsen, 2012). However, practically efficient solutions are still a distant dream.

SmartMHealth: Real-Time Mental Health Monitoring Framework for India

Our SmartMHealth framework aims at the development of a low-cost smartphone based, unobtrusive solution for continuous mental, emotional and activity status monitoring of individuals. The proposed system shall provide real-time feedback about an individual's mental health. This continuous data when shared with a central monitoring unit (node) or self-checked by individuals can alarm in case of possible imminent mental health threatening conditions like stress, increased cardiac activity etc.

The proposed SmartMHealth App shall be a smart phone-based app to monitor physiological, emotional signals as well as physical activity rate of its user. Figure 1. depicts the major components of the proposed SmartMHealth framework.

Figure 1. Architecture of Smartphone based SmartMHealth App

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1 visualizes the concept of a possible SmartMHealth app that could passively monitor the user's usage patterns and send alarm signals to the central monitoring node in case of any deviation. However, this should not be considered as standard system design, as actual implementation may vary significantly. As can be seen from Fig.1 of all possible smart wearable devices we have chosen SmartMHealth as a smartphone enabled app. It can be argued that any other low-cost smart device can also be used, however smartphone was a natural choice as almost 94% of the world population are cell phone subscribers and Internet users irrespective of external factors like place of residence, level of education, etc. (Chan, Estève, Fourniols, Escriba, & Campo, 2012; Vashist, Schneider, & Luong, 2014). Further, behavioral health analytics startup Ginger.io has also identified smartphones as "automated diaries" that can provide valuable insight into the mental well-being of any individual including mentally ill patients (Matheson, 2014). Smartphones inherently produce significant behavioral data regarding an individual in the form of location, calling and texting records as well as app usage history. This data can be easily used to map a user's daily patterns. A deviation in this pattern is enough to raise an alarm. The alarm can be transmitted to the individual under observation as well as their health care provider as well as the central monitoring node. The central monitoring node with the help of appropriate machine learning algorithms can help analyze the humongous passive health data collected to usable information for passive health care monitoring of healthy individuals. The details of the smartphone-based apps, required resources for creation of the central monitoring unit as well as the machine learning algorithms are being worked out at the time of this writing and shall soon be discussed and implemented. This tool would be effective in realizing the world of augmented mental health.

CONCLUSION AND FUTURE SCOPE

As per our analysis, for effective solution of mental disorders India actually requires a paradigm shift from the hospital care to community care. This also calls for an early diagnosis of alarming mental conditions and thus shifting from treatment to prevention. As a country, we need to rise and realize that mental health is not a social stigma, it is not a government policy initiative and neither just a personal initiative. Instead mental well-being and health is more of community care and monitoring.

Chapter 18
Appreciative Inquiry and Mental Health Improvement:
A Review on Applicative Potential at Individual Level

Malabika Tripathi
https://orcid.org/0000-0002-5052-2953
Amity University, Kolkata, India

ABSTRACT

Appreciative inquiry is an 'asset-based' approach that focuses on the positive things of life. Through its 4D cycle and principles it generates transformation of organization. AI when practiced goes through 4D cycle of discovery, dream, design, and destiny. An individual gets the scope to rediscover and reorganize when passing through these four phases. This liberates the mind through exploration and introspection. Interventions of AI even clarify the 'shadow' area of the human mind. The chapter tries to establish AI as a potential tool that can be used at individual level to aid in up gradation of mental health awareness through reviewing existing literature in this field.

INTRODUCTION AND CONCEPT OF APPRECIATIVE INQUIRY

The concept of appreciative inquiry was propounded by Cooperrider and Srivastava in 1986 but it has its origin in the theory of social constructionism (Berger & Luckmann, 1966). David Cooperrider conducted his doctoral study on physicians engaged in leadership position at United States medical centre. They were asked to tell stories about their victories and failures (Cram, 2010). Coghlan et al, (2003) in their research article mentioned that "He was amazed at the level of positive cooperation, innovation, and egalitarian governance when they were at their most effective". This led Cooperrider and his guide Dr. Srivastava to think that emphasis upon the strength and positive sides of an organization can be transitional based on the logic that "organizations move toward what they study" (Cooperrider, Whitney & Stavros, 2003). This process of AI involves 4D cycle of discovery, dream and design to shape the future

and effort to transform the destiny (Whitney & Trosten-Bloom, 2003). Culture of employee engagement can be built, and it should be fabricated through the tenacious efforts of managers and leaders in the organization, deliberate efforts can be made to build culture, positive work environment leads to positive outcome of performance (Chakraborty & Ganguly, 2019).

Conventional approaches in order to bring organizational changes were criticized by many researchers, then this new approach came into being which included both social and psychological perspective (Gergen 1982, Gergen 1990, Bushe & Coetzer 1995). Appreciative inquiry is research method which focuses on organizational change though positive attributions i. e. appreciative inquiry emphasizes on exploring the strength of the organization in lieu of weakness for its growth and prosperity. In the recent past the application of appreciative inquiry in the organizations has grown brilliantly (Dick, 2004).

BACKGROUND

Appreciative inquiry was created to provide an unconventional approach to solve organizational problem and was an alternative for problem solving approach (Beattie, 2018). Problem solving method mostly deals and focuses on what is not doing well or wrong in the organization, where as appreciative inquiry deals and encourages the positive things as capable components behind organizational development. Watkins et al (2016) described appreciative inquiry as an efficient tool to change social system. They also depicted that it is also capable of bringing change in complex human world. According to Bushe (2007) the method of appreciative inquiry is not only limited to positive characteristics but a pursuit of novel ideas, theories, models that discover and manifest cumulative desires. Many researchers also commented that AI should not just merely be treated as a tool for organizational development but an ideology and inclination which can reform and reshape primarily the process of organization learning, design and development (Watkins & Mohr 2001).AI is more about "both a philosophy and a worldview, with particular principles and assumptions and a structured set of core processes and practices for engaging people in identifying and co creating an organization's future" (Coughlan et al, 2003). The applicative potentials of AI are vast. The method and principles of appreciative inquiry were thoroughly investigated by many researchers. For example- Van Buskirk (2002) conducted his research on urban catholic schools and found satisfactory transformational results. AI was proved to be useful even in enhancing personal relations (Klem, 2005) of the individuals. Kaye et al (2008) in their research also explained that AI interventions provides the opportunity to its participants -to explore and depict the best experiences of life, assessment of life giving components and to express the tales of their personal eminence. Laertius & Yonge, (2006) described that AI principles are reinforced by the psychology of adult development through introspection or knowing oneself and actualizing one's innate strengths. These avenues of self reflections through narrations become the pillar for transformation even at individual level. Appreciating the good things in life, being content, grateful and interpersonal resilience improves one's sense of well being. These factors can even contribute positively towards the improvement of participant's mental health.

CONNECTION BETWEEN APPRECIATIVE INQUIRY AND POSITIVE PSYCHOLOGY

Positive psychology is another approach which also emphasizes on the strength instead of the weakness to study human behaviour, thoughts and actions more systematically. Positive psychology started its journey with Martin Seligman (2003). Positive psychology focuses on happiness, joy, gratitude, resilience, compassion, inspiration etc. Peterson and Park (2014) defined "Positive psychology is the scientific study of what makes life most worth living". The outlook of positive psychology is optimistic in nature. Peterson (2003) articulated that this leads to the accomplishments of the desired and relevant circumstances. According to Seligman "The field of positive psychology at the subjective level is about positive subjective experience: well-being and satisfaction (past); flow, joy, the sensual pleasures, and happiness (present); and constructive cognitions about the future—optimism, hope, and faith" (2005). This psychological approach also works on individual as well as in 'group level'. There it functions as civic righteousness and institutions which encourages individuals towards better "citizenship: responsibility, nurturance, altruism, civility, moderation, tolerance, and work ethic" (Seligman, 2003). Just like positive psychology appreciative inquiry also is optimistic in nature thoroughly focusing on the positive aspects of what is doing well and doing more of it. Many researchers have suggested that appreciative inquiry approach is influenced by the concept of positive psychology (Seligman et al, 2005). Kobau et al (2011) in their research promoted the importance of mental health in public health. To conduct the research they focused on the principles of positive psychology. They concentrated on positive attitudes, psychological capital and strength of the individuals and how these factors can contribute towards the growth as a whole. They found that positive emotions has multidisciplinary effect on improving the overall well being of human life staring from physical health, professional endeavors, family and financial conditions. This asset based approach of positive psychology can be used to boost up resilience and promoting mental health.

Positive psychology and AI both disciplines deal with appreciation of the present situation, which incorporates gratitude, resilience, optimism and hope. The psychology of appreciation or being grateful to the things a person have is closely associated with both the fields. Positive psychology gives way to progress in a manner where pivotal point is optimism. Appreciative inquiry also gives the opportunity to liberate one's own desire and thought to bring a dynamic change. To describe the process of positive psychology Seligman referred that "there are human strengths that act as buffers against mental illness: courage, future-mindedness, optimism, interpersonal skill, faith, work ethic, hope, honesty, perseverance, the capacity for flow and insight, to name several. Much of the task of prevention in this new century will be to create a science of human strength whose mission will be to understand and learn how to foster these virtues in young people." (2003). AI can be regarded as that 'science of human strength'. Therefore the synergy between positive psychology and appreciative inquiry can bring about a dynamic change in the promotion of importance of mental health and its awareness.

The aim of this article is to establish AI as an efficient positive approach for the improvement of mental health among individuals through transformation. This will also try to decipher how appreciative inquiry can be coupled with other existing intervention of the same field for the above said purpose.

APPRECIATIVE INQUIRY AND MENTAL HEALTH

Appreciative Inquiry (AI) is an approach to organizational change, or more generally- a change in human systems, which has gained increasing popularity among practitioners and has sparked the interest of the academic community over the last 20 years (Whitney & Trosten-Bloom, 2003). David Cooperrider and Suresh Srivastava developed the theory of AI in the year of 1986 for his doctoral dissertation. Hence, the most often cited definition of AI is that of Cooperrider, Whitney and Stavros (2003):

Appreciate Inquiry is the cooperative, co-evolutionary search for the best in people, their organizations, and the world around them ... AI involves the art and practice of asking questions that strengthen a system's capacity to apprehend, anticipate, and heighten positive potential. (Cooperrider, Whitney & Stavros, 2003)

Coghlan, Preskill and Catsambas (2003) describe AI as "both a philosophy and a worldview, with particular principles and assumptions and a structured set of core processes and practices for engaging people in identifying and co-creating an organization's future." AI has been described by observers in several ways such as: a paradigm of conscious evolution geared for realities of the new century (Hubbard, 1998); as an offspring and "heir" to Maslow's vision of a positive social science (Chin, 1998; Curran, 1991); as the most important advance in action research (Bushe, 1991) and so on.

A study done by Clossey, Mehnert and Silva (2011), showed that AI has been found to facilitate recovery in mental illness, as it empowers individuals and creates a supportive, client-centered environment. AI seeks to overshadow "what went wrong and who is at fault" and focus on "what can be done to make things better". This creates an environment which enables an individual to discover, dream, design and deliver their desired behaviour. In a study conducted by Julia L. Hennessy (2014) discusses and explores the possibility of AI being a research tool for mental health services. In this four-stage model, each stage has its respective inquiry (Cooperrider, Whitney & Stavros, 2003; Whitney & Trosten-Bloom, 2003):

- **Discovery:** Questions asked here are: "What gives life? What is good about our past and present?" This stage focuses on discovering and valuing what the organization already has.
- **Dream:** It involves envisioning what might be to what has already been discovered.
- **Design:** Based on the previous stage, organization members identify which ones of their stories and dreams will be transferred into reality.
- **Destiny:** Here, the organizational members collectively commit to and set out to create what they desire.

There are five core principles of AI:

- **The Constructionist Principle:** Organizations are human constructions, that is, organization's reality is constructed by the questions people ask.
- **The Simultaneity Principle:** Change begins the moment the present is questioned. These questions become the stories out of which the future is conceived, discussed and constructed.
- **The Poetic Principle:** Like a poem, the organization's past, present and future are endless sources of learning, inspiration and interpretation.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **The Anticipatory Principle:** One's present behaviour is influenced by the future anticipation. The more positive and hopeful the future image is, the more positive the present action will be.
- **The Positive Principle:** The more positive the questions are used to guide a change process, the longer lasting and effective the change becomes.

Researchers have shown that positive imagery evokes positive emotions and positive emotions move people towards a choice for positive actions (D.L. Cooperrider, Whitney & Stavros, 2008). To achieve positive imagery, it is important that every individual in the organizational team has a positive and balance mental health state. In a study of teams, it has been shown that cognition dominated by negative imagery proved to be an impediment in the teams' performance (D. Cooperrider, 2000). AI is a powerful way to change an organization's cognition from being negative to being generative and creative (Bushe, 2000). It is so because AI views organizations as living human systems and change is done by the process of cognitive shift (Nilakant & Ramnarayan, 2006); Lewis, Passmore, & Cantore, 2008). AI does not revolve around hiding or fixing the weaknesses. It rather focuses on strengthening the areas of strength and promoting positive change.

Mental health is not referred to as the absence of any mental illness but to our emotional, psychological and social well-being. In 2011, a case study conducted by Lea Waters and Mathew White was done on K-12 private boys' school in Australia. The aim of this study was to study the effect of implementation of a strategic plan of fostering student well-being. This school established a three-year old strategic plan where the goal was to build a dynamic and comprehensive wellbeing program for its students. The Senior Leadership Team (SLT) decided to adopt AI as a guiding approach to develop, implement and monitor this wellbeing strategy in the school. Towards the end of the three-year old plan, several changes took place, such as:

- A positive psychology interest group was formed which brought together 70 people across the school who didn't have much contact due to role difference and geographical separation.
- At the first parent-teacher meeting for senior years, every student's mentor discussed on the student's well-being, character development and academic accomplishment.
- The Physical Education Department volunteered to start weekly well-being activities such as yoga, mindfulness, and Tai Chi.
- The teachers and counselors started working together towards a common goal of boosting students' wellbeing, and so on.

These findings show that when members of the organization unite to work around an appreciate topic, it breaks down traditional barriers and promotes mental health.

A study done by Anthony Scerri, Anthea Innes and Charles Scerri (2016) investigated the results of using method of AI in dementia patients in hospital wards. AI was used to implement the person-centered dementia care in the hospital. Since life is challenging and difficult for not only the individual with dementia but also for the doctor, nurses and staff members, this study implements a number of action plans in accordance to AI. Using AI approach, the staff attitudes towards individuals with dementia improved. Furthermore, inter- professional collaboration was also enhanced. Engaging in AI workshops not only brought big positive changes in the organization in hospital wards, but also small changes in staff practices were observed and noted.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Another study done by Jaclynn L. Glasgow (2008) aimed to discover successful teaching practices of a low socio-economic elementary school that met the standards of excellence. One of the methods used for this qualitative study was the AI method for discovering positive aspect of this organization. As stated by Thatchenkery (1999), AI seeks to discover and heighten the "life-giving-forces". AI is a team learning method where the participants are brought together to bring about a positive change. The findings of this research suggested that AI has the "potential" to change teachers' educational practices and empower the participants and spark a new vision of hope, optimism and a passion for teaching.

"AI emphasizes empowerment and encourages participants to see their organization as a community that can envision and create a positive future, emphases that are compatible with the philosophical stance of the recovery model." (Clossy et al, 2011, p-261).It is a process which encourages the appreciation of things which add values to human system while functioning at their best. It enables analysis of strength, success, values and aspiration at individual as well as in organizational level through asking questions or narrative storytelling. It emphasizes that human being alone and collectively has distinctive virtues and skills which can lead to a better subjective world through moving away from problems and concentrating more on the relevant positive ideas and imaginations (Moore, 2008).

According to World Health Organization (WHO, 2014) mental health is "... a state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community". Medilexicon's medical dictionary defines mental health as "Emotional, behavioral, and social maturity or normality; the absence of a mental or behavioral disorder; a state of psychological well-being in which one has achieved a satisfactory integration of one's instinctual drives acceptable to both oneself and one's social milieu; an appropriate balance of love, work, and leisure pursuits." Nordqvist (2017) in an online article described that mental health is a combination of an individual's cognitive, behavioural and emotional well being. It comprises of how an individual 'think, feel and behave'.

AI helps in bringing a positive change in organizational structure utilizing its resources. This is done through structured or semi structured interviews of the participants. Participants explore themselves as well as the situations through the different stages of 4D cycle of Discovery, Dream, Design and Delivery or Destiny. Passing through each phase of this cycle an individual can also re-discover himself and his internal motivation is increased through unleashing the facts that he can dream, design and implement to bring about a significant positive change in his life. This process of self discovery is very important for improving the mental health of any individual. Hennessy & Hughes (2014) in their research described the utility and challenges of AI. They investigated that AI can be used as a research tool for mental health services due to its transforming nature. They also said that it can bring positive changes in mental health consumers. Bushe (2010) described AI as a life giving process. "AI builds on and amplifies this natural tendency by explicitly inviting people to collectively inquire into their system's life-giving properties and positive anticipatory images of their common future. AI theorists argue that while engaging in these joint activities people are building new generative connections that bring a feeling of joy, aliveness, hope, caring, and potential, leading people to create more and new things without being told or asked to do so" (Verleysen et al, 2015, p-5). This explanations along with the operative principles of AI implies that if it is properly administered it can play a pivotal role in upgrading the mental health of individuals. Acosta & Douthwaite (2005) in their research concluded that interview sessions of AI gives participants the opportunity and freedom to express their positive experience and contribution making them more confident in empowering a difference. The storytelling sessions teaches appreciation of human values and potential as important notion for changes. They also depicted that AI helps in building

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

a strong self image and enables the individual to be achievement oriented through its existing principles and cycles as it transforms the best past into effective present and future. The positive approach of AI also contributes in self-organization (Bushe & Kassam, 2005) which can boost up the metal health at individual level. According to Chakraborty & Mishra (2019) exercising AI in individual level creates self motivation, liberated attitude, effective learning. This attributes makes a person more intrusive in their search for strength and optimism which makes them more successful and creative in life. From the existing literature of this field it can be said that AI interventions are extremely useful for improving mental health of an individual collectively as it unleash the hidden motivation to do better in life as well as improving coping strategies. Thus along with the organizational development, application AI interventions in upgrading the mental health at individual level can be proved to be beneficial and must practiced elaborately.

APPRETIAVE INQUIRY AND SHADOW AREAS OF HUMAN PERSONALITY

Karl Jung (1968) deciphered that there are certain trait among individuals which they tend to deny or do not accept. In his terms shadow is "everything that the subject refuses to acknowledge about himself, for instance, inferior traits of character and other incompatible tendencies" (p. 284). Kolodziejski (2004) in her doctoral research explored the concept of shadow more meticulously at different arenas of inter-intra personal, group and organizational level. She expressed shadow " as that which is feared and suppressed, that which is considered inappropriate and shunned, that which is unbearable to hold consciously and denied" (p. 64). She also described shadow as a broad spectrum of hidden desires and cognition starting from suppressed potentials capabilities to insubstantial emotions. It includes both positive and negative characteristics to be identified by self or others. Sometimes the concept of shadow is misinterpreted as negative action but is just the byproduct of the same. AI mostly focuses on strength which in turn creates awareness within the individual regarding their own potentiality hidden in the shadow area (Fitzgerald et al., 2010).AI can reveal the repressed strength of an individual justifying the differences which paves the way for their individual development. The measurements of AI can also be used to uncover the shadow area of human mind to bring it into light through transformations.

THE TRANSFORMATIVE ASPECT OF APPRECIATIVE INQUIRY

Many researchers have successfully proved that appreciative inquiry can create and transform changes at both organizational and individual level. It imparts transformational learning. This transformative nature of Cooperrider's AI has some similarities with Mezirow's (2000) components of transformative learning. "Mezirow (2000, p. 22) suggested that transformation usually occurs in some form of the following 10 stages: 1.A disorienting dilemma 2.Self examination with feelings of fear, anger, guilt, or shame 3.A critical assessment of assumptions 4. Recognition that one's discontent and the process of transformation are shared 5. Exploration of options for new roles, relationships, and actions 6. Planning a course of action 7. Acquiring knowledge and skills for implementing one's plans 8. Provisional trying of new roles 9. Building competence and self-confidence in new roles and relationships 10. A reintegration into one's life of conditions dictated by one's new perspective" (kaye et al, 2008, p- 635-636). Mezirow concentrated on desynchronizing dilemma. Based on which Allen (2007) wrote that,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

abashment of dilemma enables an individual to perceive himself, the world and personal relationship in better polarized manner. Reduced confusion enables an individual to make better decision; they become more constructive by using the cues of excellence from their past life. The proper execution of AI can also modify a person internally. Being an action oriented approach AI allows a person to introspect and be a responsible part for future success. Denovan et al (2007) illuminated the complementary nature of both AI and transformative learning for human growth. Both disciplines allows self reflection through narratives and stories which leads to transformation by digging out the positive strength and aspiration which may work in positive direction towards uplifting the mental health of an individual. Barrett (1995) suggested that 'appreciative approach' is an ability to perceive life beyond its existing problems. In this context Fredrickson et al (2003) reported that positive emotions prevent depression and helps in building optimism, resilience and improves relationship. It enhances individual well being, and AI focuses mostly on positive aspects of life which in a nutshell can be narrated as 'assest'.

FEW RESEARCHES DONE ON MENTAL HEALTH USING THE INTERVENTION OF APPRECIATIVE INQUIRY

The researches on AI were more focused on organizational development and collective improvement. It is a strength based method, which encourages and explores positive feedbacks by contributor (Reed 2006, Reed *et al.* 2008). However, by using the methods and principle of AI benefit at individual level can also be ensured as it allows one individual to liberate his thought and actions. This process is can be considered fundamental by psychologists to improve the mental health of any person.

Shiner et al (2008) also used appreciative inquiry method to improvise the well being of the patients with severe mental illness which impairs the overall functioning of an individual. It was a health promotion programme of the persons with severe mental illness. Semi structured qualitative interviews were conducted using AI principles. Participants had severe mental illness like chronic major depression, bipolar mood disorder and some were under the spectrum of schizophrenia. The interviews were conducted regarding their positive experiences about the IN SHAPE programme, the subjective quality most which were most appreciated and considered important for the success of the programme. They were also encouraged to share their views on core components and suggestions for the betterment of the programme .The interviews were recorded and transcribed. The result vividly reported that the In SHAPE programme and interventions of AI helped them to focus on a healthier life style, which most of the patients with severe mental disorder ignores. Through the interviews of AI it was established from their perspective that exercise, social interaction and boosting up self confidence aided the individuals suffering from severe mental disorders and it also paved their way towards physical as well as psychological well-being.

Moyle et al (2010) conducted their research on old age population to measure their mental well being through resilience. They applied multinational appreciative inquiry approach to study these parameters. The participants were from Germany, Australia, UK and South Africa. The minimum age of the participants was restricted to 65 years. Present researchers followed the 4D method (Discover, Dream, Design, Delivery) developed by Cooperrider et al (2003) for appreciative inquiry. This study shows us that instead of concentrating on negative sides of life mental health can also be improved through focusing on the positive aspects. The results based on the interview of the respondents revealed that being active through various brain gym, healthy family set up, social connection, community get together, more responsibil-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ity, self determination improves mental health of the elderly people and keeps them satisfied in life. Allen (2008) also supported that old age people can maintain their well being based on active life style, spending time with grand children, through exercising, volunteering in social activities etc. Resilience was proven as key factor behind well being of older people in both the studies.

Bonham E. (2011) explored the 4D model of appreciative inquiry in his research upon the youth offenders. Amalgamation of impulsive behaviour expectations influenced by culture was observed among the subjects. The detained youth under juvenile justice system were summoned to find openings to express their own stories and life experiences that can make their future better. The qualitative nature of interview pattern and stories were analysed with the help of 4D cycle Cooperrider & Whitney, 2001). The result proved to be beneficial for juvenile offenders as they were able to perceive self empowerment and envision positive changes in their life.

Daskivich et al (2015) conducted their research on a group of physicians. Whether in training or in practice this community faces a lot of psychological troubles in terms of stress, depression and anxiety resulting in increased number of the suicidal cases. The objective of the research was to find out and impart available current strength or resources by the trainee and residents physicians to enhance their sense of well being and establish a stress free functional learning environment. The ACGME Council of Review Committee Residents comprising of 29 participants conducted an appreciative inquiry session. The focus was to find available resources, envisage constructive learning environment to aid in wellness, to modify the existing infrastructure to help in that process of improvement. The suggestions were analysed and common point of concern were indentified. The result which came out through appreciative inquiry suggested that interventions like more awareness in the areas of stress and depression management, treating depression with care, thorough guidance by senior members, supportive work culture and more knowledge about mental health area of depression and stress management can lead to better well being of the resident/ trainee physicians. Considering this profession as both rewarding and challenging the tangible goals reached through appreciative inquiry had all the potential to deal with the mental trauma of the resident physicians.

From the above cited researches it is evident that AI has all the potential to be used as a tool for generating awareness about self and re-discovering it. These features of AI can be a boon in the mental research areas if executed thoroughly. But, unfortunately very fewer studies were carried out by the researchers at individual level. This article can highlight the need and usefulness of AI to enhance the mental health at individual and group level. More relevant researches in this area are required.

Though AI being practiced as an 'asset-based' approach and its benefits were highly appreciated by many researchers, still its pitfalls were also discussed by some. One of the customary disadvantages of this approach is that it completely ignores the shadows or problems. In this context Ellis & Davidi (2005) commented that learning experiences from both success and failures enables a person to modify his mental models. Thus, it may be said that focusing on some negative points are also important sometimes depending upon the need of the situation.

CONCLUSION

Appreciative Inquiry is such a domain which follows the path of positivity. Embracing positive approach can solve a lot of existing problems of human life. The process of AI is pain free in nature, thus it has an in build essence of happiness. It focuses on the successful experiences of the past to make the future

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

better. Acknowledging and being grateful towards the events of life brings the sense of accomplishment in individual which in turn is capable of enhancing one's over all well being. In this context the work of Froh et al (2008) is very relevant. They conducted a study on the role of 'counting blessings' in terms of gratitude to enhance the subjective well being of the adolescents. The result of the research suggested that being grateful or having a positive outlook towards life is associated with satisfaction in life and it also helps in reducing negative experiences.

Implications

In this paper an attempt was made to prove AI as an important approach to improve the mental health of an individual. The success stories of AI as a potential factor for the organizational transformations and development are plenty in number. However, the process of AI includes participant and gives them the opportunity to explore their inner qualities, strength which can boost their motivation and confidence (Chakraborty & Mishra, 2019). Thus, this approach of AI must be practiced more in mental health improvement at individual and group level. Unfortunately elaborative researches are yet to be done in numbers. This paper furthers points out the need for more researches on this field. The present article also suggests a relevant area of research by exploring the effect of exercising different model and principles AI to improve or upgrade mental health at individual level. For example, is the adherence of action towards positive changes remained intact after the intervention of AI got over? This approach is capable of bringing a dynamic change in the arena of mental health awareness.

Chapter 19
Digital Heath Interventions in Mental Health

Aleksandra Stanimirovic
University of Toronto, Canada

ABSTRACT

Technological renaissance of the last century stimulated the application of digital interventions in the healthcare domain. Digital healthcare interventions (DHIs) could be implemented through smartphone applications (apps), remote monitoring and tracking devices, and wearable computers. Technology is positioned to transform how mental healthcare is delivered and accessed. In fact, remote active and passive monitoring of parameters, such as mood, activity, and sleep, could be integrated with therapeutic interventions. However, the transformation entails combined conscription of science, regulation, and design. Implementation, adoption, and evaluation of DHI present special challenges. This chapter presents brief history of DHIs in mental health and frameworks an evaluation strategy in terms of the appropriate methods required for appraisal of DHIs.

INTRODUCTION

Defining Digital Health Interventions [DHIs]

Twenty years ago digital health interventions [DHIs] were nothing but a distant impossibility. The revolution of information technology [IT] in the last century means that technology can be utilized to confront pressing healthcare needs. The range and scope of DHIs and digitally delivered healthcare services have evolved rapidly since Eysenbach's (2001) initial description of Internet-enabled or computer-enabled interventions. (Hollis et al., 2017) Early DHIs in the mental health field were based on static content with limited interactivity and were 'fixed' in terms of access (e.g. via a PC or laptop, requiring a wired Internet connection), whereas users were required to be in a specific location to access the intervention. Examples of these DHIs include computerised cognitive behavioural therapy typically mimicking, face to face (FtF) delivered CBT sessions by providing a series of discrete modules that users complete (Hollis et al., 2017)

Initial approaches are often referred to as 'tele-health', 'tele-medicine' or 'tele-psychiatry' and fall within the broad description of 'eHealth. (Hollis et al., 2017) Over the last decade, the increased popularity and availability of mobile digital technologies, such as smartphones and wearable technologies, has led to the development and evaluation of mobile DHIs, also known as 'mHealth' (see Table 1 below). (Hollis et al., 2017) mHealth DHIs include devices such as smartphone applications ('apps'), remote monitoring and tracking devices, and wearable computers (e.g. smartwatches, virtual reality headsets). Remote active and passive monitoring of parameters, such as mood, activity and sleep, are now being integrated with therapeutic interventions. Hence, the distinction between mHealth digital monitoring and interventions is likely to become increasingly blurred. (Hollis et al., 2017) (Murray et al., 2016) Mental health DHIs target a range of psychological disorders and differ in design and functionality. (Chandrashekar, 2018) National institute of mental health (NIMH) categorizes mental health DHIs into six categories based on: 1) functionality: 2) self-management; 3) cognition improvement; 4) skills-training; 4) social support; 5) symptom tracking; and 6) passive data collection. (Chandrashekar, 2018) Evidence indicates that technology present a tremendous opportunity for delivery of high-efficacy mental health interventions in domains of anxiety, depression; and schizophrenia. Considering scarcity of accessible mental health care professionals. and lack of mental health care access in rural and urban areas, DHIs have emerged as a practical tools that may bridge the mental health treatment gap. (Chandrashekar, 2018) Technology is well-poised to transform how mental health care is delivered and accessed, however the transformation requires the combined conscription of science, regulation, and design. (Chandrashekar, 2018)

Table 1. Glossary of common terms and abbreviations used in the field of digital healthcare

Term	Definition
Digital health intervention (DHI)	Interventions that provide information, support and therapy (emotional, decisional, behavioural and neurocognitive) for physical and/or mental health problems via a technological or digital platform (e.g. website, computer, mobile phone application (app), SMS, email, videoconferencing, wearable device)
eHealth (Electronic Health)	Internet-based healthcare delivery/anything health-related that uses information and communications technology (Blackwell et al.), incorporating computers or Internet in its delivery
Internet, online/web-based interventions	Computerised program or service delivered through the Internet (e.g. a website), designed to create a positive change in behaviour or health status with different levels of support (e.g. completely unguided, human-supported)
Computer-based/computer-delivered interventions	Similar to Internet-based interventions, but usually refers to a program delivered via a computer: the intervention may be via the Internet or an offline computerised program (e.g. CD-ROM, or installed software). Includes psychoeducation and psychotherapy packages, 'serious' games and neurocognitive 'brain training' interventions
Computer, Internet-based or mobile-based CBT	Delivery of Cognitive Behavioural Therapy (CBT) via computer (cCBT), Internet (iCBT) or mobile devices or applications (mCBT). Collectively may be referred to as electronically delivered CBT (eCBT)
mHealth (Mobile-delivered Health)	Subdivision of eHealth focusing on delivering healthcare-related information, interventions and monitoring through portable electronic/mobile devices and technologies, such as smartphones, tablets and wearable devices. Examples of mHealth for mental health include smartphone applications ('apps'), text/SMS-delivered interventions and patient monitoring devices
Telehealth, telepsychiatry and telemedicine	Delivery of health services and treatment via telecommunications technology (e.g. videoconferencing/SMS/email), including: online counselling and therapy that may be synchronous (e.g. real-time videoconferencing) or asynchronous (e.g. email /SMS).

*Note: Adapted from: (Hollis et al., 2017)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Generally speaking, DHIs are complex interventions with multiple intertwined components, and typically have multiple aims, including; 1) enabling users to be more informed about their health; 2) share experiences with others in similar positions; 3) modify perceptions and comprehension around health, 4) remotely assess and monitor specified health states; 5) titrate medication; 6) realize health priorities and reach congruent treatment decisions; and 6) improve communication between patients and various healthcare professionals [HCPs]. (van Beugen et al., 2014) DHIs have been heralded as revolutionizing access and equity of care including the ways in which individuals monitor and improve their health behaviors by improving outcomes, reducing costs, and improving the patient experience and increasing patient engagement. DHIs vary widely with respect to clinical range, format, functionality and mode of delivery, including mechanisms through which they aim to change mental health and well-being.

Clinical Range

Devices and programs using digital technology to support behavior change are increasingly ubiquitous, being adopted for use in patient diagnosis and treatment, remote monitoring and self-management of chronic diseases. (Michie, Yardley, West, Patrick, & Greaves, 2017) In fact, DHIs have been utilized to: 1) promote healthy behaviors such as smoking cessation (Free et al., 2011); and physical activity (Vandelanotte, Spathonis, Eakin, & Owen, 2007); 2) improve outcomes in people with long-term conditions such as heart failure, (Hunting G, 2015) hypertension (McLean et al., 2016) and diabetes (Pal et al., 2014); 3) provide remote access to effective treatments (van Beugen et al.); 4) improve mental health conditions. (Zhuo et al., 2015)

Available DHIs vary in the breadth of psychopathology that they address. Typically, they tend to be disorder-specific but a few are even more precisely targeted such as one designed for people with suicidal thoughts. (van Spijker, van Straten, & Kerkhof, 2014) On the other hand, some are "transdiagnostic" in scope and have a broad clinical range indicating a great potential clinical effectiveness.(Craske et al., 2009; Titov et al., 2011) There are well established DHIs for depression; anxiety disorders and insomnia. Most have been designed as self-help programs that are meant to be used on their own or with some form of support. These treatments vary markedly in their content, clinical range, format, functionality and mode of delivery. (Andersson & Titov, 2014)

Format

DHIs designed to address mental health conditions vary in their format. Interventions can be designed as face-to-face treatment that may entail having regular weekly sessions. Others modify the format to match the way that websites or apps are meant to be used. (Ben-Zeev et al., 2015) Typically, modified format results in briefer, more frequent, sessions compared with face-to-face treatment, and often the overall length of treatment is shorter. (Ben-Zeev et al., 2015) Further, DHIs may vary in their structure. Some are linear, progressively leading users through the intervention step-by-step, whereas others have a variety of modules which may be applied with some flexibility. (Ben-Zeev et al., 2015)

These interventions often require some level of personalisation or so called "tailoring". Tailoring can imply little more than matching the text and clinical examples to the user's demographic group [e.g., gender specific - female]. meanwhile others go beyond by incorporating algorithms that generate a treatment which matches aspects of the user's psychopathology. (Abdullah et al., 2016) These algorithms may be acquired from strategy specific to the treatment or the recommendations of experienced

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

clinicians. It is likely that, machine learning may be used for this in the future. (Abdullah et al., 2016) An alternate to tailoring is permitting end-users to pick out elements of the intervention that match their specific concerns. (Abdullah et al., 2016) Additional studies are required to evaluate which of the tailoring approaches lead to improved patient outcomes.

Functionality

During infancy DHIs compromised of text and thus resembled printed self-help programmes. This is changing. As technology matures, additional attention was devoted to their appearance, appeal and ease of navigation. Nowadays, most DHIs may embrace features such as: 1) learning exercises; 2) self-monitoring tools; 3) progress reports; 4) downloadable documents; 5) audio- and video-files; 6) audio- and video-feedback; 7) avatars; 8) quizzes and games. Currently there are multifaceted and technologically sophisticated DHIs to address social anxiety disorder (Stott et al., 2013) and post-traumatic disorder (Wild et al., 2016); meanwhile several interventions have been designed game format, a form that may particularly suit younger users (Merry et al., 2012). Further, novelties that may likely to gain ground in the near future are: 1) the use of virtual reality-based procedures as the equipment required is becoming more readily available; and 2) artificial intelligence-informed communication with the end-user. (Fairburn & Patel, 2017)

Mode of Delivery

DHIs in domain of mental health are provided via websites and can be accessed on a wide range of devices. However, some may not suitable for viewing on the small screen of the typical smartphone. (Donker, Petrie, et al., 2013) Others interventions are app-based and have been designed specifically with smartphones in mind. Whether interventions are website-based or app-based impacts the form that they can take and the functions that can be used. Some DHIs engage both modes of delivery; such as a website-based intervention with an accompanying app for purposes such as self-monitoring or planning ahead. (Donker, Petrie, et al., 2013)

The Promise and Challenges of DHIs in Psychiatry

Evidence suggests that DHIs are increasingly being adopted by individuals living with mental illnesses such as schizophrenia and bipolar disorder, as a means of better understanding and managing their condition.(Biagianti, Hidalgo-Mazzei, & Meyer, 2017) The portable, connected nature of wearable devices pragmatically supports remote and valid capture of clinical information in various settings—both actively, such as self-rated assessments, and passively, using instruments to size objective markers of social, emotive and cognitive states, meanwhile ensuring reduced user burden. (Biagianti et al., 2017) Information can be transferred back to the users and and clinical teams in real time, offering the opportunity to facilitate self-management, and ensure timely, preventative interventions. (Biagianti et al., 2017)

However, majority of DHIs in mental health have only been evaluated in small studies focused on short-term feasibility, albeit with mostly positive findings.(Firth & Torous, 2015) (Lewis & Wyatt, 2014) This has raised questions around interventions' long-term impact in more diverse patient groups. (Biagianti et al., 2017) It is imperative to accumulate scientific evidence on DHIs impact on mental health using rigorous evaluation frameworks meanwhile considering heterogeneous patient population and long

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

term impact. (Lewis & Wyatt, 2014) (Chan, Torous, Hinton, & Yellowlees, 2015) (J. B. Torous, Chan, Yellowlees, & Boland, 2016) This will be required to ensure alleged benefits are realised, and to warrant that benefits outweigh potential harms such as breaches of security and privacy. (J. Torous & Roberts, 2017) At present, it is unclear as how: 1) to optimise the process of designing effective DHIs focused on mental health domain that are both timely and cost-effective;2) to select methods to ensure the optimal clinical dimensions to be targeted; creating interventions that may adapt to a shifting and ever-changing technological landscape, while retaining their core functionality; 3) to optimally determine as to what degree to integrate end users in the design process.

As suggested by Biagianti et al. [2017], the following dimensions should be considered when designing DHIs in arena of mental health: 1) Define the intervention based on unmet clinical need; 2) Develop meaningful partnership; 3) Ensure user-centered design; 4) Determine the appropriate software platforms; 5) Assess the use of appropriate grade devices. (Biagianti et al., 2017) Each one of these is described in substantial detail.

Define the Interventions

The first step is to define an intervention and mitigate the potential that technology is deployed solely for the purpose of implementing technology alone, rather than being applied to target specific clinical problems. (Biagianti et al., 2017) At the initial stage, it is vital to ensure that a specific clinical dimension and unmet need drive the research question; including definition of essential parameters and key variables. Clinical researchers are uniquely positioned to guide development of research questions and DHIs by learning from patients, recognising areas of unmet clinical need, and then considering which of the various properties of DHIs might be most appropriate. As the field develops further, tools should be merged into multidimensional, modular and more flexible platforms. (Biagianti et al., 2017)

Develop Partnerships

Interdisciplinary partnerships among clinicians, patients, big data scientists, software engineers and user experience designers are essential in ensuring that an intervention meets scientific and technical standards. (Biagianti et al., 2017) During this phase it is critical to apply 'team science' principles (Borner et al., 2010). The principle entails regularly scheduled meeting and initiatives that would promote interdisciplinary dialogue, and ultimately the formation of a collective knowledge base. Prior to any collective work, it is critical for agreement to be reached between collaborators on issues of payment/financial support, academic credit, authorship, intellectual property, and data ownership, storage and security. (Biagianti et al., 2017)

Ensure User-Centered Design

Evidence suggests that interventions are more likely to be adopted for long-term use when they provide inherent value for the 'user' in managing their condition, or improve critical aspects of their functioning and well-being. Bottom-up approach, involving end-users [i.e. patients/caregivers] in the co-development of DHIs has therefore become central to this goal. Yet, it is unclear as to how this should be implemented, as only a limited number of studies to date have reported user-involvement during the DHI development.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Killikelly, He, Reeder, & Wykes, 2017) End-users must remain integral to forming the research agenda, clinical focus and technology selection over the entirety of the development cycle. (Biagianti et al., 2017)

Native vs. Existing Software Platforms

Native software platofrm requires up-front expenditures of time, energy and capital. Yet, it allows adhoc modifications to address specific difficulties of people with mental conditions to be taken into account, including cognitive impairments, poor technology literacy and text reading level.(Rotondi, Eack, Hanusa, Spring, & Haas, 2015) Nonetheless, potential risks associated with building native technology such that rapid technological advances may make the prototype for the intervention already obsolete and uncompetitive by the time the development process is complete. This may have profund implications on the acceptability and scalability of the intervention. (Rotondi et al., 2015) This can be overcome by outsourcing design and development to established firms, so that the intervention is regularly maintained and enhanced. This may entail supplemental costs and such may be unaffordable to early stage researchers. (Rotondi et al., 2015)

An alternate is to capitalise on available solutions if these: 1) meet specific needs and goals; 2) are secure; and 3) adhere to current ethical and clinical governance structures. (Biagianti et al., 2017) Advantages include a significant reduction in costs and the possibility to promptly test the feasibility and acceptability of the technology in the clinical population. However, researchers may have limited control over design and development process. Further, they may need to adapt DHIs to the rapidly changing features of the tool, which may lead to difficulties associated with consistency of study procedures and replicability of findings. (Biagianti et al., 2017)

Regardless whether one opts for naïve versus existing platforms, allowing interoperability between mobile operating systems is desirable, particularly android and iOS systems, in order to maximise the reach and generalisability of the intervention. It is desirable to employ software that could be freely downloaded regardless of the device. (Biagianti et al., 2017)

Consumer vs. Clinical Grade Devices

A key objective is to design and develop DHIs that are affordable and acceptable for prolonged use. Devices are to be validated in clinical populations. In the case of wearable devices, data may be preprocessed on the device using unpublished algorithms, to which the research team may have access. The process may raise concerns regarding validation, data quality, replicability and scientific acceptability. (Naslund, Aschbrenner, & Bartels, 2016; J. Torous, Kiang, Lorme, & Onnela, 2016)

Albeit very useful, consumer devices convey some limitations. Although technology needs to be 'good enough' to address the clinical question, it may not represent the most innovative technological option. Although, one attempts to curtail variability between devices by ensuring all participants are equipped with standardised study devices, and by primarily examining longitudinal within-person variation. This may not always be possible. Considering swift development cycle of consumer devices, each platform should be designed as to integrate with novel technologies devices as they emerge, thus 'future-proofing' the intervention. (Biagianti et al., 2017)

As the technological landscape rapidly advances, new opportunities will arise for delivering DHIs for mental health. Strong collaboration between academic and industry partners are required to fuse the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

advantages of consumer and clinical grade technologies in the design and development of devices that assimilate into the users' lives, while delivering clinical-quality data. (Biagianti et al., 2017)

The Contribution of DHIs to Psychological/Psychiatric Treatments

DHIs, including digital technology in general, have been heralded as presenting massive potential as scalable tools to improve outcomes, to widen access and meet the increasing demand on mental health services. As a result of the widespread availability of digital technology, treatments of mental health conditions has been undergoing momentous changes Most of DHIs are forms of cognitive behaviour therapy that have been modified from existing face-to-face treatments or from self-help books based upon them. (Andersson, Cuijpers, Carlbring, Riper, & Hedman, 2014) Some may represent a simplified versions of the original treatment and are little more than collections of "tools. Others preserve both the treatment's procedures and the strategies that govern their use. At large, DHIs in mental health domain seem to make more use of behavioural than cognitive procedures and contain a prominent educational component. It has been popular for DHIs to present themselves as educational programmes rather than treatments, and deliver the intervention in "lessons", instead of "sessions" (Andersson et al., 2014).

There are digital versions of psychotherapy including: acceptance and commitment therapy (Pots et al., 2016); behavioural activation (Ly et al., 2014); interpersonal psychotherapy (Donker, Bennett, et al., 2013); mindfulness interventions (Spijkerman, Pots, & Bohlmeijer, 2016); and problem-solving therapy (Kleiboer et al., 2015). However, these variations have received less research attention than the cognitive behavioural ones. Similar to cognitive behavioural interventions, they vary in the range to which they retain the strategies and procedures of the original treatment

Truly novel DHIs are few and far between. Examples include: positive cognitive bias modification to treat depression (Blackwell et al., 2015); virtual reality based exposure in the treatment of anxiety disorders (Valmaggia, Latif, Kempton, & Rus-Calafell, 2016) and persecutory delusions (Freeman et al., 2016); and the use of robotic technology to improve social interaction in autism spectrum disorders and dementia (Riek, 2016). The use of a computer game to block the reconsolidation of intrusive traumatic memories remains at the experimental stage (James et al., 2015).

THE APPLICATION OF DHIS IN PATIENT POPULATIONS

DHIs for Children and Young People With Mental Health Problems

Recent advances in computerised technologies and programming has created the possibility of more interactive and adaptable cCBT that may fit the needs of young people though use of gamification and 'serious games'. (Hollis et al., 2017) Typically, it has been presumed that children and young people (CYP) will prefer DHIs considering their ubiquitous digital activity. Yet, evidence remains inconsistent as to whether: 1) DHIs for CYP are clinically and cost-effective; 2) CYP prefer DHIs to traditional services; 3) DHIs widen access to treatment: 4) traditional evaluation and adopted methods are the most appropriate. (Hollis et al., 2017)

The assessment of effectiveness of DHIs has been based on evidence from RCTs, with the majority conducted on CBT focused in domains of depression and anxiety in adolescents and young adults, with significantly less research focused on other clinical areas and therapeutic interventions. Generally speaking,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

there is limited support for the role of computerized cognitive behaviour therapy (cCBT) in improving symptoms of depression and anxiety in CYP. Further, there is evidence from 'head to head' trials that therapist-guided (remote) cCBT is as effective as face to FtF CBT. (Sethi, 2013) Trials have typically focused on older adolescents with mild and moderate symptomatology. Thus, it remains unclear as to whether DHIs are useful for CYP who present with more severe symptomatology typically found presenting to mental health services. (Hollis et al., 2017) Evidence indicates that trials with active comparators demonstrate reduced benefit of DHIs than those with non-active controls. There is some evidence that human support, either in the form of a therapist's guidance or researcher contact, may be favourable in terms of adherence and effectiveness. DHIs for Attention deficit hyperactivity disorder (ADHD), Autism Spectrum Disorder (ASD), eating disorders, psychosis and post-traumatic stress disorder (PTSD) demonstrate limited benefits. Also, there is a notable lack of evidence concerning the cost-effectiveness of DHIs in CYP. To summarize, the heterogeneity of DHIs and limited quality of many studies make it difficult to draw definitive conclusions about the effectiveness of DHIs and the role they should play in mental health services for CYP. (Hollis et al., 2017) Past research highlights a plethora of valid research questions and methodological issues that need to be considered for the field to move forward.

DHIs for Adults With Mental Health Problems

There are increasing numbers of DHIs available for use in adults with severe mental issues. Published literature unveils strong evidence for the feasibility of using smartphones to augment the care of people with schizophrenia (Firth & Torous, 2015). In fact, a systematic review of five studies focused on using smartphone apps for treating symptoms of schizophrenia demonstrated app retention was 92%, and approximately 3.95 patient-app interactions took place each day. (Firth & Torous, 2015) Self-reported patient experience survey results revealed high adherence, positive user experience, and broad-ranging clinical benefits. High rates of engagement and satisfaction with an array of apps indicates the nascent potential of this technology. Yet, overall evidence regarding the efficacy of such interventions remains limited. (Firth & Torous, 2015) Further, a meta-analysis of 18 randomized controlled trials (RCTs) covering 22 mobile apps demonstrated that using apps to relieve symptoms and self-manage depression significantly reduced patients' depressive symptoms compared to control conditions ($g=0.38$, $P<0.001$). (Firth et al., 2017) Authors noted that smartphone-based therapies yielded the most benefits for individuals with mild to moderate, rather than major, depression. (Firth et al., 2017) Findings from systematic review indicate that overall short-term usability and feasibility of technology are high in the SMI population, implying the potential utility of digital technology for incorporation into treatment of SMI. (Batra et al., 2017) Authors note that real-world, naturalistic studies using larger samples will further facilitate the integration of digital technology into everyday mental health care, meanwhile evaluating its long-term effectiveness.

DHIs for Seniors With Mental Health Problems

Evidence suggests that older adults (65+) have the potential to use tailored smartphone interventions to self-manage their illness. A group of researchers from Dartmouth developed a smartphone-based intervention using an adaptive systems engineering framework and principles of user-centered design. (Fortuna et al., 2018) The findings noted that a peer-delivered and technology-supported intervention designed to improve medical and psychiatric self-management is feasible, acceptable, and is potentially associated with improvements in psychiatric self-management, self-efficacy for managing chronic health

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

conditions, hope, quality of life, medical self-management skills, and empowerment with older adults with serious mental illness (Fortuna et al., 2018). They found that even patients with limited technical abilities could use this app successfully (Fortuna et al., 2018). Evidence indicates that DHIs are associated with several advantages compared with traditional psychosocial interventions, such as: potential for individually tailored, just-in-time delivery along with wide dissemination and high population impact (Fortuna et al., 2018; Whiteman, Lohman, Gill, Bruce, & Bartels, 2017). But the process of adapting an existing psychosocial intervention to a DHIs mandates an adaptation for a high-risk group with limited health and technology literacy (Whiteman et al., 2017) and should be evaluated with studies containing larger and more representative population samples.

Chapter 20
Mental Health Clinical Decision Support Exploiting Big Data

Jan Kalina
The Czech Academy of Sciences, Czech Republic

ABSTRACT

The complexity of clinical decision-making is immensely increasing with the advent of big data with a clinical relevance. Clinical decision systems represent useful e-health tools applicable to various tasks within the clinical decision-making process. This chapter is devoted to basic principles of clinical decision support systems and their benefits for healthcare and patient safety. Big data is crucial input for clinical decision support systems and is helpful in the task to find the diagnosis, prognosis, and therapy. Statistical challenges of analyzing big data in psychiatry are overviewed, with a particular interest for psychiatry. Various barriers preventing telemedicine tools from expanding to the field of mental health are discussed. The development of decision support systems is claimed here to play a key role in the development of information-based medicine, particularly in psychiatry. Information technology will be ultimately able to combine various information sources including big data to present and enforce a holistic information-based approach to psychiatric care.

INTRODUCTION

The objective of this chapter is to discuss clinical decision support systems, their benefits, the importance of big data for clinical decision making, and their analysis within clinical decision support. Particular attention is paid here to psychiatry, namely to its specific features preventing telemedicine tools to become more widely spread or to specifics of statistical analysis of psychiatric data.

First, general principles of decision support systems together with their potential and limitations will be described. Recommendations for the design, implementation and validation stages are given, stressing that clinical decision support systems may bring new unexpected sources of errors which must be anticipated. While modern technology undergoing a dynamic progress allows a more effective diagnosis and therapy, the increase in effectiveness does not necessarily imply higher safety of patients and thus the criteria of effectiveness and safety must be considered jointly.

The interest in clinical decision support for the particular field of psychiatry penetrates throughout this chapter. While decision support systems are generally acknowledged to have potential for increasing the quality of healthcare, they have not apparently penetrated to a routine usage in psychiatry yet. Therefore, distinctive challenges for the development of telemental healthcare tools are discussed based on literature research on recent references. Decision support systems contribute to the shift of clinical practice to the ideals described as information-based medicine, which will include the analysis of big data as its integral part. Within psychiatry, there will be a need to overcome specific and rather serious barriers before the mental healthcare can reach the ideals of the information-based psychiatry.

CLINICAL DECISION SUPPORT SYSTEMS WITHIN CURRENT HEALTHCARE

Medical decision making can be described as a process of selecting an activity or series of activities among several alternatives integrating uncertainty as one of its intrinsic aspects with an influence on healthcare (Zvárová & Zvára, 2011). The physician solves the medical decision-making task based on knowledge and data connected to the cognition and determination of diagnosis, therapy and prognosis (Berner, 2016). Decision support systems can be described as very complex systems with a potential to compare different possibilities in terms of their risk. Thus, they represent potentially very useful and powerful e-health tools for the clinical decision-making process, capable to solve a variety of tasks, to analyze different information components, to extract information of different types, and deduce conclusions from them. While the first systems based only on expert knowledge were not sufficiently successful, improved performance has been obtained with systems learning the knowledge from clinically relevant data.

Up to now, clinical decision support systems have established their place as inherent part of e-health with an indisputable ability to improve clinical decision making and with a facility to contribute to a further transformation of clinical medicine (Hanson & Levin, 2013; Lech et al., 2014). There are specialized decision support systems focused on finding the diagnosis within individual clinical fields or prescription of medicaments. However, the search for the appropriate therapy is more complex and depends on many factors and only a few decision support systems aiming at therapy have been sufficiently evaluated up to now. There has been even less attention paid to decision support systems for prognosis, while there are still obstacles to apply decision support systems in healthcare routinely, although everyday healthcare would greatly benefit from reliable interdisciplinary and multidisciplinary systems.

DEVELOPING CLINICAL DECISION SUPPORT SYSTEMS

Designing and implementing a decision support system is a very complex and demanding process. The usage of decision support systems is strongly dependent on factors of legal, social, technical, economical and ethical environment. If the systems should offer a truly unobtrusive and easy-to-use interface, they must meet the needs of the particular healthcare providers and therefore their introduction requires changing organizational and workflow issues of hospitals as well as their healthcare specialists. Also, it is important to realize that adopting a foreign decision support system typically requires translating the system to the local language together with accommodating all details to the local environment.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

A clinical decision support system acquires data from a variety of input sources (manual input, interface with a different software, data import from electronic health record). Because the data may be massive, effective tools for storage are needed, as well as communication platforms allowing interoperability with other e-health devices. Particularly, a communication platform between the electronic health record and decision support system becomes a necessity, because there exist so many different versions of electronic health records (Moja et al., 2014).

The implementation of a decision support system should start with a pilot version, which can reveal some weaknesses of the first plan. In addition, the process of implementing a reliable decision support system requires an intensive and long-range validation. The system must also allow for an effective but sufficiently thoroughgoing configurability and parameter tuning. The system should be evaluated at different healthcare providers (e.g. in different hospitals as well as at different self-standing physicians) under a variety of different conditions. In a validation mode, the system should be repeatedly exposed to a cycle form formulating requirements, proceeding to proposing the design (or modifications of the last version), implementation of modifications, and multi-level testing under artificial conditions, and ending with testing in real situations. The evaluation cannot be based entirely on statistical evaluation of the correctly classified diagnosis or prognosis, but also on patient safety and seriousness of misclassifications.

Each decision support system in real healthcare applications requires a permanent and laborious monitoring and maintenance. This is especially important immediately after introducing the system to real applications. Concurrently, the feedback from physicians is very important. The physician should immediately contact the supplier if having doubts about the precision of the recommendations of the decision support system. The supplier must remain open to proposals for improving the system and prepared to correct all mistakes quickly. This practice is opposite to hospital information systems, which are typically delivered as closed systems without a simple possibility of modifications.

In the course of operating the system, actualizations must be also implemented with the aim to adapt the system, taking into account possible errors, new results of medical research, availability of new technologies, or actualizations of the electronic health records. Also, medical guidelines become outdated quickly and it is necessary to follow their recent trends. Actualizations performed while the system keeps working also require consideration of patient safety issues. Big systems require more essential actualizations, especially if they were developed more spontaneously rather than as a result of well-considered preparations with a sophisticated design.

BENEFITS FROM CLINICAL DECISION SUPPORT SYSTEMS

A clinical decision support system improves the quality of the provided care. This section summarizes various positive effects of clinical decision support systems. At the point of care, they allow to exploit medical devices fully not only from the medical, but also from the technical point of view. They also allow an economic evaluation of any planned therapy or care and thus a significant reduction of financial costs. The ability of the systems to perform healthcare planning may be beneficial for health authorities. The systems may potentially incorporate patients' beliefs, which remain neglected across clinical disciplines but become increasingly interesting in the subjective health with cognitive and emotional components (Ortendahl, 2007).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The system brings benefits also to the physician, ensuring more comfort, a higher effectiveness and more time for the patient, and also a reduction of errors. It may be especially favorable during stress (e.g. at an emergency ward) or for treating complicated patients. Particularly (but not only) a less experienced physician may benefit from using a decision support system, which exploits the level of knowledge reflecting the latest developments even in a narrow domain of medicine (Kalina et al., 2013). The system may save human resources or reduce the implicit bias of healthcare professionals (FitzGerald & Hurst, 2017). The available data allow to remind the physician important aspects of family and personal history or diagnostic examinations, to warn about side effects or possible addictivity (e.g. of painkillers), to propose new alternatives not immediately apparent to the physician, or to prevent mistaking different samples. Still, it is the physician who remains to carry the responsibility for the medical decision-making processes in combination of scientific and empirical knowledge to infer the interpretation in all steps of healthcare provision. It is also only the physician, who can exploit non-quantified knowledge obtained through education, experience and intuition.

The medicament management can be greatly improved by a decision support system, which computes the amount of medicament or transmits an alert or warning signal about an incorrect prescription. It can evaluate critical situations and offer notifications and reminders with the ability to react quickly in life-threatening situations. It can warn the physician that a particular patient requires an alternate medicament dosing, e.g. because of higher age and/or a joint usage of other medicaments. It can identify patients with the risk of medication overdose, misuse (in patients with dementia) or abuse (in patients with schizophrenia). The decision support system is also helpful at transfers from one medicament to another. It reminds possible contraindications or avoid superfluous operations in the process of therapy planning or evaluate risk assessment.

From the data management point of view, clinical decision support systems can connect and aggregate various data types and search for their associations (e.g. between genetic information and fMRI brain images) for an individual patient. They can also screen over very large databases of medical images, which can be subsequently evaluated by an expert. A major advantage is the ability to visualize the available data chronologically, presenting a nice and well-arranged graphical output. The systems also have the ability to handle measurements performed by different medical devices, which measure in different units or on different scales.

The systems may access rigorous scientific knowledge by searching references in external information sources. If connected to a web search machine for extracting clinically valid information in large bibliographic databases of research articles, they save the physician also a time-consuming search for knowledge across free text. Decision support systems also have a potential to search automatically for previously performed clinical trials on a given topic in databases.

CLINICAL DECISION SUPPORT SYSTEMS AND PATIENT SAFETY

Improving healthcare quality requires to integrate a correctly and effectively determined diagnosis together with patient safety, where the latter is not automatically guaranteed by medical procedures, even if they reflect the most recent scientific knowledge. On the other hand, defensive healthcare with a sole focus on safety cannot ensure effective results. While the concept of patient safety is not primarily concerned with improving the effectiveness of healthcare, a correct diagnosis is crucial for achieving a higher level

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of patient safety. The ability of clinical decision support systems to improve patient safety by removing adverse effects of healthcare was appraised e.g. in the review by Gebru et al. (2015).

It is possible to distinguish between two different basic types of errors in healthcare. The first type is caused by limitations of current technologies or level of medical knowledge. These errors can be eliminated only in the future after discovering new scientific facts. The second type of errors are adverse effects of healthcare caused by human factors or system failures. A wrong diagnosis determination can fall into any of the two categories. An example of a wrong diagnosis resulting from an error of the second type is a physician's failure to carry out important clinical examinations of a particular patient, causing a superfluous time in the hospital or even death of the patient.

Patient safety as a field within healthcare considers only the second type of errors: preventable medical errors under the current level of technologies and medical research. Patient safety can be understood as a freedom for the patient from unnecessary harm or potential harm associated with healthcare. It studies not only diverse effect of healthcare, but also proposes ways for preventing or reducing medication-related errors or errors in diagnosis and allows to save also human and financial resources as a consequence. All this means that e.g. an ineffective therapy of a rare disease or even a lack of available therapy for severe rare diseases (e.g. Huntington's chorea) does not represent an issue for the area of patient safety.

Clinical decision support systems prevent medical errors and reduce the risk of treatment complications or redundant deaths of patients. They would not expose patients to redundant clinical studies, but rather save them from an unnecessary burden. By increasing the speed of the decision making the physician obtains more time and the probability of medical error decreases. The systems also look for inconsistencies, errors and omissions in the treatment plan. There exist even small decision support systems designed primarily for improving patient safety or healthcare quality control, which can yield patient-specific, evidence-based recommendations. However, the future seems not to be in specialized self-standing decision support systems designed only for patient safety, but primarily in multifunctional decision support systems covering the patient safety as one of their areas. In the current fast pace of development, big and reliable systems can be created only by large suppliers.

Patient safety may be threatened by any new technology and decision support systems do not represent an exception, as they may contribute to new (possibly unexpected) opportunities of errors or accidents. The sources of errors include a computer collapse, data overload, automated actions without the knowledge of the physician, the change of the system or software update, latent or system errors, entering the data incorrectly, misusing or losing sensitive data, or data protection violations. In case of collapse of the decision support system, the physician is not removed from ethical and legal responsibilities. The human factor is another source of problems, and the correct usage of the decision support system requires a well-educated physicians or healthcare professionals with a proper level of statistical literacy as well as computer literacy, who are free from fear of being limited by computers in the decision making process.

CLINICAL DECISION SUPPORT SYSTEMS IN PSYCHIATRIC CARE

Combining Various Types of Psychiatric Data

Like in other clinical fields, the amount of data relevant for psychiatric care rises enormously. Massive data of various sources and types represent a valuable capital for bringing new psychiatric knowledge, so far underutilized with a potential for a dramatic change of current practices of healthcare. This was

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

documented by the review paper by Stewart & Davis (2016), who cited 198 references on applications of big data in mental health research. So far, big data in the psychiatric context are measured primarily for research purposes, while they also have potential to contribute to improving both the efficiency of clinical decision making as well as patient safety (Monteith et al., 2015).

The knowledge used by decision support systems may be integrated from an expert system created by top-class experts, but this knowledge should be validated on real data. Medical guidelines that describe recommended procedures for diagnosing specific diseases and/or their treatment represent an additional source of knowledge. A list of examples of various data types, which are relevant in psychiatry, together with particular examples includes:

- Numerical data, e.g. data on family and personal history, results of clinical and laboratory examinations in various forms (including gene expression measurements)
- Data measured by e-health tools for patient monitoring, e.g. non-stop wearable sensors
- Signals, e.g. analysis of EEG
- Voice records, e.g. detection of schizophrenia relapse in smartphones applications or detection of depression due to voice changes in a speech record
- 2D, 3D or 4D brain images, e.g. diagnosis of schizophrenia from facial images
- Using fMRI images, e.g. study of irreversible physical changes in the brain due to Alzheimer's disease
- Text in natural language, e.g. description of symptoms and signs, unstructured medical reports in the electronic health record, or analysis of computerized databases
- Molecular genetic data, e.g. study of genetic predisposition to bipolar disorder or mood disorders, genetic networks, or corresponding epigenetic mechanisms (Mahgoub & Monteggia, 2013)
- Social networks, e.g. diagnosis of a depression relapse or automatic mood detection of a facebook user (Appelbaum & Kopelman, 2014)
- Biochemical or biophysical brain models using differential equations (Anticevic et al., 2015)
- Time series, e.g. pharmacokinetic models for ethanol in the brain of an alcoholic, or drug efficacy models

From the statistical point of view, clinical decision support systems learn and apply classification rules allowing to assign a given (new) patient to one of given groups. It is a complex task to learn this classification rule from various input sources. The analysis of psychiatric data is difficult not only because of the plethora of various data types listed above, but also complicated by other common data properties:

- Different data types, including numerical data (continuous or categorical), together with other data types (text, images, videos, graphs)
- High dimensionality of data, i.e. a high number of variables (features), while its adverse effect is denoted as curse of dimensionality
- Different formats of the output as the cause of using a proprietary software by various suppliers
- Different units or different scale of different variables
- Small number of samples (patients)

Telemedicine in Mental Health: Potential and Barriers

This section describes the beneficial impact of decision support systems in the field of mental healthcare. In general, all positive effects of decision support systems described above are valid in psychiatry as well, but other specific benefits will be analyzed in this section. Numerous telemedicine tools are currently under development for psychiatry for remote decision making on diagnosis, therapy and prognosis, but also for psychiatric management or care. Until recently, clinical decision support systems seemed not to be extensively used in psychiatry, although their potential becomes already more acknowledged (Koposov et al., 2017). Various attempts for diagnostic decision support systems have produced frustrations (Bergman & Fors, 2008). This is true also for the rare examples of decision support systems proposed for finding the correct therapy for psychiatric diseases. Nevertheless, telepsychiatric or telemental health services become popular in developed countries, where they contribute to transforming the psychiatric care (Deslich et al., 2013) and help to increase access to mental healthcare.

Particularly, telepsychiatry enables to offer the psychiatric care also to patients with substance abuse problems, who would otherwise dare to search for a clinical intervention, or to highly sensitive individuals. Thus, telemedicine contributes to destigmatization of the psychiatric care (Maulik et al., 2015). Further potential can be found in reducing medication-related expenditures or providing intensive attention. Examples include online monitoring of biochemistry results, managing suicide attempts, video-consultations between a psychiatrist and patient, or mobile smartphone apps for schizophrenic patients. A promising area for decision support systems can be described as management of depression care (Fortney et al., 2010).

Only realizing the barriers for decision support systems in the psychiatric context will allow to overcome them. Sometimes it is claimed that the main limitation of clinical decision support systems is the health information technology itself (Deslich et al., 2013), without acknowledging limitations also in the clinical dimension of the task. However, also intrinsic limitations of psychiatry must be kept in mind. Therefore, it is possible to divide possible barriers of clinical decision support systems in psychiatry to four clusters:

Intrinsic barriers

- Decrease of work productivity (i.e. a need for additional time)
- System not fully automatic
- Insufficient technical support
- Inferior results (e.g. results on diagnosing mental disorders compared to an experienced psychiatrist)
- Negative effects on patient safety

Environmental barriers

- System not adapted for a particular physician/hospital
- System not able to obtain important data (e.g. not integrated with a particular hospital information system)
- The current status of the legislation worldwide still remains to be a big obstacle of a wider usage of decision support systems, particularly the requirement of paper-based healthcare record keeping

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Barriers in the psychiatrist-system interaction

- Unrealistic expectations of the psychiatrist (e.g. no tolerance to software errors) or distrust of the system
- Often, the psychiatrist hesitates to change opinion due to prejudices
- Possible aversion of the psychiatrist to ideas of personalized healthcare, preference of one-size-fits-all approaches
- Complicated interpretation of the classification rule (i.e. if etiology of the disease is immensely complex, but the physician expects a fast, simple, comprehensible and justified answer)
- Subjective interpretation of the system instructions, which may depend on text understanding
- The success is also determined by the personality of the psychiatrist (mainly his/her age, sex, sociocultural background and experience), experience with psychiatric diagnosis making and with the system itself, while the performance of the system is improved if the physician is trained (Bergman & Fors, 2008)

Barriers due to specific aspects of psychiatry

- Unclear or unknown cause of the most common psychiatric illnesses
- Controversy concerning the classification of psychiatric diseases (Thornton, 2013)
- Various shapes and forms of the same disease (e.g. dementia), with a multitude of complex and heterogeneous symptoms and signs
- Current models based on genetic information fail to exploit the potential of epigenetics, while the activation of gene functions or their silencing plays a crucial role in the pathophysiology of psychiatric diseases (Mahgoub & Monteggia, 2013)
- Too many factors are relevant for diagnosis making
- A purely biological perspective may ignore environmental stimuli (stress, hectic lifestyle, sleep deprivation, anxiety causes, somatic symptoms, non-clinical factors with cognitive and emotional components, risk, worries, some other unexpected issues), which play a major role in the development of civilization diseases (Ortendahl, 2007)
- Subjective health dimensions (beliefs or quality of life of psychiatric patients) may not be realiable due to disrupted boundaries between imagination and reality
- Psychiatric guidelines suffer from vagueness or indeterminacy in formulations (e.g. level of cognitive impairment, delusion);
- Complete lack of guidelines for specific tasks, e.g. for work ability evaluation for a mental health patient (Kemppinen et al., 2014)
- Determining the diagnosis based on objective checking a list of individual and conceptually independent symptoms and signs, while a skilled diagnostic judgment may be an exercise of tacit knowledge

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

STATISTICAL ASPECTS OF CLINICAL DECISION SUPPORT

Statistics vs. Machine Learning or Data Mining

Solving the classification task of clinical decision support systems is commonly performed by exploiting multivariate statistical methodology. This is able to capture the multivariate structure (i.e. correlation structure) of biomedical data, but at the cost of technical and often strong assumptions. Nevertheless, data analysis practitioners often adhere to machine learning tools or heuristic data mining approaches. In this respect, the methods or heuristic tools are commonly used without verifying the statistical assumptions. When these are fulfilled, statistical methods are more powerful compared to machine learning or data mining tools. This section has the aim to explain their differences and to discuss advantages of the (bio)statistical methodology.

In contrary to (multivariate) statistics, machine learning is commonly believed to contain universal (or universally valid) methods. Although often neglected, its methods including artificial neural networks or support vector machines do require certain (at least implicit) statistical (i.e. probabilistic) assumptions in order to solve classification tasks. On the other hand, machine learning methods do not commonly require a specific probabilistic distribution, which makes them more flexible tools compared to statistical methods.

Data mining can be characterized as a process of information or knowledge extraction from a dataset, revealing and investigating systematic associations among individual variables in a much more heuristic way compared to traditional statistics (Dziuda, 2010). It combines established methods for exploratory data analysis (EDA), descriptive modeling, classification and regression with heuristic principles, while classification together with regression are commonly denoted as predictive data mining. The concept of data mining can be described as the analytical part of the overall process of extracting useful information from empirical data, which is traditionally called knowledge discovery.

There are various advantages of statistical methods in comparison to machine learning approaches. Unique properties of parametric estimation in the multivariate normal model compared to machine learning techniques include:

- Comprehensibility
- Available diagnostic tools (together with remedies for the situation with violated assumptions)
- Efficient computation
- Available modifications for high-dimensional data (e.g. lasso-type regularization);
- Possible modifications robust to outliers (Kalina & Schlenker, 2015)
- Available hypothesis tests
- Less tendency to overfitting
- Confidence interval for parameter estimates
- Confidence band (region, ellipsoid) for the whole set of parameters

On the whole, statistical methods can be rather easily accompanied by additional tools for verifying the assumptions or for modifying the methods for non-standard situations.

Principles of Biomedical Big Data Analysis

Learning the classification rule for clinical decision support systems requires to pre-process the available biomedical data, i.e. cleaning and preparing for subsequent analyses. If the data are big, this pre-processing may actually represent the most time-consuming part of their analysis. The exploratory analysis includes primarily visualization tools (histograms, box plots or quantile-quantile plots for individual variables, or scatter plots for pairs of variables). If individual variables are measured in different groups, then descriptive statistics (quantiles, means and variances) or test statistics (of the F-test or chi-square test) are useful to evaluate the difference among the groups.

Recently, specific statistical and machine learning methods have been proposed for the analysis of big data, which is often denoted as big data analytics. This is true also for data with the number of variables p exceeding the number of observations n, which are commonly denoted as high-dimensional. Traditional statistical methods seem improperly used for big data, while on the other hand, principles of EDA seem still undervalued. Particularly, hypothesis tests are unsuitable as they have a too large power for a large number of observations (Terwisscha van Scheltinga et al., 2013).

Dimensionality reduction (variable selection, feature selection) methods are generally recommended to simplify subsequent analysis of big data. It can (perhaps surprisingly) improve the result of a consequent analysis in spite of losing some relevant information. On the other hand, it would be too strict to reduce the set of variables to a too small number of relevant ones.

Therefore, intrinsic variable selection ensuring sparsity (ignoring redundant variables) seems as the most promising approach, optimized for the supervised task (Matloff, 2017). It is recommended to ensure sparsity by regularization tailor-made for the classification task, so the analysis does not require any variable selection prior to the classification task itself.

Even recent biostatistical research papers continue to critically discuss statistical and data mining methods for big data or high-dimensional data (Matloff, 2017). Experience of researchers is critical mainly to neural networks or support vector machines for not being as good as presented in theoretical papers on simulated data. A list of such aspects of high-dimensional data, which are continuously debated by experts and their opinions seem dramatically different from one paper to another, will be now presented:

- Suitability of particular methods (and method selection) for the particular data, because no data analysis method is uniformly optimal for all available datasets
- Model choice (i.e. reduction of a model to a suitable sub-model)
- Quantifying model performance (standard concepts of reliability or validity have a tendency to a false optimism for big data due to overfitting, i.e. models can appear predictive even if the data are completely random)
- Assumptions of individual methods
- Recommended sample sizes
- Suitability of standard classifiers for data observed under matched case-control studies (standard approaches completely ignoring the paired structure of the data are suboptimal, e.g. in the study of features obtained in brain images by Balasubramanian et al. (2014))
- Efficient algorithms for computation (some of the methods, although theoretically suitable for data with a large n, are implemented in commercial software in a computationally inefficient or numerically unstable way)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Comprehensibility of the results, which must be clearly interpretable from the point of view of the medical research topic; otherwise the methods are not suitable e.g. for patient critically ill or at highest suicide risk

There are numerous open problems concerning the analysis of big and high-dimensional data. Especially methods combining effectiveness with reliability are highly desirable (He & Petoukhov, 2011). Intensive attention has been also paid to sensitivity of existing methods to the presence of outlying or wrongly measured observations in the data (Kalina, 2014).

Specific Statistical Challenges of Analyzing Psychiatric Data

Statistics represents an essential aspect of medical informatics (Scotch et al., 2010) and a standing service for achieving its tasks. Apart from data quality issues, specific analytical challenges characteristic for psychiatric data will be considered in this section. Possible challenges in the analysis of psychiatric data mostly follow directly from the discussion of various sources of data presented above.

- No clear interpretation of the methods, while a clinical interpretation is crucial in psychiatry (Terwisscha van Scheltinga et al., 2013)
- The data structure is often complex, e.g. longitudinal or repeated measures data are very common (Gueorguieva, 2017)
- The data show trends or more complicated patterns across time
- Specific properties of magnetic resonance images of the brain (small effectiveness, non-homogeneous signal-to-noise ratio, spatial autocorrelation) or other medical imaging devices
- Noisy images contaminated by outliers (Kalina, 2018)
- No systematic comparisons of performance of various data mining methods across various biomedical applications
- Difficulty to combine measured data with tacit knowledge, which can be described as context-dependent practical knowledge based on a complex evaluation of the patient's psychological whole (Thornton, 2013)

The most common tasks of analyzing data in psychiatry seem to be classification or clustering. Most researchers in psychiatry or neuroimaging are unaware of recent methods for the analysis of big or high-dimensional data and the arsenal of these methods only starts to penetrate to these research fields. This may be explained by unreliability of newly proposed methods implemented in commercial statistical software, or delay with their implementation.

THE DAWN OF INFORMATION-BASED MEDICINE

The concept of evidence-based medicine (EBM) is nowadays widely accepted as a unifying idea describing the ideal practice of medicine. In this section, it is explained that the clinical practice is gradually undergoing improvements towards more advanced ideals which may be denoted as information-based medicine. This vision of future medicine emerges from the established principles of EBM and goes far beyond it.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The pioneering approach to EBM originally proposed by Guyatt et al. (1992) spread out quickly as a progressive idea during 1990s. The concept of evidence had primarily the meaning of current best evidence in making decisions about the care of individual patients (Sackett et al., 1996) and was later refined as a thorough, unique, and critical use of the best objective and most topical proofs in the process of decision making about the diagnosis, therapy, and prognosis for individual patients. The practice of evidence-based medicine integrates clinical expertise of individual physicians with these proofs, i.e. clinical evidence acquired within systematically performed clinical research.

The cornerstones of EBM require that physicians demonstrate their capability to use up-to-date research results and exploit them in their everyday clinical practice. This includes e.g. searching and systematic critical evaluation of clinical research publications, analysis of activities, risk analysis, or analysis of ethical and legal consequences of using a given approach. By considering economic analysis of costs (Kemppinen et al, 2014), EBM contributes also to healthcare effectiveness.

Clinical trials remain to be the main source of medical knowledge within EBM. This is true in spite of their serious disadvantages, which include artificial conditions or averaged results obtained by statistical methods for an averaged (virtual) patient, without reflecting his/her individual situation. From the statistical point of view, principles of personalized care require to consider clusters of patients or quantiles (even multivariate quantiles) instead of averaging the results. The entire dataset in a clinical trial is also typically forbidding to draw more precise conclusions for an atypical (statistically outlying, extreme) patient. Decision support systems may help to decide whether a new clinical study should be performed. While each clinical study must undergo an ethical review process, many of current clinical studies are superfluous. The same studies are namely carried out repeatedly or have an inappropriate design, which does not allow to generalize the results to be valid also under different conditions.

Criticism of current practice of clinical trials includes the data collection or risk of unintentional avoiding some important variables (James et al., 2015). Besides, proponents of personalized healthcare promote clinical trials with small sample sizes, i.e. performed on small groups of specific patients. In reality, there is however a tendency for clinical trials to be ceaselessly bigger and more expensive. In addition, the behavior of patients is known to be influenced by their sole presence in a clinical trial.

While numerous e-health tools are appealing primarily as commercial products, their dynamic development can be accelerated only after new results of basic research become available. This is true e.g. for the whole segment of m-health. The market of available applications has been denoted as selective without a clear roadmap of the m-health domain and a first systematic ontology for the field was proposed only recently (Cameron et al., 2017).

Current clinical practice is constantly enriched by quickly emerging new results of basic (i.e. not only clinical) research obtained by the analysis of large datasets measured by new biomedical technology. Beyond the EBM, the clinical practice is hoped to gradually converge to an ideal state characterized by the model of information-based medicine (Borangíu & Purcarea, 2008), connecting basic biomedical research with patient-specific information. The role of tools of medical informatics is to perform the integration of knowledge from various sources, primarily from basic research (i.e. understanding diseases on a molecular level), epidemiological studies, and examinations of an individual patient. At the same time, basic research together with information technology and big data analysis extend the possibilities for a targeted healthcare solution beyond the current concept of EBM and allow to overcome its limitations.

The concept of information-based medicine as a recent and perspective medicine paradigm describes the effort to transform the evidence for the (imaginary) averaged patient towards a real individual participative patient based on his/her individual data with clinical as well genetic or metabolic parameters.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The concept starts to find first applications, such as the study of Senders et al. (2018) exploiting artificial intelligence in clinical decision making.

INFORMATION-BASED PSYCHIATRY

The current paradigm of evidence-based medicine in the specialty field of psychiatry has been called by various synonyms, including evidence-based medicine in psychiatry, evidence-based clinical practice in psychiatry, evidence-based mental health, or evidence-based practices for mental health (Hanson & Levin, 2013; Lech et al., 2014).

Clinical decision support systems together with other e-health tools and with results of the basic research (e.g. in neuroscience or molecular genetics) strongly contribute to bringing new sources of medical knowledge (and thus the decision-making process) closer to an individual patient, improving the effectiveness of therapy and patient safety. The availability of big data together with a new biomedical knowledge, as described in the visionary paper by Monteith et al. (2015), may allow to make the therapy efficient, compared to the current state when the therapy of common diseases aims only at easing the suffering of patients. Integration of molecular medicine with clinical psychiatry will be of course a demeaning task due to a large gap between the two fields and a transform of psychiatry will be able only by means of a paradigm shift (Demkow & Wolanczyk, 2017).

Currently, an on-going transform of psychiatry can be anticipated, which is enabled by a vast number of technological tools recently introduced for psychiatric care. The fast improvement of technology and rise of big data of various types and formats from unthinkable sources have a potential to contribute to clinical usage. For all these reasons, the paradigm of evidence-based psychiatry should be replaced by deeper ideas going more beyond and the information-based medicine can be expected to develop also in the area of psychiatry. Thus, it is possible to introduce the concept of information-based psychiatry (IBP) intended for the ideals of information-based medicine within psychiatric practice. Some emerging directions of psychiatry have been already described under different concepts in available literature:

- Predictive, preventive, personalized and participatory medicine (Auffray et al., 2010), where predictive healthcare is often denoted as predictive analytics, i.e. stands on big data and their analysis for prediction for an individual patient;
- Evidence-based pragmatic psychiatry (Paulus, 2017), which exploits an empirically based decision making;
- Computational psychiatry, which has been introduced as a concept for computationally demanding approaches to analyzing data measured for psychiatric patients (Maia, 2015; Demkow & Wolanczyk, 2017);
- Precision care (Stein & Smoller, 2018).

Decision support systems may also contribute to shared (collaborative) decision making in routine mental healthcare (Fortney et al., 2010). As a by-product, the transform of healthcare will go hand in hand with the transform of nursing towards information-based nursing. A particular evidence of the drift of psychiatry towards participative healthcare is also the current international transition of mental health services towards community-based services (Slade, 2017), applying patient (client)-centered approaches in healthcare.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

One might have the feeling that information technology restricts the physician by limitations of hardware and software. However, it is exactly the information technology, which offers to capture a human body and subsequent healthcare in a holistic approach, because it has the capacity (if correctly organized) to store all available data (including big data) and information, to analyze them, and search for associations. In this way, information technology performing a holistic approach to information (Zvárová, 2014) encompassing the subjective data, especially useful in psychiatry, may capture the full bio-psycho-socio-spiritual model of health. This has the potential to incorporate a high quality of diagnostics with principles of patient safety.

Contribution of the Work

The amount of clinical data relevant for clinical decision making rises enormously and so does the amount of biomedical knowledge obtained as result of basic research. This naturally complicates the process of clinical decision making. This chapter discusses general principles of clinical decision support systems mainly for diagnostics and therapy, together with specifics in the field of psychiatry. Numerous benefits of decision support systems for physicians and for an individual patient at all levels of care are characterized in the chapter. If appropriately implemented, the systems reduce the burden for patients and also reduce costs, which is important not only in psychiatry, where the number of patients as well as the financial demands have increased remarkably world-wide.

Clinical decision support systems can be characterized as prospective e-health tools with a unique ability to extract information from various sources of (big) data. Their importance increases, as the systems unlock tremendous potential to improve both the healthcare quality and patient safety and also may combine objective and patient-subjective data with expert knowledge. They may successfully exploit also the most recently proposed tools for big data analytics, even in spite of high computational demands.

The vision of information-based psychiatry together with discussing its assumptions or barriers preventing its development represent also a contribution of this chapter. The development of telemedicine tools in psychiatry is currently slowed down or complicated mainly by unrealistic expectations and barriers, including general barriers or barriers in the interaction between e-health tool and the psychiatrist. Specific barriers typical for the field of psychiatry have obtained the least attention so far. Reliable statistical or data mining procedures for learning a reliable classification rule for the decision support system are highly desirable. Again, for the particular context of psychiatry, tailor-made methods for the data analysis (e.g. in the form of brain images) are required for extracting relevant information from big data coming from various sources in various formats.

Big data as a still underutilized capital for clinical decision making represent a key accelerator of improving the efficiency of clinical decision making as well as patient safety. Reflecting the dawn of big data in clinical medicine and their analysis, the popular concept of evidence-based medicine is surmounted by the vision of information-based medicine formulated in this chapter. The most recently initiated transforms of psychiatry towards information-based principles are described here as perspective and progressive, although limited by various specifics of psychiatry and thus incessantly slowed down compared to the higher pace of development acquired within other clinical fields. E-health tools contribute to psychiatry transformation and development of information-based psychiatry, i.e. psychiatric care based on information-based principles. However, its ideals assume also a fundamental progress of basic research in molecular genetics and particularly in neurosciences in order to perform an individualized healthcare based on individual clinical, genetic or structural brain imaging parameters.

PROJECT DESCRIPTION

A large portion of the presented work in the field of clinical decision support stems from the project Robust analysis of high-dimensional data in the years 2014-2016. The project was financed by the Neuron Fund for Support of Science, a private fund in the Czech Republic.

The cross-disciplinary part of the project focused on applying methods to particular high-dimensional data. An important research direction was the research of modifications of resting-state brain networks of schizophrenic patients (Kalina & Hlinka, 2017). The spontaneous brain activity of patients was measured and compared with that of healthy individuals. The analysis of the high-dimensional fMRI measurements was performed by robust classification methods. The final robust classification rule is able to find the diagnosis of a new individual very reliably.

Within the project, a cardiovascular genetic study was also analyzed, extending the results of Kalina et al. (2013). The very aim was to find a relatively small set of genes responsible for the development of cardiovascular disease. Diagnostic tests were investigated, which are based entirely on gene expression measurements of individuals. Another practical result is a robust pre-processing procedure for images obtained by Illumina BeadChip microarrays (Kalina, 2018).

Theoretical interests of the project were devoted to such statistical procedures for the analysis of high-dimensional data, which are robust (resistant) to the presence of outlying measurements (outliers) in the data. The particular interests of the project were devoted to robust classification for clinical decision support (Kalina, 2014) or to robust dimensionality reduction by means of a minimum redundancy maximum relevance criterion (Kalina & Schlenker, 2015).

Jana Zvárová passed away in July 2017. After the end of the project, Jan Kalina continues the research focused on connecting classification and decision support with robustness. The methods are applied within in the field on machine learning, particularly (again) to fMRI measurements of patients with mental disorders.

ACKNOWLEDGMENT

The work was supported by the project 19-05704S of the Czech Science Foundation.

Chapter 21
Socialization or Social Isolation?
Mental Health Community Support in the Digital Age

Kim Heyes
Manchester Metropolitan University, UK

ABSTRACT

This research project specifically examines the experience of online community support groups as reported by users. The project began out of concern that healthcare providers in the Global North are directing people with mental health problems to online services, without seemingly understanding the impact that this may have on the individuals. The research findings will be of particular interest to mental health practitioners and service providers in the UK and elsewhere in the Global North, and aims to influence decisions made for policies around developing new online mental health services.

INTRODUCTION

There are many people living and surviving in the community with mild to severe mental health problems who do not have easy access to professional health and social care services. Globally, we have started to see a demand for more choice in how healthcare provision is provided, however constant cuts to healthcare budgets in the Global North mean that options such as telehealthcare and online services are seen as a cheaper alternative, and are often billed as a more effective solution (Chambers *et al*., 2016). This is despite much research showing that there is little to no benefit of this method of support, particularly that of peer to peer online support communities (Eysenbach *et al.,* 2004).

This chapter specifically examines the experience of online community support groups as reported by users. Twenty-five participants answered between one and six open questions posted on three different mental health forums. The research began out of concern that healthcare providers in the Global North are directing people with mental health problems to online self-care or peer to peer support services, which may not be suitable for all mental health patients. Despite a paucity of research showing completion rates of professional online therapeutic support interventions are rare (Simco *et al*., 2014),

those that do complete the set programmes have been found to benefit from the support (Learmonth *et al*., 2008). However, statistics released in January 2017 by NHS Digital (the UK National Health Service) show that more people than ever are turning up at hospital emergency departments in the UK to receive support for mental health issues (NHS Digital, 2017). Since 2011, the numbers of people going to emergency hospital departments because of their mental ill health has increased by over 50%, and this is also the case for those under the age of 18 (NHS Digital, 2017). This shows that despite a growing number of professional and peer to peer online support services, there may still a growing need for face-to-face intervention.

This chapter suggests that through the identification of positive experiences of online mental health support forums, suitable resources can be developed cheaply and effectively in order to reduce the effects of mental illness, and support those who are unable to find support elsewhere.

BACKGROUND

Worldwide the spending is disproportionately low on mental health (between approximately 2 and 50 USDs per capita), and the lack of financial support has resulted in cuts to services, especially public sector services that support people with mental health problems within their local communities (WHO, 2015). Others are unable to access such support, perhaps due to living arrangements, or because of the negative stigma associated with mental health (Corrigan *et al.,* 2005; Link *et al*., 1999; Star, 1955). Globally, one in ten people are estimated to have a mental health issue, yet up to two thirds of these do not access any type of support services (WHO, 2015). It is of great concern that budget cuts and negative attitudes to mental health issues may lead to an increase in people isolated through lack of professional service support, so it is vital to understand the social factors that shape the way people may seek support in different formats.

The wellbeing of people with mental ill health is highly related to the experience of social isolation and the lack of social support (Corry 2008; Steptoe *et al*. 2013). More recently, there has been a shift in thinking when it comes to treatments with many patients (in general) taking an active role in deciding on the best method of healthcare provision for themselves (Allen *et al*., 2016). Brown and Calnan (2016) found that the level of trust between providers and service users was of vital importance. If trust is lost, it can exacerbate mental health issues and increase isolation (Heyes, 2017). However if trust is fostered, then the result is likely to be positive and isolation is reduced. Therefore, it is important that service users have a choice regarding their preferred method of care in order to get the best possible outcome for the individual (Allen *et al*., 2016; Heyes, 2017).

User-led initiatives (which can also be organised around other health and lifestyle issues), such as cancer support groups and bariatric surgery patient support groups, are part of a wider sociological phenomenon of social movements around self-care and peer patient support (Das & Faxvaag, 2014; Tanis, 2008). These groups are usually informally created, such as individuals with mental ill health issues setting up their own peer to peer support groups, or backed by non-governmental organisations. The central aim of these is to bring users together for mutual support and to reduce isolation (Barak *et al*., 2008; Mind, n.d.). Therefore, there is a need to examine the specific mechanisms that make up social support to understand who is benefitting from the current provisions (Kawachi and Berkman, 2001; Eysenbach *et al*., 2004). There are also a great deal of online mental health professionally led community support groups, although there has been less analysis of these (Eysenbach *et al*. 2004). It is

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

apparent that there is a paucity of academic knowledge in this area, which demands research attention in order to maximise the effectiveness of such groups in the wider context of social and health care support (Eysenbach *et al*. 2004).

Political Framework

Understanding a particular political framework when discussing mental ill health is important, as it is often the case that the whole discourse around mental health is a result of political decisions (WHO, 2005). UK social policy focuses on enabling people to live and manage symptoms, as far as possible, within the community and providing that they have the mental capacity to cope (Mental Capacity Act, 2005; The Care Act, 2014; The Mental Health Act, 2007). However, the majority of people with mental ill health living 'within the community' do not benefit from the resources available to them (Morris, 2012). Isolation from meaningful community engagement often leads to loneliness and further co-morbidity issues, such as depression or substance misuse, particularly if subjected to discrimination and abuse (Link *et al*., 1997). Crabtree and Haslam's (2010) study on positive and negative implications of group identification demonstrated that a group support setting could reinforce supportive frameworks, and that this could outweigh the negativity felt by stigmatisation by non-group members. They recommended that a qualitative study should be conducted to explore the causal variables of relationships within the group settings and the effects that these may have on each individual (Crabtree and Haslam, 2010). There is a vast amount of knowledge about how community support groups are perceived by service users, whether they find them useful and in what ways they are helpful (Cruwys *et al*., 2013; Steffens *et al*., 2016; Welbourne *et al.,* 2013), yet there is still little understood about how people utilise online support for mental health issues. Welbourne *et al.,* (2013) suggest that this may be because motivations are often different for other online peer to peer patient groups, so research findings in one online health support area may not necessarily translate to others.

The most recent policy in the UK, The Care Act (2014), was launched on 1st April 2015. The Act focuses on the wellbeing of the individual with care needs, and also that of the carer (as long as they are not a paid service). By signposting these individuals to face-to-face community support services, there is a reliance on creating sufficient support systems in the local area. The cost objectives to creating these communities is to save money in the long run through 'fixing' problems that could arise from isolating people with care needs initially. Often carers of people with disabilities (physical or mental) suffer from mental health problems or physical ill health as a result of their caring role, consequently having to seek expensive health provisions for themselves (paid for through public funding) (Whybrow and Heyes, 2016). Therefore, social connections are important in preventing further or future health issues.

A study by the NIHR (Pinfold *et al.,* 2015), focused on the effects of communities on individuals with severe mental health issues (SMI). This exploration found that the family network can be viewed in many different ways, and these are not always positive, despite good intentions. The findings suggest that those with little familial interaction, but regular interaction with stable service providers (social services/ support worker/ priest and so on) were the happiest in their environment, and were likely to have a better health outcome than those with close family ties and/ or inconsistent relationships with service providers (Pinfold *et al.*, 2015). The lack of understanding around mental health has also lead to some people being segregated from family and friend connections, which could lead to further isolation or seeking identity in other ways, such as within online communities (Link et al, 1999; Pescosolido, 2010).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Isolation and Stigma

Isolation continues to be a significant risk factor for morbidity, across the age spectrum (Holt-Lunstad *et al*., 2015). There are many people for whom isolation is not an option, but something that is forced on them through age or ill-health, and a vast number of those people may not get the help they need (Hawkley and Cacioppo, 2010; Uchino, 2006). Online support may mean that vastly more people get access to the support they need as and when it is required rather than having to wait for a GP or counselling appointment (Learmonth *et al*., 2008).

The stigma surrounding mental ill health is still concerning, particularly as it has been found to have a detrimental effect on help-seeking (Clement *et al,* 2015). Recent data collected by Schomerus *et al.* (2016) showed that even when members of the general public expressed understanding of mental ill health, attitudes towards acceptance of people with mental health issues are not altered. Although this experiment was a relatively small sample (n=1679), the findings show how important it is for mental health professionals to approach public attitudes in the future. Similarly, a recent study by NSUN (National Survivor User Network) for mental health in the UK (Beresford *et al*., 2015), found that service users believed that stigma was still evident in social dealings on a daily basis. The general belief held, was that stigma around mental health was formed by an outdated understanding of the medical model (Beresford *et al*., 2015).

Mental health issues, tend to be predominantly diagnosed using the medical model of the Diagnostic and Statistical Manual of Mental Disorders (DSM), however there are many people living and surviving in the community with mild to severe mental health problems who do not have access to medical or psychological support and/or would not welcome professional labelling or intervention. It is not fully understood what causes mental illness, or indeed if mental illness really exists (see Szasz, 1961, for arguments around this). Frances (2013) argues that the DSM is a way of creating control within society and of the medical profession, maintaining governance over what is normal and abnormal. The DSM is not necessarily an accurate portrayal of mental ill health, but it is generally accepted as the diagnostic criteria for most of the world's mental state (Frances, 2013).

Medical approaches to treating individuals with mild to moderate mental ill health issues in the UK can vary from involuntary incarceration, to providing signposting information about charitable services that can help with grief or suicidal thoughts, medication, and referral to counselling or online support services. However, Evans-Lacko *et al.,* (2013) argue that despite this range of possible medical actions, in general, medication is relied upon in general practice and in hospital care. They go onto note that mental illness should be treated as seriously as physical illness and that this need for dealing earnestly with mental health issues is increasingly important (Evans-Lacko *et al.,* 2013). However, there is a dominant and continuing lack of will in treating and understanding mental ill health, both socially and medically (for example see Maclure, 1988; Cuijpers, 2003; and Frances, 2013). It is therefore important to understand how individuals feel about their own mental health, and their choices and preferences in how they want to receive help and support (Heyes and Whybrow, 2016; The Care Act, 2014).

Health research is also still fixated on the idea of the medical model, with little psychological research into online mental health forums utilising a social constructionist approach (Burr, 2015). However, some health researchers (Link et al, 1999; Pescosolido, 2010), focus on interpersonal dynamics and social networks which highlight the issues of social withdrawal and link to community theories. Yuill et al., (2010) advocate the idea that a true perspective on health can only come from a consideration of both medical and social models for mental health, creating a pathway for multidisciplinary research in mental health.

Online Communities

Online forums have become commonplace amongst internet users worldwide. The number of worldwide users hit 3 billion in 2014, and is now approximately 3.5 billion in 2017, which is approximately 46% of the world's population (internetlivestats.com, 2017: online). Several hundred thousand forums now exist on the internet, with the number growing exponentially on a daily basis (Carroll, 2014). In Japan in 2007, the top discussion forum, 2-channel, was receiving in excess of 2.5 million posts per day (Carroll, 2014). This has since closed down, but currently one of the most popular worldwide sites, Reddit, receives approximately 1.5m users per day, with around 40,000 subscribers to their mental health threads (Reddit.com, 2015: online).

The idea that society has easy access to everything because it is on the internet may be a misnomer. The NHS in the UK (for example) puts information on the internet to make sure that it is easily and readily accessible, most businesses have websites that are 'user friendly', and adverts tell us to look online for further information. However, it is not easily accessible to the 54% of the world's population that do not have internet access. There are also varying reasons as to why the 46% that could in theory access the internet, may not. Illiteracy, learning difficulties, and fear, are just a few reasons that may prevent online activity. Those who are comfortable with using the internet are therefore given options about how to utilise the choice given to all consumers, whether that is which healthcare services to use, or where to buy their groceries. The people in society that may already be able to gain information from multiple sources are choosing whether to consume information online, and this can be for convenience, personal preference, or accessibility. However, those who do not find online information accessible may miss out, as it may be assumed that information has reached everyone because of its online presence.

Patient forums have gained in popularity (Blank and Adams-Blodnieks, 2005; Neal *et al*., 2007). The idea of the expert patient in the UK means that those with health needs are encouraged to learn about their conditions so that they can be best placed to manage them (Coulthard *et al*., 2013; Davidson *et al*., 2012). There are now many thousands of Mental Health community support groups online, and they provide various methods of information and support. The majority of the specialised forums will link (via 'click through' hyperlinks) to easy to read information produced by public health bodies. However, some rely on the information provided by their members, with potential problems such as misinformation being an issue (Neal *et al.,* 2007). Consumer choice means that people can search the various forums and decide which one they wish to participate in. In order to participate, the consumer must feel as though they will learn to trust the forum, trust the other users, but most importantly, they need to feel as though they can participate and get some support (Easterbrook and Vignoles, 2013; Hornsey and Jetten, 2004; Guo and Cheng, 2016). Noelle-Neumann's (1974) Spiral of Silence theory states that people within society needed to gauge public opinion in order to understand how they can interact on a similar level to avoid isolating themselves. Therefore, it is imperative that the forum chosen by the consumer is one that shares similar ideas and opinions as themselves. As with offline support groups, if the user does not feel as though they are part of the ingroup, they may refrain from the group, and isolation may continue (Tajfel and Turner, 1979). The similarity to offline groups can also mean that those who struggle to participate in offline face-to-face interactions may also struggle to participate in online communities.

Definitions of community vary greatly, however they tend to focus on community being a group of people with a common interest or that are geographically linked (Delanty, 2010, McMillan and Chavis, 1986). Using a virtual platform that does not feel as constricted as face to face contact may enable vulnerable people to explore support systems that they may feel unable to access in the 'real' (offline) world

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

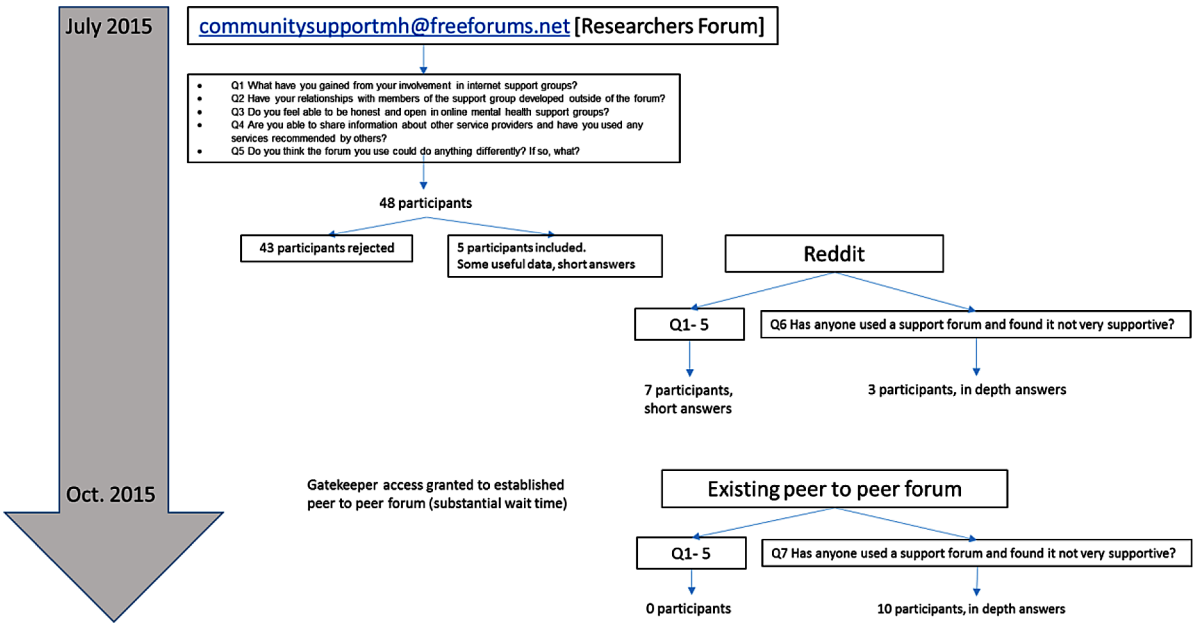
(Bell, 2007). For example, those who hide their mental health issues in everyday society may feel as though they can be open and honest with those in a virtual capacity due to the anonymity of the sphere (Suler, 2004). Most beneficial to users is the anonymity of being online (Daine *et al.,* 2013), particularly if the stigma of having a mental health problem is something that they are trying to escape. However, forums that are receiving 1.5 million hits per day tend to have so many threads added every minute, that it can be difficult for all posts to be seen by users. The consequences of this could be that someone who is asking for help for the first time may be missed, and they will think that they are unwelcome, ignored and therefore, become further isolated (Daine *et al*, 2013).

Woong Yun and Park (2011) looked at the relationships of participants of online communities, and found that often people act the same way within forums as they would do in offline ('real') life. This means that if they are open and trusting in the offline environment, they will be the same online. However, Schiel (2005) states that a person who is not really known to us cannot be a friend and therefore must not be trusted. Blanchard *et al.,* (2011) believed that trust was an important aspect of fostering relationships within virtual communities, and generally, people followed normal social practices expected in an offline community. They found that sanctioning behaviours when someone had acted inappropriately were also an important aspect of fulfilling normal social practices, so when members could rely on others to sanction inappropriate behaviour, trust within the community would grow (Blanchard *et al.,* 2011). However, trolling has become an issue in recent years, particularly within social media, and along with this research, has been shown to decrease trust within virtual spheres, and therefore may increase negative online experiences for users (Herring *et al.,* 2002; Heyes, 2017; Phillips, 2015; Rafferty, 2011).

There is, however, a sense of community created by a shared identity (Ren *et al.,* 2012). In the case of mental health forums, people may be seeking information and advice from people who have had similar experiences (Ren *et al.,* 2012; Tate and Zabinski, 2004). This help may boost self-esteem if the individual has found a community that they can identify with (King and Moreggi, 1998; Ren *et al.,* 2012). The 'field' of virtual community support groups may therefore be a platform that can replicate face-to-face community support groups, and the security of the individuals' identity within this (Tate and Zabinski, 2004; Wood, 1989; Yalom and Leczcz, 2005).

Although the study of online community support groups is somewhat different to the offline groups, the comparison between online and offline is necessary in order to fully understand if there are significant differences. Richardson (2015) ascertains that online and offline should not be considered as completely different entities, as both are communities built through complex multi-dimensional relationships. The on and offline segregation should perhaps therefore be reconsidered as different ways of forging relationships, these being within different social spaces (online) and via different modes (through forums, blogging sites or social media). These different fields may then require different research methods, or the adaption of existing methods in order to revolutionize community psychology and social theory research (Kozinets, 2010).

Baym (1995) had been a participant of an online group before deciding to conduct her research. Over three years she asked questions, took surveys and analysed the text, her method being an ethnographic one that progressed over time, alongside her own understanding of the group. The idea of virtual research evolving as it happens is also supported by Chandler (2016). She found that the lack of rich data in some forums meant that her data collection methods needed to evolve alongside the researchers understanding of forum participation. Chandler (2016) found that in order to maximise the participants to her work on self-harm, she utilised the mass forum Reddit. This provided an inordinate amount of participant responses and yielded some interesting and good quality data. This type of ethnographic research has



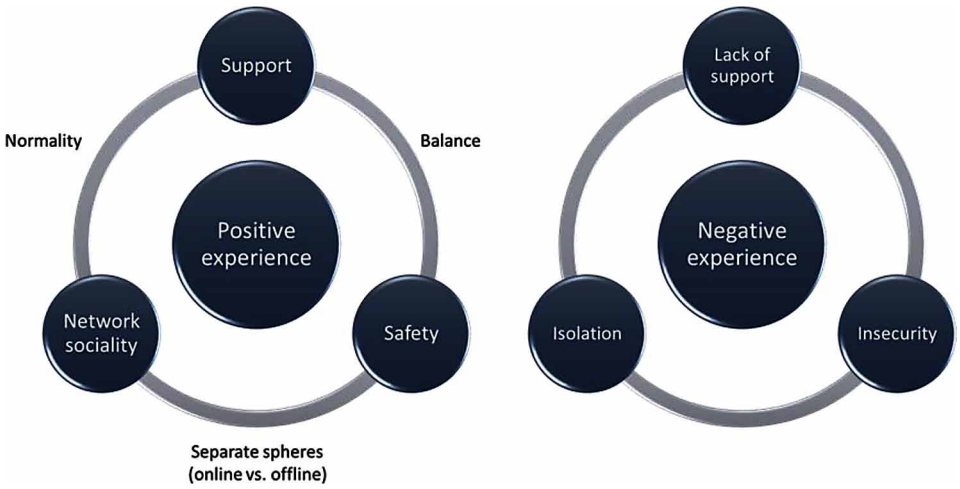
EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

been termed virtual ethnography, and is a growing phenomenon in online research (Rheingold, 2003). In this particular research (Heyes, 2017), virtual ethnography also involves the idea of the researcher being a 'tolerated observer' (Hine, 2010: 10), a presence that is apparent to the participant, but does not hinder the information given. Markham (2004) believes that ethnographic research in general has flaws, however, the lack of physical cues in virtual ethnography could actually add to, rather than inhibit the analysis of the research.

METHOD

A virtual ethnography study was conducted over a three month period between July 2015 and October 2015. Sixty-five participants answered between one and six questions on one of three forums: 1) a forum created for the purpose of the research called communitysupportmh.freeforums.net; 2) threads set up within Reddit's mental health section; and 3) a peer to peer community support forum that wished to remain anonymous (See Figure 1). No further information was taken about the participants, and there was no follow up contact (apart from to remind them that they could withdraw from the study if they wished). Forty-three participants were disqualified from the research due to giving identifying features or not meeting the criteria (i.e. when asked what they gained from being part of a support forum, replied that they had never used one). Gender was not deemed an important factor within this research, and as such, names of the participants were anonymized using an online name generator (http://myusername-generator.com/) to avoid gender bias. Open questions were posted as individual threads on each forum in order to create free flowing dialogue. Ethical approval was granted by Manchester Metropolitan University Ethics committee in July 2015.

Figure 1. Method timeline



EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

FINDINGS

The research data was analysed manually using thematic analysis (Boyatzis, 1998; Braun and Clarke, 2006), and second coded using NVivo 11. Through coding, several themes began to emerge. These were reduced to three main issues: safety; support; and network sociality. Minor themes included balance, normality and separate spheres (of offline and online worlds). It emerged that if at least one of the main themes was in place, the participant was likely to have a positive experience of online community support, and therefore, an increased feeling of socialization. If all of the themes were negative, the experience is likely to be negative, and the result would be an increase in social isolation. The minor themes were present in the positive experiences; however, further research needs to be conducted to find the relationship between these themes and the negative experiences (see Figure 2).

Figure 2. A model of online support experiences

DATA ANALYSIS

The analysis of the themes that emerged can be put into three main categories: Safety, Security and Network Sociality. These encompass a number of other areas that were brought up, including trust, the balance between on and offline life, and how normal the person feels. This section shows how the data were analysed in order for the researcher to defend these three main themes.

Safety

As discussed in the literature review, and confirmed by Brown and Calnan's. (2016) study and Blanchard *et al.*'s (2011) model, trust can be an issue for members of online communities, however, this does not necessarily deter them from online social engagement. Not being able to participate in real life means that alternative methods of group participation are sought, however it may not be identified as 'true'

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

interaction but a 'disembedded subjectivity that is somehow 'lifted out'' (Giddens, 1984, cited in Wittel, 2001: 51), a concept that can help some of the participants feel safer.

Online communities are an unknown entity, and trying to build a sense of a shared social space can be difficult when the participants may have different notions of culture and societal norms (Ostrum, *et al*., 1993). Safety therefore comes from a sense of 'good' culture within an online mental health community: one that is supportive; offers help and advice; and has participants with similar (perceived) social capital.

However, even when praising one of the forums, many participants still brought up issues and bad experiences they had had previously with other forums. The majority of people still struggled to trust other online participants, being wary of 'exploitative' and 'sneaky people', whilst also expressing defeatist attitudes towards expecting policies to be followed, or for moderators to do anything. The shared culture of the community can then turn into a bad experience and threatens the individual's idea of a safe environment.

Part of online forums is the fact that there are moderators or senior members keeping users safe from harm, which in Urowa's case (names are generated from an online name generator) did not seem to help or keep the participants from harm. Some of the participants gave examples of forums that had started well, but then went on to destroy the trust that people had in them. Unayi, describing it as:

Unayi: *[A forum] was 100% anonymous. The sneaky people trying to squeeze people for personal details happened every few sessions I connected to in the last few weeks it was open. Creepy. Trusting anonymous people on the internet is not recommended in any situation.* [Reddit, Q6]

The experience of having their safety compromised reminded several participants of experiences of offline interactions. Seven of the participants stated that they do not trust people outside of the internet either, with Unayi admitting that they would not trust their spouse or their friends 'to act in my best interest'. Schiel (2005) agrees, stating that people cannot be treated as friends if they are an unknown entity. The idea that the online community is made up of people that may have no real similar offline capital, means that they could never be trusted as they probably have an ulterior motive (Schiel, 2005).

However, there were many participants who felt as though it was easier to trust people on the internet that those offline, particularly on the basis of their shared identity (Tate and Zabinski, 2004; Suler, 2004):

Udefwl: *(I am) More honest than I can be face to face with people* [Researchers Forum, Q3]
Poufi: *Far more honest than I could be with friends and family* [Researchers Forum, Q3]
Vafez: *I have made some really nice friends on here and they have not judged me for being different.* [MHF, Q7]

Those who feel unable to be open and honest in their offline relationships (perhaps due to the nature of their mental health issues), can find it easier to be open and honest with strangers who share similar health issues, and also easier to offer support. The safety of these interactions comes from the anonymity that may make other people fearful of online interaction (Daine *et al*., 2013; Guo and Cheng, 2016), and this can cause conflict for the participants when trying to find a safe community in which they feel comfortable enough to become a permanent part of. If they do not feel a sense of safety in online interactions, they are unlikely to feel supported in an online community support forum.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Support

Participants offered their comments as helpful support, even if they had no 'real' (professional) insights to offer. This could be that by providing a support mechanism to others by offering encouragement actually makes them feel better about themselves, rather than directly seeking help for their own issues. They do not feel that they are burdening others with their own stories and have the associated positive feelings of altruism (Brown and Calnan 2016). One of the participants specifically noted that writing their own posts made them feel anxious, but commenting on other people's posts made them feel good.

Other participants did not realise that they were participating to feel better about themselves. An example of this kind of interaction is that of Jaqdudi (Reddit), who had participated and lurked in several forums, was sceptical of the support that they offer. Some of these interactions were trying to show that they were actually part of 'normal' offline interaction, they were just passing by and happened to stop to comment.

Jaqdudi: *I don't honestly have many problems that can't be solved by Googling a specific question or maybe talking to my friends.* [Reddit, Q6]

However, interwoven in between this scepticism of receiving support through forums, they also try and act as though they would still be ok with receiving support – when asked if they have thought about using the forums for more than they already have, the reply was 'Sure, if the need arises'. It is interesting that they have felt the need to be lurking on a mental health forum, and also felt compelled to answer the research question even though they deny the need for support. Jaqdudi was one of the people that posted the most in terms of discussion about the use of forums, but also seemed to be unable to express (perhaps even unaware of) how they use support forums. Through being helpful and answering research questions and supporting others, they may not perceive themselves as needing support at all.

This need for reassurance of being normal was also seen in some of the other participants, expressing how many close friends or family members they have in the offline world, trying to give an air of flippancy to their answers. This guarded behaviour shows that participants such as Jaqdudi, like to be part of a community, but do not feel as though they can ask for support. This may be due to a lack of trust, or that they may be cautious about giving too much information about themselves on a platform that users are often told to be wary of giving too much information to, due to the few that abuse the system. This could drive the participants into becoming part of the out-group in the online communities, resulting in them becoming segregated from the community. However, it could also mean that they are receiving personal gratification through supporting others, and therefore do not need to divulge personal information in order to benefit from being part of the community (Welbourne *et al.,* 2013).

Network Sociality

Being social is something that comes naturally to some people, and as discussed in the literature review, is difficult for those who are seen as being deviant from dominant social norms around their health and wellbeing. Network sociality is not so much wanting to be part of a social community, but is the need for interaction in order to understand one's own identity (Wittel, 2001). Those seeking online health support communities generally want to find or exchange, informational and/ or emotional support (Welbourne *et*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2013). This identity and support seeking is evident throughout the data, and this section will explore isolation, identity and consumerism through the over-arching concept of network sociality.

Through the analysis, it is clear from the number of participants that had been part of multiple forums (at least 8), that the choice afforded by the amount of community support forums subjects users to (at least) as much consumerism as they would be offline. They can decide how many forums they wish to engage in, and whether to lurk, participate or go elsewhere. These choices are helpful to those who may not want to seek advice from a GP or offline services, however the possibility to use orthodox health and wellbeing services is still there for those who may wish to do so, and if necessary they can chose whether to use them concurrently. However, trying to find a supportive community that is right for the individual can prove difficult for people with mental ill health. The stigma of having a mental health problem in offline communities can be the cause of individuals seeking solace in the online world (Goffman, 1963; Link, *et al*., 1997). Therefore, participating in any community, online or offline, can cause feelings of anxiety and uncertainty about how one's posts will be received and responded to by others.

As one participant states:

Ripem: *Writing about my own issues as a new post gives me anxiety (probably the vulnerability aspect) [sic].* [Reddit, Q1]

The idea of disclosing personal information for someone with mental health problems can be fraught with fear of the consequences. For an individual to decide to disclose this type of information to a new community can be seen as a huge risk. This leads participants to describe a process of 'lurking' on the forums before actually making that crucial first post and connecting to an online community.

One participant mentioned quietly evaluating forums, prior to actively being involved through posting. Although the actual numbers of those who lurk online in forums and never post personal information is not known, the activity is commonly discussed in literature about the use of online forums (Schneider *et al.*, 2013; Rafaeli *et al.*, 2004). The participants want to become part of the community, so lurking can help them to assess if the people already contributing are similar to them, reducing the possibility of alienating themselves from the offset (Blanchard *et al.,* 2010; Bourdieu, 1990; Noelle- Neumann, 1977). Six of the ten participants of the established Mental Health Forum expressed that they were constantly fearful about isolating themselves from the offline world, rather than worrying about not fitting in with the online world.

Three of the participants were unclear on the role of online relationships within the context of broader social experiences, they noted the aim for online forums is to enhance interactions with others. Similarly, Jawodaza notes that interaction with others is important, but s/he struggles with friendships in the 'real world', so utilises the forum as a method of interaction and support without the emotional ties of friendship. S/he also states that having this form of interaction is better than nothing at all:

Jawodaza: *If you feel up for having 'real' company, but are choosing to go online instead, it probably is worth giving yourself a boot up the backside and start getting out a bit more.*
But sometimes it's not that straightforward. I don't have many friends, the friends I do have are older and have their own families/lives.
Though even if I had people to socialise with, sometimes it's really difficult.
So for me it's better to be on here than have nothing. X [sic] [MHF, Q7]

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Getting the balance right between online and offline interaction was a common concern amongst the participants on all three forums. Argyle (1969) argues that human interaction is a necessity and Steptoe *et al*. (2013) back up this contention by stating that those who are isolated from physical interaction have a higher risk of mortality. However, Kendall (2002) and Hine (2004; 2008) believe that technology has moved on considerably in recent decades and that limited human face to face interaction may not be as mortifying as it once was. Younger generations have grown up with online social relationships, and therefore, these types of interaction may prove to be more beneficial than having no offline contact at all. Kendall (2002) also states that most people do not use the internet instead of living offline, blending the online and offline worlds provides benefits, without having to worry about one type of interaction dominating one's life.

In line with Kendall's (2002) vision of the benefits of a 'blended world', thirteen of the participants stated that they felt comfortable with a blending of worlds, by utilising online support when they feel as though they are unable to cope with human interaction:

Kabeegi and Exogu both expressed that they found it difficult to talk to people in the real world, particularly if they do not have experience of similar mental health issues. By seeking support online, they feel more comfortable and are able to be honest about their feelings. This could be due to the shared values created through previous interactions on the forums, or a shared illness (and therefore understanding of what each other may be going through).

However, two of the participants saw the interactions between offline and online as separate spheres that provide an alternative place to air feelings and ideas, with no other agenda:

Vafez: *…cant mix with real people outside,…. this forum is great and a life saver for me* [MHF, Q7]
Jaxuq: *i find them helpful as i cant do real interaction with ppl [people] except my parents who work [sic]* [MHF, Q7]

These posts from Vafez and Jaxuq, emphasise interaction online and offline as separate arenas, the online space providing unique opportunities for mental health discussion. There is an interesting theme here, which also emerged elsewhere in the data, of online interaction not being 'real'. However, it clearly is real in the sense that it achieves interactional imperatives in terms of relating to another person and is valued by these respondents. Being online though allows a sense of 'playing at' interaction and experience, the stakes are not so high as face to face. This idea of 'playing' at being online is similar to those who utilise online games to help escape from the real world into a fantasy one (Hine, 2004; Calleja, 2010). Escapism could be therapeutic, allowing some relief from mental health issues, and summoning up support from those who appear to understand you, in a non-threatening way (Calleja, 2010).

However, choosing a forum in which to participate can itself be a difficult task, and one that is not as simple as just lurking until the right one is found because of the emergent and fast-changing nature of these social spaces:

Unayi: *…good ones [forums] can go bad quickly. [A forum] was originally brilliant, then it started to fill up with [..] assholes along with exploitative people…* [Reddit, Q6]
Urowa: *Most of the listeners [through support chat on the forum] did their best to change the subject. Then there was one who first started telling me who I can and can't consider a friend and then gave me a nopology [opposite of apology] when I confronted him.* [Reddit, Q6]

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The participants reported that forums could quickly change and 'go bad' with changes in who was using them, arguments and disagreements, breaking out or trolling. Participants were asked if they had had any negative experiences of forums and to expand on why these were not good. Four participants, similar to Unayi and Urowa's experiences in the quotes above, expressed that they had on occasion had disagreements with other forum members and were dissatisfied with the way that it was handled. In these cases, they typically went on to describe how they no longer trusted anyone online or offline, despite the fact that they claimed to have good friends and other social relationships. Urowa however, described their experience as unfortunate rather than confidence destroying, and was disappointed with the way that their particular issue was handled. In this case, the site moderators did not want to get involved, despite having a clear behaviour policy on the site. This is ultimately an illustration spanning all three of the main themes, and showing that they are indeed linked to whether or not a person has a positive or a negative experience of online community support.

Despite these difficulties, eight of the participants argued that identifying with the people in a community support forum can be the key to success and were positive about their experience. Knowing that there were other people having/ or had been through similar experiences seemed to give the participants a sense of relief in having found 'normality':

Imeifl: *I've gained happiness in finally reading about other people like me. I've heard they exist, but until I discovered [a forum], I could never know for certain* [Researchers Forum, Q1]

Thoqwhon: *For me, I can be the 'real me' on here. … I find it near impossible to let [my friends and family] know that I'm not good and I try to be smiley to deflect concerns.* [MHF, Q7]

These participants seemed to have found a sense of identity authenticity that they could not display elsewhere. Having a sense of being like others and sharing issues is important. They feel accepted within this community and they no longer have to pretend in order to fit into offline society's idea of normal. In the online support forums, the majority of the participants feel that they have become part of an in-group (Tajfel and Turner, 1979; Yalom and Leczcz, 2005; Tate and Zabinski, 2004; Wood, 1989; Bourdieu, 1985) which can boost self-esteem and reduce feelings of anxiety and isolation (King and Moreggi, 1998).

CONCLUSION

This research sought to investigate and clarify what was important about the interactions within virtual mental health support groups and to provide an insight into these communities in order to influence policy and practice. By assessing the impact of online support networks for people with mental ill health, it has become clear that there are gaps in social policies and health care provision. Social constructions that surround mental ill health make it easy for vulnerable people to become invisible in society due to isolation (Corry, 2008; Steptoe *et al.*, 2013), and people can be reluctant to look at alternatives, such as online sources. Face to face mental health support groups, or negative experiences in online community spaces may have detrimental effects on people with mental health issues seeking alternatives.

The research found that there were benefits to most of the participants in terms of creating support networks that would take the place of, or supplement offline communities, and therefore as a result would reduce isolation. There were some negative consequences however, and the reluctance of some participants to fully immerse themselves into online communities meant that they used multiple sites

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

without any affiliation to a particular community. This could make the individual feel further segregated from being supported by a community, and therefore more isolated than before initial online contact.

Users of the community support groups are generally positive about the support that they receive, and find it beneficial to communicate with people with similar experiences. However, the few who have had negative experiences reported that they no longer have any trust in the groups. Those with security issues however, keep using forums but err on the side of caution by not giving away too much personal information.

Good quality online support groups with a high level of peer support seem to be difficult to find, despite the number available. Forums that are successful usually have hundreds or even thousands of users daily, which makes them susceptible to exploitation. In turn, they either close down, or users may leave to find alternatives. They are useful in creating network sociality, providing a community in-group, and helping to boost self-esteem, thus enhancing quality of life for those who are isolated in offline communities. These are however, difficult to set up and can take a long time to attract members, which can be problematic in terms of creating the ideal solution for online community support for mental ill health. The model of online support, in Figure 2, aims to help with building understanding of the impact of this type of social support, although further research needs to be completed in order to recognise how this can be used to influence policy and practice.

One issue that should be addressed around information provided on the internet, is the assumption that everyone accesses it. With around 56% of the world's population still without access to the internet, this assumption can leave vulnerable people without the help they need. However, to those that are able to access it, the amount of information about mental ill health available online can be valuable to people, especially as cuts to funding look set to continue despite numbers of people diagnosed with mental health conditions rising. Lengthy waiting lists for counsellors and specialists may force people to seek alternatives, and those with access to online services may find their consumer prowess is vital in receiving alternative care. However, more research into the effectiveness of this is necessary, and will be a continual process over the coming years as the nature of the consumer changes.

It is also imperative that we do not assume that because the individual has access to the internet, that they will then wish to utilise this as their main method of treatment. Some people will continue to use face-to-face methods as their preference, or they may decide to refuse any treatment at all. Through offering choices in healthcare provision, we must ultimately respect the decision of the individual.

FUTURE RESEARCH DIRECTIONS

The idea of community being similar online to offline is something that has not been explored in great detail within social or community psychology, and it is therefore difficult to ascertain how best to utilise these communities or engage those who are still isolated. The changing nature of online also means that research needs to stay current. The changes in technology and the increase in the use of social media, predict that the interwoven nature of online and offline will become more complex, particularly when vulnerability such as mental ill health is taken into consideration, and where the individual is at in their life stage (Hine, 2008; Third *et al.*, 2014). Bridging to other support mechanisms has not been something that has been found within this research, and it is important that when seeking alternatives to conventional methods of support (i.e. offline), the participants of online support forums need to be careful that they are not self-diagnosing, or hiding a problem that needs medical attention. Therefore, the next stage of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

this research will be to conduct in depth interviews with users of online mental health community support to understand why they utilise online support, and if they felt it was beneficial.

KEY TERMS AND DEFINITIONS

Ethnography: A method of research that involves non-participatory observation of participants in their normal environment, for example, at a weekly group meeting.

Expert Patient: The empowerment of a user of healthcare services, through the education of their condition and treatment.

Lurking: When users of online spaces watch, read or look at, but do not contribute to the discussion.

NHS: The National Health Service. This is the healthcare service that is provided in the UK. It is paid for with Government funds and is free at the point of access to residents of the UK.

Offline: Anything that happens when not connected to the internet.

Online: Anything that is accessed through, or actions taken, whilst connected to the internet.

Peer to Peer: Discussions or connections that happen with people of the same perceived status, such as users of forums. Medical doctors for example, may be a professional rather than a peer when participating in forum discussions.

Stigma: A negative association with social characteristics, traits or health issues.

Trolling: A means by which individuals attack others online through inflammatory comments.

Virtual Ethnography: A method of research that involves observation of participants in their online environments, for example, an internet chat room.

This research was previously published in Novel Applications of Virtual Communities in Healthcare Settings; pages 28-55, copyright year 2018 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 22
Virtual Communities, Machine Learning and IoT: Opportunities and Challenges in Mental Health Research

Christo El Morr
https://orcid.org/0000-0001-6287-3438
York University, Toronto, Canada

ABSTRACT

Mental health challenges such as stress, anxiety and depression are on the rise worldwide. Health virtual communities (VCs) is a rising paradigm that has proven to be efficient and effective in delivering mental health interventions that address self-management, diagnosis and treatment targeting people facing mental health challenges. However, current Health VCs have limited application; they lack the ability to provide access to coordinated services and to continuously collect and integrate data originating from different devices in a streamlined manner. The Internet of Things (IoT) and machine learning represent a unique opportunity to expand the Health Virtual Community applications in the mental health domain; however, they represent a unique situation where challenges arise. This article will discuss the opportunities and challenges that virtual communities, machine learning and IoT represent for mental health research.

INTRODUCTION

Health informatics is at the verge of a profound technological change that will have a deep impact on the healthcare system in term of processes, policies and jobs. This article aims to explore the impact of Machine Learning, the Internet of Things and Virtual Communities on Mental Health research.

MENTAL HEALTH: A GLOBAL EPIDEMIC

Mental health is a global crisis with over 80% of people suffering from mental-health disorders living in the Global South (Ngui et al., 2010). The World Health Organization (WHO) considers depression as a global crisis (2018). In 2015, a study from the Canadian Mental Health Association showed that roughly one out of every five Canadians (at some point in their lives) will be diagnosed with a mental disorder, usually in the form of an anxiety disorder or depression (Canadian Mental Health Association, 2016). In the USA, 31% of college students experience mental health challenges (American College Health Association, 2009) and the numbers are similar in Europe (World Health Organization, 2014). The total economic cost of mental health in Canada amounts to more than $14 Billion per year (Stephens & Joubert, 2001). In 2013, the United States spent around $201 billion on mental disorders (e.g. stress, anxiety, depression). One cannot underestimate the need to provide continuity of care, including a myriad of related social services, to the people with mental illness.

THE ROLE OF INFORMATICS

While non-medical based therapeutic interventions, such as mindfulness, Acceptance and Commitment Therapy (ACT) (Caset et al., 2018; Hoffmann et al., 2018; Ostergaard et al., 2018), and Problem Solving Treatment (Gojani et al., 2018; Ghasemi et al., 2017), exist and can address mental illnesses (e.g. anxiety, stress), they cannot be provided in face-to-face manner for every person in need for them for the simple reason of lack of large specialized professional body; besides, face-to-face solutions can be extremely costly. Informatics can play an important role in scaling up mental health intervention for the provision of professional mental health care, set management of mental illness, and mental health promotion and prevention.

Moreover, individuals with mental illness, do not only need health professional care but also associated social services. Indeed, people face social economic barriers when dealing with mental health; some of these barriers are related to accessibility, lack of financial and professional resources, and social stigma (Perlick et al., 2010), lack of available services (Kaur et al., 2018), help seeking avoidance (VanHeerwaarden et al., 2018), and cultural barriers (Leong & Kailbatseva, 2011). Hence, the need for technology-based solutions to overcome economic and social barriers in relation to mental illnesses is high. Indeed, technology can be built to be accessible, provide ability to reach remote services, allows discovery of available services in a certain geographic location, encourages overcoming cultural barriers and stigma by connecting people from the privacy of their rooms to online services, and it support a sense of anonymity and privacy (Morr et al., 2017). Hence, technology-based programs open the door for alternative solutions to provide therapy targeting those who would otherwise not have the ability to seek out or receive services.

HEALTH VIRTUAL COMMUNITIES: A RISING PARADIGM

Virtual Communities or online communities are a group of people with shared interests and goal, specific roles, and connected through an information system and a myriad of devices (Rheingold, 2000; Nonnecke et al., 2006; Preece, 2000). When the members are connected through a mobile technology then

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the virtual community is said to be mobile. Mobile Virtual Communities is different than just mHealth by the community aspect; a community interaction and reciprocity are part of any virtual community application an mHealth can be individual and do not allow interaction between users.

Health virtual Communities have proved to be an efficient way to connect people to health care professionals including therapist, doctors, nurses address health challenges effectively, this includes diseases such as cancer (DuBenske et al., 2014), chronic kidney diseases (El Morr et al., 2014), Peripheral Arterial Diseases (El Morr et al., 2016), pulmonary hypertension (Matura et al., 2013), and mental health (El Morr et al., 2017) on local and global levels (El Morr et al., 2014). Recent research on mental health VCs, particularly applying online mindfulness techniques, has also showed promising results (El Morr et al., 2017).

However, two items are still not on the current agenda of Mental Health VCs: Coordination of services and Integration of data from ambient environment. Coordination of services is paramount for the people with mental illness (Guerrero et al., 2016; Morre et al., 2016), such as housing (Shah et al., 2018), employment (De Moortel et al., 2018), and food (Maritnex et al., 2018; Maynard et al., 2018).

IoT and Machine Learning represent two opportunities to address those two missing agenda items within the virtual community research in mental health.

THE ROLE OF IoT AND MACHINE LEARNING

Mental Health Service Coordination

Health Service coordination is a challenge in healthcare (Alfredsson et al., 2017; Diez-Canseco et al., 2018; Leung et al., 2018; Ramanuj et al., 2018; Wakida et al., 2017; Yi et al., 2016); in particular, mental health services are scattered and disintegrated (Braithwaite, 2008; Piper, 2013), which creates a system where it is complex for patients to locate what services are availability and where. From the healthcare (and social service) providers perspective the system is disintegrated in another way: providers cannot access all the pieces of data related to their patients. The overall situation makes mental health illness one of the most challenging situations within and across services (e.g. healthcare, social).

The continuum of care for mental health extends beyond the point of care to the social services; people with mental health illness usually have other challenges mainly social (e.g. housing, income), and those social aspects influence mental health in their turn (Compton & Shim, 2015), hence the term "social determinants of health" (Raphael, 2016). However, the current eHealth tools target the healthcare delivery within a strict biomedical model of health that excludes the social determinants of health; the result is translated in inefficiencies and higher cost. While mental health VCs exit, they usually address education or symptom management; they do not address the myriad of individuals' needs: social as well as medical.

IoT provide an opportunity for a connected experience including (1) the exploration of options and services available, and (2) the integration of care (medical and social). Indeed, IoT allows collection of interconnected and up-to-date data emanating from different service providers (medical and social), which provides an opportunity to fill a huge void in care: streamlining the coordination of care within and across services.

Once data is available through IoT, predictive analytics allows this can be achieved by matching the patients' needs with available services, automating appointment scheduling, and addressing individual

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

context while streamlining the process. The result would be the delivery a holistic service to patients while cutting operation cost. The perspectives of positive impact of IoT and machine learning to provide an integrated interconnected experience are limitless and an open field of research within the virtual community context (and arguably outside that context).

Diagnosis, Prevention and Promotion

Diagnosis of mental health challenges at an early stage can help overcome them much sooner and cheaper; while Apps provide many ways to detect physical (e.g. number of steps walked) and mental (e.g. mood entered by user) health data, we do not have ways to access those data in a continuous way that does not require and error prone user active intervention.

IoT represent an opportunity to collect seamlessly data feeds originating from the different devices and integrate it within Electronic Health Records (EHRs) or personal health records (PHRs); sensors, for instance, can capture indicators of mental health, such as heart rate variability (Davila et al., 2017; Insoo & Bhagat, 2016; Pirbhulal et al., 2015; Sugita et al., 2015) and use them to monitor mental health state. The result is a myriad of measurements that can serve as input for machine learning algorithms.

Diagnosis Analytics provide an opportunity to detect and recognize (i.e. diagnose) mental health illnesses (e.g. stress, anxiety) when they occur (Hu et al., 2015); while predictive analytics assist in predicting their occurrences which allows providers to take necessary steps to avoid progression of illness in a disease prevention effort.

Finally, IoT also can provide an opportunity for mental health education; members connected by a virtual community (permanent or ad-hoc) can receive suggestion of materials to read, exercises to do (e.g. breathing techniques) or even food to eat, to the different "objects" in their environment (e.g. fridges, smart watches, TVs, tablets). The total experience aims at providing community members with a connected mental health promotion opportunity (Marquez et al., 2016).

CHALLENGES

While IoT provides an important opportunity to address mental health challenges on the individual and the population levels, it presents major technical and non-technical challenges that innovators and researchers in technology need to address appropriately; among these challenges we will discuss: privacy/confidentiality and safety.

The main question for a "connected" person is how her/his right for privacy protected and how professionals accessing her/his data respect their obligation of confidentiality. IoT represents a challenge for privacy (Duan et al., 2016; Nieto et al., 2018), as the interconnected devices can be ad-hoc, and would be present in private (e.g. at home) as well as in public spaces. Creating privacy policy framework for IoT would be crucial for health and non-health applications. Organizations (similar to TRUSTe for websites) that guarantees the level of trust individuals can put in the "things" around them would be of major importance in order to drive innovation and adoption of IoT in healthcare. As breaches of privacy/confidentiality would need to be investigated, policies that provides framework for IoT-Forensics.

Data security is a permanent challenge in IT; however, in IoT and health (and mental health in particular) the virtual community members' own safety is very sensitive: hijacking of a mental health related "object" could be very harmful and possibly fatal for any individual.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Machine learning is a challenge too, scientists inventing AI algorithms have raised concern in relation to the way algorithm learn and make decisions. Mechanisms that makes algorithm decision transparent to health professionals need to be in place and are currently missing.

Finally, while technology provide opportunity for better health they are also a source for safety concerns; research has shown that once IT is embedded in a health environment it is a safety challenge as it can introduce unforeseen modes of interaction and failures that affect patients' safety (Coiera et al., 2017; Hodgson et al., 2017; Magrabi et al., 2016; Wang et al., 2017; Wang et al., 2017). IoT and Machine Learning safety is important factor to investigate.

CONCLUSION

Information and Communication Technologies (ICT) has changed the way people communicate, interact, educate themselves and others, and deliver health care. The IoT and machine learning are creating new ways of interaction between individuals and objects around them, which will impact how individuals interact with their health professionals and among themselves. The Internet of Things and Machine Learning can provide a wholistic mental health ecosphere that connects community members and health professionals in real time if needed. Both, IoT and Machine Learning, are expected to improve disease diagnosis and prevention and health promotion efforts in matters of health and mental health in particular. New possibilities to provide connected care using IoT, Analytics and VCs, appear to be an opportunity that can lead to innovative applications in mental health; however, a new model that maintains privacy/confidentiality and patient safety is needed.

Chapter 23
Efficacy of Telemedicine in Psychiatry and Mental Health Nursing

Michael Jones
Marshall University, Huntington, USA

Girmay Berhie
Marshall University, Huntington, USA

ABSTRACT

Adoption and implementation of telecommunication services which allow psychiatric services to be delivered have increased availability of care to patients in remote areas. Past studies have suggested that telepsychiatry services are comparable to traditional face-to-face services; and patients typically considered telepsychiatry an acceptable alternative. The purpose of this research was to examine and describe the efficacy of psychiatric care delivered via telemedicine (telepsychiatry) to determine whether telepsychiatry could improve outcomes for patients. Seven electronic databases were utilized with a total of 22 articles that were referenced as a basis for this literature review. The findings suggest telepsychiatry is an effective alternative compared to traditional methods. Future research should include controlled experiments that compare telepsychiatry to face-to-face psychiatry and incorporate newer technologies into the research.

INTRODUCTION

The adoption of telemedicine technologies used for delivering psychiatric treatments has been slower than in some areas of conventional medicine, however its use in this arena is making gains; an evidence-based treatment in which therapists can record psychotherapy sessions and make them available to patients through mobile devices and allow patients to review the sessions later (Luxton, et al., 2011). Treatment compliance can be improved by apps that record and date-stamp treatment homework review, track therapy appointments, and send patients or providers alerts related to treatment needs or crisis management

(Luxton, et al., 2011). It can clearly be seen that there have been successful and useful implementations of telepsychiatry with alleviating problems of workforce shortage and lack of facilities in underserved areas. Some findings also suggested that mental health services delivered using telepsychiatry were comparable to services delivered face-to-face, and there was no evidence that such services caused harm to psychiatric patients (Krupinski et al., 2002; Saeed et al., 2011). But, in order to truly implement this, mental health care providers need to know if the outcomes are comparable. Therefore, the purpose of this research was to examine and describe the efficacy of psychiatric care delivered via telemedicine (telepsychiatry) by conducting a literature review of the past research and uses of telepsychiatry. That is, this research will strive to answer the question, "Does telespychiatry equivalently or to a better extent fill the gaps in lack of availability in mental health care services?" Consequently, this research was also useful in determining whether telepsychiatry could improve outcome measures for mental healthcare patients.

BACKGROUND

Telepsychiatry, the provision of psychiatric care to remotely located clients and electronic exchange of mental health care information across distances, has the potential to revolutionize patient care (Norman, 2006). There are two major problems area that telepsychiatry can improve. One is access to mental health services where patients have difficulty due to lack of appropriate facilities such as rural, urban (Hilty, Luo, Morache, Marcelo & Nesbitt, 2002). Secondly, numerous literature sources suggest that telepsychiatry has the potential to alleviate health care workforce shortages in remote and underserved locations (Antonacci, Bloch, Saeed, Yildrim & Talley, 2008; Grigsby, et al., 2002; Krupinski, et al., 2002; Saeed, Diamond & Bloch, 2011).

According to the National Institute of Mental Health (2008) in the Strategic Objective 3 of the 'Strategic Plan,' it is important that adaptive designs which include patient preference be applied to psychosocial and biomedical intervention research. The strategy also aimed to adopt novel approaches in research models that identify new brain-behavior-environment research objectives that center on the functioning of the individual(s) as a whole. Telepsychiatric services were shown not only to be acceptable, but also even preferred by some mental health patients (Krupinski, et al., 2002; Saeed, et al., 2011).

With new developments in information and communication technologies, many online and mobile applications (apps) are now available to support mental health, including a wide spectrum of electronic interventions (e-spectrum), which have the potential to expand and enhance the scope of patient-centered mental health care interventions. One of the earliest examples of such e-therapies was an internet-based program called MoodGym, an online cognitive behavioral therapy approach designed to help people identify symptoms of depression and teach them coping skills (Rickwood, 2012). Since then we have seen many other technological advances. For example, the use of smartphones have seen dramatic growth: in 2008, only 10% of mobile phone usage in the U.S. occurred via smartphones, but by the end of 2010, the iPhone alone accounted for 55% of the mobile internet traffic in the country. Such devices have revealed numerous opportunities for using mobile apps for a variety of behavioral healthcare tasks (i.e., monitoring symptoms, treatment progress and compliance) (Luxton, McCann, Bush, Mishkind & Reger, 2011; Shepard, Rahmati, Tossell, Zhong, & Kortum, 2010).

Along with mobile applications, there have been other technological advances that have enhanced mental healthcare through telemedicine. According to Deslich, Stec, Tomblin & Coustasse (2013), highly interactive audiovisual teleconferencing systems – such as the unified communications systems

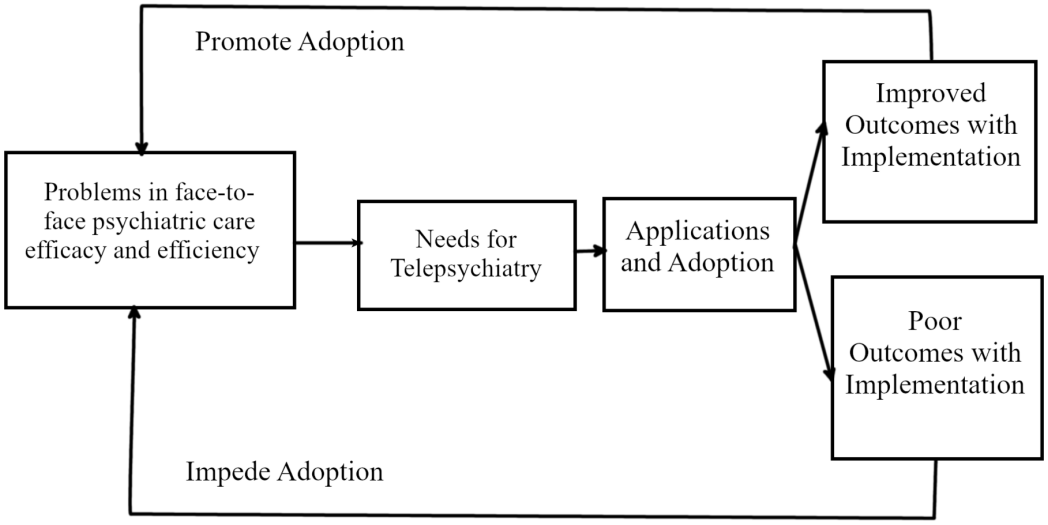
EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

developed by Polycom, Inc. – have been very successful in addressing the needs of both patients and providers who have engaged in telepsychiatric approaches to mental healthcare. Not only does such a system give patients greater ease and more options for interacting with healthcare providers remotely but can increase the flexibility and utility for providers by providing desktop videoconferencing and real-time access to a patient's Electronic Health Record (EHR), as well as to other computer applications (Deslich, et al., 2013). Also, according to Cucciare, Weingardt & Humphreys (2009), researchers have also studied the efficacy of internet-based systems for monitoring outcomes and making improvements in traditional treatments for Substance Use Disorders (SUDs), which would allow clinicians to obtain feedback in 'real time' from outpatients, on measures related to substance use and treatment satisfaction.

EFFICACY OF TELEPSYCHIATRY

Methodology

A literature review compiled findings published between 2002 and 2013, in an attempt to stay current in research. Twenty-two scholarly sources were used to assess the use of telepsychiatry in mental healthcare treatment. The following search terms/combinations were used to narrow the search criteria: 'telemedicine' OR 'telepsychiatry,' OR 'telehealth,' OR 'eHealth,' AND 'substance abuse,' OR 'mood disorder,' OR 'depression,' OR 'treatment compliance.' Only academic peer-reviewed journal articles or Health Information Technology (HIT) practitioner literature were included. All of the relevant research that was used came from the electronic databases: EBSCOhost, MEDLINE, psycARTICLES, psycINFO, PubMed, Google Scholar, or the American Telemedicine Association website.



References were reviewed and were determined to satisfy the inclusion criteria if the material provided accurate and reliable information about telemedicine with a particular focus on psychiatric care or mental health nursing. This research followed the systematic search steps and a modified research framework utilized by Yao, Chao-Hsien and Li (2010). The use of this conceptual framework is appropriate as the focus is on the sub-area of telemedicine application to psychiatry. To research how telepsychiatry can be utilized to improve psychiatric care, it is first necessary to recognize the existing problems in psychiatry and issues that drive and impede adoption of telepsychiatry. Yao, Chai-Hsien, and Li argue that problems in face-to-face psychiatric care demonstrate needs for telepsychiatry, which in turn lead to applications and adoption. Improved outcomes promote adoption; poor outcomes impede adoption (Figure 1). Figure 1 depicts the process of telepsychiatry adoption in mental healthcare.

Results

This section will examine the literature of various outcome measures for patients who were treated with either Telepsychiatry or Face-to-Face Psychiatry that are summarized in the following Table 1 in the appendix. An open, uncontrolled trial study conducted across family practices in Montreal, Canada, during 2010-2011, investigated the feasibility of using telephone therapy delivered by psychiatric nurses in conjunction with a behavioral informational self-care media toolkit to provide telepsychiatric support to eligible patients, aged 40 or older, who met the criteria of having at least mild depression based on

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Conceptual framework: Mental healthcare treatment via telepsychiatry

a score of 5 or greater on the 9-item Patient Health Questionnaire (PHQ-9) (McCusker et al., 2013). A six-month follow up on the participating patients revealed evidence of improvements in depressive symptomology: clinical significance measures on the PHQ-9 change over baseline measures indicated that 57% of participants demonstrated at least a 50% decline in their PHQ-9 scores (McCusker et al., 2013), (Table 1).

The efficacy of a telemedicine-based care model was developed to allow small clinics that do not employ on-site psychiatrists to deliver evidence-based collaborative care via telepsychiatric care (Fortney, et al., 2007), and a randomized, controlled trial was conducted for 365 Veterans Affairs (VA) Primary Care (PC) patients whose PHQ-9 scores were 12 or greater (indicating Major Depressive Disorder). Participating VA patients were randomly assigned to either the intervention group whose cohorts received treatment remotely; or to the control group whose patients received traditional on-site psychiatric care for depression. Multivariate analyses results indicated that cohorts in the intervention group had greater adherence to treatment at six months follow-up, as well as at twelve months follow-up. Furthermore, the intervention group cohorts were two times more likely than control patients to respond to treatment by six months, and they were 2.4 times more likely to have reached remission by twelve months (Fortney, et al., 2007), (Table 1).

A 16-week randomized, controlled trial conducted in 2003-2004 evaluated the efficacy of telephone-based cognitive-behavioral psychotherapy for depression against a strong control consisting of face-to-face therapy, in Multiple Sclerosis patients recruited via Kaiser Permanente of Northern California's database; and via the National Multiple Sclerosis Society (Mohr et al., 2005). The study was employed for 127 patients who met the eligibility criteria. Improvements in major depressive disorder frequency were statistically significantly higher for the telephone-based cognitive-behavioral therapy treatment group over the control group; the treatment group also had significantly better scores than the control group on the Depression Rating Scale, and on the Positive Affect Scale (Mohr et al., 2005) (Table 1).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Results of various outcome measures for patients who were treated with either telepsychiatry or face-to-face psychiatry

Finding #1 - McCusker, et al., 2013	
Design • Open, uncontrolled trial study • Family Practices in Montreal, Canada • Eligible patients with Depression, age ≥ 40 • n=53	**Intervention/Measure** Telephone Therapy delivered by Psychiatric Nurses in conjunction with Behavioral Self-care Media Toolkit PHQ-9 Scores at Baseline and 6-month follow-up
Finding Clinical Significance Measures on change at 6-month follow-up over Baseline for PHQ-9 Measures: 57% of the Patients showed decline in PHQ-9 Scores ≥ 50% (i.e., Improvement)	
Finding #2 - Detweiler, et al., 2011	
Design • Open, uncontrolled trial study – 12 months (2008) • VA Medical Center in Salem, Virginia and Fort Bragg Healthcare Clinic • Soldiers being treated for combat-related mental health problems • (n=120)	**Intervention/Measure** Interdisciplinary telepsychiatry service for all soldiers in the study Daily functioning measured via Global Assessment of Function (GAF) score GAF measured at baseline and 12 months
Finding Statistically significant increase in GAF from 58.0 at baseline to 62.3 at final visit ($p < 0.001$)	
Finding #3 - Montes, et al., 2010	
Design • Randomized, controlled trial study – 16-week trial • Schizophrenic outpatients at 198 community health centers across Spain who were clinically stable and being treated with a single, oral antipsychotic medication (n=960)	**Intervention/Measure** Intervention group received telepsychiatric nursing care remotely Control group received routine face-to-face psychiatric nursing care Evaluation of treatment adherence compared for both groups at baseline, every 30 days, and at week 16
Finding No significant difference between intervention group and control group at baseline (88.2% and 90.0%, respectively) Significant improvement in treatment adherence from baseline through week 16 for intervention group (88.2% to 96.7%, p=.007); but not for control group (90.0% to 91.1%) Progressive increase in adherence over time for intervention group: Month 1 = 92.2% Month 2 = 94.3% Month 3 = 95.7% Month 4 = 96.7	
Finding #4 - Mucic, 2008	
Design • Satisfaction survey • Mental health services patients in Denmark and Sweden who participated in an international telepsychiatry service from May 2006 – October 2007 • (n=23)	**Intervention/Measure** Survey questionnaire measured patients' level of acceptability and satisfaction regarding telepsychiatry Each patient answered eight questions at the end of the 18-month study Questions were designed to measure a patient's perceptions of usefulness, comfort level, achievement of treatment goals, and satisfaction with quality of care related to the telepsychiatry treatment received (see Table 2)
Finding 87% of the patients reported willingness to recommend telepsychiatry to a friend Only four percent of patients reported feeling uncomfortable after received care via Televised methods When asked if patients received enough information about telepsychiatry: 83% said yes in high degree; 17% said yes in some degree 83% reported achieved treatment goals via telepsychiatry in high degree; 17% reported achieved goals to some degree

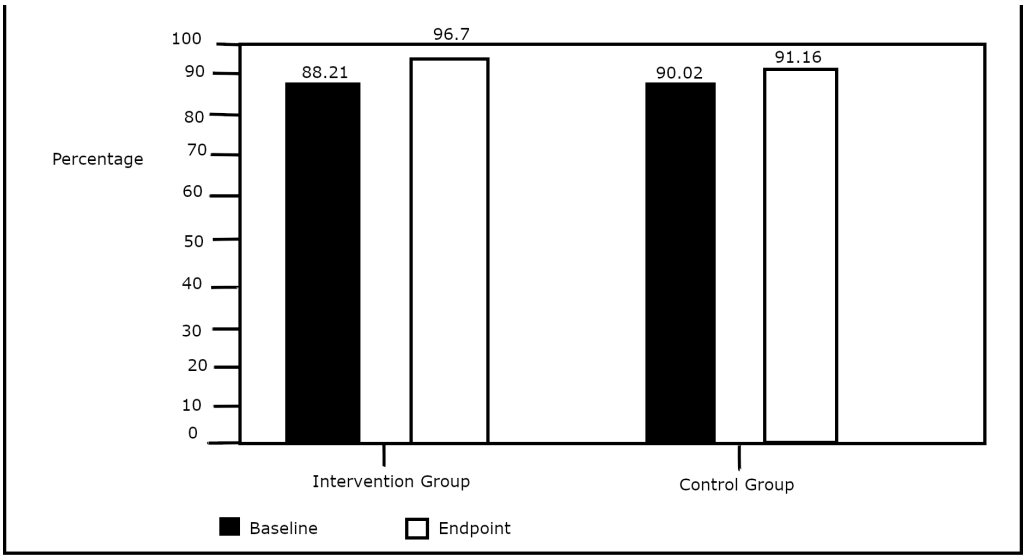
Table 1. Continued



Finding #5 - O'Reilly, et al., 2007	
Design • Randomized controlled trial study – four months (2007) • Patients at the Thunder Bay Regional Hospital in Ontario, Canada, who had been referred by their PC physician for psychiatric consultation • Only included patients with baseline BSI scores that fell into dysfunctional range • Intervention group n=138 • Control group n = 148	**Intervention/Measure** Intervention group: patients received telepsychiatric consultation and follow-up via Polycom 512 View Station and large screen monitor Control group: patients received face-to-face psychiatric consultation and follow-up GSI and MH scores collected at both baseline and four-month follow-up CSQ measure collected at four-month follow-up
Finding No significant difference was found between intervention group and control group on change from baseline to four-month follow-up for either GSI or MH measures* No significant difference was found between intervention group and control group on CSQ measures at four month follow-up* *See Table 3	
Finding #6 - Fortney, et al., 2007	
Design • Randomized, controlled trial study • Arkansas VA Primary Care patients with Major Depression (PHQ-9 Score ≥ 12) • Telemedicine-based care model developed for small VA clinics in Arkansas that lack onsite psychiatrists • Intervention group (n=177) • Control group (n=218)	**Intervention/Measure** Intervention group cohorts received treatment via offsite telepsychiatry Control group cohorts received traditional onsite psychiatric care Multivariate Analysis employed to compare measures on adherence to treatment and Depression Scale scores at 6-month and 12-month follow-ups
Finding Greater adherence to treatment for intervention group than controls at both 6-month follow-up (Odds Ratio [OR]=2.1, p=.04), and12-month follow-up (OR=2.7, p=.01) Intervention cohorts two times more likely than Controls to respond to Treatment (PHQ-9 Score < 12) by 6 months (p=.02) Intervention cohorts 2.4 times more likely than controls to have reached remission by 12 months (p=.02)	
Finding #7 - Mohr, et al., 2005	
Design • Randomized, controlled trial study – 16-week trial • MS Patients with Depression recruited via Kaiser Permanente of Northern California and regional chapters of the National MS Society (n=127)	**Intervention/Measure** Intervention group received telephone-based supportive emotion-centered therapy, 16 weeks Control group received traditional face-to-face supportive emotion-centered Therapy, 16 weeks Both groups measured on Depression Rating Scale and Positive Affect Scale
Finding Intervention group had statistically significant improvement over controls for: (1) frequency of major depressive disorder (p=.02) (2) Depression Rating Scale (p=.02) (3) Positive Affect Scale (p=.008)	

A four-month, randomized, controlled trial study conducted at 198 community health centers in Spain from October 2006 to November 2007 examined the efficacy of a telephone-based psychiatric nursing strategy for increasing adherence to antipsychotic medication treatments among schizophrenic clients (Montes, Maurino, Diez & Saiz-Ruiz, 2010). Outpatients at the participating community mental health centers who met the eligibility criteria: patients who had a Diagnostic and Statistics Manual of Mental Disorders, Fourth Revision-specified Schizophrenia diagnosis and were 18 years of age or older, were deemed to be clinically stable, and were being treated with a single, oral antipsychotic medication were recruited to participate. The participants were randomly assigned to either the intervention group who

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

received telepsychiatric nursing care remotely, or to the control group which received routine face-to-face psychiatric nursing care. Intervention group patients were contacted by a psychiatric nurse via telephone; the patients received standardized treatment instructions and information regarding the treatment, and were assessed about knowledge of their medication regimen, missed doses and incomplete adherence. Baseline and week 16 evaluations of both experimental groups by a psychiatrist revealed that although there had been no notable difference in adherence between the intervention and control groups at baseline (88.2% and 90.0%, respectively), by the completion of the study, there was significant improvement in treatment adherence from baseline through week 16 for the intervention group (88.2 to 96.7%); but not for the control group (Figure 2).

Figure 2. Change in the percentage of patients who were considered adherent to treatment over baseline between the intervention group and the control group

* **Change from baseline to endpoint was statistically significantt for intervention group only**

In addition, there was a progressive increase in adherence over time for the intervention group after each telephone session: 92.2% at month 1, 94.3% at month 3, 95.7% at month 3, and 96.7% at month 4 (Montes, et al., 2010), (Table 1).

An open, uncontrolled trial study conducted in 2008 employed an interdisciplinary telepsychiatry service which connected the Veterans Affairs (VA) Medical Center in Salem, Virginia and a health care clinic at Fort Bragg army base, in order to better manage soldiers being treated for combat-related mental health problems (Detweiler, et al., 2011). The study investigated the efficacy of the telepsychiatry services for a group of 120 soldiers during the first 12 months of the service's operations. Overall improvement in daily functioning was assessed using the mean global assessment of function score, demonstrating a significant increase from 58.0 at baseline to 62.3 at the final visit (Detweiler, et al., 2011), (Table 1).

A satisfaction survey was conducted with mental health services patients in Denmark and Sweden who participated in an international telepsychiatry service over an 18-month period beginning in May 2006 and extending through October 2007, to measure the patients' level of acceptability and satisfac-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion regarding telepsychiatry (Mucic, 2008). The patients who participated were given a questionnaire at the end of the 18-month study with eight questions designed to measure patients' perceptions of the usefulness, comfort level, achievement of treatment goals, and satisfaction with the quality of care related to the telepsychiatry treatment they received (Table 2).

The results in Table 2 summarize the responses for the 23 patients who completed the survey; in general, patients expressed a relatively high degree of acceptance and overall satisfaction with the telepsychiatry treatments. Only four percent of the patients reported feeling uncomfortable receiving care via televised methods. Furthermore, most of the patients (87%) reported that they would recommend telepsychiatry to others (Mucic, 2008), (Table 1).

A randomized controlled trial at the Thunder Bay Regional Hospital in Ontario, Canada (2007), investigated the effectiveness of telepsychiatry versus face-to-face psychiatry on patients who had been referred by their PC physician for psychiatric consultation. Outcome measures included the Global Severity Index (GSI) subscale of the Brief Symptom Inventory (BSI), the Mental Health (MH) subscale of the 36-item Medical Outcomes Study Short Form, and the Client Satisfaction Questionnaire (CSQ), (O'Reilly, et al., 2007). Only those patients with baseline BSI scores that fell within the dysfunctional range were included, and randomly assigned to either the telepsychiatry group or the face-to-face group. Psychiatrists and patients in the telepsychiatry group interacted via a Polycom 512 View Station and a Sony Trinitron large screen monitor. For the face-to-face group, the psychiatrists were flown to the Thunder Bay Hospital and provided in-person care. Psychiatrists in each condition of the study (telepsychiatry versus face-to-face) were assigned an equal number of patients and provided psychiatric consultation and short-term follow-up to the patients. GSI, MH and CSQ outcome measures for patients in both groups are summarized in Table 3.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Follow-up results on outcome measures – GSI, MH and CSQ – for patients referred for psychiatric consultation: Telepsychiatry versus face-to-face

Measure	Baseline Score		Four-Month Score	
	Mean	SD	Mean	SD
GSI[a]				
Face to face (N=148)	56.5	10.1	49.7	13.3
Telepsychiatry (N=138)	56.9	10.2	49.7	12.6
MH[b]				
Face to face (N=148)	24.0	12.4	30.9	15.7
Telepsychiatry (N=138)	23.8	12.0	31.7	14.2
CSQ[c]				
Face to face (N=129)	-	-	23.0	5.7
Telepsychiatry (N=125)	-	-	22.7	6.0

[a]Global Severity Index of the Brief Symptom Inventory. Possible scores range from 30 to 80, with higher scores indicating more distress.
[b]Mental health subscale of the 36-item Medical Outcomes Study Short Form. Possible scores range from 0 to 100, with higher scores indicating higher functioning.
[c]Client Satisfaction Questionnaire. Possible scores range from 8 to 32, with higher scores indicating higher satisfaction.
Source: O'Reilly et al. (2007).

The results showed no significant difference between the telepsychiatry group and face-to-face group for GSI and MH scores at both baseline and four-month follow-up. In addition, the mean CSQ measure collected at four-month follow-up did not differ significantly for the two groups. The results suggested that psychiatric consultation and short-term follow-up provided via telepsychiatry was as effective as that which was provided face-to-face (O'Reilly et al., 2007) (Table 1).

CONCLUSION

Use of Telepsychiatry has shown benefits to patients in a number of patient care contexts and healthcare settings. The study findings cited in this paper suggest that telepsychiatry is at least as effective for delivering psychiatric care as more traditional face-to-face methods; and in some cases telepsychiatry showed greater efficacy in promoting improvements in depression ratings and adherence to treatment than face-to-face psychiatric care. Additionally, telepsychiatry was generally well-received and satisfaction survey scores were high on average. The findings reported by Montes, et al. (2010) suggested that telepsychiatric nursing care delivered to schizophrenic patients who were clinically stable improved treatment adherence. It is possible that in general, mental health patients who are less compliant to treatment that is given face-to-face, due to stigma or feeling uncomfortable when interacting directly with caregivers, might demonstrate increased adherence to treatment when it is delivered remotely via telepsychiatry.

According to García-Lizana & Muñoz-Mayorga (2010), telepsychiatry might provide a reasonable alternative to more traditional, in-person treatment approaches, for situations where arranging face-to-face assessments are impractical or burdensome; however, the authors stated that further study was required to determine whether telepsychiatry can be a suitable replacement for ongoing psychotherapy.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

This statement was echoed by O'Reilly, et al. (2007), in the study cited in this paper which suggested that telepsychiatric consultation and short-term follow-up were as effective as face-to-face methods; but with the caveat that such findings did not imply that other forms of mental health services, such as psychotherapy, would have the same efficacy when provided via telepsychiatry.

The benefits of using telepsychiatry were readily apparent for situations in which patients that lived in remote areas, or had limited access to transportation, were able to access needed mental health services that may have been difficult or impossible to obtain otherwise.

The studies involving telepsychiatry for patients with depression seemed to provide relatively clear outcome measures from standardized depression scales such as PHQ-9, and all but one included more homogeneous samples of patients than studies that used broader inclusion criteria; this helped to reduce the chances for extraneous factors to have affected the outcome measures.

The high percentages of patient acceptability of telepsychiatry services in the study by Mucic (2008) suggested patients felt comfortable interacting with the telemedia, and in general found the telepsychiatric experience to be acceptable, at the least.

The open, uncontrolled trial study by McCusker et al. (2013) could have been improved by inclusion of a control group. Another limitation with this study was related to the selection criteria in which patients had a comorbid condition; it is possible that spurious relationships between the comorbid variables and the intervention may have affected changes in the PHQ-9 follow-up measures and served to confound the relationship between telepsychiatry and changes in depression scale measures.

This literature review had limitations related to the search strategy employed, and researchers' and publication bias might have affected the quality and availability of the research material selected. In addition, the conceptual framework utilized for this study was adapted to telepsychiatry applications and has not been specifically tested with telepsychiatry.

This research is consistent with the past belief that telepsychiatry has been shown to be a safe and effective method for delivering psychiatric care and has the benefit of offering patients that reside in remote areas greater access to mental healthcare providers. In terms of the efficacy as a complete replacement or alternative, the study findings cited in this paper suggest that telepsychiatry is at least as effective for delivering psychiatric care as more traditional face-to-face methods. There were some areas of telepsychiatry, such as promoting improvement in depression patients and adherence to treatment, which showed greater efficacy than face-to-face psychiatric care. Further research is necessary to study the use of interactive technology through controlled experiments. This research will be useful for gathering additional evidence for the benefits associated with telepsychiatric approaches to mental healthcare.

Future Telepsychiatry Research

Existing evidence that telepsychiatry can vastly increase the provision of needed behavioral healthcare services to patients with limited access should be supplemented with new evidence. Future studies should include more controlled experimental trials with diagnosis-specific groups, and double-blind designs to increase the likelihood that the study is valid; and should include telepsychiatric methods which go beyond telephone-based and videoconferencing systems, such as those which are EHR-linked, or incorporate interactive computer simulations such as 3-D virtual worlds.

According to Gorini, Gaggioli, Vigna & Riva (2008), 3-D virtual worlds function as three-dimensional social networks which provide novel means for developing social skills, socializing, and interacting with others via realistic, 3-D animated avatars. The potential for interactive health networks, virtual patient

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

support groups, and a host of other interactive patient services are practically limitless. Therefore, research projects which center on telepsychiatric services that incorporate such virtual worlds are warranted and should be highly encouraged.

Chapter 24
Social Media for Mental Health Initiatives

Gemma Richardson
Humber College, Canada

ABSTRACT

Social media has added a new dynamic for those living with mental illness. There are several benefits to using social media to obtain information and support for mental health issues, but there are also new challenges and drawbacks. This chapter explores social media for mental health initiatives, with a focus on two case studies: Facebook's suicide prevention tools and the Bell Let's Talk campaign. These case studies highlight the unique ways that social media can be harnessed to raise awareness and provide support and resources to vulnerable populations, while also providing insights into the challenges of utilizing these platforms.

INTRODUCTION

The proliferation of social media platforms has inevitably had an impact on online help seeking for mental health issues. Asynchronous message boards have been used since the early days of the Internet for mental health support and information seeking, but social media platforms have added a new dynamic. On the one hand, these platforms can be heralded as welcome ways to break down the barriers for those seeking help in several ways due to the accessibility, convenience, and geographical reach of these platforms. Some social media sites also offer user anonymity, which can potentially alleviate some of the fears around stigma. On the other hand, however, there are several problematic aspects to using social media platforms for mental health initiatives, including the potential for trolling, bullying and other negative interactions, and the potential for online communication to increase isolation through minimizing face-to-face social interactions. There are increasing concerns that use of social media may in fact be *contributing* to mental illness, especially among vulnerable youth.

In light of these challenges, several social media platforms have initiated mental health initiatives for users. Other organizations have decided to harness the power of social media to increase awareness and dialogue on mental illness. In this chapter, the evolution of some of these initiatives is discussed, with a particular focus on Facebook's suicide prevention efforts and the Bell Let's Talk campaign. In the summer of 2016, Facebook made its updated suicide prevention tools available globally. Users of the platform can flag posts from friends if they are worried about the potential for self-harm and several options then appear in a drop down menu (including a list of resources, sending a message of support or having the post reviewed by someone at Facebook who can then reach out with helpful information). This initiative and some of the responses to it are examined in this chapter.

The Bell Let's Talk campaign is also explored. This campaign has generated a massive amount of support in Canada each January through the use of social media platforms (and in particular hash tags) to open up the dialogue on mental health (and ultimately raise money for mental health programs with each social media share or post using the #BellLetsTalk hashtag). These two particular case studies provide insights into the involvement of social media in mental health initiatives, both the positive aspects and the criticisms arising from them. The chapter concludes with a look ahead to what is needed and how there may be a continuing evolution in how these platforms are utilized for mental health initiatives.

USE OF SOCIAL MEDIA FOR MENTAL HEALTH INITIATIVES

While social media adds new dynamics and possibilities for mental health initiatives, the use of the Internet has long had strong appeal to people with stigmatized illnesses who wish to obtain information or assistance (Klein & Wilson, 2002; Berger, Wagner & Baker, 2005). Some forms of stigma can be avoided through anonymously seeking information online about mental illness. There are social media sites that build on this appeal by allowing created identities if the user desires (including Twitter, Instagram and Reddit) while others seek to remove anonymity (including Facebook, where users are strongly encouraged to use real names and have friends and family attached to their account who can see their posts and Facebook-related affiliations).

Now not only are those living with mental illness using social media to obtain information and support, but health care providers are also turning to these platforms. Most major mental health organizations have some form of presence on social media and use these platforms for outreach. Research into how social media can be utilized by health practitioners and organizations is also gaining in popularity. The National Institutes of Health in the U.S. has awarded several million dollars in research funding to explore using social media to advance prevention and treatment of addiction (National Institutes of Health, 2014). This builds on previous research in this area, such as that from a team of Microsoft researchers who explored how social media posts could be used to detect depression in users. De Choudhury, Gamon, Counts and Horvitz (2013) found that social media posts made by Twitter users in their study contained useful information to identify the onset of major depression—opening the possibility for the development of tools for use by healthcare agencies or individuals. Their study indicated that volunteers with moderate to severe depression were more likely to post negative messages, were less socially active on Twitter and were more concerned with health and relationships.[1]

There are some clear benefits to using social media for mental health initiatives. According to the Pew Research Centre (2017), 77% of adults in the U.S. own smartphones (for adults under age 49 this percentage is much higher). This means many people have smartphones on them at all times, allowing

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

them to access social media platforms at all times of the day. Seeking support and information through these online platforms does not limit one to conventional business hours, meaning that support and information is accessible when conventional resources are not available. The ubiquitous nature of smartphones with access to social media platforms also means that the geographic reach of mental health initiatives can be expanded to remote and underserved communities.

As noted above, much research has found that online resources are particularly attractive for individuals with stigmatized identities, as help-seeking and socialization in face-to-face situations are associated with high levels of stress for members of such groups (Parr, 2008). Many social media platforms allow for stigmatized individuals to seek help in an anonymous fashion without face-to-face interactions. The use of social media in mental health initiatives can also be viewed as empowering. Social geographer Hester Parr believes that envisioning a person living with serious mental health problems "as technically proficient, intimately networked, emotionally nuanced and socially competent challenges stigmatizing conceptualizations of the damaged, alienated and pathologized patient-subject" (2008, p. 159). Social media also allow for a unique peer-to-peer sharing that can offer those living with mental illness a sense of comradery that cannot often be found in a practitioner-patient setting. A study conducted by Hughes and Cohen (2011) indicated that those with lived experiences offer meaningful information to people with similar conditions through online forums. This sense of community can be an important aspect for those who turn to social media for information and support.

There are, of course, challenges with these open and fluid discussion-based platforms on social media. Since the early days of the internet, problems with open communities where anyone can join and comment existed. For instance Sandy Stone (1999) documents the rise and subsequent demise of CommuniTree in the early days of Internet-based discussion forums in her work *The War and Desire of Technology at the End of the Mechanical Age.* She discusses the hard lessons about what was and what was not possible in an unstructured and unprotected conferencing environment, painfully learned through direct experience with the "system bashers" (p. 117). Similar problems still exist today and have even multiplied with the advent of Web 2.0. What we would now call trolling is a major problem for those seeking support online who participate in open groups or ones linked to social media like Facebook that do not allow for more anonymous forms of online existence. There has been increasing media attention to cases surrounding cyber-bulling and suicides, as well as the fears provoked by tragic cases such as that of Nadia Kajouji, the Canadian university student who was encouraged to kill herself in 2008 by a man in an online discussion group posing as a fellow suicidal female. These are ongoing challenges for social media platforms offering mental health support: usually anyone can participate and potentially make the situation worse.

The Samaritans, a well-known British suicide prevention group, introduced an app in 2014 that alerted users whenever someone they followed on Twitter posted troubling phrases that could indicate a potential risk for suicide—only to quickly disable the app a week later when it became evident that this data could easily be used to prey on vulnerable people. The app gave no notification to those being monitored and while there was potential for people to intervene when it appeared someone was in distress based on their Twitter posts, that also meant there was potential for vulnerable people to be identified and targeted. Using social media posts to diagnose depression or identify suicidal individuals is fraught with danger. As Munmun De Choudhury, a former member of the Microsoft team studying depression, points out, "we have to think very carefully about who gets access to these tools and what the boundaries are for technology used to make judgements about individuals" (as quoted in Singer, 2014, para. 29). The Samaritans app led to public outcry over their assumption that anyone and everyone

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

had the appropriate training and expertise to monitor social media accounts using these experimental algorithms that ultimately labelled Twitter users. There were also concerns over who had access to this information and how it could potentially be used against someone by employers or even insurance companies. This case indicated the great need for much more research on monitoring social media for intervention opportunities. The fear of being labelled by one of these algorithm-based tools is part of the larger concern around stigma and identity online when it comes to mental illness. In a Canadian study, researchers found youth interviewed about using social media to seek mental health information worried about being judged and discussed the connections between social media, bullying and stigma (Rasmussen-Pennington, Richardson, Garinger & Contursi, 2013). For these reasons, the youth in the study preferred *not* to use social media to access mental health information.

In addition to these drawbacks and concerns, there are those who question the helpfulness of social media all together and some even blame these platforms for increasing mental health issues, especially involving vulnerable young people. Technology critic Sherry Turkle (2011) laments how technological devices such as smartphones have ultimately resulted in us being "alone together" - shutting out the people right in front of us in favour of staring at a screen, where "the performance of connection seems connection enough" (p. 9). Pantic, Damjanovic, Todorovic et al. (2012) found in their study of high school students that there was a statistically significant correlation between symptoms of depression and the amount of time spent on social networking sites. Other research has indicated that some social media pose risks for potential addictive behaviour (La Barbera, La Paglia & Valsavoia, 2009; Kuss & Griffiths, 2011) or can have a negative impact on self-esteem (Mehdizadeh, 2010). While these type of studies are often picked up by media to "sound the alarm" over social media use by youth, it must be noted that there are conflicting studies and some research has actually indicated that use of Facebook can enhance self-esteem (Gonzales & Hancock, 2011) and that online communication with friends and family through social media sites is associated with a decline in depression (Bessiere, Pressman, Kiesler & Kraut, 2010). These studies do not offer conclusive evidence one way or the other, leaving the impact of social media on mental health a topic of much debate.

SUICIDE PREVENTION MEASURES ON FACEBOOK

Several social media platforms have launched their own built-in mental health initiatives to assist users. Facebook's suicide prevention initiatives are explored here, but Facebook is not the only platform to launch this type of program. The popular photo sharing platform Instagram launched a new tool in 2016 to alert them to users who may be in distress. Once a user has flagged a post for showing signs of possible self-harm or depression, Instagram then sends a message to that person with resources to offer support. They also have banned some hashtags that promote self-harm or eating disorders, and searching for other concerning hashtags will automatically bring users to a support page. The microblogging site Tumblr launched an initiative in 2015 called Post it Forward to encourage users to share their stories of bullying, mental illness and other similar issues and to post messages of kindness and encouragement in a variety of media formats. The goal of the project is to reduce stigma and encourage a positive and supportive online environment. Programs like these show that it is not just researchers and mental health organizations that are turning to these platforms, but the platforms themselves that realize they can play an important role in promoting mental health initiatives. It should be noted that while these initiatives are

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

undertaken by private companies, they often work in partnership with government-funded organizations and charities that provide services and resources (such as Facebook's partnerships discussed below).

Facebook is one of the largest and most well-known social networks, with more than 1.23 billion daily active users worldwide as of December 2016 (Facebook Newsroom, 2017). While there are numerous studies that examine the potential imitative effect of reports of suicide in traditional media,[2] the effects of suicide notes posted to online platforms like Facebook on predisposed individuals have not been studied in any depth. As Ruder *et al*. (2011) point out, suicide notes posted to Facebook are instantly available to a large number of individuals, quite different from traditional suicide notes. This instant access by a variety of people provides opportunity for Facebook users to intervene directly or seek help from emergency services. There have been cases of individuals posting their intent to attempt suicide on Facebook as a status update, which has then prompted friends or family to take action after seeing such a post online (with some able to successfully intervene, while others were sadly too late). Examples include: a 28-year-old man in Switzerland posted his intent and the location where he planned to jump to his death but unfortunately after notifying the police his friend arrived at the location too late (Ruder et al., 2011); in Israel a police search located a 44-year-old man injured but still alive after a suicide note he posted on Facebook the day prior alerted friends (Levy-Stein, 2009); a former contestant on the television show American Idol posted what appeared to be a suicide note to Facebook, spurring his family and friends to contact the authorities, track him down and have him evaluated at a nearby hospital (Dunkerley, 2014). These examples indicate that there are cases of Facebook users actively seeking to intervene in suicide attempts of other users.

In 2011, Facebook began their partnership with the National Suicide Prevention Lifeline and the Substance Abuse and Mental Health Services Administration. This marked the first time that users who saw a suicidal comment by a friend could report this to Facebook. In March 2016, Facebook announced an update to their suicide prevention tools, including streamlined reporting, integrated suicide prevention tools to help people in real time on Facebook Live (the platform's live video streaming service), and perhaps most importantly, live chat support from crisis support professionals through Facebook's Messenger (the platform's direct messaging and live chat service). Facebook reviews content reported them and prioritizes reports of suicide. Once a post is reported as a potential suicidal statement, Facebook then sends a message to the user encouraging them to call the National Suicide Prevention Lifeline or to join a confidential online chat session with a crisis worker. The site offers "pre-populated text messages to make it easier for people to start a conversation" (Callison-Burch, Guadagno & Davis, 2016) when trying to reach out to a friend. Users of Facebook Messenger have the option to message with a crisis support worker directly through the Messenger app. The organizations partnering with Facebook to offer this service include the National Suicide Prevention Lifeline, the National Eating Disorder Association and the Crisis Text Line. Users watching live videos on Facebook Live can reach out to someone directly who they believe is in distress or the video can be reported to Facebook. The person sharing the video that was reported will then see a set of resources on their screen: choose to reach out to a friend, contact a help line, or see tips. All of these measures may potentially reach a suicidal individual and encourage them to seek help right away.

Facebook has also now started to pilot the use of artificial intelligence to identify posts that likely include thoughts of suicide. For now this is only limited to the U.S. Once a post has been identified by the algorithm, the Community Operations team then reviews these posts and determines whether to provide resources to the person who posted the content. As mentioned earlier, algorithms that identify suicidal or depressed individuals are fraught with ethical issues. First, they are in their infancy and require a great

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

deal more research and testing. Second, who may have access to the data gleaned by these algorithms is controversial—information that someone may have a psychiatric disorder or be suicidal can have negative consequences for employment, housing opportunities and international travel, among other aspects. Privacy protection of this data is important and having potential information about someone's mental health (whether assumed or accurate) in the hands of a for-profit company raises concern. While suicide prevention is an important goal, the ethical layers must be carefully considered with all technology-based interventions, including these updated tools available through Facebook.

BELL LET'S TALK

Perhaps one of the most common uses of social media in relation to mental health initiatives is for raising awareness. The large reach instantly available through social networking sites make them very attractive tools for stigma reduction campaigns and encouraging greater understanding of mental illness. Using social media for these campaigns bypasses an initial reliance on traditional media because news outlets usually only pick up on the content once it has already achieved a large and widespread audience. Whether through viral videos shared on YouTube or hashtags that quickly trend on Twitter (such as #StopTheStigma and #WhatYouDontSee), there are a variety of ways to use social media to increase awareness and dialogue on mental illness. The Bell Let's Talk campaign is perhaps one of the largest and most successful of the campaigns utilizing social media for this aim.

Bell Media is part of the massive Bell Canada Enterprises (BCE) media conglomerate. The company spans both media content (owning radio stations, television stations and web sites) and media distribution (providing wireless, cable, internet and home phone services). In 2010, Bell launched the Let's Talk Campaign with the purpose of opening up the national dialogue on mental health and to generate funding for mental health programs. Social media is a key component of the campaign, with the idea being that through online social networks, individuals have the power to spread a message that can potentially change minds. It also allows those living with mental illness a chance to share their own experiences. The biggest component of the campaign is a dedicated day each year in January—the Bell Let's Talk day. During this 24-hour period, Bell pledges to put 5 cents towards mental health initiatives for every call or text made on their network by Bell subscribers, as well every time a post is made on Twitter and Instagram using the #BellLetsTalk hashtag, anytime a Snapchat user sends a snap using the Bell Let's Talk geofilter, and anytime a Facebook user watches one of the Bell Let's Talk videos.

There has been a steady increase in the number of interactions on Bell Let's Talk day each year since the campaign began. Starting with 66,079,236 interactions in 2011, the campaign grew to 131,705,010 interactions in 2017 (Bell Canada, 2017). The campaign features a variety of celebrity ambassadors and has received support through the social media accounts of notable people, including the Prime Minister of Canada, pop star Justin Bieber, comedian Ellen DeGeneres and actor William Shatner, as well as dozens of other celebrities, professional athletes and Canadian politicians. As of 2017, the campaign has generated 729,065,654 interactions, raising over $86 million for mental health initiatives (Bell Canada, 2017).

There is no doubt that the Bell Let's Talk Day is an incredibly successful social media campaign and the need to talk openly about mental health problems is a message that has been spread wide and far. Not only does the campaign aim to open up dialogue and reduce stigma, but the tangible effect of raising money for actual programs makes this a very popular initiative for millions of people to get involved in. With the ease of simply retweeting or using a hashtag, social media users can participate and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

contribute. Going beyond awareness and emphasizing the importance of community support programs for those living with mental illness allows the campaign to escape much of the criticism of other initiatives dubbed "slackivism", whereby social media users do very little to actually contribute to concrete solutions. Social media allows for new forms of dialogue on mental health and the Bell Let's Talk Day perfectly harnesses the power of this medium.

However, this does not mean it is completely free of criticism. Each year, there are those who use the day to disparage the company behind this campaign and highlight some of the problematic aspects of this campaign. When a massive telecommunications company is behind a campaign that encourages people to use their telecommunication devices to participate, it justifiably raises some suspicions. It must be noted that the campaign and its corresponding hashtags and social media mentions are not generic—it is not "Let's Talk" but instead "*Bell* Let's Talk". The company's name is uttered in every single tweet and share. This is no doubt a massive marketing campaign, not just a campaign for mental health. Perhaps this is one of the more intriguing aspects of this campaign, as it not only raises awareness and money, but it also gets the company's name out there and attaches goodwill to their name. As the employee who oversees the Bell Let's Talk campaign told *The Globe and Mail*, the campaign has "also helped people see Bell in different, more positive light and made them think about giving Bell a second chance" (as quoted in Ladurantaye & Krashinsky Robertson, 2013, para. 5). Whether it be frustrations as a Bell customer or animosity towards the company in the increasingly concentrated Canadian mediascape, these concerns seem to be put aside by many people each year who participate in the campaign. The very tangible element of raising money for mental health programs and research no doubt helps move this beyond a marketing and awareness campaign so that more people want to participate. The hashtag does inevitably get used each year by some who are displeased with the company[3], but the vast majority are genuine interactions and participation with the campaign. As with the Facebook suicide prevention initiative, the Bell Let's Talk campaign involves a private company partnering (or in this case, providing funding) to publicly-funded organizations and programs for those living with mental illness.

LIMITATIONS AND FUTURE RESEARCH

This chapter is by no means a complete look at the current landscape for social media and mental health initiatives. Facebook's suicide prevention tools and the Bell Let's Talk campaign were used as case studies here to highlight some of the issues at stake, but there are certainly many others that warrant research and discussion. Larger studies that look at impacts of these media tools and campaigns are required—the financial outcomes are known for the Bell Let's Talk campaign but potential impacts on stigma reduction are much more difficult to measure and assess. Potential future research projects could involve surveying individuals who have sought mental health treatment and support to find out how they were directed to that service and what role, if any, social media played. While incredibly difficult to navigate both logistically and ethically, it would provide highly interesting and necessary data if individuals who have attempted suicide could also be surveyed to find out what role, if any, social media has played in their lives and whether it resulted in early intervention for suicide attempts. As mentioned earlier, the studies that have been done about the impact of social media on mental health are limited, conflicting and do not offer conclusive evidence that there is necessarily any harm being done or that these tools are beneficial, leaving this a topic of much debate.

CONCLUSION

The use of social media by those living with mental illness continues to expand, as it offers a new way to connect to seek community, support and information. Naslund, Aschbrenner, Marsch and Bartels (2016) argue that online peer-to-peer connections through social media give individuals living with mental illness a chance to challenge stigma through personal empowerment and providing hope. Individuals can learn from their peers online, provide mutual support and help promote treatment across a wide demographic (Naslund, Aschbrenner, Marsh & Bartels, 2016). Social media also appeals to health practitioners, mental health organizations and researchers. These new forms of communication can help to monitor, identify and treat mental illness, potentially changing how psychiatry is practiced in the future (Peek, 2015). While these encouraging aspects must continue to be harnessed to benefit as many as possible, it is critical that the ethical implications that come along with this use of Web 2.0 are addressed. Privacy and the safety and well-being of everyone involved must be at the forefront of any discussions about how to use social media to benefit mental health initiatives.

KEY TERMS AND DEFINITIONS

Algorithm: A set of rules or procedures a computer program carries out to complete a task. Each algorithm is a sequence of instructions.

Hashtag: A user-generated method of categorizing content on social media. By placing the # symbol before a keyword or phrase, users categorize their content into easily searchable content areas.

Mental Illness: A range of health conditions that involve thinking, mood and behaviour. Examples include depression, anxiety disorders, addictions, eating disorders and schizophrenia.

Peer-to-Peer: Can refer to decentralized computer networks sharing information between them, or (as in the case of this chapter) people who provide information or support to others with whom they share a common identity. Peer-to-peer information or support is direct between the participants and does not involve outsider experts or authority figures.

Social Media: Web site that allow users to generate content and share with others. Online forms of communication that allow for large-scale sharing, networking and discussion.

Stigma: Negative feelings, beliefs or associations to something. Can be unfair and inaccurate beliefs, but often widely held. Literally means a mark of shame.

Suicide Prevention: Efforts to intervene in the actions of a suicidal person to cease harm or potential death, or to stop suicidal thoughts from being acted upon.

ENDNOTES

1 When this type of initiative was put into actual practice, there were, however, negative consequences and public outcry (see the discussion of the Samaritans app later in the chapter).

2 See, for example, Phillips 1974, 1979; Barraclough, Shepherd & Jennings, 1977; Berman, 1988; Bollen & Phillips, 1982; Kessler & Stipp, 1984; Gunnell, 1994; Fekete & Schmidtke 1995; Hassan, 1995; Stack 1996, 2002, 2005; Etzersdorfer & Sonneck 1998; Pirkis & Blood 2001; Hawton & Williams, 2002; Pirkis et al., 2002, Gould, Jamieson & Romer 2003; Au, Yip, Chan & Law 2004; and many others.

3 For example, on the day of the January 2017 Bell Let's Talk day, CBC published a damning article about a Bell employee who claimed to have been fired for her mental illness (Weldon, 2017, January 25). Sharing this article using the #BellLetsTalk hashtag showcases some of criticisms launched at the campaign and the company behind it. The year prior, another scathing article was published by a former Bell Media employee who claimed her job with the company was incredibly stressful yet her contract did not grant her access to the employee benefits package to seek mental health support (Ho, 2016). This was also shared using the #BellLetsTalk hashtag.

This research was previously published in Global Perspectives on Health Communication in the Age of Social Media; pages 210-224, copyright year 2018 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 25
Virtual Reality as a Tool for Mental Health and Conscious Living and Death:
Immersive Contemplative Approaches to Existential Anxieties

Dorote Weyers-Lucci
Institute of Transpersonal Psychology, Sofia University, USA

ABSTRACT

In this chapter, the authors look at the possibilities of impact of VR in the mental health and wellness area through the lens of contemplative practices and immersive experiences. The area of existential anxieties is often stigmatized or difficult to address directly. Death is the most transformative journey possible but may not be viewed this way. Immersive experiences designed to encourage and allow for non-dual experiences can support this transition. They are difficult to design since non-dual experiences by their very nature are both deeply personal and yet totally impersonal at the same time. Yet, the authors examine how existential anxieties are the perfect framework for a non-dual experience. The wellness app StarflightVR serves as an explorative tool. We mention a past study in this area, which revealed that it is possible to mitigate depression by addressing anxiety on a daily basis through this immersive contemplative VR experience. The authors build on this study with existential fear mitigation examined through an online workshop experience and StarflightVR.

INTRODUCTION

In this chapter, we first focus on Virtual Reality (VR), and its positive impacts on mental health. It has been shown to have therapeutic benefits, offering a bridge between transpersonal psychology and the latest technology (Carvalho, Freire, & Nardi, 2010; Chirico et al., 2016; Cukor, Spitalnick, Difede, Rizzo, & Rothbaum, 2009; Diers et al., 2015; Freeman et al., 2014; Glantz, Rizzo, & Graap, 2003). VR has been

shown to improve quality of life (Anderson, Rothbaum, & Hodges, 2001), reduce post-traumatic stress disorder (PTSD) (Cukor et al., 2015), and to be effective as a tool in psychotherapy (Rizzo, 2010). The use of VR to work with anxiety disorders is ideal because of its immersive quality. Immersion can be defined by the ability to get into a different point of view. It has also been defined as taking on another story: "A Zen-like state where your hands just seem to know what to do, and your mind just seems to carry on with the story" (Brown & Cairns, 2004).

Immersion is especially promising if mixed with testing physiological mechanisms of the anxiety response as well. Physiological measures such as heart rate, brain waves changes, respiration rate, and skin conductance in response to a virtual environment can be easily and objectively measured. This in turn contributes to an objective assessment of anxiety and depression (Wilhelm & Roth, 2001).

VR may well prove to be a major mental health tool in the future. Immersive virtual environment technology has already been used in therapy for phobias (Côté & Bouchard, 2008; Wiederhold et al., 2002), stress (Bouchard, Baus, Bernier, & McCreary, 2010, Riva et al., 2006; Villani, Preziosa, & Riva, 2006), anxiety (Harris, Kemmerling, & North, 2002; Repetto & Riva, 2011), exercising (Bryanton et al., 2006), and memory problems (Brooks & Rose, 2003; Klinger, Chemin, Lebreton, & Marié, 2006). Additionally, the effects of VR on anxiety symptoms has been examined. In their study, Gorini et al. (2010) concluded that VR for relaxation represents a promising approach in the treatment of general anxiety disorder (GAD). This is because VR enhances the quality of the relaxation experience through the elicitation of the sense of presence generated within the immersive experiences. Slater et al. (1994) define presence as a psychological sense of being in a virtual environment. This sense of presence is that which supports the quality of the relaxation. These types of studies underline the fact that clinical cases such as GAD can also benefit from the VR treatments.

Over the past few decades, VR has been used successfully in a myriad of psychotherapeutic applications. For example, VR has a long history of use for the treatment of PTSD within exposure therapy (Cukor et al., 2015) which reintroduces the patient to the traumatizing event. VR-based therapies allow the clinician to present compelling and controllable scenarios which can be immediately stopped or de-escalated if patients become too anxious during treatment (Kwon, et al., 2009).

VR is also useful for habit training within behavioral therapy. Iribarren, Prolo, Neagos, and Chiappelli (2005) listed the following evidenced-based psychotherapeutic methods for treatment of PTSD: Cognitive-behavioral psychotherapies (i.e., systematic desensitization, relaxation training, biofeedback, cognitive processing therapy, stress inoculation training, assertiveness training, exposure therapy, combined stress inoculation training and exposure therapy, combined exposure therapy and relaxation training, and cognitive therapy), psychological debriefing, pharmacotherapy, and eye movement desensitization reprocessing therapy (EMDR). According to Iribarren et al., evidence-based practice (EBP) is a clinical approach requiring that decisions about health care be based on the best available, current, valid, and relevant evidence. These practices are a conglomeration of the best available resources in clinical treatment (Dawes et al., 2005).

Conversely, VR is also useful in the mental health arena due to its ability to generate a relaxing experience that stimulates the senses while it integrates with the polyvagal system (Porges, 1995, 2009). Porges is vastly cited in this field for his polyvagal theory. The polyvagal theory proposes that the evolution of the mammalian autonomic nervous system provides the neurophysiological substrates for adaptive behavioral strategies. It further proposes that physiological state limits the range of behavior and psychological experience. This vagal integration therefore, can help to provide a deep sense of relaxation and give patients the ability to build vagal muscle. This in turn facilitates autonomous stress

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

regulation. VR is also key in delivering Mindfulness practice. By focusing a person's attention through the immersive qualities of VR, the sense of being there is more easily achieved (Navarro-Haro et al., 2017; Rice & Schroeder, 2017).

Another compelling aspect of VR is that one's visual system's ability to interpret the surrounding environment is duped into accepting the provided visual stimuli as real. This leads to repercussions in the body, and therefore in one's psychophysiology as well. The viewer reacts as if this is happening here and now. This psychophysiological connection is important for the mental health field because it is the basis for permanent behavior change. Antonio Damasio (1996), scientist, researcher, and expert in neuroscience, proposed the somatic marker hypothesis which describes the capacity of the ventral medial prefrontal cortex and the amygdala to monitor the body's past and hypothetical responses through somatic markers. These markers are located in the brainstem and the VS/nucleus accumbens (reward center) for the involuntary system and the higher cortex for the voluntary system. Both systems are a part of the upward and downward loops within the body to and from the brain. According to Damasio (2010), "the brain's protoself structures are not merely about the body. They are literally and inextricably attached to the body. They are resonant loops that connect back to the brain and then back to the body. A body brain bond." (pp. 470-473). If these loops are broken, such as with PTSD or chronic anxiety, then the person will not be able to integrate the exterior information properly. However, equally important, if these bonds are reconnected permanent behavior change becomes possible. In other words, exposure therapy is effective because the VR environment exposes the whole person to an event, which they can then process and integrate psychophysiologically.

If continuously exposed to in small doses, VR can help to shift one's whole countenance, approach to life, and provide a platform for transformation in their lives (Weyers-Lucci, 2016). VR has been used for healing in other ways as well. VR in combination with EEG technology has been shown to heal certain neural imbalances such as stroke, aging, and autism. Studies that employed brain-computer interface (BCI) technologies and VR included using this interface for rehabilitating stroke (Lechner et al., 2014), the motor-imagery BCI for stroke rehabilitation (I Badia et al., 2013) and paraplegic patients (Donati et al., 2016), and the use of BCI for training normal aging subjects (de Tommaso et al., 2016) as well as those subjects with autism disorder (Amaral et al., 2017) and attention deficit hyperactivity disorder (Rohani & Puthusserypady, 2015). Additionally, VR has shown a capacity to reengage and/or build multiple cortical functions (Baumann et al., 2003; Carrieri et al., 2016; Lin et al., 2008; Schedlbauer et al., 2014) and showed a capacity to optimize the coding efficiency of the sensory cortex (Ansuini et al., 2006; Keller et al., 2012; Ravassard et al., 2013; Schindler & Bartels, 2013; Sofroniew et al., 2015).

Currently there is a need for more research focused on the therapeutic process within VR and not purely on its effectiveness. Maples-Keller, Bunnell, Kim, and Rothbaum (2017) proposed investigating factors such as emotion processing, psychophysiological markers during exposure, and the therapeutic alliance. Their view is that research testing hypothesized mediators and moderators of VR-based treatment will prove informative in the future. This ongoing research study will be focusing on this need.

Working with VR enables mental health practitioners and researchers to create the environment necessary for an immersive, whole body experience that could mimic the state of these feelings of knowing (FOK), a type of metacognition coined by Damasio in his neurocognitive approach of whole body sensing (2010). An example of whole body experience of the feelings of knowing could be a Gestalt or a felt sense (Oleary, 2013; Gendlin, 1992, 1994). This is another aspect that makes VR uniquely suited for working with existential fears.

STARFLIGHTVR AS A NEUROAESTHETIC/ NEUROPHENOMENOLOGICAL TRANSPERSONAL EXPERIENCE OF DEATH/LIFE

StarflightVR is a mobile VR experience set up to engage a whole body experience of a contemplative, non-dual state of death/life. It was designed using hypnotherapeutic principles focused on dehypnotization (Casey, 1987 and Elias, 2006) and neuroaesthetic principles of the integrative and meaning making power of art (Pelowski, et al., 2017). It is an immersive experience that is visually and auditory-based and is meant to give the illusion of letting go into the unknown, very much like it would be to let go into an entirely different state such as a nondual experience, or an experience resembling a near death experience (NDE) like a mindfulness-induced NDE (van Gordon et al., 2018). It is used in this study as one of the immersive experiences.

StarflightVR is also based on the "perceptual illusion of non-mediation" (Lombard and Ditton 1997), which proposes that the illusion becomes reality for the user. In this case, it is the disappearance of the body that actually reinforces the feeling of being fully present in the moment within oneself. Therefore, while experiencing letting go into this environment, flying and without a physical body it becomes possible to experience a state similar to a non-dual state, a meditative state, an egoless experience, or a near-death experience (NDE).

This hypnagogic-based design of a space also impacts emotions according to aesthetic perception, which has been shown to activate the bilateral insula which we attribute to the experience of emotion (Cupchik, 2016). In this case the emotions are soothed, and the ability to observe their fluctuations is supported.

Tracking the movement of the eyes is optional in the experience but could be used to track a participant's focus, whether open or closed focus (based on mindfulness meditation principles). This has a direct effect on brain integration. Deliberate eye movements in therapy have been demonstrated to induce a state of relaxation, or decreased psychophysiological arousal (Shapiro, 2014). One hypothesis is that this relaxation response is a reaction to changes in the environment, part of an orienting response that is elicited by the shifts of attention caused by the repeated bilateral stimulation, which links into processes similar to what occurs during R.E.M. sleep (Shapiro, 2014).

Within the StarflightVR experience there are five chapters or function: sleep, energize, guided meditation, story, and experiences. The sleep experience will be used for the current ongoing research study.

The sleep experience itself can be described as follows: The cadence and design of the star field and the accompanying audio track helps bring the user into a state of flow and calm. The background at first appears to be static and the user is encouraged to observe this with a non-critical mind. It evolves in both color and pattern first into a green and golden background, as if one is in the center of the galaxy, and then gradually, through a color progression, into a calming violet field.

These immersive visuals are able to provide a safe environment to experience a shift of state. The visual and auditory experience can become a whole body experience:

When we relax into our senses, and into our body sensations we are able to access the full picture of the situation at hand. From a neural perspective this means that we are using our lamina1 nerve information from the body and integrating that in various ways into the brain. (Siegel, 2012. p. 172)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Users can open their focus to the field and or choose to follow an object as it glides by. Alternatively, they can observe the quasars with their peripheral vision as those appear and become absorbed into black holes.

Virtual Reality allows for a 360º experience, and therefore allows full peripheral vision to help attenuate existential anxieties. The use of peripheral vision has been shown to be an excellent method for shifting from the awake, aware state into calmness and quiet (Lachenmayr, 2006).

StarflightVR's audio track is designed to resonate with a heartbeat at rest, giving hypnotic cues to settle the sympathetic nervous system (Elias, 2006). It helps shift the brain, and therefore the psychophysiology, into the alpha, alpha/theta state of deep, restful relaxation helping to encourage and enhances the sleep experience (Weyers-Lucci, 2016). This technique induces the breathing to automatically synchronize with the visual and audio flow.

The Greater Good Center in Berkeley completed a recent study on awe and its benefits to human health (Keltner, 2003). The practice of noticing moments of awe is in itself an amazing healing therapy for inflammation, and other stress-related diseases. The momentary experiences of awe stimulates wonder and curiosity (Keltner, 2003). In this case travelling through space in StarflightVR, gently rocked by the rhythm of the heartbeat at rest supports this sense of awe. Awe, in itself, also automatically invites the experience of the present moment. In this way it has the effect of binding social collectives, and enabling more collaborative actions.

From a transpersonal perspective the link existing between art and the artist are examples of transpersonal connection. Ultimately, this is the point of immersion. The painter of an artwork for example, and the viewer are engaged not only in the process of making sense of the existing reality, but they are also linking to an engagement and a transformational property. This is a form of absorption (the ability to be immersed in inner imagery) (Luhrmann, Nusbaum and Thisted 2010) and is important from a pedagogical as well as an artistic perspective. The relationship of the viewer to the painting is similar in some way to that of the relationship of the artist to the painting, however, the viewer becomes the observer in this case and the painter becomes the creator together they are then, as Steiner would qualify it, "the knowing doer" (Steiner, 1964). The knowing doer of Steiner, is also the psychologically mature individual who has attained "embodied consciousness" under Assagioli (1965), who is also the person who has become aware of his own depths and shadow formations as with Jung (1959). In other words, once internal imagery is expressed harmoniously and clearly as an outer form, the sense of presence in everyday life is reflected in a sense of flow.

From a neuroaesthetic perspective such an experience is a complex artistic process that crosses cognitive, kinesthetic and emotional functions, (Pelowski, et al, 2017) and sparks the activation of mirror neurons while the individual is "connecting" with art (Schott, 2015). The reaction or resonance that is established with a work of art or a specific relationship and connection reminds one of the *participatory spirituality* (Ferrer, 2017), approaches. In conjunction with the painting the viewer can possibly attain higher levels of self-awareness:

Most religious and spiritual endeavors, we should stress here, are aimed not so much at describing or explaining human nature and the world, but at engaging and transforming forming them in creative and participatory ways, and may therefore call for different validity standards than those emerging from the rationalistic study of the natural world. (Ferrer & Sherman, 2000. p.150-152)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, in this case, both the creator and the viewer engage not only in the process of making sense of the existing reality, but also linking to an engagement and a transformational property.

A symbol using abstract visuals supports a transcultural approach that is based in archetypal imagery (Jung and Franz, 1964). The abstract approach itself can be seen as a lack of cultural interpretation or methodology of presentation and reception of information. The cultural code, or subcontext, is left open and therefore interpretation becomes transculturally rooted:

The visions of the Jewish mystic are not entirely constituted by his or her subjective imagination, but actually reflect ontological realities that have the capacity of being seen within the imagination of the visionary. This is so because the imagination is...the organ that puts one in contact with spiritual realities that are perceptible to each individual according to the dominant images of one's religious and cultural affiliation. (Ferrer & Sherman, 2000. p.150-152)

This transcultural approach informs the way colors are used in StarflightVR. Distinct wisdom traditions and theories around color differ in their approach yet converge in interesting ways. For example, the colors of sleep within StarflightVR reflect a progression through the color system and are designed to be experienced in an immersive and symbolic manner. This approach to color therapy is grounded in transpersonal psychology. Distinct wisdom traditions and theories around color differ in their approach, yet converge in interesting ways. Rudolf Steiner, founder of Anthroposophy (a philosophical system, and a base for healing methodologies, and other systems such as pedagogy and agricultural systems), was less interested in providing a steep ladder for awakening methodologies, rather than to "awaken at a higher level," meaning a higher level of psychological maturity so that the humans become "stronger souls." (Steiner, 1995). His priority in his approach towards transpersonal phenomena and higher levels of consciousness was directed towards a training of the senses, and a targeted methodology and pedagogy to achieve embodiment, and psychological maturity. Therefore, his way of handling color is entirely different from for example the point of view of the Kabbalah (Lancaster, 2011) or Wilber's pyramid where color is a reflection of a state of consciousness and an energy (Wilber, 2006). Or as Sufi Junayd would say, "the water takes on the color of the cup," (Ferrer & Sherman, 2000, p.150-152). Therefore, wherever the person is, in terms of transpersonal development, they reflect that particular state as a color. The inner maturity reflects in the level of consciousness, which in turn reflects a color (Wilber, 2006). How the individuals interpret, live, and evolve within that color scheme is very personal. Yet Steiner also proposes that there is an aura color specific to every individual. This color is exuded as part of the personal color scheme within the four temperaments in Anthroposophy, and reflects the soul state of being (Steiner, 1995). Allowing for an immersion in color in StarflightVR then mimics this transformative potential. In the end, the intent is to unite, to bring together that which has been held as separate into one non-dual experience of life/death.

Ultimately, the intention of StarflightVR, from a neurophenomenological perspective, is to produce the same changes and transformation in the human brain that is triggered by mindfulness states (Davidson et al., 2003; Hölzel et al., 2011; Kilpatrick et al., 2011). These have important clinical implications, such as reducing automatic affective processing, altering one's relationship to pain and addiction, and leading to the cultivation of compassion (Farb, Anderson & Segal, 2012, pp. 6–7, Garland et al., 2018). For the purpose of mental health it is not necessary to experience death/life as in the Mahasi Sayadaw tradition of Vipassana for example, where there are the stages of insight, called "dukkha nanas," which can generate fear of death and terror (Koster & Oosterhoff, 2004). The proposition here is that of gen-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

erating an experience which gives a taste of the non-dual state while gently supporting transformation and neurogenesis. Instead of working with mindfulness-induced NDEs, we are working here with VR-induced NDEs. StarflightVR's content was created to be gentle and avoid any possible negative side effects of VR exposure therapy.

FEAR OF DEATH AND IMMERSIVE EXPERIENCES

Immersive experiences are uniquely effective in inviting transformation because they work on a deep-rooted phenomenological level and may also integrate socially. Therefore, they can address both individuality and social transformation. Diana Eck, a professor of comparative religion at Harvard University, recognizes in her work that the diversity of cultures is a demographic fact and shares in *Death Makes Life Possible*, a research project and book by Dr. Marilyn Schlitz and Deepak Chopra which takes an immersive approach to coming to an understanding about death (Schlitz & Chopra, 2015):

Because pluralism allows us to celebrate the differences in an effort to find our own deeper truths and paths of meaning, engaging in the world's traditions approach to death and existential anxieties also engages the individual to become more fully human and reflect and examine their own lives and world-view (ibid., p. 93)

An immersive experience in which we engage with the conversation of death and its surrounding myths, archetypes, and psychology can be an incredibly powerful experience.

This integration of different sensing and perceptive methodologies mimics a case study on the same subject of an immersive six-week experience of the *Gestalt of Death* (Weyers-Lucci, 2018). The study was set up with a regular weekly online Zoom meeting rhythm with two participants and myself. Every online meeting included meditation, reflection, sharing, and support in the same order. Discussion points were based on *Death Makes Life Possible* (Schlitz, 2015), NDEs that both participants revisited and shared, as well as other inner and outer experiences related to existential anxieties or feelings of wellness and growth. Sensing, inner knowing, spiritual co-creation also known as *participatory spirituality*, (Ferrer, 2017), and deeper experiencing were a part of every meeting. Other elements included the journaling exercise. All participants continuously practiced focusing on the *Gestalt of Death* for those six weeks. This is the manner in which Anderson (1998a), for example, approached her methodology of intuitive observations: "Each cycle contains both intuitive and analytic activities that invite the researcher's psyche to roam freely within the boundaries set by the cycle. The researcher's psyche roams freely but not aimlessly" (p. 244).

In this example, the participants were also involved in the same activity. We used steps delineated by Claire Petitmengin-Peugeot (1999) to set up an environment for intuitive knowing, or focus. She described four "interior gestures" (p. 246) that pervaded her research: (a) the gesture of letting go, slowing down, and of interior self-collection; (b) the gesture of connection with a person, object, problem, or situation; (c) the gesture of listening with senses and awareness open and attentive; and (d) the intuition itself (in Anderson, 1998). We also discussed and shared diary entries and photography. At the end of the six weeks, both participants made a collage of their journey into death and rebirth. The organic inquiry brought out the need to discuss rebirth as an integral part of the *Gestalt of Death*, rather than a separate area. Ferrer (2017) stresses this type of experiencing when he speaks of *knowing by virtue of*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

being. This for him entails a rejection of the subject-object dilemma that is, according to him, part of the Cartesian worldview. In his view of "bringing forth" an experience, rather than a point of view that is divided between object and subject, it is rather something that happens in unison and is never divided. In this case, both the participants and the researcher became absorbed into the experience of death and rebirth as a continuum.

An immersive experience then, resembles a meditative training in which skills are learned that encourage the individual to change habit patterns and neurological/epigenetic expression and engage in life in a transformed manner. Stages of transformation such as those proposed by Wilber (2006) can be applied here. It is through a phenomenological pattern of insights that transformation can occur because it leads to self-knowledge and dehypnotization in a regular rhythmic fashion of perception and expression. Essentially this is based in a non-dual approach:

The action of meditation can be very simple. It is perceiving the process of becoming, with its wanting, desiring, pushing, and pulling. You can just be aware of all that because it is not Being. The more you are aware of this movement of becoming and allow yourself the possibility that it is not working regardless of what it is moving towards, the more you can observe and experience the gap directly. And if you don't follow any movement, attitude, or reaction to it, you may find yourself to be complet (p. 93, Almaas, 2000)

Or as Elena Avila, practitioner states (cited in Schlitz, 2015):

Healing is remembering who we are—re-remembering, not being dismembered, but remembering. We are already given to the power that rules our fate, and we cling to nothing so we have nothing to defend. We have no thoughts, so that we can see. We have no fear, so that we can re-member ourselves, detached and at ease. We will dart past the ego to be free. (pp. 173-174)

USING A GESTALT RESEARCH APPROACH WITH IMMERSIVE EXPERIENCES

Gestalt is a German term signifying a particular formation, patterning, shape, or even person that is perceived as holistic unit over its component parts. Every gestalt is unique, as is every person or situation. Listening to a gestalt is then feeling the particular flavor of the essence or uniqueness of a person, situation, or process. This essence could be seen as being a reflection of consciousness itself (Almaas, 1986). This unique sense, or gestalt, emerges in the immersive environments. The gestalt will manifest differently for every participant, yet certain types of data will reflect a group process accompanied by physiological data underlining state changes from an objective, biological, and existential perspective.

Gestalt therapy was founded by Fritz Perls (Encyclopedia Brittanica, 2012), who was born in Germany and was a student of Sigmund Freud. In gestalt therapy, the client learns to listen into one's own unique sense of what is true using the same skills as the integrative research skills listed above. It is concerned with developing a client's ability to connect with what is true, and in expressing this authentically to others in everyday life (Perls, 1951). In gestalt, therapy finding the "unique sense" of something is called "finding your unique contact boundary" (Oleary, 2013, p. 24). Gestalt is a relational therapy: congruence, authenticity, and honesty are some of the key terms describing the relational capacities that are fostered in this approach. In the same way, using gestalt principles in research aims toward the discovery of the *unique contact boundary* (Oleary, 2013) of the research matter and how it influences itself and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

its surroundings, as well as how it expresses itself in the world. Working with gestalt means enhanced awareness of sensation, perception, bodily feelings, emotion, and behavior in the present moment. It is, in effect, taking research skills and using them intentionally to bring out a specific "shape" of something, (in this study, for example, the gestalt is that of death). In gestalt, relationship is also emphasized along with contact between the self, the environment, and the other. It is about finding the connections between the points within the research and letting them emerge from the unconscious as well as from the subconscious and conscious. To do this, it is possible to work with two types of emergence that are related to the kinesthetic and proprioceptive skills and, in that way, to the gestalt of something. These are the lightning flash of recognition and the slower coming to of inspired knowing. The flash can be described in the following manner:

Brilliancy arrives at insight in one shot, at a glance, as if intuitively. It doesn't need to go through the various correlations. It is fast and breathtaking. However, it does not see the details of interactions and relationships between the various elements of the situation. We arrive at insight, but most of the time we don't know how we got there. There isn't as much perception, understanding, or knowledge in the process of arriving at the insight, which often makes it difficult to communicate it to others. However, since the Diamond Guidance has Brilliancy as an aspect, it can use the capacity for direct illumination by simply seeing the **gestalt** *without also seeing how the illumination came about. (Almaas, 2000, p. 412)*

The researcher can slow the process and delve into more somatic aspects, or make use of the *Felt Sense* approach (Gendlin, 1992), to inquire into the details of the experience of gestalt and the way the participants are *touching* this essence and the way they are being *touched* by it. This *sensing* quality also ties back to Damasio's *Feelings of Knowing* mentioned earlier (Damasio, 1999).

This gestalt approach to the research may also be useful to address the difficulties that can arise through encountering difficult emotions or feelings:

Some people can withdraw from reality by means of profound spontaneous trances, usually secondary to stress or psychological trauma, and create a fantasy experience by narrowly focusing their attention on imaginary structures or remembered traumatic events while blocking out external reality. (Castillo, 2003, pp. 13-14)

These trances, or unconscious and subconscious overlays, cut off the ability to inquire more deeply and effectively stop the ability to see things as they are.

This is the same phenomenon looked at earlier from the different perspectives of neuroscience, existentialism, and transpersonal psychology. Grounding through feeling the sensation of the body in the moment is helpful in seeing things more clearly, as in *focusing* (Gendlin, 1992). Playfulness, added onto kinesthetic and proprioceptive, is a welcome tool as well. Playing with a gestalt or a sense of an essence through the body could help with triggers and difficult emotions as they may emerge while dealing with topics like death.

From the perspective of neuroscience and neuroplasticity, applying gestalt therapy principles and combining them with immersive experiences and virtual reality exposure is an opportunity to create behavioral changes that could be permanent (Rizzo, 2017). The connection between gestalt and immersive experiences from this perspective lies at the heart of the visual and perceptive networks—those networks from without and those generated on their own from within, those attention-demanding tasks, and the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

stimulus-dependent tasks. The network associated with attention-demanding tasks is referred to as the task-related network, and the network associated with stimulus-independent thought during the resting state is referred to as the default mode network (DMN). The two networks are believed to be negatively correlated (Josipovic, 2016).

There are, however, challenges in observing and collecting data about the DMN because by definition, it is activated when the brain is not triggered by any outside factor. According to Lifshitz, Cusumano, and Raz (2013), it is challenging to manipulate the DMN in experiments since it activates spontaneously when there are no external task stimuli. Actually, the brain is capable of generating a whole independent universe of conscious experiences when it is disconnected from an outside environment; that is, the brain generates this universe without the task network activation (Nir & Tononi, 2010). How does the visual system then activate without external stimuli? It seems that sensory deprivation increases neuroplasticity, and that therefore the state of sensory deprivation within meditation is also an area of interest. Dehypnotization is essentially the act of self-remembrance. The common aspect to meditative practices from different traditions is the element of progressive dis-identification from thought (Walsh, 1979). Walsh (1979) posited that the normal state of being revolves around thoughts and cognitive constructs, which are layered to produce a hypnotized or trancelike state. From a transpersonal psychology perspective, meditation is a tool in the process of self-remembering (Walsh and Shapiro, 2006, Casey, 1987).

The visual system operates by distinct rules; it is an interoceptive system, driven by the subconscious with distinct patterning. A gestalt is a phenomenological shape incurred through internal perception and underlined by neurophysiological expression (Varela, 1995). The sum of a vision is not just the image produced in the eye when one is looking at something, but it is also influenced by the internal gestalt. When looking at an image, the visual networks only register a fraction of this same image. The rest is aggregated through information from the past and the networks of memory and past experience (the hippocampus comes into play here. This processing of information may be the root cause for continuous negative interpretation of the environment in depressive subjects. As shown by Dainer-Best, et al. (2018), sustained attention for negative stimuli in subjects suffering from depression symptoms shows how what is seen is sustained by the perception of the information provided by the visual sense. This sustained attention seems to alter what is perceived from person to person. This change in perception, of self and of the people and things in the world around one, is what changes behavior.

The visual sense is also social, since there are instances of similar brain activity when watching the same movies. The inter-subject correlation analysis used in the Hasson study (2010), for example, shows the impact or control that a given movie may have on the brains of spectators. The analysis measured similarity in brain activity amongst participants. One hypothesis is that certain visual stimuli are processed in the same manner, and that the integration of these particular signals are also similar between people. These universals would be the same universals as the signals of fear and fear of death, especially in crowds or larger audiences. The neurological connection between humans affects the field of vision as well it seems. This fine attunement is the basis for mirror neuron theories (Siegel, 2006) and attachment theory (Bowlby, 1982, 1988). It is also a possibility for transformation, as shared from the research of DMLP and *Living Deeply* (Schlitz, 2015, Vieten, Amorok and Schlitz, 2007). And like others who have reported having near-death experiences, renowned remote viewer, Joseph McMoneagle found a doorway into personal growth that leads away from a primary focus on self-enhancement and toward supportive and meaningful social behaviors. As research on the positive trajectories of terror management and worldview transformation suggest, the experiences guided him to reprioritize intrinsic over extrinsic goals and priorities. "It shifted his view from a small "me" to a larger interconnected "we.'" (ibid., p. 54).

It seems that most visual signaling is interpreted from the subjectivity of the first-person perspective, and from the memories attached to that particular body mind, as well to the viewpoint coming from its subconscious structure. What is not known is where are these networks of activity and sensory information integrated?

According to Cavanna and Trimble (2006), some visuo-spatial imagery studies suggest the involvement in internally guided attention and manipulation of mental images, as well as the integration of mental imagery from the first-person perspective (i.e., introspective integration). These studies support the hypothesis that the precuneus (area of the brain involved in a variety of complex functions, which includes recollection and memory, integration of information (gestalt) relating to perception of the environment, cue reactivity, mental imagery strategies, episodic memory retrieval, and affective responses to pain) is the center point for this integrative activity, and for the visual network as well. Is it possible to postulate that the fear of death is likely to be seen in the brain as a lack of integration? If so, brain structures such as the precuneus would be smaller and structures such as the amygdala would be larger in subjects with chronic, unconscious existential anxiety and depression.

The sense of sight is also of primary importance in embodiment, in other words, the sense of being in a body. Sight seems to have an integrative function in self-perception of the body, coupled with the vestibular system. This system is divided into visual exteroception—the visual perception of the location and movement of the limbs (Crook, 1987)—and visual proprioception and kinesthesis. This combination makes gestalt a powerful tool to work with when researching existential fears and their brain and body maps.

EXISTENTIAL PERSPECTIVE ON THE FEAR OF DEATH

The existential psychotherapist and writer Yalom (1980) outlined what he considered to be the ultimate concerns of humankind: (a) death, (b) isolation, (c) meaninglessness, and (d) freedom. As a psychotherapist, Yalom was primarily interested in how these existential concerns inform the therapeutic process. He believed that psychological difficulties stem from an inability to reconcile with these existential concerns. Thus, his sessions included a thorough examination of the way every individual accommodates these concerns. Yalom believed that the liberation of suffering and sorrow would occur once the client has made peace with their circumstances.

According to psychodynamic theory, Yalom's view represents the specific tension of dual instincts of ego and libidinal instincts (Greenberg & Mitchel, 1983). The demands of the external and internal environments are the birthplace of the superego. This is the force that manages interpersonal demands and the need of the child for approval from their security-providing adults. Failure to find balance among these demands may freeze life-enhancing movement forward that resides in the libido. Character structure rests in part on the role of the superego. The superego manages the safekeeping of its owner. According to Greenberg (1983), "Growth is always compromised for the sake of security" (p. 107). Therefore freezing, whether it be muscles themselves or the lack of movement that comes from a suppressed libido, could easily lead to frozen expressions, frozen muscles, and frozen facial traits. In other words, frozenness itself becomes a "being" (Greenberg, 1983, p. 107), blocking movement forward as growth is compromised for security. Greenberg (1983) stated, "In Freud's revised view, meaning is determined by the ebbs and flows, and a complex interplay of life and death instincts" (pp. 552-553). In the end, Yalom (2009) provides a solution to the existential psychologists' dilemma:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

A denial of death at any level is a denial of one's basic nature and begets an increasingly pervasive restriction of awareness and experience. The integration of the idea of death saves us; rather than sentence us to existences of terror or bleak pessimism, it acts as a catalyst to plunge us into more authentic life modes, and it enhances our pleasure in the living of life. (pp 89-91).

A denial of death causes stress, anxiety, and possibly depression in the individuals experiencing this *death denial*. The physiological effects of denial should become measurable because stress stimulates the sympathetic nervous system while inhibiting the vagus nerve (Porges, 1995; Sahar et al., 2001). Therefore, typical stress-related brain wave patterns and their relaxed counterparts could clearly demonstrate a stress state or a parasympathetic-based state. These can be analyzed to understand the effects of the fear of death, and of relaxation/natural flow. It seems possible to defreeze individuals by having them be immersed in a gestalt of death experience. This invites an examination of the possible effects of immersive experiences, including VR, as a psychotherapeutic tool for existential anxieties.

FEAR OF DEATH AND EXISTENTIAL ANXIETY AND DEPRESSION

As mentioned previously, fear of death/existential anxiety is considered to be a basis for anxiety and depression in existential psychotherapy (Yalom, 2009), cognitive based therapy (CBT) (Lazarus, 1997; Scherer, 2005), and terror management theory (Becker, 1973). At its core, the existential perspective proposes that dread is the basis of human emotional life. This theory stipulates that it is the fear of death that motivates our reality, and is the core of human experience, which results in existential anxiety. This anxiety in turn sets up a filter to create a specific experience of reality. However, the processes associated with the creation of filters are typically nonconscious.

Nonconscious fear processes themselves cannot not be approached in the same manner as conscious fear processes (LeDoux, 2014) and may require a different approach to managing uncontrolled fear states. Existential psychotherapy focuses specifically on the fear of death (Yalom, 2009). Fear of death is considered to be at the basis of unconscious, uncontrolled fear states (Beck & Weisshaar, 1995; Lewis, 2014; Ottens & Hanna, 1998). The distinction between conscious and unconscious is important because the predisposing factors for each may be different and therefore need to be addressed in a different manner (LeDoux, 2014). Fear conditioning is one form of Pavlovian conditioning that has received considerable attention (Fendt & Fanselow 1999, LeDoux, 2000) and has been studied extensively. Pavlovian fear conditioning posits that certain environmental stimuli predict certain aversive events. Pavlovian conditioning forms neural representations of the conditioning itself and, therefore, an alteration in the perception of the subjects who are conditioned (Maren & Holt, 2000).

One experiment that clearly shows this is the *Little Albert Experiment* (Watson, 1920). The researcher, Watson, presents Albert, a human infant, with a novel white rat. Albert responds with curiosity and reaches out to touch the animal. Watson then subsequently pairs appearances of the white rat with a loud and aversive noise. Watson again presents Little Albert with the white rat after the rat had been paired with the loud noise. Unlike his initial reaction of curiosity to the rat, Albert now responds to the rat with fear. He moves away from the rat and cries. The circuits associated with this conditioned response are not the same as those that respond to natural threats occurring in the environment (LeDoux, 2014). The unconditioned fear response is one that responds unconditionally, naturally, and automatically to fear

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

triggers. An unconditioned fear response could, for example, be rats who are exposed to a predator odor (trimethylthiazoline), to elicit unconditioned freezing behavior.

Terror management theory associates an increase of self-esteem when confronted with death with a reduction of death anxiety (Becker, 1973). The existential approach proposes that it is the fear reaction to mortality that causes social reactivity and hatred towards unaccepted population groups. There seems to be a hierarchy of fear reactions, that goes from attachment patterns (Bowlby, 1988) to social worldview and acceptance into social groups. Acceptance into social groups then entails existential fear reactions based on perceived threats to the group worldview. According to Freud the individual literally rescinds their individuality and becomes a barbarian. A group Freud claims, is impulsive, changeable and irritable, and is led almost exclusively by the sub conscious (Freud, 2005).

The fear of death or existential anxieties is deemed to be a basis for general anxiety disorders and therefore depression, lack of self-esteem and other psychological and social pathologies (Becker, 1973; Yalom, 2009; Schlitz, 2015; Sapolsky, 2001).

Is it possible to attain a more objective, clearer view life through an immersive six-week experience of the gestalt of death? The elemental movement when faced with death is a reactive, instinctual race into safety. The fear of death is a deeply wired biological reaction to threat faced by an organism. As Solomon, Greenberg, and Pyszczynski (2015) mentioned in their analysis of the fear of death in *Worm at the Core*, "The fear of death is one of the primary driving forces of human action" (ibid., p. 119-120). This natural driving force, however, can flip into a chronic state. According to Sapolsky (2001), being stuck in the state of chronic anxiety can lead to other psychological and physical imbalances such as depression.

Psychological pathologies related to existential anxieties that could be addressed are to name a few: General Anxiety Disorder (GAD), Obsessive Compulsive Disorder (OCD), Seasonal Affective Disorder (SAD), Panic Disorder (PDA), Post Traumatic Stress Disorder (PTSD), Major Depressive Disorder (MDD), as well as other anxiety-related disorders. Developing a tool for patients or people with these disorders is of prime importance. The current figures for these existential anxiety-related disorders are alarming, nationally within the U.S., and on a world scale.

According to a global study by the World Health Organization (WHO; 2017), GAD affects 6.8 million adults, or 3.1% of the U.S. population, yet only 43.2% are receiving treatment. Women are twice as likely to be affected as men. GAD often co-occurs with major depression. PDA affects 6 million adults, or 2.7% of the U.S. population. Women are twice as likely to be affected as men. SAD affects 15 million adults, or 6.8% of the U.S. population. The leading cause of disability in the U.S. for ages 15 to 44.3, MDD affects more than 16.1 million American adults, or about 6.7%of the U.S. population age 18 and older, in a given year.

The figures worldwide are equally concerning. Depression is the leading cause of disability worldwide. Almost 75% of people with mental disorders remain untreated in developing countries with almost 1 million people taking their lives each year. In addition, according to the WHO (2017), one person in 13 globally suffers from anxiety. The WHO reports that anxiety disorders are the most common mental disorders worldwide with specific phobia, major depressive disorder, and social phobia being the most common anxiety disorders.

Virtual Reality (VR) and/or an immersive experience of the gestalt (phenomenological form/shape) of death may prove to be a unique, comforting, and supportive approach to treat these existentially based anxieties and provide a microcosmic, detailed, and scalable approach to a global problem. Even though mental health is crucial for all development (economic, educational, labor, etc.), the WHO notes that

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

based on the WHO Global Health Expenditure database (2017), the global median of domestic general government health expenditure per capita in 2015 was US $141, thus making government mental health expenditure less than 2% of global median of government health expenditure.

Additionally, low-income countries are faced with a lack of resources that is apparent in the distribution of mental health tools nationally. However, responses vary significantly across income groups with 85% of high-income countries reporting that income support is provided compared to only 11% of low-income countries.

As clinical psychologist Dr. Daniel Freeman says, there is "something beautiful" (Freeman et al., 2016, p. 63) about how VR works. Findings show that patients report satisfaction with VR-based therapy and may find it more acceptable than traditional approaches.

Researching VR and other immersive techniques, such as an experience of the gestalt of death in a workshop, is friendly to the research participants and can eventually be successfully implemented as a future treatment modality. An early study on virtual reality exposure (VRE) for patients with post-traumatic stress disorder (PTSD) due to motor vehicle crashes demonstrated that patients reported very high satisfaction with VRE. In a sample of 150 patients with specific phobias, the refusal rate for VR exposure (3%) was lower than for in vivo exposure (27%), providing preliminary evidence that VR-based exposure may be more acceptable to patients.

One study in a PTSD sample found equivalent satisfaction between VRE and imaginal exposure, while another found increased satisfaction for VRE (Delarosa et al., 2012). In a sample of 352 post-9/11 US soldiers, the majority reported that they would be willing to use most of the technology-based approaches for mental health care included in the survey (e.g., VR; Wilson et al, 2008). Additionally, 19% of those who reported that they would not be willing to talk to a counselor in person reported being willing to use VR approaches to access mental health care, suggesting that VR may potentially address some barriers to treatment (Wilson et al., 2008).

A combination of different approaches, including technological, and non-technological, need to be examined as well. For example, a small-scale RCT ($n = 20$) study used VR in conjunction with biofeedback for patients to practice relaxation exercises during treatment (Kim et al., 2008). Patients were randomly assigned to VR with biofeedback, VR without biofeedback, or wait-list control condition. Although the study did not have enough power to examine between group differences, it provides preliminary support for the feasibility of using VR for patients with GAD. Thus far, this study has been the only one to examine the use of VR in treating GAD in this manner. In the same way, there needs to be additional research done on non-technologically based treatment immersive methodologies in the area of existential anxieties (Cukor et al., 2009).

The dearth of studies may be due to the difficulty associated with creating standardized VR scenarios that are able to capture the numerous, varying, individualized worries of patients with GAD. Given this complication, VR-based treatment programs could focus on some of the more common worries among patients with GAD (e.g., health anxiety, something happening to a loved one). Alternatively, or if a patient's worries are not readily addressable with such scenarios, VR- based treatment could serve as a visual guide for breathing exercises and for practicing relaxation or mindfulness-based approaches. Another interesting area is the study of the use of avatars in immersive experiences and how they shift our deepest perceptions of self (Bailenson, 2018; Bailenson & Kim, 2007).

CONCLUSION

The aim of the current study on the effects of immersive experiences on the fear of death is to understand the individual's personal gestalt of death, and then apply this understanding to the individual's fear of death/existential anxieties. The mental health imbalances associated with these existential anxieties will be addressed in this manner. The research encompasses the applicability of technology such as VR to help mitigate and/or measure symptoms of existential anxiety (depression and neuroses). The rhythm and structure of the study is based on the natural or organic process of insight (Clements, 2004), the cognitive loop process of transformation through perception/expression (Perceptual Shift Hypothesis) (Weyers-Lucci, 2018), or clear thinking as per the scientist, academic, and nondual teacher (Almaas,1986). This loop of insight enables access to a gradually increasing *objective* or clear view of internal and external processes. As Almaas described:

We mean seeing things, seeing internal or external things as they are, instead of subjectively. Subjective is the antithesis; it means according to our positions, feelings, filters, beliefs and attitudes. So objective perception means pure perception, free from all positions, bias, filters, conflicts, intentions etc. It is perceiving whatever it is without any obscuration or intermediacy, so we see it just the way it is in itself. (ibid., p. 5)

Chapter 26
Mental Health and Cognitive Behavioral Therapy:
Advanced Issues and Approaches

Kijpokin Kasemsap
Suan Sunandha Rajabhat University, Thailand

ABSTRACT

This chapter reveals the important perspectives on mental health, mental illness, and technology utilization; mental health education and mental health nursing; the overview of Cognitive Behavioral Therapy (CBT); CBT, depression, anxiety, and insomnia; CBT and Obsessive-Compulsive Disorder (OCD); and CBT and heart failure. Mental health strengthens the individuals' ability to have healthy relationships; make good life choices; maintain physical health and well-being; handle the natural ups and downs of life; and grow toward individuals' potential. Mental health is associated with higher productivity, better performance, more consistent work attendance, and fewer workplace accidents. CBT is a goal-oriented psychotherapy treatment that takes a practical approach to problem-solving skills. CBT involves recognizing the unhelpful or destructive patterns of thinking and reacting, thus modifying or replacing these patterns with more realistic or helpful ones.

INTRODUCTION

The severity and high levels of disability associated with mental illness have led to the increased global efforts to address the mental health problems, in particular those targeted at prevention (Martin & McKay, 2014). Health problems often track from youth to adulthood, indicating the requirement to effectively understand the overall health of young people with mental illness (McCloughen, Foster, Huws-Thomas, & Delgado, 2012). The emerging mental illness increases the existing stress and contradicts the expectations of this stage, as many young adults encounter physical and emotional weakness for the first time and divert from intended plans (Cameron, 2014). As health information becomes available through the Internet and the Web 2.0, mental health professionals are able to develop the strategic plans for taking care of their patients (Prasad, 2017).

With the advent of the Internet and the Web 2.0, mental health services have led to an increase in the presentation and care of mental health patients in generalist health settings (Brunero, Jeon, & Foster, 2012). There is an abundance of research available about the utilization of information and communication technology (ICT) in mental health (Namle, Ghapanchi, & Amrollahi, 2016). The rapid application of technology offers the potentially innovative approaches to promoting mental health among young people, addressing a significant public health challenge (Burns, Blanchard, & Metcalf, 2013). Technology designed specifically for health has proved useful as a complementary form of providing the mental health services (Marks & Bowers, 2015). Mental health patients need to be able to reintegrate in the community to achieve the full normality (Cooper, 2010).

The advances in modern technology have created a diverse field of applications for the care of people with cognitive impairment (Georgakopoulos, Chatzidimitriou, & Tsolaki, 2015). The web-based CBT has several benefits compared to the face-to-face treatment, including high treatment reliability, increased convenience, reduced cost, and scalability (Newby, Twomey, Li, & Andrews, 2016). CBT is a relatively efficacious intervention for a range of psychological disorders when delivered in the well-controlled research trials (Levita, Duhne, Girling, & Waller, 2016) and refers to a collection of therapeutic techniques and strategies that are used to alter behavior by teaching individuals to actively participate in understanding their own thoughts and behaviors (Cajanding, 2016).

This chapter is based on a literature review of mental health and CBT. The extensive literature of mental health and CBT provides a contribution to practitioners and researchers by revealing the advanced issues and approaches of mental health and CBT in the health care industry.

Background

Research into mental health has resulted in a wide range of information and publications covering different aspects of mental health and addressing a variety of problems (Hadzic & Dillon, 2010). In the health care industry, the contemporary models of mental health care emphasize the importance of multidisciplinary approaches in supporting the recovery for individuals (Rosenberg & McDermott, 2016). There is an important relationship between physical activity and mental health (Happell, Platania-Phung, & Scott, 2011). It is essential to have a fundamental shift in the context of the provider–service user relationship to effectively facilitate service users' engagement in their mental health care (Newman, O'Reilly, Lee, & Kennedy, 2015).

Mental health is the successful performance of mental function that results in productive activities, fulfilling relationships, the ability to adapt to change, and the ability to cope with adversity (Matthews, Doherty, Coyle, & Sharry, 2008). Mental health issues often become obvious as adolescents emerge into young adulthood (Albritton, Angley, Gibson, Sipsma, & Kershaw, 2015). Mental health promotion is concerned with achieving the positive mental health and well-being in the general population as well as addressing the needs of those at risk from mental health problems (Wand, 2011). The number of children experiencing mental health issues is underreported, as children, especially younger ones, are often below the threshold for diagnosis because they do not yet meet the criteria (Graham, Killoran, & Parekh, 2016).

CBT is an integration of two theories that were separately born to respond to psychological disorders (i.e., behavioral theory and cognitive theory) (Selene, Omar, & Silvia, 2016). Behavioral theory in its strictest form, focuses only on observable and measurable behavior and ignores all mental events. Cognitive therapy focuses on the role they play and how these cognitions determine feelings and behaviors (Ledley, Marx, & Heimberg, 2010). That is why cognitive behavioral approach aims to understand all

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

knowledge, skills, and psychological techniques that are able to solve all those psychological complications that arise in the course and treatment of the disease.

CBT is based on the premise that since cognitions can be intentionally modified through a process called cognitive restructuring, it is possible to transform the negative and irrational thinking into the rational and balanced thoughts (Deacon, Fawzy, Lickel, & Wolitzky-Taylor, 2011) toward leading to more productive behaviors, healthy emotional responses, more positive appraisals, and the relief of feelings of anxiety and depression (Dimidjian & Davis, 2009). CBT intends to encourage thinking focused on positivism and hope in how patients perceive their disease process until the end of their lives (Selene et al., 2016).

ASPECTS OF MENTAL HEALTH AND COGNITIVE BEHAVIORAL THERAPY

This section provides the important perspectives on mental health, mental illness, and technology utilization; mental health education and mental health nursing; the overview of CBT; CBT, depression, anxiety, and insomnia; CBT and OCD; and CBT and heart failure.

Important Perspectives on Mental Health, Mental Illness, and Technology Utilization

Mental health is one of the leading causes of morbidity worldwide (Fleury et al., 2012). Mental health services for children and adolescents in low-income and middle-income countries are extremely scarce and greatly limit access to the appropriate mental health care (Morris et al., 2011). In recent years, policymakers in high-income countries have placed an increasing concern on the value of maintaining good mental health toward improving the quality of life (McDaid, Knapp, & Raja, 2008). In practice, people managing mental health difficulties struggle to improve their quality of life (Kidd, Kenny, & McKinstry, 2015). Medications lessen or attempt to control the symptoms of mental illness (Bathory, 2015).

In the Western world, there is an increasing concern regarding the ability of health care professionals to meet the physical health care needs of those diagnosed with mental illness (Walker & McAndrew, 2015). Supporting both mental health and well-being is an important aspect of primary care (McKinlay et al., 2011). Public mental health deals with the promotion of mental health, the prevention of mental disorders, the reduction of mental health inequalities, and the organization of mental health service provision (Wahlbeck, 2015). Public mental health efforts are needed to raise caregiver mental health literacy in health care settings (Mendenhall & Frauenholtz, 2015).

Adolescence is the period of highest risk for the development of mental illness (Plaistow et al., 2014). The relationship between childhood maltreatment and adolescent aggression is well-documented (Hoeve et al., 2015). People with serious mental ill health suffer the excessive physical illness (Collins, Tranter, & Irvine, 2012) and have increased the rates of physical ill-health and reduced the contact with primary care services (Happell, Platania-Phung, & Scott, 2013). They often prematurely die from the common physical illnesses, such as cardiovascular disease and diabetes (Happell, Scott, & Platania-Phung, 2013).

Mental intelligence of an individual is important to all humans (Hashim, Kaur, Bahar, & Ismail, 2016). People with intellectual disability (ID) experience higher rates of major mental disorders than their non-ID peers, but in many countries have difficulty accessing the appropriate mental health services (Evans et al., 2012). A positive relationship between the mental health consultant (MHC) and early care

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and education staff is important for achieving the positive early childhood mental health consultation outcomes (Allen & Green, 2012). Infant and early childhood mental health consultation has emerged as one of the most effective strategies for supporting young children's socioemotional development (DeNatale, 2013). Mental health consultation can increase individuals' competence in specific areas related to children's socioemotional development (Heller et al., 2011).

The Internet allows mental health organizations to provide the mental health services to more people through the new models of care (Calvo et al., 2016). The rapid growth of information technology (IT), such as the Internet, smartphones, and videoconferencing, has improved the access to mindfulness therapies, which focus on enhancing individual's awareness of the present moment toward improving mental health (Krolikowski, 2013). Mobile tracking is the latest burgeoning area in the field of technology in mental health care with mobile apps, SMS protocols, and new devices used to track mood and behavior in order to improve both mental health and well-being (Kauer & Reid, 2015).

Mental Health Education and Mental Health Nursing

Education is an important approach to attracting students to the field of mental health nursing (Happell et al., 2014). Professional education and policy strategies increasingly emphasize the need for service users to be involved in the education of all nursing students, including students undertaking mental health field programs (O'Donnell & Gormley, 2013). The educational preparation of mental health nursing students in higher education must address the philosophical, conceptual, social and ethical dimensions of contemporary mental health care practice (McKie & Naysmith, 2014).

Collaboration between school-based and community-employed professionals is critical to the success of school mental health (SMH) programs (Weist et al., 2012). However, the changes to the educational preparation of the nursing workforce in mental health continue to have the profound effects on the availability of sufficient numbers of skilled graduates willing to work in this field (Happell & McAllister, 2014). Nurses working in mental health settings are placed to provide the exercise advice for people with mental illness (Stanton, Reaburn, & Happell, 2015). Accessing mental health services is a critical step toward reducing the burden of mental illness (Dardas & Simmons, 2015).

The nursing profession must have a responsibility to the global community to ensure that registered nurses are educated to meet the health challenges and the needs of the health consumer in the 21st century (Wynaden, 2010). Hamdan-Mansour et al. (2011) stated that the changes in mental health services have an impact on the practice of mental health nurses. Clinical placements in mental health are the significant preparation for undergraduate students to maximize the improvement in the positive attitudes to the care of people diagnosed with a mental illness and to mental health nursing (Happell & Platania-Phung, 2012).

Mental health nurses have a significant role in improving the physical health of people with a serious mental illness (Robson, Haddad, Gray, & Gournay, 2013). An approach focusing on reducing underinsurance for all mental health services among rural residents may help reduce the unmet mental health needs among the rural residents privately insured (Ziller, Anderson, & Coburn, 2010). Rural nurses represent the skilled mental health toward helping the capital in their local communities and providing the early mental health services in the rural communities (Wilson & Usher, 2015).

School nurses play a critical role in the provision of mental health services in the school environment and are the significant members of the coordinated student mental health team (Bohnenkamp, Stephan, & Bobo, 2015). Mental health nurses have the potential to make a significant contribution to enhancing the access to mental health care through the flexible and innovative approaches (Happell, Palmer, &

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Tennent, 2010). Mental health nurses who are older, have more clinical experiences in mental health care, and demonstrate the greater empathy expressed more positive attitudes toward people with mental illness (Hsiao, Lu, & Tsai, 2015).

Negative attitudes of mental health professionals have been identified as a major barrier to achieving the effective mental health service delivery (Byrne, Happell, Welch, & Moxham, 2013). Through recovery-focused support aimed at avoiding deteriorating physical health, mental health nurses can significantly contribute to improving the current rate of premature death experienced by people with enduring mental illness (Hardy & Thomas, 2012).

Overview of Cognitive Behavioral Therapy

Cognitive behavioral therapy (CBT) is a type of psychotherapy that helps individuals identify and teaches skills to modify the unhelpful thinking patterns, feelings, and behaviors (Eapen & Walter, 2016). CBT interventions include many behavioral interventions and incorporate various cognitive strategies toward identifying, challenging, and altering the counterproductive thoughts (Cassin et al., 2016). The individuals' cognitive processes play an essential role in the development and maintenance of their emotional and behavioral responses to them (González-Prendes & Resko, 2012). Freedland et al. (2015) indicated that CBT is effective in improving mood and reducing anxiety.

Research on process factors in psychotherapy can be divided into two perspectives: one emphasizing specific and unique factors for the specific treatment orientation, and other emphasizing trans-theoretical mechanisms, frequently termed common factors (Messer & Wampold, 2002). Researchers emphasizing the specific factors in the treatment hypothesize that the therapist's adherence to and competence in delivering treatment in accordance with the specified theoretical and technical model are important in explaining psychotherapy outcomes (Haug et al., 2016). Higher therapist competence is related to the better treatment outcomes in the CBT of depression (Kuyken & Tsivrikos, 2009).

CBT can improve the outcomes for youths with chronic pain in research trials (Kashikar-Zuck et al., 2012) and in clinical settings (Lynch-Jordan et al., 2014). CBT is of importance in the pediatric chronic pain populations given the potential risks and side effects of pharmacotherapy for pain (Cunningham et al., 2016). CBT for chronic pain typically utilized the combination of cognitive strategies (e.g., distraction, thought modification, and problem solving) and behavioral approaches (e.g., activity pacing and relaxation training) to improve the functioning and reduce the pain symptoms in youths.

Cognitive Behavioral Therapy, Depression, Anxiety, and Insomnia

CBT is viewed as the first-line treatment for both depression and anxiety disorders, as a stand-alone intervention for the mild-to-moderate cases, or in combination with pharmacological treatments for more complex cases and those with comorbidities. Depression and anxiety disorders represent two of the top five leading causes of disability worldwide and have high comorbidity rates, share many similar symptoms, features, latent structure, and vulnerability factors (Goldberg, Krueger, Andrews, & Hobbs, 2009). Tully et al. (2014) suggested that CBT may have the significant impact on alleviating the cognitive symptoms among HF patients with a depressive comorbidity.

Understanding the nature of the anxiety facets that are relevant to the delivery of CBT elements is important for two primary reasons: the identification of clinicians who will need the additional support to deliver the specific elements of the therapy and the planning of interventions to support those clini-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

cians (Farrell, Deacon, Dixon, & Lickel, 2013). The therapist competence/adherence and the working alliance have contributions to the outcome from CBT for anxiety disorders (Haug et al., 2016).

Insomnia is a common clinical condition with an annual prevalence of 10-20 percent (Buysse, 2013) and approximately 6 percent with a chronic trajectory, such as persisting for more than 3 months (Ohayon, 2002). Chronic insomnia is associated with a number of negative health outcomes (e.g., obesity and metabolic dysregulation) and increases the risk of myocardial infarction (Palagini et al., 2013), susceptibility to infections (Patel et al., 2012), and depression (Staner, 2010). Sleep-specific CBT appears to be efficacious and feasible in treating posttraumatic stress disorder (PTSD) symptoms (Ho, Chan, & Tang, 2016).

Cognitive behavioral therapy for insomnia (CBT-I) has been found efficacious in improving sleep outcomes (Okajima, Komada, & Inoue, 2011) with acute effects comparable or superior to those found for pharmacotherapy (Smith et al., 2002) and these effects have been maintained for up to 3 years. While CBT-I is desired by many patients preferring non-pharmacological approaches (Espie, Barrie, & Forgan, 2012), the challenge remains to make it accessible to meet population needs regarding the limited availability of trained therapists (Perils & Smith, 2008). The web-based CBT-I can improve insomnia severity, sleep efficiency, subjective sleep quality, wake after sleep onset, sleep onset latency, and total sleep time (Zachariae, Lyby, Ritterband, & O'Toole, 2016).

Cognitive Behavioral Therapy and Obsessive-Compulsive Disorder

Obsessive-compulsive disorder (OCD) is the highly debilitating disorder, in which many patients inadequately respond to the standard outpatient care (Dowling et al., 2016). CBT, consisting of exposure and response prevention (EX/RP), remains the most prominent psychological treatment for OCD with substantial empirical support (Abramowitz, Taylor, & McKay, 2009). Specialized EX/RP alone, or in combination with serotonin reuptake inhibitors (SRIs), can be equally effective for improving OCD symptoms (Foa et al., 2005), and is more effective than placebo, stress management training (SMT), antidepressant monotherapy (Simpson et al., 2008), or antipsychotic augmentation (Simpson et al., 2013).

Patient scan experience the significant improvements to OCD symptoms and psycho-social functioning with large effect sizes (Veale et al., 2016). Knopp et al. (2013) indicated that while factors associated with treatment outcomes within these settings are highly varied, OCD symptom severity, marital status, hoarding pathology, and alcohol misuse are recognized as the predictors (Veale et al., 2016). The intensive doses of EX/RP serve as an opportunity to address the previous difficulties and optimize the response to CBT (Dowling et al., 2016).

Cognitive Behavioral Therapy and Heart Failure

The diagnosis and complications associated with heart failure have been well-established to adversely impact an individual's physical and psychosocial well-being, and interventions (e.g., CBT) have demonstrated positive benefits among patients with HF (Cajanding, 2016). Heart failure significantly impacts an individual's physical and emotional functioning (Burke, Jones, Ho, & Bekelman, 2014), increases psychological distress and negatively affects mood (Moser et al., 2010), disrupts psychosocial adjustment (Carels et al., 2004), and leads to the significant impairment in an individual's quality of life (Samartzis, Dimopoulos, Tziongourou, & Nanas, 2013).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cardiac rehabilitation and disease management programs appear to be useful in improving the functional capacity, exercise tolerance, quality of life, and mortality among patients with heart failure (Austin, Williams, Ross, & Hutchison 2008). Cardiac rehabilitation programs targeting psychosocial factors in the form of CBT has been previously shown to improve the outcomes among patients with cardiovascular diseases, including those with coronary heart diseases (Gulliksson et al., 2011) and heart failure (Freedland et al., 2015).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of mental health and CBT will provide the potential opportunities for future research. Health information technology (health IT) makes it possible for health care providers to better manage patient care through the secure use and sharing of health information (Kasemsap, 2017a). Health literacy is about how patients understand health information about health and health care, and how they apply that health information to their daily lives, utilize it to make health-related decisions, and act on it (Kasemsap, 2017b). Health professionals must commit to promoting for improved health literacy in health care organizations and should establish the specific health care goals toward improving health literacy in strategic plans, performance plans, programs, and educational initiatives (Kasemsap, 2017c). Critical thinking is the unbiased examination of assumptions underlying current beliefs to assess their correctness and legitimacy, and thus to validate or invalidate the beliefs (Kasemsap, 2017d). Problem solving is the process of working through the details of a problem to reach a solution (Kasemsap, 2017e). An examination of linkages among mental health, CBT, health IT, health literacy, critical thinking, and problem solving would seem to be viable for future research efforts.

Neuroscience is the field of study encompassing the various scientific disciplines dealing with the structure, development, function, chemistry, pharmacology, and pathology of the nervous system (Kasemsap, 2017f). Cognitive neuroscience is the study of higher cognitive functions in humans and its neural foundations (Kasemsap, 2017g). Considering the associations among mental health, CBT, neuroscience, and cognitive neuroscience should be further studied.

CONCLUSION

This chapter explained the important perspectives on mental health, mental illness, and technology utilization; mental health education and mental health nursing; the overview of CBT; CBT, depression, anxiety, and insomnia; CBT and OCD; and CBT and heart failure. Mental health strengthens the individuals' ability to have healthy relationships; make good life choices; maintain physical health and well-being; handle the natural ups and downs of life; and grow toward individuals' potential. Mental health is associated with higher productivity, better performance, more consistent work attendance, and fewer workplace accidents. Employers can strengthen and safeguard their businesses by choosing employee health plans with strong mental health benefits.

CBT is a goal-oriented psychotherapy treatment that takes a practical approach to problem-solving skills. Its goal is to change patterns of thinking or behavior that are behind people's difficulties, and so change the way they feel. CBT involves recognizing the unhelpful or destructive patterns of thinking and reacting, thus modifying or replacing these patterns with more realistic or helpful ones. CBT works

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

by changing people's attitudes and their behavior by focusing on the thoughts, images, beliefs, and attitudes that are held and how these processes relate to the way a person behaves, as a way of dealing with emotional problems. During CBT, patients learn the specific skills that they can use for the rest of their lives. These skills involve identifying distorted thinking, modifying beliefs, relating to others in different ways, and changing behaviors.

KEY TERMS AND DEFINITIONS

Anxiety: The uncomfortable feeling of worry about something that is happening or might happen in the future.

Behavior: The response of an individual or group to an action, environment, person, or stimulus.

Cognition: The utilization of conscious mental processes.

Cognitive Behavioral Therapy: The treatment for individuals suffering from mental illness that tries to change the way they think and behave.

Depression: The state of feeling very unhappy and without hope for the future.

Insomnia: The condition of being unable to sleep, over a period of time.

Mental Health: The condition of individuals' mind and whether or not they are suffering from any mental illness.

Mental Illness: The illness that affects the individuals' mind.

Therapy: The treatment that helps individuals feel better and grow stronger, especially after an illness.

ABSTRACT

Mental wellbeing was the centerpiece of the Indian system of medicine. Many healthcare issues are resolved by the peace of mind and brain stimulating processes. Of late, Government of India adopted many systems of medicines that are complementary to the modern allopathic medicines and named it AYUSH system of medicine. In this Ayurveda, Yoga, Homoeopathy, Siddha, Unani, Swa-rigppa, and additional healing systems are represented. There is also a great need for psychological wellbeing due to the rapid increase in stressful life situations. The current modern medical care is not adequate to provide mental health services in the society. At the same time, many indigenous and AYUSH system have come into action and solve the problem the best way it possible. The chapter focuses on the role of AYUSH system in catering to mental wellbeing in India. The policies of the government of India are to promote mental health and wellbeing in society. The specialties of various systems of medicine in curing the mental health conditions have been elaborated.

BACKGROUND

The AYUSH services are used by Indian population very widely over a period of time. The Care and cure is assured in many aspects of healthy life in the population which otherwise deprived from the modern biomedical system of medicine. The modern biomedical system of care is very costly and difficulty to reach by masses in India. The faith of people is always with the AYUSH system of medicine due to its services in millennia of Indian culture and society. The AYUSH services are always targeted in a holistic manner and there is less barriers to access by the people for the services. The Indian system of medicine

look at various mental health ailments with harmony in the system which causes less side effects and cure for many diseases. The body and mind are taken as a whole while prescribing medicines in most of the cases. So, there would be cure at mental level.

The World Health Organization defined traditional medicine as the combination of the knowledge, skills, and practices based particularly on the theories, beliefs, and experiences which are indigenous to different cultures irrespective of explicable or not, and helping in management of health, prevention, diagnosis, improvement or treatment of both physical and mental illness (World Health Organization, 2000). The use of traditional medicine in various mental ailments is widely practiced in the world for the benefit of the patients. In India different system of traditional medicines were in use since ancient times with proven results for cure and prevention of mental health ailments. The traditional medicine services were usually accessible to the members of the society widely across time. So, these are the first line of treatment for the community even in unorganized community for mental health services. Moreover, the social and cultural cohesion among members of the society help in dealing with many issues of mental health in the community itself instead of modern day hospital facility which help in recovery of many mental health conditions.

The therapeutic cure of each system of medicine is also well documented by the practitioners of the respective particular system. Many of the practitioners receive training in informal way without going to formal training in the designated institutes in ancient time. The knowledge also transmitted from one generation to other very first in the informal way of training and capacity building by proper handholding. Many of the knowledge are tacit in nature and can be learn by close observation and treatment by the healers. Latter on with the help of codified ancient knowledge many things transmitted easily through generations. These treatment procedures are also many a time evidence based and the method to capture evidence is quite different from the modern laid down guidelines.

Latter on with the trust of the people and requirement of alternative system or complementary system governments start adopting these methods in the system of common public services. It has been found that there is also need of curative system for all mental health ailments. Whereas, the modern system has limited medication for limited mental health ailments. Which necessitates the requirement of alternative system of medicines to provide full coverage for wide rang mental health conditions. At this juncture, the alternative systems comes into picture with their age old curative actions which thy otherwise practiced in the process of cure along with winning the trust of the community.

A large number of people take alternative medicines exclusively or along with the modern biomedicine for many acceptable reasons like faith and cultural acceptability, low cost, and firm belief on the systems of medicine. Moreover, India have starkly very low number of specialists available in the field of psychiatric which provide systematic modern biomedicines for cure of mental health cases (Thirthalli, J., Zhou, L., Kumar, K., Gao, J., Vaid, H., Liu, H., ... & Nichter, M. (2016).

Methodology

This study reviewed various types of reports like existing policies of AYUSH, various guidelines of AYUSH services implementation, and reports of AYUSH systems of medicine in different states and central government. The literature reviewed policy and programme documents, and un-published grey literatures in the form of notes and reports at relevant sections. This is a secondary analysis to elaborate the existing policies and implementation of AYUSH services, and its' loopholes in implementation in mental health services. The opinion and experience of AYUSH care providers are also taken into con-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

sideration while treating mental health cases in the respective places. This article describes the existing policies and procedures of mental health services in hospital and community by providing AYUSH medicines in mental health. The details of efficacy of each system of medicine is explained in various sections based on evidences found in literatures directly and indirectly relating to their system. The scientific studies were taken from indexed databases like PubMed, Scopus, and Web of Sciences. The evidences were found out for various mental health ailments and explained the situation and readiness to incorporate those in the mental health programs. The philosophy of each alterative system of medicine is discusses based on the context of mental health services. Ethical approval was not required as all data are used from secondary sources. However, the opinions and arguments of implementing staffs have been gathered without harm to them.

FINDINGS

Mental Health policy in India

Mental Health policy 2014 in India has a vision for improvement of mental health conditions. The policy primarily focus on promotion of mental health care, prevent mental health illness, accelerate recovery of mental illness, and de-stigmatization of mental health conditions. Additionally, it focus on the inclusion of various socio-economic groups for the treatment of mental health. Steps are also taken for increase in accessibility and affordability of quality mental health services throughout the life of a person in the community. The important goals are reduction of distress and disability among mental health patients. The reduction of premature mortality caused by mental health need to be addressed according to the policy. A country wide campaign can be initiated for better understanding of the mental health conditions which would allow creation of awareness in the nation. The creation of stewardship and leadership are desparately needed at various level of governance like national, state, and district levels (Ministry of Health and Family Welfare, Government of India (2014).

There are various acts in India from time to time enacted for the creation of good health in the community. Among them acts and regulations like Mental Health Act-1987, National Mental Health Programme-1982, District Mental Healthcare Mode, District Mental Health Programme-1995, Persons with Disabilities Act-1995, Right to Persons with Disabilities Bill-2002, Mental Healthcare Bill-2013, National Mental Health Policy- 2014, and The Rights of Persons with Disabilities Act- 2016 played crucial roles and responsibility (Kaur, R., & Pathak, R. K. (2017).. All these acts and regulations have their own advantage and weakness in the implementation process. However, still optimal mental health services are not achieved in the community due to poor implementation and lack of adequate resources at various levels.

The policies usually consists of a set of values well organized, having principles and objectives for the improvement of improving health along with reduction of disease. (Whiteford HA, Degenhardt L, Rehm J, Baxter AJ, Ferrari AJ, Erskine HE. Charlson FJ, Norman RE, Flaxman AD, Johns N, Burstein R, Murray CJ. Vos T (2013). Whereas, a specific program is all about setting interventions with specific objective to promote the health along with prevention, treatment and rehabilitation. The program also well monitored and evaluated for further improvement and funding purpose (6. Mental health policy, plans and programmes—updated version 2 (2005) [6]. All these transformative aspects in mental health program implementation played a role for transforming the society in achieving desired targets. The vi-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

sion by the policy would lead to take strong steps in building capability of mental health through various programs in the community. Over a period of time stewardship is supposed to be there for creation of health care facilities in grass roots level.

Mental health issues including suicide considered to be serious problem globally. As usual India is the largest country for adolescent population which group need more attention for mental health. Evidences found that there preventive care can be provided by peers to the population of mental health adolescents (Roy, K., Shinde, S., Sarkar, B. K., Malik, K., Parikh, R., & Patel, V. (2019). Among the age group of 10-23 years almost 22.9% people live with years lived with disability (YLD). The problems have significant effect on the individual, their family and society at large.

Historical Development of AYUSH System in India

Ancient india have its own system of medicine deeply entrenched in the sciences of Vedas where atharva veda deals with Ayurveda and healing art for the mankind. In British India though there was many people depend on the Indian system of medicine still then very less patronage was there from the British India government. Only princely states provide some shorts of patronage that to trusted few on the provision of medical care relating to indigenous systems. However, people use indigenous medicines at their own trust and resources including mental health. The Government of India through high level committees like Bhore (1946), Mudaliar (1961), and Srivastava Committee (1975) try to reform the health care system in which additional effort were also exerted for improvement of Traditional Complementary and Alternative Medicine for the care of common people in an institutionalized manner [1-3]. Whereas, the National Health Policy (1983) envisaged a phased integration of indigenous medicine with modern medicine for both preventive and cure of various diseases at grass roots level which also include healthy living [4]. With the aim to improve the alternative systems of medicine government create a separate wing known as Department of Indian System of Medicine and Homeopathy (ISM&H) in 1995. The department latter on renamed as AYUSH for stronger emphasis in the year 2005 with more focus to cater many people in the community. In the year 2005, the National Rural Health Mission (NRHM) tried to mainstream AYUSH in many parts of the country in which a lot of AYUSH health centers were opened for the wide spread services of the population with the help of doctors, medicines, and procedures of the respective AYUSH system of medicine [5-7]. The NRHM focuses more on many non-communicable diseases to be cured at AYUSH centers in the county which also focus on mental health. Mental Health conditions are a serious concern at the grass roots level where availability of psychiatrist is highly constrained. However, in 2014 the real change happen when Ministry of AYUSH was established to independently take decisions without much consultation with the ministry of Health and Family Welfare for the propagation of alternate medical systems. The ministry have additional work of stressing on medical education, quality control, drug standardization, and research and development for the wider dissemination of services [8].

Further, the National Health Policy 2017 (NHP-2017) focused more on independent functioning of AYUSH centers in the county for wide rang e of services along with challenging disease conditions which are otherwise difficult to cure in the current biomedical systems. The NHP-2017 make targets for achieving good health including mental and spiritual health among the population within a time fram. It also make provision of funds for functioning of various programs in india with a defined target and time line.

Role of AYUSH System in Mental Health in India

AYUSH system played an important role in serving mental health cases at various level. This is palpable from the trust of the community and evidences gathered by various scientists and clinicians or healers. There is also an ongoing process of evolution of the treatment procedures in alternative system of medicines along with proved and established processes. All the evidences are documented in ancient scripture, and ethnographic evidences in the community. Though clinical trial and many other systemic issues are still exists in gathering evidences, still many aspects in bits and pieces are already proved in the system. AYUSH system is recognized by World Health Organization for cure of many diseases. Indian government also recognize the AYUSH system as a proper interventions for various health conditions including mental health specialization. Various research wings of AYUSH ministry like Central Council for Research in Homoeopaty (CCRH), and Central Council for Indian Medicine (CCIM) invest in conducting research in mental health to address the steepening issues in mental health in India. Further, a lot of investment happen in provision of manpower, medicines and hard infrastructure in provision of mental health services to patients in public health services.

Ayurveda

Ayurveda has its origin in Vedas more than 5000 years ago dealing with art of healing. It classify Tridosha (ie, three bioforces, vata, pitta, and kapha) which is embedded in the theory of humor in the body for maintenance of healthy life. Medications usually involves natural substances, special diets regimen, purification rituals, and some surgical procedures for cure. Mental health uses many of these procedures for prevention and cure in the society by adopting various prosedures (Thirthalli, J., Zhou, L., Kumar, K., Gao, J., Vaid, H., Liu, H., ... & Nichter, M. (2016).

Mental illness and mental health found in Indian texts like the Atharva Veda and other Vedic texts along with traditional system of medicines of Siddha, Unani, and Ayurveda where the detailed explanation is found on mental health and disorders. Latter on the mental hospital found ‘chemical revolution’ in psychiatric management which is a measure departure from the existing treatment of mental conditions especially in early part of nineteenth century (Sundaram, S.K., Kumar, S. (2018). Ayurveda stil played a big role in management of mental health in India by catering to masses despite the presence of modern-day psychiatric in different hospitals.

Studies shows that there is link of gastrointestinal system and mental health in Ayurveda which is also linked with depression. These age old findings also corroborate with the modern biomedical concept of health. Major Depressive Disorder (MDD) is associated with gut dys-regulation which ultimately linked with mental health (Steer, E. (2019). So, when treatment of mental conditions are taken into condition the entire gastrointestinal system is given importance in addition to preventive care.

The control of various dermatological diseases according to ancient medicine systems (e.g. Ayurveda, Yoga, and Unani) are practice of meditation, exercises, and related practices. The branch of psychodermatology takes care of many dermatological problems by keeping the mind healthy. The integrated approach to skin disease involves taking care of mind, skin and psychological stress (Shenoi, S. D., & Prabhu, S. S. (2018). Thias care and cure is very evidenced from the scientific data and have good impact on the health care system.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Ayurvedic psychiatry help a lot in treatment of many diseases relating to psycho-social concern. It also supplement allopathic and vernacular concerns it high degree of pragmatism (Lang, C. (2018). So, mental health concerns are addressed in the course of time in various branches of traditional medicines to get cure. The specialized branches of Ayurveda have fair dealings with the emerging concerns.

An six day intensive program having holistic instruction and experience in the sphere of mind-body practices usually develop to a remarkable and sustained shift in the overall perception of self-awareness which is part of favorable well-being (Mills, P. J., Peterson, C. T., Pung, M. A., Patel, S., Weiss, L., Wilson, K. L., ... & Chopra, D. (2018). All these proven evidences shows that the Ayurveda have propor regimen for the treatment of the diseases of mental health origin. The systems also help in achieving many aspects of the diseases as an early response.

Neuropsychiatric and neurodegenerative disorders like Alzheimer's disease, Parkinson's disease, schizophrenia, epilepsy, depression and anxiety are posing serious concerns in the society. Whereas, Ayurveda is having solution for treatment along with various nootropic herbs having multiple bioactivities in different disorders. Scattered information is available pertaining to traditional Ayurvedic remedial options for various mental disorders (Sharma, R., Kabra, A., Rao, M. M., & Prajapati, P. K. (2018). Ayurvada helps in cure of many diseases of old age and related to mental health with sharp menthod of treatment in the system. There is also holistic approach for care and cure which is evident from the system of medicine.

Siddha

The Siddha system is contemporary of Ayurveda and mostly flourished in south India. Many of the procedures relating to practice of medicine is similar to the ancient Ayurveda and mostly found in Tamil literature. So, the diagnostic and treatment follows concepts of mind for cure. Siddha help in care and cure of largely south Indian people with the treatments mostly aligned with herbal systems of medicine. The Indian systems of medicine mostly take care of many aspects of care among the mental health patients which is evident from the studies. There are established methods for cure of mental health diseases and certified by the concerned board for the cure of patients. The contribution of Siddha as a system of medicine towards the care and cure of mental health cases is immense. People of certain region also impose faith on the methods of cure without having any detrimental effects.

Yoga

Yoga embodies the unification of a person's consciousness with universal consciousness for achievement of goal of life with a healthy living. There is absolutely no intervention of pharmaceutical regimen for the health of a person. Rather various postures (Asanas), breathing control mechanisms (Pranayama), and Meditation procedures (Dhyana) are adopted as practices to get cure or maintenance of health (Thirthalli, J., Zhou, L., Kumar, K., Gao, J., Vaid, H., Liu, H., ... & Nichter, M. (2016). There are many findings confirm the cure or relative wellbeing of patients by practice of Yoga in different cases and particularly mental health cases.

A therapeutic review of Neti kriya confirm that many disease conditions relating body and mind were cured and especially help in many disease of respiratory tract. Jala neti (Nasal water irrigation) help in enhancing presence of mind, intelligence and improve vision (Meera, S., Rani, M. V., Sreedhar, C., & Robin, D. T. (2019). All these aspects help in mental wellbeing of a person in different situations. Energy

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

is gatyered by practicing Yoga which is very useful in maintenance of health for long period of time in the case of human being. Yoga is not just practices in India but also spread in the entire globe for the benefit of the people in various countries. The mental health remain good among the Yoga practicing people.

In United States of America practice of Yoga practices with special focus on mindfulness helps in safe and effective intervention for paediatric groups. Evidence also found that yoga can control mental health issues among the adolescent populations (Stephens, I. (2019). All these achievements of yogic practice help in solving many issues of Adolescent groups.

Laughter Yoga (LY) is found to be useful for cure of symptoms of depression within short term period. The LY also help in reduction of residual mood, anxiety and stress symptoms among adults. The LY can be used as a method to reduce depression and improve quality of life (Bressington, D., Mui, J., Yu, C., Leung, S. F., Cheung, K., Wu, C. S. T., ... & Chien, W. T. (2019). The form of Yoga may differ but the effects are always found to be positive if practiced in life for improvement of mental health.

The Mind-body exercises in the form of Yoga offer good cure for the rheumatoid arthritis (RA) patients which leads to improvement of both physical and mental health. In adult worker participating in Yoga have better physical function and mental health can be created by the practice (Greysen, H. M., Hong, O. S., & Katz, P. (2019).

The Yoga is becoming a popular approach for the improvement of the quality of life (QoL) among women with breast cancer as a supplementary care practice in addition to the modern medicine. A meta-analysis was done to assess yoga-specific effects relative to other physical exercise intervention (eg, aerobics) with breast cancer. The study found that yoga is effective as other exercise interventions in improving the QoL of women (El-Hashimi, D., & Gorey, K. M. (2019). The quality of life can be improved even among the patients with critical conditions by practice of Yoga. These thighs are now ad days very popular in different hospitals as additional methods of care due to efficacy.

A study has been conducted among the patients with chronic hemodialysis those suffer from an increased cardiovascular disease, deconditioning, fatigue, sleep disturbances, anxiety and depression, and decreased health related quality of life. Here Yoga is reported to have positive effects over distress and functional performance among the chronic diseases. Interestingly Yoga help in improvement in quality of life, reducing pain, reducing fatigue, solving sleep disturbance, and improving physical functions (Kauric-Klein, Z. (2018). Overall yoga found to be a complementary methods of treatment for the people having many diseases. Mental health and Yoga help in improvement of the system to a great extent.

Naturopathy

The very science of naturopathy advocates for effective use of five fundamental materials like earth, water, fire, air, and ether (space). There is strong advocate of use of these concepts both internally and externally and requirement of changing lifestyle and diet for cure. Pharmacological medications are not advocated for use and practice of spirituality is highly encouraged. Naturopathy provide a scope for going natural. Our system always finds a natural concept to remain healthy both physically and mentally. There are trainers suggests how to go natural way of life. For cure of many ailments. The nature provides many methods without biomedicine for care and cure in the society. The natural processes are always helping in many aspects of human being for the care and cure.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Homoeopathy

Homoeopahy as a system put primacy on mental symptoms for cure and care. Many diseases show mental symptom due to various reasons and can be cured by interventions of medications having cure for mental diseases. The mental symptoms guide a lot to achieve cure in different form in homoepathy. The usual mental conditions like hallucination, depression, illusion, outburst, excessive happiness or sorrow, craving for something, headstrong etc. are some of the important conditions for interventions by homoeopatic drugs.

Contrary to the biomedical model of health homoeopathy considers entire body in a holistic manner and provide services in a broader view with much responsibility. Homoeopathy takes care of the physical, mental and emotional aspects of people for cure. Whereas, other alternative practices like yoga, hypnotherapy and meditation put primacy on 'functional' spiritual practices in which the responsibility in fixed on the person for individual care (Bell, F. (2000).

Evidences found that homoeopatic drugs improve 'sensation of well-being', and support the working of ultra-high dilution effects which otherwise cannot be proved by the existing laboratory methods (Kuzeff, R. M. (1998).

A study found that the sleep disorders among alcoholic is reduced by taking homoeopathic medicines. The homoeopathy treatment can be used to help clients in breaking the cycle of alcohol dependence (Rogers, J. (1997). There are many more diseases can be cured by the method of homoeopathy especially of mental diseases for complete cure. This is trusted methods of treatment in hundreds of countries for the treatment of several diseases. Today the diseases have different concerns for cure and homoeopathy help in many of cases.

Unani

Unani methods way back to the practice of medicines and teaching of Hippocrates and Galen in medicine which is also known as Greco-Arabic (Unan means Greece) medicine.

Though it is established in the Middle Age with the patronage of Arabian and Persian kingdoms and their doctor, but latter on Mughals make it their court medical system with sufficient patronage. So, it become a part of Indian medicine and people adopt it with enormous faith. Unani system of medicine based on the idea of various humours like blood components, phlegm, and both yellow and black bile. It usually adopt similar process like regimental therapeutic procedures, special diets regimen, medicines from available herbs and surgery (Thirthalli, J., Zhou, L., Kumar, K., Gao, J., Vaid, H., Liu, H., ... & Nichter, M. (2016).

The Unani medicine is very ancient and tested by Greek civilization almost 2500 years ago. The Unani medicine aims for near no disease condition in leading a healthy life. The Unani medicine advocate clean and fresh water, clean air and consumption of fresh food for maintenance of disease free life. There is also requirement of maintenance of balance on body and mind for metabolic activity to maintain the evacuation of wastes. The system of medicine largely advocate for promoting health, preventing disease and achieving cure through various regiments and diet therapies (Lone, A. H., Ahmad, T., Anwar, M., Sofi, G., Imam, H., & Habib, S. (2012).

In medicine systems like Ayurveda, Unani, or Chinese traditional medicine the imbalance of different 'elements' and factors for disease are important. Rectification of those imbalances pave the way to cure (Bhuiyan, P., Khatun, Z., Jahan, S., Morshed, T., Rahman, S., Afsana, N. A., ... & Rahmatullah, M. (2013).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is lack of treatment of patients due to various causes in psychotherapy. Whereas, almost four-fifth of population of India in one way or other depend on Ayurvedic and Unani systems of medicine along with religious treatments consisting of prayers, fasting and various witchcraft and magical rituals (Bagadia, V.N., Shah, L.P., Pradhan, P.V., Gada, M.T. (1979). The faith of Indian people is obvious for the systems of medicines. The cure and care is beyond doubt for mental health conditions.

Malankholia (Melancholia) a condition having mental health concerns like constant grief, fear and dubious aggression is cured by Unani medicines and regimen. This has been well explained in ancient book of "Kitab Al-Havi." The detailed management of diagnosis and treatment of melancholia has been described in the Unani system of medicine by this the suffering of humanity can be mitigated to a great extent (Ahmed, N. Z., Alam, A., Khalid, M., Sheeraz, M., & Qamri, M. A. (2015). Many mental health conditions are well explained in the treaties for cur eof mental health conditions.

Sowa-Rigpa

Sowa-Rigpa is a method of cure well known as the science of healing and otherwise called Amchi medicine. It's also well known as Tibetan medicine which is recognized by government of India for its efficacious cure and provision of services to a section of Indian society. The system of medicine is practiced mostly in Himalayan region by both Tibetan and Indian people especially by tribal and Bhot people. This system adopts many nuances of Ayurveda by adopting predominantly the pharmacological (herbal) interventions (Thirthalli, J., Zhou, L., Kumar, K., Gao, J., Vaid, H., Liu, H., ... & Nichter, M. (2016). There are many codified method of cure for mental health conditions.

The policies of the government of India are to promote mental health and wellbeing in society is discussed thoroughly.

The specialties of various systems of medicine in curing the mental health conditions have been elaborated.

Chapter 28
Answering the Call for School-Based Mental Health:
Culturally Competent Intervention and Support

Maxine Blanche Langdon Starr
Sunflower Therapies, USA

ABSTRACT

A largely unmet need exists for school-based mental health services by students who are of an ethnic minority and who may not have insurance, access, and/or the knowledge of mental health services. These same students may not receive effective, culturally sensitive counseling services, interventions, or valid/accurate measures of psychological testing. In order to resonate and connect with these students who need the most help and support despite these barriers to accessing quality treatment, what is the school-based mental health provider to do? This chapter will initially discuss a comprehensive review of culturally competent interventions for school-based mental health providers as well as recommendations for culturally competent training for mental health providers and school staff to ensure that culturally competent collaboration and appropriate support exists for all students.

INTRODUCTION

It has been well documented that students who are receiving education in 21st century schools are facing an incredible number of social emotional stressors; including but not limited to: Poverty, violence, harassment, substance abuse, depression, anxiety, and difficulty in their family relationships. It has been estimated that 20% of students have a diagnosable psychiatric disorder, but less than one quarter of these students are receiving any sort of specialty mental health services; most of which the school provides. For example, in California as of 2010 and the introduction of AB 2632, which shifted the responsibilities of providing school mental health services from county agencies to schools, required that the burden of responsibility fell upon school districts to ensure proper support was met for the social and emotional

needs of their students (Beam, Brady, & Sopp, 2013). However, the method and determination of who (i.e., if it is the responsibility of school counselors, school mental health providers, school psychologists, and/or licensed marriage and family therapists or social workers) is to provide these services is still largely up to the school district's discretion. The following section will separate some key distinctions of the professionals who provide counseling services within the schools, whose roles and titles will be used interchangeably throughout this chapter, who are often recruited to provide such services (this may change by state; examples given are mainly within California):

- **School Counselors:** Typically hold graduate degrees and a credential. Trained in various counseling techniques, often with an emphasis in academic and career/vocational counseling.
- **Marriage and Family Therapists:** Typically hold graduate degrees and a license in the respective state(s) they practice within. Trained in various counseling techniques, often with an emphasis on working with the family system.
- **School Psychologists:** Typically hold graduate degrees and may hold an additional license as Educational Psychologists. Trained in various counseling techniques, often with an emphasis on psychoeducational testing.
- **School Social Workers:** Typically hold graduate degrees and a license in the respective state(s) they practice within. Trained in various counseling techniques, often with an emphasis on working within organizations (e.g., hospitals; clinics) utilizing the appropriate community resources to assist their clients.

A greater unmet need for these mental health services exists for students who are of an ethnic minority and who may not have insurance, access, and/or the knowledge of mental health services. Additionally, these same students may not receive effective, culturally sensitive counseling services, interventions, or valid/accurate measures of psychological testing (Dana, 2007). Researchers have pointed out that there are few studies which have looked specifically at racial and ethnic disparities in mental health; and: "Racial and economic minorities are at elevated risk of persistent mental disorders into adulthood, even though they demonstrate similar or lower prevalence rates in adolescence" (Alegria, Green, McLaughlin, & Loder (2015, p.1).

KEEP IN MIND: THE HISTORY OF COUNSELING

School personnel need to remember the history of counseling in general, specifically where at the outset, upper class Caucasian males were offered privilege not known to other ethnic groups to receive what we currently refer to as mental health treatment. Counseling in and of itself often carries the assumption that professionals are offering what is seen as normative, ideal behavior or adherence to a uniform idea of what is considered less desirable or pathological. The Western world seems to be addicted to the idea of measuring, quantifying, sorting, and logically organizing. The ideas cast into the shadows of our society appear to be disorganization, chaos, qualifying, or acceptance of the unknown. Of course, both ways of perceiving the world—as rational and irrational as well as logical and illogical—are necessary; the question seems to be, why can we not have both? (Goodchild, 2012; Starr, 2015).

Researchers Constantine & Sue (2005) add, "Historically in psychology, the perspectives of racial, ethnic, cultural, and sexual minorities have been marginalized or ignored in mainstream theoretical and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

empirical work" (p. 39). This may be in part due to the premise that study of psychology is seen in large part from the Western perspective as an evidence-based, logical science that measures human behavior. Author Laungani (2002) argued, "By denying and denigrating the contributions of philosophy, religion, art, literature, all of which go toward constituting a culture, a psychology was created that was sterile and fragmented" (p. 389).

Questions for professionals within the discipline of psychology to consider include:

- Can behavior really be operationalized, observed, measured, manipulated?
- Can we understand the true nature of the soul with this perspective?
- Are we taking into account the self that we present to the world and our inner selves that we remain private?

Certainly psychology also needs to take into account its own shadow material and what cannot be seen or measured (Starr, 2015). Additionally, Laungani (2002) pointed out that historically, many premises and assumptions about individuals from a supposed cultural background that have been made about other cultures were not even witnessed by the authors who did not go so far as to even physically travel to the countries about which they were writing. This is certainly a testament that school counseling professionals should not be using the positions of making wide generalizations or assumptions from which to counsel students. There is another example from the literature where a community resource worker referred a Chinese family who had recently relocated to the United States to a Buddhist temple so that they could experience a sense of belonging outside of the school they were attending; without realizing that the family actively practiced Christianity (Ingraham, 2000).

Upon reflection, a student working in school mental health provided some insight into her experience working with students from a culture different than her own:

I used to think, 'Why is there a Black History month? There isn't a White History month.' Now I see that every day, every month is White History something…Now, I make sure to speak up in school meetings about White privilege…Now, I include issues of privilege and oppression in my case notes and write-ups. (Singh, 2010, p. 560).

In Westernized societies, this same tradition where principles of individuality and independence are often emphasized as positives; whereas reliance on the collective, and also members of the person's support group, is often underemphasized (Hobson & Kanitz, 1996).

The construct of what exactly defines student success within the schools have been defined historically from a male, Caucasian perspective (Fraise & Brooks, 2015). A school based example can be seen where a high school track coach complained about a student from a Native American background who would never finish a race without letting the other students catch up to him so that they could all finish the race at the same time. The coach did not see that the teen valued collectivism over individualism (Herring & Runion, 1994).

Various cultures may have different interpretations of how to resolve conflicts, attitudes towards whom and how much to disclose in counseling, and approaches to knowledge. In Western society, conflicts are seen as least desirable, but the resolution to conflict is often discussing the conflicts face to face – as in, but not limited to, counseling. However, in places such as Micronesia, open conflict is viewed as demeaning and inappropriate.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In Western society, it is somewhat common to reveal personal information and one's feelings, whereas in other cultures, it may not be commonplace or even seen as appropriate (Uehara, 2005). In European cultures, information that can be measured is seen as more valid than ways of learning through oral tradition, as is commonplace in many countries outside of Europe and the United States (Uehara, 2005).

Additionally, it should be taken into account that the interpersonal practice of counseling: "Provokes a range of dynamics given the nation's sociopolitical reality. People, the counselor and the [student] come together in a sociopolitical reality to address any number of life-impacting dilemmas or issues" (Arredondo, 1999, p. 103). Therefore, it is imperative that counselors also partake in non-counseling based interactions, such as community events, celebrations, groups, and clubs to facilitate their perspective of minorities as being less of an exercise, and more inclusive (Arredondo, 1995).

Counselors can advocate for systemic change, if needed, in order for students to interact collaboratively towards a common goal without barriers. For example, students should be able to all participate in after school activities and the school can come together as a whole to ensure that access to uniforms and transportation is a possibility for any student who wants to participate. Counselors can also encourage intergroup friendships to increase meaningful relationships between students on campus, reduce prejudice, and dismantle socially constructed barriers of race, ethnicity, and culture. In turn, this can help to reduce bullying and violence and create a more positive school climate (Pica-Smith & Poynton, 2015).

Consider the History of Education

Just as school counseling staff will have to remember some lessons about the history of psychology, they will also have to remember the history of education and how this juxtaposes with their duties as helping professionals working within the context of schools. Many students from cultural backgrounds other than White were historically denied access to education. Languages other than English were not allowed or taught in schools. Assimilation was forced, diversity was not tolerated, and monolingualism was encouraged (Noltemeyer, Mujic, & McLoughlin, 2012).

Similarly, the concept of emotions was not considered to fit into the paradigm of learning as it was conceptualized by school administrators; just as many Eastern theories of healing were left out of what is currently referred to as Westernized helping perspectives. Specifically with regard to emotions, which are at the cornerstone of most counseling theories and interventions, the helping professional must remember that emotions have historically not had a place within the educational framework. Research highlighted by Coss (2013) has pointed out:

Emotions are of paramount importance in students' reflections on beliefs, norms, values, and assumptions of their own culture, though they have been traditionally omitted from education for sustainability frameworks. (p.21).

Perhaps there is a fear that exists about emotions not being measureable, or controllable, so this fueled the motivation to prevent them from becoming an integral part of the discussion, but it is our job as counselors and mental health professionals to bring about what is not being attended to. We have the difficult job because it is our duty to partake in and often begin conversations that are often viewed as difficult.

Further Cultural Considerations

School professionals will need to be sensitive to the issue that perhaps neither individualism nor collectivism should be viewed as superior to one another, and utilize caution that they are not favoring one principle over another in their relative counseling approaches and treatment of students and their families. Many Western schools take pride in promoting individual achievements and may not promote enough exposure to collectivistic rituals. School professionals should keep in mind that many parents of students who come from diverse backgrounds have viewed school as "a very unwelcoming place. Work will be needed to ensure that a warm and open environment is created" (Suzuki, Alexander, Lin & Duffy, 2006, p. 436).

Some ideas for schools to incorporate a more welcoming environment include involving outside community spiritual leaders and healers (e.g., clergy, rabbis, local curanderos), oral history traditions, cultural exchange programs, and/or cooperative learning (Ponterotto, Mendelowitz, & Collabolletta, 2008). Professionals should strive to assess a student's presentation in various contexts; including but not limited to: Generational history, English-language fluency, acculturative stress, social economic status, and sexual orientation so that, "They can understand the subjective world of the [student] and eliminate the potential of personalizing societal and institutional problems; e.g., blaming the victim" (Constantine & Sue, 2005, p. 42). Families may also need to be given explicit knowledge about the school (e.g., culture, expectations, methods to access services, strategies to develop successful relationships with school personnel, and ways to support their child's learning) (Ingraham, 2000). Researchers Gerstein, Rountree, & Oronez (2007) pointed out that professionals should balance the interrelationships and totality of the multiple levels of a student's experience at the individual, group, and universal level; as well as within the contexts of that experience (i.e., individual, family, and cultural).

School counseling staff need to keep in mind that students from lower social economic backgrounds and/or diverse backgrounds may not have access or awareness to the same technology or other resources as their classmates and offer resources to assist them as needed (Hughey, 2011). They need to consider the impact of the media, and specifically technology – including the Internet, television, and social media as influences upon what dominant messages or mainstream cultural norms are being stressed to students, which undoubtedly have an impact on the behavior and attitudes of students (Uehara, 2005). They will also need to consider the relative influence of parents, authority figures, and peers on student's perceptions, emotions, and behaviors (Starr, 2015).

Counselors can collaborate with teachers and have students write reflections upon viewing movies or video clips to expand their awareness about different cultures. Questions for reflection may include:

- *Where do these people live and how are their homes similar and different from yours?"*
- *Would it be easy to get to know and make friends with people your age who come from this group?*
- *What would make it difficult to get to know and make friends with students about your age from this group?*

Counselors can also collaborate with teachers about ways that a particular classroom might be able to adopt another classroom from a different country and digitally exchange information about important public figures, holidays, events, family and classroom life from each culture (D'Andrea, 1995). Counselors can encourage teachers and staff to talk openly about students' lives and experiences and incorporate discussions around difference, culture, and race rather than ignoring them (Ullicci, 2009).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Research has also shown that students from diverse backgrounds with differing learning abilities who actively engage in cooperative, small group learning activities tend to foster more positive attitudes towards teachers and other students, improve race relationships, and support relationships of students with disabilities, including emotional and behavioral disorders. It is also helpful for students to engage within organizational structures such as school council committees and to be involved with the school's decision-making process. This can also foster greater connectedness within the relationships that students have with school staff (Rowe, Stewart, & Patterson, 2007).

Power Dynamics in Counseling

There is also the issue of the power differential as it relates to the counseling process. Depending upon various influences, including the theory or approach the counselor subscribes to practicing as well as the counselor's background that also plays a part in how much power or influence they have over a session (Ingraham, 2000). The special rights, privileges, and/or advantages some people may receive as a result of belonging to certain racial, gender, or social groups as well as the relationship of privilege to power and oppression are important concepts for counselors to be aware of and teach to their fellow staff and inform their work with students (Patrick & Connolly, 2009). DeVaris (1994) provided the following recommendation for helping professionals [note that use of the word 'patient' can also be applicable for working with students]:

They should sensitize themselves to their own power issues by exploring the roots of their own sense of helplessness and powerlessness to ensure that they are not acting out unresolved power needs in their treatment relationships…They should examine their treatment strategies for potential sources of harm. They should explore their own personal biases and prejudices honestly and consider professional or personal activities that will challenge these assumptions…the process of effective psychotherapy gives considerable power and respect to the patient. It activates a patient's self-curative capacity and their active participation in the change process. (591-592).

The counselor's own belief system about how effective they believe they are with a multicultural population of students needs to be taken into account when it comes to effective and ethical school counseling. Researchers went so far as to introduce what they refer to as *Nice Counselor Syndrome* or *NCS*, which essentially illustrates the school counseling professional's fear to take a stance of social justice because they are, "Fearful of being disliked and can be targets of professional ostracism when they do not conform to the traditional role of being noncontroversial, nice, supportive, and friendly helpers in the school setting" (Bemak & Chung, 2008, p. 375). Counselors must also keep in mind that many cultures, such as within the Sikh community, believe that seeking help can be a sign of weakness (Singh & Singh, 2019).

Counselors may believe that they are powerless to do anything to change the status quo within their school communities, which then may lead to a combination of feelings, including but not limited to anger, guilt, anxiety, apathy, and feeling paralyzed to deal with any issues because they are seemingly larger than the role of one person at one school site. Collaboration and recognition of these feelings amongst professionals is key to processing these emotions so that school mental health professionals at all levels can feel safe to develop an attitude that what they are doing through advocacy and/or taking on social justice does indeed matter for all students (Bemak & Chung, 2008). Maintaining a strengths-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

based approach, where counselors, "Search for the assets of the school constituents and build on those assets to develop effective academic and social programs for students and families" (Galassi, Griffin & Akos, 2008, p. 178) is essential for promoting the best future outcomes. Providing written, verbal, situational (e.g., allowing the student to contribute to the situation) and/or gestural encouragement for students, keeping in mind of some students who may have sensitivity in these areas due to their culture or experiential background (Herring & Runion, 1994). For example, many African American families are noted to have cultural strengths in the areas of domestic harmony, cohesive extended family, spirituality, religion, and survival skills.

A solution-focused approach allows the person coming in for help to be the expert of their situation. This may help to stabilize the power differential that often exists within the counseling dynamic. Utilizing a strengths based approach can help decrease the stigma of mental illness and the idea that a mental illness may shame the family name, as is common within Asian and Latino cultures. An example is where Sarah, a 17 year old, was meeting with the clinician and her parents following her re-entry into school after being hospitalized on an involuntary hold. Instead of emphasizing the negative emotions or focusing on how,

…Fear of shaming the family might have negatively affected Sarah or dwelling on the complaints of the parents, the clinician emphasized the parents' positive intention of protecting Sarah from the unhelpful gossip and led the parents to notice their strengths in handling Sarah's illness by focusing on what the parents found helpful in the process (Lee, 2003, p. 391).

Additionally, researchers Harvey, Harvey, & Shera (1995) introduced the idea of *learned hopefulness*, or what they term: "The flip side of helplessness…Learning and employing problem-solving skills successfully and exerting positive control during various learning experiences leads both to a sense of actual control and to an ability to cope personally and effectively with daily events, daily stress, and daily problems" (Harvey et al., 1995, p. 43). Similarly, the hope for this chapter is that the reader is able to find helpful and applicable resources to have a starting place in order to promote an effective, evidence based, culturally informed practice for work with the students, families, and staff within the context of schools.

Best Practices for Schools

According to best practices for school counseling, there is a need to be, "Recognizing and responding to the central role of culture 'as a predominant force in shaping behaviors, values, and attitudes in schools" (Lindsey, Roberts, & Campbell Jones, 2005, p. 22). Researchers Ponterotto, Mendelowitz, & Collabolletta (2008) also provided the important reminder, "There is a growing body of research supporting the link of multicultural exposure, perspectives, and interactions to academic achievement, school connectedness, career achievement, and quality of life, particularly in adolescents and young adults" (p.98).

School based counselors need to remember that the school campus in and of itself constitutes a culture; and need to be able to reflect upon how the school culture on campus may coincide with a student's cultural background, beliefs, experiences, and values. They also need to reflect upon the role that their own culture, background, beliefs, experiences, and values (whether conscious or not) factors into how they view their school environment and the students who attend the institution. These factors all come into play when it comes to the delivery of appropriate school based mental health services, since the understanding of one's environment is crucial to being able to offer the needed assistance to a student.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

All staff who provide any type of classroom instruction and intervention should also be involved in this conversation, as "integrated lessons can assist students across curricula" (Schellenberg & Grothaus, 2011, p. 223).

Schools are the bridge when it comes to connecting parents and the larger community; therefore, mental health services and interventions should seek to also connect these larger systems together in a way that enhances cohesiveness and fosters cultural understanding (Schellenberg & Grothaus, 2011). A sense of connectedness characterized by strengthened social relationships in schools has been shown to bolster mental and emotional well-being (Rowe et al., 2007). At the large-scale level, otherwise referred to as the macrolevel, stakeholders should also consider the influence of public initiatives, politics, government perspectives, and funding for education at both the federal government and local levels that may be influencing the policy and practice of the school system (Arthur & McMahon, 2005). Schools should be aiming to enhance their social capital, which is characterized by, "Strong social bonds, high levels of interpersonal trust and norms of reciprocity" (Rowe et al., 2007, p. 528). Members of the school community have great influence over policies and procedures within the school setting; including but not limited to:

- Codes of discipline
- Standards of behavior
- Democratic systems of school governance
- Mutual respect and attitudes about how staff treat one another
- Attitudes about how the larger community may be involved within the school, and
- Attitudes adopted by staff towards parents and students.

Schools and districts must also consider the physical space of their building and classroom layout, appearance including classroom lighting, space, use of color, and functionality of spaces (Rowe et al., 2007). In contrast, actions that may be considered blatantly oppressive and contribute to unwelcoming school conditions include having access to limited educational resources, unsafe buildings, and overcrowded classrooms (Borrero, Yeh, Cruz, & Suda, 2012).

Academic and cultural contexts are often at odds with one another for youth of Color. Borerro et al. (2012) pointed out that for example, "Many African American youth believe that in order to become academically successful, they must 'become raceless' or 'act white'. Some Middle Eastern and Latino/a youth believe they have to give up their ethnic identity in place of an academic identity" (p.2).

Working Models of Culturally Competent Services

Working to understand the intersections of these principles can help all students initially to engage with the curriculum offered by the school and with their larger community, similarly to the MTSS (Multi Tiered Systems of Supports) or RTI (Response to Intervention) model, where at the first tier, all students are given access to culturally competent services in order to facilitate optimal social and emotional, and ultimately improve their ability to function academically. If the student continues to struggle despite being exposed to universal strategies, then the second level of interventions is introduced, wherein the student may participate in pull out groups or receive more intensive group level interventions. If these interventions prove to not be sufficient, the student may be referred for tertiary level interventions, which may include intensive individual strategies (Schellenberg & Grothaus, 2011). Early response is critical;

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

as the longer the student goes without intervention, the more they are at risk of failing and ultimately, these so-called "failures" (e.g., being sent to the office for discipline issues, not grasping material due to lack of sleep or access to a private sleeping area at home) may lead to decreasing their worldview that the educational system wants to help them to succeed in academics; and ultimately, at life (Heavner, 2015).

Programs have been developed to standardize and facilitate delivery in the schools in terms of their duration and content in a "one size fits all" approach, but often fail to realize the individual risk factors, cultural backgrounds, and unique needs of every student. Additionally, school based counselors and mental health providers may not be adequately meeting the needs of students if the program offered is not the right fit for their unique set of circumstances and lead to less participation in the intervention(s) offered and students potentially to dropping out of the intervention altogether. The school based practitioner may also need to reflect upon whether a student may be appropriate for a group based intervention, or if they need more individualized support.

Research has supported programs such as a SMART [Sequential Multiple Assignment Randomized Trials] design with two tracks of interventions, an initial Tier 1 intervention and two possible Tier 2 interventions. One track of the SMART design features behavioral support strategies and the other track offers socio-emotional learning [SEL] training. According to the researchers, "The SMART design is implemented in multiple stages with individuals randomized multiple times to various intervention options across stages…thereby balancing participant characteristics" (August, Piehler, & Miller, 2018, p. 89). Despite much of the current research regarding school-wide systematic tiered intervention to target students with mental health needs, there still remains work to be done in this area, as culturally and linguistically diverse students continue to be overrepresented within special education, discipline actions, and the juvenile justice system (Graves & Castro-Olivo, 2018). The interventions that are successful in an upper middle class school district with a primarily Caucasian student population may not see a similar outcome in an inner city school district with a primarily working class Latino student population. School staff should all take the aforementioned factors into account when planning mental health interventions that best suit the students they are trying to serve.

Varying Degrees of Counselor Education

Another discrepancy in emphasizing a collaborative approach when providing culturally informed best practices of mental health delivery in schools comes to understanding the gap in education between the various stakeholders both at school and within the greater community. For example, an educator takes different classes in a graduate school program than a social worker in order to become credentialed to work in the schools or in the community. The educator may know more about teaching and learning, but a social worker may hold more knowledge about whole child development and youth mental health. Even more complex is the community based mental health provider, who may measure a student's need based on current psychopathological indicators or symptoms, versus a school psychologist or school based mental health professional, who may view the severity of a student based on their ability to perform at school from an academic or social perspective. Researchers Ball, Anderson-Butcher, Mellin, & Green (2010) emphasized the importance of all stakeholders coming together and setting up systems from which all members could learn about each other's profession and gain a mutual understanding of the viewpoint of the particular culture of not only the practitioner's lens but also to develop a mutually agreeable framework about the cultures and backgrounds of the students they serve within their respective communities. Researchers Lewis, Hartwell, & Myhra (2018) point out: "Professionals need to be

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

aware of the potential for harm to marginalized clients due to implicit bias, stereotyping, and dominant social systems such as heteropatriarchy and racism" (p. 330).

All stakeholders in a child's education need to be not only taking ongoing trainings related to cultural competency (knowledge), but also need to be reflecting upon how their presence when working with students may unknowingly and unintentionally bring these biases into the interventions they provide [awareness] and then be able to apply appropriate procedures to address these disparities [skills] (Lewis et al., 2018).

Importance of Completing a Needs Assessment

Since every school district and even individual school site can vary greatly in terms of diversity and cultural need, the first course of action at any site level should be for designated members of the school staff to explore and research which cultural groups, languages, and norms are represented in their respective communities and on their individual campuses. The use of a needs assessment can be useful in this planning phase in order to identify existing services offered in comparison to materials, services, and staffing configurations that may be needed; and then in the future to address ongoing needs (Johnson, 1995). The wider lens of international relationships must also be addressed, since technology and study abroad programs make travel more possible than it ever has been, and students will need to be prepared for increased interaction with diverse groups of people in and outside of the school environment (Ponterotto et al., 2008). Approaching the needs assessment as well as examining existing counseling programs from a strengths perspective; wherein current resources are promoted from a "deficit reduction to a strengths-identification emphasis" would be imperative to effectively foster collaboration and a cohesive school community (Galassi, Griffin, & Akos, 2008, p. 180).

Importance of Collaboration

Collaboration within schools, as well as within the wider community can be helpful in order to facilitate connections where outside experts, including but not limited to parents and families, community stakeholders [e.g., outside service providers], interpreters and/or translators may be needed for meetings, gatherings, or other school activities (Klotz & Canter, 2006). Incorporating collaboration into a social justice program within a class or as a separate class where conflict mediation skills can be taught and embraced, offering parents education classes, as well as implementing an onboarding process for students who may be new to the district and the area can be important stepping stones to increased levels of belonging and diversity amongst all parties (Johnson, 1995). It may be important to set time aside to follow a process known as BID (Briefing, Interaction, and Debriefing) so that all parties are educated as to the reason(s) they are meeting together, any professional or culturally specific terminology, and sufficient time be made to follow up following the interactions so that a plan may be devised to plan the best possible outcomes (Langdon & Saenz, 2016). Incorporating family and cultural community members who have what is known as 'resonance' to the student can be helpful; in other words, that these individuals have shared similar life experiences or represent valued life experiences so that they can experience a definitional ceremony in order to form a reflecting team that can provide an authenticating experience (Bitter, Robertson, Roig, & Disqueact (2004).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The more groups, norms, and languages of a school are explicitly known once a needs assessment is completed, the greater possibility that a comprehensive district in-service or training may be helpful to train school staff in how to best work with the population which is represented in their school(s). Staff must avoid also applying blanket strategies or cookbook methods, wherein they apply the same practice to multiple individuals from a similar cultural group without considering individual differences or the student's worldview (Nastasi, 2006). They must also employ strengths based strategies where possible, so that a foundation for helping students from preschool through their high school years and beyond is established (Galassi et al., 2008). Modeling positive intercultural relationships among staff for the students can be an excellent intervention in promoting attitudes of acceptance and belonging (Buhin & Vera, 2009). Examining which lenses may be most helpful in providing assistance to various students from diverse backgrounds. Researchers Jackson, Holt, & Nelson (2005) cited four types of general helping models: The Moral model, where a person is responsible for creating and solving their problems; The Compensatory model, where a person is not responsible for creating their problems but is responsible for solving them; The Medical model, where a person is not considered to be responsible for creating their problems nor are they responsible for solving them; and the Enlightened model, where a person is considered to be responsible for creating their problems but is not responsible for solving them. For example, many Latino cultures believe in the external locus of control, or that there are problems that they are not individually responsible for, which may ultimately clash with a Westernized ideal and the Moral and/or Compensatory model of helping. The researchers also discussed the idea that the models of helping may be influenced by the social economic status of the schools in which professionals practice; e.g., "The Compensatory or Moral models would be characteristic of more affluent schools, whereas counselors working in poor schools would subscribe to the Enlightenment or Medical models" (Jackson et al., 2005, p. 208). In addition, the researchers also found that more Latino counselors endorsed the Enlightenment or Medical models, placing more external responsibility on factors outside the student's control in their study (Jackson et al., 2005). Researcher Uehara (2005) provides a social justice guidance strategy curriculum for groups spanning 13 weeks; including:

- An introduction session outlining the rules for the group,
- Students learning to introduce themselves,
- Creating self-portraits,
- Experiential activities focusing on the element of trust and emphasizing tolerance between families,
- Using bibliotherapy and reading a story centralized around the theme of tolerance and awareness,
- Bringing in community individuals to speak about their diverse experiences within the community,
- Watching videos about prejudice and discrimination,
- Listening to music that has lyrics about a topic relating to a multicultural theme,
- Participating in an experiential exercise to teach and appreciate similarities across cultures, an experiential exercise to highlight examples of discrimination and for students to relate to their own lives,
- Participating in a creativity project using hands of different fabric or drawing to illustrate friendship and diversity, and
- A closure activity (e.g., a potluck highlighting foods from various cultures) for elementary school counselors to implement at grades two through four because students may be the most impressionable in this age bracket (Uehara, 2005).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, learning about music and/or playing styles of music different to which students may be accustomed allows them the opportunity to, "Place themselves into the lived experiences of cultures distant from their own. Music serves to address cultural diversity…build intercultural relations and understandings" (Cox, 2013, p. 23).

Exercises for Developing Cultural Competence Among School Staff

Staff must recognize that developing cultural competence is considered as, "A life-long process of professional development…and reflective practice" (Nastasi, 2006, p.9) as staff must recognize that they too identify from a particular cultural background which, if not made conscious or explicit as an integral piece within the counseling process, can lead to bias when counseling the student. For example, a school counselor may think nothing of simply inviting a student's parents to a school meeting to address grades; when in fact this may be seen as an insult to the student's family if the counselor does not also invite the extended family to weigh in on the matter (Ponterotto et al., 2008). Authors Harvey, Harvey, C.M., & Shera (1995, p.45) added:

By focusing both on the natural resources of the [student] and on a natural partnership for empowering [students] and their families, the helpers' perceptual 'set' shifts from the exclusive to the inclusive where the seekers and their families have active roles in enabling, empowering, and functioning.

Researchers Bemak and Chung (2008, p. 373) suggest counselors ask and reflect upon the following question:

Do I genuinely believe that all children can achieve and learn at high levels; and if I do, how can I foster greater academic success by helping reduce the academic achievement gap that disproportionately affects poor youth and students of color?

Other helpful exercises and training principles for in-service training for school staff about best multicultural counseling practices include role playing, examining media imagery about journeys of immigrants or refugees, and reviewing articles and research findings pertaining to multiculturalism and diversity (Constantine & Sue, 2005). Experiential activities are especially helpful; as one participant in an exercise noted, "You can read all you want about white privilege, but until you experience lack of privilege you can't really understand it" (Patrick & Connolly, 2009, p. 125).

School staff can also learn about the importance of modeling a caring affect for developing a positive working relationship with students (Hughey, 2011). The use of games as experiential methods of instruction have been shown to be effective in enhancing participant's learning, such as the game entitled *Bafa Bafa*, wherein the group of participants is divided into two separate cultural groups, the Alpha and Beta cultures. Each culture learns about their own set of norms, rituals, and traditions; and then goes about to communicate and observe the other culture. The two groups engage in a follow up discussion to debrief about their experience.

Another possible game is that of the *Step Forward Step Back* exercise, where either the participants create an identity using a character with varying cultural demographics (e.g., race/ethnicity, gender, sexual orientation, socioeconomic status) or they participate as themselves, and either step forward or back depending upon whether the person or the character is a member of the dominant, more privileged

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

culture. More suggestions for experiential games in the area of training include Multicultural Jeopardy or Cultural Bingo (Kim & Lyons, 2003). A metaphorical activity for participants to complete was suggested by Singh (2010, p. 557) whereby participants would:

Utilize everyday objects (e.g., magazine cut outs, photographs, found objects around your home or workplace) to create a 'social justice quilt' that represents the most salient aspects of your identity (e.g., race/ethnicity, gender, sexual orientation) and history of personal social justice advocacy that shape how you view social justice theory, the nature of human challenges and resilience, and the reasons you have chosen a helping profession.

School Counseling Professionals as Change Agents

School staff who are counseling students from a multicultural lens also need to incorporate social justice advocacy into their work, whereby they work with students and communities to "remove barriers and promote change" (Cook, Krell, Hayden, Gracia, & Denitzio, 2016, p. 176). School counselors are often referred to as *change agents* within their respective school sites, as they are in a position to, "Affect attitude through changing awareness, providing necessary knowledge and skills, and enhancing opportunities that foster respect for cultural differences" (Uehara, 2005, p. 46). They should be asking themselves the following types of questions when it comes to implementing competent, multiculturally sensitive counseling interventions: "Is this intervention reflective of the student's cultural experience? Would other members of this culture recognize this intervention as a positive representation of the culture? Would you recommend your intervention with this cultural group to other professionals based on your experience?" (Suzuki et al., 2006, p. 435). In order for a school culture to ultimately be realized, the conclusion needs to be made that culture outside of the school, just as the dynamics and culture within school, are forever changing and should be frequently updated and revised as the need arises (Fraise & Brooks, 2015).

Importance of Establishing a Working Alliance

One of the key aspects to establishing an effective counseling relationship is that of the therapeutic working alliance. Many ethnic minority students may not experience the therapeutic alliance, perhaps because of the cultural misunderstandings and miscommunications that may occur between counselor and students because of stereotyping or shaming (whether unconscious or conscious on the part of the helping professional). The counselor should avoid using stereotyping or assuming and instead use their clinical judgment to assess a student's level of acculturation, developmental level, ability or ease of providing insight to their current needs, as well as their cultural values, behaviors, interpersonal relationships, and expectations (Roysircar, 2009). Many Western notions of counseling are accustomed to a direct approach to building a working alliance. Counselors may need to adjust this mode of delivering services to indirectly connect, e.g., take a nondirective stance when aligning with the student or family and allowing them to direct the conversation (Singh & Singh, 2019). While teachers are not counselors, the counselor and/or mental health professional staff can provide training for teachers on how to build relationships with their students that are in the spirit of productive, working alliances in order to foster positive, supportive school connections.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Researchers Cook et al. (2016) also suggest partnering with local universities to promote multicultural fieldwork for counselors, and receiving support and ongoing training with university faculty. Training and practice in universally important counseling skills such as empathy, genuineness, openness to learn from students who have different cultural background and experiences from that of the clinician, and the importance of not making generalizations about the student's background and being able to maintain a stance of curiosity about learning more. For example, a student shared that he had a sibling, and the counselor assumed the student's sibling was his twin; when in fact the student shared that her sibling had a different mother (Cook et al., 2016). Researchers Ponterotto et al. (2008, p. 94) added that the principles of *social initiative*, which involves, "Embracing and initiating cultural interactions in a wide variety of contexts"; as well as flexibility, which involves, "Cognitive resiliency that promotes seeing new cultural situations as a positive challenge rather than as a stress marker" are inherent to the practice of multicultural counseling. Researcher Bemak (2005) outlined the important principle of empowerment for consideration from school professionals, whereby:

…An individual gains control over their lives and decisions. In order to accomplish this, those who typically make the decisions must relinquish their power and authority, as the previously disempowered gain greater control to manage their own lives. (p.403).

The concept of flexibility in adjusting to the styles of student's personalities and cognitive styles should be taken into account by school counseling staff for better student retention and improved attitudes about school culture. Helping students to gain flexibility in the way that they cope cognitively and improving communication, problem solving, and coping styles as they compare and contrast with traditional and modern cultures to maximize, model, and encourage a stance of flexibility (Trusty, 1996). Teaching self-advocacy skills can be helpful to teach students how to be self-motivated to set goals for current and future outcomes (Hughey, 2011). Taking on the stance of the learner themselves and maintaining curiosity about the types of food, traditions, and games can be helpful to building rapport with students of diverse backgrounds (Suzuki et al., 2006).

A perspective entitled the Culture Specific Pedagogical (CSP) counseling model can also be taught to educators to enhance their knowledge of applying helpful multicultural interventions (Marbley, Bonner, McKisick, Henfield, & Watts, 2007). According to the authors, the CSP model is, "Designed to address the construct of diversity-sensitive training as a possible factor for the P-12 prospective teachers' lack of efficacy toward teaching culturally and racially diverse students" (Marbley et al., p.8). The CSP Model embraces three theoretical approaches – multicultural counseling and therapy (MCT), culture-specific pedagogy, and counseling and continues over time. Pre-and post-surveys are given to participants to monitor baseline and ongoing levels of staff's comfort levels with their multicultural development throughout the process. Growth groups led by a trained mental health professional focus on the following: "Feelings and interpersonal engagement, learning through action instead of just dialoguing, and on the present rather than the past" (Marbley et al., 2007, p. 13). The researchers recommend that at least one facilitator of the counseling group be representative of that of the dominant culture of the group they are facilitating – for example, if the majority of the group is Caucasian, then one of the facilitators should also be Caucasian. The third step within the CSP model is for teaching staff to have classroom experiences around multicultural awareness and sensitivity, including but not limited to readings, experiential exercises, class discussions, and community experiences. The last step of the model is centered around a process involving termination and a debriefing discussion where the diversity experience is reflected

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

upon and follow up counseling can be offered if needed. It is important that counselors provide a safe, confidential space where the participant's emotions can be processed without judgment (Marbley et al., 2007).

CONCLUSION

This chapter has reviewed the disparity that continues to exist around providing culturally competent counseling within the confines of a school environment to meet the needs of diverse student populations. This disparity may be due to a variety of factors; including but not limited to:

- Differences in education levels and experiences of school counseling staff,
- Differences in training of school staff towards adopting a multicultural framework for working with diverse students,
- Potential biases that may exist towards certain cultural groups,
- Power differentials that may exist between staff and students,
- A lack of awareness of available services which seek to accommodate the various modalities by which students from various backgrounds effectively learn,
- The history of counseling and education, and others (Beam, Brady, & Sopp, 2013; Patrick & Connolly, 2009).

This chapter has reviewed some potential starting points for school counseling staff to learn about the various levels of training for school counseling professionals as well as explore ways to integrate their expertise to form a school climate. It has aimed to demonstrate how school counseling staff can serve as change agents for their relative school sites through fostering educational opportunities for staff and continued professional and personal growth, and provide culturally appropriate ways to integrate parents, families, and communities together for the benefit of helping students effectively navigate their educational journeys (Uehara, 2005). At first glance, students may not always initiate or seem as if they need help, but if their needs are understood from a multicultural lens, more can be done to promote early intervention. Ultimately, this can promote greater overall student well-being and foster success in many lessons taught within and outside of the traditional classroom. After all, if schools are truly the bridge to the wider community, then a greater effort needs to be put forth to understand the unique needs and cultural representation of the students who are members of the student body. A conscious policy and procedure of openness, awareness, and flexibility from all who belong to the school community can be made possible in order to establish and serve the culture of the school itself.

Chapter 29
The Mental Health Interpreter:
The "Third Space" Between Transference and Counter-Transference

Sarah Parenzo
Bar Ilan University, Israel

Michal Schuster
University of the Free State, South Africa

ABSTRACT

This chapter aims to provide an interpretation of the role of the mental health interpreter, using the concept of "third space" taken from the field of cultural translation and the psychoanalytical concept of transference/counter-transference. Such interpretation provides a unique and novel analysis of the work of the mental health interpreter through the perspective of the "third space", thus enabling a broader view of the interpreter's role in the therapeutic session. The authors' insights are based on a reflective journal written by the first author while working as an interpreter during a parental training in a public mental health clinic in Israel. By reviewing the different roles, powerplays, and challenges in this third space, the authors will suggest some practical recommendation regarding the training and supervision of mental health interpreters, allowing them to serve as competent and ethical mediators between the patient and the therapist.

INTRODUCTION

The literature on interpreters in public services (including mental health interpreting) has long been recognized the interpreter-mediated session as an interaction (Wadensjö, 1992) in which not only the main parties have distinct voices (e.g. "the Voice of Medicine" and "the Voice of the Life-world", as Mishler [1984] refers to them) but also the interpreter. Brisset and colleagues (2014) have found that collaboration with a competent interpreter helps the healthcare provider to better listen and understand the patient's lifeworld (Leanza, Bolvin & Rosenberg, 2013). Such examination of the interpreter's dynamics

in public service settings challenges "the myth of the uninvolved interpreter" (Bot, 2003) and assumes a more present, active and involved role for her (Hseih, and Nicodemus, 2015). The dynamics in the triadic encounter are even more significant in mental health settings, as will be further elaborated later on.

This paper aims at analyzing the work of the mental health interpreter from a new perspective – that of the "third space", thus enabling a broader view of the interpreter's role in such settings. The authors base their insights on a reflective journal written by the first author while working as an interpreter during a parental training in a public mental health clinic in Israel. She interpreted between Hebrew and Italian throughout 20 sessions that took place between January and August 2016. With the background of a mental health worker and a trained interpreter, her observations refer to the linguistic, cultural and psychological aspects of the interpreted session.

BACKGROUND

Language, Interpreting and Health

The importance of the mother tongue in psychotherapy is extensively discussed in the literature (Amati-Mehler, Argentieri & Canestri 1990, Santiago-Rivera & Altarriba, 2002). The centrality of words in psychoanalytic psychotherapy is crucial as a pathway to analysts' and patients' access to the content and effect of pathogenic unconscious, fantasy, memory and complexes and contribute to an effective therapy.

A meta-analysis of 76 studies found that therapies offered in the patient's mother tongue were twice more effective than therapies offered in English (Griner & Smith, 2006), with more effectiveness being measured when the therapy included culturally adapted measures. In the macro level, patients who are not proficient in the country's primary language may encounter barriers to the use of mental health services (Sentell, Shumway, & Snowden, 2007), as well as higher rates of treatment dropout, recurrent and longer hospitalizations, poor adherence to medication and treatment recommendations, lower client satisfaction. Naturally, all these barriers may contribute to health disparities among fragile populations.

When patient-therapists language concordance is not possible, the session should be mediated through an interpreter (Brisset et al., 2014). Based on understanding of the importance of language in psychotherapy, some therapeutic models, e.g. the Cultural Consultation Service (CCS) in Canada, suggests considering the social, cultural and political context of the patient's behavior and symptoms, to provide better diagnosis, assessment and treatment plan (Kirmeyer et al., 2003). In such cases, cultural mediators (sometimes referred to as cultural 'brokers') eliminate not only the language gaps, but become go-betweens who sensitize clinical practitioners to patients' belief systems and encourage patients to "trust" the institutional system. According to Miklavcic and Leblanc (2014) who studied the Canadian CCS mentioned above, cultural brokers can help in assimilating the immigrant's point of view to the healthcare system and broader society, by offering a more inclusive two-way exchange of the other's perspective.

Since the triangular encounter of the therapist-patient- interpreter requires specific expertise and preparation, many providers often lack the appropriate training to effectively use interpreters during therapy. For example, a survey among mental health providers in Montreal, Canada, revealed that even when linguistic resources such as interpreters were available, many providers were not aware to issues like the dynamics in the triadic encounter, the possible roles of the interpreter, and key elements for a successful interpreter-mediated intervention (p. 1245).

The Complexity of Mental Health Interpreting

Interpreting in mental health settings requires special knowledge, awareness and skills. Interpreters in mental health have a responsibility for the co-construction of meaning, which is one of the basic and most important process acquiring within a therapeutic encounter (Leanza, Bolvin, and Rosenberg, 2013). The interpreter's choices, even on the renditions of small, allegedly non-informational utterances, may either exclude or marginalize the principal participants. Successful mediation, on the other hand, may help building an emotional rapport (Farini, 2013).

In addition to general linguistic and interpreting skills, the mental health interpreter should be able to identify meta-linguistic issues, such as unusual linguistic choices or unique forms of languages, that may be important for an accurate diagnosis and treatment (Registry of Interpreters for the Deaf, 2000; Santiago-Rivera & Altarriba, 2002). Mental health interpreters should also be aware of extra-linguistic factors, such as the nature of the session (for example, an intake interview) and the setting (i.e., the combination of concrete and subjective elements in the psychotherapy framework that are set up to provide continuity, consistency and containment). For example, the length of therapeutic sessions may affect the ability of the interpreter to keep focused.

Another important element is the interpersonal dynamics in the room (Hlavac, 2017). Interpreters must be able to cope with silence, anger, tears and mistrust. Moreover, their feelings that things are not going according to their own common sense regarding the nature of the conversation and patient-therapist dynamics, may leave the interpreters confused and frustrated. Anderson (2012), a mental health interpreter, accurately phrased the effects of these emotions: "When the interpreter silently questions the course of therapy, subtle emotional overtones may be disruptive to the therapeutic relationship. […] Their innate responses can add some emotional nuances to the interaction that were unintended by the therapist, and eventually to subtly degrade the quality of trust and rapport between therapist and client". That said, the interpreters' performances have interpersonal and clinical consequences on the shifting boundaries of task, identities, and relationships in therapist-patient interactions (Hseih & Nicodemus, 2015)

Despite the fact that interpreters can be emotionally affected by their mere presence and involvement in therapeutic sessions, studies addressing issues of emotions in interpreter-mediated encounters are few and quite limited (Hseih & Nicodemus, 2015). Similar cultural background or past experiences may evoke significant emotional impact (Miller et al., 2005; Tribe & Morrissey, 2004), as well as the fact that the interpreter usually speaks in the first person. On the other hand, studies have shown that such exposures could also lead to substantial personal growth among the interpreters (Hseih & Nicodemus, 2015; Splevins et al., 2010). In any case, most interpreters do not receive supervision[1] or support, and may be at risk of developing secondary or vicarious trauma (Splevins et al., 2010).

The following chapter is aimed to shed light over the need of therapists and interpreters to identify and acknowledge such emotional impact, and be prepared to handle its implication, both for the success of the therapy and the interpreter's emotional well-being and his/her proper professional conduct.

THEORETICAL FRAMEWORK

The Third Space no. 1: The Cultural Translation Perspective

Almost all aspects discussed so far regarding the interpreter's position in the consulting room are generally framed as "problematic", often used to highlight the difficulties that this service presents to all involved parties. However, the authors would like to suggest a different view of the role of the interpreter in mental health settings, which points out, next to the difficulties and "traps" it creates and faces, the potential added value that his/her presence can bring to the table of successful therapy. To this end, the authors will rely upon the sociolinguistic concept of "third space" articulated within the theory of cultural translation by the scholars Homi Bhabha (Bhabha, 1994) and Judith Butler (Butler, 2012).

Bhabha is one of the pioneers of post-colonial studies of literary criticism. In his thinking, identity is shaped by a complex and uninterrupted negotiation that finds its most fertile ground in hybrid and intermediate spaces. The latter, better known as "third space", is the theater of cultural translation (Buden et al., 2009), a platform to the development of identity and the creation of cultures. Engaging into the relationship with the other means to take the risk of his unconscious, of the displacement of the point of view, to identify with the untranslatable (Bhabha, 2016). In such a condition of liminality and paradoxes, people are constantly in motion, engaging in dialectical processes and exchanges: "It is in this space that the authors will find those words with which we can speak of ourselves and others" (Bhabha, 2006, p. 157).

In the wake of Bhabha's thought on cultural translation, Judith Butler (Butler, 2012), a comparative literature researcher who specializes in moral philosophy and gender studies, identifies the place of the meeting with the other as the third space, which forms the basis of the ethical relationship par excellence: "a relation to alterity […] as constitutive of identity" (Butler, 2012). In other words, translation is not merely the interpretation that a translator performs on a literary or social script; rather, the translation itself – and particularly its encounter with otherness – becomes a model for ethical and political action (Bermann, 2014). The very title of Butler's book, *Parting Ways* (Butler, 2012), alludes to a constant transformative and translational movement, and is in a perpetual duality between belonging and detachment, which she "solves" by suggesting the uncertainty of ambivalence as a guarantee of ethics. Only then, in the ethical encounter that implies a continuous transition between worlds and in the departure from the origin, religious, spiritual, and cultural content can be reworked and translated into renewed and relevant ethical resources for the here and now. Furthermore, Butler's ethical responsibility implies listening to often "remote and foreign" human voices (Butler, 2013, p. XII), and to the abandonment of certainties to the unknown: "Translation cannot be a simple assimilation of what is foreign into what is familiar; it must be an opening to the unfamiliar, a dispossession from prior ground, and even a willingness to cede ground to what is not immediately knowable within established epistemological fields" (Butler, 2012, p. 12). Thus, Butler's account on cultural translation concerned with cultural differences echoes Bhabha's, as both are seeing the introduction of foreign elements into another culture as potentially conjuring something 'new' out of the encounter between two competing 'languages' (Lloyd, 2007, p. 153).

Bahadir (2004) addresses the post-colonial ethos in order to deal with the cultural, social, political and professional identity of public services interpreter: "Interpreters, too, are engaged in a borderline activity, producing other cultures against the background of their own cultures, and creating a new space, a third culture, 'something like culture's 'in-between', as Bhabha would put it." (Bahadir, 2004, p. 816). In the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

globalization era, when profiles are multiple and easily subjected to hybridization, Bahadir stresses the need of resistance to the fascination of the one-dimensional dehumanizing ideal of the interpreter as an invisible, transparent, neutral and objective agent. This expectation of being impartial and factual clashes with her being a third party in between, "steadily moving from involvement to detachment, and back" (Bahadir, 2004, p. 807). In performing this back and forth act that recalls Butler's fluctuating dynamic, the interpreter should be self-critical and self-reflecting, sufficiently aware of his/her own culture and of the fact "that seeing, reading, writing (i.e., translating) the other culture to mine means incorporating it into 'my world' in order to make it comprehensible and thus, 'digestible'" (Bahadir, 2004, p. 807).

Bahadir encourages interpreters to focus on freedom, responsibility and visibility as vital elements for professional ethics for interpreters experts in intercultural communication. Hence, in addition to the bag of "duties" implicated in his/her job, the interpreter working in the consulting room has many powers that still need to be identified. As Levinas put it, the interpreter plays the role of both a witness and a judge (Levinas, 1961), acting as a moral authority over therapist and patient. Paradoxically, it is a passive, mirror-like power, as the interpreter will not actively purge the contents of the dialogues; instead, his/her presence pushes the parties towards greater ethical and critical content.

This aspect of the third space, then, refers to the negotiation and mediation functions the interpreter's role entails. By acting as an influential author of tension between ethics and justice, a bit like a tennis court's net, the presence of the interpreter can stimulate both interlocutors in the consulting room to pass over only those contents that are sufficiently "high" to go above the net. The interpreter, who is serving as a "host" during the session, much like a referee, can act as a witness to the truth, an impartial judge and ethical guarantor of intimate exchanges.

The Third Space no. 2: The Psychoanalytical Perspective

Since the therapist in the presented case study operated in a psychodynamic psychotherapy framework, the interpreter's experience will be conceptualized using the notion of transference/countertransference, that is central to psychoanalysis theory and practice (Racker, 1968; Searles, 1978; Laplanche, 1988). The concept of the third space is also a prominent part of the psychoanalytical discourse, viewing the analytic session as a third space (Winnicott, 1971), which is the place transference and countertransference take place.

As first conceptualized by Freud (Freud, 1895), one of the conditions that makes analysis possible is the establishment of a two-way relationship, called 'transference' and 'counter-transference', between patient and therapist. This is a living relationship, in which there are constant movements and changes (Joseph, 1985). As Joseph noted, "everything of importance in the patient psychic's organization based on his early and habitual ways of functioning, his fantasies, impulses, defenses and conflicts, will be lived in some way in the transference (Joseph, 1985).

Notably, the concept of transference has undergone significant changes and developments since Freud, through the contributions of analysts like Winnicott (Winnicott, 1956), Kohut (Kohut, 1968) and others (Mitchell 1988). Nonetheless, contemporary therapists still agree that much of the therapy's potential depends on the ability to work with transference and counter-transference (Nissim Momigliano, 1984).

Having examined the theories mentioned above, one can assume that the differential between those psychoanalytical transference flows is actually the third space of cultural translation. In the presented case study, there is a guest in this third field: the interpreter. In this triadic exchange, the interpreter sits

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

between therapist and patient so that they maintain visual contact with each of the participants throughout the session. In order to guarantee an easy flow, the interpreter has the responsibility of delivering the contents from one side to the other with great precision and sensitivity, as well as to fulfill his/her task paying attention to all the details.

Although one could say that the translation process is fundamentally mechanical and immediate, it almost always involves an interpreter's choices, which rely on his/her linguistic and cultural background, as well as her personal experience. Thus, it is reasonable to assume that the sentence translated to the recipient will not be identical to the one offered by the originating interlocutor, especially in circumstances where the emotional burden is considerable. In that case, the interpreter is at risk of being entangled in the transferential relationship, which may push him/her to modify the text, even unconsciously.

In order to explain this possible implication of transference on the translation process and product, the concept of 'lateral translocation' should be introduced. Initially discussed in the context of group psychotherapy (Yalom, 1975), lateral translocation describes the way that transference within the group is always in movement[2] (Baranger & Baranger, 2011), and becomes possible engines of development and transformation for all participants. Besides the main patient-therapist transference, a part of the projections is directed towards the other participants who make up the relationship with the therapist. The therapeutic alliance in the group retains the participants in a joint care project, where they perceive reciprocal feelings of closeness and solidarity. Despite the differences between group dynamics and an interpreted intervention, the mental health interpreter, too, is involved in the therapeutic alliance (Chiappano & Ferruta, 2012). Therefore, it may be assumed that interpreter is not immune to the development of such transfer and empathy experiences towards other members.

CASE STUDY: INTERPRETING IN MENTAL HEALTH

Israel is home for about 8 million people, shared by diverse linguistic and cultural communities. The largest linguistic group is Hebrew, seconded by Arabic and Russian. In total, there are about 30 languages spoken (or signed) in Israel – by either native minorities, Jewish immigrants, work migrants and asylum seekers – mainly from African countries (Ethnologue, 2018).

Despite this linguistic diversity, training of interpreters in mental health services is extremely limited. A directive from 2011 by the Ministry of Health requires all healthcare institutions to provide culturally and linguistically competent services (Ministry of Health, 2011). Although the ministry offers telephone interpreting services for medical institutions, these are mainly used in general hospitals, as well as in primary and secondary care. Since 2013, initiatives by the NGO – the Jerusalem Intercultural Center, in cooperation with mental health centers, have started offering focused medical interpreting skills training for bilingual workers of the hospitals. However, these initiatives did not last long; apart from these local initiatives, no special training was offered to interpreters in mental health. In fact, most requests for interpreting services in this area were addressed on an ad-hoc basis.

This was the case in the current therapy, too, since Italian is a very marginal language in the country[3]. In January 2016, the first author was offered to interpret in a series of parent training sessions, for Italian – Israeli parents of a 12-year old girl. The author was never specifically trained to provide interpreting services in the mental health field. However, since she has the background of both translation (Ph.D. studies at an Israeli university) and mental health, she felt as she could take this assignment, and allow the family the access to mental health services.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The parent training took place in a Children's and Adolescents' Clinic, which is part of the Public Mental Health Service in one of Israel's largest cities. The sessions took place once a week, besides Jewish holidays and a few cancellations made by the patient herself. The insights described here were documented in a reflective journal written by the first author, in which she wrote down mostly personal impressions and feelings after each session. All personal details, including the child's name and the location of the therapy, have been changed here to prevent identification.

The individual therapy of Rebecca and the parental training were initiated by Rebecca's school. The family immigrated to Israel from Italy when Rebecca was 10. She presented adaptation and learning difficulties, partly due to language barriers and partly to emotional challenges of different nature linked in some measure to tensions at home. A report issued by the school discussed the possibility of domestic physical violence. Therefore, Rebecca was placed under an individual therapeutic program first, and then in peer group therapy, while both parents were invited in parallel weekly training sessions. While Rebecca was able to master Hebrew well enough in order to undergo therapy, her parents, who had difficulty with the language, had to use an interpreter. It should be noted that is no formal arrangement for Italian-Hebrew medical (or other) interpreters. However, due to the Ministry of Health's directive regarding language accessibility to health services (2011), the relevant function in the mental health system made an effort to find an interpreter to take part in the therapeutic sessions.

Except for the first meeting, which both parents attended, only the mother participated in the remainder of the sessions. As a result, the parental training phase was, for the most part, a series of individual therapeutic session with the mother. Thus, there were three participants in the room: the psychologist, Rebecca's mother (herein referred to as "the patient") and the first author, serving as the interpreter (hereafter "the interpreter"). The intake sessions have been conducted by a male psychologist, but after a couple of sessions, he was replaced by a female psychologist. The therapy was never formally ended, but rather abruptly stopped, due to some financial difficulties of the parents.

The descriptions and reflections reported in the first author's reflective journal were analyzed to understand her role as an interpreter, her involvement and the dynamics in the room, all in light of the "third space" concept.

DISCUSSION

The Interpreter as an Agent in the Cultural Third Space

The interpreter, as a guest in the consulting room, must be transparent enough to avoid disturbing the intimacy of the therapeutic encounter and patient's sensitivity, while also able to provide the therapist with all the necessary information. This double chore requires facilitating verbal and nonverbal communication, as well as mediating concepts and cultural practices, as warranted by the circumstance.

The family, consisting of the father, mother, and their two children, came from a large Jewish community in Italy, and whose members belonged to different social spheres and economic classes, as in the case in most Jewish communities in Central and Northern Italy. Having immigrated for Zionist and religious reasons, once in Israel, this family was faced with a number of social acceptance difficulties, especially in terms of employment, with resulting financial challenges.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Awareness by the interpreter of intercultural gaps, such as different systems of values, roles of family members, taboos, authorities and educational systems, is likely to be an added value. Therefore, interpreters, especially in community settings, are sometimes acting as "cultural interpreters" or "cultural mediators" (Albertini & Capitani, 2010). In our case study, this cultural mediation was manifested in a number of ways. First, when the interpreter had the impression that the translation was not able to communicate all the subtle details and feelings, she felt the need to add some more information in order to make the therapist aware of the gap.

In order for the therapist to understand the social context, the interpreter was often elaborating on the social structure gaps, as well as the dynamics within the Jewish community in Italy. These features included, among other things, a difficulty to openly discuss some issues with other community members, feelings of shame due to economic difficulties and some miscommunication between the more and the less affluent community members. These dynamics may have led to feelings of isolation and loneliness, in a community that is a minority in Italy. Another cultural issue that had to be clarified, in the opinion of the interpreter, are family dynamics (e.g., family roles and everyday dining habits), as well as discourse patterns in typical Jewish families.

Such difficulties and frustrations would have likely impacted the domestic environment. It is important to point out that in Italy, even today, and certainly as it pertains to older generations, the possibility of using "moderate physical violence" against children as an educational and corrective method is still socially tolerated. The Italian law does not explicitly establish whether it is lawful to slap one's own children (Codice penale, Articolo 571 - Article 571 c.p. -Abuse of the Means of Correction or Discipline), as the jurisprudence has not yet been established in a secure and predictable manner. Thus, where the border between legal correction and abuse appears blurred, the law prefers to leave it to each individual case. This attitude is also a significant cultural gap that the therapist had to be made aware of by the interpreter.

Another cultural aspect that should not be underestimated is the respect for privacy and confidentiality of information. At the beginning of the therapy, the psychologist took care of introducing the interpreter to the patients, while emphasizing that her presence will not in any way undermine the secrecy and confidentiality of the sessions. However, the risk that the interpreter may, even involuntarily, establish family connections through the local community network was high. As the Jewish-Italian community is so small, the interpreter in our case actually knew the patient's employers, and it just so happened that she ran into them at a circumcision party at the end of therapy. Anticipating that this could happen, the interpreter consulted with the psychologist before taking part in the event, agreeing to keep as much physical distance and discretion as possible, as not to embarrass or making the patient uncomfortable.

Indirect cultural mediation was also performed outside the therapy room. One of the psychologists initiated a debriefing meeting with the parents and the interpreter present, after the first session. During this conversation, the parents had quarreled in Italian. The therapist noticed that the interpreter found herself in a very complicated situation, having too much power in her hands that she did not know how to use ethically. Thus, he suggested to talk things over with the interpreter after the session, so she could express her personal impressions and any relevant information that would help him understand the situation or the patient. The therapist listened attentively, though it was not officially defined as supervision. At some point, the second psychologist started to join these meetings, bringing this kind of open-hearted conversation to an end. From that moment on, the therapists-interpreter conversations became very concrete and informative, mainly focusing on language gaps. This type of events raises an ethical question: is confidentiality limited only to people outside the therapy, or also referring to the relationships between different members within the room? This area is considered a kind of a grey zone,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

indicating the need for more explicit roles to regulate the interpreter's work, and protect not only the therapist but also the interpreter – who do not enjoy the same legal, professional and ethical protection as psychotherapists get.

When no fixed rules regarding the supervision of interpreters exist, certain dynamics are being left to the discretion of the subjects involved. The interpreter, in this case, found it very useful to exchange information with one of the therapists after the sessions, during which she provided the latter with some clarification on the family background. These short conversations helped her, in return, to better her understanding of certain attitudes and responses. However, while the first psychologist in charge of the family always made himself available to accept short feedback from her, the second therapist was hastier and less available.

The biggest challenge for the interpreter was to find a way to be active in the communication while letting the patient and therapist remain the main actors. In order for this latter condition to occur – to act as a supervisor in transparency and professionalism – the interpreter must be able to manage production and awareness of the emotional content she conveys, so as not to become too entangled nor empathic, risking, in both cases, an involuntarily manipulation of the content she is supposed to deliver. This brings us to the discussion regarding the development of transference and counter-transference by the interpreter herself.

The Interpreter's Transference Within the Psychoanalytical Third Space

Acting in the third space of the intersection between the transference and counter-transference, or in the differential between the "flows" coming from both the therapist and the patient, the interpreter is exposed to the risk of excessive identification, rescue fantasies or, at least, of developing over-empathy toward the patient. Thus, it is crucial that the interpreter be placed in the condition of managing her involvement and emotional burden in the session. Otherwise, she might develop lateral transfers or extreme empathy that could compromise the "sterility" of the therapeutic setting.

Following Joseph's advice stating that "everything of importance in the patient's psychic's organization […] his fantasies, impulses, defenses and conflicts will be lived out in some way in the transference" (Joseph, 1985), the first author's reflections (taken from her private journal written during that time) shows she did cope with complex fantasies, impulses, defenses and conflicts while interpreting the therapy. The risk of identification presented itself in different ways. For example, the patient spoke of an "unresolved relationship with the absent maternal component" and, like the interpreter, "had gone to a non-Jewish school where she had been the victim of episodes of anti-Semitism that influenced her choice to emigrate to Israel", as the interpreter recalled thinking during the session. These common childhood experiences in the same motherland have challenged the first author in terms of identification, and, using the first-person while interpreting, made it even stronger. Notably, the risk of identification tends to be more evident when the patient and interpreter belong to small communities.

Another thought that crossed the interpreter's mind was related to the family's financial situation: "The patient was also living in a condition of financial deprivation, akin to the circumstances in which one of my close acquaintances was living as a result of bankruptcy procedures". Personally exposed to some financial difficulties of Italian friends recently immigrated to Israel, the interpreter had a hard time separating her personal experience from her professional ones, resulting in greater empathy toward the patient. At the same time, other notes demonstrated the sensitive subject of wishing to have a closer alliance with the therapist, risking a situation of "inferiority" and isolation of the patient:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

"In addition, within what is already an asymmetrical dynamic, i.e., the therapeutic encounter, the fact that I perceived greater intellectual and social affinity with the therapist could have caused an implicit alliance between the latter and me…".

The interpreter's personal experience undergoing psychoanalysis seemed to show up and "disturb" the course of the interpreting. After one of the sessions, she wrote to herself: "By chance, the patient had the same name as my personal analyst. I wonder how it could affect fantasies of inversion of roles, where I to identify myself with the therapist, or worse, going above her." Other notes show that situations when the therapist answered differently from what the interpreter would have imaginably done were a constant cause of frustration for her.

These examples demonstrate the effect of the mediating role on the interpreter, such as feelings of over-identification, anger, and empathy, alongside the willingness to bridge the language and cultural gaps, even when this is not necessarily required. The strong influences of the transference and counter-transference on the interpreter, just like those experienced by the therapist, require great awareness and self-control, in order to avoid taking professionally inappropriate decisions.

CONCLUSION AND CLINICAL IMPLICATIONS

Based the concept of 'third space' elaborated in cultural translation by Bhabha (1994) and Butler (2012), the authors suggest looking at the interpreter in the consulting room as a special guest acting in the third hybrid and liminal space, which is placed in the intersection produced by the transference and counter-transference between patient and therapist. In doing so, the interpreter could provide a significant contribution to the therapeutic process. However, for this to happen, it is crucial that the interpreter will be able to manage his/her own involvement and emotional burden in the session. Otherwise, lateral transfers or excessive empathy might compromise the quality of the interpreting, thus "contaminating" the content and the triadic dynamic of the session.

Such delicate complexities emphasize the need for tailored supervision for interpreters, "built-in" in his/her professional work routine, incorporating both classic therapist training and interpreting studies theories. An effective clinical supervision should address the multiple aspects of emotions expressed by the patient and provider, and the culturally, linguistically and professionally appropriate ways to handle them (Hseih and Nicodemus, 2015). Moreover, it could help the interpreter to manage the personal emotional burden, allowing him/her to not only provide an impartial service as possible but also to better develop greater awareness, self-criticism and self-reflection in the therapeutic situation. These were stressed by Bahadir as essential skills of the interpreter, improving him/her to function as a linguistic and cultural broker in the session.

Reviewing the set of dynamics within the third space, it is also suggested that interpreters would receive the appropriate tools to make a judgment in situations of moral dilemmas resulting from their space in the room, as well as from the triadic relationship. The interpreter might – consciously or unconsciously – make interpreting-related decisions that will affect the therapy. This ability, to decide whether to deliver a message, or even slightly change it (even though a different tone of voice, or the addition of physical gesture) carries with it tremendous powers. Thus, interpreters must be aware of the powers they hold and their possible implications on each of the participants (including themselves) and the therapy as a whole.

FUTURE RESEARCH DIRECTIONS

As the acknowledgment of the interpreter's involvement in the emotional aspects of psychotherapy is relatively new, many questions and arguments raised earlier require further research. Here are some issues directly stemming from the current analysis: what is the potential influence on the interpreter in other therapeutic frameworks, such that are not based on working with transference/counter-transference? To what extent should the interpreter be informed on the patient-provider dynamics in the room? On the one hand, such knowledge will help him/her be more aware, and be able to transmit faithfully even the slightest nuances. On the other hand, such a background may "contaminate" the translation or hamper her neutrality. Such issues should hopefully be explored in future studies, contributing to our understanding of the interpreter's place and role in mental health settings.

LIMITATIONS

This chapter is based on the experiences during a therapeutic process of a single family, by a specific interpreter. The emotional responses of the interpreter described above may have been influenced by the therapist's choice of therapeutic framework. The insights and model proposed here should be further examined in various types of therapies, involving interpreters from diverse personal and professional backgrounds.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

ENDNOTES

1 The term "supervision" in this context refers to conversations between professionals, aimed at enhancing one of the professionals' effectiveness at work (Dean, Pollard, & English, 2004).

2 Baranger and Baranger (2011) introduced the concept of a bi-personal field to describe the dynamic process of analysis, the location of the projections and cross introjections and counter-identifications between analyst and patient.

3 According to recently published data, the Italian community in Israel is composed of approximately 15,000 people, most of whom probably have proficiency in Hebrew (Della Pergola, 2014).

ABSTRACT

First responders, including Emergency Medical Services personnel and firefighters, support community members in times of crisis. When responding to emergencies, first responders often experience both direct and vicarious trauma. Over time, the pace and intensity of a career as a first responder leads to poor health habits and high risk for mental health issues including posttraumatic stress disorder. Due to concern about peer perception and mental health stigma, these professionals are less likely to seek mental health supports to manage and process trauma. This chapter explores Narrative Therapy as an ideal option for mental health treatment of first responder trauma, providing a collaborative approach to therapy using the natural coping strategy of storytelling.

INTRODUCTION

First responders, including Emergency Medical Services (EMS) personnel and firefighters, have increased risk of mental health issues due to exposure to trauma over a career (Jones, 2017). More specifically, first responders have increased risk of mental illness symptoms including PTSD, depression, anxiety, sleep issues, substance use, and suicidal ideation as compared to other helping professionals and the general public (Martin, Tran, & Buser, 2017). Risk for such symptoms increase for first responders located in rural areas, working longer shifts, and those without social supports at home (Jones, Nagel, McSweeney, Curran, 2018). Mental health supports, such as Employee Assistance Programs (EAPs) are critical for addressing the high risk for Posttraumatic Stress Disorder (PTSD) and suicide among first responders (Heightman, 2016). This chapter explores storytelling as a natural coping strategy for first responders, and proposes use of Narrative Therapy as means of trauma-informed mental health counseling for this population.

BACKGROUND

Emergency Medical Services (EMS) includes Emergency Medical Technicians (EMTs) and Paramedics. The scope of practice outlined by the National Highway Traffic Safety Administration defines the roles and training of EMS (USDOT, 2007). In this scope of practice, EMTs focus on basic life support (BLS) services which encompass treating and transporting stable patients not in imminent harm of death or disability. Beyond the training of EMTs, Paramedics represent the highest level of certification for EMS. Paramedics oversee the work of EMTs and direct firefighters on scene in the interest of prioritizing patient health outcomes. Paramedics perform invasive medical procedures for advanced life support (ALS) services addressing life-threatening emergencies during patient treatment and transport (USDOT, 2007). Nationally, 70% of EMS personnel are EMTs, and only 24% are Paramedics (USDHS, 2017).

EMS as a field is generally young. The Highway Safety Act of 1966 established the Department of Transportation (DOT; NHTSA, n.d). This marks early organization and development of the EMS system as represented today, with DOT tasked with regulation and implementation of training standards (NHTSA, 2011). Mainstream media representation of EMS dating back to the 1970s, primarily with the television show *Emergency,* began to create both public awareness of 911 services, as well as public misconceptions about emergency support in communities (NHTSA, n.d). EMS often work closely with, or cross train as firefighters. Nationally, 40% of EMS work directly with fire departments (NHTSA, 2011).

Early firefighters in the 1800s in the US were largely volunteers (Kenlon, 1913). Later, through central government regulation, firefighters established a fraternal order or "brotherhood" still recognized today in response to early rivalries between volunteer firefighting communities. In modern firefighting, the United States Fire Administration (USFA) trains, supports, and governs firefighters as a division of the Federal Emergency Management Agency (FEMA), first established in 1973 to address fire prevention (Kruger, 2018). Firefighters focus on fire prevention and response in the community (USDHS, 2017). Training for firefighters includes Firefighter I and Firefighter II certifications (NFPA, 2019). Both levels of certification include foundational training including response to alarms, tools and equipment for fire management, navigating environments safely to address fires, and helping rescue fire victims. The Firefighter II certification includes further skills training with a wider variety of equipment than Firefighter I.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nationally, 71% of fire departments are staffed by volunteers, and as such, 56% of all firefighters in the US are volunteers (USDHS, 2017). While less common, 17 states also use volunteer EMS (USDOT, 2007). Volunteer first responders often receive no pay for their services or are paid per call (NVFC, 2014). While volunteers still experience camaraderie and the culture of first responders, they may experience this culture differently than career first responders. Further, volunteer first responders experience trauma and stress without as many supports and benefits. For example, it is rare for volunteer first responders to have access to benefits, including EAPs (Heightman, 2016). As such, volunteers may be more likely to experience mental health issues with greater barriers to treatment in coping with exposure to trauma inherent in emergency support services (Stanley, Boffa, Hom, Kimbrel, & Joiner, 2017).

IMPACT OF CAREER ON FIRST RESPONDER WELLNESS

First responders experience high risk for various health issues as a result of their career. Some risk for physical and mental health issues relate to the inherent stress of supporting community crisis. For example, prolonged stress and exposure to fire-related incidents creates high risk for heart disease for firefighters, with nearly half of deaths while on duty caused by cardiovascular events (Kales, Soteriades, Christophi, & Christiani, 2007). EMS routinely experience risk of harm including exposure to communicable diseases, and performing medical procedures in a vehicle traveling at high speed without wearing a seatbelt (Blau, Eggerichs-Purcell, & Bentley, 2012; Weaver et al., 2015). For first responders, the unpredictable nature of a typical shift, when it is unknown when the next "call" will come, does not support much focus on personal wellness. As a result, EMS and fire personnel report poor overall personal health habits both at work and during personal time including speeding, smoking, drinking, and poor eating habits (Pirrallo, Levine, & Dickison, 2005). Further, alcohol and tobacco use represent significant health risks for first responders (Carey, Al-Zaiti, Dean, Sessanna, & Finnell, 2011). For example, firefighters use smokeless tobacco products at a higher rate than the national average, many of whom only starting use after becoming a firefighter (Jitnarin et al., 2017). Beyond high stress, sleep deprivation, poor health habits, and the unpredictable nature of a typical shift, trauma experienced during community crisis represents perhaps the highest health risk for first responders.

Trauma and Mental Health Stigma

First responders experience trauma both directly through potential for physical or emotional harm, or through repeated exposure to traumatic experiences of patients and their families known as vicarious trauma (Trippany, Kress, & Wilcoxon, 2004). This exposure to trauma is inherent during routine job duties responding to community crisis for both firefighters and EMS. Sleep disturbances due to shift work and unpredictable calls represent high risk for mental health issues, suicidal ideation, and unhealthy alcohol use (NEMSMA, 2016; Vargas de Barros, Martins, Saitz, Bastos, & Ronzani, 2013). Routine and repeated exposure to trauma also increases risk of PTSD for firefighters and EMS personnel (Klimley, Van Hasselt, & Stripling, 2018). In response to training and experience, first responders focus on the needs of patients and victims on the scene, disregarding the impact of the chaotic and emotionally charged environment in the moment to fulfill the responsibility of supporting community members (Palm, Polusny, & Follette, 2004). Further, as part of first responder training, experienced personnel often haze or push new EMS and firefighters to "toughen up" and not react to trauma exposure on the job. Thus

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

following these traumatic events, firefighters and EMS often experience thoughts and mental images (e.g. flashbacks, dreams) related to vicarious trauma but may not have a supportive outlet to process them (Jahnke, Poston, Haddock, & Murphy, 2016). Over time, repeated exposure to trauma without adequate mental health supports leads to increased risk of PTSD and suicide among the first responder population (Martin et al., 2017; Stanley, Hom, & Joiner, 2016).

First responders experience a strong camaraderie, which encourages fire and EMS personnel to depend mainly on peers for support (Regehr, Hill, Goldberg, & Hughes, 2002; Stanley et al., 2016). While common coping for work-related stress and trauma are social supports, due to stigma and first responder culture, there is aversion to using peers as supports in interest of preserving a reputation and image at work (Lanza, Roysircar, & Rodgers, 2018). To address critical incidents experienced in the field, the first responder population can benefit from mental health treatment conducive to the unique population and impact of experiences in the field (Jones, 2017). Prevention focusing on locus of control and developing resilience to promote healthy coping can help mitigate risk factors. Also, interventions that are trauma-informed are critical (Kleim & Westphal, 2011). Mental health stigma and barriers to mental health treatment prevent first responders from seeking supports for mental health issues. First responders experience fear in seeking mental health supports, as counseling carries a perception weakness by coworkers (Vogel, Cohen, Habib, & Massey, 2004). Further barriers include scheduling appointments around shifts and lack of knowledge about supports available (Haugen, McCrillis, Smid, & Nijdam, 2017). First responders often believe mental health practitioners do not understand first responder culture, or the experiences of EMS and firefighters which deters them from seeking professional support (Heightman, 2016).

First responders experience critical events in the field, which represent direct and vicarious trauma (Martin et al., 2017). This experience occurs throughout a career, as typical work duties include attending to community crises. For example, Jahnke (2018) described the typical shift as attending to community members on the worst day of their life. Over time, first responders become desensitized and cynical as means of coping (Jahnke et al., 2016). Tempered emotional reactions become even more difficult when having to navigate expressing compassion and empathy for victims on scene, but avoiding emotional reaction after the emergency is over (Boyle & Healy, 2003). While peer supports represent a protective factor, fear of retribution or tarnishing of reputation deter first responders from processing trauma within the first responder community (Stanley et al, 2016). With no safe outlet, eventually, emotional avoidance becomes a survival tactic leading to burnout and compassion fatigue (Regehr, Goldberg, Glancy, & Knott, 2002). Often first responders turn to use of alcohol as a socially acceptable means of coping with trauma (Gallyer et al., 2018). Substance use, especially alcohol, to cope with trauma leads to high rates of addiction within the first responder community (Fjeldheim et al., 2014; Jahnke, 2012; Poston, 2012). Dark humor represents another commonly accepted means of catharsis to manage emotional reaction to vicarious trauma (Scott, 2007; Tangherlini, 2000). Along with dark humor, first responders often use storytelling as a natural coping strategy to process experiences with peers (Tangherlini, 2000).

SOLUTIONS AND RECOMMENDATIONS

Created by White and Epston, Narrative Therapy's premise is that clients build narratives based from their perceptions of self and others (White, 2007). These narratives, referred to as dominant narratives, are socially constructed, based on language, and are a way that clients' construct their reality (Combs

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Freedman, 2012; White, 1995; 2007). Dominant narratives, often confirmed or modified based on interactions with environment, become clients' absolute truth regardless if they are positive or problematic (White, 2007). Problematic dominant narratives are socially, culturally, and politically induced and are the cause for clients' problematic behavior and/or mental health concerns, especially when are incongruent with their lived experiences (Brown & Augusta-Scott, 2007). In Narrative Therapy, clients are the owners, authors, and experts of their own subjective narrative and counselors are the experts in Narrative Therapy (Combs & Freedman, 2012). Narrative Therapy involves four non-linear, free flowing cyclical steps that requires active collaboration between the client and the counselor (White, 1995).

The first step in Narrative Therapy is identifying the problematic dominant narrative that is causing the client distress (White, 1995; 2007). During identification, clients also determine their memberships and association with the dominant narratives in the past, present, and future (Vorster & Phipps, 2009; White, 1995; 2007). Counselors' role in this stage is to provide the space for clients to tell their story. The second step is deconstructing the dominant story. During the deconstruction process, clients break down their dominant story into manageable parts and explore what parts contradict or support each other (Payne, 2006; White, 2007). Counselors support this process by inquiring about their culture and experiences that support the dominant narrative and determining the conception of the problematic narrative (Carr, 1998; Payne, 2006). During the deconstruction process, counselors also help clients to externalize the problem. White (1995) believed that a problematic narrative is powerful because it becomes entrenched in clients' identity; thus, clients become unable to separate themselves between their selfhood and the problem. Clients externalize the problem by objectifying it as something outside of themselves, and often assigning a name to this problem (Carr, 1998; White, 2007). After assigning a name to the problem, clients explore the problems' power and influence over their lives (White, 2007). Externalizing the problem helps empower clients to take control of the problem and visualize the problem as something more manageable (Payne, 2006).

The third step involves reauthoring and re-membering the dominant narrative. In this stage clients revise their problematic dominant stories into stories that are more congruent with their lived experiences (White, 2007). Parts of the problematic dominant narratives either neglected or conflicting, represent "unique outcomes" or "exceptions" (White, 2007, p. 61). White (2007) described that clients are often fascinated by unique outcomes and by placing emphasis on the exceptions or neglected parts, counselors can start the process of reauthoring (Combs & Freedman, 2012). Clients also revise their membership and re-engage in neglected identities and resources that clients want to re-integrate into their narratives (White, 2007).

The fourth step includes performing definitional ceremonies. Definitional ceremonies involves a ritual where clients can share their new and more congruent narrative (White, 2007). Some ceremony options include letter writing (Combs & Freeman, 2012), performance in group therapy (Duba, Kindsvatter, & Priddy, 2010), or the use creative arts such as artwork (Bennett, 2008), music or video recordings (Combs & Freeman, 2012). Definitional ceremonies thicken and strengthen the new narrative and provide meaningful connections to the future (Combs & Freeman, 2012).

Narrative Therapy has gained momentum as a holistic and widely used intervention for diverse populations. In a simple literature search, there are over 5000 articles on Narrative Therapy, and almost 3000 in the last 10 years alone. Narrative Therapy has been proposed to treat trauma (e.g., Bullen, 2015; Cloitre, Garvert, & Weiss, 2017; Lee, 2017), grief (e.g., Hedtke, 2014; Turns & Macey, 2015), anxiety (e.g., Horner & Tully, 2016), and depression (e.g., Lopes, Gonçalves, Fassnacht, Machado, & Sousa,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2014; Rodríguez Vega, Bayón Pérez, PalaoTarrero, & Fernández Liria, 2014). These issues represent key mental health concerns for EMS and firefighters (Martin et al., 2017).

First responders possess a number of natural coping skills, including the use of storytelling as a means of processing and understanding experiences (Tangherlini, 2000). Narrative therapy similarly utilizes storytelling to deconstruct and reconstruct experiences (White, 2007). By starting with the telling of stories, Narrative Therapy draws on the existing coping skills of first responders and can aid in the building of trust and rapport with the first responder population. Given the enduring stigma of help-seeking behavior among the first responder population (Vogel et al., 2004), it is critical to utilize trauma-informed practices that reduce stigma. Narrative Therapy emphasizes the externalization of the problem, highlighting the idea that the person seeking services is not weak or broken, but is a healthy person faced with a problem (White, 2007). The attribution of problems to experience rather than to the person can help to destigmatize the help-seeking experience. The first responder occupation is often an integral part of the first responder's identity and the first responder culture undoubtedly impacts the perception of self and others. Narrative Therapy considers and identifies how the role of culture and context impact the dominant discourse (White, 2007). The emphasis on the constructed narrative and the role of cultural context may help to mitigate the feeling that mental health professionals do not understand first responders. The following example provides illustration of Narrative Therapy with the first responder population to support trauma while addressing stigma.

Example of Narrative Therapy

Marc is a 28-year-old, Caucasian, cisgender male who is currently working as a firemedic in an urban setting. In this role, he has cross trained as a firefighter and a paramedic, providing primarily medical support for patients but fire support as needed during calls. He has worked as a firemedic for approximately 4 years. Marc lives with his girlfriend of two years and identifies this relationship as supportive.

Recently, Marc experienced a traumatic call in which a young child died after drowning in a swimming pool. Marc performed CPR at the scene but was unable to resuscitate the child. Marc's supervisor, per department protocol, required him to see a counselor after the critical incident on his last shift. At first, Marc reports he feels fine, and that events like the child's death is simply "part of the job." After some prodding from the counselor, and reminding about the confidentiality of their discussion, Marc reluctantly shared he has been having trouble sleeping and had a few nightmares about the event in the week since the call. He has noticed feeling more irritable and is dreading returning for his next shift, which is unusual as Marc takes great pride in his identity as a first responder. Marc's girlfriend had also encouraged him to use the counseling supports provided by his county benefits, as she noticed an increase in arguments with Marc since this most recent incident. He reports that he is coming to therapy to appease his girlfriend and supervisor but is reluctant to talk about the recent traumatic event. He acknowledges that he has been more irritable lately but feels that he needs to just "get over it" when asked about vicarious trauma. Marc reports he had seen a counselor in the past under recommendation from his job after another instance of trauma but did not find it helpful. He felt that the counselor did not understand him and wanted to give him a diagnosis, which he worried would impact his job or his coworkers' perceptions of him.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Identifying the Narrative

In initial therapy sessions, the counselor focuses on building rapport and highlighting the therapy process as non-judgmental and collaborative. The counselor shows genuine interest in Marc's experiences in the field, and asks questions about what it is like to be a firemedic. Marc, feeling passionate about his career, answers her questions and then naturally begins to tell her about different calls he has experienced during his career. Drawing on his natural coping strategy of storytelling, the counselor invites Marc to further share his storied experiences as a firemedic. Marc is initially reluctant to talk about negative work experiences but speaks of his positive relationships with coworkers and sense of camaraderie in his work. Marc discusses how his family supported his desire to become a firemedic, and talks about looking up to his father, who worked as a police officer. After building a foundation of trust and collaboration in early sessions, Marc begins to open up about some of the trauma he has witnessed, including the most recent incident with the child's death.

Even as Marc tells stories of being a witness to significant and intense trauma, the counselor notices that he tends to shy away from emotional language when describing his experiences. When the counselor asks about this disconnect, Marc responds by explaining that expressing emotions is not helpful, and that his he is more effective in his job when disconnected emotionally from patients. He expresses a need to "get over" and laugh about his experiences rather than discuss his feelings. From discussion of how Marc has responded to repeated exposure to trauma, Marc and his counselor are able to identify a dominant narrative in his life in which he feels he must shut down his emotional responses and act as though the traumatic events he witnesses do not impact him.

Deconstructing the Dominant Story

Finding that he enjoys telling stories with the counselor, Marc continues to see the counselor. He asks the counselor not to tell his supervisor that he continued to come to sessions after his required "check-in" following the critical incident with the child. In the process of deconstructing the dominant narrative of emotional detachment and being "tough", Marc is able to recognize that the culture of first responders as well as the culture in his family of origin shape this narrative. Marc discusses his father's career as a police officer and his stoicism. Marc finds that his father instilled the idea that men did not express emotions related to traumatic events, especially men who served the community. Men who serve the community must be strong and tough for others who need them. In remembering how his father interacted with other police officers, he remembered their jokes with each other and habit of getting together for a beer after shifts and telling stories. Marc learned from his father that, as a man, the way to deal with trauma was through isolation, dark humor, and alcohol use; these coping strategies further reinforced through his own work as a first responder.

A critical piece of the deconstruction process of Marc's narrative was the externalization of his response to vicarious trauma. Marc believed that his emotional response to vicarious trauma indicated that something was wrong with him or that he was too weak to handle his work. The feelings of helplessness he experienced as a result of being unable to save a child led Marc to view himself as inadequate for his work. Through the process of externalization, the counselor helped Marc to readjust his view of himself and the issue of trauma, emphasizing that the problem was the ongoing trauma experienced as a result of his occupation, rather than a personal weakness in not being able to cope with the trauma. The counselor highlighted normal responses to vicarious trauma and emphasized how Marc's reaction to trauma was

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

common. Over time, Marc was able to distance his concept of self from his response behaviors to trauma and was able to recognize that his experiences were a typical response to a problematic experience, the frequent exposure to trauma. He found validation in knowing that he was not broken or unable to serve his community because of these trauma responses.

Reauthoring and Re-Membering

In the reauthoring process, the counselor encouraged Marc to identify how he would like to see himself respond to ongoing stressors and create a narrative of healthier coping mechanisms and support. In his original dominant narrative, Marc saw himself as inadequate, weak, and helpless when he struggled to deal with ongoing vicarious trauma. Through the restorying and reauthoring process, he was able to identify exceptions to these feelings; remembering times when he performed his work capably, helped others, and gained a sense of purpose and gratification from his work. Marc was able to identify how he ideally wanted to deal with stressors, including involving his girlfriend in his coping rather than pulling away from her. Marc identified wellness activities he would like to use to cope, including fishing with his father. Rather than conceptualizing his inability to tolerate ongoing trauma as a personal weakness, Marc was able to alter his narrative to highlight his strength in caring for others and engaging in emotionally and physically challenging work. As the original problematic narrative was prominent at work and often exacerbated by work culture and peers' coping mechanisms, Marc and the counselor talked about how his new narrative would fit with his peers at the fire station. He processed that although he feared that his peers would not accept his new narrative, in time, he could model for them better coping mechanisms and help them seek support when he saw signs of trauma.

Definitional Ceremony

As Marc and his counselor approached the end of their work together, the counselor asked Marc to engage in a definitional ceremony, celebrating and sharing his new narrative. Marc elected to write a letter to his future self, who would undoubtedly encounter more trauma throughout his work. In this letter, Marc reminded his future self of his inherent strength and ability to cope with the trauma he would encounter. He highlighted the positive aspects of his work and his stories of strength and caring for others. Marc encouraged his future self to utilize healthy coping strategies and seek support from those around him. Marc asked his girlfriend to attend a therapy session with him and shared this letter with her, inviting her to share in his experience and identifying how she could continue to support him. Through the Narrative Therapy process, Marc came to view himself through a preferred narrative in which he encountered problems but did not ascribe the problems nor his reactions to them as an inherent weakness. Marc was able to utilize storytelling, a natural medium, to tell new stories about himself, his world, and his experience. Through the therapy process, Marc felt respected and empowered as the author of his experiences rather than pathologized and stigmatized. In terminating therapy, the counselor reminded Marc she was always available to him if he needed to come back. Marc left feeling the counselor genuinely cared and was interested in his work, comfortable with returning if his trauma again became overwhelming in his career.

FUTURE RESEARCH DIRECTIONS

The previous example provides an outline for how the principles and processes of Narrative Therapy integrate specifically with the work of first responders. Though the first responder population could undoubtedly benefit from mental health care to address the effects of exposure to ongoing trauma, stigma around help-seeking behavior creates a significant barrier to receiving care (Vogel et al., 2004). When first responders have received treatment that has felt ineffective, this can further dissuade them from seeking therapy. As in the example, many first responders may feel that practitioners do not understand their experiences and may feel judged (Heightman, 2016). Further, first responders often feel misunderstood and unappreciated by community members (NHTSA, n.d). The collaborative and non-judgmental experience and the emphasis on the client as the expert and author of experience may help to engage first responders in the therapy process. This collaborative process using a natural coping skill of storytelling may also help overcome the perception that community members do not care about first responders.

After establishing a foundation of trust and collaboration, the four-step process of Narrative Therapy can unfold. The above example illustrates how a first responder client may engage in Narrative Therapy. By beginning with the telling of stories, Narrative Therapy taps into the innate storytelling mechanism that many first responders use to process and understand experiences (Tangherlini, 2000). By creating a comfortable space for the client to tell stories, the counselor allows for the expression of positive and negative stories as a dominant narrative emerges regarding the work, culture, and experiences unique to first responders. Through the process of deconstructing the dominant narrative, first responders are able to externalize the problem, mitigating the stigma of trauma responses and the tendency to attribute typical reactions to personal weakness (Lanza et al., 2018). Externalizing the problem can also involve naming the problem to help separate the problem from the client's personhood. In Marc's example, he could have named the problem "*get over it"*. In further deconstructing the narrative, as seen in the example, first responders are able to identify how their experiences and culture may support or contradict the dominant narrative. Additionally, first responder clients could explore exceptions to the dominant narrative as part of the deconstruction process. Although not seen in the example, Marc could have explored when he felt competent at his job, despite patient loss, or when he or his coworkers discussed openly job traumas and their struggles with loss without engaging in avoidant coping mechanisms. Findings exceptions to the dominant narratives helps first responders demystify the strength of dominant narratives and naturally leads to the reauthoring process.

Through the reauthoring process, first responders are able to identify exceptions to the dominant narrative and create new stories of themselves that are more congruent with their lived experiences. Regarding trauma, first responders are better able to conceptualize trauma and trauma reactions as external, no longer tied to internal conceptions of strength or weakness. This helps combat stigma in seeking supports outside of their work community. As seen in the example, first responders are encouraged to identify a new narrative of coping and managing the ongoing trauma encountered in their work. Through definitional ceremonies, the client solidifies these new narratives (White, 2007).

It is important to remember that the deconstruction and reauthoring of experience is a cyclical and non-linear process (White, 1995). Though the above example highlights these steps in a particular order, the therapy process often involves a constant deconstruction and reconstruction of narratives that may intersect and overlap. In examining, deconstructing, and reauthoring experiences through Narrative Therapy, counselors can work to build trusting and collaborative relationships with first responders that may serve to mitigate the stigma of help-seeking and create lasting change in the first responder culture.

CONCLUSION

First responders experience strong stigma against help-seeking behavior, like attending counseling, despite repeated exposure to trauma throughout a career. Without adequate mental health supports, first responders face high risk for compassion fatigue, PTSD, and suicide. Mental health providers have an obligation to find evidence-based and effective ways to reach this population of clients to address trauma experiences. Narrative Therapy as an approach using the natural coping skill of storytelling presents an opportunity to connect with and support the first responder community while addressing underlying mental health stigma.

KEY TERMS AND DEFINITIONS

Compassion Fatigue: The gradual loss of the capacity to care for the suffering of others after repeated need to support others over time.

Direct Trauma: An unusually stressful event happening directly to an individual.

Dominant Narrative: The common story, lens, or perception of the principal societal group.

Externalization: A mental health tool of imagining issues or symptoms to be an independent idea instead of an ailment or affliction of the individual.

First Responder: A common term for professionals including emergency medical services personnel and firefighters trained to respond to community emergencies.

Posttraumatic Stress Disorder: A stress-related disorder occurring after a traumatic event characterized by symptoms including sleep disturbance, distressing dreams, avoidance of reminders of the traumatic event, negative mood, and emotional reactivity for at least one month after the traumatic event.

Stigma: The shame perceived or expressed by others when an individual is associated with a certain group, need, or condition.

Vicarious Trauma: The impact of exposure to unusually stressful events experienced by others over time.

Chapter 31
Individual Funding for People With Mental Health Issues:
Opportunities, Tensions, and Outcomes

Christina David
RMIT University, Australia

Carmel Laragy
RMIT University, Australia

Elizabeth Hudson
RMIT University, Australia

ABSTRACT

This chapter outlines the key features of individual funding programs and examines their suitability for people with mental illness. This is a contested area with some writers concerned that mental illness is different from other types of disability and unsuitable for individual funding. The recovery model and the episodic nature of mental illness are seen as conflicting with individual funding eligibility criteria for consistent and permanent disability. The counter view is that flexible individual funding is ideally suited to meeting the fluctuating needs of people with mental illness: its key principles of empowerment and self-direction being consistent with the recovery paradigm. Evidence from Australian and international studies is reviewed, suggesting that successful outcomes can be achieved if the necessary supports and resources are available to meet people's needs.

INTRODUCTION

The past four decades have seen a marked increase in individual funding models internationally and in Australia, particularly in disability and aged care. Individual funding aims to shift choice and control to people using services through flexible budgets in a services market, with the option to self-direct arrangements if preferred. This chapter explores the implications of these approaches for people with

mental illness. Factors influencing choice, control and access to services will be considered, given the episodic nature of mental illness and principles of the recovery paradigm. The authors consider key debates, opportunities and risks for people with mental illness and the ensuing challenges for individual funding policy, implementation, and practice. These challenges have been scrutinised in Australia as the National Disability Insurance Scheme (NDIS) rolls out and grapples with ways to respond to the needs of people with mental illness. This major reform offers important lessons for Australia and elsewhere regarding mental health service and support systems. The chapter concludes with recommendations for policy, practice and further research.

BACKGROUND

Individual funding is linked to the broader personalisation agenda in disability and aged care, seeking to promote greater choice and control for people using services in a competitive market model. Individual funding has emerged in response to the shortcomings of previous block funding models where service users were tied to one provider, restricted to services the provider offered, and did not know the budget allocated for their support. From a government's perspective, the previous model provided limited accountability for public funds, as service providers had discretion to distribute funds between running costs and participants' supports.

Individual funding was seen as a mechanism for overcoming these limitations; giving people with disability more choice and control over services, and therefore in their lives. Disability advocates, particularly from the field of physical disability, lobbied for its introduction, as did western governments interested in potential cost savings and finding a way of meeting their obligations to give rights to people living with disability (Dickinson, 2017). Individual funding was seen as a mechanism to encourage creative planning and provide a wider range of supports to meet individual needs and preferences. People with reduced decision-making capacity would be assisted by family or professionals as appropriate. Importantly, individual funding was to place the person at the centre of the decision-making process: to choose their supports and give them greater independence and improved quality of life (Alakeson, 2008; Croft & Parish, 2016).

Individual funding programs reportedly commenced in the 1960s and 1970s when parents of children with disabilities in Canada (Hutchison, Lord, & Salisbury, 2006), and Vietnam veterans with disabilities in the US (Yeandle & Ungerson, 2007) lobbied for community living. Subsequently an array of individual funding programs has emerged in disability and aged care services, with many different structures, administrative arrangements and names. Self-directed support (SDS) has emerged as the most common name being used in Scottish legislation (2013), by the United Kingdom (UK) advocacy group *In Control* (2017), and by the *Cash and Counseling* program in the US (RWJF 2010). Under the umbrella term of self-directed support, the UK has personal budgets and direct payments (Hamilton, Tew, Szymczynska, Clewett, Manthorpe, Larsen, & Pinfold, 2016). Other terms are used elsewhere with some European countries referring to 'cash-for-care' (Da Roit & Le Bihan, 2010) and Australian aged care using the term 'consumer directed care' (CDC).

These programs have core features in common despite their various names and configurations. An assessment of personal needs is undertaken, a budget is allocated to purchase services and supports, and the person has a degree of control over what is purchased. There is an important difference between programs that expect the person with individual funding to self-direct their budget by arranging their

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

supports, employing staff and managing their accounts, and programs that offer support to assist or undertake all these tasks. The UK Direct Payments program is an example of the former, and the US *Cash & Counseling* program an example of the latter.

Much research demonstrates positive outcomes for people with mental illness in the US programs; the strongest evidence of the benefits of individual funding for this group coming from the *Cash & Counseling* program. Evidence based on randomised controlled studies with large numbers of people across 15 states showed that people could self-direct their budget with appropriate support, achieving a wide range of positive outcomes (Barczyk & Lincove, 2010; Shen, Smyer, Mohoney, Simon-Rusinowitz, Shinogle, Norstrand… del Vecchio, 2008).

Other research identifying positive outcomes includes an Australian study that looked in depth at the experience of 16 people using individualised funding who had consistent contact with managers in positive person-centred relationships. This study found there were practical and psychological benefits for consumers and that consistent support for self-direction enabled their growth and capacity to build hopeful lives (Peterson, Buchanan, & Falkmer, 2014).

In a systematic review of the international literature Laragy, Sanders, and Brophy (2015) also found positive outcomes for people with mental illness using individual funding models. These included less time in psychiatric hospitals and criminal justice settings, creative use of funding to facilitate independent living, continued education or work, more personal relationships, and improved social life. Importantly there were no adverse outcomes for participants when they were given appropriate support (Laragy, Sanders, & Brophy, 2015).

These international findings suggest that individual funding programs have the potential to give people with mental illness more choice and control. Better outcomes are achieved if adequate support for planning and management is provided and appropriate support services are available (Croft & Parish, 2016; Simon-Rusinowitz, Croft, Loughlin, & Mahoney, 2013).

Other studies have identified mixed outcomes. In particular, the National Direct Payments Survey (NDPS), a collaborative project of three UK research teams, highlights a range of challenges for mental health users as well as reports of direct payments significantly improving lives (Glasby & Littlechild, 2016). In their summary of the NDPS, Glasby and Littlechild (2016, p. 54), identify a number of barriers for people with mental illness in the program. These include:

- The underuse of advance directives (a statement which outlines the person's treatment preferences should they become unwell) to support people with episodic mental illness when planning for crisis situations;
- Limited resources to meet people's needs as care packages for mental health fail to delineate financial responsibilities between the clinical, mental health and social care sectors;
- Lack of specific mental health expertise in those providing support to people in establishing or managing direct payments.

The differences in program outcomes raises the question: do program characteristics impact on their outcomes? While this is an emerging field and more research is needed, the evidence to date suggests they do.

It has been difficult to produce a rigorous evidence base regarding the effectiveness of individual funding models because they are so diverse (Dickinson, 2017). Despite the limitations, studies have identified a range of factors that appear to impact on outcomes. An important and recurrent theme is

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that the way a model is implemented has an impact on the outcomes achieved (Dickinson, 2017; Laragy & Ottmann, 2011). Evidence suggests that well designed self-directed support models, when properly implemented and resourced, have the potential to facilitate consumer control and produce better outcomes for all participants, including people with mental illness (Alakeson, 2008; Barczyk & Lincove, 2010).

Two systematic reviews have identified the following as necessary conditions to achieve positive outcomes in individual funding programs:

- Choice to participate in self-management or traditional service delivery;
- Provision of appropriate cognitive, physical and cultural supports for active participation in planning, choice making, and support co-ordination;
- Flexible and adequate funding to meet needs and goals;
- Flexible and responsive review mechanisms and processes;
- Culturally appropriate, accessible and targeted information about program policies, spending guidelines, and services;
- Culturally appropriate services;
- Support to manage administrative demands;
- Peer support;
- Organisations and staff working from an empowerment and rights-based approach;
- Adequate workforce conditions;
- Support and oversight to manage risks;
- Access to a developed market which can offer appropriate services (Dickinson, 2017; Laragy & Ottmann, 2011).

An important debate relating to the conditions in which individualised funding takes place concerns access and equity and the limits of market approaches to provide adequate social supports for marginalised and disadvantaged groups (Fawcett & Plath, 2014). In particular, there are concerns that individual funding approaches do not invest in the collective structural reforms required to address deeply embedded social inequality. There are concerns that this will reproduce disadvantage for vulnerable groups, particularly in the absence of adequate supports to engage and participate (Dodd, 2013). Related to this critique are concerns regarding 'thin' markets where services do not exist to meet diverse and complex needs (Croft & Parish, 2016). These risks are likely to be particularly high in rural and remote areas. There are concerns for marginalised groups, including those with mental illness, and those with limited social supports and/or capacity to advocate for their needs when required supports are not available (Bigby, 2013; Miller & Hayward, 2017).

Despite these debates, Australia reflects international trends in adopting individual funding as a central component of the NDIS reform. It is suggested that Australia's experience can offer key insights into the particular needs of people with mental illness and how individual funding models can best respond. The following section describes key features of the NDIS and the integration of mental health.

THE NATIONAL DISABILITY INSURANCE SCHEME

The NDIS is based on individual funding in a fee for service market based model (Productivity Commission, 2017). The scheme was introduced in trial sites around Australia in 2013, full transition began in July

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2016, and by 2019 it is expected to support 456,900 people with disability, referred to as 'participants' (NDIA 2015). The scheme has 64,000 participants identified by the NDIS as having a psychosocial disability (Joint Standing Commitee, 2017). The *NDIS Act 2013* is based on rights and principles outlined in the United Nations Convention on the Rights of Persons with Disabilities (UN General Assembly, 2007). It stipulates that participants have choice and control in the pursuit of their goals, and the planning and delivery of their supports. The legislation uses the term 'psychosocial disability' when referring to mental health issues that result in 'severe effects and social disadvantage' (Joint Standing Commitee, 2017, p. 3). The introduction of the NDIS received bi-partisan political endorsement, support from the disability and community services sectors and significant support and commitment from people with disabilities and their carers (Bonyhady, 2014). It is widely considered to be having a significant social and economic impact nationally.

Prior to the NDIS, state based disability individual funding programs offered varying levels of choice and control through different options for funds administration (Purcal, Fisher, & Laragy, 2014). Some allowed participants to hold the funds, employ their own support workers, purchase support from a wide range of sources and account for spending. Others were individual funding in name but were little different from traditional block funded services (Laragy, Fisher, Purcal, & Jenkinson, 2015).

The NDIS model of support is based on a plan being developed with a facilitator, approved and funded by NDIS administrators. The support and choice model offers participants three options for controlling and administering their individual package. These are full self-management, management through a financial intermediary, or management through the NDIA. The person's capacity and their interest in having administrative responsibility and greater choice and control determines the model used. In June 2017, 8% of NDIS participants fully self-managed; 10% partially self-managed; 13% had their plan managed by a paid service; and 68% had their plan managed by the National Disability Insurance Agency (NDIA 2017, p. 21).

Integration of Mental Health Into the NDIS

Representatives of the physical and intellectual disability sectors lobbied for reform in disability funding and services and the establishment of the NDIS. Some commentators argue that the design of the NDIS is better suited to people with a physical or intellectual disability than those with mental health problems (McGorry & Matthew, 2016; Mental Health Australia, 2016; Williams & Smith, 2014). Contentious issues include the fact that people with psychosocial disability face barriers accessing the NDIS because they do not identify as having a disability; and because the concept of permanence, a key eligibility criterion for an individual funding package, conflicts with key principles of the recovery model (Bonyhady, 2014; Brophy, Bruxner, Wilson, Cocks, Stylianou, & Mitchell, 2015; O'Halloran, 2014). Other arguments suggest that programs such as the NDIS continue to promote a biomedical model and 'categorise' people with disabilities through clinical diagnosis (Davies & Gray, 2015; Slade & Longden, 2015).

These concerns about supports and outcomes for people with mental health issues in the NDIS have been reflected in initial reviews and studies. The NDIS has commissioned an extensive evaluation and has released its *Intermediate Report* (Mavromaras, Moskos, & Mahutea, 2016). The findings are based on quantitative data and interviews in the five trial sites with participants, family members and carers (N=62), NDIS registered disability service providers (N=25), senior personnel in workforce organisations (N=15) and NDIS staff (N=46). While the quantitative and qualitative evidence indicated improvements in the choice and control NDIS participants experience and better outcomes overall, this was not the case

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

for people with mental illness. People with mental illness and psychosocial disability reported that the portal used to communicate with the NDIS was difficult to navigate, they had less choice and control over their supports since becoming NDIS participants and some received fewer supports.

Similar findings for NDIS participants with mental illness were reported in a smaller study conducted in one of the trial sites (see Warr, Dickinson, Olney, Hargrave, Karanikolas, Kasidis, . . . Wheeler, 2017). After conducting 47 interviews with participants they reported:

- Participants with diverse needs and circumstances, including people with mental illness and those from socioeconomic disadvantaged backgrounds need more support;
- Plans are not sufficiently flexible to meet people's fluctuating needs, including people with mental illness, and 'contingency plans' are needed to purchase services, equipment and support on an ad hoc basis;
- Services were 'thin' in some areas and did not meet diverse needs, especially in rural areas;
- Rural participants spent a significant portion of their funding allocation in travelling to services;
- When participants were unable to access services listed in their plan, the item was deemed to be unnecessary and it was removed at the next review.

These findings highlight some early deficiencies in the NDIS model for supporting people with mental illness. The findings are also reflected in submissions to two public enquiries into the NDIS, both of which raised concerns about the eligibility criteria and the lack of support to engage with planning and choice. One enquiry dealt specifically with the provision of services to people with psychosocial disability (Joint Standing Commitee, 2017) while another examined Costs (Productivity Commission, 2017). Despite these early implementation issues however, reports from both enquiries agreed that the NDIS presents significant opportunities for people with mental illness if the necessary supports are provided.

TENSIONS AND DEBATES

This section reviews the experience of the NDIS transition and the international literature to better understand key debates and tensions for mental health consumers, advocates and services providers in the context of individual funding reform. Consideration is given to the principles of choice, control, access and equity and the policy and practice implications of enacting these principles for those experiencing episodic mental illness.

Choice, Control, and Episodic Mental Health

Self-directed approaches have been described by some commentators as consistent with personal recovery principles (Davies & Gray, 2015). However, there are also well documented concerns regarding the limits of market forces in promoting self-direction and equitably meeting diverse needs (Fawcett & Plath, 2014; Glendinning, 2008; Lymbery, 2014).

The recent NDIS experience shows that a range of barriers can limit choice, control, and self-direction for people with mental illness (Joint Standing Commitee, 2017). Barriers include lack of mental health expertise among those in assessment and planning roles, barriers to engaging 'hard to reach' groups, and lack of appropriate mental health services including community based early intervention supports. The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

evidence highlights the point that choice and control is mediated by a person's circumstances, resources and capacity to advocate for needs, comprehend complex information and navigate complex information and service systems (Dickinson, 2017; Warr, Dickinson, Olney, Hargrave, Karanikolas, Kasidis, . . . Wheeler, 2017). This has significant implications for people with episodic conditions, fluctuating needs and capacity, and those who are socially isolated.

For people with mental health issues, fluctuating conditions and unpredictable change in needs can limit capacity to engage with complex systems and manage self-direction in a services market. The evidence suggests that support planning processes and review systems often fail to respond quickly or flexibly to fluctuating needs. The Joint Standing Commitee (2017) reported that the NDIS planning approach, established at the point of entry to the scheme, failed to sufficiently build in early intervention supports to help engagement and choice making and to prevent relapse (2017). Research into the experiences of NDIS participants in the Barwon trial site also found that people with fluctuating conditions, such as those with both physical and psychosocial disabilities, had 'no scope' for a 'contingency plan to purchase services, equipment and support on an ad hoc basis' (Warr, Dickinson, Olney, Hargrave, Karanikolas, Kasidis, . . . Wheeler, 2017, p. 8).

An evaluation of the UK direct payments model also found that mental health service consumers desire more accessible contingency funding to ameliorate mental health crises, in order to maintain their choice and control (Spandler & Vick, 2006). Furthermore, the authors of this study recommended advance directives as a possible mechanism for providing greater flexibility in payments and self-directed support during crises. This evidence supports recommendations that assessment, planning and delivery choices need to be flexible, giving due regard to the implications of episodic and fluctuating conditions and changes in people's needs (Glendinning, 2008; Mitchell, Bruxner, & Brophy, 2014).

Access, Eligibility and Recovery Principles

A key debate concerns the lack of fit between recovery principles and the language of permanent disability central to NDIS eligibility requirements. Recovery has been described as a self-defined, non-linear journey involving hope, social inclusion, and fostering psychological, physical, emotional, and spiritual wellness (Anthony, 1993). It has been argued that self-direction is a key tenet of recovery and that individual funding programs provide an opportunity to put 'recovery principles into practice' (Simon-Rusinowitz, Croft, Loughlin, & Mahoney, 2013, p. 5). However, the language of permanence central to individual funding eligibility across many programs has been described as being at odds with the concept of hope central to the recovery paradigm. Related to this is the requirement for a clinical diagnosis which reflects a medicalised approach focused on symptoms rather than a personal notion of recovery (Davies & Gray, 2015; Slade & Longden, 2015).

In their literature review on mental health and the NDIS, Nicholas and Reifels (2014) examined a cross-section of Australian and international health services to determine the language used to regulate eligibility. Their findings reveal that the term 'permanent' as an eligibility requirement is used in a range of jurisdictions including Australia, New Zealand, the UK and the US, whilst terms such as 'long-term', 'indefinite duration' or 'not expected to improve' are used in Canada.

People experiencing episodic disability who shift between periods of illness and recovery do not fit standard categories; consequently, disability classification becomes problematic (Fulcher, 1989; Lightman, Vick, Herd, & Mitchell, 2009). This episodic phenomenon is proving a barrier to service access for people with psychosocial disability in the NDIS. Submissions to the Joint Standing Commitee (2017)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

identified that many people experiencing 'severe and functionally disabling mental ill-health' were found to be ineligible for individual funding (2017). This included young people for whom it would 'not be possible (or clinically advisable) to diagnose the illness as a "permanent" condition' (Joint Standing Commitee, 2017, p. 11). The inquiry also described the reluctance of many medical professionals to diagnose symptoms as a 'particular illness' or to assess it as 'permanent or likely to be permanent' (p.11).

The requirement for a clinical diagnosis also fails to take into account negative identity issues associated with stigma and shame. Some people experiencing mental illness avoid the association with disability as the assignation of labels can compound the effects of stigmatisation (Forrester-Jones & Barnes, 2008; Goffman, 1963). Studies have found that people with mental illness can be 'trapped in unsatisfying situations in order to avoid [mental illness] disclosure' and fear of being 'found out' (Stuart, Arboleda-Flórez, & Sartorius, 2012, p. 9). Simon-Rusinowitz et al. (2013) concluded from their literature review of self-direction in mental health that these approaches require 'a paradigm shift from the medical model of illness and disability to the more holistic recovery model' (p. 10) and that critical principles of self-determination and person-centredness are at risk if funding and support models are compromised by eligibility limitations.

A contrasting position argues that diagnosis, particularly for those with invisible disabilities such as mental illness, is an important process for appropriating supports and obtaining medical acceptance (Shakespeare, 2014).

As noted previously, the way programs are implemented is critical. In Australia, the speed of NDIS implementation has impacted on the quality of assessment and planning with implications for people with mental illness (Hallahan, 2015). Pressure to meet targets has disadvantaged those who may require more time and support in the eligibility and planning process, who are least informed about their rights within funding systems, and who are least able to navigate complex service systems and choices (Productivity Commission, 2017).

NDIS participation rates indicate early problems with eligibility for this group with 19% of those with psychosocial disability who applied being rejected. This eligibility rate was the lowest compared to other disability categories such as people with intellectual disability who had an acceptance rate of 97.5%. Furthermore, during 2016-2017, the rejection rate of people with psychosocial disability increased compared to other primary disability groups (Joint Standing Commitee, 2017, pp. 15-16).

IMPLICATIONS FOR POLICY AND PRACTICE: SOLUTIONS AND RECOMMENDATIONS

The review of the NDIS and additional evidence presented above lead to the following policy and practice implications.

Promoting Choice, Control, Access and Recovery

The principles underpinning individualised and self-directed approaches are consistent with the self-determined and highly personal nature of the recovery paradigm. However, research indicates that there is sometimes a gap between policy intentions and implementation. To ensure that people with significant mental ill-health can enjoy greater choice and control in their lives, specialised supports are required to facilitate assessment, engagement with services, and to support choice making.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Clinical and symptom based assessment and eligibility criteria can act as a barrier to service access. A clinical conception of recovery can negatively impact on service participation and progress toward recovery goals. Concerns regarding the limits of clinical diagnoses to identify eligibility and inform planning may be addressed by assessment tools which focus instead on functional capacity. The Joint Standing Commitee (2017) recommended this approach for the NDIS, suggesting the development of a validated 'fit-for-purpose' assessment tool which would better accommodate the needs of people with psychosocial disability (Rec. 4).

Building the service sector capacity and knowledge of recovery principles is also key to the successful implementation of individual funding in a mental health context. Equipping authorities, decision makers and practitioners with the appropriate professional development, supervision and tools can be an effective means of creating a shared understanding. Examples include recovery learning modules via interactive webinars and websites such as those commissioned by the NDIS (Mental Health Coordinating Council, 2017).

Primary health professionals also need to be suitably informed about mental health services to ensure they can provide timely and accurate information about funding and support options. Specialised supports need to be provided by appropriately trained staff experienced in mental health.

It is evident that people who are better resourced and who can self-advocate, or who have someone who can advocate for them, do better in individualised funding programs where supports are purchased from a services market. People already marginalised or less able to negotiate and co-ordinate their supports are likely to be further disadvantaged in this context. They require appropriate and timely information and assistance to engage and make informed choices about market based supports.

Assertive outreach designed for people with mental illness is needed to support people with mental illness who may not identify as having a disability and who therefore will not access programs like the NDIS. This approach should include face to face contact and other strategies designed to engage 'hard to reach' groups. Outreach might also be needed to engage the person's supporters and family carers who are navigating services.

Community capacity building strategies have also been identified as important in building confidence, influencing community attitudes toward disability and mental health, and increasing access, inclusion, and choice. Strong evidence supports co-design approaches to capacity building and strategies which build on the lived experience of mental health consumers (Williams & Smith, 2014).

Giving people with mental illness choice and control also relies on access to a 'thick', diverse and mature market, ready and able to provide quality and culturally appropriate services across a continuum of needs. Historically, a funding and service gap in mental health has resulted in a distinct lack of meaningful choice. Many are doubtful that market approaches will be able to address complex and fluctuating mental health needs (Gooding, 2016). Governments may need to intervene strategically in market dynamics to ensure a minimum level of service in 'thin' market areas, such as rural and remote regions which have traditionally struggled to provide adequate mental health supports.

Optimising Opportunities to Promote Recovery

The individual funding model is an enabler to recovery if properly executed with adequate supports, and when aligned with the principles of person-centredness. Assisting the person to develop a plan appropriate to their needs has been shown to be important to the success of the self-direction process. In contrast to the traditional medical model, person-centered planning focuses on strengths and capabili-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ties, integrating family and social network supports with mental health services. A team approach with all those involved working from an empowerment and person-centred perspective has been shown to be important. With these supports people with mental illness are better able to participate in decisions regarding provider and service choices.

Because eligibility criteria requiring the demonstration of permanent disability can be in tension with recovery principles of hope and optimism, there is a strong argument for review of this language and related policy. Such review would seek to better reflect recovery principles and reduce barriers to proving eligibility (Joint Standing Commitee, 2017). The Joint Standing Committee (2017) called for a review of the NDIS Act 2013 to revise permanence as an eligibility provision and consider if the term 'psychiatric condition' is required.

Finally, there is a need for more rigorous long term research into the experiences of people with mental illness using individual funding (Webber, Treacy, Carr, Clark, & Parker, 2014). Data needs to be collected showing the numbers of people experiencing mental illness who do not identify as such, and who need assistance to seek help. This data will highlight gaps and support positive change in policy and practice.

CONCLUSION

This review has shown that there is no simple answer to the question, 'do individual funding programs result in positive outcomes for people with mental illness'? This is because programs are complex, they have various designs, they provide different levels of support, they operate in diverse contexts, and they can be implemented to different standards. It is clear that successful outcomes can be achieved for people with mental illness if programs provide the necessary support and if required services are available. It was noted that the NDIS and other programs that use 'permanent disability' as eligibility criteria need to reconsider this approach. The concept of a permanent disability is misplaced because mental illness fluctuates and people work to a recovery model. The problems identified in the research are not insurmountable; programs that provide good support achieve positive outcomes. As individual funding programs are widely used to provide supports to people with mental illness, there is an imperative to ensure that issues are resolved and the rights of people with mental illness are upheld.

Chapter 32
Interpreting and the Mental Status Exam

Meghan L. Fox
Independent Researcher, Rochester, USA

Robert Q Pollard Jr.
National Technical Institute for the Deaf, Rochester Institute of Technology, USA

ABSTRACT

The necessity of engaging qualified interpreters to work in partnership with mental health clinicians when serving patients with a limited English proficiency (LEP) is gaining widespread support. Numerous research studies have documented improved patient health and satisfaction outcomes in this regard. Psychiatric practice often involves complexities of thought, language, and communication that clinicians and interpreters must appreciate. One such topic is engaging LEP patients in the mental status examination (MSE). This chapter describes the nature of the MSE, challenges when interpreting for the MSE, strategies for handling such challenges, and approaches for effective collaboration between interpreters and mental health clinicians regarding the MSE and cross-linguistic mental health care more broadly. The current state of scholarship in the field of mental health interpreting and training opportunities for interpreters who seek to improve their knowledge and skills in the mental health arena also are discussed.

INTRODUCTION

There is growing evidence that individuals with limited English proficiency (LEP) experience obstacles to safe and high-quality healthcare (Wu & Rawal, 2017). Language barriers between patients and medical clinicians are common, and are associated with poorer quality of care, misdiagnosis, medical errors, and lower patient satisfaction (Flores, 2005; Divi, Koss, Schmaltz, Loeb, 2007; Ku & Flores, 2005; Ngo-Metzger et al., 2007; Woloshin, Schwartz, Katz, Welch, 1997). Language assistance provided by qualified interpreters has been shown to increase healthcare utilization as well as improve clinical outcomes and patient satisfaction (Flores, 2005; Jacobs, Shepard, Suaya, & Stone, 2004; Karliner, Jacobs, Chen, & Mutha, 2007). Generally LEP patients view the availability and quality of interpreting services as crucial;

the use of interpreters and the perceived quality of interpreters' translations are strongly associated with the quality of care overall (Baker, Hayes, & Fortier, 1998; Dang et al., 2010; Green et al., 2005; Kline, Acosta, Austin, & Johnson, 1980; Kuo & Fagan, 1999; Lee, Batal, Maselli, & Kutner, 2002; Moreno & Morales, 2010; Ngo-Metzger et al., 2007).

Many oversight bodies recommend that healthcare clinicians working with LEP patients engage the services of professional interpreters to safeguard quality of care, patient safety, informed consent, and appropriate patient participation in healthcare decisions (Joint Commission, 2009; Registry of Interpreters for the Deaf (RID, 2007a). The use of interpreting services also is gaining advocacy within healthcare systems (Sleptsova, Hofer, Morina, & Langewitz, 2014). An interpreter provides an important linguistic and cultural link between the patient, clinician, and the healthcare system itself.

The use of qualified interpreters early in the sequence of *mental health* service interventions also is associated with better clinical practice and has been shown to be more cost-effective in light of the potential fiscal consequences of inadequate diagnosis and poor referral decisions (Bischoff et al., 2003). As healthcare systems develop and increasingly adopt policies regarding LEP patients and interpreters, it is important that interpreters and clinicians alike understand key issues in psychiatric practice that impact the nature and quality of interpreting work, such as how clinical interviews are optimally mediated by interpreters, including the mental status examination (MSE). The remainder of this chapter describes the MSE (and its variants), common challenges when interpreting for the MSE, tips for managing such challenges, strategies for effective collaboration with medical clinicians, and concludes with information regarding the current state of scholarship in the field of mental health interpreting and training opportunities for interpreters who seek to improve their knowledge and skills in the mental health arena.

BACKGROUND

What is the Mental Status Exam? The MSE is an important component of many clinical interviews. Its results can inform the patient's history, diagnosis, and treatment plan (Barnhill, 2014). All medical clinicians are trained to do the MSE, but it is most often used by clinicians in the mental health field. Its frequent use and value are comparable to taking a patient's vital signs in other fields of medicine. So why does this matter for interpreters? A patient's preferred language and culture must be taken into account when conducting and interpreting the results of the MSE. Linguistically and culturally, the patient must be able to understand the MSE questions and communicate their answers, while the clinician must be able to interpret the patient's responses in light of potential linguistic and cultural differences between clinician and patient (Pollard, 1998a; Norris, Clark & Shipley, 2016). Interpreters play a crucial role in ensuring that these linguistic and cultural elements are accurately conveyed and considered in this important phase of a patient's clinical assessment and care.

The MSE can be thought of as a broad cross-sectional assessment of a patient's cognitive and emotional state and capacities. While the MSE most frequently is conducted with patients being served in mental health settings, MSEs also may be conducted in primary care and other medical settings – whenever a patient's cognitive and emotional state and capacities are in question or simply must be documented. The MSE will most certainly be conducted during a mental health clinician's first contact with a patient and may be repeated frequently with the same patient, particularly in emergency or inpatient psychiatric settings. The interaction that comprises the MSE can vary considerably in length – being briefer when the MSE is repeated with a patient whose previous MSE results already have been documented or when

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

a clinician has little question that a patient's basic cognitive and emotional state are intact and unremarkable. An effective MSE can provide crucial data for immediate diagnostic and treatment decisions and inform more longitudinal mental health perspectives (Barnhill, 2014).

The assessment of mental status begins the moment the clinician meets the patient – at least it has begun in the *thought world* (Dean & Pollard, 2013) of the clinician. While some aspects of the MSE may include specific questions posed to the patient, for the most part, MSE data is gathered through observation and seemingly casual conversation, where the clinician is attuned to listening for key MSE information as the patient relays their story or answers broad questions (Robinson, 2008).

Though at times seemingly informal, the MSE nevertheless is a multifaceted clinical tool that involves a set of standardized observations and inquiries that reveal information regarding multiple domains: sensorium and cognitive functions, perception, thinking, feeling, and behavior (Robinson, 2008). Table 1, based, in part, on Robinson (2008), lists specific topic areas that are assessed under each of these domains. Almost always, a clinician's formal MSE documentation will address each of the topics listed, via the data gathered through observation, informal dialogue, and formal questions.

Table 1. Domains and topics assessed via the mental status exam

Domain	Topics Assessed
Sensorium & Cognitive Functions	• Level of consciousness • Attention • Concentration • Orientation to person, place, date, and situation • Memory (short and long-term) • Fund of knowledge • Intelligence • Capacity for abstract thinking • Reality testing
Perceptual Anomalies	• Hallucinations • Delusions • Illusions • Depersonalization or derealization
Thought and Language	• Quality of speech • Thought content • Thought form • Suicidal and/or homicidal ideation • Insight • Judgment
Emotional Status	• Affect (shorter-term emotional states) • Mood (longer-term emotional states)
Behavior	• Appearance (e.g., hygiene) • Posture and gait • Motor activity • Degree of openness regarding the interview • Attitude toward the examiner

While clinicians will document most or all of the above topics in the patient's medical record after conducting the MSE, to an untrained observer (including many interpreters) the interview that yields MSE data may not appear to be an "examination" at all. If open-ended questions do not yield some of the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

desired MSE data, the clinician will usually ask more specific questions that focus on key MSE topics. Sometimes, patients will be asked to respond to specific MSE-related questions (e.g., "What is today's date?") or perform certain tasks (e.g., copy a drawing or follow a written command). (More on this topic in the next section.) Some clinicians use MSE checklists to gather key data in a more structured manner.

MAIN FOCUS OF THE CHAPTER: INTERPRETING FOR AN MSE

Assuming that interpreters are familiar with the complications and nuances of working in a bilingual-bicultural environment and working in mental health settings in particular (Pollard, 1998a; Tribe & Lane, 2009; RID, 2007c, Vernon & Miller, 2001), interpreting for the MSE when it is conducted in a conversational manner should not be particularly difficult. Of course, any time a translation challenge or relevant cultural issue arises, one should inform or educate the clinician about that challenge or issue. Asking a clinician to rephrase a question that was difficult to translate or explaining why a translation is difficult or noting how a question or topic bears particular cultural relevance are common choices an interpreter might make in such situations. But bear in mind each of the topics presented in Table 1 since the clinician will desire specific data regarding them.

For example, communication regarding, emotions, mood, unusual thoughts or sensory experiences, are particularly important to convey because they are not easily observed. Also not easily recognized by the clinician will be relevant characteristics of *how* the LEP individual is communicating. Is their speech (or sign language) unusually fast or slow or odd in other ways (see the section on "dysfluency" below)? Are the thoughts expressed by the patient (e.g., communications with the spirit world) possibly considered unusual in the clinician's culture but common in the patient's culture? Anticipating these important possibilities before they arise is the best preparation for interpreting during the MSE.

Specific Questions and Procedures Sometimes Used During the MSE

Beyond what may appear to be typical conversation about a patient's emotions, life difficulties, etc., there are many specific questions and procedures that may come up during the MSE. Each of these questions or procedures relates to one or more of the topics listed in Table 1. Interpreters should be prepared to encounter these questions and procedures, some of which may seem unfamiliar or strange. Some patients express surprise or even annoyance that these questions or tasks are asked of them, especially when they feel that the clinician is digressing from addressing the concerns that brought them to the facility. It is usually sufficient for the interpreter (or better yet, the clinician) to explain that these questions or tasks are presented "to everyone" or otherwise convey that, in mental health settings, these questions or tasks are common.

Regarding the topic of orientation, clinicians may ask the patient to state who they are, where they are, the day and date, or even ask questions that should involve common knowledge such as who the president of the United States is.

Regarding attention and concentration, clinicians may ask patients to do arithmetic problems in their head (not on paper) such as a task known as *serial 7s* (Teng, 2018). Here, a patient is usually asked to subtract 7 from 100 (the correct answer is 93) but then continue subtracting by 7s (e.g., 93 – 7 = 86, 86 – 7 = 79, etc.) for a short while. Another common technique is to ask the patient to spell a familiar word backwards. Often, the clinician will choose the word "world" (where the correct answer would be

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

d-l-r-o-w). However, if one has translated the word "world" into the patient's preferred language (e.g., "mundo" in Spanish), the task would be problematic or not make sense at all unless the clinician was informed that the word "world" was changed to another word via the translation. In the video accompanying *Mental Health Interpreting: A Mentored Curriculum* (Pollard, 1998a), a Spanish language interpreter encounters this problem and asks the clinician if he wants the patient to spell *world* or *mundo* backwards.

Regarding short-term memory, clinicians may ask patients to remember a short list of words, then recall them perhaps 20 minutes later. In some cases, when a patient has difficulty recalling one or more of the words, the clinician may give them a hint (e.g., "It was a color.") or even offer multiple choices (e.g., "Was it red, blue, or green?")

Other procedures are intended to investigate the patient's language functioning. One such strategy is asking the patient to comply with a sequence of verbal commands (spoken or written) beginning with one-step commands (e.g., "Close your eyes") and progressing to more complex commands with multiple steps (e.g., "Point to the ceiling, then point to the door, and then to the main source of light in this room"). Another technique may involve asking a patient to read aloud from a paragraph or from a list of single words. Patients may be asked to spontaneously generate a written sentence. When these language-based MSE tasks are administered, especially involving reading or writing, LEP patients may not be able to respond or respond inappropriately which could be mistaken for symptoms of cognitive impairment. Interpreters should immediately discuss with the clinician any potential challenges in assessing patients using these language-based techniques, including how translation of spoken instructions (or responses) might affect the results.

Other MSE tasks may involve writing, drawing, or other motor functions. Patients are sometimes asked to copy a drawing that is shown to them, using another piece of paper. These drawings are usually geometric figures such as two oblong hexagons that intersect. Sometimes, patients are asked to perform an imaginary motor function such as threading a needle. A common procedure is to ask patients to draw a clock (that is, an analog clock face, not a digital clock) and set the hands of the clock at "ten past eleven". This specific wording, in English, is critical to the task; saying "ten minutes past eleven o-clock" would disrupt the information the clinician is looking for. This part of the clock drawing command presents translation difficulties in many languages and the clinician should be informed of this.

Finally, in assessing abstract reasoning, it is common for clinicians to ask patients to explain the meaning of a proverb. English language proverbs such as "people who live in glass houses shouldn't throw stones" or "a rolling stone gathers no moss" might be presented. Here, the clinician is looking for an abstract versus a concrete explanation of the proverb's meaning. While some LEP individuals may be familiar with the proverb(s) presented or be able to figure out an abstract explanation even if they are not familiar with the proverb, it is typical for LEP individuals to be unfamiliar with proverbs in a language in which they are not fluent. Again, clinicians should be alerted to this problem if a proverb inquiry is made during the MSE.

Other Potential Complications When Interpreting for the MSE

The Bilingual, Bicultural Environment and Fund of Information

Interpreters know that, frequently, differences between two languages cannot easily be bridged, especially in a word-for-word way. Unfortunately, clinicians who are monolingual may not understand this and erroneously presume that whatever is said in one language can be mapped, in a direct fashion, to words

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that have similar meaning in the other language. Dean and Pollard (2005) offer useful guidance to readers who do not fully understand the nature of interpreting work which sometimes requires translation strategies that are unknown, even unexpected, by monolinguals.

Interpreters also make translation and behavioral decisions based on cultural and contextual variables in the service environment, as well as their own experiences as members of an LEP community (since most interpreters' first language is the non-English language with which they were raised). Interpreters are usually the only person in the room who truly understand the bilingual, bicultural factors at play. This information could directly impact a clinician's ability to achieve the objectives of a MSE and/or other evaluation and treatment goals and must be openly discussed (Raval, 2003). Differentiating between bilingual, bicultural factors that are truly relevant to the situation from those that may reflect the interpreter's own personal themes, biases and assumptions – especially in mental health settings – is a valuable outcome of such frank discussions (Tribe & Lane, 2009).

LEP individuals may be immigrants, refugees, or deaf persons who have had difficulty acquiring a spoken/written language such as English (which is common in the deaf population). One consequence of limited proficiency in a majority culture's language, or less familiarity with that culture itself (as is often the case with immigrants and refugees) is a lower "fund of information" (Pollard, 1998b) regarding the country or culture in which they now live, regardless of one's intelligence or educational attainment. Fund of information deficits are the result of multiple factors that impede access to information in the majority language (e.g., radio, television, magazines, overheard conversations, etc.). When LEP or deaf patients "don't know things" that a clinician assumes are common knowledge, errors in MSE conclusions can result. Deficits in fund of information also can hinder a patient's understanding of, and cooperation with evaluation and treatment in mental health and other medical settings. Gathering information about communication and learning history in both family and school contexts can help to differentiate between fund of information gaps, limited intellect, and mental health symptoms.

Dysfluency

It is not unusual in psychiatric settings to encounter patients whose primary language is not fluent or even proficient (i.e., their language is "dysfluent"). Certain mental illnesses and neurological conditions can interfere with individuals' thought processes, language abilities, or both. For example, psychotic illnesses, mania, strokes, dementia, drug or alcohol intoxication, and certain developmental disorders all may cause language dysfluency symptoms. Dysfluency generally takes one of three forms: (1) a general lack of language proficiency that significantly impairs communication with the individual or (2) specific, disruptive errors in language use that are atypical of average users of that language, but which do not significantly impair communication, or (3) language articulation problems that are not suggestive of a thought disorder per se (e.g., slurred speech). All of these forms of dysfluency are important to notice and convey to clinicians – the interpreter is typically the only person in the room who has the ability to notice such language problems.

Since virtually all (hearing) persons are proficient, if not fluent, in their preferred language, even seemingly minor dysfluent language events *might* be indicative of important psychiatric or neurological impairments. For this reason, mental health clinicians are taught to attend to even the subtlest of language dysfluency events. Andreasen (1980) describes no fewer than 20 specific types of language dysfluency that may be observed in psychiatric settings, giving examples of each type (as manifested by native English speakers with psychiatric disorders).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Here is an example of obvious, general dysfluency, directly quoted from a native English-speaking patient with schizophrenia who was responding to a psychiatric interview captured on film in a training video series for mental health clinicians (Wohl & Csernansky, 1994):

Well there the before on the clock, that's the 6, 7, 8, 9, 10, 11, 12, 1, 2, 3. They go by those numbers of the clock. And when you do the 25 after that's the after side of the clock. We go by the 1, 2, 3, 4 and 5 of the clock and the 5 you go right left to 7 number on the clock is the 5 number. You go right left to that number. That's what the 25 is. If you don't do something they tell you to do and Jesus makes the shotgun sound and then phone rang not to answer the phone or the doorbell.

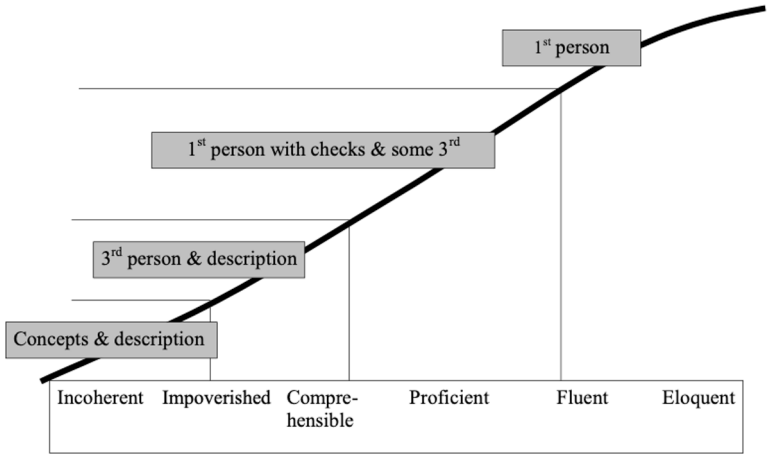
This language sample is so disturbed that it would be nearly impossible to translate accurately. There is simply not enough logic or structure in the patient's language to convey sufficient meaning to the interpreter to allow her/him to form a coherent translation into the target language. (In the interpreting field, we denote that interpreters are receiving an utterance in one language, the "source language," and translating it into another language, the "target language"[1]). Dysfluent language of this severity is most certainly evidence of significant psychiatric or neurological impairment. If the interpreter translated only those parts of this utterance that she/he understood, in effect, "cleaning up" the language sample and failing to convey to the clinician the severe dysfluency that was otherwise evident, critical diagnostic information would be hidden from the clinician's awareness. The key here is to note that the patient's language, in large part, is not coherent. An interpreter's assumption of, or search for meaning in this language sample would be both fruitless and counter-productive. Below, we will address what an interpreter still can do to be helpful to the clinician, even when confronted with such severe language dysfluency.

Here is a different language sample demonstrating a much *less* severe degree of dysfluency that is nevertheless significant enough to have diagnostic relevance. It is also a direct quotation from a native English-speaking patient from the same diagnostic interview film series cited above. She is discussing the death of her mother. This patient was filmed during the manic phase of bipolar illness.

She had cancer of the spinal cord when I was 11-years-old and they had to take out her back, eight inches of her back out to kill the cancerous tumor. So that means she was paralyzed from her breast down for 21 years of her life. She died the age of the year I was born, '61. I believe everything has a purpose under heaven…I believe that's the time that God wrote down she is going to die before she hit her 62nd birthday. She was going to die and be my guardian angel at 61 of the year I was born.

Notice this patient's unusual phrasing involving numbers as well as her reference to her mother being paralyzed from "the breast down." Other portions of this interview revealed that the patient expressed a great deal of sexualized ideation. Native English speakers might say that a person was paralyzed from the "neck" down, the "waist" down, etc., but not the "breast" down. The several odd references to numbers in this language sample are even more noticeable. The severity of language dysfluency is subtler than in the earlier language sample and does not impair understanding as severely. Yet, even these language anomalies are diagnostically relevant. Again, ignoring such language anomalies or "cleaning up" the language in one's translation would hide important diagnostic information from the clinician.

While encountering language dysfluency is one of the most challenging aspects of interpreting in mental health settings, it is also one of the most important – where the interpreter's response to this challenge typically holds diagnostic and/or treatment significance. Most interpreters who work in com-



EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

munity settings have not encountered language dysfluency associated with psychiatric or neurological disorders, but it is not unusual to encounter in mental health settings. Despite the challenges involved, there are still helpful ways the interpreter can respond.

Again, the first rule is to not "clean up" dysfluent language or otherwise speculate what the patient "probably means" and then provide the clinician with a fluent, coherent (and misleading) target language translation. While a verbatim translation may not be possible when a patient's language is seriously dysfluent, interpreters still have options.

Figure 1 below portrays different options interpreters have when encountering dysfluent language. At the base of the figure is a scale of language dysfluency where fluent or even eloquent language is depicted on the right end of the scale. When language is of good quality, as depicted here, interpreters will normally translate in the first person and have little difficulty. Remember, here we are referring to the patient's preferred or best language. While most individuals are fluent in their preferred language some patients with psychiatric or neurological disorders are not. Thus, fluency (and logic) should never be presumed when interpreting in a mental health setting.

Figure 1. Translation options when confronted with language dysfluency

The middle portion of the scale is meant to depict language that is somewhat poorer in quality, such as proficient (but not fluent) language or language that is comprehensible (i.e., generally understandable, for the most part) but not even proficient in quality. Here, an interpreter will usually translate in the first person, when the language is good enough to allow this, but will often need to ask the patient to repeat or clarify what they said. Another option in this range of language dysfluency is to switch from first person translation to "third person" translation (e.g., "He was describing a physical fight he had with a friend, but it is not clear if this happened recently or long ago or which person punched which person first"). While a third person translation does not provide the clinician with the exact detail that the interpreter might desire, it still provides the "gist" of the language sample and further alerts the clinician that the interpreter is having difficulty translating the patient's language, therefore making the clinician aware that there is probably a degree of dysfluency being manifested by the patient. If the clinician truly cares about the unclear content, she/he can interrupt and ask the patient to clarify. But, more likely, the clini-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

cian may want to know (later) from the interpreter the nature of the translation difficulty she/he observed when the switch to third person took place. Such information may well reveal the type of dysfluency the patient was manifesting (Andreasen, 1980).

At the left end of the scale at the bottom of Figure 1, are the terms "MLS" (meaning "minimally language skilled"), where very little of the patient's language is clear and/or logical and "incoherent," where virtually none of what the patient is communicating is understandable. Again, this certainly can happen when patients have severe psychiatric or neurological impairment, but interpreters still can be tremendously helpful in such situations. As shown in Figure 1, while first person translation in such situations is likely impossible, there might be segments of the patient's language that are sufficiently understandable for a third person translation. But even when that is not possible, interpreters can still *describe* what they are observing in the patient's language. Such description can be extremely helpful to clinicians who are trained in identifying different forms of language dysfluency.

For example, there is a dysfluency symptom known as "clanging" in which patients are drawn to the structure of the language they are using and not the logic of what they are attempting to say. With hearing patients who "clang" they may put together a sentence with words that rhyme or begin with the same sound but, together, the sentence does not make sense. Deaf patients who clang also are drawn to the structure of sign language (and lose sight of the logic of their communication) by putting together a sentence that uses several signs involving the same handshape but, again, which do not make sense as a complete utterance. Since clinicians working with interpreters will not recognize rhyming, sign language handshapes, etc., the only way they might suspect that a patient might be clanging is for the interpreter to inform them that these types of phenomena are occurring.

While clanging is only one example of the many language dysfluency symptoms one might encounter, two key points remain – interpreters should always explain to the clinician (either in the moment or afterward, as the situation warrants) unusual language events that they observe and, second, never insert clarity or logic in a patient's language utterances when such clarity or logic is weak or absent. Failure in either regard "hides" potentially crucial diagnostic and/or treatment information from the clinician that may well impede or curtail the treatment that the dysfluent patient deserves.

Interpreter-Clinician Partnership in Mental Health Interpreting

When interpreters and clinicians work together in providing access to care for patients whose first language is not English, there are multiple benefits for all, especially patients. The following section offers considerations in developing a collaborative relationship and environment for the interpreting of MSEs, others psychiatric interviews, and medical appointments generally.

Like other venues of interdisciplinary teamwork, in medical contexts, preparation helps clinicians and interpreters work together most effectively. Interpreters should be recognized as fellow "practice professionals" (Dean & Pollard, 2013, 2018) on the service team. Familiarizing oneself with local interpreting agencies, national interpreter organizations and their codes of ethics or professional conduct, and specific guidelines for working with interpreters in medical and mental health settings can be very useful (Tribe & Morrissey, 2004). Written guidelines and contracts about interpreters in medical settings can include specifics regarding confidentiality, roles and responsibilities, and other professional and ethical issues (Sills, 1997). Introducing interpreters to key hospital or office staff, inviting their participation in continuing education lectures or courses and relevant meetings helps integrate interpreters with the broader

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

medical team and environment (Tribe & Sanders, 2003). Clinicians could also provide a dictionary of medical terms available for interpreters to consult (Tribe & Morrissey, 2003).

Hiring qualified interpreters who have experience, training, and are comfortable in mental health and/or medical settings is valuable for many reasons, but is especially important when initial diagnostic (e.g., MSE) and treatment planning decisions are being made. Determining the client's preferred language, including dialect, and finding an appropriate interpreter with a background in both the patient's preferred language and mental health work is often a challenge that can be streamlined when interpreter referral agencies and clinicians work together. If possible, interpreters and patients should be matched for gender, age and religion, particularly if this is relevant to the meeting or consultation (e.g., in cases of sexual assault or intimate partner violence) (Patel, 2003; Nijad, 2003). If multiple appointments are anticipated and the patient and interpreters agree, then the same interpreter should be requested for ongoing appointments whenever possible. When that is not possible, interpreters should be encouraged to pass along key information about the assignment (e.g., key names and relationships that are discussed, important facts that have been established, etc.) to new interpreters who will be involved so that continuity of communication can be maximized between the clinician(s) and multiple interpreters.

Interpreted appointments almost always take more time than appointments where clinicians and patients speak the same language and schedules should be planned to accommodate that extra time. A 10-15 minute "pre-session" before the appointment begins, in order to explain the purpose of the meeting and clarify any technical concepts, vocabulary or jargon, cultural issues, and nonverbal communication norms that may arise should take place whenever possible. If using technical vocabulary or procedures other than discussion is anticipated, familiarizing the interpreter with these terms or procedures beforehand can allow for smoother communication during the appointment (Tribe & Morrissey, 2004). Even planning the physical arrangement of the environment, so that it is conducive to a three-way conversation is helpful (Tribe & Morrissey, 2004).

The value in taking the time to prepare in advance for interpreter-clinician collaborations cannot be overstated. Beyond the interpreters and clinicians themselves, interpreter service agencies, office managers, and human resources personnel also can be helpful in this preparatory stage.

If pre-appointment preparation is done well, this maximizes the likelihood that the clinician and interpreter can concentrate effectively on their respective duties during the appointment itself. Ultimately, when the appointment begins, the clinician, interpreter, and patient should all feel comfortable; it should be obvious to the patient that these fellow practice professionals "know what they're doing." Leading off with an open discussion, where all involved acknowledge that interpreted conversations present unique challenges is fundamental (Tribe & Morrissey, 2004). This can be achieved by first clarifying the interpreter's professional role and addressing confidentiality boundaries (Tribe & Sanders, 2003).

Being mindful of pacing and turn-taking is especially important when working with interpreters. They cannot interpret for more than one person speaking at a time and, as noted, words or concepts in one language do not always have exact equivalents in another language, sometimes requiring extra time for an effective bilingual, bicultural translation. Clinicians and interpreters should not discuss anything in front of the patient that is not intended for the patient to understand. That is, all communication conducted in the patient's presence should be translated. If issues arise which require private discussion between the interpreter and clinician, the interpreter can explain this to the patient and a break can be taken so that the interpreter and clinician can confer or, better yet, these things can be discussed in private before or after the meeting (Razban, 2003; Baylav, 2003). Particularly in mental health settings, it also is advised

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that interpreters not be alone with the patient/family without the clinician present (e.g., in a waiting room) to maximize confidentiality and professional boundary-keeping.

The collaboration between clinicians and interpreters should continue after the appointment as well. The appointment experience is often rich with communication dynamics, curiosities, and ideas for feedback that can be discussed during a short debriefing session. Any translation, cross-cultural or other challenges the interpreter noticed should be shared with the clinician. Debriefing on how well the clinician and interpreter worked together as a team is another important topic which may involve questions or even constructive criticism regarding their working partnership. Discussing arrangements for future communications and appointments also can occur at this point. This "post-session" is a wonderful opportunity for these practice professionals to share information and resources that may help one-another continue to develop their skills in bilingual, bicultural mental health work.

Continuing Education and Mental Health Interpreting

The lack of well-regulated training for interpreters is an issue in many countries (Dean & Pollard, 2001; Tribe & Sanders, 2003; Hwa-Froelich & Westby, 2003). Interpreter qualifications, training, and other professional and even legal requirements vary widely (Tribe & Morrissey, 2003). The effectiveness of interpreter preparedness and on-the-job judgement, whether regarding translation, behavioral, or ethical decisions depend a great deal on their familiarity with the setting in which they are working (Dean & Pollard, 2013). Unfortunately, interpreters often function or are trained as "generalists" – as if their bilingualism and cross-cultural knowledge prepares them to work with equal effectiveness in any setting. This is quite inaccurate. Medical and mental health settings, legal settings, and educational settings, especially post-secondary ones, present particular challenges regarding the requisite knowledge, vocabulary, and experience to perform competently as an interpreter (Pollard, 1998a, RID 2007a, 2007b, 2007c).

An interpreter's role is complex and demanding. Their work requires a variety of skills, including knowledge of specialist terminology, ability to reflect on meaning, memory skills and the ability to convey accurately the meaning of the content expressed (Tribe & Morrissey, 2003). Interpreters benefit greatly from continuing education, support, and supervision (Dean & Pollard, 2009, 2013). Interpreters who work in mental health settings also may need supervision and consultation resources around matters such as therapeutic boundaries, confidentiality, therapeutic practice, and the consequences of communicating traumatic material (e.g., vicarious trauma). Interpreter organizations should consider how to incorporate mentoring, consultation, and supervision into continuing education programs for all interpreters, especially those working in mental health and medical specialties.

Two organizations have created certification processes for medical interpreters: the Certification Commission for Healthcare Interpreters (CCHI) and the International Medical Interpreters Association (IMIA). The CCHI exam assesses healthcare terminology, interactions with other healthcare professionals, interpreting encounters, and cultural responsiveness and includes consecutive and simultaneous interpretation in addition to sight translations. The IMIA Certified Medical Interpreter status is available for Spanish and nearly 30 other languages and requires successful completion of written and oral exams (VanderWielen, 2014).

The United States presents a mix of state legislation and individual organization policies regarding medical interpreting. Even though the above two national organizations provide certification processes for medical interpreters, various state certification programs also exist. Pollard (1998a) developed a popular mental health interpreting training curriculum conducive to various interpreter training environments

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

(e.g., small group, large group, individual, etc.) Other notable resources for mental health interpreter training include the Alabama Department of Mental Health's Mental Health Interpreter Training (MHIT) program, the CATIE Center's mental health interpreter training program at St. Catherine's University, Cambridge College's Mental Health Interpreter Certificate program, the Cross Cultural Communication Institute (CCCI) Mental Health Interpreter Certificate, the University of Minnesota's Interpreting in Refugee Mental Health Settings training, a program run by the National Latino Behavioral Health Association (NLBHA), and the National Asian American Pacific Islander Mental Health Association (NAAPIMHA) Mental Health Interpreter Training Program (MHITP). In 1978, the U.S. Congress passed the Federal Court Interpreters Act, mandating that the U.S. courts establish a program to facilitate the use of certified and otherwise qualified interpreters in judicial proceedings instituted by the United States (VanderWielen, 2014).

CONCLUSION

The presence of qualified interpreters in mental health settings is gaining popularity. The benefits to patient access and satisfaction in healthcare, diagnosis, and treatment are many. The MSE is a central component of assessment in mental health settings that is used to examine and document various aspects of a patient's cognitive and emotional functioning. Some elements that impact interpreting for the MSE lie in the assessment techniques utilized by clinicians and some in the challenges that LEP patients may present (e.g., dysfluency, fund of information gaps). A collaborative and open relationship between clinicians and interpreters is the key to conducting a proficient MSE and bridging the gaps between the clinician, patient, and interpreter. Utilizing cooperative guidelines helps to organize interpreter and clinician roles and responsibilities before, during and after interpreter-mediated appointments. Supporting the progress of mental health interpreter training and certification programs is essential to promoting the vital role of interpreters in mental health care.

Chapter 33
Ageing and Mental Health:
A Psychological Aspect of Later Life

Neelam Verma
Talk to Cure, India

ABSTRACT

Estimated research findings suggest that almost two-thirds of adults with psychiatric conditions do not receive the required treatment services. This chapter enables readers to understand various aspects of ageing, how physical and mental health aspects are correlated, and which mental health conditions are most common in later life. The chapter also discusses major models of mental health in the context of ageing. Major psychiatric and psychological conditions that are most common in old age are outlined along with a major milestone of old age (i.e., retirement: a major lifestyle change that pushes older people towards psychological problems and adjustment issues with a new phase of life). A brief description is presented on the current status of psychiatric and psychological services for mental health issues of the elderly. The chapter concludes by summarizing the contents of discussed areas. Studies are presented throughout the chapter to accompany and enrich the discussion and validate the chapter content.

INTRODUCTION

When we talk about ageing and mental health it undoubtedly involves studying geriatrics. Geriatrics involves medical paradigms of old age such as clinical conditions and strategies to treat them. In psychology, a branch especially devoted to study ageing and provision of clinical services for older adults is *Geropsychology*. The field expands knowledge of normal ageing process and develop treatment modalities to address problems that occur when people age. Most individuals enjoy a good time in later life; however, American Psychological Association says that it is anticipated that the number of older adults with mental and behavioural health problems will almost quadruple from 4 million in 1970 to 15 million in 2030. Mental health conditions adversely affect the ability to function especially in later ages. World Health Organization (1948) defines health as "a state of complete physical, mental and social wellbeing and not merely the absence of disease or infirmity." Since the description of health includes mental health and wellbeing, it must be taken into account that psychological health is an important paradigm of

one's overall health including older adults, and need to be recognized and treated with equal urgency as required for other physical illnesses. A conceptual definition given by Baltes and Baltes (1990a) explains normal ageing as" ageing without biological or mental pathology". It thus concerns the ageing process that is dominant within a society for persons who are not suffering from a manifest illness. Further in their conceptual framework optimal ageing has been referred as a kind of utopia; namely, "ageing under development-enhancing and age friendly environmental conditions" and pathological ageing characterizes an "ageing process determined by medical aetiology and syndromes of illness".

If we see the above definition of normal ageing which says that "normal ageing does not include manifestation of illness*"* it will be difficult to justify the fact presented by Centres for Disease Control and Prevention and the Merck Company Foundation [CDC & MCF](2007) which advocates that "chronic disease is typical of the experience of ageing". According to their database, in United States more than 80% older have at least one chronic medical illness and 65% older have at least two chronic medical illnesses. For example, Arthritis is considered to be an age-related illness but old age does not manifest its occurrence because every older does not suffer from this condition. Also, the functional ability or disability which is an important part of old age which affects the ageing process. Functional disability could be present physically (weakness, deterioration in physical health, inability to walk properly or slow walking etc.) or mentally (stress, irritability, and deterioration in cognitive skills). These functional manifestations of ageing are commonly seen in our own family members who are getting aged. Often, presence of physical illnesses leads to psychological issues or vice versa. According to Cohen (1992):

- Psychogenic stress (or stress that has psychogenic basis) may lead to health issues.
- Medical illnesses or other health problems may lead to emergence of psychiatric conditions.
- Interaction of coexisting mental and physical health problems may lead to occurrence of other psychological or physical health issues.
- Social and psychosocial resources may affect the course of psychological or physical health problems.

Plethora of literature talks about conceptual, statistical and functional aspects of ageing and mental health but there is lot more to explore. Further contents of the chapter will unfold other aspects of ageing and related mental health issues.

MAJOR MODELS OF MENTAL HEALTH IN CONTEXT OF AGEING

Psychodynamic Model

Psychodynamic model of psychological functioning is considered to be the oldest, yet most comprehensive model in context of psychological wellbeing and disorders. Its contribution as mental health model in later life was relatively late but the presented facts turned out to be as good as presented in the very first theory of this school proposed by Sigmund Freud; originally called psychoanalytic model. Journey from psychoanalytic model to psychodynamic model involved contribution of many legends of the field. Explanation of psychodynamic theory revolves around basic personality structure, developmental process and interpersonal relationships. This school of thought emphasizes on the complex interrelation among cognitive, emotional and motivational forces that work on formation of personality. As psychoanalytic

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

explanation of personality development emphasizes a linkage between childhood experiences and development of adult personality, the theory in context of later life advocates strong correlation between adult personality and old age. Precisely, the theory says that elderly come to their latter part of lives extremely influenced not only by their childhood experiences, but also by their adult episodes and adaptations made during that phase of life. According to Newton and his colleagues (1986) the individual enters later life with a personality structure that reflects a long history of life experiences. In later life the adult confronts age correlated events (retirement, physical changes and illness, loss through death of friends and family) and the internal psychological changes can re-evoke unresolved conflicts. Despite of external events being important for adjustment with ageing process, individuals' basic personality has been found to be the mediator of adaptation in old age. Hildebrand (1982) explained that how difficulties in later life affect the mental health of elderly. these difficulties included fear of diminution/loss of sexual potency, threat of redundancy in work roles or being replaced by younger people, the need to reconsider and perhaps remake the marital relationship after children left, awareness of one's own ageing, illness and possible dependence, awareness that what one can achieve now is limited, the feeling of having failed as a parent, loss of partner and of intimacy, and the fact of one's own death in terms of narcissistic loss and pain. Mental health in later life demands overcoming all these fears and threats, and those who are able to negotiate them are said to have a good mental health. Cohler (1993); Schiff and Cohler (2001) emphasized the importance of '*deriving meaning'* as a major component of mental health in old age. According to their perspective, meaning must be worked out for the entire life cycle in the form of a coherent '*narrative'* that explains the continuity of an individual's life in the face of interruptions and adverse events, and those who fail to establish this integrity and unable to preserve or build a coherent narrative suffer from mental health issues in later life. Psychodynamic theory explains the nature of old age mental health issues with following assumptions or causal factors:

- **Childhood Losses Re-Enact as Losses in Old Age:** The model emphasizes importance of childhood trauma or loss and its impact on intra-psychic structures. Adaptive capacity is affected especially in cases of loss of attachment figure in childhood and grief caused by that evokes the anxiety of living in an unprotected world (due to loss of attachment figure). Wounds of childhood trauma or bad experiences definitely leave their scars that affect an individual for the whole life. Significant losses in old age evoke re-experience of negative feelings or grief experienced in childhood and increase vulnerability to get affected easily in similar situations.
- **Underdeveloped Self or Immature Defences Cause Insufficient Strength to Deal with Psychological Challenges of Later Life:** As discussed earlier about Erikson's developmental tasks in different ages, it is important to note that developmental tasks keep changing in every stage of development and those who have not mastered the earlier stage face difficulty while facing the current developmental task. It affects the ability to adapt in new situations. Gutman (1987) establishes a relationship between personality defences and loss using immune system analogy. He advocates that loss is dominated only when one's personality is vulnerable to the loss and those are affected most with losses of old age who adapted to early losses in immature ways. Precisely saying, an underdeveloped self, exaggerates the capacity of loss to induce or provoke pathology in later life.
- **Decline or Loss of Physical, Emotional and Cognitive Strengths Weakens the Functioning of Ego:** Self psychologists have pointed out the negative impact of physical and functional decline on self-esteem and balancing it by finding restitution for loss. If the surroundings of an older adult are

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

not supportive enough or they fail to maintain the ego functioning they might use compensatory mechanisms (possibly pathological in nature) like putting the blame on others for their losses or remembering or recounting past achievements and glories.

- **Personal Narratives Cannot Integrate with Events and Transitions of Later Life:** Life constructs of earlier adulthood may be inadequate or insufficient to integrate experiences and expectations of old age into personal narratives requiring a developmental shift or transition and inability to make the transition may lead to develop vulnerability towards personal fragmentation.

Psychodynamic model focuses on the transitions of inner processes over the life span of an individual. It emphasizes the development of strategies to cope with the imbalance between inner life and outer world and how interpersonal dynamics in old age continue to have a great impact on quality of life.

Eriksonian Psychosocial Development Model

Erik Erikson's model is an epigenetic model of psychosocial development which describes human development across life. It comprises of a series of eight developmental challenges from infancy to old age where every stage is a foundation for the next stage. The theory emphasizes that not meeting the developmental challenges adequately in midlife results in stagnation and emotional despair in later life (Erikson, 1984; Erikson & Erikson, 1998). The eight stages of development comprise of two opposing statements representing the challenges faced by a person at a particular stage. Following description provides a glimpse of eight stages and their significance for later life and associated mental health aspects.

1. **Trust vs. Mistrust:** This stage belongs to infancy in which infants receive care from their primary care givers. If the care is consistent, predictable and reliable they develop a sense of trust and virtue of hope. Failure to meet the needs of this stage leads to mistrust in all other relationships made in future. This may also result in anxiety and insecurity in later life.
2. **Autonomy vs. Shame and Doubt:** This is the stage of discovering skills by learning to do self tasks such as walking, buttoning, putting on clothes etc. children allowed and encouraged to learn with trial and error are thought to be more confidant and develop the virtue of will. on the contrary, children who are not given ample opportunity to learn or consistently criticized for accidents made during this learning begin to feel inadequate in their skills and suffer from low self esteem and a sense of failure in later stages of life.
3. **Initiative vs. Guilt:** At this stage, individuals begin to plan and initiate activities with playmates. If given opportunity, they develop skills to lead others and make decisions. Conversely, if they are excessively controlled or criticised in their decisions or initiatives they develop a sense of guilt. This leads to control them always and they lack in self initiatives throughout their lives. If a healthy balance is maintained between initiative and guilt it leads to the virtue of purpose which helps them in retaining a good psychological health in later stages of life.
4. **Industry vs. Inferiority:** Teachers play an important role at this stage of development as the child learns to read, write, perform sums etc. Peer group has a greater significance at this stage and a major source of child's self esteem. Encouragement and reinforcement to take initiatives and perform tasks successfully develops a sense of pride in the children and they feel confident to achieve goals later in life. Conversely, if they are restricted to initiate tasks by teachers and parents they begin to feel inferior and start doubting their potentials. If a healthy balance is maintained between

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

competence and modesty, it leads to the virtue of competence which is one of the major aspects of life satisfaction and sense of achievement. Subsequently, it helps in carrying out all tasks of personal and professional life confidently and developing a sense of fulfilment in late life.

5. **Identity vs. Role Confusion:** This stage belongs to the search of self and personal identity by exploring personal values, beliefs and goals. The person learns and explores about what role he or she will occupy as an adult. Also, it involves exploration of two identities i.e. sexual and occupational. Accepting the body image and understanding the physiological changes during adolescence leads to the virtue of fidelity which is important to accept others and maintain relationships in further stages or adulthood. Failure to establish an understanding of self may cause role confusion and identity crisis which results in rebellion tendencies, negative identity and feelings of unhappiness with self. Such feelings result in poor mental health in later life when a person goes to other physiological changes and loss of physiological and cognitive skills.
6. **Intimacy vs. Isolation:** This stage belongs to formation of relationships with others and commitments for long term with people other than family. Successful completion of this stage results in healthy relationships, fulfilment of commitments, a sense of security and safety and care in other relationships. On the contrary, avoiding intimacy, fear from committing to others and hesitation to form intimate relationships leads to isolation and loneliness. Successful completion of this stage leads to the virtue of love that helps in maintaining close and intimate relationships.
7. **Generativity vs. Stagnation:** This stage belongs to the establishment of career, settlement in personal and professional life, beginning and raising family/children and a sense of being responsible. Successful completion of this stage leads to the virtue of care; however, those who fail to succeed at this stage suffer from stagnation and feel unproductive.
8. **Ego Integrity vs. Despair:** In context of ageing, this is the most important stage of this model. Individuals are considered senior citizens at this stage as the productivity goes low and they explore life as a retired person. This is the time where an individual cherishes accomplishments of life and develops a sense of integrity through what has been achieved in life. Successful completion of this stage leads to the virtue of wisdom which provides a sense of completeness and develop acceptance of death as a natural process without fear and regrets. If an individual at this stage sees his or her life unproductive and regrets for the decisions made in earlier stages, it leads to dissatisfaction, despair and often depression characterized by hopelessness.

The theory advocates that if the challenges of one stage are not resolved they are likely to affect further stages and stay as a problem in later life. Each and every stage has a major contribution in an individual's life; however, Generativity may have particular significance in context of ageing as it is linked with emotional and cognitive capacities; an important functional aspect of later life (Mc. Adams, 2001; Slater, 2003). Erikson; 1950, proposed a series of developmental tasks in adult life such as forming intimate relationships, being productive and committing to guide younger generation (experiencing generativity), and coming to terms with past and future in the face of upcoming death with wisdom (experiencing ego integrity). According to him, those who failed to meet these developmental challenges successfully in their adulthood were thought to be more vulnerable to emotional distress as they aged. Other sources indicate that integrity versus despair and disgust are more often associated with later life as mature forms of psychological achievements in adulthood are integrated into a comprehensive sense of wisdom in old age (Erikson et al., 1986, pp. 55-56). Consistent with Erikson's model, a wide range of research findings suggests that relationships, work and identity formed in social contexts have

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

important implication for healthy ageing (Cohen, 2004; Everard, Lach, Fisher, & Baum, 2000; Sato et al., 2008; Thomas, 2011). However, more researches are needed to establish links between Erikson's developmental model and cognitive and psychological functioning of people ageing.

Cognitive Behavioural Model

Cognitive behavioural model is an integration of two distinct approaches i.e. *cognitive* and *behavioural* which turned out great together. Cognitive model emphasizes the importance of thoughts and belief system to maladaptive behaviours and negative emotions. Dobson and Dozois(2001); Dozois, Frewen and Covin (2006)suggested that all cognitive theories share three fundamental hypotheses i.e. 1. Cognition affects emotion and behaviour 2. Cognition can be monitored and changed 3. Cognitive alteration can bring desired emotional and behavioural changes. The behavioural model focuses on behaviour rather than emotion, motives or biological factors. This model suggests that an individual's behaviour is the result of interaction between the person and environment and according to the principles of learning theory it supports the notion that environmental cues influence the acquisition, performance rate and termination of certain behaviours. The model supports primarily observable behaviours; however, some internal behaviour like feelings and thoughts are equally covered under the basic learning principles that are possible to modify through behavioural management techniques. In behavioural approach, the term "mentally healthy" has an alternative term called "adaptation" which denotes capacity to effectively meet one's own needs within the environment. Individuals unable to adapt to their environment are said to have mental health issues due to certain factors such as 1. Learning maladaptive behaviours or frameworks, 2. Inability to learn appropriate behaviours due to poor or unsupportive learning environment, and 3. Poor self-regulation or responding to wrong environmental contingencies. Cognitive behavioural paradigm of mental health for older adults (similar for other population as well) focuses on patterns of thoughts, values, belief system and behaviours leading to adaptation and adjustment in the current environment or impairment in one's functioning. Here, especially with elderly, the process of adjustment might be challenging because of some common challenges associated with age and decline in overall functioning. This limited functional ability restricts them to respond appropriately to environmental contingencies. Conversely, freedom from responsibilities (Looking after family, career, education of children etc.) makes them more responsive towards social situations or stimuli. Baltes and Baltes (1990b) advocate that older adults show high rates of adaptability or "behavioural plasticity" to modify their behaviour and adjust to the changing capacities and environment. This adaptation takes place through selective optimization and compensation for the lost skills. Some research findings suggest that the life in nursing homes is highly challenging for older adults in reference to their mental health as it limits the environmental stimulation (all work is done by the hospital staff), thus their responsiveness towards environmental changes fails to adapt and adjust (Molinary, 2000; Rosowsky, Casciani, & Arnold, 2008; Snowden, Sato, & Roy-Byrne, 2003).

The cognitive behavioural model enables to understand a framework in which problem behaviour is easily identified and treated. Knight and Satre (1999); Satre, Knight and David (2006) emphasized the significance of this model for cognitively intact elderly to treat conditions like depression, anxiety, insomnia etc. Some other treatments, especially more behaviourally focused (for example, incontinence program, improving activities of daily living, self-care etc.) have been found to be successful even on cognitively impaired older adults.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Stress and Coping Model

This model presents a stress and coping perspective especially to work with elderly. Research work done by Aldwin (2007) suggested that it is useful to see stress and coping mechanisms as a process with three major elements i.e. 1. Strain an internal state of an individual, 2. Stressors; external events, and 3. Transactions: an experience derived from the interaction between an individual and his/her environment.

Strain encompasses physiological reactions of an individual such as sympathetic activation, parasympathetic suppression, neuroendocrine changes, and changes in immune functions, and emotional reactions such as positive or negative feelings, emotional numbness etc. Studies on mind body relationship are not new in the field but such researches have worked behind studying a relatively new field i.e. psychoneuroimmunology (PNI) that studies the interaction between physiological processes, nervous system and immune system of human body. Gruenewald and Kemeny (2007) studied and suggested substantial link between clinical depression and adverse immune response and geriatric population has been found to be most affected by this condition. Penedo and Dahn (2005) studied a similar line and established a correlation among stress caused by being diagnosed with cancer and its treatment, other stressors of life and subsequent health status. It thus clarifies that the stress does affect the immune system and there is an established link between the two.

Stressors are the events or conditions that cause stress or strain in an individual. Having problems in marriage, being victimized in a crime, death of a loved one are few examples of traumatic experiences that cause stress. Similarly, there could be other types of stressors like physical environment (weather), stress related to individual role (daughter to care for ageing parents, single parent to give healthy upbringing to children), and stress related to routine hazards such as traffic, conveyance etc. stress and stressors are distinct from each other in terms of their occurrence as stress is generally chronic but stressors are mostly acute. An individual faces stress in various contexts in a life span and when it comes to older adults it is even important. In cases of older adults social, historical and physical/non-normative contexts play a very important role in generating stress and it all concerns a series of events for them as being in a later age makes them see these things throughout their life span. An older would be a witness of all three contexts thus would be influenced by all three categories. Age graded influences cover entering school or passing out from college, history graded influences cover a particular historic period in which the individual has lived such as world war, terrorist attacks in country or a natural disaster. Non-normative influences are usually unexpected and may occur at any point of life such as loss of a loved one at a time when it is unlikely to happen or a big financial loss in business. Krause (1995a) suggested significant influence of financial strain on social and mental wellbeing of older adults. Its significance was found to be prominent for depressive symptoms and physical illness as well.

Transactions are the third important element as well as highlighting a cognitive dimension of the stress process. It summarizes the interaction between person and environment with a basic assumption that a person's perception of the stressor affects his or her coping response. Performance in final exams may have a different dimension for different students. Some may take it as a challenge for their intellectual skills; some may see it as a threat to their mental health and wellbeing, while others may take it as an opportunity to enhance their knowledge in the course topics. The perception of performance for final exams would influence the action of the students. In this process, appraisal of the intensity of stressor also plays an important role and it is said that stressors appraised with stronger intensity generate stronger emotional and physiological responses. Lazarus and colleagues explained coping based on perception of stress as problem focused and emotion focused coping. Problem focused coping focuses

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

on altering the problem whereas emotion focused coping focuses on regulating the stress causing emotions. According to Lazarus and Folkman (1984) problem focused coping is implemented where there is an amenability to change the situation and emotion focused coping is used where nothing can be done to alter the situation. A person's style of coping depends on how a person perceives the stressful event and in many cases individual's use the combination of both styles to cope with a problem. Skaff (2007) presented perception in terms of 'Sense of control' over the event as a central element and a classic study done by Zautra, Reich and Newsome (1995) found links between sense of control, loss of autonomy and mental health amongst elderly. Their study focused on mental health of elderly in view of adapting to a phase of loss of autonomy caused by either decline in physical or mental abilities or due to loss or bereavement. Results showed high association between sense of personal control over events and positive mental health. Review of the results and literature by Skaff (2007) suggested that entering into old age with a strong sense of control is highly adaptive and promotes wellbeing of elderly.

Although the researches have been synthesized well in this field but the findings may not be implemented on every older adult. Thus, according to Gatz, Kasl-Godley, & Karel (1996) the approach needs to be more pragmatic as coping with stress involves an individual factor and said to be a function of three major elements i.e. 1. Level of vulnerability (includes genetic effect, acquired biological vulnerabilities and physiological factors affecting adaptation of the individual such as pessimistic tendency, poor problem solving and communication skills), 2. Stress being encountered (includes psychosocial and environmental elements and individual's way of perceiving the stress), and 3. Protective factors (include biological, social and psychological elements that help to moderate the stress by being physically active, having effective coping strategies or having a good social support network).

This model helps to understand that how the interaction between person and environment (i.e. individual capacities and environmental characteristics) affect the development and course of psychological disorder and influence the mental health and well-being of elderly. This area of work is highly progressive; however, caution needs to be taken while implementing this model in research work as we are still in process of learning about stress, coping and ageing altogether. Despite of limited knowledge this framework could be utilized while working with elderly and challenges of their life.

Family Systems Model

A family systems model focuses on interrelatedness of elderly with their families. It explores importance of considering ways in which their positive mental health is enhanced by supporting and smoothening the family functioning. Also, the model assesses the possibility of family dysfunctions that might be causing deterioration in mental health of elderly. In today's world where we have made communications limited to texting and phone calls, it is a positive fact that despite of isolation and abandonment of elderly from their families, they have been found to have regular contact with their children. In a research done by Troll & Bengtson (1993) it was found that even very old parents around the age of 85 years managed to have weekly face to face meetings and high frequency of phone calls/letters/greeting cards or gifts with at least one of their children. In this context, technology has been found to have a positive impact on parent- child relationship in old age when children are mostly far from their parents either for education or for occupation. According to Pruchno, Blow, and Smyer (1984) families are primary components of the "life event web" in which the ripple effects of major life changes are felt. Parent-child ties are very important yet crucial to understand. In early years parents provide care to their children and as ageing takes place the role reverses and children are expected to be the caregiver of their parents; however, the latter

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

one is not guaranteed. Still, the care giving process from parents goes on for their children throughout their lives as they grow and need assistance from their parents for career, marriage, nurturance of their own children, marital conflicts, and divorce, physical or psychological illness and so on. According to Fingerman et al. (2009) an older adult being taken care by their children and great grandchildren is a common image in society and accurate as well because care giving and care receiving are important functions of families and later-life families. Indeed, families serve plenty of other functions for older adults other than just providing needed care such as providing mutual support in times of stress, help indecision making, sharing views on family tasks, celebrating individual developmental milestones etc. There are changes in the quality of relationship with family members and older adults that take place with time and as the person ages. Qualls (1995a) advocates that in a lifetime there are three major life transitions that cause restructuring of family relationships namely 1. Emptying and re-emptying of the nest, 2. Retirement, and 3. Onset of chronic physical illness. These life transitions affect various aspects of family relationships like time structure, individual roles, communication among family members, power balance, gap between generations and nurturance. Despite of such changes families often find an organization in new relationship patterns and familial structure.

The systems model also emphasizes on social context and conceptualizes family as a social unit. Thus, the problems are acknowledged to reside in the social unit (family) rather than an individual (family members facing the problem). Although the problems are particularly faced by one single individual, it is more distressing if the social unit is unable to manage it effectively. An elderly in the family suffering from Alzheimer's diseases would be a concern for everyone and if the problem is not being managed well by the family members it will worsen the wellbeing of the elderly and caregivers as well. Systems approach advocates that social units promoting fulfilment of family members needs are considered to be functional and those who are unable to do so or inhibit the process are considered problematic. Hence, mental health of elderly in systems model is not conceptualized on individual level, it is rather a mutual concept as everyone affects others and vice-versa. Families with poor functional structure are likely to face problems and unable to meet demands of family members throughout the life span including later life. However, many times even well-functioning families are stuck in problems and unable to adapt to the situation. Family with a demented family member would definitely face problems while taking care of the individual if they are unaware of basic issues related to that condition. Inability to provide appropriate care causes stress among family members and also affects the quality of relationship. The model also emphasizes on examining the interpersonal environment of family as mental health of older adults is highly influenced by the family characteristics and dynamics. The basis to demonstrate impact and utility of systems model for elderly's mental health is limited but the research works done by Qualls and Noecker (2009); Shields, King and Wynne (1995); Gaugler et al. (2008) and Mittelman et al.(1996) are promising. More empirical work is needed to establish the importance of systems model in context of elderly's mental health; however, available researches and their outcomes cannot be discarded.

MAJOR PSYCHIATRIC AND PSYCHOLOGICAL CONDITIONS OF LATER LIFE

As our loved ones grow old they are likely to have changes in their life that are common in old age such as normal forgetfulness, decreased attention, physical illnesses etc. According to National Institute of Mental Health, about 20% of individuals aged 55 years or older face mental health issues, but unfortunately around one in three of them do not receive required clinical attention. A major problem to detect

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

psychiatric condition in older adults concerns physiological disorders that usually lead to secondary psychological or psychiatric disorders and overlap while diagnosing the problem. Many times even the common physical and emotional stressors in old age might be a cause of concern and put elderly at risk of developing major psychiatric conditions. The Geriatric Mental Health Foundation has proposed some conditions that may trigger the onset or development of psychiatric disorders in elderly such as physical disability, long term illness (like cancer or CVDs), Alzheimer's disease causing dementia, medical conditions affecting cognitive processing such as thyroid or adrenal disease, change of environment, illness and death of loved ones, interactions of medication, substance/alcohol abuse, and malnutrition or poor diet pattern. Gatz and her colleagues (1996) suggested three types of influential factors causing development of mental health conditions i.e. 1. Individual's level of vulnerability (biological and physiological factors affecting the risk of developing such conditions), 2. Stress (both kind of stressors like environmental and social stressors could cause development of psychiatric conditions in elderly), and 3. Protective factors (psychological, biological and social buffers for development of psychiatric conditions in old age). They suggest that risk factors and protective factors together make the individual susceptible to develop mental disorders.

There are some other demographic factors also that contribute to the psychiatric conditions among elderly. A study done by Singh, Kumar and Reddy (2012) suggested depression to be the most common problem amongst elderly. Other conditions included anxiety disorder, substance abuse, organic disorder and alcohol dependence respectively. Prevalence of psychiatric disorders was reported to be high in the illiterate population as compared to the literate population and females were reported to be more affected by psychiatric conditions as compared to males. Usually it is thought that older living in the old age homes have poor mental health, but results of this study turned out to be surprising as elderly living in community were found to have high rates of psychiatric disorders as compared to those living in old age homes. Based on empirical work following are some of the major psychiatric and psychological conditions seen in later life including conditions related to cognitive impairments:

Delirium

Delirium is a common condition causing cognitive impairment in older adults. Inouye et al. (2014b) defines Delirium as a state of acute and sudden change in attention and overall cognitive function is a serious medical problem for older persons which are often fatal. It is found to be the most frequent concern of older persons aged 65 years needing hospitalization. The condition is often unrecognized despite of its increased rate of incidence and prevalence, and poor prognosis put patients at risk of developing long term cognitive impairments (Pandharipande et al., 2013; Rudolph et al., 2010, Saczynski et al., 2012). Delirium is a potent risk factor for increased rate of mortality and illness among elderly along with long term care placement (Saxena & Lawley, 2009).

Dementia

According to American Psychiatric Association (2000) Dementias are a class of brain disorder characterized by irreversible declines in cognitive functioning that interfere with social and occupational functioning of an individual. It is most commonly seen in older adults because of its high prevalence in old age. It is estimated that approximately 35.6 million people had dementia worldwide in the year 2010. In this account, the population with dementia is expected to be 65.7 million in the year 2030 and 115.4

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

million in the year 2050 (Prince et al. 2013). According to the Alzheimer's Association, approximately 5.2 million Americans have Alzheimer's disease (most common cause of dementia) and it is estimated as the sixth leading cause of death in United States (Theis et al., 2013). Major risk factor for dementia is ageing and gender has been identified as another risk factor for development of this condition as females being at higher side of the risk (Sheshadri et al., 2008).

Depression

Depressive disorder is believed to be normative with ageing; however, the rate of this condition is relatively lower in older adults as compared to younger adults. Despite of its lower rate among older adults many studies based on the epidemiological framework consistently report presence of clinically significant depression among around 15-25% elderly. Thus, the condition must be taken seriously especially if encountered in later life. Many times the symptoms might be so minor that they do not meet the diagnostic criteria of any of the category specified for depression in the classification system; however, the impact of even minor symptoms of depression on physical and mental health cannot be denied. A review study done by Fiske et al. (2009) indicated that institutionalization could be a risk factor for depression in later life as nursing home residents reported an increase in symptoms. Old age is a phase of life where people go through so many changes in their own life and their surroundings. Loss of a loved one, limited resources for enjoyment, and poor social and familial support along with poor coping mechanisms may contribute to the development of depressive symptoms (Zarit&Zarit, 2007). Another study highlighted Depression being a prevalent and disabling condition in elderly increasing the rate of mortality and negatively influencing quality of life (Sivertsen, Bjorklof, Engedal, Salbaek & Helvik, 2015).

Schizophrenia

Views on schizophrenia were first presented by Kraepelin (1971) as Dementia Praecox because the condition resulted in progressive deterioration in an individual's cognitive and functional ability. Initiation of this condition was believed to be in young adulthood; however, studies on schizophrenia and ageing possess strong challenge to this belief. Studies conducted by Reeves and Brister (2008) on older population have resulted in initiation of the disorder in middle and old age. Although the studies vary on the onset of schizophrenia but it's clear that it could be early-onset schizophrenia (occur in late life as lifelong disorder) or late-onset schizophrenia (first occur in old age). While some studies indicate worsening of the cognitive and functional decline symptoms of schizophrenia in old age, other indicate substantial improvement in the symptoms with growing age (Folsom et al., 2009 and Jeste et al., 2003) and rest show elderly struggling with the persistent symptoms throughout the life span (Palmer, Heaton, & Jeste, 1999). Schizophrenia in old age is a challenging situation even for the health practitioners as there are many comorbid situations that complicate the condition. Common factors include medical comorbidity such as hypertension, diabetes, cardio vascular diseases, obesity etc. other factors include substance abuse, cognitive decline and premature institutionalization for elderly (Andrews, Bartels, Xie, & Peacock, 2009; Bartels, 2004; Rystedt & Bartels, 2008). Many times negative symptoms of schizophrenia overlap with the neurological cases having traumatic brain injury (TBI) involving frontal lobe functioning (Jackson, 1984).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Anxiety Disorders

Epidemiology for anxiety disorder suggests its occurrence in older adults more than the depressive disorder. Studies conducted in the United States (Kessler, Berglund, Demler, Jin, & Walters, 2005) and in Canada (Streiner, Cairney, &Veldhuizen, 2006) have signified elderly reporting symptoms sufficiently prominent to be diagnosed under the category of anxiety disorder. Among various categories of anxiety, phobias (Cairney, et.al., 2007) are most commonly reported. Since old age brings so many associated medical conditions it is difficult to establish a clear-cut diagnosis because the symptoms subjectively reported by elderly might be overlapping with symptoms of their medical conditions like heart diseases, hypertension etc. Also, there are various psychiatric disorders that overlap anxiety symptoms, and depression is commonest amongst them (Beekman et al., 2000; Mehta et al., 2003). Depression is also believed to have a neurological and psychological linkage to anxiety (Teachman, Siedlecki, & Magee, 2007). Apart from depression personality disorders (Coolidge, Segal, hook, & Stewart, 2000) and dementia (Twelftree & Qazi, 2006; Fisher & Noll, 1996) are also found to be comorbid with anxiety.

Sexual Disorders

It is believed that older adults are not interested neither capable of sexual activities; however, the recent pharmaceutical advances have made a remarkable impact on sexual functioning of men (Potts, Grace, Vares, &Gavey, 2006). Reduced rate of sexual activities in old age relates largely to the physiological changes among men and women and also it is normative in this age which may not necessarily be a sexual disorder. The rate of sexual activities dramatically drops in persons aged 75-85 years (Lindau et al., 2007). Reason for the same, apart from sexual disorder could be loss of partner, medical conditions and disabilities which affect the access as well as opportunity of sexual activities. Diagnostic criteria for sexual disorder remains same for individuals of all age group (including old age) and most common conditions are erectile dysfunction (genital erection during the sexual activity) and dyspareunia (pain during sexual activity) among men and women respectively and both men and women are vulnerable to sexual dysfunctions due to medical illnesses that interfere with sexual response. Attitude towards sexual activities and sexual response also influences the rate of being sexually active in old age and the findings vary across cultures as well as across gender. It is found that intensity of physical & emotional pleasure and satisfaction is reported to be low by women as compared to men, and western countries reporting higher satisfaction with sexual activities as compared to Asian countries (Laumann et al., 2005). Sexual functioning also has a linkage to cognitive impairments in old age and especially in cases where one partner is a victim and other is the caregiver. It is found that affection and sexual functioning, both declines in couples if any of the partners is diagnosed with dementia (Wright, 1998). Despite of changes in individual's sexual response many would report their sexual functioning satisfying as they are able to cope with the changes caused by ageing without identifying or may be without focusing on them. Another study pointed erectile dysfunction being most common among men and arousal disorder among women; in addition, the study also highlighted that biology plays an important role in male sexual dysfunction whereas psychology plays an important role in female sexual dysfunction (Sathyanarayana, Shajahan, Darshan & Abhinav, 2015).

Sleep Disorders

Sleep disturbances are commoner among elderly than any other age group. Almost half of all older adults experience or reports sleep difficulties at some point of life. Insomnias are most commonly reported by elderly and the pattern of difficulties may involve difficulty initiating or falling asleep, difficulty falling back to sleep after awakening in night-time or early morning awakening. In a study, approximately 15-45% reported difficulty initiating sleep, 20-65% reported interrupted sleep, 15-54% reported terminal insomnia and 10% reported non-restorative insomnia (Ohayon, 2002). Bio-psychosocial model is best to describe the sleep disorders amongst elderly as their condition may be caused by physiological (medication induced insomnia), psychological (due to depression), and social factors (interference due to house hold responsibilities). Chronic illnesses and their treatment drugs have adverse effect on sleep and they may significantly contribute to sleep disorders in old age (Ancoli-Israel & Ayalon, 2006). Psychological causes of sleep disturbances usually involve anxiety, depression, loneliness, worrying etc. (Quan et al., 2005). Social causes behind sleep disturbances may include looking after a cognitively impaired partner who has the tendency to roam around the house during night or due to institutionalization because most day time is spent in bed which decreases or disrupts the sleep during night.

Substance Use/Abuse

Substance use and abuse among elderly is a complicated issue as it is difficult to understand the presentation of effect of substances due to their medical illnesses and drugs being taken for treatment of the same. Also, the misuse of prescribed drugs or medication by elderly is another issue and its use among elderly is common and higher than marijuana. In figures it would lay approximately 0.8% vs. 0.4% (as found in National Survey on Drug Use and Health, 2007). Apart from alcohol, use of prescribed benzodiazepine and opioids has been found to be in frequent use in later age. It is estimated that approximately 20-25% elderly (aged between 50-65 years) have substance abuse problems and consumption of alcohol by them is more than the standard set by National Institute of Health (NIH); however, only 3-5% have diagnosable substance use disorder (Behavioural Health News 2015). It is estimated that by the year 2030 the number of elderly with substance use issues would double especially for prescribed and illegal drugs. A systematic review done by National Survey on Drug and Health (NSDUH) in the United States suggested that more than 2/3rd men and half of women (aged 50 years and above) consume alcohol. Amongst them, the percentage of heavy drinkers was noted as 12.2% and binge drinkers as 3.2%. Approximately 6.7% elderly aged 65 years and above were found as heavy or binge drinkers (Blazer et al., 2009). It is found that women drinkers under 65 years of age are at higher risk of social isolation and economic deprivation (Choi & Dinitto, 2011). Use of other illicit drugs among elderly is rare and there is scarcity in the researches and literature. Initial epidemiological researches reported 11.3% prevalence of alcohol misuse among Indian population aged 55-64 years and 16.8% population aged 65-74 years (Sethi & Trivedi, 1979). One community based study reported 10% prevalence of alcohol use in the population aged below 60 years of age (Gupta et al., 1995). Prevalence of alcohol use disorders is found to be high in urban elderly population as compared to the rural elderly population of India (Nadkarni, Murthy, Crome& Rao, 2013 and Srinivasan, Vaz, & Thomas, 2010).

Personality Disorders

There is little known about the Personality Disorders (PDs) in later life probably because of the difficulty to carry out long term researches with elderly. Reason for the same could be medical conditions of elderly, high dropout rate, and unwillingness to participate in studies. DSM-V (Diagnostic and Statistical Manual of Mental Disorders) defines a personality disorder (PD) as "an enduring pattern of inner experience and behaviour that deviates markedly from the expectations of the individual's culture" (p. 646). This definition implies that maladaptive personality traits occurred during the adolescence or early adulthood may persist in later life; thus have a chronic course of illness. Despite of this assumed chronicity of PDs in later age there are limited resources of knowledge available focusing on PDs in adults aged 65 years or older. An integrative literature review suggested 3-13% of prevalence rate of PDs among elderly (Van Alphen, Derksen, Sadavoy & Rosowsky, 2012). A study conducted by National Epidemiological Survey on Alcohol and Related Conditions (NESARC), which is the largest study on prevalence of PDs in later life suggested that the prevalence of at least one PD in old age was 8% and among various categories of PDs, Obsessive Compulsive PDs covered most of the sample. Along with this, disability, medical and mental conditions of elderly were found to be highly associated with PDs in old age (Schuster, Hoertel, Le Start, Manetti & Limoson, 2013). Despite of limited literature at least recent findings indicate towards an optimistic future of researches to know more about PDs in old age. Having more knowledge about this area would definitely help in developing better assessment tools and treatment plan for elderly with PDs.

Elderly Abuse

Elderly abuse is a community based problem instead of an individual concern. Abuse might be physical, psychological, sexual, verbal, financial, intentional or unintentional. Definition of elderly abuse developed by Action on Elder Abuse in the United States (Action on Elder Abuse Bulletin, 1995) and further adopted by the International Network for Prevention of Elder Abuse says that "Elder abuse is a single or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust which causes harm or distress to an older person." This definition holds a greater impact of outcomes of researches conducted in various countries like Canada, the United States, China, Finland, India, Greece, Ireland, Norway, Israel, Poland and South Africa (Koseberg & Garcia, 1995). Research works focusing on identification of factors for elderly abuse have identified several factors contributing to abusive and neglecting behaviour of family members towards the elderly living in home. Some studies identified cognitive impairment as one of the reason for such abuse (Pillermer, 1988), whereas others denied the fact (Paveza, 1992, and Cooney & Mortimer, 1995). Female elderly have been identified to be at greater risk for abuse due to economical disadvantages (Aitken & Griffin, 1996), on the contrary, male elderly in community based studies were identified to be abused more by their spouses, children and other relatives (Pillermer & Finkelhor, 1988 and Podnieks, 1992). As result of such neglectful and abusive behaviour elderly suffer from depression and psychological distress as compared to their non-abused peers (Bristowe & Collins, 1989; Phillips, 1983). Not only depression, but alienation, guilt, shame, fear, anxiety, denial and post-traumatic stress are also found to have a link with elderly abuse (Booth, Bruno & Marin, 1996 and Goldstein, 1996). Elderly abuse is a sensitive issue and must be taken care of. There is a need for awareness about human rights and prevention of abuse of older people. People working in institutional and community settings must receive a basic training

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

for detection of elderly abuse and offering primary help to them. There is a wide literature available on psychiatric and psychological conditions among elderly; however, only the most common conditions are presented here in this chapter. Apart from the above mentioned conditions there is one paradigm of old age that every employed person faces at a particular time in life. With a time which technically says goodbye to one's career and profession i.e. "Retirement". We will discuss here, how this phase of life affects one's life and how it connects to one's psychological wellbeing.

RETIREMENT: A PHASE OF TRANSITION

Retirement is one of the biggest transition phases of an individual's life as it brings a drastic change in regular life style; however, for some, retirement may be stressing; for others, it may be a relaxing moment. In the literature of psychology retirement has been found to be a potentially stressful factor for retirees (Salami & Samuel, 2010) and researchers have been able to find out causal relationship between retirement and stress caused by that (Hammen & Constance, 2005). Since retirement leads to decrease in financial status it has been found to be linked with decreased subjective wellbeing and lower life satisfaction (Diener et al., 1993). Retirement may also cause decreased social networking which leads to social isolation and further leads to psychological distress (Sugisawa et al., 1997). Many research findings suggest mixed results on retirement and its impact on one's wellbeing. Dave et al. (2006) suggested that retirement causes 6-9% decline in mental health. Another study was conducted by Bonsang, Erik and Klein(2012) on two different samples including people with voluntary and involuntary retirement which indicated that there is no significant effect of voluntary retirement on one's wellbeing, however, the impact was found to be significant in case of involuntary retirement. Although there is less availability of literature on gender differences related to this concern of retirement and mental health as most research work has been done including the male sample. Some available researches suggest that men are found to be more affected by the retirement as compared to women as men report a greater degree of loss of social status after retirement (Barnes, Helen & Parry, 2004). No doubt retirement could be a great source of stress but it could be seen as a reward after long years of consistent work. Many people live even better life after retirement by being physically active and involving themselves in activities they could not participate during their career. They see this phase as exploration of themselves and devote time to their young age passions and hobbies. Staying physically active, being connected to social groups, spending time with spouse, volunteering for social services are some very good examples of healthy retirement.

CURRENT SCENARIO OF ELDERLY MENTAL HEALTH: THE FACT SHEET

It is well recognized that mental health of elderly is a globally neglected issue; however, it has been able to draw attention of mental health care providers in recent times. Required concern and appropriate actions in this direction have made the situation far better and commendable for elderly mental health as elderly are expected to be more active in family and community activities. Concerns of mental health professionals have been able to identify several issues important in elderly mental health such as abuse and maltreatment in old age, stereotypes against active ageing called ageism, poverty in later life, institutionalization etc. Involvement of civil societies, non-government and non-profitable organizations, and mutual efforts of community and mental health care providers are expected to gain good results

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

for promotion of mental health of older persons. In the year 2015, WHO organized the first ministerial conference on global action against dementia that focused on public health and economic challenges posed by Dementia that has been identified as a public health challenge and need action at national and international levels. Dementia and depression have been included in the WHO mental health gap action programme (mhGAP) which aims at improving concerns and care for mental, neurological and substance use disorders by providing guidance and health care services to the elderly. The Institute of Medicine (IOM, 2012) and The Substance Abuse and Mental Health Services Administration (SAMHSA) reported lack of trained professionals working in the field of elderly mental health care and this shortage is likely to increase as the older population grows year by year. It has been confirmed by the researchers that older adults are less likely to receive mental health care services as compared to young adults and even if they receive some amount of care it is least likely to be delivered by a trained geropsychologist (Karel, Gatz & Smyer, 2012). Due to coexisting physical symptoms they are most likely to receive treatment in primary health care centres rather than particular mental health care centres (IOM, 2012). Also, medications are the first line treatment offered to elderly; however, they are rarely offered counselling and psychotherapy as an alternative treatment modality (Koh et al., 2010; Arean et al., 2002).

Mental health care issues of elderly are crucial and need prompt response of mental health care providers. Not only professionals, even family members and social network can modify current scenario of old age problems. They may work as a dignity booster for older adults and play a protective role in treatment outcomes of elderly's mental health and related interventions. Mental health in later age can be tackled well by promoting healthy ageing. Encouraging older people to participate more in meaningful and fruitful activities, bonding with family and peers and being physically active are very good sources of maintaining a good later life. Promoting healthy lifestyle among older adults can bring drastic changes in the current scenario of elderly mental health which requires contribution of mental health care professionals, authorities behind making provisions and policies about elderly mental health care, community and most importantly care givers.

KEY TERMS AND DEFINITIONS

Elderly Mental Health: Elderly mental health refers to conditions affecting mental health aspects of individuals who are ageing.

Geropsychology: A branch of psychology that deals with the process of ageing and related mental health issues. It is also known as geriatric psychology or gerontology.

Mental Healthcare Services: A group or government, private or lay organizations operating at a community/state/national/international level to aid in the prevention and treatment of mental disorders.

Old Age: Old age refers to ages nearing or surpassing the expectancy of human beings, and is thus the end of human life cycle.

Psychological Conditions: A state of mind of an individual with emotional and behavioural problems that need intervention by a mental health professional.

Psychological Wellbeing: It refers to overall satisfaction with one's life characterized by self-acceptance, sense of autonomy, establishment of quality ties to others, pursuit of meaningful goals, continued growth, and ability to manage complex environment to meet personal needs and values.

Chapter 34
The Social Mandate to Deal With Mental Health:
A Comparison Between Interventions in a Mental Health Center, a School, and a Psychoanalytic Office

Alberta Mazzola
Independent Researcher, Italy

ABSTRACT

The chapter aims to explore the construct of mental health in a psychoanalytic perspective with a psychosocial approach. In particular, the chapter studies mental health by analysing traces to detect social mandate characterizing different mental health agencies. The highlighted hypothesis could be interpreted as that social mandate is a clue of local cultures about mental health, which determine fantasies about mental health issues, grounding on symbolizations shared by professionals, users, and community. The chapter introduces three clinical experiences of interventions, carried out in different contexts: a public mental health service, a public middle school, a psychoanalytic private office. All the presented experiences concern mental health field, even though they are characterized by different features in terms of subjects, methods, professionals, users, and organizations involved. The chapter explores those differences in order to focus on transversal issues.

INTRODUCTION

The wide concept of Mental Health could be considered deeply related to the concept of Well-being, which is even more wider than the first one. For instance, Merriam-Webster dictionary (n.d.) indicates Well-being as *the state of being happy, healthy, or prosperous* and the Cambridge dictionary's definition is (n.d.): *the state of feeling healthy and happy.* All the previous definitions about Well-being include the concept of Health. But what is Health, and in particular, what is Mental Health? Not a question with a

simple or unambiguous answer. This chapter aims to focus on the concept of Mental Health, to explore it by studying different points of view about this topic.

It will be proposed, in particular, to consider Mental Health as a complex topic, historically and locally characterized, a culturally determined object. Getting to the heart of the epistemological matter, this chapter is not going to study Mental Health as a natural object, but as a cultural one. It is not going to take Mental Health as an object passible of being measured with examinations that could be replicated in any time and space, regardless the analyser's involvement. Whereas the chapter is going to explore the concept of Mental Health as a cultural construction, based on symbolizations which are shared in a particular social context, historically and territorially determined, which means characterized by local cultures. In this epistemological perspective, the analyser's point of view it's not something irrelevant or something which should be controlled to clean examination field. Contrariwise researcher's evolvement could be considered as a clue. For instance researcher's fantasies and feelings could be treated as a trace to explore issues' symbolizations in shared local cultures.

In this chapter's perspective, Mental Health is founded on local culture. Namely local cultures found different symbolization about Mental Health in Rome, in Tonga, or in Bangkok.

The author lives and works in Italy, in Rome, she is a Clinical Psychologist and Psychoanalyst, specialist in Psychological Intervention for the Person, Organizations and Communities, with professional experiences in different contexts and organizations dealing with Mental Health.

According with the previously introduced epistemological framework, the initial question can be rearranged as: how could the concept of mental Health be defined?

On 30 March 2018, on its official website, World Health Organization (WHO) describes Mental Health as:

Mental health is an integral and essential component of health. The WHO constitution states: Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity". An important implication of this definition is that mental health is more than just the absence of mental disorders or disabilities. Mental health is a state of well-being in which an individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and is able to make a contribution to his or her community (World Health Organization, 2018).

WHO's definition of Mental Health implies multiple elements which compose a complex concept:

- Mental Health does not coincide with the *absence of mental illness* but it's something more (and it's not exactly defined);
- Mental Health concerns the individual (*realizing his or her own abilities*) and the relations with his/her coexistence contests (*to make a contribution to his or her community*).

WHO identifies a multifactorial concept, composed by individual and relational factors. In accordance with that, this chapter will provide a Psychosocial perspective.

Both in Literature and in internet it is possible to find several interesting works about interventions based on a psychosocial approach. Those psychosocial interventions combine a psychological perspective, mainly concerning an individual target, and social perspective, generally aiming to determine actions on a community level. Whereas, the theoretical and methodological perspective here provided it's something different from that. We assume a Psychosocial perspective not only for interventions but also

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

for analysing phenomena. We aim to explore phenomena concerning the relation between the individual and the social context.

In this perspective, Mental Health is not considered as an individual feature, as an object existing in nature but as a social construction, based on symbolizations that are shared in a particular cultural context. Common symbolizations ground people's fantasies and actions in those contexts they share. Let's think, for instance, to Mental Health agencies' users and professionals, they share symbolizations about what Mental Health agencies are and what they do.

This chapter aims to analyse the concept of Mental Health by studying the social mandate characterizing agencies supposed to deal with it.

In particular, this chapter intends to contribute to the debate on Mental Health, focusing on a question: how is Mental Health perceived by professionals working in different agencies with the mission of deal with it and by their users? The highlighted hypothesis is that users' demand could be considered as a trace of socially shared symbolizations about Mental Health, on which fantasies about agencies' and professionals' utility and social mandate are built on.

The chapter will introduce three experiences of psychological intervention within different organizational contexts in Rome. The first one is a psychoanalytic work with a young woman who turns to the professional because of her anxiety problems.

The second experience refers to a psychosocial project pursuing school inclusion, carried out by a non-profit organization, with middle school classrooms, through walks to explore street art in surrounding urban suburbs. The last one is a psychotherapeutic work with a woman, demanded by a psychiatrist to test her supposed dissociative disorders.

What do these interventions have in common? Experiences so different from each other by subject, method, professionals, users and organizations involved, can all fall into the category of interventions to support Mental Health. The chapter aims to explore those differences in order to identify transversal issues. The highlighted hypothesis is that what seems to characterize Mental Health is precisely the complexity of concept itself that includes a heterogeneity of professional practices and social meanings. This could sound obvious but it is not if you consider diffused cultural trends in sciences, which are globally widespread, such as Evidence-based medicine. Evidence-based medicine refers to an epistemological approach which treats phenomena as objectivable, looking for invariants, supposed to be always valid regardless geographical or historical conditions, namely regardless of local cultures (Bower & Gilbody, 2005).

Evidence-based approach is pervasive in Mental Health field too, determining professional practices grounded on a medicalization process of psychic and relational phenomena, looking for individual invariants. Often, this perspective lead to identify Mental Health with the absence of diagnosis of mental disorders.

Whereas in this chapter's perspective, Mental Health could not be detected by identifying solely individuals as unit of analysis. Contrariwise it is crucial to re-inscribe individuals into relational dynamics and social coexistence system they belong to. In accordance with this unit of analysis's definition, we need to settle specific methodologies that allow to study relationships between individuals and changing social contexts of coexistence.

Hence, this chapter intends to explore heterogeneity by referring to different cultures evoking professional practices and shared meanings in Mental Health field.

It seems necessary to focus cultural premises concerning Mental Health professional practices as a clue to detect how local cultures ground specific object of intervention. Therefore the chapter intends to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

focus on users' and professionals' interpretations about Mental Health and about social mandate to deal with it. These interpretations can be considered as a trace of shared symbolizations which determine common representations of agencies' function, influencing users' demands and provided services.

Furthermore, the chapter intends to analyse social mandate turned to Italian Mental Health agencies by studying institutional documents and also by providing an historical perspective on Italian Mental Health system's development.

BACKGROUND: A LEAD THROUGH COMPLEXITY

This paragraph aims to presents theoretical categories useful to analyse Mental Health construct, as a lead through complexity.

Throughout the chapter, the analysis will proceed basing on an Evidential Paradigm (Ginzburg, 1986). When we refer to the concept of "paradigm", we are implying a connection with an overall conceptual construction (Kuhn, 1970), determining a particular epistemology, grounding a specific research tradition.

We refer to qualitative research perspective, aiming to detect social, individual and situational phenomena by analysing details, inconspicuous aspects, small clues, revealing something bigger and submerged (Demetrio, 1992). Qualitative research's aim is idiographic, focusing on the particular, pursuing to deepen knowledge about the specific case study, instead of looking for general laws (Coggi & Ricchiardi, 2005). The goal is not to reach an "absolute truth", but to get closer to a deeper understanding of investigated phenomena (Caronia, 1997), by studying clues and detecting traces.

In a methodological perspective, we could assert that this chapter practices inductive investigation procedures, namely knowledge originates from the observation of specific collected data. This way to proceed is highlighted in *Myths, emblems and clues* (1986), where Carlo Ginzburg analyses three examples to study their conjectural methods: Giovanni Morelli, an Italian art critic; Sigmund Freud, father of psychoanalysis; Conan Doyle's fictional character, Sherlock Holmes. All the three cases proceed by detecting infinitesimal traces, which lead to the comprehension of a deeper and otherwise unattainable reality. Pictorial marks (for Morelli), clues (for Sherlock Holmes) or symptoms (for Freud) are treated as traces revealing wider phenomena.

Furthermore, the chapter is based on psychoanalytic approach, psychosocially oriented. In accordance with this theoretical framework, the chapter aims to explore Mental Health not through an individualistic perspective but through a relational point of view.

As we previously said, the chapter proposes to consider Mental Health as a complex topic, historically and locally characterized. Mental Health is treated as a culturally issue, not as an object existing in nature by itself. We are not going to take Mental Health as an object passible of being measured with examinations replicable in any time and space, regardless the analyser involvement. Whereas we are going to analyse the concept of Mental Health as a cultural construction, based on symbolizations which are shared in specific social contexts, determined by history and territory, which means determined by local cultures.

Furthermore the chapter proposes to consider Mental Health issues, not as a characteristic of the individual but as the precipitate of collusive systems' failure. Individuals could take decision to react to pain related to collusive systems' failure, turning a demand to agencies symbolized as competent with specific issues.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The concept of collusive systems' failures refers to social systems of coexistence grounding on collusive assets, which fail. This perspective is based on the Theory of Collusion, a psychological psychoanalytic oriented model about emotional dynamic determining social relationships, conceived by Renzo Carli and Rosa Maria Paniccia (2003). In accordance with this model, social construction of reality begins by setting emotional meaning to different aspects of social experience, creating emotional symbolizations shared with people who participate to the same context. Colluding, from the Latin "cum-ludere", properly refers to this process of shared emotional symbolization (Carli & Paniccia, 2003).

In accordance with a psychoanalytic perspective, it's possible to assert that we proceed by constructing events through emotional symbolization of specific aspects of reality. In other words, we can identify reality through emotions concerning our way to symbolize reality's aspects. Furthermore this way to emotionally symbolize events is related to specific local cultures we participate to. Hence we should not presume events evoke emotions, whereas we assert emotions found events' construction. Otherwise, if this highlighted hypothesis is wrong, we wouldn't detect the complex common sense construction, that we could define as a collusive process, functioning in prescribing and protecting emotional system shared in a specific social context.

Individuals could experience a discrepancy between subjective feelings and common sense prescribed emotions. Such kind of experience could entail complex emotional reactions, often felt as painful, and could imply feelings like guilt, shame, social isolation or adaptation inadequacy.

Furthermore, reconsidering Mental Health within this perspective, it is possible to reinterpret individual's requests for psychological support and psychological distress as the precipitate of collusive systems' failure, which concerns the individual experience of a discrepancy between subjective emotions founding reality and common sense prescribed feelings. In accordance with this perspective, collusive process indeed work to socially share emotions grounding experienced events (Carli & Paniccia, 2012).

Hence we could reckon how can psychoanalytic psychotherapy specifically contribute to the debate on Mental Health? A psychoanalytic psychosocially oriented approach could provide criteria to clinically analyse contexts where Mental Health interventions are set, by detecting their peculiar local cultures grounding on collusive systems. In particular, we refer to interventions based on the Analysis of Demand model, whose objective and method concern the development of competence to detect emotions experienced in relations, using them as a trace, as a resource to explore problems encountered within those relations founding on specific collusive systems (Carli & Paniccia, 2003).

Moreover, we propose to focus how the individual, with his subjective decision, defines his state or experience as normal or pathological. Indeed Mental Health professional intervenes only if individual subjectivity comes to the decision to consult him. Therefore medical diagnosis is secondary to a sort of important subjective diagnosis acted by an individual who decides to define himself as diseased (Canguilhem, 1998). Absence of absence of pain is transformed in presence of illness, which could be object of diagnostic procedures. This symbolic process deeply marks the relationship between citizens and Mental Health system. Indeed this symbolic process founds on local culture based on a collusive system which requires an act of "proclaiming himself" as diseased, as a reaction to pain. Through this symbolic and emotional process the individual become "a user". Indeed becoming a user is requirement to establish a relation with Mental Health system. In a collusive dynamic, individual and coexistence context, share symbolic dimension setting the relationship with Mental Health agencies.

Coexistence context's social mandate entail mental diseased person identification, as an individual who because of his "different" behaviour contributes to the failure of conformist social systems.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social mandate requires diversity isolation and institutionalization, to protect collusive system holding social relations founded on common sense emotions.

Social system protect common sense establishment, by requiring that "non-compliant" individuals are assigned to specialized professional organizations. As far as possible, Mental Health agencies are required to seek the *restitutio ad integrum* of those deviating from common sense people (Carli, Paniccia, Caputo, Dolcetti, Finore, & Giovagnoli, 2016). Individual affected by *mental disorders*, as defined as a result of a diagnostic process, they are not "aware" of emotions violating common sense. Otherwise if this awareness is active, then we are faced with "common emotional disorders", therefore with a request for *psychological distress*. In Mental Health assistance system, this difference grounds a distinction between psychiatric and psychological intervention (Carli & Paniccia, 2012).

Finally, we want to highlight possible developments regarding Mental Health system: agencies required with the social mandate of take care of Mental Health, could focus problems in social coexistence, besides diseases by working on demand, local cultures and coexistence issues. Analysing users' demand means dealing with recurrent critical social events and problems, some of which are indications of social emerging emergencies (Vari, 2014).

THREE EXPERIENCES OF INTERVENTION IN THREE DIFFERENT AGENCY DEALING WITH MENTAL HEALTH

This paragraph introduces three clinical experiences in Mental Health field, aiming to explore differences in order to identify transversal issues. In particular, the analysis focus on social mandate which characterize different agencies dealing with Mental Health. Indeed the analysis will consider institutional documents and users' demand, as traces to explore local culture about Mental Health and about organizations dealing with it.

The clinical experiences we are going to present, are carried out by the author, with the role of psychologist, in collaboration with different teams. All the interventions we are going to introduce take place in Rome in 2017-18. They are set in different context: a public Mental Health Service, a psychoanalytic private office, a non-profit organization actualizing a project with a public middle school in the territory of a roman suburb. The data we are going to present are collected by analysing literature and reported clinical experiences, in accordance with a psychoanalytic approach, psychosocially oriented, based on the Analysis of Demand model (Carli & Paniccia, 2003).

A Psychosocial Perspective On A Public Mental Health Service Intervention

To present first intervention, which takes place in a public Mental Health Center, it is necessary to introduce Italian public Mental Health services' current organization, besides providing an historical perspective of its development.

Mental Health Center (for brevity, we will call it CSM, using the Italian acronym) is the organism that on behalf of the Department of Mental Health (for brevity, we will call it DSM) and the Local Institution for Healthcare, up to the Ministry of Healthcare, has the mandate to accept and to filter citizens' requests. The purpose of CSM is to *promote and protect health, both on an individual and a collective level*, for resident population and people standing in its own territory, to allow the best quality of life as possible, by providing services for *prevention, therapy, rehabilitation* (Ministero della Salute, 2006).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

On its official website, Local Institution for Healthcare defines Mental Health as a fundamental area of intervention, aiming to combine actions addressed to *support social inclusion* and actions addressed to *take care of psychic distress, psychiatric disorders and disabilities* (ASL Roma1, n.d.).

In the previous lines, it's possible to spot traces (in italics) of Local Institution for Healthcare's purposes. In particular:

- promote and protect Health, both on an individual and a collective level;
- support social inclusion;
- take care of psychic distress, psychiatric disorders and disabilities.

These definitions show differences about the object of intervention: "individual and collective Health" should not be considered the same concept of "psychiatric disorder", they are different constructs. The concept of "psychiatric disorders" evokes a purely *individual* issue, whereas the concept of "individual and collective Health" refers to a social dimension, evoking *relations* and *coexistence contests*.

"Psychiatric disorders" and "individual and collective Health" could be considered as traces of different shared symbolizations about Mental Health Services' scope.

Organization determines specific goals, which could be considered as traces of organizational social mandate, since social mandate founds on symbolizations about organization's function shared by professionals, users and community it lies in.

Specific symbolizations about organization's social mandate and purposes lead to determine specific goals and to define specific strategies and devices to reach those goals, according with the organization's scopes.

Different symbolizations lead differences in term of paradigms, methodologies and tools for interventions. In a wider perspective, they lead differences in term of representations about professionals' work and relationship with organizations' users (Mazzola, 2018).

It is possible to highlight once again how the notion of Mental Health is wide, complex and composite. It includes several and different constructs, coexisting in a heterogeneous category. In depth, mental disorder and individual or social distress represent two of the objects included in Mental Health category, despite the differences characterizing them.

Mental disorders evoke an individual perspective, with a focus on a person's idiosyncratic patterns and traits. Psychiatry provides theories and tools appropriated to deal with this topic.

On the other hand, the construct of individual and social distress evokes a relational perspective, with a focus on local context of coexistence. Psychology and Psychoanalytic Psychotherapy provide dedicated methodologies to deal with this issue.

What does this difference could be considered as a trace of? To inquire this question we propose to analyse agencies assigned to deal with Mental Health in an historical perspective, from asylum's existence to actual Mental Health services assets' development.

In Italy in 1978, Law No. 180 is approved, promoting a complete reform of psychiatric assistance, determining the progressive replacement of psychiatric asylum with a radically new model of territorial Mental Health service system.

Law's approval takes place under the pressure of deinstitutionalization movements diffused in Trieste and in other areas of Italy. At the time of the promulgation of the law, turnover of patients is minimal.

Law No. 180 aims to promote a cultural change, by asserting that even in psychiatric field Mental Health system must found its bases on person's rights to healthcare, contrariwise the assessment of so-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

cial dangerousness. In accordance with Law's issued values' asset, treatments turn to a voluntary basis. Law No. 180 establishes that no one can be hospitalized in psychiatric hospitals. Despite, in case of hospitalization needed, since Psychiatric asylum are removed, the Psychiatric Diagnosis and Treatment Services of general hospitals carry out clinical treatments.

A law, which dates back to 1904, previously ruled mental Health system in Italy, focusing on a specific social need, which is "protect society from mental disorders".

Process of hospitalizations started after a psychiatric certification and a commissioner's order to alienate civil rights to diagnosed person. Mental Health care was administered by local districts, each of them refers to their own asylum. Law No. 180 starts a process leading to asylums removal, on a national scale. By the end of the '90s, with all asylums' closure, new Mental Health services are introduced, with the aim to ensure mentally diseased people shall conduct their lives in an inclusive social context.

After Law 180's approval, it begins a long lasting process of wide Mental Health system's reorganization, involving administrative and institutional levels. New provisions are introduces on a national and regional basis, new regulatory frameworks are established to progressively determine Mental Health Departments' responsibilities, provided services, settled goals and procedures, involved professionals, determined targets and intervention standards.

In March 1999, Italian Ministry of Health announces the successful final closure of all public asylums. This event could be considered as the ending stage of a poignant cycle, more than two decades lasting. Italian Mental Health system reform represents a long and complex course, with a high historical and symbolical impact on Italian society on different levels, since it evokes heated debates among professionals, family members, administrators, politicians, involving Italian public opinion in a broad sense.

In 1981, Local Departments of Mental Health are established, as institutes entitled to rule territorial district on a technical, administrative and managerial level, programming and providing services, projects and activities.

Residential and housing groups are enhanced to provide accommodation addressed not only to previously hospitalized users but also to new users, never hospitalized before, turning Mental Health services because of precarious living conditions or involved in family conflicts. Mental Health agencies' aim includes rehabilitation, training and socialization, actualized through recreational and leisure activities such as expressive workshops, literacy courses and schooling.

In the mid of the '80s the number of cooperatives involved in Mental Health work placement grow and their range of competences and activities is gradually extended. In the following years, cooperatives increasingly focus on interventions aiming to promote empowerment for people with handicaps and disabilities or affected by addiction problems or social marginalization. Cooperatives work develop in a social entrepreneurship perspective. Cooperatives' social purposes meet Mental Health Departments' ones. Thus in the '90s Departments run a significant work to support Mental Health services' users to fully exercise their citizenship rights, namely as workers. Mental Health Departments and cooperatives' scope connection leads to enlarge cooperatives' business, providing new services and activities addressed to Mental Health services' users. Cooperatives' offer extends to rehabilitation and empowerment programs, with different specific focuses, such as accommodation, work, education and training, social inclusion, network building, self-help groups.

In 1975-1976 the first CSM was established with the purpose of supporting previously hospitalized patients and dealing with new users' crisis. CSMs run as day centers and work to reduce hospitalized patients' number and to shorten hospitalization's duration. It is interesting to highlight that CSMs are

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

introduced before the national reform (Law 180), when asylums are still working. Hence for a while two different organizational and cultural assistance models operate at the same time (IDeaSS Italy, n.d.).

Law No. 180 is considered a worldwide example as a symbol of culture revolution in its field, since it radically changes Mental Health care and assistance methods. It is indicated as the first law in the world which bans asylums, representing a symbolic victory for people who worked for it, determining a huge cultural heritage, entailing nowadays living trains.

In accordance with Carli and Paniccia's work, we propose a psychosocial interpretation of Italian Mental Health system development.

In the '60s, '70s and in the beginning of the '80s italian asylum system collapses. At the same time, an emerging culture spreads. Growing values of equality and minorities protection condemn every act of diversities institutionalizing or marginalization. Meanwhile in that historical period Psychiatry attempts to actualize Mental disorder affected people's reintegration to social and familiar context. A new category it is introduced: "the psychiatric operator", which transversally includes psychiatrists, psychologists, nurses and all mental health professional workers, all together involved in pursuing users' social reintegration. Hence analysing Mental Health services development it is possible to remark that ideological base grounds social reintegration process, determined as attempted outcome. Social reintegration process was based on values rather than dedicated methodologies and differentiated contributions of various professional perspectives, entailing the lack of formalized techniques grounded on specific theories. Hence ideological tension replaces professional technicality.

In the mid of the '80s until the end of the '90s, social reintegration is at first juxtaposed and then replaced by psychotherapies, addressed to new users (as common emotional disorders affected users) and, when it is possible, addressed to traditional psychiatric users. Psychotherapy shows an increasingly clear and specific attempt to take care of mental disorders defined by using DSM psychiatric nosography categories. A pervasive return of technicality occurs, concerning not psychiatric movement but Psychotherapy. Both in Mental Health agencies and in professionals' orientation we see behavioural techniques gradually prevailing over psychoanalytic and systemic approach. Contrariwise the highlighted hypothesis is that a complex phenomenon, as social reintegration is, could not be chased by applying techniques pursuing interventions addressed to specific and limited objects, such as behaviours. Indeed psychoanalytic perspective with a psychosocial approach proposes categories to reinterpret social reintegration phenomenon as a psychosocial intervention within users' relation with coexistence context, where problems defined as mental distress emerge (Carli & Paniccia, 2011).

Furthermore this chapter aims to study Mental Health in a relational and psychosocial perspective grounded on psychoanalytic models, by focusing the area of Mental Health agencies. As we said, the highlighted hypothesis is that users' requests could be considered as traces of social mandate founded on symbolizations shared in local cultures. According with this focus we could inquire: what kind of requests users turn to Mental Health agencies?

Let's introduce a case study, set in a public Mental Health service: a CSM sited in Rome.

A woman turns to CSM because she got episodes of amnesia and disorientation. She asks for neurological examination, to check for the presence of dementia. A CSM psychiatrist visits her and, after excluding dementia, demands her for a psychological visit to verify the presence of dissociation disorder. When the CSM psychologist meets her for the first time and asks about her request, the woman starts crying and telling about her sentiments of anxiety and sadness. The psychologist, who is the author of this chapter, treats the woman's request with the Analysis of Demand approach. The woman reports problems within relations with her coexistence contests. Throughout a psychotherapeutic work, it was

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

possible to reinterpret woman's demand. In this case, the woman emotionally denied her desire in relations, in which she acted with a sacrificial approach. At one point her relational pattern seems not to work anymore for her and she feels disoriented, both in a figurative way (emotionally) and in a proper one (with episodes of amnesia). She feels powerless facing problems with her family and at work and she feels assailed by sentiments of anxiety and sadness. The woman's demand to take care of her relations in crisis is turned to a CSM through a request to check a medical problem (amnesia). We could say the woman *medicalize* her issue, since she transform an emotionally complex relational problem in a request treatable through a medical approach.

Analysing CSM users' requests, it's possible to highlight recurring events like the clinical situation just introduced: in several other encountered cases, CSM receives demands to deal with relational problems, through requests of checking medicalized symptoms.

Not only the woman treats her issue as a symptom, but also CSM psychiatrist does (checking for dementia), properly according with his area of competence and in accordance with the determined goal of dealing with Mental Health, interpreted as mental disorders.

CSM users and professionals seem to share fantasies about CSM as an agency dealing with medical problems. Regarding medical problems, we intend to refer to individual related issues, which are liable of diagnosis and treatments, better if it's a pharmacological one not concerning emotional users' and professionals' subjectivity involvement.

It's worth to report a difference among *individual* and *subjective* level.

Merriam-Webster (n.d.) defines individual as "being an individual or existing as an indivisible whole", where individual is defined as *a particular being or thing as distinguished from a class, species, or collection: such as a single human being as contrasted with a social group or institution*. Instead *subjective* is defined as *relating to the essential being of that which has substance, qualities, attributes, or relations; characteristic of or belonging to reality as perceived rather than as independent of mind*.

It's possible to underline differences among two different constructs: on the one hand, individual as a whole, isolated from a species; on the other hand subjective with relations and perceptions, we could say with emotionally involvement.

According with the highlighted hypothesis about professionals' and users' symbolizations as a trace of social mandate, we could identify CSM as Mental Health agency dealing with individual problems treatable by medicalized approach, in accordance with the purpose of taking care of mental disorders. Whereas, CSM also got the scope of dealing with individual and social distress, which evokes social mandate to deal with users' request as result of relationships and coexisting contexts in crisis, with a focus on users' emotional distress about it.

Furthermore we could say that person who choose to turn Mental Health agency a request for psychological distress is the one who decide to take charge of a problem shared by coexisting system participants (Carli, 2015). As we previously said, we propose to define Mental Health issues not as a characteristic of individual but as precipitate of collusive systems' failure. Individuals could take decision to react to pain concerning coexistence collusive systems' failure, turning a demand to agencies symbolized as competent with specific issues.

We outline a possible development of CSM social function: it could be useful to work on a cross analysis about individual requests reported in a determined territory, to provide a social interpretation about local emerging issues, in order to plan interventions not only for individual treatment but for collective prevention too.

A PSYCHOSOCIAL PERSPECTIVE ON A PSYCHOANALYTIC PRIVATE OFFICE INTERVENTION

Moving to another context, what kind of requests are turned to a psychoanalytic psychotherapist working in a private office?

Let's introduce a case study, set in a psychoanalytic psychotherapeutic private office, located in Rome.

A woman turns psychotherapist because of her feelings of anxiety. She says she is worried about her academic career, since she is afraid not to take last university exams. Throughout a psychotherapeutic work based on Analysis of Demand approach, it is possible to re-interpret the client's demand, who presents issues with her familiar and university contexts. She wondered about her life according with what she expected others would consider the right way for her, but at one point this strategy doesn't work anymore, since she feels a growing anxiety approaching her graduation. She is afraid for her future and feels paralyzed by the idea of taking a choice, facing her resources and her limits to identify desires and chase them.

As for CSM, analysing psychotherapeutic private office clients' demand, it is possible to trace recurring events. Psychoanalytic private office clients' demands often concern emotions perceived as wrong, unacceptable or problematic. These requests found on symbolizations of emotions as something dangerous and to be treated in private, in a confidential and discreet treatment context. Comparing with CSM users' demands, the psychotherapeutic requests are not symbolized as grave because medicalized symptoms, but because idiosyncratic.

In a different way comparing with CSM, the request are often at individual level, too. While, as we said, in CSM the unit of analysis is individual with his own medicalized symptoms, in psychotherapeutic private office social context seems to disappear and everything is an intimate place where to bring personal sentiments. Furthermore emotions could be disconnected by relational context which they are related to. Hence psychotherapeutic private office could be symbolized as a place out of time and space, as a metaphor for inner space, where to fix problems with personal feelings and emotions. These symbolizations could be shared in collusion by professionals and clients, evoking for both of them different related fantasies, such as some of the more widespread: fantasies about a place where to face limitless client's inner world ruled by frightening feelings; fantasies about professional's emotional neutrality (all the field is dedicated to customer's inner word); fantasies about not reportable or analysable professional's procedures because of an emotional nature of the work (perceived in opposition to a rational way to proceed); and so on. Moreover, we may consider psychotherapeutic literature, where there are many contents analysing psychotherapeutic setting of interventions, on the contrary it's hard to find professional contributes on social impact. The topic doesn't seem to provoke a particularly heated debate within the scientific community, if compared to other themes, such as the psychoanalytic setting and its variations. The unit of analysis is one again focused inside the office, detached by the context it lies in.

Document analysis provides other traces about psychotherapeutic private office's social mandate. Searching for Italian laws ruling psychotherapeutic private office's activity, it's possible to discover there are not many documents but the Article No. 41 of the Constitution of the Italian Republic:

Private economic enterprise shall be free. It may not be carried out against the common good or in such a manner that could damage safety, liberty and human dignity. The law shall provide for appropriate programmes and controls so that public and private-sector economic activity may be oriented and coordinated for social purposes (Senato della Repubblica, 1948).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, psychotherapeutic private office, as private economic enterprise, should be *oriented for social purposes* and *shall provide for appropriate programmes and controls.*

What kind of programmes and controls are determined for psychotherapeutic private office's activity?

It is possible to refer to the Art. No. 2229 of the Italian Civil Code (1942) declaring that intellectual professions' exercise requires registration in dedicated registers or lists. Verification of registration requirements, list maintenance and disciplinary power over register's members are delegated to professional associations, under State supervision.

Hence the Constitution of the Italian Republic determines psychotherapeutic private office's activity must aim at social purposes and its activity must be ruled and controlled, switching level, by professional's behaviour.

Also on a legal level, norms concerning contexts (office and its social purposes) are juxtaposed with individual (professional and his behaviour).

Furthermore according with the highlighted hypothesis about professionals' and clients' symbolizations of Mental Health agencies as a trace of social mandate, we could identify psychotherapeutic private office as an agency deputed to deal with individual issues, too. Psychoanalytic psychotherapeutic office is symbolized as an intimate place taking cover from the social context. A place where to fix troubles with personal feeling and emotions, symbolized as idiosyncratic and problematic for the person who turns the request. We suppose psychotherapeutic private office professionals' social mandate is properly to deal with private individual issues.

Whereas, focusing on a psychosocial perspective, it's possible to propose an implied psychotherapeutic private office's social function in developing clients' relationships in coexisting context by working with the person who turns a psychotherapeutic request.

A PSYCHOSOCIAL PERSPECTIVE ON A NON-PROFIT ORGANIZATION INTERVENTION AT SCHOOL

Introducing the third case study, we propose a shift in terms of intervention's target, moving from individual to context. If in the previous two clinical situations, psychological interventions were carried out after an individual's request, in this case a clinical intervention is developed as psychosocial project addressed to a roman public middle school and its classrooms.

Regional district administration wanted to finance projects facing schools' dropout problems.

A non-profit organization composed of psychologists proposes a project whose aim is to develop relation between school and the area in which it is located. The project is based on a reinterpretation of dropout phenomenon, as a student's reaction to sentiments of isolation and uselessness felt within the relation with school coexistence context. The assumption is: if at school it's possible to get interesting activity, you want to get there. The project aim to work with school, at school and in school time, to explore students' interests related to a common object: territory, which school and students' family share. The territory we are talking about is a roman suburb, where most of the students live and where school is sited.

This intervention was carried by a team composed by the author and three colleagues, all of them psychologists. Every professional works with one classroom composed by 15-25 students aged 10-12. On a first stage, the project aims to explore students' interests and connections between interests and territory. Later, all the classrooms work to create a thematic map, linking emotional relevant places

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

with point of interest to discover, planning territory exploratory walks that every classroom takes on its own. In the end, all the groups together plans a final event where the 4 classrooms meets and share their works. Teachers and families are invited to come to the final event to share their thoughts and stories about territory. As we said, every classroom choose a theme to elaborate. The chosen topic are: street art, history, trade and craft, classroom's story, in the surrounding suburb. Indeed the project's main aim is not to work on themes, but to intervene on students' relationship with classmates and the wider coexistence context at school, throughout working on themes.

The project's purpose is to develop relation between school and territory in order to develop the relation between students and school coexistence context, to contrast sentiments of isolation and uselessness, founding dropout phenomenon.

Hence it's possible to underline that this intervention lies in Mental Health field, by a reinterpretation of the construct. Indeed this project proposes a reinterpretation of Mental Health as an issue concerning coexistence system, rather than only related to problematic individuals. Dropout phenomenon is not solely a matter of students, it is actually a matter of sentiments connected to relations in coexistence contests, invoking schools, families and actors sharing a specific territory.

Dropout phenomenon is treated as a trace of risk of social isolation, which requires prevention interventions, according with WHO's definition of Mental Health, previously showed in this chapter: *Mental health is a state of well-being in which an individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and is able to make a contribution to his or her community* (World Health Organization, 2018).

Within this intervention, psychologists assume a psychosocial perspective to propose a reinterpretation of Mental Health interventions as prevention of social isolations.

CONCLUSION

Throughout this chapter, we explored the construct of Mental Health in a psychoanalytic and psychological perspective with a psychosocial approach. In particular, the chapter analyses the construct of Mental Health by studying different organizations aiming to deal with it. The chapter introduces three clinical experiences of Mental Health interventions, actualized in different contexts. It's highlighted how the three proposed experiences represent different ways to regard to Mental Health, showing different users' and professionals' interpretations, defining different kind of interventions. Throughout the chapter we look for traces to detect social mandate characterizing different Mental Health agencies. The highlighted hypothesis is that social mandate is a trace of local culture about Mental Health, which defines fantasies about Mental Health issues, founding on symbolizations shared by professionals, users and community.

The chapter intended to explore differences between Mental Health agencies and their local cultures in order to identify transversal issues. The highlighted hypothesis is that what seems to characterize Mental Health is precisely the complexity of the concept itself which includes a heterogeneity of professional practices and social meaning.

After all, we could say Mental Health is actually a social mandate to intervene. With the purpose of planning interventions aimed to take care of Mental Health, it is important to focus on social mandate, which is locally, historically and culturally connoted.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The first clinical experience introduces CSM local culture, whose social mandate identify a Mental Health agency dealing with individual problems treatable with a medicalized approach, according with the scope of taking care of mental disorders. Whereas CSM purpose of taking care of individual and social distress evokes social mandate to deal with users' request as a result of relationships and coexisting contexts in crisis, with a focus on users' emotional distress about it.

The second clinical experience is set in a psychoanalytic psychotherapeutic private office. It emerges symbolizations about a decontextualized context. In psychotherapeutic office's local culture, the social context seems to disappear and everything is an intimate place where to bring personal feelings detached by the relational context which they are connected to. Thus the office can be defined as a private economic initiative which, according to the Italian Constitution, must be addressed for social purposes. Social function of a psychoanalytic office may seem given for granted but it is not. We suppose psychotherapeutic private office professionals' social mandate is to take care of problems with personal feelings and emotions.

Comparing psychoanalytic psychotherapeutic private office and CSM, it's possible to remark that the requests are often at an individual level in both cases. While, as we said, in CSM the unit of analysis is individual with his own medicalized symptoms, in psychotherapeutic private office the focus is individual with his own idiosyncrasy.

In first and second case, we see interventions addressed to individuals, even though the unit of analysis is the relation between individual and social context. The third case introduces a new difference: the intervention is address on a social level. It's a psychosocial intervention carried out by a non-profit association and addressed to 4 classrooms in a public middle school. The project aims to develop relation between students and school coexistence contexts, to contrast sentiments of isolation and uselessness, founding dropout phenomenon. The association, composed by psychologist, work on the social mandate providing a new interpretation of it: facing dropout, means facing social isolation, as a preventive Mental Health intervention.

In conclusion, all the introduces experiences are based in Mental Health field although they show differences in terms of professionals and teams, targets, goals, tools and context of intervention. However it's possible to underline a transversal dimension: local cultures defines social mandates which determine users' requests and professional's goals of interventions.

Through the analysis of different Mental Health organizations' social mandate, it seems possible to draw a broad and heterogeneous scenario, including the diagnosis for individual to development of knowledge on problems of coexistence systems in crisis.

We could conclude highlighting that what seem to characterize crosswise Mental Health field is the amount of demands dealing with grave sentiments determining intervention's request addressed in first person or for another person.

Indeed Mental Health could be considered as a complex issue concerning local cultures which means concerning coexistence and social level although it relapses on an individual level. We remark that it is important for professionals and agencies dealing with Mental Health to analyse social mandate and users' requests, in order not to settle automatic procedures but to plan organizational developments oriented to social impact.

Chapter 35
Mental Health Education and Literacy in Schools: The Australian Experience

Matthew Dale
Mind Australia, Australia

ABSTRACT

This chapter will look at the current situation concerning youth mental health in Australia and provide information about youth mental health literacy, which was first coined by Jorm in 1997. A literature review of current Australian mental health promotion and education programs being offered in schools will be conducted as well as examples of some of the better-known ones that have been implemented internationally. The evolution of mental health education in Australian schools will be examined so as to provide a perspective of how some of the current programs came into being or existence. The main aim of this chapter will be to highlight the high prevalence of mental illness that exists amongst young people in Australia and how implementing mental health education in schools can be beneficial and helpful in improving their mental health and wellbeing. Mental health education in schools can help in breaking down the stigma surrounding mental illness. Another benefit is that young people will be able to identify mental health problems earlier amongst their peers and in themselves, which can lead to early help seeking, especially due to young people gaining a higher level of mental health literacy through mental health education programs.

INTRODUCTION

Australia has been active during the past 20 years in the development and implementation of Mental Health Policy and Mental Health Promotion. In the Fourth National Mental Health Plan 2009 - 2014 (Commonwealth of Australia, 2009), the Australian government in its wisdom and foresight choose to make Prevention and Early Intervention as its Priority Area 2. In the Summary of Actions (Commonwealth of Australia, 2009) in point one it noted that it would "work with schools, workplaces and communities to deliver programs to improve mental health literacy and enhance resilience" (p.32). Following on from

that it included as a further action to "implement targeted prevention and early intervention programs for children and their families through partnerships between mental health, maternal and child health services, schools and other related organisations" (p.32). One of the indicators for monitoring that this change had been made was to observe the "proportion of primary and secondary schools with mental health literacy components included in their curriculum" (p.32).

It is interesting to note that with all the best intentions of the Australian government to make Prevention and Early Intervention a mental health priority in the Fourth National Mental Health Plan that this was inexplicably missing from the Fifth National Mental Health Plan of 2017 - 2022. The Black Dog Institute in its *'Submission in response to the Draft 5th National Mental Health Plan'* (Back Dog, 2016) said that the plan was "silent on prevention and yet it is potentially a powerful solution to chronic mental illness and should be included as a key strategy" (p.10). It went on to add that "prevention programs are most effective when implemented early" and that they "strongly believed that school-based prevention is critical to reducing the overall burden of mental illness on the community" (p.10).

This chapter will look at the current situation that exists in Australian schools concerning youth mental health and the seriousness of this health problem. It will explore why mental health education in schools is so important and the benefits for implementing it into curriculum. It will also investigate why being mental health literate is significant in improving both peers and a young person's own mental health.

Before examining the various mental health promotion and education programs that currently exist in Australian schools, it will look at what has happened in Australian schools from a historical perspective, including initiatives such as MindMatters and KidsMatter. The Australian experience of mental health education in schools will also be compared to the international experience by examining what exists as well as what has worked and not been so successful overseas.

The chapter will also reflect on what are some of the problems and barriers that exist in implementing mental health education in Australian schools as well as the benefits of introducing it into the school curriculum and the future of mental health education in Australian schools.

YOUTH MENTAL HEALTH IN AUSTRALIA

There has been considerable research and study carried out about the onset of mental illnesses and mental health problems in people, not only in Australia but around the world. The evidence suggests that three in four mental health disorders emerge by the age of 24 and half by the age of 14 (Kessler, Berglund, Demler, Jin, Merikangas, & Walters, 2005; Sawyer, Arney, Baghurst, Clark, Graetz, & Kosky, 2000; McGorry, Purcell, Hickie, & Jorm, 2007). In 2013 - 2014, around a quarter of all young people aged 16-24 years in Australia had a mental disorder (approximately 26% or 671,000 young people). One in seven children and adolescents aged 4 - 17 years experienced a mental disorder in 2013 - 2014, which is equivalent to 14% or 560,00 young people. Depression impacts on the lives of 1 in 35 or 2.8% of young Australians aged 4-17. The statistics for anxiety are even greater where 1 in 10 adolescents aged 18 - 25 and 1 in 25 children aged 13 - 17 experience the condition. (Orygen Youth Health, 2008). Of concern was the fact that there was an increase of probable serious mental illness in the age group 15 - 19 from 18.7% in 2012 to 22.8% in 2016 (Mission Australia, 2016). Lawrence and colleagues (2015) commented that mental disorders were the leading cause of illness and disability for young people aged 10 to 19 years, ahead of any physical disease.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is evidence to support that only about one-third of young people and adolescents with a mental disorder will actually seek help. Of that one-third only about 30% of young people will seek referrals for psychological therapy (McGorry, Purcell, Hickie, & Jorm, 2007; Rickwood, Deane, Wilson, & Ciarrochi, 2005). As can be seen from the previous statistics about youth mental health and mental illness, it is a serious health problem in Australia which something needs to be done about soon. Young people and adults responsible for looking after young people need to improve their mental health literacy so that young people who are presenting with early mental health problems can seek appropriate mental health treatment. Early intervention and prevention is crucial and mental health promotion and education programs in schools, as long as they are implemented properly, will go a long way to addressing some of these problems and concerns.

WHY IMPLEMENT MENTAL HEALTH EDUCATION IN SCHOOLS?

The importance and significance of implementing mental health education in schools, both locally here in Australia as well as overseas cannot be underestimated. Later in this chapter there will be a discussion about the benefits of doing so as well as some of the challenges and implications that present themselves to schools in trying to introduce mental health promotion to the curriculum. Within schools you are able to assemble a captive audience where they can be educated about important mental health and wellbeing information. This can be delivered and rolled out to large numbers of young people at the same time. In Australia, as in most countries, it is compulsory to attend school up until a certain age. In the state of Victoria it is currently 17. Barry and Jenkins (2007) highlighted just how important the emotional and social development of young people is during the time that they attend school and that it provides an excellent opportunity to create a positive environment where they can thrive.

Schools are able to create a sense of community and belonging which will help some young people who are either socially isolated or more at risk of developing mental illness than other students, to be able to maintain good mental health. The onset of mental illness is high in childhood and adolescence. It is well known from the evidence that 75% of all mental illnesses develop before the age of 24 so it makes sense to target this age group with effective, evidence-based mental health education programs so as to be more preventative than reactive, when a young person becomes unwell. By introducing Mental Health Education into schools, it will help to improve mental health outcomes for Australians by reducing the incidence or impact of risk factors while building up people's protective factors and thus help children and adolescents to access support early if difficulties do arise. Well-planned and thought out Mental Health Education programs can also have an impact on improving the mental health literacy of young people and students which in turn can lead to building stronger resilience during adverse times and help in breaking down the stigma that exists in relation to mental illness. The positive outcome of all of this would see young people accessing mental health services earlier. Good mental health in childhood also provides a solid foundation for managing the transition to adolescence and adulthood, engaging successfully in education and making a meaningful contribution to society (KidsMatter, Primary 2017). Working with children and young people is one potentially cost-effective way to address the impact of mental health difficulties in the community, both today and into the future. (Response Ability, 2012).

HISTORICAL CONTEXT OF MENTAL HEALTH EDUCATION IN AUSTRALIAN SCHOOLS

In 1996 the Australian government commissioned an audit to be conducted to look at Mental Health Education in Australian Secondary Schools. It was funded under the National Mental Health Community Awareness Program which was a National Mental Health Strategy initiative designed to reduce the stigma and discrimination experienced by people with a mental illness, their families and carers (Youth Research Centre and Centre for Social Health, 1996). A number of interesting findings from this audit helped guide the Australian government in the future direction of mental health education in Australian schools. It examined the National Curriculum at the time with regard to the school context of welfare while exploring the feasibility of implementing the World Health Organisation's 'Health Promoting Schools' policy.

The audit data focused on such things as what current policies on mental health and mental health education that there were, the perceptions and attitudes towards mental health in schools, particular classroom curriculum approaches, what welfare approaches were being used in schools and the involvement of community and other external agencies in school mental health education as well as what mental health education were available.

An important part of the audit report was to look at what current issues surrounded mental health education in schools as well as what the future direction of it might look like in Australian schools and what current education programs were already in operation. Issues included what actual coverage of mental health education was there in schools?; what professional development was being provided to teaching staff at schools in regards to mental health education?; how much involvement and support were external community and non-government agencies providing to schools?; where does mental health and mental illness education fit into the curriculum?; where can mental illness education be incorporated into existing programs and what medical interventions and suicide prevention programs are being conducted in secondary schools? Out of this audit the Australian government set up a mental health promotion initiative for secondary schools called MindMatters. The success of this would later produce the KidsMatter initiative for primary school students.

MindMatters

The original MindMatters pilot project began in November 1997 and lasted for about 18 months. The role out was delivered in 24 schools which included government and non-government schools. The pilot came about after an audit was completed in 1996, which examined what Mental Health Education there was in Australian secondary schools and if it was an appropriate setting for the promotion of mental health among young people. Upon completion of the evaluation of the MindMatters pilot it was decided to mass produce the resources and to disseminate these to schools with a secondary enrolment across Australia. This was carried out by Australian Principals Associations Professional Development Council and the Curriculum Corporation (Principals Australia Institute, 2017).

KidsMatter Primary

The Australian government saw the benefit of implementing a mental health education initiative such as MindMatters in secondary schools and realised that it might be even more important and beneficial
