to introduce a program that provided intervention for primary school aged children to deal with mental health problems earlier. Hence, KidsMatter Primary was introduced in 2006 and piloted in 101 schools over three years (2006 - 2009). This involved the Australian Psychological Society, the Australian Principals Associations Professional Development Council, beyondblue and the Australian Government Department of Health and Ageing (Principals Australia Institute, 2017).

The Gatehouse Project

The Gatehouse Project was a research project conducted in Victorian secondary schools between 1996 and 2001. Its aim was to promote the health and emotional wellbeing of young people by increasing connectedness and providing skills for managing life's ups and downs. Bond and colleagues (2002) referred to the Gatehouse Project as a school-based primary prevention program that offers a framework for building the capacity of school communities to address the emotional and mental health needs of students. A systematic process was used to create a whole school of change in regard to policies, programs, practices and structures. It was evaluated by using a randomised controlled trial. Findings found a reduction in the health risk behaviours of young people as well as system level changes within schools. The work of the Gatehouse Project is being further developed through the Adolescent Health and Social Environments Program (AHSEP), as well as there being national and international adaptations (Centre for Adolescent Health, 2017). An aim of the Gatehouse Project was to embed mental health promotion within the core business of school; that is to have connectedness to school and engagement with learning. The project used a variety of universal and targeted strategies at multiple levels to promote the emotional wellbeing of students combined with a whole school approach which would enhance and improve the social climate. It recognized that intervention was required for students who were more at risk due to the social environment that they came from (Bond, Butler, Glover, & Patton, 2002). The project identified three key priority areas for action; building a sense of security and trust; enhancing skills and opportunities for good communication; and building a sense of positive regard through valued participation in aspects of school life. The project emphasized the importance of healthy attachments or a sense of positive connection with teachers and peers (Bond, Butler, Glover, & Patton, 2002). The Gatehouse Project provided schools with a process of which to build on and develop new policies, programs and practices from an evidence-based platform. This included the establishment of an adolescent health team, reviews of programs, policies and practices, strategic planning to address risk and protective factors, training and implementation as well as monitoring and evaluation.

CURRENT MENTAL HEALTH EDUCATION PROGRAMS IN AUSTRALIAN SCHOOLS

MindMatters

MindMatters was originally developed by a team of academic researchers and health educational professionals. The 'whole of school' and holistic approach used by MindMatters was informed by the Health Promoting School concept and the Comprehensive School Mental Health Model, both of which were developed by the World Health Organisation (World Health Organisation Regional Office for Europe, 1994). Currently in Australia over 1,400 secondary schools are using MindMatters in some shape or form.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Also, over 10,000 school staff and significant others have attended professional development sessions and in excess of 76,000 modules have been completed. Over 33,000 people are signed up to MindMatters. As can be seen from these figures its use is quite widespread. MindMatters is currently the key national mental health initiative for secondary schools in Australia (Principals Australia Institute, 2017). Principals Australia Institute (2017) defined it on it's website as the following, "It promotes mental health and wellbeing of students in secondary schools through a flexible framework that provides useful professional learning, resources and support. The resources enable staff to work with the school community to implement four components." The initiative is funded by the Australian Government Department of Health with beyondblue being designated as the lead contract for it while Principals Australia Institute staff help to deliver the program in each of the states. The MindMatters mental health framework is built around four key components. These include:

Component 1: Positive school community
Component 2: Student skills for resilience
Component 3: Parents and families
Component 4: Support for students experiencing mental health difficulties

Together these components provide a holistic and comprehensive view of student mental health and wellbeing within the wider school community. Each component is explored through a number of standalone online modules covering different topics. These modules include animation, video, interactive tools and downloadable resources and take around one hour to complete. Each module has a facilitator guide and can be explored individually or in a group. Special face-to-face events and experienced support from Principals Australia Institute project officers complement the online resources and help schools to implement what they have learnt (MindMatters, 2017). Central to the MindMatters philosophy is that of promotion, prevention and early intervention. It is about preventing the onset of early mental health problems through promoting positive mental health through a whole of school community approach and by providing students with the skills to improve relationships and build resilience. Staff are provided with professional guidance to help identify students who may be struggling with their mental health and knowledge on how to best support and help these students (MindMatters, 2017).

The attraction and advantage of MindMatters is that it is flexible in being to implement it into a school's curriculum so as to suit their own strategy / strategies and unique circumstances. Also the mental health resources has benefits not only for students but also staff and students' families. Sheehan and colleagues (2002) highlighted that "MindMatters can be distinguished from previous single-topic health education projects because it places mental health within the core educational business of schools rather than identifying it as a 'health topic'" (p. 113). They go on to say that "the professional development of teachers is fundamental to the success of the innovation". The main focus of MindMatters is on organisational structures, the social environment and the individual within this context.

KidsMatter and KidsMatter Early Childhood

After MindMatters was evaluated and the findings were disseminated, the Australian government saw the value and importance of developing a mental health education program for children of primary school age. It recognised that providing early intervention and prevention at an even earlier age than secondary school could make a difference in the mental health and wellbeing of children. KidsMatter is a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

national collaboration between the education and health sectors. It was jointly developed by beyondblue, Principals Australia Institute (PAI), Early Childhood Australia (ECA) and the Australian Psychological Society (APS), with funding from the Australian Government Department of Health and Ageing and beyondblue. (beyondblue 2016) KidsMatter Primary is a flexible, whole-school approach to improving children's mental health and wellbeing for primary schools. It can be tailored to schools' local needs.

Through KidsMatter Primary, schools undertake a two-to three-year cyclical process in which they plan and take action to be a positive community; one that is founded on respectful relationships and a sense of belonging and inclusion, and that promotes:

- Social and emotional learning (including evidence-based social and emotional learning programs);
- Working authentically with parents, carers and families;
- Support for students who may be experiencing mental health difficulties.

When schools take on KidsMatter, they build on the work that they are already doing in these areas (KidsMatter Primary, 2017). There are three parts that make up the KidsMatter framework. They are:

1. **Guiding Principles:** The beliefs that underpin KidsMatter;
2. **The Core Components:** The areas in which schools can most effectively concentrate their learning, planning and action;
3. **The Whole School Approach:** The essential elements for working together as a school community.

The four components that make up the KidsMatter / KidsMatter Early Childhood Framework are:

Component 1: Creating a sense of community.
Target Areas: A school community that promotes mental health and wellbeing and respectful relationships, belonging and inclusion.
Component 2: Developing children's social and emotional skills.
Target Areas: Effective social and emotional learning curriculum for all students and opportunities for students to practice and transfer their social and emotional skills.
Component 3: Working with parents and carers.
Target Areas: Collaborative working relationships with parents and carers, support for parenting and parent and carer support networks.
Component 4: Helping children who are experiencing mental health difficulties.
Target Areas: Understanding mental health difficulties and improving help-seeking and responding to students experiencing mental health difficulties (KidsMatter Primary, 2017).

KidsMatter recommended that schools should follow a 7-step implementation process related to focusing attention on the four components, as follows:

Step 1: Define the issues by writing a summary statement to describe the school's current situation related to each component.
Step 2: Set goals based on each summary statement.
Step 3: Identify any concerns in achieving the goals.
Step 4: Develop a broad range of options/strategies to address concerns and achieve goals.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 5: Evaluate the feasibility of each option/strategy.
Step 6: Formalise the component plan.
Step 7: Implement the plan and review (Askell-Williams, Lawson, & Slee, 2013).

beyondblue Mental Health Education Programs for Australian Schools

Australia's well known and respected depression and anxiety initiative, beyondblue, has produced several mental health education programs for primary and secondary schools as well as resources for universities and pre-schools. The better-known programs are KidsMatter and MindMatters which have already been previously spoken about. Other school mental health education programs include the following.

SenseAbility

The SenseAbility program has been designed and developed for secondary school students aged 12 - 18. SenseAbility is a strengths-based resilience program designed for those working with young Australians aged 12-18 years. It consists of a suite of modules developed to enhance and maintain emotional and psychological resilience. It was created with classroom delivery in mind, but the modules can easily be adapted to benefit young people in other structured environments such as TAFEs and youth organisations. The program is based on cognitive-behavioural principles, the evidence-based approach which says that our thoughts play a critical role in influencing feelings and consequent behaviour. SenseAbility consists of seven modules, a DVD and a CD with downloadable curriculum materials and resources. The seven modules include:

1. Essential skills
2. Sense of self-worth
3. Sense of control
4. Sense of belonging
5. Sense of purpose
6. Sense of future
7. Sense of humour (beyondblue, 2016)

The SenseAbility package has been designed to be delivered by teachers in the classroom and lesson plans have already been developed for teachers to use. It has been designed to fit in with the Australian curriculum framework which will make it easier for school leaders and staff to deliver and assess the SenseAbility program.

Secondary Schools Program (Years 8-10)

The Secondary Schools Program (beyondblue 2016) was developed specifically for the middle secondary years 8 - 10 which is a critical time both emotionally and socially in the lives of young people. It is a 30 session program that is intended to be delivered over three years, with students participating each year in 10 weekly classroom sessions of 30 - 45 minutes duration. The sequentially developed sessions are based on cognitive behavioural theories. The program is built around the development of six senses that act as protective factors against mental health problems:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Sense of self-worth
2. Sense of control
3. Sense of belonging
4. Sense of purpose
5. Sense of future
6. Sense of humour

Program delivery is based on principles of best-practice in effective teaching using a range of interactive methods including small-group exercises and discussions, role-plays, deep-learning tasks and quizzes. Each year level is built around different themes and there are downloadable teacher manuals as well as student workbooks. This program was developed collaboratively by the University of Queensland, the Victorian Centre for Adolescent Health, the South Australian Department of Education and Children's Services, and beyondblue. It draws on national and international research and the groundbreaking work conducted with schools in Australia in the past decade (beyondblue, 2016).

thedesk (University / TAFE Mental Health Education Program)

thedesk is a free online program aimed at providing Australian tertiary students with strategies and skills for success and wellbeing during their time at university or TAFE. *thedesk* includes modules to develop problem-solving and self-management skills. Topics include getting things done, staying calm, staying connected and feeling good. It also has tools to help with everyday issues such as relaxation, challenging unhelpful thoughts, using feedback constructively and problem solving. There are quizzes about different areas of life such as relationships, physical health and mental wellbeing and an online Coffee House for students to connect with other students, share experiences, music, art, recipes and more. Links are provided to information and support services to help deal with a range of common issue. All components of *thedesk* are informed by research on the prevention and treatment of mental health problems, web-based interventions and engagement. *thedesk* toolkit provides free information about *thedesk*, including the research behind it, what's involved and how schools and teachers can help promote it among their students (beyondblue, 2016).

Black Dog Institute: HeadStrong 2.0

HeadStrong 2.0 was developed by the Black Dog Institute to make it easier for teachers educating high school students about the tough topic of mental illness. The program has been linked to the Health and Physical Education curriculum for Years 9 - 10 and links directly to curriculum learning outcomes. The HeadStrong 2.0 curriculum resource is free to download and can help students better understand mental health, and how to build wellbeing and resilience. It is a unique program that equips teachers to better understand and help young people with mental health problems. HeadStrong 2.0 includes 5 modules that are split into a series of ready-to-use classroom activities and teacher development notes. Topics include depression and bipolar disorder, seeking help, helping others, and building wellbeing and resilience. It is complemented by MindStrength, a free online learning course to help young people build resilience.

Headstrong 2.0 has undergone a comprehensive research trial and is evidence based. Research has found that the program has helped improve the mental health literacy of young people which is crucial in young people seeking early help and support for a mental health problem (Black Dog Institute, 2017).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Response Ability

The Response Ability initiative was launched in 2000 by the Australian Government Department of Health and Ageing. The aim of the program was to provide free multimedia resources and practical support to universities and teacher educators, while addressing pre-service education for secondary teachers. The main target group was secondary school students with the focus being on their mental health and well-being. The Response Ability Project was initiated in 1997 under the Australian Federal Government's National Suicide Prevention Strategy. Its aim was to influence the pre-employment education of professional groups, so graduates could play a constructive role in addressing youth suicidal behaviour. The project represents an effective collaboration between health professionals and tertiary educators, with the team comprising staff from the Hunter Institute of Mental Health and educators from the University of Newcastle (Allen & Vincent, 2005). In 2006 the government engaged the Response Ability project team to see how this program and resources could also be implemented and rolled out in both primary and early childhood education. The main idea of the initiative was to use the resources to "encourage pre-service teachers to engage with and promote social and emotional health in their teaching practices."

Inspire "ReachOut Schools" and "ReachOut Teachers Network"

The Inspire Foundation provides a couple of different resources that can be utilised by schools for mental health education purposes. ReachOut Teachers Network provides mental health and wellbeing teaching resources and online training activities as part of an initiative of the Inspire Foundation (beyondblue, 2016).

ReachOut Schools provides free educational resources, digital tools and practical tips to encourage the development of positive mental health and wellbeing across schools and extend the impact of existing programs. The service features easy-to-understand information on a full range of mental health and wellbeing issues. The school resources include innovative digital apps and online games to help students learn to take control of their mental health. Staff and parents can use ReachOut Schools to better understand the issues young people face and as a safe place they can recommend and refer students to. School professionals can also access a range of professional development webinars and information, with resources added throughout the year. School professionals are able to register for updates (ReachOut Australia, 2017).

MIEACT (Mental Illness Education ACT)

MIEACT was founded in 1993 to deliver education sessions in schools in the Australian Capital Territory (ACT) about mental illness and was formally incorporated in 1998. MIEACT secured recurring funding from the ACT Government in 2000, and since then has expanded to deliver additional programs that reduce stigma surrounding mental illness. Whilst continuing and further developing the original Schools Education Program, MIEACT has also developed education programs for the broader community, media programs, and resources for young people (MIEACT, 2016). The School Education Program (SEP) is based on the original core program that MIEACT was founded on 25 years ago. It is best designed for students or young people in Years 9 - 12. This program is delivered by pairs of MIEACT Volunteer Educators, who are people with lived experience either themselves or as a carer of someone with a mental illness. Volunteers are trained and supported to deliver the program into schools and other youth environments. The program provides students and teachers with evidenced-based information used to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

broaden the student's knowledge about mental illness. Each student is provided with a resource *Hang On To This* (HOTT magazine) which contains contact information for services which can assist young people and other stories and activities aimed at engaging young people (MIEACT, 2016).

Peer Support Australia

Peer Support Australia is a peer led, evidence based mental health education program that is offered to Australian school communities. It aims to enhance the mental, social and emotional wellbeing of young people. It does this through integrating the program into the school curriculum and sustaining it by running all year groups. By doing this it looks to support a positive cultural change across the school. The program is operated in both primary and secondary schools. The Peer Support Australia program provides:

- Training and professional development for teachers and parents;
- Student leadership training and resources;
- Peer led, skills based, experiential learning modules focusing on orientation, relationships, optimism, resilience, anti-bullying and values;
- Consultancy to assist Member schools in raising awareness of the program and planning for implementation.

There are several benefits to the program. It provides students with a supportive learning environment in which to develop the skills, understandings, attitudes and strategies to improve mental wellbeing. It also helps students to develop key skills in resilience, assertiveness, decision making, problem solving and leadership and empowers young people to support each other and contribute positively to society (Peer Support Australia, 2014).

Teen Mental Health First Aid

Since 2001 there has been several variations of the original Mental Health First Aid program delivered to members of the community not only in Australia but overseas as well. The first courses however were specific in providing Mental Health First Aid by an adult to another adult. Eventually a Youth Mental Health First Aid was developed for adults who work with young people as well as for parents so that they would be equipped with the skills necessary to help out young people who might be struggling with their mental health or presenting with early mental health problems. Over the years through research conducted by Mental Health First Aid International, it became apparent that there was a need for there to be a course to be developed for young people to be trained up in having the skills and knowledge to help and support their peers who may have mental health problems or be in a mental health crisis. Thus teen Mental Health First Aid was born. teen Mental Health First Aid is a 3.5 hour mental health education program specifically designed for students in years 10 - 12 on how to provide mental health first aid to their friends.

Research and evidence found that young people have a preference for sharing their problems with peers rather than adults, be it parents, teachers, sports coaches or other significant adults in their lives. The course curriculum is based on research that was conducted on how best a young person can support their peers who might have a mental health problem. Students learn how to develop a Mental Health First Aid (MHFA) Action Plan on how to keep their peers safe, as well as information about different

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

types of mental health problems and mental health crisis situations in young people, and the relationship between thoughts, feelings and behaviours (Mental Health First Aid Australia, 2017). Hart and colleagues (2016) said that the program would:

Focus on developing knowledge and skills in recognising warning signs that a peer is developing a mental health problem, understanding how to talk to a peer about mental health and seeking help, when and how to tell a responsible adult, where to find appropriate and helpful resources about mental illness and professional help, and how to respond in a crisis situation… teen MHFA program aims to increase mental health literacy, decrease stigmatising attitudes towards individuals with mental illness, and improve MHFA behaviours. (p.3)

MENTAL HEALTH LITERACY IN AUSTRALIAN SCHOOLS AND YOUNG AUSTRALIANS

Anthony Jorm introduced the term, 'mental health literacy' back in 1997. He defined it as "knowledge and beliefs about mental disorders which aid their recognition, management or prevention". Jorm added that Mental Health Literacy consisted of several components including:

1. The ability to recognise specific disorders or different types of psychological distress;
2. Knowledge and beliefs about risk factors and causes;
3. Knowledge and beliefs about self-help interventions;
4. Knowledge and beliefs about professional help available;
5. Attitudes which facilitate recognition and appropriate help-seeking; (and)
6. Knowledge of how to seek mental health information (Jorm, 2000).

Jorm (1997; 2007; 2011; 2012) has written much on the topic of Mental Health Literacy. He has examined it from a whole population perspective in Australia and explained the importance and need to be mental health literate in order to stay emotionally and mentally well. Some of his research in collaboration with others has focussed on Mental Health Literacy around young people of school age. He found that the lack of mental health literacy in young people is similar to that of adults. His main concern was the inability of young people to recognise mental illnesses and their failure to know what appropriate professional help and pharmacological treatment that was available. Young people have a slightly more positive attitude of receiving help from a health professional than adults but that was not necessarily reflective in their own self-help seeking preferences. Young people would still prefer to speak to a friend or family member if they have a mental health problem. Many young people also do not have positive attitudes towards the taking of psychiatric medication. His research has also found that young people are ill-equipped to provide help to peers suffering from mental illness (Jorm, & Wright, 2007). From the 2006 National Survey of Mental Health Literacy and Stigma, Jorm and Reavley (2001) in conjunction with Melbourne University uncovered some key findings about youth mental health literacy in Australia. These included:

- Only a small percentage of young people saw doctors as a source of intended help;

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- There was widespread awareness among young people that the use of substances is harmful for mental health;
- When a peer had a mental health problem, it was not often recognised by a young person to encourage professional help seeking;
- Young people viewed general and informal sources of help as interventions that would be helpful rather than specialist mental health services;
- Stigma was lower in young people who had experience of mental health problems in self or others, who had been exposed to mental health campaigns, and whose parents had less stigmatising attitudes.

Following consideration of two international studies (Skre, Friborg, Breivik, Johnsen, Arnesen, & Wang, 2013; Mcluckie, Kutcher, Wei, & Weaver, 2014) it was found that after introducing mental health education and promotion programs into the curriculum that there were definite improvements in the mental health literacy of both students and staff. More research and education is needed in order to improve youth mental health literacy which in turn will improve early intervention outcomes of young people whom are developing signs of mental health problems and mental illness.

INTERNATIONAL EXPERIENCE OF MENTAL HEALTH EDUCATION IN SCHOOLS

Around the world there are literally hundreds of mental health interventions and education programs being run (Weare & Nind, 2011). From the evidence these are most popular in Western countries such as the USA, Canada, the United Kingdom, Scandinavia and parts of Europe. Most of these appear to be quite fragmented without there being one national integrated program per country. These vary in size, coverage and the amount of mental health resources that they produce and make available. Some are privately run while others have the backing of respective federal or state government money. Askell-Williams and colleagues (2009) identified several school-based mental health education programs based on the World Health Organisation (WHO) 'Health Promoting Schools' framework. These included Social and Emotional Aspects of Learning (SEAL) from the United Kingdom, the Collaborative for Academic, Social and Emotional Learning (CASEL) initiatives in the United States of America and the European Network for Socio-Emotional Competence in Children (ENSEC). Askell-Williams and colleagues (2009) noted that "each of these seeks to develop students' social, emotional and behavioural capabilities, as well as the capabilities of schools and families to support children's wellbeing". These examples show a whole-school approach not unlike MindMatters and KidsMatter in Australia.

In 2007, a secondary school mental health curriculum, the Mental Health and High School Curriculum Guide was developed in Canada in a collaboration between the Canadian Mental Health Association and mental health experts from several different organisations and universities. This has proven to be quite successful so far.

The United Kingdom have also been proactive in implementing a number of mental health education programs. These include YoungMinds, OpenMinds and Place2Be. Place2Be is the UK's leading children's mental health charity providing in-school support and expert training to improve the emotional wellbeing of pupils, families, teachers and school staff. OpenMinds is a student-led intervention, providing mental health education to school students by training medical students to deliver workshops in local schools.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The United States has an abundance of mental health education programs. Examples of these included FRIENDS, which focuses on reducing anxiety and teaching skills for managing emotions and coping with stress among students, parents and teachers. It addresses six core topic areas, including identifying feelings, understanding one's physical responses, learning to relax, linking thoughts and feelings, developing plans for coping and practicing emotion management. Other ones were Positive Action (PA), Promoting Alternative Thinking Strategies (PATHS), Cognitive-Behavioural Intervention for Trauma in Schools (CBITS) and the American Psychiatric Association Foundation's School Mental Health Program 'Typical or Troubled?'.

BARRIERS AND PROBLEMS TO IMPLEMENTING MENTAL HEALTH EDUCATION IN AUSTRALIAN SCHOOLS

Although there are many benefits for implementing Mental Health Education into school curriculum, that is not to say that it does not come with its fair share of problems, barriers and challenges. After the original audit into Mental Health Education in Australian Secondary Schools was completed in 1996 a number of barriers were discovered. These included:

- Teachers and other school staff lacked specific knowledge and skills, and thus confidence in teaching, on these issues; this lack of information was also reflected in the prejudices of staff and others in the school;
- The specified curriculum lacked a space for mental health education; there was a lack of time in an already 'packed' curriculum;
- There was a lack of relevant and reliable resources;
- Students' and parents' values;
- Within the curriculum, health generally and mental health in particular has a low status;
- There is sometimes no continuity or commitment from teachers from year to year, across and within departments, and between teachers and other staff;
- Mental health issues are often seen as crisis-driven and individual, and thus more relevant to welfare approaches than to curriculum (Youth Research Centre and Centre for Social Health, 1996).

With the introduction of MindMatters and the two variations of KidsMatter, some improvements could be seen concerning these barriers and problems. Professional development has definitely been enhanced and the resources available to schools now is much improved to what was on offer in the past. Some of these barriers however still exist today, with schools trying to fit so much into their curriculum for example. As can be seen from the findings above there are a number of challenges that present extra stresses and pressures for teachers and schools in trying to implement Mental Health Education. Additionally, some teachers and educators believe that it is not a part of their role to provide Mental Health Education or to be a role model or provide guidance around it. Another point of contention for some schools that have even been successful at embedding Mental Health Education into their curriculum is the matter of sustainability. Some schools believe that this is not possible with their many pressing demands, changes in curriculum and changes in staff. Lastly, another possible barrier is that of the attitudes and values of some teachers and educators in regard to mental health and mental illness and their willingness to pick up delivering mental health resources.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

BENEFITS OF MENTAL HEALTH EDUCATION IN AUSTRALIAN SCHOOLS

There are a number of benefits and advantages for young people as well as teachers, families and the broader community with the introduction of mental health education into schools. With the high prevalence of mental illnesses such as depression and anxiety, young people are able to be provided with the skills, knowledge and understanding on how to manage these conditions as well as knowing what they can do to stay mentally and emotionally well in the first instance. Through having a greater understanding, insight and knowledge of mental illness and it's early warning signs, young people will be able to assist their peers in accessing important early help from mental health professionals and hopefully avoid a crisis situation. Education and knowledge will also help to break down the appalling stigma that still surrounds mental illness in the community and amongst young people, therefore enabling people not to feel judged and feeling comfortable to accept help for their mental health problems. Through the process of early intervention and prevention, young people will be able to learn to become more resilient and mental health conscious, which will help them to become more productive people who are better able to deal with stress and difficult and challenging life situations.

Introducing and exposing young people to mental health education at an early age will set a good precedent in raising children who are less judgmental towards people who have mental illness in the community as well as helping people to recognize the importance of maintaining their own mental health as much as their physical health. This would help in decreasing the amount of serious mental illness that exists in the community due to the fact that young people and future generations of adults would be more inclined to seek early help for either existing or emerging mental health problems or mental illness. Early identification of mental illness would help in decreasing the amount of admissions to emergency or psychiatric wards in hospitals, which is already under pressure and costs the Australian government millions of dollars each year.

Mental health education will also give young people a better understanding about the impact that drugs and alcohol can have on their mental health and recognizing that they may be self-medicating which may be masking what is an underlying mental health condition. A reduction in the use of drugs and alcohol will see an improvement in the mental health of young people which will also save the health system money and more importantly young people's lives.

Through mental health education young people will be raised to be more resilient and be able to better manage their stress from an earlier age which will prepare them better for adolescence and adulthood. This will lead to a more productive economy and save millions of dollars in tax payers money due to people taking less sick leave or filing claims for stress leave.

THE FUTURE OF MENTAL HEALTH EDUCATION IN AUSTRALIAN SCHOOLS

The future of Mental Health Education in Australian schools is looking bright after the announcement in June, 2017 by the Australian government of a new initiative to be rolled out in 2018. This new program will hopefully make it even more accessible and easier for schools to use than what is currently in place. The beyondblue Chairman at the time, Jeff Kennett, described the program as "a game-changer that would replace the current fragmented approach with a wholly integrated one" (beyondblue, 2017). From August 2018, beyondblue will lead a new National Mental Health in Education program with support from headspace and Early Childhood Australia, with funding from the Australian Government

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Department of Health, (beyondblue, 2016). This new initiative will transform Australia's approach to child and youth mental health care by providing a single end-to-end school-based mental health program. Covering the continuum from early childhood to secondary school, it will support mental health promotion and suicide prevention activity. The program will integrate and build on the strengths and evidence-based principles of key existing Commonwealth Government mental health initiatives being delivered in education settings.

These initiatives are:

- Response Ability
- KidsMatter Early Childhood
- KidsMatter Primary
- MindMatters
- Headspace School Support

In the meantime KidsMatter Early Childhood, KidsMatter Primary and Mind Matters will continue as normal in their current form until the new program launches in August 2018. From January 2018, headspace facilitators will deliver KidsMatter and MindMatters to primary and secondary schools, while Early Childhood Australia facilitators will deliver KidsMatter Early Childhood (beyondblue, 2016). beyondblue will continue to provide Response Ability resources to university lecturers and course facilitators who provide pre-service training to future educators, through to mid-2018. The Response Ability website will continue to be the primary information source for the pre-service training sector. In a media release from beyondblue, who were the successful bidder in a competitive tender process for the new Mental Health in Education program, their CEO, Georgie Harman affirmed that:

We will bring together the best minds from across the mental health and education sectors to build a contemporary national child and youth mental health program with the aim of helping everyone reach their full potential academically, emotionally, socially and in later life. (beyondblue, 2017)

CONCLUSION

Ever since the Australian government undertook an audit in 1996 into Mental Health Education in Australian Secondary schools, there has been a strong focus put on mental health education in schools. This is evident from the MindMatters (secondary schools) and KidsMatter (primary schools) initiatives that were successfully introduced and implemented in many schools around Australia. These initiatives also saw the introduction of other mental health education programs in Australia that have been discussed earlier. These initiatives and programs have seen Australia become one of the world leaders in school / youth mental health education as well as mental health promotion. Australia is well resourced for mental health education resources and professional development and the future is looking bright with the announcement by the government in June, 2017 of the Mental Health in Education initiative, which rolls out from 2018. This program will improve on what is already in existence by providing a seamless single end-to-end school-based mental health program from early childhood to secondary school that is wholly integrated as opposed to having separate programs in operation. From looking at the evidence that the mental health literacy of young people and students in Australia is still lacking, suggests that more

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

needs to be done about this. Hopefully the current lack of knowledge about mental illness, mental health and seeking psychological treatment amongst young people in Australia will be improved through the new Mental Health in Education initiative and that more young people will seek out and utilize mental health services earlier. It is crucial that young people learn to recognize early presenting mental health problems and know what help and treatment options are available to both themselves and to their peers. The introduction of compulsory mental health education in Australian schools as well as forming part of the curriculum would see visible improvements in the mental health and wellbeing of young people in Australia, which in return would provide many benefits and opportunities for the broader community. For compulsory mental health education to work well would require that teachers receive good professional training and support and that schools are provided with excellent resources. It may be that the Australian government employs specialist mental health education teachers for schools to deliver the content so that the regular teachers can concentrate and focus on the rest of the curriculum. Mental health education in schools will help in decreasing the likelihood of mental health problems presenting for people when they are adults or minimizing the impact for people who have a mental illness. It will help build resilience in young people and create a society where people are more accepting of mental illness, which will lead to early help seeking. Mental health literacy will improve which will only seek to benefit Australia as a community moving forward due to the fact that more Australians in the community will be more mentally healthy.

ABSTRACT

In this chapter, the authors situate mental health issues in the context of U.S. institutes of higher education. They provide a brief history of the provision of mental health services on campus and contends that postsecondary schools should shift to a campus-wide, preventive, proactive approach to promote student flourishing. Four specific areas for interventions are discussed. These include academic or curricular adjustments, increased awareness and knowledge, supportive environments, and appropriate policies and procedures. These initiatives (which are not only the responsibility of "experts") rely on the open communication and collaboration of all members of the campus community.

INTRODUCTION

The authors begin by providing a brief history of the provision of mental health services on campus. Then they discuss four areas in which campus-wide initiatives have been found effective in supporting the mental health of college students. These include curricular adjustments, community environments, mental health literacy, and campus policy. These focus areas have been selected as they are most applicable to this audience: college/university faculty and staff whose background are not necessarily in mental health. These are the professionals who will have regular contact with students, those with and without mental health issues. As such, the initiatives in this chapter can be understood and implemented by professionals without degrees in the mental health field.

OVERVIEW

With the increasing prevalence of mental illness in institutes of higher education (IHE), research suggests that colleges and universities must adapt to better serve their students. Reactive approaches and individualized counseling alone are not sufficient. Moreover, compartmentalized service (where responsibility for college student mental health resides in counseling centers) has limited influence. It is recommended that IHE shift from a targeted focus to a campus-wide focus and direct their efforts toward preventive measures (Fink, 2014; Hartley, 2012; Swaner, 2007; Wood, 2012). In the past few decades several organizations have proposed ways to facilitate this transition.

The Jed Foundation (JED), though not the only organization aimed at promoting emotional and mental well-being, is a leader in this field. It offers support to schools, students, families, and communities to strengthen mental health. JED's 7-point Strategic Plan is comprehensive, attending to the following areas: developing life skills, promoting social connectedness, identifying students at risk, increasing help-seeking behavior, providing substance abuse and mental health services, following crisis management procedures, and restricting access to potentially lethal means (JED, 2016). Such an approach affects multiple levels of the campus community from college policy, to particular organizations like student mental health services, to faculty training and involvement, to curriculum design, to student enculturation.

Building on the recommendations of JED and other relevant literature, IHE can take multiple steps to improve the mental health of college students. Academic adjustments to face-to-face and online courses have been found to mediate the negative effects of stress in academic settings. Such curricular changes include engaged learning models and course offerings in mental well-being (DiPlacito-DeRango, 2016; Fink, 2014; Mitchell, Darrow, Haggerty, & Neill, 2012; Savini, 2016; Swaner, 2007). IHE that endorse social and academic inclusion via residential communities, campus activities, and learning communities are found to be more supportive and promote a sense of student belonging, which are favorable factors of mental health (Condra, Dineen, Gauthier, Gills, Jack-Davies, & Condra, 2015; Fink, 2014). Moreover, IHE at all levels (leadership, faculty, support staff, and students) must be fully aware and fully trained to promote resilience and identify signs of mental illness (Barr, 2014; Condra et al., 2015; Hartley, 2012, Wood, 2010) to create environments in which students can flourish. Additionally, campuses should have the necessary policies and procedures in place to promote well-being and intervene when students are in mental distress (Condra et al., 2015; DiPlacito-DeRango, 2016; Murphy & Baines, 2015; Silverman, 2008; Wood, 2012).

PROVISION OF MENTAL HEALTH SERVICES ON CAMPUS

In the United States, the provision of mental health services in IHE morphed considerably during the 20th century. Amherst College is credited with establishing the first student health services in 1861, yet the first mental health services was not established until 1910 by Princeton University (Kraft, 2009; Kraft, 2011). In the first half of the 20th century, college mental health services were developed and primarily provided by psychiatrists. As the field grew, clinical psychologists and psychiatric social workers began providing services as part of a multidisciplinary team approach (Kraft, 2009; Kraft, 2011). Yet, services were often split between two departments: psychiatric mental health and other counseling resources. This model was expanded mid-century when increasing numbers of students, funded by the GI bill, entered colleges and universities (Kraft, 2009; Kraft, 2011). Increased student enrollment necessitated increased

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

health professionals on campus. It also meant providing a broader range of services to address the new needs of students. Similarly, it required a new service-delivery approach.

A shift occurred mid-century. Mental health services no longer focused solely on the "mental hygiene" of a few acute students receiving in-patient care (Kraft, 2009; Kraft, 2011). Mental health services began to have a broader purpose, serving a larger population and doing so through ambulatory care services (Kraft, 2009; Kraft, 2011). These services included career or vocational counseling, psychotherapy, medication assists, and consultation across campus. In the second half of the century, another shift occurred (Kraft, 2009; Kraft, 2011). Campus counseling centers had a growing and changing role in the provision of mental health services moving from that of "providing only direct counseling services to one that makes multiple contributions to a campus community" (Bishop, 2010, p. 249). Addressing the ever-changing needs of college students, mental health services expanded their scope to deal with drug and alcohol abuse (initiated in the '70s), public health issues (initiated in the '80s), and recently stress, anxiety, and depression. Additionally, prevention efforts and education campaigns are now a significant part of mental health services.

Today's mental health services on campus are geared toward a diverse population and intended to be proactive rather than reactive. Standards set forth by the International Association of Counseling Services (IACS) support a systemic and comprehensive campus initiative. It highlights four key functions of campus counseling services: "individual and group student counseling; prevention and outreach; consultation to faculty and staff; and contributions to campus safety" (Prince, 2015, p. 6). These standards suggest that campus counseling services are important, though not the sole factor influencing student mental health. Faculty and staff also play an essential role. Moreover, these standards indicate that mental health services do not reside in a single location on campus. This notion is echoed by Bishop (2010). In reviewing the literature, Bishop (2010) found a continued need for counseling centers to make clear their engagement in "outreach, programming, and consultation work" (p. 250), implying that mental health services in IHE are most effective when viewed as a shared responsibility.

The responsibility of college student mental health does not reside within a single department or office. It is the responsibility of the entire campus community. Many IHE have adopted a "public mental health model – a model that attempts to address environmental factors of the campus that influence students' mental health" (Prince, 2015, p. 7). Through such a paradigm, members of student affairs and student services, faculty, staff, and students themselves work together to improve well-being on campus. It has been argued that colleges and universities are well situated to have a positive effect on mental health. Postsecondary education is often the place where:

A single integrated setting encompasses their [students'] main activities – both career related and social – as well as health services and other support services. Campuses, by their scholarly nature, are also well positioned to develop, evaluate, and disseminate best practices. In short, colleges offer a unique opportunity to address one of the most significant public health problems among late adolescents and young adults. (Hunt & Eisenberg, 2010, p. 3)

Hence, the focus of this chapter: college-wide initiatives that can enhance student mental well-being.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

COMPREHENSIVE INTERVENTIONS

There are multiple ways in which IHE can support the mental health of college students. This section of the chapter focuses on building a sense of community, increasing awareness and knowledge, curriculum adjustments, and establishing campus-wide policy. Although psychotherapy and medications can be used to treat some students, they are not discussed here. Likewise, interventions for students with mental health illnesses requiring individual care from the Counseling Center and/or private mental health providers (e.g., psychologists, clinical social workers, certified counselors, licensed nurse psychotherapists, or psychiatrists) are not discussed here. As a teacher educator, such therapies fall outside of my purview. Moreover, my intent is to present strategies that can apply to many students, not simply those requiring intensive or prolonged care, and that can be used preventatively.

Building a Sense of Community to Promote Mental Health

Mental health, or flourishing, does not simply exist in the absence of mental illness. As Keyes (2005 & 2007) describes in his model of Mental Health as Flourishing, there are 13 factors associated with flourishing. These include positive affect and avowed quality of life (emotional well-being); self-acceptance, personal growth, purpose in life, environmental mastery, autonomy, and positive relations with others (psychological well-being); and social acceptance, social actualization, social contribution, social coherence, and social integration (social well-being) (Keyes, 2007). In replicating Keyes' work, Fink (2014) obtained similar findings. His analysis revealed four significant predictors of college student mental health. These include a supportive college environment, a sense of belonging, professional confidence, and civic engagement (Fink, 2014). Fink (2014) concluded that "socially supportive climates, such as easy transitions into college and supportive residence halls, as well as intermediate outcomes such as sense of belonging" were particularly strong predictors (p. 386). Myriad other researchers have noted similar associations with college student mental health, focusing especially on the type of environment in which students live and learn.

Without oversimplifying IHE, I conceptualize campuses as on a continuum from "cool" to "warm" with various degrees in between. Cool campuses are those that lack a sense of community and promote a sense of isolation. These are the campuses that have a "non-accepting culture" (Tinklin, Riddell, & Wilson, 2005, p. 507). As such, differences are viewed as deficiencies rather than natural occurrences that warrant empathy, compassion, and accommodation. On cool campuses public and personal stigma are prevalent.

Public, or social, stigma "is characterized by prejudicial attitudes and discriminating behaviour directed towards individuals with mental health problems as a result of the psychiatric label they have been given" (Davey, 2013, p. 1). In other words, it is the stigma of others (family members, friends, instructors, and the media) emanating from outside the individual with the mental health disorder. Public stigma can present as "prejudicial attitudes and discriminating behavior" (Davey, 2013, p. 2). Stereotypes of individuals with mental health disorders as dangerous or intellectually inferior can lead to social isolation and lowered expectations. Personal stigma is just as, if not more, detrimental.

Self-stigma, also known as perceived stigma, "is the internalizing by the mental health sufferer of their perceptions of discrimination" (Davey, 2013, p. 1). It occurs when the individual with mental illness believes the negative stereotypes ascribed to his/her psychiatric label. Self-stigma may result in feelings of fear and shame (Condra et al., 2015; Davey, 2013; Tucker, Hammer, Vogel, Bitman, Wade, & Maier,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2013), exacerbate symptoms of the disability (Pedersen & Paves, 2014), and heighten social isolation (Pedersen & Paves, 2014; Tinklin et al., 2005; Tucker et al., 2013). Stigma is a chief concern as it has been identified as a barrier to college students seeking help for mental illness (DiPlacito-DeRango, 2016; Hunt & Eisenberg, 2010; Pedersen & Paves, 2014; Shatkin, Diamond, Zhao, DiMeglio, Chodaczek, & Bruzzese, 2016). It can affect students' self-concept and influence their perceived need for help or their likelihood to deal with mental illness on their own.

On the contrary, warm campuses are defined by their open and accepting nature. Here, differences are not considered flaws. Rather, diversity is anticipated and welcomed. Moreover, pro-social interactions are encourage and fostered so that students do not feel a sense of alienation. Such environments are known as "welcoming culture[s]" (Condra et al., 2015, p. 277) supported by a "web of caring" (Asidao & Sevig, 2014, p. 132) and "social networks that reinforce a sense of campus community" (Silverman, 2008). In this way the camps is ecological in nature, where human beings interact with each other and with their environment. Interactions on warm campuses are different from interactions on cool campuses. They are grounded in compassion and empathy for others. Summarizing Kuh, Swaner (2007) underscores the importance of:

Small, 'human-scale' environments [that] encourage responsible, health-enhancing behavior," and emphasizes that where faculty and student contact is frequent and classes are small, "a college or university encourages its members to know each other, a precursor to caring for one another. (p. 21)

I would go farther, suggesting that positive interactions are not limited to those between students or among students and faculty. Positive interactions include all members of the campus community. This highlights the value of positive, supportive relationships grounded in getting to know and understand others.

Such warm campuses can be fostered in academic and non-academic settings. In fact, many researchers suggest that a comprehensive focus best serves college students. Classrooms can be turned into learning communities where students are engaged in meaningful ways and where students work with one another to grow intellectually and empathically (Bertram, 2010; Fink, 2014; Wrench, Garrett, & King, 2013). Residence halls, where students live in close proximity to a great number of diverse peers, are prime places to develop inclusive spaces (Bertram, 2010; Fink, 2014). Social networks and friendships are a critical component of warm campuses (Bertram, 2010; Fink, 2014; Wrench et al., 2013). Such relationships may start in the residential communities and typically expand beyond the dorm. Events and activities (academic, social, athletic, club-related, Greek life-based) can support the development of peer relationships, which shape the campus community. In addition to peer relationships, student-faculty relationships can contribute to a welcoming environment. Positive student-faculty relationships occur both inside and outside the classroom. One way to enhance such openness is to schedule events where faculty and students interact informally (Quinn, Wilson, MacIntyre, & Tinklin, 2009). In each of these ways, members of the campus gather to get to know each other and begin to form a community.

By definition, a community includes myriad individuals unified by common interests. This can include persons and agencies off campus (e.g., families, medical providers, counselors, religious groups, non-profit organizations, etc.) and on campus. In IHE, the focus of this book, everyone, including faculty, staff, and students, plays a role in developing a warm campus. Such supportive communities exist when "members look out for one another, value the individual, promote a collective identity, and are not afraid to speak out when they recognize distress" (Bertram, 2010, pp. 31–32). This environment cannot exist if mental

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

health disorders continue to be stigmatized. Anti-stigma, or stigma reduction, programs are essential as IHE move forward. Stigma reduction initiatives can include shifting to asset-oriented language use on campus, making mental health services accessible, and correcting stereotypes and misconceptions (Condra et al., 2015; Davey, 2013; Pedersen & Paves, 2014; Tucker et al., 2013; Wood, 2012).

Service provision must be actualized in ways that are humanizing and maintain students' privacy. This could include communicating clear policies (e.g., confidentiality commitments and release authorizations), locating offices in convenient and private settings, and creating supportive cultures. Supportive cultures can grow by improving and increasing mental health literacy (DiPlacito-DeRango, 2016; Murphy & Baines, 2015; Tucker et al., 2013). In these ways, campuses move to normalize mental health disorders and encourage students to access the services available to them. The following section addresses mental health awareness and knowledge of both students and faculty.

Promoting Awareness and Increasing Knowledge of Mental Health

Students With and Without Mental Health Disorders Lack Information

Research indicates that many college students with mental health disorders lack the knowledge to effectively manage their disability. One major barrier is being unaware of their rights and responsibilities as a college/university student with a disability (Condra et al., 2015). Title II of the Americans with Disabilities Act (ADA) and Section 504 of the Rehabilitation Act or 1973 (Section 504) prohibit discrimination on the basis of disability. These laws protect all individuals with disabilities, including students in elementary, secondary, and postsecondary settings. In IHE, Section 504 entitles eligible students to appropriate academic adjustments. "Academic adjustments may include auxiliary aids and services, as well as modifications to academic requirements as necessary to ensure equal educational opportunity (USDOE, 2011). Such academic adjustments can be gained if the student with the disability reports (provides documentation) that he/she has a disability to the appropriate office on campus and requests services. It is the responsibility of the college student to self-disclose and obtain academic adjustments, if needed. Students who are unaware of their rights and responsibilities are not likely to secure the supports to which they are legally entitled.

Those who are aware of their rights and responsibilities must also know how to access services on campus. Unfortunately, many college students with disabilities are either unaware of the services available to them, do not know where to go for help, or do not know the process for accessing services (Condra et al., 2015; Oswalt & Riddock, 2007; Pedersen & Paves, 2014; Quinn et al., 2009). These barriers are exacerbated by offices of student support services that are located in areas of campus either not known to or not readily accessible to students with disabilities (DiPlacito-DeRango, 2016; Quinn et al., 2009; Silverman, 2008). IHE can do a better job of educating students with mental health disorders about available services on campus and make these services readily available. Additionally, IHE can help students become self-determined human beings. "Professionals can do much to advocate for and support students, but ultimately students must learn to advocate for themselves and support each other" (Bertram, 2010, p. 32).

Students currently without mental health disorders also lack mental health knowledge. As a result, social stigma may exist. In this space, stereotypes and misinformation can breed fear and discrimination, which is detrimental for students with mental illness. Lack of knowledge also impedes the ability of college students without mental illness to help peers in crisis. If one cannot spot indicators of mental distress

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

or is unaware of the services available on campus, he/she cannot intervene in positive ways. Bystander training has recently been encouraged to address this (Bertram, 2010; Prince, 2015; Wood, 2012). As Bertram (2010) asserts, "distressed students are more likely to go to their peers with their problems. Thus, it is critical that students are offered this information in a format that will give them agency when a friend is in need" (p. 31). Moreover, lacking mental health literacy can be personally harmful. Just because a student is currently mentally healthy, that does not mean he/she will never experience mental distress. Enhancing mental health awareness and knowledge for all college students is beneficial.

Faculty and Staff Lack Information

Research also indicates that many college faculty and staff lack awareness and knowledge of mental health issues on campus. They may lack knowledge of students' rights (Condra, et al., 2015). Consequently, some faculty and staff do not realize their legal obligation to make academic adjustments. They may be uninformed about the services to which they could refer students or the process to do so (Condra et al., 2015; Mitchell et al., 2012; Storrie, Ahern, & Tuckett, 2012) and unaware of the importance of referring students for non-acute, non-crisis mental health matters (Mitchell et al., 2012). Therefore, they are not able to advise students properly. Also, they may lack awareness of particular mental health issues, early warning signs of mental illness, and how such disorders manifest for individual students (Storrie et al., 2012; Tinklin et al., 2005). As such, they are unable to identify and intervene in a timely manner for students who are at-risk.

Additionally, some faculty and staff may be unsure of how to make appropriate academic adjustments in their courses (Condra, et al., 2015; Tinklin et al., 2005). A lack of effective accommodations can negatively affect the learning environment. In some cases reluctance to make academic adjustments is related to faculty and staff holding negative attitudes about individuals with mental illness (questioning their capacity to succeed) or the concern that making accommodations will diminish academic standards and compromise the rigor of the program (Condra et al., 2015). Such misunderstandings or misperceptions can contribute to a "knowledge gap" (Storrie et al., 2012, p. 101) where faculty and staff are unsure of or ill-prepared to fulfill their role as a "first-line responder" (DiPlacito-DeRango, 2016, p. 7) and college/university students with mental health issues do not receive the academic or psychological support to which they are entitled. Training and awareness campaigns can mitigate this knowledge gap, not only for faculty and staff but also for college/university students.

Campus Training and Awareness Campaigns

Numerous researchers (Asidao & Sevig, 2014; Bertram, 2010; DiPlacito-DeRango, 2016; Hunt & Eisenberg, 2010; Mitchell et al., 2012) discuss the importance of "gatekeeper" training. As defined by the U.S. Surgeon General (USDHHS, 2012), gatekeepers are community members:

Who have face-to-face contact with large numbers of community members as part of their usual routine. They may be trained to identify personas at risk of suicide and refer them to treatment or supporting services as appropriate. Examples include clergy, first responders, pharmacists, caregivers, and those employed in institutional settings, such as schools, prisons, and the military. (p. 139)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

By extending this definition beyond the P-12 setting to the college/university environment, faculty and staff in IHE can be considered gatekeepers. Gatekeeper training aims to educate individuals on identifying and referring students who may benefit from mental health services. This model is preventive in nature. It attempts to provide faculty and staff with the knowledge and skills to make early referrals. In turn, this should increase the number of students attaining mental health services before their situations escalate to acute mental distress and reduce the number of students who commit suicide.

One example of gatekeeper training is Question, Persuade, and Refer (QPR). QPR is nationally recognized and empirically based. It involves teaching:

Front-line people (e.g., faculty, staff, friends) how to recognize the warning signs of suicide, including verbal, behaviors, and situational clues, and provides guidelines on how to question persons about suicidal thoughts, persuade them to get help and refer them for help. (Asidao & Sevig, 2014, p. 136)

It is based on the notion that early recognition and early intervention are critical. Like Cardiopulmonary Resuscitation (CPR), it is an intervention "designed to increase the chance of survival in the event of a crisis" (What is QPR?). Another example of gatekeeper training is Campus Connect. It is "experientially based and teaches constituents to recognize distress and mental health issues in students, use basic helping techniques, and refer others to resources that could provide help" (Bertram, 2010, p. 31). In addition to providing information, Campus Connect uses multiple exercises and role play activities to increase communication skills, particularly empathic listening skills, of trainees. This evidence-based model builds on connectedness and uses culturally appropriate approaches. Both trainings are similar in that they promote community engagement and comprehensive strategies to save college/university students' lives. For more information on QPR or Campus Connect, please visit their websites.

Though useful, trainings like QPR and Campus Connect are not the only options for increasing awareness of mental health disorders. Training can be targeted to particular members of the campus community, and it can be provided via multiple avenues. Training for faculty and staff, who interact with college/university students on a weekly, if not daily, basis should incorporate wide-ranging information. This includes information about prevalent mental health disorders (particularly, characteristics and evidence-based academic interventions), the process students use to obtain accommodations, supporting students by using existing campus resources, and complying with confidentiality policies (Condra et al., 2015). Academic advisors, in particular, may benefit from such training (Wood, 2012). They have an opportunity to get to know their advisees as a "whole person." Academically, advisors have access to mid-term grades, course schedules, and transcripts, which enable them to see how the student is doing across all courses. Typically, advisors also have designated advising times where they meet individually with advisees and check-in on their overall well-being and adjustment to college/university. That is not to say these conversations do not or cannot occur organically with course faculty. In many cases the time and space for such conversations is intentionally built in to the formal academic advising structure (though it may not always be capitalized on).

Training to increase mental health literacy can be provided in multiple ways. It can occur at orientation for new faculty and staff and through new or enhanced existing professional development for current faculty and staff (DiPlacito-DeRango, 2016). Though initial trainings are important, one-shot deals are not enough. Training should be ongoing (Barr, 2014). Campus Counseling Centers often play a role in such professional development but are not solely responsible. Web-based self-training modules exist and centers for teaching and learning can host workshops, professional learning communities, and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

conferences on mental health (DiPlacito-DeRango, 2016). Combined, these approaches provide faculty and staff myriad opportunities to engage in meaningful conversations about mental health. In this way, information is made accessible in multiple formats. That is not to say that mere exposure to information will positively affect dispositions and behaviors. Admittedly, some employees could simply comply, complete training sessions, then not examine and/or change their role in promoting mental well-being on campus. For any training to work, the learner must authentically want to gain new understandings and use this new knowledge to change something for the better. While training focuses more on the individual or particular groups, general awareness campaigns have the potential to reach the masses.

Public information campaigns can increase awareness and work to reduce the stigma of mental illness on campus. Such campaigns can share statistics about mental health issues and provide mental health resources (Pedersen & Paves, 2014; Price, 2015). They not only benefit faculty and staff but also students with and without mental health disorders, especially when intentionally planned and implemented. Publications, forums, and tabling events are typical approaches to advertising services (Asidao & Sevig, 2014; DiPlacito-DeRango, 2016; Murphy & Baines, 2015). Such strategies reach a limited pool of students. Attention needs to be paid to all members of the campus community, including graduate students, commuter students, and online students. Due to their specialized study located in an isolated part of campus or their primary residence off campus, these students may not see traditional marketing campaigns (Oswalt & Riddock, 2007). To reach the broadest audience, additional tools like websites, online modules, and mobile phone apps can be used to disseminate information and provide services to support mental health (DiPlacito-DeRango, 2016; Murphy & Baines, 2015).

Many members of the campus community (students, faculty, and staff) have poor mental health literacy. As a result, students are not likely to pursue services and faculty and staff are less prepared to make student referrals for services. If an overarching goal for IHE is to positively affect mental health, or flourishing, then campuses should create cultures that cultivate acceptance and awareness. Increased mental health literacy is an important part of the solution. Yet knowledge alone is not enough to reduce the number of acute mental health crises on campus. Knowledge should be accompanied by action.

Applying Newly Acquired Knowledge of Mental Health Issues

There are multiple ways IHE faculty and staff can apply what they have learned about mental health in small-group and large-group settings. Such interventions range on a continuum from low-intensity to high-intensity and can be implemented by a single faculty member or a group of specialized staff. In the following section, I will discuss curriculum adjustments, face-to-face interventions, and online interventions that are associated with college/university student mental health. These strategies can be applied by faculty and staff in all academic programs across campus.

Engaged Learning

Civic engagement, as mentioned previously, is a predictor of college student mental health (Fink, 2014). Higher levels of civic engagement are associated with flourishing. Across campus, such engagement can be promoted through Living-Learning Programs (LLPs). As defined in the *National Study of Living-Learning Programs* report, LLPs are "programs that involve undergraduate students who live together in a discrete portion of a residence hall (or the entire hall) and participate in academic and/or extracurricular programming designed especially for them" (Inkelas, Brower, Crawford, Hummel, Pope, &

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Zeller, 2004, p. I-1). In these settings, students have opportunities to regularly collaborate with peers, faculty, and community members on specialized projects. Each LLP is designed around a common theme and typically includes community engagement. In addition to campus-wide initiatives like LLPs, civic engagement can be fostered in individual courses.

In the college classroom, engaged learning has been associated with student mental health and well-being (Swaner, 2007). The concept of engaged learning is often used in two distinct, though not entirely separate, ways. First, it draws from experiential learning theory, where the individual interacts with the environment and actively co-constructs shared meaning. In this way, the individual is actively involved in or "engaged" in his/her learning (Swaner, 2007). Second, it is associated with civic engagement, where students participate or are "engaged" with communities. Such engagement occurs on multiple levels, including local, regional, national, international, and global spheres. It has mutual benefits for private life and public life, both preparing students for citizenship in a participatory democracy and enhancing the community (Swaner, 2007). Common models of engaged learning include service learning, community-based research, collaborative learning, and problem-based learning (Swaner, 2007). Internships and interdisciplinary co-teaching are other examples. That is not to say, however, that these approaches are prevalent in IHEs. Although research indicates that many of the aforementioned engaged learning pedagogies "enhance learning, increase content mastery, encourage critical thinking, and foster personal development," such learning opportunities are "offered only on a limited and elective basis on most campuses" (Swaner, 2007, p. 20). Engaged learning could be promoted by both departments within Student Affairs and throughout academic departments. At the instructor-level, additional curricular adjustments can be made to enhance and support student mental health.

Curriculum Infusion

In addition to adopting a particular pedagogical framework, faculty can promote college student well-being by infusing aspects of mental health into the curriculum. Here, I borrow Mitchell et al.'s (2012) definition of curriculum infusion: "developing class activities and assignments that introduce faculty and students to mental health topics such as depression, anxiety, eating disorders, or suicide while at the same time focusing on academic content" (p. 25). Major assignments can be scaffolded around mental health literacy and texts about mental health issues can be assigned as required readings (DiPlacito-DeRango, 2016; Savini, 2016). Not all faculty and staff are knowledgeable in this area, so collaboration with qualified personnel is important during all aspects of course design and delivery.

Such curriculum infusion can be thoughtfully merged within numerous relevant disciplines. One university, for example, established partnerships between its Mental Health Awareness Committee and faculty in various academic programs to embed mental health literacy into particular courses. Here, a Visual Studies program used art exhibits to raise awareness about emotional distress, emotional wellness, and resiliency. The Design for New Media class created posters and Public Service Announcements to increase awareness about mental health issues and related campus resources. The Applied Marking Techniques class developed a marketing campaign on behalf of Counseling Services (Mitchell et al., 2012). In each of these cases, topics related to mental health were incorporated to help students achieve course objectives. The study of mental health was not simply a course add-on. Rather, that topic served as a vehicle through which students learned course content and provided service to the campus community through such applied projects. As compared to traditional training programs, curriculum infu-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

sion produced more faculty interest and involvement in mental health promotion (Mitchell et al., 2012). Faculty awareness and action is essential in promoting well-being and in deterring mental health crises.

Faculty can take additional steps to increase mental health literacy in their own courses. They can build-in class time to announce mental health campus-wide events, distribute counseling center information, host speakers on mental health related topics, and include a statement about mental health in their syllabi (DiPlacito-DeRango, 2016; Mitchell et al., 2012; Savini, 2016). Referring to a previous point, faculty can create communities of learners. They can do this by lecturing less and integrating more collaborative projects. They can also promote forums where students talk with each other to reduce isolation, in a way creating support groups (Quinn et al., 2009; Savini, 2016). Such forums could exist in face-to-face courses, online courses, and go beyond the classroom. One university even has a "buddying system" where second-year and first-year students are paired; the returning student offering support to the new student until he/she is acclimated to college life (Quinn et al., 2009). Additionally, faculty can intervene early. Surveying the class, checking-in with individual students, and referring students appropriately are effective strategies to address mental distress (Mitchell et al., 2012; Savini, 2016). Early intervention is more likely to occur when faculty have received training and taken the time to get to know their students. All of these examples demonstrate ways faculty can make adjustments in the classroom to better support student well-being. Beyond curriculum infusion, entire courses can be offered to address mental health issues.

General Course Offerings

Research indicates that general course offerings can be effective in promoting and facilitating mental health on campus. Such courses can disseminate information on campus mental health resources and help students better understand themselves as developing social and emotional beings (Conley, Durlak, & Dickson, 2013; Wood, 2012). Courses can also help students develop generalizable life skills that allow them to face the challenges and stress of college life and learning (Hartley, 2012; Silverman, 2008). These life skills can include, but are not limited to, time management, study skills and habits, self-care, and relaxation (Damer & Melendres, 2011; Hartley, 2012). Such skills can be connected to resilience, "the process of, capacity for, or outcome of successful adaptation despite challenging or threatening circumstance," and protective factors, "the qualities of persons or contexts that predict positive outcomes under high-risk conditions" (Hartley, 2012, p. 38). Resilience and protective factors are positively associated with mental health. Programs that focus on building resilience through skills-oriented approaches are associated with increased self-esteem, self-perception, self-confidence, self-leadership, and prosocial behaviors and related to decreased emotional distress, specifically depression, anxiety, and stress (Conley, Durlak, & Dickson, 2013; Hartley, 2012). Such courses enhance social and emotional development by teaching life skills that will help students be successful in academic and non-academic settings. To be constructive, programming should be both intentionally designed and delivered.

IHE have approached general course offerings to promote mental health in several ways. For instance, a medical school offers a one-semester course entitled "Mind–Body Medicine: an Experiential Elective." The 10-week course meets weekly for two-hour sessions. Students who volunteer to participate are first led through a didactic presentation, covering topics related to physiological responses to stress and ways to cope with stress. Small groups of students are then given the opportunity to practice specific skills related to the concept of the week. Additionally, students are expected to complete homework (physical activity and meditation). Results indicate that this mind-body course reduced participants' anxiety levels

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

as students used newly developed skills "to cope more effectively with the stresses of medical school" (Finkelstein, Brownstein, Scott, & Lan, 2007, pp. 262-263).

As another example, a university offers a two-semester course to undergraduate students entitled "Risk and Resilience (R&R) in Urban Teens," which focuses on "mental health promotion, stress reduction, and resilience" (Shatkin et al., 2016, p. 205). Semester One, structured didactically, provides students with theories and practices about stress, stress reduction, and resilience. Semester Two, organized as a service-learning project, provides students the opportunity to apply their newly acquired knowledge by teaching skills and techniques intended to reduce stress to local high school students. Results indicate that, compared to controls, R&R students self-reported improvement in their mental health. "Specifically, they reported less perceived stress, better coping skills, and a reduction in dysfunctional attitudes" (Shatkin et al., 2016, p. 207).

At another IHE, a seminar on psychological wellness was offered to first-year undergraduate students. The seminar occurred weekly for 50 minutes during the fall and spring semesters. It covered a range of topics associated with psychosocial adjustment and stress management. Each seminar contained four elements: didactic instruction, journal writing about experiences and reactions, participation in class activities, and skills practice homework. Results indicate that students benefitted by an increased sense of well-being and by better managing college-related stress (Conley, Travers, & Bryant, 2013). Furthermore, the authors claim that such a course, "by taking a universal approach… can be applied to—or customized for—different campuses, contexts, and special populations" (Conley, Travers, & Bryant, 2013, p. 84). In other words, this model can be replicated throughout IHE and tailored to meet the needs of specific colleges/universities.

Admittedly, there are numerous ways to structure courses for mental health promotion. Such courses vary in size, interventions used, duration, audience, and format (Conley, Durlak, & Dickson, 2013). Taken together, the examples of skills-based courses presented here suggest that the explicit teaching of skills to enhance resilience and build protective factors are effective in enhancing mental health. Courses ranging from one semester to two semesters have been found to reduce stress and anxiety while increasing personal resources to successfully cope with college challenges. Common to the examples included here is an emphasis on both theory and practice. Students were provided conceptual schemes and evidence-based interventions and required to use their newly developed skills. Moreover, students were actively engaged in multiple settings–inside the classroom and outside the classroom (or as some students refer to it, "real life"). This suggests that one's mental status is not necessarily pre-determined or fixed. Students can learn factors that enhance mental health, hone coping skills, and implement effective practices. In this way, students act as agents to positively affect their own well-being.

Additionally, general course offerings could be tailored to two primary populations: new students and returning students. If early intervention is effective in mediating mental health crises, then it stands to reason that programming should be provided as soon as students first arrive on campus, even during orientation. But programming should not stop there. Although one- or two-semester courses have been found effective in helping students learn and apply stress coping interventions presently, some research indicates that they do not necessarily have long-term effects beyond the intervention period (Conley, Travers, & Bryant, 2013; Shatkin et al., 2016). This suggests that one-shot course offerings may need boosters, follow-up seminars, to have enduring usefulness. Furthermore, the models discussed here were offered to students on a volunteer basis. To reach a broader audience, IHE may include similar courses as part of the required coursework for all majors. In this way, such proactive and preventive interventions

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

become "systemic in higher education" as they are "integrated into the routine structure and programming of higher education institutions" (Conley, Durlak, & Dickson, 2013, p. 297).

Mindfulness Training

In addition to skills-based interventions, mindfulness-based interventions have been found effective in promoting mental well-being. Here, I use mindfulness to mean "the awareness that emerges through purposefully paying nonjudgmental attention to present moment experiences" (Bergen-Cico, Possemato, & Cheon, 2013, p. 349). One example of such training is Mindfulness-Based Stress Reduction (MBSR). Students participate in discussions about meta-cognition and the mind–body–psychological connection; they also practice multiple types of meditation and guided body scan (Bergen-Cico et al., 2013). Upon completion of this training, students reported significant levels of improvement in mindfulness and self-compassion, two measures of psychological health. Likewise, a Mindfulness-Based Stress Management (MBSM/Mindful-Gym) program produced positive results regarding mental health. Training included didactic and experiential methods which were "designed for students to pay attention to the present moment, relaxing moments, and grateful moments in life" (Phang, Mukhtar, Ibrahim, Keng, & Sidik, 2015, p. 1118). Results indicate that students benefitted from reduced perceived stress and mental distress and increased mindfulness and self-efficacy. In a modified MBSR program, participants were provided information on coping strategies during group sessions and practiced new techniques on their own at home. Results reveal that students receiving MBSR training "increased their use of problem-focused coping," and those students with self-reported "high scores on neuroticism benefitted from the intervention in terms of reduced avoidance-focused coping and an increase in seeking social support" (Halland, deVibe, Solhaug, Friborg, Rosenvinge, Tyssen, Sorlie, & Bjorndal, 2015, p. 388). Each of these measures is associated with mental health.

Mindfulness training can be used in conjunction with general course offerings and/or embedded in courses to promote college/university student mental health. Both are similar in that they incorporate theory and practice, and they have relatively immediate results with positive outcomes reported within weeks or months of intervention initiation. They differ, though, in their duration. While courses can last a semester or two, mindfulness trainings typically last five to 10 weeks. Because mindfulness training is delivered in small groups, over short periods of time, without the expectation of students to disclose personal information, it can be "a relatively cost-, time- and labour-effective intervention" (Phang et al., 2015, p. 1128).

Online Interventions

Thus far, discussion has focused on campus-based interventions, as in those courses or seminars delivered by faculty and staff in a face-to-face format. This delivery method pertains to "traditional" college students and overlooks "online" students. As our society continues to embrace technology, the number of "distance learners" will likely grow. Students taking mostly online courses may benefit from a different approach to mental health promotion.

Technology has been found effective in promoting mental health awareness and as a vehicle for intervention (Asidao & Sevig, 2014; Barr, 2014; Hintz, Frazier, & Meredith, 2015; Koydemir & Sun-Selisik, 2016; Wood, 2012). IHE websites can serve as repositories of information on mental health education and available campus and electronic services. MiTalk is one such example. It is an "interactive, multimedia

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Web site" that provides students "with knowledge and skills to get help or to help friends who may be in distress because of depression, anxiety, social identity, trauma, stress management, or other mental health concerns" (Asidao & Sevig, 2014, p. 137). YouTube and Facebook can also be used for mental health outreach (Asidao & Sevig, 2014).

In addition, technology can support student development through online workshops. Though composition may differ slightly, web-based interventions "often contain psychoeducation delivered via text, video or audio, assignments, and personalized feedback" (Hintz et al., 2015, p. 138). One university offered a 4-module training via Google sites focused on common college stressors and past, present, future control theory. Each module consisted of a narrated presentation, student examples, and application exercises. Upon workshop completion, participants who practiced present control reported less perceived stress and reductions in anxiety and depression (Hintz et al., 2015). As another example, an 8-week online intervention focusing on strengths and goals, emotion regulation, pro-social skills, problem-solving and decision-making skills, and motivation was offered to first-year students at another university. Participants who completed the 5-module training (including both didactic and experiential components) reported improved well-being in several areas, "namely subjective happiness, life satisfaction, subjective happiness, ontological well-being and psychological well-being" (Koydemir & Sun-Selisik, 2016, p. 440). This suggests that "well-being promotion through technology can be effective in facilitating a flourishing life among students" (Koydemir & Sun-Selisik, 2016, p. 442). Though only two studies are presented here, these results support similar research in the field.

There are many benefits to online mental health resources. They have the potential to reach a large audience, regardless of students' proximity to the college/university, and can be sustained (Barr, 2014; Hintz et al., 2015; Koydemir & Sun-Selisik, 2016). Electronic resources may be more readily accessed by students due to their convenience as they can be used at times that fit students' schedules and allow for user anonymity (Hintz et al., 2015; Wood, 2012). Yet, given that some students are not digital natives or do not have access to adequate technology, digital approaches should not be the only way to enhance mental well-being. IHE should use a multifaceted approach that is inclusive of the diverse student body.

Campus Mental Health Policies

Without a common mission and cohesive procedures, mental health promotion initiatives will likely be sporadic and disjointed. If communicated superficially or to certain individuals (Student Affairs staff rather than Academic Affairs faculty, for example), then useful policy will not be systemic. Rather, it will be implemented in pockets across campus. Such random practices are potentially harmful as they allow students to slip through the cracks. Unfortunately, this is often the case. "Institutionalized, coordinated, and sustainable mental health policies have yet to emerge in post-secondary schools" (DiPlacito-DeRango, 2016, p. 3). Such underdeveloped policies are seen as a barrier to college/university student mental well-being, and as such, a place for reform (Condra et al., 2015; DiPlacito-DeRango, 2016; Murphy & Baines, 2015; Silverman, 2008; Wood, 2012). A unified and comprehensive approach to mental health is desired.

Campus-wide policies should be thorough and clear. They can include guidelines for promoting mental well-being in a preventive manner and specific procedures for responding during mental health crises. Such "student-friendly policies" are seen as proactive, not punitive (Murphy & Baines, 2015, p. 23). It should be clear how the campus will establish policy and review policy. Policy should be regularly evaluated for relevance to the overall mission of the college/university, current application, and usefulness (Condra et al., 2015; DiPlacito-DeRango, 2016; Murphy & Baines, 2015; Wood, 2012).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, policy should be shared with everyone who is responsible for implementing it. Both the "how to" (detailing steps) and the "why to" (garnering buy-in) should be communicated. A policy on paper and not enacted is ineffective. It is recommended that a multi-disciplinary committee convene to create such policy.

Many IHE now have committees of administrators, faculty, and staff who collaborate to establish and review mental health policy. Though common in IHE, these committees may differ organizationally and operationally. For example, such committees go by various names, including the Campus Assessment Team, the Student Behavior Consultation Team, the Assessment and Care Team, the Student of Concern Committee, and many others (Eells & Rockland-Miller, 2011; Prince, 2015). Their mission and purpose also vary. Committees can be divided into three categories: those that focus on student behavior assessment and intervention; those that primarily manage crises; and those that combine both approaches (Eells & Rockland-Miller, 2011). In addition to setting campus-wide policy, these teams can meet to evaluate individual student cases. Through early intervention, such teams review students "who demonstrate behaviors that are disruptive or worrisome," and provide support before problems escalate (Prince, 2015, p. 7). They also engage in a process of "threat assessment," where team members determine if a specific student poses foreseeable danger to him-/her-self or others and decide on steps to address the threat (Bishop, 2010; Eells & Rockland-Miller, 2011).

Committees are unique in other ways. Team responsibilities and composition differ. For example, teams may set policy, communicate policy, manage student cases, foster cross-campus collaborations with other groups promoting wellness, and/or train and support academic departments (Eells & Rockland-Miller, 2011; Murphy & Baines, 2015). Membership may include representatives from counseling services, student discipline office, campus safety, health services, academic affairs, student disabilities office, legal counsel, athletics, Greek life, and/or faculty (DiPlacito-DeRango, 2016; Eells & Rockland-Miller, 2011). Teams have case review procedures, documentation procedures, and referral sources, yet these factors may be actualized differently from IHE to IHE (Eells & Rockland-Miller, 2011). Regardless of these differences, all teams share the common goal of promoting mental health on their campus. This goal remains important as the prevalence of mental illness in college/university continues to rise. Policy-setting and -enforcing committees are important in addressing this issue as they "provide a venue for making caring, well-reasoned, and appropriate decisions about students" who may be in experiencing mental distress (Eells & Rockland-Miller, 2011, p. 22).

Yet campuses are not alone in this endeavor. Numerous mental health resources in the local and broader communities exist. IHE can work with these agencies to enhance mental health promotion on campus. National organizations and commercial services, such as the following, can be of use: The JED Foundation (Barr, 2014; Hoover, 2003; Silverman, 2008; Wood, 2012); Campusblues.com (Hoover, 2003); Active Minds on Campus (Hoover, 2003); Center for the Study of College Student Health (Wood, 2012); Mentality (Wood, 2012); The Mental Health and Wellness Association (Wood, 2012); The Suicide Prevention Resource Center (Silverman, 2008); The American Association of Suicidology (Silverman, 2008); The Garret Lee Smith Memorial Act (Silverman, 2008); and The Historically Black Colleges and Universities National Resource Center (Silverman, 2008). The aforementioned agencies serve as examples and do not constitute a comprehensive list. They are meant to be used as potential resources, starting points, for IHE looking to strengthen mental health policies on campus.

CONCLUSION

If flourishing, as Keyes (2005 & 2007) presents it, leads to a good life, then IHE ultimately should provide students the knowledge, skills, and opportunities to flourish. This occurs not only in the absence of mental illness but with numerous factors associated with mental health, not the least of which are self-knowledge, a sense of belonging, and engagement. Today, the prevalence of mental illness on college/universities campuses is growing. Such mental health challenges prevent college/university students from flourishing. Wait-to-fail models where mental health services are provide after a serious event occurs are antiquated. They neither support the student in crisis nor the campus community. Current scholars in the field call for new initiatives, initiatives that promote mental well-being and prevent mental distress on a systemic level (Bertram, 2010; Conley, Durlak, & Dickson, 2013; Hartley, 2012; Hunt & Eisenberg, 2010; Murphy & Baines, 2015; Swaner, 2007; Wood, 2012). The responsibility for creating campuses where students can flourish is no longer the sole domain of counseling centers or student health services. This requires comprehensive, integrated policies and the collaboration of all stakeholders.

This chapter focused on strategies for college/university faculty and staff who do not have extensive knowledge or experience in fields related to mental health. It described several best practices, such as building community, gaining mental health literacy, and adjusting academic curriculum that are effective in promoting mental health. These initiatives can be instituted throughout and across departments with relative ease. Often, such initiatives do not require large amounts of money, time, or effort. They do, however, require support from all campus members. "Effective and creative intervention [is] imperative" (Bertram, 2010, p. 33). Students are best served by a "multidimensional approach that combines short-term therapeutic services with educational outreach, community support, and infrastructure for student empowerment" (Bertram, 2010, p. 33). In this way, "the campus is not made a treatment facility, but instead offers the tools for students to understand and negotiate the emotional, psychological, and intellectual components of these issues" (Bertram, 2010, p. 33). A concerted and effort and innovative approach to mental well-being is essential as IHE move forward.

Chapter 37
Activism and College Student Mental Health: A Wellness Perspective

Abby L. Bjornsen-Ramig
University of Nebraska – Omaha, USA

Daniel B. Kissinger
University of Nebraska – Omaha, USA

ABSTRACT

Activism on college campuses in the United States is a long-standing phenomenon rooted in the counter-culture movements of the 1960s. Today, local, regional, and national issues and sociopolitical influences remain closely aligned with activism in higher education, with contemporary issues shaping student activism efforts on campus. College student activism ranges from organized marches and protests to more widespread social media campaigns, targeting issues ranging from inclusion and diversity to sexual assault and intimate partner violence. Involvement in activism can influence the mental health and overall wellness of college students who engage in these activities. This chapter focuses on contemporary activism in higher education, specifically as related to the potential impact of activism on the mental health and wellness of college student activists. Also discussed are implications for student affairs professionals, university-based mental health professionals, and higher education administrators.

ACTIVISM AND COLLEGE STUDENT MENTAL HEALTH: A WELLNESS PERSPECTIVE

In higher education, student activism has served as a driving force for boosting inclusivity and democracy on campus (Cabrera, Matias, & Montoya, 2017). The organization of students toward a common social goal is the backbone of activism (Barnhardt. 2014), with objectives typically reflecting the current sociopolitical climate (Lantz, Fix, Davis, Harrison, Oliver, Crowell, & Mitchell, 2016). Through power in numbers, students express a collective voice to influence positive changes on a campus (Rojas, 2006).

Three primary objectives are associated with the current chapter: an overview of contemporary student activism in higher education will provide context to the complex nature of student involvement in activism, particularly as related to individual identity development and personal experiences with discrimination and oppression. Second, the relationship between involvement in activism and mental health will be discussed, with a focus on the application of an empirically-supported wellness model. Finally, suggestions will be provided to campus officials for fostering and supporting student activist efforts in higher education.

BACKGROUND OF THE DISCUSSION

Contemporary Student Activism in Higher Education

Path to Activism

In examining the trajectories of activism in higher education, it is clear that student involvement in activism often reflects their personal experiences with marginalization, oppression, and/or exclusion (Rhoads, 1997; Kimball, Moore, Vaccaro, Troiano, & Newman, 2016). Student activist causes have ranged from campus racial integration in the 1950's and 1960's (Caple, 1998) to inclusivity and safety for LGBT students in present day (Santos & VanDaalen, 2017). Scholars suggest that the socialization process for activism occurs early in life, and that many college students learn to become activists from parents, other early influencers, or possibly from painful personal experiences (Kimball et al., 2016). Students personally touched by issues such as racial discrimination, sexual assault, or potential deportation are often driven by their painful experiences toward collective action to address social and political inequalities, and to perhaps seek self-healing through their involvement.

Impact of Identity

The demographics of student activists have shifted with national trends in college student demographics. Compared with students half a century ago, the average contemporary college student is more likely to be a female, racial minority with a family to support, all of which can reflect novel stressors on student activists (Ruff, 2016). The historical notion of the typical college campus as an ivory tower for the elite is no longer accurate, and in fact, is imperative to abandon (Ruff, 2016). As college campuses in America become more reflective of societal demographics as a whole, it becomes critical to examine trends in college student activism through the lens of the multifaceted and intersecting identities held by the average contemporary college student.

One important objective in higher education entails facilitating students in developing an orientation toward activism (Gurin, Dey, Hurtado, & Gurin, 2002). Activism can serve as a developmental learning tool, providing students with the opportunity to engage in the democratic process on campus (Biddix, 2010). Student involvement on campus contributes to increased retention rates, as well as stronger academic performance and overall satisfaction with the college experience (Webber, Krylow, & Zhang, 2013). Activist causes can serve as a means of campus involvement that may be personally meaningful to the student. Scholars have expressed that activism is often driven by a greater sense of purpose, which develops in late adolescence. Purpose entails a drive to reach objectives that transcend the self, and may

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

be of greater benefit to society as a whole (Damon, 2008). Some researchers have asserted that a sense of purpose, like activism, is an essential outcome of the college experience (Chickering & Reisser, 1993). In essence, utilizing activism as a change agent may also provide students with a sense of purpose and meaning (Kimball, Moore, Vaccaro, Troiano, & Newman, 2016), further contributing to their personal, and perhaps professional, identity development.

The literature is ripe with examples of activism affecting identity for students in higher education. For instance, many college students with disabilities grew up surrounded by the activist efforts of their parents/guardians in explaining their disability to others to initiate greater visibility and understanding, in addition to securing the appropriate accommodations at each educational level. Those with a more empowering approach to parenting likely also taught their children with disabilities how to self-advocate, which may shape the activist involvement of these students once they arrive on a college campus (Kimball et al., 2016). To cite another example, many students identifying as DREAMers (Development, Relief, and Education for Alien Minors) become activists in the undocumented student movement, often resulting in a deeper sense of personal and political identity. "Creating and sustaining an empowered undocumented identity allowed DREAMers to project their sense of self beyond the bounds of their legal status and confirms the power of their activism" (DeAngelo, Schuster, & Stebleton 2016, p. 227). Similarly, the intersectionality of marginalized identities for many Black and Brown college students may serve to impact identity as an activist, with these students seeking involvement in movements that offer voice and visibility to issues directly affect sense of self, such as Black Lives Matter (Logan, Lightfoot, & Contreras, 2017). As an example of activism intersecting with identity beyond the undergraduate level, Graduate Students Talk (GST) is a collective of student leaders who are pursuing graduate study in psychology, with a strong focus on activism and social justice (Lantz et al., 2016). Members of GST largely endorse a sense of personal and professional identity as driving their decision to join this organization, with several students citing a broader connection between their clinical work, research, and involvement in activism (Lantz et al., 2016). Regardless of the particular cause or the educational level of the student, activists in higher education often experience the inextricably intertwined nature of the personal and political, often influencing overall identity development.

The Many Forms of Activism in Higher Education

Students seeking involvement in activism in higher education typically do not have to look far for opportunity. Activist activities on campus can range from organized protests and marches, (e.g., recent marches for Black Lives Matter; the Women's Marches after the 2016 presidential election) to online activism (e.g., sharing a link to a powerful video or article; promoting activist groups/activities on personal social media pages). Student involvement in activism can be peripheral or central to their day-to-day lives, and may depend upon individual views about how activism is defined.

Researchers in one qualitative study examined how Black and Brown students at a Primarily White Institution (PWI) defined activism on a continuum, ranging from activism in the form of simply being present on campus, to activism being all-consuming in the lives of students (Logan et al., 2017). These scholars outlined five forms of activism. First, *existence as resistance activism* simply entails minority student visibility at a PWI, particularly when the campus climate is perceived as hostile toward minority students. Second, *social media activism* capitalizes on modern technology in the form of Facebook, Twitter, individual blogs, and similar forms of electronic activism, and was described by students as a more accessible path to activism. Third, *intellectual/educational activism* involves facilitating others

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in becoming more aware of current issues, and developing others as critical consumers of information. Fourth, *front line activism* flies in the face of social media activism, and demands a physical and hands-on approach (e.g., protests and marches), including the personal discomfort and sacrifice that oftentimes accompany such approaches. Finally, *activism consumes life* is self-explanatory, and applies to students who define their identities and actions almost exclusively in the activism realm (Logan et al., 2017). Outside of this particular study, the primary categorization of student activist activities in the literature seems to be whether social media plays a role. In the sections that follow, the intersection of social media and student activism will be discussed in greater detail, as this issue predominated much of the current literature.

Champions of Social Media Activism

Social media touches most aspects of contemporary life in the United States, including student activism in higher education (Cabrera et al., 2017). Some scholars herald social media as a critical tool for many objectives of activism, including disrupting power dynamics, building communities, and raising awareness about issues on campus (Linder, Myers, Riggle, & Lacy, 2016). Social media platforms often serve as an organizing tool in contemporary student activism in higher education (Biddix, 2010), and as a result, an internet presence is typically a component of most student activism (Cabrera et al. 2017). "If social justice is the overall goal, then online activity can and needs to be one component of this strategy" (Cabrera et al., 2017, p. 411).

Social media activism (also referred to as digital activism or cyberactivism) has emerged as a tool of choice for many students to share their stories and to reach audiences that might otherwise be inaccessible (Linder et al., 2016, Lantz et al., 2016). For example, participants in a recent qualitative study discussed the bias of media outlets in covering college sexual assault cases. These students argued that media coverage typically focuses on attractive, White, middle-class women, and largely excludes victims who do not fit this prototype. Participants asserted that social media provides both visibility and an emotional outlet for the many diverse faces of sexual assault, and allows both victims and advocates to directly criticize the media for failing to address the intersection of privilege and identity with sexual assault (Linder et al., 2016). As an activist response to the pervasive nature of sexual assault among college students, the group *Know Your IX* (www.knowyourIX.org) was founded in 2013 with the objective of empowering students to end sexual violence in schools. This political advocacy group allows like-minded activists and supporters to join forces digitally, and to experience the validation and strength in numbers that might otherwise be inaccessible without the use of online media platforms (Linder et al., 2016).

In addition to sexual assault, social media has provided widespread visibility to a variety of other student activist causes, such as the Occupy Movement and Black Lives Matter (Lantz et al., 2016). Interestingly, neither movement originated in higher education, but both quickly spread throughout a large number of college campuses via social media, ultimately resulting in a more open dialogue about income inequality and racial injustice (Cabrera et al., 2017). In sum, through challenging the idea that activism must entail a physical presence through protests or marches, both researchers and activists have opened the door to a variety of mechanisms through which students can make their voices heard. Some scholars have asserted that social media transcends the boundaries of power and privilege, providing visibility to students who may otherwise remain in the shadows due to lack of time or resources (Linder et al., 2016).

Critics of Social Media Activism

Although scholars and students alike sing the praises of online platforms for increasing the visibility and accessibility of student activist activities, social media activism is not without critics who assert that activism exclusively through online mechanisms is akin to slacking, or taking the easy way out. The term *slacktivism*, coined less than a decade ago, is defined as "political activities that have no impact on real-life political outcomes, but only serve to increase the feel-good factor of the participants" (Christiansen, 2011, p. 1). As a more concrete example of this criticism, the number of activists donating money to support a given cause on social media is typically a very small fraction of the number of slacktivists heralding their "support" for the same cause in the form of likes or retweets (Morozov, 2009; Cabrera et al. 2017). Perhaps ironically, the more public the act of slacktivism, the lower the likelihood for more meaningful activism efforts to follow (Kristofferson, White, & Peloza, 2013). In this sense, the primary criticism entails slacktivists utilizing social media activism as a means of personal impression management (curating a particular online image) rather than authentic passion for social change.

In spite of some of the more scathing critiques of social media activism and its effects (or lack thereof), some scholars have noted that the line between activism and slacktivism is vague at best, and that mass slacktivism may now be an important component of activism (Cabrera et al., 2017). In other words, slacktivism and activism may frequently go hand-in-hand, with slacktivism serving as a launch pad for more traditional forms of activism (Jones, 2015). For every argument that slacktivism is synonymous with political ineffectiveness (Christiansen, 2011), and individual gratification (Kristofferson et al., 2013), there is a counterargument for the widespread visibility that social media activism provides (Vie, 2014). For example, Facebook users en masse have demonstrated their support for LGBTQ equality by applying a rainbow filter to their profile pictures, serving to highlight the widespread prominence of LGBTQ issues. Such awareness campaigns can lay the groundwork for future activism in the form of lobbying, raising money (Vie, 2014), or perhaps visibility as an ally at campus events such as Pride. Counter to the aforementioned argument regarding impression management, perhaps social media activism serves as an important tool for communicating the role of activism in individual identity.

In sum, the arguments for and against the use of social media activism are complex, but largely positive, particularly when the notion that online activism can spearhead in vivo activism. One additional arm of this topic entails the impact of social media on mental health, which bears mixed findings in the literature. In spite of criticisms that social media use contributes to mental health and self-esteem issues for young adults (Chen & Lee, 2013), other scholars have demonstrated the benefits of social media, noting higher levels of perceived social support, more favorable relationships with family, and overall greater wellness (Asbury & Hall, 2013). Social support and wellness, in addition to visibility and fighting for social reform, seem to be influential factors for college students who seek involvement in activism on campus. In the section that follows, the impact of activism on college student mental health is discussed in greater depth.

MENTAL HEALTH CONSIDERATIONS

Activism and Student Mental Health

Mental health issues among college students are certainly not a new concern. According to a large annual survey of staff at university counseling centers, students struggle with disorders related to anxiety and depression most frequently (Center for Collegiate Mental Health, 2016). At PWIs, both Black and Latinx students report greater social isolation and depression than do White students (Ancis, Sedlacek, & Mohr, 2000). Coupled with a lower likelihood of seeking mental health treatment due to cultural stigma, many minority students are at a heightened risk of incurring negative mental health consequences (Gonzalez et al., 2005). Activism by definition is a quest for social change, and often focuses on groups historically silenced by society. Many students are compelled to become activists due to the climate on their campus (Logan, Lightfoot, & Contreras, 2017). Student experience of oppression or discrimination in some capacity often correlates with involvement in activism (Breslow et al. 2015; Logan et al., 2017).

THE PERSONAL IS POLITICAL

College students often find themselves drawn toward activism and protest as a result of feeling marginalized (Ruff, 2016; Logan et al., 2017). For example, two recent movements that have predominated student activism in higher education are Black Lives Matter (BLM) and Deferred Action for Childhood Arrivals (DACA). Researchers examined Black and Latinx involvement in both movements, and found that Latinx students were more likely to become involved in both causes when they had previously been the target of racial microaggressions. Prior political involvement predicted activism in BLM for Black students and in DACA for Latinx students. Additionally, both Black and Latinx students exhibited greater involvement in BLM than in DACA, presumably due to the larger social media presence of BLM (Hope et al., 2016). Researchers concluded that particularly for Latinx students, involvement in political activism serves as a positive coping strategy against experiences of discrimination (Hope et al., 2016).

Similarly, there has been a rapid influx of activism by undocumented college students in recent years for a variety of reasons, including negative mental health outcomes (Teranishi et al., 2014), discrimination and microaggressions (Kim & Diaz, 2013), and lack of resources to facilitate access and success in higher education (Nora & Crisp, 2009). Activism allowed undocumented students to band together to work toward equal rights in higher education, and achieve a strong collective identity in the process, serving as a protective factor for mental health (D'Angelo, Schuster, & Stebleton, 2016).

In a related example, members of the aforementioned activist group for psychology graduate students, Graduate Students Talk (GST), noted that part of their reason for becoming involved in this organization was to process difficult emotions arising from ongoing incidents of police brutality against black men (Lantz et al., 2016). The opportunity to converge with other like-minded graduate students to create a safe space for processing anger, disappointment, and hopelessness, as well as a commitment toward action for change, motivated many students to join GST (Lantz et al., 2016). To reiterate, activism may serve as one means of rallying against oppression, and is therefore a means of coping with the negative effects of discrimination (Santos & VanDaalen, 2017).

The degree to which activism fulfills the role of coping strategy seems to be dependent on the type of activism (low versus high risk) with the latter more strongly associated with physical, social, legal, and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

potentially financial consequences (Santos & VanDaalen, 2017). Given that the purpose of activism often entails challenging status quo power structures, risk serves as one of the primary distinguishing factors between student slacktivism (likely low risk) and student activism (potentially high risk) (Cabrera et al. 2017). Any kind of activism entails some degree of civil disobedience (Rojas, 2006), which exposes college students to varying degrees of personal risk. When personal risk becomes a chronic stressor, anxiety, as well as depression and hopelessness, can be an outcome for student activists.

MISPERCEPTIONS OF STUDENT ACTIVISTS

Complicating the matter of risk associated with activism involvement is the recent mischaracterization of many student activists (e.g., those standing against racial inequality) as attempting to restrict free speech (Halewood, 2016). Researchers have posited that some of the language associated with contemporary activism (e.g., microaggressions, safe spaces, trigger warnings) causes others to perceive that they are being told to what to say and what not to say, often resulting in mocking or trivializing activists and their efforts as a form of backlash (Halewood, 2016). Critics of progressive student activism in higher education often fail to grasp the reality that targets of microaggressions often experience perpetual exhaustion from a daily onslaught of ignorant comments, which can impede not only their experience in college and academic performance, but also their mental health and wellness (Halewood, 2016). We often struggle to respect what we do not understand, or that we misunderstand.

Student activists often become the target of criticism from anonymous voices online, labeling their advocacy for necessities such as safe spaces and access to mental health services as unnecessary grumbling (Ruff, 2016). The irony is that such criticism emphasizes the initial motivation to engage in activism: raising social consciousness and striving toward change. Activism cannot exist without the dichotomy of both hope and agitation (Cabrera et al., 2017). Sparking agitation in others often drives the unpopularity of many activists (Bashir et al., 2013). Even if they are able to dodge critique from others in their immediate surroundings, college student activists may experience emotional wear-and-tear from the necessity of chronically explaining their efforts and attempting to educate those who may not understand their motivations and objectives (Ruff, 2016). Additionally, balancing traditional academic demands with engagement in student protest groups can be a challenge for many. Researchers have outlined several detrimental physical impact of activism on college students, such as decreased appetite, decreased sleep, and overall exhaustion (Ruff, 2016). In light of the toll that activist involvement can take on contemporary college students, examining their means of support becomes critical.

SUPPORTING STUDENT ACTIVISTS ON CAMPUS

Researchers have called into question the role of universities in providing support to students engaged in activism, particularly given the chronic stress that often accompanies student protest (Ruff, 2016). Student activists, often from underrepresented groups, have asserted that university officials remain largely unaware of the time commitment and emotional reserves required to engage in activism outside of the classroom (Ruff, 2016). Although counseling services exist on most college campuses, minority students commonly seek counseling and support from professors or student organization sponsors with similar backgrounds under the assumption that staff at campus counseling will not understand their

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

motivations and experiences in campus activism causes (Ruff, 2016). Additionally, students engaged in campus protests and other forms of activism have heralded the importance of social support and encouragement from fellow activists as a primary avenue for self-care (Ruff, 2016). Fellow student activists not only carry a deep understanding of one another, but also offer camaraderie and support in the ongoing fight for social change.

STUDENT ACTIVISM THROUGH A WELLNESS LENS

To reiterate, depression, anxiety, and other forms of emotional and psychological distress are common among college students (American College Health Association [ACHA], 2013; Castillo & Schwartz, 2013) and negatively correlated with academic performance and retention (Eisenberg et al., 2009). Campus counseling centers serve only a small minority of students who could benefit from professional mental health services (Castillo & Schwartz, 2013; Zivin, et al., 2009). These realities indicate the necessity for preventative mental health initiatives on campus, particularly for more vulnerable populations such as student activists. A holistic approach is essential to fostering the wellness and sense of balance for student activists in light of the variety of roles they fulfill as a student, an activist, and more broadly, as a productive member of society.

As individuals, each activist draws from and applies their own unique set of strengths to their work, while the collective strengths of the group merge to add depth and structure in the battle for societal change. As such, it is imperative for student activists to have self-awareness of the unique strengths and assets they bring to the table to help the greater group. This holistic, strength-based perspective is the essence of the counseling-based wellness approach. Wellness is "a way of life oriented toward optimal health and well-being in which the body, mind, and spirit are integrated by the individual to live more fully" (Myers, Sweeney, & Witmer, 2000, p. 252). Although attending to student wellness is a noted goal of higher education institutions (LaFountatain, Neisen, & Parson, 2006), early efforts centered almost exclusively on academic and retention concerns (Isaak, Graves, & Mayers, 2006; Hermon, 2005). In more recent years, scholars have begun investigating the wellness of specific college student populations (Watson & Kissinger, 2007; Gieck & Olsen, 2007; Young, Turnage-Butterbaugh, Degges-White, & Mossing, 2015). Although the wellness of college student activists remains unexplored, many of the principles of the evidence-based Indivisible Self Model of Wellness (IS-WEL; Myers & Sweeney, 2005) apply to student activists (see *Figure 1*). A brief overview of this model is outlined in the section that follows.

Indivisible Self Model of Wellness

The IS-WEL is a holistic, strengths-based model with a higher order factor defined as *Total Wellness*. This factor underscores the importance of considering the totality of the activist's individual strengths. *Total Wellness* is divided into five second-order factors: *Creative Self, Coping Self, Physical Self, Social Self, and Essential Self.* Within the second-order factors are seventeen distinct third order factors that align with Adler's (1954) basic life tasks of work, friendship, love, self, and spirituality (Myers & Sweeney, 2005). This strengths-based, multidimensional view of wellness holds promise for measuring the overall wellbeing of student activists, as well as individual strengths (through the lower order factors) they bring to the activist stage.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Student activists may seek activism due to strong traits within the *Essential Self*, which encompasses "our essential meaning making processes in relation to life, self, and others (Myers and Sweeney, 2008, p. 86). Within the second-order *Essential self* are several third order strengths relating to comfort with spiritual beliefs, cultural identity, and orientation toward self-care (see *Figure 1*). These factors may drive the initial choice to become involved in activism, and may determine the level of activist involvement. For example, a student activist possessing the strength of *control* may choose to use their strengths behind-the-scenes as an event organizer. Alternately, a student activist with a strength in *friendship* may use their abilities to connect in a meaningful way with members of their community, and/or to work directly with campus administrators and student affairs professionals in gaining the necessary permits for an activist-related event on campus. Another student with a strength in *thinking* might design event posters and other social media marketing strategies. These examples are consistent with *intellectual/educational*, *front line*, and, to a limited degree, *social media activism* (Logan et al., 2017), and illustrate how personal strengths (alone or in combination with the strength of others) may be instrumental in a student's perception their role in activism, as well as their degree of engagement in activism.

The IS-WEL's strengths-based approach holds that student activists may possess strengths across multiple wellness dimensions. The wellness model posits that everyone possesses strengths, some of which may be unrealized, under-utilized, or under-developed. Overall, the holistic wellness paradigm as framed by the IS-WEL can provide an evidence-based, detailed profile of subjective sense of wellbeing. Implementing this model in higher education may allow researchers to gain insight about how activism could influence a student activist's perceived wellness, while uncovering potential links between specific wellness traits and college student activists (e.g., the specific activist roles best suited for each individual activist). This shift in perspective honors and promotes college student involvement in activism, as opposed to criticizing or quieting student efforts for social change, meeting the aforementioned higher education objective of fostering an orientation toward activism (Gurin et al., 2002). Several recommendations for working toward this objective are outlined in the section that follows.

SOLUTIONS AND RECOMMENDATIONS

Recommendations for Designing Curricular and Co-Curricular Experiences

Mission statements for most institutions of higher education include some level of commitment to both diversity/inclusion, as well as service to others (Hope et al., 2016). As such, increasing the availability of service-learning courses that infuse social justice into the general education curriculum could serve as a powerful intervention for indirectly supporting college student activists. Similarly, living learning communities can provide a meaningful opportunity for students to be surrounded by a diverse group of their peers who share common academic interests. Powerful experiences such as these, which intentionally expose students to issues that are impactful for segments of the student body (Hope et al., 2016), facilitate not only visibility of many activist issues, but also transparent and corrective dialogue around more difficult topics.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Recommendations for Diversity-Related Campus Programming

For many college students, particularly those from more homogenous and/or rural areas, their first exposure to diversity comes with their first steps onto their college campus. Many students may have a vocabulary peppered with words or phrases they may not realize to be offensive; others may lack basic skills in respectful communication and academic discourse; even students identifying as activists may approach their work in ineffective ways that lead to administrative penalties. As such, student affairs professionals in counseling or diversity offices may do well to offer best practices workshops (which could perhaps also be integrated into required coursework) on respectful communication, as well as appropriate mechanisms for engaging in activism to avoid sanctions from university administration (Hope et al., 2016). Making such information readily available may serve to circumvent much of the tension between student activists and campus officials.

Recommendations for Campus Officials

Many college student activists are quite young, with some not yet reaching adulthood. The courage and determination exhibited by young activists in asserting themselves with upper level administrators, and/or in the face of a hostile campus environment, is commendable (Hoffman & Mitchell, 2016). When examined through the lens of exposing novel methods for pursuing social change, and giving a voice to those who are silenced, it becomes quite clear that university officials (including faculty, staff, and upper administration) can learn a great deal from new wave young activists on campus (Halewood, 2016; Hoffman, & Mitchell, 2016). As such, campus officials are encouraged to maintain an attitude of curiosity and openness toward student activists. Existing literature highlights that it is imperative for "…faculty, staff, and administrators to create an activist friendly environment, and engage in advocacy work themselves for purposes of modeling, education, and to signal support and safety to students" (Lantz et al., 2016, p. 303). Taking this one step further, it is important for faculty to invite and embrace diverse student perspectives in the classroom, creating a safe environment for academic discourse that may challenge both students and faculty to adopt novel perspectives (Martin, 2014). Faculty who work more directly with students may also fill the role of facilitating access to upper administration, as students are often unfamiliar with the proper channels and hierarchy of communication (Linder et al., 2016). Moreover, campus officials would do well to maintain an awareness of current events on social media in order to anticipate and reduce potential harm to students (Linder et al., 2016). Administrators can keep abreast of student issues "…by observing public social media spaces where minoritized students are sharing their concerns" (Linder et al., 2016, p. 241).

Recommendations for Improving the Activist-Administrator Relationship

Student activism requires that higher administrators and student affairs professionals attend to a host of interpersonal, logistical, financial, legal, and media concerns (Harrison & Mather, 2017). The increased numbers of activist-related events on campus, coupled with and the uncertain and omnipresent role of social media (Brazelton, Magolda, & Renn, 2012) serve to complicate this task for many campus officials. In order for administrators to initiate and maintain favorable relationships with student activists, they must cognizant of the many diverse student communities on any given campus; inclusion must be a primary administrative objective. Student activists and administrators may interpret one another's actions

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in negative ways, which may be detrimental to the administrator-student alliance. For example, student activists identifying as minorities perceived administrators as detached from the emotional challenges related to their activism (Ruff, 2016). In the current climate, administrators are advised to resist the urge to use bureaucracy as a shield from conflict or honest engagement with displeased student activists (Clover, 2012). Failure to engage in honest discourse with student activists may only serve to create a further sense of disempowerment, causing each side to become more steadfast in their positions (Biddix, Somers, & Polman, 2009; Hoffman & Mitchell, 2016). Communication and collaboration between administrators and student activists are crucial elements to facilitating positive campus activism outcomes, and administrators are becoming more sensitive to the emotional dimensions of the student experience of activism (Harrison & Mather, 2017). In contrast to recent examples in the media, (Flaherty, 2017, Ruff, 2016) students broadly tend to perceive administrators as capable of effectively communicating with them, while maintaining openness to systemic change (Broadhurst & Martin, 2014).

FUTURE RESEARCH DIRECTIONS

Early trends are emerging that engagement in activism has an impact on the mental health of college students. However, this research appears to be in its infancy, and there are many opportunities for scholars passionate about this topic. In light of the paucity of research on the mental health and wellness of student activists, it is recommended that future investigations focus on the mental health impact of specific types of activism (e.g., social media vs. in vivo) for college students. Intervention studies are indicated to explore the impact of wellness-based programming on the mental health of student activists. In particular, the IS-WEL model may provide a viable framework for higher education professionals in counseling and student affairs through which individual strengths might be isolated and nurtured to boost effectiveness in specific activist roles. This model can also draw on areas for growth in student activists, as many individuals may engage in activism at the expense of other important areas of wellness. Wellness deficiencies are imperative to address for all college students, and perhaps for student activists in particular given the additional stressors that precede and follow their engagement in activism.

CONCLUSION

Student activism in higher education is anything but a new phenomenon. Activists tend to strive toward social change due to the impact of their own experiences, often integrating their activist work into their personal and professional sense of identity. Activism can take many shapes and forms; contemporary student activists often make use of social media to boost visibility of various causes, and to provide a voice to those who are silenced. Involvement in activism can take a toll on the mental health of student activists, and it may be critical to conceptualize the holistic functioning of activists across roles from a wellness perspective. The multifaceted nature of higher education environments requires that all campus stakeholders reflect on their attitudes and potential biases toward both activism and student activists. Such changes can serve as a catalyst for facilitating stronger and more meaningful campus relationships, and can facilitate a deeper understanding of the role student activism in boosting the overall health and wellness of all campus stakeholders.

KEY TERMS AND DEFINITIONS

Activism: Individual or collective action to effect widespread change in social and/or political realms.
Holistic: Interconnection between parts of the self (e.g., emotional, spiritual, physical, etc.).
Identity: Self-concept related to how one views self and how one is viewed by others.
Inclusion: Opposite of exclusion; refraining from discrimination based on differences.
Slacktivism: Offering support to a social or political cause through primarily digital means.
Social Media: Mechanisms of communication that occur digitally, and with widespread reach.
Wellness: Holistic health and balance in all aspects of the self.

Chapter 38
Interagency Collaboration to Improve School Outcomes for Students With Mental Health Challenges

Kristina Bixler
Indiana University, USA

Jeffrey Alvin Anderson
Indiana University, USA

ABSTRACT

Students with significant emotional-behavioral concerns and mental illness tend to experience poor educational and social outcomes. This chapter describes some of the challenges facing schools that are responsible for educating students with and at-risk for mental health challenges. Although some students encounter numerous risks, thereby increasing the chances of developing mental illness and failing school, there are also protective factors that can be identified and harnessed to counterbalance such risks and promote higher levels of resilience. By examining relationships among factors such as poverty, mental well-being, family engagement, resiliency, and school performance, a school-focused, community-based framework is suggested for responding to and overcoming these challenges. This chapter provides practical guidelines for schools, community agencies, and families to work together to support and engage young people who are at-risk for school failure due to emotional-behavioral concerns and mental health challenges.

INTRODUCTION

Partnerships among families, schools, and communities can be created and harnessed to support academic achievement for students with mental health needs (e.g. Adelman, & Taylor, 2006a; Adelman & Taylor, 2006b; Anderson, 2002; Conwill, 2003). Practitioners and researchers alike are now calling for a broader focus on collaborative efforts in schools and children's social services that include prevention, in addition to targeted early and intense interventions, across child-serving systems (e.g., education, health, child welfare, etc.) (Anderson & Cornell, 2015). The significance of this chapter is that it provides a practical orientation for schools and community agencies to work together, along with families, to successfully engage students, particularly young people who are at-risk for school failure due to emotional-behavioral concerns and mental health challenges. First, the chapter describes some of the challenges facing primary and secondary schools that are responsible for educating students with mental health challenges by examining the interconnected relationships among poverty, mental health, and school performance. The authors then argue that in this field, much of the research base examining academic failure has been limited by focusing on risk factors, often to the exclusion of critically important individual variation within subgroups of children with and at-risk for mental health challenges. While such research has uncovered important risks that correlate with school failure, our narrow attention on risks has reduced our ability to understand how resiliency influences academic and social development.

Once a better understanding of risk and resiliency has been established, the second goal of this chapter is to provide a practical guide for developing interagency prevention and intervention approaches, designed to bring together the entire community resource pool to reduce the number of students who fail in school due to unmet mental health needs. Interagency collaboration has been defined as "the process of agencies joining together for the purpose of interdependent problem-solving which focuses on improving services to children and families…" (Hodges, Hernandez, & Nesman, 2003, p. 292). Current policy implications supporting school-based interagency collaboration also are presented. It is further argued that by using resiliency within a collaborative model consisting of individual, family, community, and school assets, effective pedagogical and social approaches can be applied that allow young people with and at-risk for mental illness to succeed in and out of school. A number of well-known preventative and early intervention models are described. Finally, some specific steps for creating models of interagency collaboration are discussed.

BACKGROUND

Although the relationships between school functioning and mental health challenges are not fully understood (Epstein, Nelson, Trout, & Mooney, 2005), scholars have suggested wide-ranging interactions among school and non-school factors may be at fault, which can include clinical, familial, and environmental variables (Anderson, 2011). Explanations for the poor academic achievement for students with emotional challenges have included (1) poor grades leading to aggression; (2) aggression leading to poor grades; (3) a reciprocal relationship between poor grades and emotional challenges; and (4) other underlying factors that cause both poor grades and emotional challenges (Epstein et al., 2005; Barriga, Dorans, Newell, Morrison, Barbetti, & Robbins, 2002). Adelman and Taylor (2006a; b) described a continuum with causes from environmental factors, causes coming from within the person, and a transactional view caused by an interaction between the environment and the individual.

STUDENTS WITH MENTAL HEALTH RISKS

In the United States (U.S.), students with mental illness often have been labelled by the mental health community as having *serious emotional disturbances* and/or by schools as having *emotional disabilities*[1] (e.g., Anderson & Mohr, 2003). These terms can encompass numerous other labels and diagnoses such as conduct disorders and emotional-behavioral disabilities. Furthermore, this chapter expands the focus beyond young people with the most significant mental health challenges to also include students who may not be formally labelled but nonetheless are at great risk for school failure due to mental health challenges. While the percentage of young people identified as having significant mental health challenges has been estimated in the 3-6% range, when students who are at-risk are included, this figure increases significantly (e.g., Anderson, 2016). The purpose of taking the more expansive position of including youth who are at-risk is to promote capacity building for models in schools and communities for earlier intervention and prevention of mental illness (Anderson & Cornell & Cornell, 2015).

Overall, the population of students who have or are at-risk for mental health challenges has been documented as failing or risking failure across a wide range of domains, including home, school, and community (see e.g., Bradley, Henderson, & Monfore, 2004). Although researchers have indicated that as much as one-fifth of children in the United States has been diagnosed with a mental health disorder, only a small percentage of them will receive treatment (Rones & Hoagwood, 2000). It is estimated further that more than 40% of the young people experiencing these kinds of challenges will exhibit externalising behaviours aggressive enough to result in school suspensions. It is doubtful that students with serious behavioural challenges are effectively serviced by their schools (e.g., Walker, Ramsey, & Gresham, 2004); thus, the authors argue, schools need additional supports to assist this population of students in succeeding in school.

In fact, poor progress and outcomes for this population of young people has been documented in every school domain, including attendance, achievement, school behavior, social skills such as friendships with peers or relationships with teachers, involvement in extra-curricular activities, secondary graduation, and successful progression to post-high school work or training (Bub, McCartney, & Willet, 2007; Lopes, 2007; Reinke, Herman, Petras, & Ialongo, 2008; U.S. Department of Education, 1998; 2001; Vitaro, Brendgen, Larose, & Trembaly, 2005). Although researchers who study risks and resiliency for youth with mental health challenges advocate for increased focus on modifying negative trends (Edgeland, Carlson, & Stroufe, 1993; Wong, & Donahue, 2002), the continued reliance on using methods that emphasize risks to the exclusion of identifying protective factors may be limiting the growth and development of the field (Anderson, Howland, & McCoach, 2015).

Risk and Resiliency

Risk factors for mental illness can include internal influences, such as biological and psychological risks, as well as external influences like family and community risks (Trussell, 2008). Biological risks include those that can impact the central nervous system and development of the child and can increase the potential that students will have difficult dispositions and poor social and problem-solving skills (Garmezy, 1993; Trussell, 2008). Such difficulties can stem from prenatal damage such as exposure to alcohol, drugs, and/or malnutrition during pregnancy (Trussell, 2008). Psychological factors are described as "individual personality characteristics that are associated with poor future outcomes" (Trussell, 2008, p. 150). Depression, substance abuse, other mental health issues, and ineffective parental role models

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

are some examples of psychological risk factors (Reid & Eddy, 1997). These kinds of psychological concerns also appear to be more prevalent in people who experience socioeconomic disadvantages and the consequential environmental stresses (Webster-Stratton, 1990; Webster-Stratton & Hammond, 1998).

The relationships children form with their families and the people around them help develop their personalities and their ability to connect with others (e.g., Anderson & Mohr, 2003). Children who grow up in abusive or neglectful homes may have difficulty forming healthy, loving relationships with others and struggle to regulate their own emotions (Toth & Cicchetti, 2004; Trussell, 2008; Barnett, 1997). Research has shown that those who have difficulty developing healthy relationships are at greater risk for depression and substance abuse (Toth & Cicchetti, 2004). Children who have grown up in abusive environments also may avoid intimacy or displaying emotions and may have higher rates of aggressive behaviour or harming others (Trussell, 2008). Children with these risk factors are almost twice as likely to be arrested during adolescence (Toth & Cicchetti, 2004).

Family difficulties, stressful life events, and community risks such as crime and high levels of poverty, are examples of external influences that can negatively impact students with mental health challenges. Family risks are considered to include those characteristics of a family that can be detrimental to a child's development such as "severe parental conflict, overcrowding within the home, and a parental history of criminal behaviour or psychopathology" (Trussell, 2008, p. 150; Toth & Cicchetti, 2004). Families experiencing significant poverty or economic difficulties may experience higher levels of stress, increasing risks for abuse or neglect due to lack of parental engagement (Baydar, Reid, & Webster-Stratton, 2003). Stressful life events, which cause undue hardship on a family, such as the death of a parent, parental divorce, and surviving a life-threatening experience (Trussell, 2008), can also increase the risks for school challenges. Living in situations of significant poverty can increase exposure to parental stress during infancy. This can lead to emotional dysregulation, which in turn increases children's risks for developing more negative symptoms in elementary school (Essex, Kraemer, Armstrong, Boyce, Goldsmith, Klein, Woodward, & Kuper, 2006).

Risk factors, experienced in isolation or cumulatively, can increase the likelihood of negative or undesirable outcomes in school and other life domains. However, the presence of risk alone does not lead to poor outcomes for all children (Oldfield, Hebron, & Humphrey, 2016). Although greater risk is associated with the likelihood of experiencing negative outcomes, such as school failure (Garmezy & Marsten, 1986; Rutter, 1985; Werner & Smith, 2001), not everyone in a given risk group will fail; nor will all of the members of a specific group experience similar levels of risk. Indeed, when data are aggregated, risk status is not equal for all students with mental health challenges (Anderson, Howland, & McCoach, 2014). Students who are resilient to various risks tend to possess protective factors. For example, Werner and Smith (1992), described five factors or attributes that may reduce the negative influences of risks: 1) having an even temperament; 2) having a positive and meaningful relationship with an adult; 3) having an outside support system to help develop self-confidence; 4) having an interest in one's own future by setting goals and making decisions; and 5) being of average intelligence. Researchers have noted that students who are more resilient may possess certain protective skills, know their self-worth, and/or have had effective parenting (Masten, 2006).

Resiliency also appears better developed when students have parents who are caring, nurturing, and communicate openly with their children (Trussell, 2008). Likewise, scholars have pointed out that schools need to be considered among the most potentially powerful protective factors. Through instructional practices, curriculum, teacher perceptions, social support, and community building, schools can encourage and support resiliency in children (Masten, 2006; Trussell, 2008). Young people come to school with

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

a variety of academic, behavioural, and social strengths and needs. In spite of the levels of individual need, attending an effective school correlates with how successful a student will be in school (Masten, 2006). On the other hand, attending under-resourced or ineffective schools can present another set of risks to students' learning and social development (e.g., Chen, Anderson, & Watkins, 2016). The literature examining what it means to be an ineffective school has identified common themes, including a) lack of materials and supplies, b) overcrowded classrooms, c) teachers who are inadequately trained, d) staff turnover, e) high absence rates by students and staff, and f) a highly mobile student population (Trussell, 2008). Therefore, researchers have demonstrated that learning best occurs when healthy, reciprocal relationships exist among families, schools, and communities (Kim, Sheridan, Kwon, & Koziol, 2013).

Legal Support for School-Based Interagency Collaboration

Unfortunately, under-resourced schools tend to have a harder time building and sustaining resiliency in their students (Chen et al., 2016). In the U.S., during the years following the passage of the Federal No Child Left Behind (NCLB) legislation in 2001, it became increasingly clear that the patterns of poor academic outcomes observed in many under-resourced schools were going to be difficult to reverse (Blank, Melville, & Shah, 2003; Dryfoos, 2005; Tagle, 2005). During this time period, advocates called for more and better involvement of families in schools and more support from community social service agencies, especially in schools serving poor and disadvantaged neighbourhoods and populations (Dryfoos, 2000; Harris & Wilkes, 2013). With the U.S.'s recent passage of Every Student Succeeds Act (ESSA), which replaced NCLB in late 2015, some of those same advocates are expressing hope because the new law emphasises authentic family engagement in schools, as well substantive community involvement. According to the National Center for Mental Health in Schools (NCMHS, 2016), ESSA is intended to "(1) significantly improve the academic and developmental outcomes of children living in the most distressed communities of the United States, including ensuring school readiness, high school graduation, and access to a community-based continuum of high-quality services; and (2) provide support for the planning, implementation, and operation of full-service community schools that improve the coordination and integration, accessibility, and effectiveness of services for children and families, particularly for children attending high-poverty schools, including high-poverty rural schools." Moreover, the authors stated that ESSA clearly acknowledges that the coordination and integration of community support services in schools is necessary for overcoming barriers to learning and teaching (NCMHS, 2016). This follows efforts by the U.S. Department of Education (2000) to set expectations for schools to deliver practices that foster mental health well-being. Schools are the ideal environment for students to learn the academic, behaviour, and social skills necessary for developing into healthy young adults (e.g., Anderson, 2016; Anderson, 2016; Powers, 2002).

Supporting Under-Resourced Schools

Scholars have argued that service coordination and integration can help under-resourced schools increase their effectiveness (Anderson & Cornell, 2015; Dryfoos, 1994; 2005). By strengthening family social support networks, interagency collaboration can help to expand opportunities for parents, schools, and agencies to work together. Interagency collaboration also can help increase the interconnectedness of schools and their neighbourhoods (e.g., Coleman, 1988). For example, support for finding stable housing and employment counselling can be offered to parents and caregivers within their children's schools by

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

community agencies (Anderson, 2000). Mental health screenings can be provided in schools by clinicians from nearby community mental health centres. Moreover, by providing the organizational framework for schools, communities, and families to work together in creating multi-tiered systems of supports, school-based approaches can provide the kinds of supports necessary to help children and youth with or at-risk for emotional-behavioral challenges succeed in school, while simultaneously supporting youths' families and teachers (Anderson & Cornell, 2015).

Drawing from *community schools* approaches (Dryfoos, 2005) in education and systems of care initiatives in the children's mental health field (Stroul & Friedman, 1986; Stroul & Blau, 2010), contemporary interagency frameworks in schools provide children and their families, as well as teachers and administrators, access to a variety of community supports (e.g., caregiver support groups, behavioral training for adults who work with students) and services (e.g., family case management, therapeutic services, residential treatment facilities) to address the wide range of possible physical, emotional, academic, and social needs students may be experiencing that can interfere with learning (Rones & Hoagwood, 2000). In such a framework, each system, agency, and school commit to operating under a community-wide tiered network or system of support. Partners, including families, collaborate with the goal of supporting individuals, schools, and families, to improve the overall functioning of students with and at-risk for mental health challenges and school failure (e.g., Chen et al., 2016).

As the focus of these collaborative efforts has shifted from children with mental illness and their families to the entire population of young people within a community, broader, more comprehensive approaches to interagency collaboration that include prevention are being created (Anderson, 2016). Services and supports are not only being offered in schools, but agencies and schools are starting to collaborate in new and innovative ways (Anderson & Cornell, 2015). For example, in one interagency model called the Full Purpose Partnership (FPP), located in Indianapolis, Indiana, *care coordinators* who act as case managers for the school and community are housed within participating schools (Anderson et al., 2010). These care coordinators are responsible for implementing four components core to the FPP model: (a) effective curricula and instruction; (b) inquiry driven, data-based decision-making; (c) systems of care and wraparound principles (including authentic family involvement; strengths-based practice; cultural competence; and interagency collaboration); and (d) school-wide positive behavior supports. Each of these components is conceptualised through a three-tiered system of school-wide supports (Sugai & Horner, 22002), focusing on prevention, early intervention, and comprehensive intervention. Borrowing heavily from positive behavior interventions and supports, which in turn was adopted from the field of public health (Walker, Ramsey, & Gresham, 2004), the multi-tiered system simultaneously coordinates prevention (what schools do to ensure that all students are successful); early intervention (what schools do to intervene quickly and effectively when students experience challenges); and comprehensive intervention (what happens when students are experiencing chronic levels of school challenges).

Community-school collaborations like the FPP make it easier to identify gaps in community service networks, thus allowing for the creation of new services and supports to fill those gaps. The ultimate goal is that each child serving system or agency, including schools, will collaborate to offer prevention efforts at the base level and more intensive targeted services to smaller numbers of individuals as needed (Anderson et al., 2010). Another goal is to move away from children's social services systems that historically were expert-driven, overly restrictive, fragmented and uncoordinated, costly, absent, or separated from the natural settings where children's challenges occur (Johnson, Zorn, Yung Tam, Lamontagne, &

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Johnson, 2003; Stroul & Blau, 2010). By offering services and supports that are family-driven, youth-guided, and grounded in strengths orientations, caregivers are empowered to become decision-making partners in the planning of such services (e.g., Anderson, Wright, Smith, & Kooreman, 2007; Atkins, Hoagwood, Kutash, & Seidman, 2010).

Educating Students At-Risk for School Failure

With the passage of ESSA in the U.S., schools now have a clear legislative mandate to connect school and community supports through collaborations among educators, families, and communities. A beginning framework for the systematic integration will require schools and their communities to "(1) coalesce existing student and learning supports into a cohesive component and (2) over a period of several years, develop the component into a comprehensive intervention system that is fully interwoven into instructional efforts. Such a component is key to enabling all students to have an equal opportunity to learn at school and all teachers to teach effectively. This type of systematic approach is especially important where large numbers of students are not succeeding" (NCMHS, 2016; p. 15). It is clear that students need to experience success to increase their resiliency and that schools are ideal places for success to occur (e.g., Keogh, 2000). Thus, a critical area of importance for schools is the use of effective classroom methods (Wang, Haertel, & Walberg, 1998). For example, teachers can use evidenced-based practices for instruction to improve opportunities for students to succeed. This is particularly important for students who are at-risk for various types of school failure. Researchers have shown that teachers improve learning by creating safe and caring environments where students feel comfortable taking risks and by using positive behavioural techniques such as verbal praise and positive reinforcement to enhance student learning and classroom management (e.g., Jones & Jones, 2015). Most teachers understand that their own teaching styles can create increased risks for students (Trussell, 2008). It is well understood that teachers should avoid yelling or using negative verbal remarks, which may potentially cause students to be disruptive or disengaged (e.g., Anderson & Mohr 2003). Educators should also realise that some students have deficits in prerequisite skills that may interfere with their ability to meet the grade level requirements. Likewise, curricular content should be interesting and flexible enough to address the individual strengths and needs of students (e.g., Adelman, & Taylor, 2006a; b). When developing school curriculum, educators should not only incorporate student interests into the curriculum, they should plan for the necessary attention and instructional remediation, to ensure that their students who are at-risk for failure have necessary opportunities to succeed (Trussell, 2008; Brooks, 2006).

Teacher perceptions and expectations of their students also influence how successful students are in school (Anderson, Howland, & McCoach, 2014). Both teachers and students view antisocial peers in negative ways (Walker et al., 2004); therefore, teachers need to be trained in classroom management skills such as posting rules and consequences, setting behavior goals for classrooms and individuals, and following through with the management plan for the class (Jones & Jones, 2013). Educators who spend time with and learn to understand both the challenges and strengths of their students who are at higher risk for school failure can serve as an important protective factor for this population of students (Brooks, 2006; Trussell, 2008). At-risk students who have a positive relationship with an adult tend to be more successful in dealing with challenging situations and are more likely to succeed (Werner & Smith, 1992; Trussell, 2008). Another protective factor for students at-risk is social support. Friendships with peers and adults provide an important source of social support, which can act as a buffer for students who have experienced a stressful life event (Werner & Smith, 1992; Brooks, 2006; Trussell, 2008). Resilient

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

students are more likely to turn to their friends during times of crises (Werner, 1989). Thus, schools should provide opportunities for students who are at risk for failure to develop relationships with peers and adults. In fact, an important goal of schools should be to help students develop social competence (Consortium on the School-Based Promotion of Social Competence [CRPSC], 1994). Social competence involves students working on their citizenship skills, which include: problem-solving, assertive decision-making, communicating clearly, regulating emotions, managing and resolving conflict, resisting pressure from peers, and developing positive personal relationships (CRPSC, 1994; Farrell, Meyer, & White, 2001; Griffin, Botvin, Nichols, & Doyle, 2003).

Schools can work to improve and ensure positive outcomes for all students, including students at higher risks for failure, and promote resiliency by building a strong sense of community both in classrooms and throughout the entire school (Battistich, Schaps, Watson, & Solomon, 1996). By creating warm and caring environments where students feel safe and valued and by teachers providing effective instruction, educators are helping students succeed (Battistich et al., 1996). At the school level, a governance body is established, directly involving parents and caregivers as decision-making partners, designed to eliminate territorial issues among partnering community agencies. Support for teachers to use the best, evidenced-based instructional and classroom management practices is provided, as is assistance for teachers to connect and stay connected with the families of their students. Incentives, benchmarks and expectations for interagency collaboration are developed, implemented, and monitored. The governance group systematically builds linkages among schools, families, systems, and agencies to support broader goals of community wellness and improved overall functioning for students, their families, as well as teachers and administrators (see, e.g., Anderson & Cornell, 2015).

Examples of School-Based Approaches

School-based interagency programs should incorporate universal preventative interventions that focus on students' social and problem-solving skills (Anderson et al., 2010). Preventative interventions need to target all students, with a specific focus on young people who are at a higher risk for developing emotional-behavioral difficulties. This is especially important for youth who may "fall through the cracks"; which is when students exhibit symptoms and signs but do not qualify for services (Chen et al., 2016). Many different preventative programs have been developed for schools. Such approaches can vary but they typically assist students in developing and using appropriate social and emotional skills. For example, Promoting Alternative Thinking Strategies (PATHS) is a school-based prevention program that "aims to increase children's ability to discuss and understand emotions, facilitate the development of self-control, promote a positive peer climate, and enhance interpersonal problem-solving skills" (Rones & Hoagwood, 2000, p. 229). Another prevention program, Linking the Interests of Families and Teachers (LIFT), is designed to prevent or reduce aggressive and antisocial behaviour for elementary students who live in neighbourhoods with high crime rates (Rones & Hoagwood, 2000). The Family and Schools Together (FAST) Track program targets kindergarten students who are oppositional and aggressive. Researchers have noted that students who completed FAST were less likely to be referred to special education and exhibited less aggressive and oppositional behaviour than those who did not receive these services (Rones & Hoagwood, 2000). The Life Skills Training (LST) Program is a skills-based substance abuse program, which teaches students skills on how to manage anxiety, build self-esteem and relationships, communicate effectively, be assertive, and resist peer pressure (Rones & Hoagwood, 2000).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, the Kaleidoscope program is a rapid response program designed by the Indianapolis Public School system in Indiana to provide supports for students who are experiencing difficulties with their behaviour in the school setting, as well as for their teachers and families (Wang, Cornell, & Anderson, 2016). In brief, the program theory is that students who start exhibiting behaviour problems in school can be assisted through intensive, comprehensive interventions before challenges escalate. While the purpose is to intervene early to prevent the need for more intensive interventions and placements, when necessary, the program also guides the process for students who require more intensive support (e.g., special education services). Kaleidoscope uses a team-based approach, pairing a behaviour specialist and social worker who provide coordinated services and supports across home, school, and community. An example of team efforts can include: 1) designing intervention plans, which include interventions at home and school; 2) relationship building among caregivers and school personnel; 3) educating parents about how to communicate with professionals in their community; 4) educating teachers and other school professionals about classroom management; 5) educating families, teachers, and other school professionals about how mental health related issues can affect learning; 6) conducting environmental assessment and modifications to increase opportunities for learning; and 7) easing frustrations among the adults living and working with youth experiencing mental health challenges. Kaleidoscope staff members are also trained to navigate the organisational culture already in place in the schools in which they work and then assist educators in building healthy engagement with the parents of students in those schools.

School-based interagency programs tend to have similar components, such as flexibility and individualization (e.g., Chen et al., 2016). Programs often include opportunities for teaching parents and teachers to use effective behaviour management skills. These preventative programs can be integrated into the general education curriculum and, of course, need to be developmentally appropriate for the students (Rones & Hoagwood, 2000). To be successful, Rones and Hoagwood (2009) stated that clear, specific guidelines are needed clarifying how the program should be implemented. Teachers, caregivers, and others actually implementing the program should receive feedback about their efforts and school leaders need to support teachers by funding both the training and maintenance sessions as well as monitor program fidelity (e.g., Anderson et al., 2010).

Guidance for Developing Interagency Frameworks

Interagency collaboration can reduce fragmentation and redundancy and allow service gaps to be identified and filled. However, to have effective interagency collaboration, schools and community agencies must have dedicated staff, be willing to understand and respond to philosophical differences, and have appropriate funding and time for such engagement (Anderson-Butcher & Ashton, 2004; Gonsoulin & Read, 2011). While most child-serving agencies have their own funding and management systems, these functions may conflict with the ability of the agencies to work together (Anderson, 2000; Anderson, 2000; Tapper, Kleinman, & Nakashian, 1997; Johnson et al., 2003). Thus, systems, schools, and agencies have to be willing to share relevant information to coordinate the most effective configurations of services and supports for each participating child and her or his family (Johnson et al., 2003; Gonsoulin & Read, 2011).

Arguably the key component of effective interagency collaboration is sustaining clear and open communication and cooperation with the other agencies (e.g., Chen et al., 2016). When students are involved with two or more agencies, someone will need to coordinate meetings and facilitate shared decision-making. Scheduling these meetings is not easy and takes time and resources (Tapper et al.,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

1997; Gonsoulin & Read, 2011). One straightforward task to develop frameworks and infrastructure for interagency collaboration is the creation of memoranda of understanding (MOU). The MOU can serve many purposes but at a minimum, it can clearly outline how participating agencies and schools will share information regarding the needs of specific students, such as demographic information, information about strengths and challenges and data related from student records (Gonsoulin & Read, 2011). For example, if a goal is improved school attendance, information about current and future performance will be needed. Developing MOUs allows all partners to delineate both how and what information will be shared, which can include medical records, information about the family, and educational records (Gonsoulin & Read, 2011). MOUs should also clearly address confidentiality and specific procedures in terms of what information can be shared, how it can be shared, with whom the information can be shared, and who from each agency will grant permission for the sharing of information (Tapper et al., 1997; Gonsoulin & Read, 2011). By outlining the information and goals shared, this establishes trust among the partners. Leaders from all partnering agencies and schools, along with legal staff, can help navigate the MOU, ensuring compliance with national, state, and local laws (Gonsoulin & Read, 2011). Further, by sharing fiscal responsibility and staff, the interagency team can benefit from the expertise of multiple disciplines (e.g., health, education, social work), while working to eliminate duplication of services and fill in service gaps (Tapper et al., 1997; Gonsoulin & Read, 2011). However, the sharing of funds can be a complicated process, which often requires changes in existing policy and law. Many public and private agencies have to provide evidence regarding their collaboration efforts in order to receive funding (Gonsoulin & Read, 2011).

These partnerships continue to benefit all stakeholders in the community (Anderson-Butcher, 2004). The benefits include teachers, families, and counsellors understanding the many issues students may be facing; increased support among school professionals and the families; and more effective psychoeducational programs for youth with mental challenges (Tourse & Sulick, 1999). Research has shown that students have increased academic achievement and reduced behaviour issues due to interagency collaboration (Smith, Armijo, & Stowitschek, 1997). Collaboration among agencies has helped improve school attendance for students in addition to the quality of the students' learning experiences (Hatch, 1998). Anderson (2011) found that school functioning significantly improved between the time students enrolled in a local community-based interagency system of care and up to 36 months, post-enrollment. Moreover, these longitudinal improvements also were found to be significantly associated with improved clinical functioning over time. In an earlier study, Manteuffel, Stephens, and Santiago (2002) also reported that school performance and attendance improved from enrollment in a system of care to two years post enrollment for a national sample of young people served by interagency systems of care.

CONCLUSION

Emphasising a strengths orientation to service provision and authentically partnering with families have dramatically changed how society works with young people with mental illness, and their families (Anderson, 2011). Indeed, best practices now require that children's mental health and social services be *family-driven* and *youth-guided* (Stroul & Blau, 2010). Perhaps the most challenging aspect of such interagency initiatives is building and then sustaining trusting relationships not only among service providers but with the child and family. Personnel from schools and child-serving agencies must first acknowledge that children and their families are experts about their own circumstances. Thus, students

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and families will be considered as full partners in all teaming, treatment, and decision-making processes. Gonsoulin and Read (2011) provided a number of practical suggestions for working with families: 1) schedule meetings when it is convenient for the family; 2) ask the family to define their basic interests and needs; 3) define roles of family and participating professionals; 4) find local support groups for the family; 5) provide child care for the family to facilitate meeting attendance; 6) arrange for transportation for families to attend the meetings; 7) provide food, snacks, and beverages when meetings occur during mealtimes; 8) use technology (email, phone conferences, and web conferences) to eliminate unnecessary face-to-face meetings; 9) ensure that children and family are empowered not only to share their own stories but to take leadership roles in these processes; and 10) eliminate the use of professional jargon. The authors recommend that professionals start by adopting and adhering to these simple suggestions.

Viewed as a way to overcome intractable patterns of educational failure occurring in many seriously under-resourced communities, interagency collaborative initiatives are emerging in schools and children's social services across the U.S and elsewhere. Combined with other recent innovations such as multi-tiered student supports (MTSS), Response-to-Intervention (RtI), and trauma-informed service provision, these kinds of partnerships offer multiple pathways for schools to better achieve their primary goal of academic growth for all students, including young people at higher risks of school failure. Moreover, the recent ESSA legislation in the U.S. highlights the importance of supporting learning through organised networking and collaboration among educators, families, and community social services agencies. However, it is critical that school-community partnerships and authentic family involvement in schools do not become just another educational "fad" that comes along, consumes a lot of time and resources, and then fades away. With appropriate development and support for communication, coordination and wide-ranging community backing, schools and community agencies can begin to think and act in new ways.

KEY TERMS AND DEFINITIONS

Family-Driven: Families are the primary decision-makers in the care of their own children and authentically contribute to all policymaking and procedures governing care for all children in their community.

Interagency Collaboration: Systematic communication and cooperation among child-serving agencies (school systems, mental health services, welfare services).

Mental Health: The field of study and practice that focuses on the psychological and emotional well-being of an individual.

Prevention: Stopping something before it happens.

Protective Factors: Qualities that people possess or interactions with others that predict better outcomes for people who face adversity.

Resiliency: The ability to recover from risks or difficult life experiences.

Risk Factors: External and internal influences that can lead to poor outcomes for people.

School-based Interventions: Strategies or techniques used by the school to help students improve their academics, behavior, and/or social skills.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Systems of Care: Clusters of organizational strategies that are focused on improving outcomes and grounded in a set of principles, including cultural competence, strengths-focused, family-centered, and least restrictive/community-based.

Youth-Guided: Young people are fully involved in all decision-making role related to their own lives and authentically contribute to all policymaking and procedures governing care for all children in their community.

ENDNOTE

[1] In 1997, the Individuals with Disabilities Education Act was reauthorized and the term SED was shortened from 'Serious Emotional Disturbance' to 'Emotional Disturbance' (ED) (Anderson and Mohr (2003) and Anderson (2000) discuss labels and diagnoses in education and mental health).

Chapter 39
Providing Primary Prevention and School Mental Health Services to LGBTQ+ Children and Youth:
A Resiliency-Based Approach

Elizabeth K. Rhoades
Southern Connecticut State University, USA

ABSTRACT

This chapter provides an overview of the difficulties facing LGBTQ+ youth in schools and their barriers to healthy psychosocial development. The risk and resiliency model is applied to these challenges, and specific risk factors and resiliency factors are explored. The focus is on means to foster healthy growth and development in sexual minority students through developing school-based programs and practices that have been proven to increase resiliency. The chapter provides specific strategies for school-based mental health professionals to use to increase resiliency in sexual minority youth through the application of school-wide policies and practices. Strategies for making such systemic changes and garnering support are also presented.

INTRODUCTION

School-based mental health professionals such as school counselors, school psychologists and social workers use their skills on a daily basis to promote healthy overall development for all students. In order to prevent the development or worsening of emotional, behavioral or academic problems, prevention and early intervention services are vital tools to accomplish this goal. Application of the risk and resiliency model can identify strategies to address areas of concern and help students to succeed despite adversity. This chapter applies this model to the experience of LGBTQ+ youth in schools and suggests

how school mental health professionals can make schools safer and more nurturing environments for sexual minority youth.

BACKGROUND

Public schools have often struggled in their attempts to meet the needs of diverse groups of learners. Issues of racial and economic segregation and means of providing appropriate services to meet the needs of students with disabilities created controversy and enormous challenges. Schools' efforts to meet the needs of sexual minority youth have followed a similar path and the difficult journey continues. The National Education Association's (NEA) status report on GLBT issues in education notes that, "Hostility and apprehension toward homosexuality and gender nonconformity—reinforced over many decades by law, medicine, religion, and other cultural and societal institutions and conventions—continue to plague GLBT youth and adults in schools in every region of the nation, even as signs of greater inclusion and acceptance appear in some areas" (Kim, Sheridan, & Holcomb, 2008, p. vii).

Healthy social and emotional development in LGBTQ+ children and youth is a relatively new concept. Only in 1973 did the American Psychiatric Association (APA) remove homosexuality as diagnostic category of mental disorder (Baughey-Gill, 2011). Gender identity disorder was not removed until 2012, although gender dysphoria remains a controversial and related diagnosis. These identities were defined as manifestations of psychological disorders until relatively recently and public opinion and understanding of sexual minority individuals is still evolving. As society's primary public institution responsible for teaching social norms and guiding the development of children and youth, schools' understanding and skills in meeting the needs of LGBTQ+ individuals continue to evolve.

School mental health professionals are in a unique position to provide both individual and systemic support for sexual minority students. The role of school support personnel (counselors, social workers, and school psychologists) in meeting the developmental and mental health needs of LGBTQ+ children and youth (setting the tone, needs assessment, developmental guidance activities, using the positive behavioral interventions and supports (PBIS) process to meet the needs of LGBTQ+ children & youth, working with parents, administrators & school personnel, training issues, providing consultation) is ideal for developing school-wide policies and practices to support these children and youth. In addition, school mental health professionals can use their clinical skills to meet the individual mental health and emotional needs of sexual minority youth. Not surprisingly, these students say they would be more comfortable discussing LGBTQ+ issues with a school-based mental health professional such as a school psychologist, counselor or social worker (52.8%) than a teacher (42.3%), school nurse (30.1%), school administrator (25.9%) or coach (18.4%) (Kosciw, Greytak, Zongrone, Clark, & Truong, 2018).

SUPPORTING HEALTHY DEVELOPMENT IN LGBTQ+ CHIDREN AND YOUTH

Healthy LGBTQ+ Youth

Definition of Healthy LGBTQ+ Youth

As stated previously, the concept of healthy LGBTQ+ individuals is a relatively new concept to many. Like other healthy individuals, healthy sexual minority individuals are able to learn and grow, meet developmental and social challenges, develop and maintain rich and rewarding relationships, and move towards their potential despite occasional adversity.

A Note on Self-Definition

While the majority of LGBTQ+ youth define themselves in those terms and see themselves as members of a sexual minority, this is not the case for all. LGBTQ+ children and youth are a large and richly diverse group of individuals with a variety of perspectives and views. Ritch Savin-Williams (2005, 2006) reports that many adolescents currently do not define themselves in the same way as previous generations who engaged in same-sex activity. Despite being open in their romantic and sexual relationships, they often reject the word "gay." They may want to avoid the political label or frightening life course many associate with being gay. These teens do not see their life as all that different from their straight peers. They do not reject their actual attractions or report deep emotional difficulties. In sum, they "don't want their sexuality to define them" (Savin-Williams, 2006, p. 16). While internalized homophobia or safety concerns may play a role for some of these youth, others feel a greater fluidity in their sexual expression or do not perceive themselves as fitting the gay stereotype. In their view, they may be best understood through understanding adolescent development generally.

A Note on Intersectionalities

LGBTQ+ individuals are also vulnerable to all of the social stigma, marginalization and discrimination that occur within the larger society. Issues of race, gender, religion, social class, and other factors impact each individual's experience. While a discussion of all of these factors is beyond the scope of this chapter, it is clear that they have a major impact on the LGBTQ+ individual's lived experience.

LGBTQ+ Youth Vulnerabilities

Russell and Fish (2016) provided a review of the current knowledge of mental health issues in LGBT youth. LGBT individuals in adulthood clearly have higher levels of substance use and abuse, depression, anxiety, post-traumatic stress disorder and suicidality. Research indicates that LGBT youth have elevated risk for emotional distress, depression, anxiety, and suicidality (Fish & Pasley, 2015; Needham, 2012; Marshall, Dietz, Friedman, Stall, & Smith, 2011). Of all of these concerns, suicide risk is the most pressing.

Adams, Hitomi & Moody (2017) conducted a meta-synthesis of research on suicide within the adult transgender community. Their review of 42 Canadian and U.S. studies found that 55% of the participants had considered suicide at some point and 29% had made one or more suicide attempts. Kuper, Adams

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and Mustanski (2018) found even higher rates of suicide ideation in their sample of young transgender and gender nonconforming individuals recruited for an online survey. The vast majority (83.7%) reported suicidal ideation in the last year with most of them screening positive for suicide risk (81.3%). However, a much smaller proportion of the larger group (10.9%), said they had made a suicide attempt in the last year. An even higher percentage (95.5%) reported suicidal ideation at any point in their life and 32.3% reported having made a suicide attempt at any point. Gender-related victimization, negative self-concept, and depressive symptoms were related with negative outcomes.

Rivers, Gonzalez, Nodin, Peel, and Tyler (2018) conducted a qualitative study of LGBTQ+ individuals in England who had attempted suicide during their adolescent years. Issues of isolation, religious conflict, stresses associated with coming out, concurrent mental health issues, and grief all played a major role in these individuals' youthful suicide attempts.

The Risk and Resiliency Model

Early research into the development of LGBTQ+ youth, like early studies with most marginalized groups, came from a student-at-risk model. From this viewpoint, researchers enumerated the many negative experiences of discrimination and harassment faced by sexual minority youth and the correlation of such experiences to numerous negative developmental outcomes. This was a valuable exercise and helped to lay the foundation for understanding the day-to-day challenges many LGBTQ+ youth face. A shift in thinking towards the resiliency approach, however, can provide mental health professionals and schools with information that can be used to develop policies and practices that can actually help students to negotiate healthy overall development despite adversity. Resilience can be defined as the ability of the individual to adapt and function in a relatively healthy matter despite adverse experiences. In the words of Olsson, Bond, Burns, Vella-Brodrick, and Sawyer (2003), "Resilience does not so much imply an invulnerability to stress, but rather an ability to recover from negative events" (p. 2).

While most individuals have a clear understanding of the term "risk factors," or factors that are correlated with negative outcomes or developmental problems, fewer may be aware of resiliency factors. The resiliency framework focuses on key variables known as "resiliency factors" that help buffer the individual against negative experiences and assist continuing positive development. These factors include individual characteristics such as intelligence and a positive temperament, key individual skills such as effective oral communication and social skills, personal attributes such as flexibility and self-esteem, family variables such as parental warmth and cohesion, community variables such as resources and programs to assist, and school variables such as supportive peers and positive relationships with teachers (Olsson, et al., 2003). The current chapter will focus on those resiliency factors which can be developed or supported by schools and school personnel.

Key Risk Factors and Outcomes

A Lack of Safety

Maslow's pivotal 1943 work postulated that individuals have a hierarchy of needs and that lower level needs must be met for the individual to be able to focus their energy and attention on meeting higher level goals and challenges. The need for safety is essential, falling just above physiological needs such as air and water on Maslow's scale. Unfortunately, many sexual minority youths do not feel safe at school.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fears and safety concerns are paramount for many LGBTQ+ youths in their schools. In the Gay, Lesbian and Straight Education Network's (GLSEN) 2017 school climate survey, "59.5% of LGBTQ+ students felt unsafe at school because of their sexual orientation, 44.6% because of their gender expression, and 35.0% because of their gender" (Kosciw, et al., 2018, p. xviii). These concerns led to frightened students starting to withdraw from the larger school community. They often refused to come to school at all (34.8% missing a day in the last month and 10.5% missing four days or more), avoided locations like bathrooms (42.7%) and locker rooms (40.6%), refused to attend school functions (75.4%) or join in after-school clubs and activities (70.5%). Nearly 1 in 5 had actually changed schools for these reasons and others planned on leaving school altogether. According to GLSEN, "of the LGBTQ students who indicated that they were considering dropping out of school, a sizable portion (42.2%) indicated that they were doing so because of the harassment they faced at school" (Kosciw, et al., 2018, p. xx).

Gender Non-Conformity as the Root

It is the appearance of gender non-conformity that is the root of most acts of homophobic harassment. According to Kim (2008),

Bullying of GLBT students stems largely from discomfort with students who do not conform to traditional gender roles in their appearance or behavior, i.e., who are gender-nonconforming. A student's actual sexual orientation may be far less relevant to his or her social victimization than his or her gender identity or gender expression." (p. vii)

Both LGBTQ+ youth and their heterosexual peers are the victims of homophobic harassment with resulting damage to their academic, emotional and physical functioning (D'Augelli, Pilkington, & Hershberger, 2002).

Physical Assault

Fears for physical safety are often well-founded. LGBTQ+ students report frequent harassment, bullying and assault at school. Of the LGBTQ+ youth responding to GLSEN's 2017 school climate survey, 70.1% reported homophobic harassment with 59.1% reporting harassment based on gender expression. Physical acts of aggression against this population were common. LGBTQ+ students were frequently physically intimidated, as in being pushed (reported by 28.9% for sexual orientation issues and 11.2% for gender expression) or physically assaulted such as being hit with a fist or a weapon (reported by 12.4% for sexual orientation issues and 24.4% for gender expression). Sexual harassment was also very common with 57.3% having been the recipients of unwanted touching or sexualized remarks at school in the last year. Cyberbullying was also reported by 48.7% of these LGBTQ+ students (Kosciw, et al., 2018).

Slurs & Homophobic Language

Nearly all of the respondents to GLSEN's 2017 school climate survey reported hearing homophobic language and slurs at school and being hurt by them. For example, 98.5% heard the word "gay" used in a pejorative way, 70% of them heard this frequently, and 91.8% said this caused them distress. Other homophobic slurs were reported by 95.3% of respondents with 60.3% hearing them often. The vast

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

majority (94%) of these LGBTQ+ students heard distressing statements about gender expression with 62.2% hearing them regularly. Hearing targeted slurs against transgender individuals were reported by 87.4% of the respondents and 62.2% heard these regularly. Even more distressing was the fact that 56.6% heard members of the faculty making homophobic remarks and 71.0% had heard school staff making pejorative remarks about gender expression (Kosciw, et al., 2018). Accroding to Kosciw, et al. (2018),

hearing biased or derogatory language at school, especially sexist remarks, homophobic remarks, and negative remarks about gender expression, was a common occurrence. However, teachers and other school authorities did not often intervene when anti-LGBTQ+ remarks were made in their presence, and students' use of such language remained largely unchallenged. (p. 132)

Most Harassment is Never Reported

Most of these incidents never come to the attention of school staff. According to GLSEN's 2017 school climate survey, "55.3% of LGBTQ+ students who were harassed or assaulted in school did not report the incident to school staff, most commonly because they doubted that effective intervention would occur or feared the situation could become worse if reported," and "60.4% of the students who did report an incident said that school staff did nothing in response or told the student to ignore it" (Kosciw, et al., 2018, p. xix).

Discriminatory School Policies and Practices

Many schools engage in discriminatory practices that further erode LGBTQ+ students' sense of acceptance and belonging at school. A 2017 survey of LGBTQ+ students found that 62.2% reported having experienced these at their school. Discriminatory experiences included the refusal to allow the development of a Gay-Straight Alliance (GSA) (14.8%), refusal to allow same-gender dates at school functions (11.7%), punishment for displays of affection that are allowed for other students (31.3%), and not allowing clothing considered inappropriate for their legal gender (22.6%). LGBTQ+ students reported having been banned or discouraged from school sports (11.3%). Many students even reported school practices that prevented them from fully engaging with the school curriculum such as prohibitions against writing about or discussing LGBTQ+ issues for school assignments (18.2%) or engaging in free speech activities such as wearing t-shirts or other items that espouse LGBTQ+ causes (13%) or discussing such issues in school clubs or other extracurricular activities (17.6%) (Kosciw, et al., 2018).

Heteronormativity in not Safety

Short (2017) found in his qualitative study of Canadian schools that many LGBTQ+ students saw school safety as more than freedom from physical violence and bullying. They saw equity as a factor and addressing heteronormativity in general, and in the curriculum in particular, as essential to the safety of their identities. In the words of one of his interviewees,

Safety for queer kids is about changing things, not protecting things. I mean, of course, that you have to protect kids, but that's a given, isn't it? But it's not just about bullying, I mean, in a physical way. We're bullied by just the culture we're in. (p.14)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In their 2017 survey of LGBTQ+ students, GLSEN found that only a minority (19.7%) "were taught positive representations about LGBTQ+ people, history, or events in their schools; 18.4% had been taught negative content about LGBTQ+ topics" (Kosciw, et al., 2018, p. xxii). Less than half (41.0%) said their school library had sources for information on LGBTQ+ issues. A survey of high school students found that only 20.8% said LGBTQ+ topics were taught in their school building (Greytak, Kosciw, Villenas, & Giga, 2016). One barrier to an inclusive curriculum may be the feelings and comfort of the school faculty. Less than a third of teachers surveyed (33.1%) expressed comfort in including LGBTQ+ related content in their lessons (Greytak, et al., 2016).

Sex Education is Particularly Problematic

Only a fraction of LGBTQ+ students surveyed (6.7%) reported that their school's sex education curriculum included LGBTQ+ content (Kosciw, et al., 2018). According to GLSEN, quoted by Greytak, et al. (2016),

there is evidence that much of the sexuality education in U.S. schools is not inclusive of LGBTQ+ people and issues, and, that even when LGBTQ+ issues are acknowledged, they may be presented in ways that stigmatize or marginalize LGBTQ+ people. (p. 40)

Under 5.0% of LGBTQ+ middle and high school students said they experienced an affirming message on LGBTQ+ issues in their health curriculum. Not surprisingly, sexual minority youth were more likely to rate their sex education classes as unhelpful in comparison to other youth (46.5% vs. 29.9%) (Greytak, et al., 2016).

School Discipline

There is evidence that school discipline may also be a factor in the alienation of LGBTQ+ students from their schools. The majority of sexual minority youth surveyed by GLSEN said they had been disciplined at school (62.8%), far more than their non-LGBTQ+ peers reported (45.8%). This trend continued for high school students who did not conform to gender norms with 55.2% having received discipline in school in comparison to 45.9% of students displaying gender normative behavior. LGBTQ+ students in the GLSEN survey were more likely to have been suspended than their non-LGBTQ+ peers (24.9% vs. 14.5%). Even more concerning is the fact that LGBTQ+ students may be disciplined in a discriminatory manner. Greytak et al. (2016) note that

Research from GLSEN's National School Climate Survey and others suggests that LGBTQ+ students may be disciplined for being open about their identity or breaking rules that are not enforced for their non-LGBTQ+ peers. LGBTQ+ youth who are gender nonconforming may also be more likely to face school discipline due to school rules that prohibit some types of nonconforming gender expression, such as gendered dress codes. (pp. 30-31)

For example, a transgender student who identifies as female may be suspended for wearing a skirt which is in defiance of the school dress code for a male student, the gender assignment he was given at birth. LQBTQ+ students are also likely to be disciplined in relation to incidents of their own victimiza-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion. Students who reported receiving higher levels of LGBTQ+-targeted victimization were also more likely to have been disciplined in school than their peers without such victimization (54.7% vs. 43.9%) (Greytak, et al., 2016). Students who have been victims of homophobic bullying have been reprimanded for "bringing on the bullying" themselves due to their status as being out members of a sexual minority.

Impact

Experiencing harassment, bullying, and discrimination at school is directly related to negative school outcomes for LGBTQ+ youth. Kosciw and colleagues (2013) found "in-school victimization predicted decreased self-esteem and worse educational outcomes (lower GPA and more missed days of school)" (p. 54). A 2017 survey of LGBTQ+ youth found that those who experienced more homophobic victimization were more likely to miss school days (63.3% vs. 23.1%), had poorer academic performance (GPA of 3.0 vs. 3.3), were more likely to have been the recipients of school discipline (54.1% vs. 30.3%) and were much less likely to pursue higher education after high school than those who had experienced less victimization at school. Similarly, students in the same survey who reported more victimization based upon their gender expression were much more likely to have missed school (61.6% vs. 23.2%), had poorer academic performance (GPA of 2.9 vs. 3.3), were more likely to have been the recipients of school discipline (52.1% vs. 30.8%), and were half as likely to pursue higher education after high school than those who had experienced less such victimization. Students who experienced higher levels of victimization were also more depressed and had poorer self-esteem (Kosciw, et al., 2018).

Experiencing bullying at school can lead to academic difficulties, erosion of feelings of connection to the school and emotional difficulties in LGBT youth (Kosciw, Greytak, Bartkiewicz, Boesen, & Palmer, 2012). One study found that victims of homophobic victimization were even more likely than those with victimization without homophobic overtones to consider suicide, 5.8 times vs. 2.86, as likely as peers who were not victimized (Russell, Sinclair, Poteat, & Koenig, 2012).

Students who reported LGBTQ+ discrimination showed similar negative outcomes. Those who experienced such treatment were more likely to miss school (44.6% vs. 15.7%), had poorer academic performance (GPA of 3.1 vs. 3.4), were more likely to have been the recipients of discipline at school (44.0% vs. 26.5%). Students who experienced discrimination were more depressed and had poorer self-esteem (Kosciw, et al., 2018).

Minority Stress Theory

Minority stress theory has been used to explain the numerous negative outcomes related to the victimization of LGBT youth. Given the disproportionate discrimination, harassment, and stressors these individuals face, physical, emotional and academic difficulties are likely to follow. Hall (2018) stated, "LGBQ-specific stressors can be categorized into four domains: prejudice events (e.g., harassment, violence, discrimination, rejection), expectations of prejudice events, concealment of identity, and the internalization of negative societal attitudes and beliefs (e.g., internalized homophobia)" (p. 265). All of these impact sexual minority youth. Studies indicate many long-term emotional problems which are correlated with homophobic victimization including depression, anxiety, trauma-related stress, and suicidal behavior. In addition to these emotional concerns, youth have experienced such harassment also tend to have more risky sexual behaviors, poorer school attendance, and report they are more likely

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to drop out (D'Augelli, et al., 2002; Poteat, Mereish, DiGiovanni, & Koenig, 2011; Almeida, Johnson, Corliss, Molnar, & Azrael, 2009).

Limited Educational Aspirations

LGBTQ+ students have frequently been found to have more limited educational aspirations. GLSEN's study of LGBTQ+ high school students were more likely to say they planned to leave high school before graduation than their non-LGBTQ+ peers (2.7% vs. 0.8%). Accordingly, they were also less likely to plan to continue their studies after high school (9.6% vs. 5.7%). The same was true for student who did not conform to gender norms in comparison to those who were gender normative. They were more likely to state their intent to leave high school early (3.1% vs. 0.5%) and were more likely to have no plans for college (12.6% vs. 4.2%) or graduate school (Greytak, et al., 2016).

Key Resiliency Factors

Johns, Beltran, Armstrong, Jayne & Barrios (2018) conducted a comprehensive review of English and Spanish language articles in peer reviewed journals spanning the years from 1999 to 2014. Their review yielded 27 protective factors for positive outcomes in transgender and gender atypical youth. Four of these protective factors strongly emerged across multiple studies – individual self-esteem, positive relationships with parents, positive peer relationships, and gay straight alliances – and are discussed in the following sub-sections.

School Belonging

Wallace, Ye, and Chhuon (2012) examined high school students' sense of belonging within their schools. Their analyses identified four key experiences that were related to feeling of belonging including a general connection to faculty, a connection to a specific faculty member in the school, actively participating in a school-based extracurricular activity and a perception that one fits in with their peer group. In addition, they identified a factor previously unidentified in research, the adolescent's feeling of being known by a teacher, having his or her true identity recognized. Adolescents bereft of connection and belonging either at home or at school feel emotional pain (Cohn & Leake, 2012). Students who experience higher levels of victimization or discrimination report less school belonging (Kosciw, et al., 2018).

Social Support

Youth with more positive peer relationships have better mental health overall and are less likely to report depression or loneliness (Johns, et al., 2018). Strong and supportive friends also helped provide an anchor when parents were rejecting. McConnell, Birkett, and Mustanski (2015) studied various types of social support and mental health outcomes across a sample of LGBTQ+ youth. Youth with less social support had higher levels of loneliness, depression, anxiety and suicidality. Higher SES youth had significantly higher levels of overall social support while poorer youth reported less social support. Males also tended to have lower levels of social support than females. Adams, Hitomi & Moody (2017) found that friend and family support were correlated with better mental health outcomes.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Family Support

LGBTQ+ youth who feel affirmed and accepted by their families report lower depression and fewer suicidal thoughts (Eisenberg & Resnick, 2006; Ryan, Russell, Huebner, Diaz, & Sanchez, 2010). Johns and colleagues (2018) found that positive relationships with parents and family support was associated with higher self-esteem and later initiation of sexual intercourse. Youth who perceived their parents as more supportive were less depressed and felt more life satisfaction. Rivers, et al. (2018) found that around three fifths of their sample reported little family support and those with higher levels of family support also tended to have higher support from other sources. Many sexual minority youths, however, feel they do not have this option. Many LGBTQ+ youths are not out to their parents although they may be open to their friends. Therefore, these students are unlikely to share their victimization experiences with their parents and lack their support when dealing with these experiences.

Positive Relationships with Supportive School Staff

Supportive school staff are vital to the success of LGBTQ+ students. Youth who had a positive relationship with a supportive member of their school staff had better attendance and were less fearful at school (Johns, et al., 2018). In their comprehensive review of the role of school supports in mitigating the roles of victimization and harassment in LGBT youth, Kosciw, et al. (2013) found that,

Perhaps the strongest positive influence for LGBT students, as shown from our results, was having supportive adults at school. The number of supportive educators was one of the stronger predictors of a less hostile school climate and of greater self-esteem for LGBT students. Not surprisingly, the number of supportive educators was associated with positive educational outcomes; specifically, students who reported having more supportive educators were likelier to report higher GPAs and less likely to have missed school. Further, supportive staff might be especially helpful for students who are highly victimized, given the significant interaction between victimization and educators for missing school. Our findings related to supportive educators might reflect the myriad ways that these individuals can influence the school climate for LGBT students. Supportive staff might provide the personal connection needed to help keep students in school and buffer against severe victimization. Staff also might make the environment safer and more affirming directly for these students by intervening when homophobic remarks are made and anti-LGBT victimization occurs, providing support for individual students and perhaps advocating for school-wide efforts, such as affirming and protective policies and practices among staff and administration. (p. 58)

While almost all LGBTQ+ students (96.7%) surveyed could name at least a single supportive staff member in their school building, only 61% could name more than 6 adults in the building who were supportive of LGBTQ students with just 38.8% identifying 11 or more such staff members. A sizable minority (39.8%) said their school administration was at least somewhat supportive of LGBTQ+ students (Kosciw, et al., 2018). Having a significant number of school staff who they recognized as supportive of LGBTQ+ students made a difference. Students who were in schools where they could name at least 11 supportive adults reported feeling less afraid because of their sexual orientation (43.4% vs. 79.2%) or gender expression (34.8% vs. 51.0%) and said they were less likely to miss school due to such fears (20.1% vs. 48.8%) when compared to students without supportive adults. They performed better academically

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

(GPAs of 3.3 vs. 3.0) and were less likely to consider dropping out and more likely to say they planned to continue their education after high school. They had a greater sense of school belonging (Kosciw, et al., 2018). Students who perceived their teachers as insisting upon respectful and safe spaces in their classrooms, reported less homophobic bullying (Poteat, DiGiovanni, & Scheer, 2013).

Barriers to Support from School Staff

While teachers regularly have to intervene in student behaviors such as bullying and name-calling, their comfort with doing so varies with the type of harassment observed. Techers surveyed reported feeling least comfortable in addressing disparaging remarks made about gender expression (49.3%) and transgender individuals (50%) (Greytak, et al., 2016). Many teachers may have had little training on how to provide specific support to LGBTQ+ students. In a GLSEN survey, the majority of teachers reported that they had received preservice or other professional development on general issues of bullying (85.1%) and diversity (76.4%). Yet fewer had received any specific training on support for LGB (32.9%) or transgender (23.6%) youth and topics (Greytak, et al., 2016). Training in these areas was directly related to more supportive practices with LGBTQ+ students. Of teachers who had received specific training in dealing with LGBTQ+ issues, 70% said they were providing active support to these students. Of those who had not had such training, less than 40% provided such support (Greytak, et al., 2016).

GLSEN surveyed high school teachers and found that over one in four (26.4%) said they had worked to support LGBTQ+ students. The majority of teachers who had not shown such support were further questioned as to their reasons or barriers from doing so. Teachers' own personal and religious beliefs were a major factor with

over half (51.7%) of teachers indicating that they believed addressing LGBT issues was not necessary or appropriate, or believed that because these issues had not come up in their classes, there was no need to address them. Over a quarter of teachers (26.2%) identified external pressures as barriers to engaging in LGBT efforts, such as lack of administrative support, or backlash from parents or community. Just about one in five (19.0%) teachers noted that they faced logistical barriers, such as not having enough time to include these issues in their teaching or not knowing how to include them. (Greytak, et al., 2016, p. 67)

GLSEN asked teachers what actions might be most useful in helping making schools safer for LGBTQ+ youth. The greatest majority (91.3%) said that establishing "anti-bullying and/or anti-discrimination policies that explicitly protect LGBTQ+ students" would be helpful (Greytak, et al., 2016, p. 75). Such policies provide guidance to teachers on when to take action and give them the permission (and obligation!) to do so even when they may be uncomfortable. The vast majority of teachers (89.2%) also said administrative support would be helpful. Guidance from the school's administration and the feeling that administrators would be supportive if parents or community members questioned the teacher's actions can help them feel safer to address LGBTQ+ issues directly. The vast majority of teachers (88.8%) also felt further training would be helpful as would establishing a GSA in the school (85.6%) (Greytak, et al., 2016).

Gay-Straight Alliances

Gay-straight alliances (GSAs) are school clubs or organizations that serve a support and advocacy function for LGBTQ+ youth. Consisting of LGBTQ+ youth themselves as well as peer allies, these groups started in the 1980s as research about the stress and accompanying psychological toll on LGBTQ+ youth became widely known (Mayberry, 2013). Some school administrators used this data as a way to "justify to higher-level administrators, school boards, and community members the presence of GSAs on their campuses" (Mayberry, 2013, p. 36). Since that time, these groups have spread widely and now number in the thousands across the U.S. Their mission has also evolved from that of merely providing support to LGBTQ+ students to the broader purpose of challenging the "heteronormalizing institutional practices that exclude and stigmatize nonheterosexual identities" (Mayberry, 2013, p. 36). According to GLSEN's 2017 school climate survey,

GSA student clubs continue to serve as a potent force for positive change, and the LGBTQ+ students that lead them are changing their schools and their world for the better. Progress in the growth of GSAs continues, bucking the concerning trends, and more than 50% of LGBTQ+ students are in schools that now have one. (Kosciw, et al., 2018, p. xiii)

The presence of a GSA improves student attendance and participation in the school's GSA leads to improved school climate and improved self-advocacy (Johns, et al., 2018). Research shows that GSAs help students develop and improve positive social support networks (Hecht, 1998; Lee, 2002). In addition, the presence of such groups in schools leads to other positive psychosocial outcomes for LGBTQ+ students, including decreases in suicidality (Goodenow, Szalacha, & Westheimer, 2006; Walls, Freedenthal, & Wineski, 2008). Lee's (2002) qualitative study of high school student GSA members reported that their participation had led to academic improvements, better attendance, and better relationships with school administrators, teachers, family and peers. These students were less anxious about being "out" with their peers and felt safer, reporting less harassment and actually feeling more belonging and connection to their school. Kosciw and Diaz (2006) reported that the presence of a GSA in a school was associated with better attendance and greater feelings of safety and school belonging in LGBTQ+ students. A study of Massachusetts schools with GSAs found that LGBTQ+ students attending schools with such organizations were "half as likely as those in schools without a GSA to report experiencing dating violence, being threatened or injured at school, or missing school because they were afraid to go" (GLSEN, 2007, pg. 1). Poteat, Sinclair, DiGiovanni, Koenig, and Russell (2013) found that LGBTQ+ students in schools with a GSA reported less frequent sexual behavior while under the influence of alcohol or other drugs and students generally (both LGBTQ+ and not) reported less suicidality than those attending schools lacking such a support group. A prospective study found that having a GSA predicted decreasing LGBT-related harassment from year to year (Ioverno, Belser, Baiocco, Grossman & Russell, 2016).

A 2017 survey of LGBTQ+ students found that attending a school with a GSA made a noticeable difference in school climate. The presence of a GSA was associated with fewer LGBTQ+ students frequently hearing the word *gay* in a homophobic manner (62.7% vs. 78.5%), hearing homophobic slurs (53.4% vs. 68.1%), or hearing ugly remarks about gender expression (53.4% vs. 68.1%). Students in schools with a GSA said school staff were more likely to intervene when hearing such remarks (18.2% vs. 11.3%). School staff in schools with GSAs were reported to be more supportive and fellow students

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

more accepting. This difference in school climate appears to lead to greater feelings of safety and better attendance as well as an increased sense of belonging (Kosciw, et al., 2018).

GSAs can help students in many ways. The club's advisor(s) can provide a visible and supportive adult within the school building. The group can increase staff awareness of LGBTQ+ issues and make it more likely that staff will intervene in situations of bullying and harassment. Since LGBTQ+ students frequently avoid extracurricular activities and school events, membership in the GSA can help these students develop a greater sense of school connection and belonging. Relationships with both LGBTQ+ peers and straight allies can blossom and increase students' sense of social support as well as increase the social norms of LGBTQ+ acceptance throughout the school. When GSAs support and nurture student activism, this may further increase students' self-esteem and feelings of efficacy. Through social and political action, students can be exposed to the larger world in a positive and supported way, make new relationships, and gain a sense of their own power.

Inclusive Curricula

Inclusive curricula can help increase student engagement, thereby improving student academic achievement, graduation rates, and post-secondary educational goals. Attending a school that intentionally includes LGBTQ+ content within the curriculum is related to greater feelings of safety among LGBTQ+ youth (Russell, Kostroski, McGuire, Laub, & Manke, 2006). According to Kosciw and colleagues (2018), having an LGBTQ+-inclusive curriculum was related to many positive outcomes for these students. Students surveyed in schools with such curricula reported fewer homophobic slurs (42.9% vs. 64.6%) or hurtful comments about gender expression (51.1% vs. 65.1%). LGBTQ+ students in these schools felt safer and reported lower levels of LGBTQ+-related victimization. Their grades were higher (3.3 vs. 3.2 GPAs) and more of them had plans for continuing education after high school. They reported that peers were more accepting (67.6% vs. 36.0%) and they had a greater sense of school belonging than those in schools without LGBTQ+-inclusive curriculum (Kosciw, et al., 2018). Another student noted that an LGBTQ+-inclusive curriculum was a key component in moving school culture in the direction of inclusivity and equity. She saw her school's gay and lesbian studies course as important: "I think courses like this make that possible. It just sends a message, you know. Oh, I just love my school" (Short, 2017, p. 19).

Anti-Harassment Policies that Specifically Mention LGBTQ+

While most of the LGBTQ+ students surveyed say their school has a specified anti-bullying policy (79.3%), few of them had a policy that specifically included sexual orientation and gender expression (12.6%), with even fewer reporting that their school district had specific policies to protect gender nonconforming individuals (10.6%) (Kosciw, et al., 2018). Youth who reside in communities with anti-bullying policies that specifically state the protection of LGBTQ+ individuals have less self-reported suicidality (Hatzenbuehler & Keyes, 2013). LGBTQ+ students attending schools with inclusive anti-bullying policies were less likely to hear homophobic slurs (46.6% vs. 62.5%) or hurtful remarks about gender expression (51.0% vs. 63.7%) than those in schools with a more generic policy. Students in these schools reported less homophobic LGBTQ+-related victimization and were more likely to tell school staff when such incidents occurred, feeling the adults' responses were more effective (Kosciw, et al., 2018).

Schools with specific policies for dealing with gender nonconforming and transgender students had such students report much less discrimination during the school day in terms of refusal to use their chosen

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

name and preferred pronouns (22.5% vs. 47.5%), using their preferred restroom (23.5% vs. 51.9%) or locker room (26.1% vs. 48.1%), or being prohibited from wearing clothing not considered appropriate for their gender (9.0% vs. 28.3%). Fewer transgender or gender nonconforming in schools with such policies reported missing school because of fear for their safety (54.7% vs. 67.0%), and they reported greater feelings of school belonging (Kosciw, et al., 2018).

Middle School Is Tough

The middle school years may be a particularly difficult time for sexual minority youth both in terms of increased harassment and fewer resources. According to GLSEN's 2017 school climate survey,

LGBTQ+ students in middle school had more hostile school experiences than LGBTQ+ students in high school, including experiencing higher rates of biased language, victimization, and anti-LGBTQ+ discriminatory school policies and practices. LGBTQ+ middle school students were less likely than high school students to have access to LGBT-related school resources, including GSAs, supportive educators, LGBTQ+-inclusive curricular resources, and inclusive policies. (Kosciw, et al., 2018, p. xxvii)

RECOMMENDED STRATEGIES FOR SCHOOL-BASED MENTAL HEALTH PROFESSIONALS TO FOSTER RESILIENCY IN LGBTQ+ CHILDREN AND YOUTH

1. **Become an Ally:** According to Cooper (2016), "A key role of a school-based ally is to use the power and influence they have as an educator to advocate for the rights of LGBTQ+ students and ensure safe schools for all" (Communiqué, p. 32). Make a commitment to fulfill this role through as many of the activities listed below as possible.
2. **Work to Gain Administrative Support:** Use clinical, consultation, and collaboration skills to garner support from school administration. Nearly all of the resiliency strategies presented in the current chapter require or would greatly benefit from the active engagement and clear support of school and system administrators. Cooper (Communiqué, 2016) provides suggestions for gaining administrative support. She suggests using data-based approaches, illustrating the need for change with statistics or observed behaviors within the school. Emphasizing that change will improve the safety of the school and benefit all students is likely to resonate with administrators, particularly if a clear and specific action is proposed.
3. **Develop a GSA or Support an Existing GSA:** Serving as faculty advisor or supporter of a GSA helps to identify a staff member as a supportive adult on campus. The existence of a GSA has enormous benefits for school climate and LGBTQ+ youth resiliency.
4. **Support and Enforce Title IX Provisions:** Current interpretation of existing school law provides some guarantee of protection. Failure to apply protections has led to lengthy and expensive court cases for school districts. According to GLSEN (2016), the "U.S. Departments of Justice and Education jointly released specific guidance to schools and districts clearly stating that discrimination based on transgender status is in violation of Title IX and detailing school's specific responsibilities to ensure transgender students' rights are protected" (p. 38).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. **Review Discipline Policy & Practices:** Becoming a member of the school's Positive Behavior Support (PBS or PBIS) team can be an effective way to help make changes in the school's discipline practices and the larger school climate. Look at school data to determine if LGBTQ+ students are receiving a disproportionate amount of discipline. Investigate to see if these students are being disciplined for behaviors that are not cause for penalization for their non-LGBTQ+ peers. Once data have been collected and analyzed, make appropriate policy and practice changes. This might include changes such as developing a gender neutral dress code. Help to institute more positive behavior supports to all students who display behavior difficulties. This might include social skills training, conflict mediation, or "cool down" spaces within the school.
6. **Support Non-Exclusionary Discipline Practices:** A focus on restorative practices as opposed to exclusionary discipline can be a powerful tool in transforming the school culture for both bullies and the victimized.
7. **Provide Professional Development & Training to School Staff:** Most school administrators (69%) say that training is needed in order to help their school staff intervene to effectively address LGBTQ+-related harassment and bullying and most (75%) think their staff would be receptive to efforts to increase support and safety for LGBTQ+ students (GLSEN & Harris Interactive, 2008). Teachers agree and the vast majority have reported that staff development would help makes schools safer for LGBTQ+ youth (Greytak, et al., 2016).
8. **Help to facilitate a school atmosphere in which LGBTQ+ staff, families, and students feel safe and encouraged to be out:** Greater numbers of individuals within the school community who are open and authentic will help to lessen stigma and bias overall as non-LGBTQ+ individuals within the school community develop positive relationships with their LGBTQ+ colleagues. This will also allow LGBTQ+ students see appropriate role models, and feel a greater sense of belonging within the school community. Contact with LGBTQ+ peers leads to intergroup friendships and fewer self-reported homophobic acts (Poteat et al., 2013). Being open about their sexual identity is linked with stronger academic achievement, higher self-esteem, and fewer difficulties with anxiety and depression in sexual minority students (D'Augelli, Grossman, & Starks, 2005; Kosciw, Palmer, & Kull, 2014).
9. **Provide support to teachers in developing a more inclusive curriculum:** Assist faculty with resources to positively include LGBTQ+ individuals, issues, and history within their discipline. Two sources of outstanding resources on these topics are GLSEN's Educational Resources page ("Educational Resources," glsen.org/educate/resources) and Teaching Tolerance's Classroom Resources page ("Classroom Resources," tolerance.org/classroom-resources). Suggest ways to embed such content within existing curriculum standards.
10. **Help to make extracurricular activities safe and affirming for LGBTQ+ students:** This might include providing training and support to athletic staff and coaches as well as those who serve as advisors to other clubs and activities.

FUTURE RESEARCH DIRECTIONS

While research has supported a handful of school-wide practices (e.g., GSAs, inclusive curricula) that provide a resiliency function for LGBTQ+ youth, there is still a need to investigate other policies and practices that may be helpful. Moreover, there is a need for research to establish more individual

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and small group supports and mental health services that may promote healthy development in sexual minority youth. While adolescents have been the focus of most existing research, a deeper look at the developmental experiences and needs of younger LGBTQ+ individuals is crucial. Early intervention is key to halting the development of long-term problems in most populations. Promoting the resiliency of younger individuals is an important goal. Finally, research on the most effective means for educating and supporting school-based mental health professionals, school and district administrators, and teachers as they do this work is recommended.

CONCLUSION

Supporting the healthy growth and development of all students within schools is the goal of school staff generally and school-based mental health professionals in particular. Understanding the challenges faced by LGBTQ+ youth is essential in meeting their needs. Using a resiliency-based approach, mental health professionals can help support and guide their schools towards practices that have been proven to nurture the development of sexual minority youth and increase their resiliency. The rewards of such work will benefit society, families, schools, and the students they serve.

KEY TERMS AND DEFINITIONS

Ally: An individual who uses their power and energies to help support LGBTQ+ individuals.

Gay, Lesbian, and Straight Education Network (GLSEN): An organization founded by teachers dedicated to making schools safe, affirming and inclusive places for LGBT youth.

Gay-Straight Alliances (GSAs): School clubs or organizations consisting of LGBTQ+ youth and peer allies that serve a support and advocacy function for LGBT youth.

Minority Stress Theory: An explanation for the numerous negative outcomes related to the victimization of LGBT youth. Given the disproportionate discrimination, harassment, and stressors these individuals face, physical, emotional and academic difficulties are likely to follow.

Resilience: The ability of the individual to adapt and function in a relatively healthy matter despite adverse experiences.

Resiliency Factors: Variables that help the individual buffer against negative experiences and move forward.

Sexual Minority Youth: Young people who do not identify as heterosexual and/or gender typical.

Chapter 40
Inherent Requirements and Social Work Education:
Issues of Access and Equity

Steve Boucher
RMIT University, Australia

ABSTRACT

The aim of this chapter is to contribute to addressing issues of access and equity in social work education for people with mental health disabilities. The objective is to carefully consider the introduction of inherent requirements in universities, and particularly in relation to social work education, in Australia. A targeted review of relevant literature including legislation, policy, and practice standards frameworks identifies the parameters of inherent requirements and possible areas of discrimination. Consideration of the use of inherent requirements in social work education is from a human rights social justice perspective that acknowledges the strength and resources of people and communities and actively advocates for the protection of disability rights.

INTRODUCTION

The generation of knowledge through research is not a neutral activity. What is investigated, how and by whom is intrinsically political and invites the question, what is the purpose of this inquiry? This is particularly true when it comes to studies which serve to delineate the terms on which historically oppressed groups are to be granted access to mainstream activities. As I consider literature relating to the participation of "mad" students in tertiary education I believe that it is essential for me to clearly state my own experience, position and purposes.

I am a person whose life and perspectives have been fundamentally shaped by the experience of disability, both physical and psychological. Furthermore, I have worked as an advocate within the tertiary sector and in an organisation which has encouraged me to dedicate myself to actively fighting against discrimination alongside students with disability. My approach to research comes from an originally Marxist understanding of how experience is shaped through social processes of class based oppression,

deepened by the application of critical disability studies to understand how the material experience of living within a 'disabled' body/mind is mediated by discourses, physical and social structures which serve to limit and marginalise the participation (and perspective) of those who deviate from a medicalised 'norm'. For me, the purpose of scholarship is to take a side and consciously work to develop tools for change.

The management of disability within the western tertiary sector is a complex and contested space (Bessant, 2012). Despite the rights of students with disabilities being protected by legislation, critical authors have noted that university practices focus on short term individualised accommodation, within existing educational practices, at the expense of change towards a more truly inclusive system (Jung, 2003; Meacham, Tandy, Giddings, Vodde, Curington, Morris, & Holliman, 2004). From a disability rights perspective, disability is tolerated on the proviso that individual students comply with institutionalised rituals and norms within a system which often considers 'it' to pose a threat to underlying academic and professional standards (Poole, Jivraj, Arslanian, Bellows, Chiasson, Hakimy, Pasini, & Reid, 2012; Price, 2011; Quinn, Wilson, MacIntyre, & Tinklin, 2009).

A growing trend with Australian universities has been to articulate statements of 'inherent requirements' in order to help programs define their standards in relation to disability (Brett, Harvey, Funston, Spicer, & Wood, 2016). To date these statements have received little critical scrutiny despite their apparently pivotal significance in drawing boundaries to inclusion (McNaught, 2013). Whether these statements will act as a platform for more inclusive practice or create further rationales for limiting the participation of students with disabilities remains to be determined.

The literature review in this chapter provides a background for an investigation into the potential impact of the statements in social work, a discipline with both a long history of managing 'unsuitable' behaviour and an active commitment to inclusive and empowering practice (Meacham, Tandy, Giddings, Vodde, Curington, Morris, & Holliman, 2004). It provides an overview of disability accommodation within the Australian university sector with a particular focus on the experience of students with depression and anxiety, amongst the most prevalent disabilities on campus, which are also often unaccommodated by disability support systems due to low disclosure rates and structural barriers to support (Markoulakis, 2014; Martin, 2010). The review concludes by examining social work's literature on professional suitability and critiques of its practices regarding mental health.

BACKGROUND

The Australian Tertiary Education Sector

The preceding three decades have been a time of significant structural change in Australian higher education (Watts, 2016). Reforms have caused an expansion in student enrolments and the number of public universities (Harvey, Burnheim, & Brett, 2016). Public providers now face direct competition from private colleges and within a globalised marketplace, for fee paying international student enrolments necessary to maintain institutional budgets in the face of reductions in government funding (Marginson, 2006). A key reform has been to link tertiary education to labour market outcomes and universities have refocused teaching away from disciplines such as liberal arts into vocational and professionally focused programs (Watts, 2016). This can add another level of regulatory complexity as programs also have to teach towards accreditation standards set by professional qualifying bodies (Harvey, Burnheim, & Brett, 2016; McNaught, 2013).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Universities are heavily regulated (Probert, 2015). Public universities' primary source of government funding are commonwealth grants through the Higher Education Support Act which are linked to enrolled student load and which require compliance with external quality frameworks, particularly the *Threshold Standards for Higher Education Providers* and the *Australian Quality Framework* which respectively set mandatory standards for facilities, staffing and administration and the educational levels of qualifications (DIISRTE, 2011; Watts, 2016).

Universities are required to meet equitable performance targets. First elaborated by the Commonwealth in *A Fair Chance for All* (1990), targeting focuses on recruitment of students with characteristics which have traditionally been underrepresented in higher education, including people with disability (Harvey, Burnheim, & Brett, 2016). This regime has succeeded in increasing both participation and completion rates for students with disability (Brett, 2014). The increased participation of these students adds another significant regulatory overlay to higher education, anti-discrimination law (Varnham & Kamvounias, 2009).

DISABILITY RIGHTS IN UNIVERSITIES

Although universities are covered by state equal opportunity legislation (Varnham & Kamvounias, 2009), government funding and service agreements stipulate compliance with the Disability Discrimination Act, 1992, (Cth) (DDA) (Urbis, 2015). Section 22 of the DDA prohibits discrimination in education, including by refusing to accept or placing unreasonable conditions on admission, denying access to benefits or services, expelling a student and/or by developing or accrediting criteria which will have these effects (DDA, 1992). The Act also applies to bodies which regulate professional qualifications (s19). The definition of 'disability' in the Act is broad and is explicitly based on a social model of disability (Howe & Duffy, 1992). Similar to disability rights legislation in other English-speaking countries, such as Britain, Canada and the United States (Harvey, Burnheim, & Brett, 2016), the foundational assumption is that discrimination occurs as the product of an interaction between an individual's impairment and social conditions ranging from policies and standardised expectations through to aspects of the built environment (Howe & Duffy, 1992). Section 6 of the DDA has the effect of requiring adjustments to be made to requirements placed on people with disability where reasonable alternatives can be identified (Australian Human Rights Commission, 2011).

A legislative instrument, the *Disability Standards for Education*, *2005*, (DSE) provides detailed guidance on how the Act is to be implemented across schools, vocational education providers and universities. Standard 3 establishes processes for making adjustments and is generally considered to be the most critical standard in higher education (AHRC, 2011). There is not an automatic right for the impact of a disability to be accommodated (AHRC, 2011). Education providers must balance a number of factors, including the nature of a disability's impacts on particular requirements, the views of the affected party and the broader impact of making an adjustment including costs and benefits (DSE, 2005, Part 3). An additional significant proviso is that:

In assessing whether an adjustment to the course or program in which the student is enrolled, or proposes to be enrolled, is reasonable, the provider is entitled to maintain the academic requirements of the course or program, and other requirements or components that are inherent in or essential to its nature (DSE, 2005, 3.4(3)).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In universities, reasonable adjustments are typically recommended by specialised units located outside of academic programs (Jung, 2003; Timmerman & Mulvihill, 2015). The system requires students to provide medical documentation to verify their status as disabled and only captures students who are prepared to disclose their condition (Jung, 2003). Although common adjustments to assessment have been demonstrated to have high validity (Konur, 2002), their implementation is at the discretion of academic staff who sometimes refuse to make accommodations (Fuller, Healey, Bradley, & Hall, 2004). Studies of the system of seeking accommodations have documented that students find it time consuming and difficult to navigate (Markoulakis, 2014).

INHERENT REQUIREMENTS IN HIGHER EDUCATION

Despite a significant early judgement, W v Flinders University, which considered inherent requirements in relation to a teaching practicum (Dickson, 2012), inherent requirements in education have received very little attention in academic publications until recently (McNaught, 2013). Borrowing from principles established for considering claims of discrimination in employment, Watts and colleagues at Curtin University first enunciated a framework for Australian university programs to define inherent requirements in the year 2000. Although the term still has no universally accepted definition it is commonly understood that inherent requirements should be explicitly based on fundamental requirements for learning and practice as distinct, for instance, from the methodologies used situationally to teach or assess these requirements (Bialocerkowski, Johnson, Allan, & Phillips, 2013; Dickson, 2012).

Watts and colleagues' (2000) central arguments were that universities need to define inherent requirements in order to assist prospective students to make informed choices before enrolment and to facilitate determining which adjustments were reasonable. This position was strongly advocated by a number of universities during the 2010 and 2015 reviews of the DSE (DSERT, 2012; Urbis, 2015). The reviews found that greater clarification of the relationship between inherent requirement statements and the Standards was required with the 2015 review concluding that the application of inherent requirements in the vocational education context was inconsistent and contested (Urbis, 2015). Brett and colleagues (2016) identified the University of Melbourne as the first to publish statements across all programs but noted that these were typically brief and generic. Despite notes of concern, universities have begun to publish increasing numbers of statements (Bialocerkowski, Johnson, Allan, & Phillips, 2013). More significant to the process of developing statements was the introduction of Western Sydney University's Inherent Requirements of Nursing Education (IRONE) project in 2010-11 (McNaught, 2013). IRONE set out a detailed framework of domains for requirements which is now being applied to other health disciplines across Australia (Bialocerkowski, Johnson, Allan, & Phillips, 2013).

Brett's (2016) study is the first large scale attempt to map statements in Australian tertiary education. Conducted in 2015 its targeted search located a total of 78 unique statements. The authors noted that methodological difficulties with the search, which focussed primarily on fields of education where it was known that statements existed together with its time limited rather than longitudinal nature, meant that this figure underestimates the likely true number of statements. Statements themselves vary considerably in detail, 17 are of less than 500 words and 30 are 2000+ (p. 21). There are differing frequencies with which statements are encountered by university grouping and field of education (pp. 22-3) with the greatest prevalence being in health, where 59% of programs surveyed had a statement. In social work and community welfare the figure was 9 out of 31 or 29% of sampled programs (p. 24).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

While the statements show a degree of borrowing from other institutions they do not all cover the same categories. Brett provides a Table (p. 24), reproduced below, of the general categories employed to group requirements together with their frequency.

These broader categories are split into sub-domains which contain specific statements of requirements. Exemplars given by Brett (pp. 30-2) include:

Table 1. Frequency of common domains in inherent requirement statements (reproduced from Brett, 2016)

Category	Number of inherent requirement statement including category	Percentage of inherent requirement statement including category
Verbal and non-verbal	73	93.6
Behavioural stability	66	84.6
Cognition	65	83.3
Written	52	66.7
Motor skills	51	65.4
Ethical behaviour	48	61.5
Literacy	44	56.4

Verbal and Non-Verbal Communication: "*Effective and efficient verbal communication, in English, is an essential requirement to provide safe delivery of care*."

Behavioural Stability: "*Students will be exposed to highly complex human situations and will be required to have behavioural stability to manage these events competently and professionally.*"

Cognition: "*Consistent and effective knowledge and cognitive skills must be demonstrated*."

Motor Skills: "T*asks that include fine motor skills include being able to grasp, press, push, turn, squeeze and manipulate various objects and individuals*."

Brett found that only nine statements provided information about their legal basis. None included explanatory case studies or reference to complaint processes and the rights individuals could rely on to seek accommodations (p. 25).

The lack of contextual information accompanying the individual requirements suggest that the statements will be problematic for both people with disabilities and the universities. The DSE requires that adjustments be made to requirements to avoid discrimination with universities currently providing students with adjustments such as Auslan interpreters, rest and recovery breaks in assessments and participation aids to assist with motor tasks (Konur, 2002). Performance requirements such as the manipulation of equipment falls into an additional legal dimension of adjustment; whether an institution (or future employer) has an obligation to provide modified equipment (AHRC, 2011). Such decisions require consideration of whether modifications will result in 'unreasonable hardship' by placing a strain on overall resources (Waldeck & Guthrie, 2004). That a university can undertake a greater level of expense than a small employer is uncontroversial but raises the question of how universities should manage the boundary between education and preparation for future employment (Brett, 2014; Harvey, Burnheim, & Brett, 2016).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

There has been little analytical scholarship on the potential impacts of statements. In the context of a case study regarding a visually impaired physiotherapy student's participation in professional placement, the authors noted that statements of inherent requirements may have a discriminatory effect by not taking adequate account of personal factors such as a student's adaptability and resilience (Johnston, Mackintosh, Alcock, Conlon-Leard, & Manson, 2016). Noting that several of the common domains of requirements will potentially impact on the participation of students with mental health issues, McNaught (2013) questions whether the statements, in potential combination with requirements for mandatory reporting of impaired health, will deter students from disclosing these conditions to their universities.

PARTICIPATION OF STUDENTS WITH DEPRESSION AND ANXIETY

Students with mental health problems are participating in tertiary studies in increasing numbers. College counselling services in the United States have reported increases both in the number of students seeking help and the severity of their symptoms (Wyden, 2007); a trend which has been reported across English speaking countries. Although higher levels of distress in students are often reported (Larcombe, Finch, Sore, Murray, Kentish, Mulder, & Williams, 2016), these increases have been found to be reflective of broader societal trends which include the common age of onset of disorders, more widespread awareness and diagnosis and improved treatment regimens (Cvetkovski, Jorm, & Reavley, 2012; Hunt & Eisenberg, 2010; Stallman, 2010). Retrospectively analysing files from an English university counselling centre, Schwartz (2006) found that the underlying prevalence and degree of student distress was relatively stable over the period from 1992 to 2002. Exactly identifying the prevalence of mental health problems amongst students has been complicated by different studies employing different methodologies and cut off points for identifying serious levels of distress (Buchanan, 2012). If, it is accepted that the mental health of the Australian student body is reflective of that of the broader community, the yearly prevalence rate of depression alone is 11% (APS, 2012). This makes the accommodation of mood disorders is a serious issue for universities. Large scale studies of the impact of disease by the Australian Institute of Health and Welfare (2016, pp. 38-9) have estimated that mood and substance abuse disorders contribute 24% of the non-fatal burden of disease, and that the contribution of depression and anxiety is greater within the age groups traditionally entering university:

Table 2. Contribution of depression and anxiety to non-fatal burden of disease by age and gender

		Depression	Anxiety
15-24 year olds	Males	8.3%	7.1%
	Females	11%	14%
25-44 year olds	Males	8.5%	7.5%
	Females	10%	12%

Study can be a stressful experience and students have been shown to be at heightened risk of developing depression and anxiety while at university (Hunt & Eisenberg, 2010). Students experience greater stress during first year (Cooke, Bewick, Barkham, Bradley, & Audin, 2006) and distress across their degrees

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

with one Australian study of over 6000 students finding that 19.2% of students demonstrated clinical symptoms of anxiety and depression (Stallman, 2010). Compounding these issues are low disclosure rates and significant delays between the onset of mental health problems and treatment (El Ansari & Stock, 2011; Kessler, Olfson, & Berglund, 1998; Laidlaw, McLellan, & Ozakinci, 2015; Olfson, Kessler, Berglund, & Lin, 1998; Thompson, Hunt, & Issakidis, 2004; Wang, Berglund, Olfson, & Kessler, 2004). Although there is a generally decreasing trend over time in help-seeking delays these remain significant (Christiana, Gilman, Guardino, Mickelson, Morselli, Olfson, & Kessler, 2000).

Many students do not seek assistance from campus services (Hunt & Eisenberg, 2010; Julal, 2015; Kerns, 2013; Rosenthal & Wilson, 2008). A large-scale study of six colleges in Pennsylvania found that 73% of student in distress were not seeking help (Popple, 2013). Reasons for not seeking assistance have been linked to a lack of awareness of services and the existence of stigmas around mental illness (Laidlaw, McLellan, & Ozakinci, 2015; Lustig, Madon, Hyun, & Quinn, 2006; Rickwood, Deane, Wilson, & Ciarrochi, 2005; Thompson, Hunt, & Issakidis, 2004). Studies which spanned students and graduate practitioners in law and medicine students have confirmed the existence of high levels of perceived public stigma together with reluctance to seek help (Chew-Graham, Rogers, & Yassin, 2003; Di Stefano, 2010). More recent general scholarship has found that attitudinal factors are the primary barriers to seeking assistance (Hunt & Eisenberg, 2010). Psychological research into mental health stigma with students has tended to explore the difference between internalised feelings of shame and perceived public stigma towards the condition. Although heightened levels of concern about public stigma are reported (Eisenberg, Downs, Golberstein, & Zivin, 2009), it is commonly found that internal factors more critically influence disclosure and help-seeking decisions (Golberstein, Eisenberg, & Gollust, 2009; Hunt & Eisenberg, 2010).

Qualitative studies provide a rich insight into the lived experiences of students with mental health conditions illustrating reasons for not disclosing and experiences following disclosure. While most participants report positive experiences these are not universal (Martin, 2010; Timmerman & Mulvihill, 2015). In a meta-synthesis of existing studies of students who had disclosed Ennals, Fossey and Howie (2015) found that a common theme was of encountering difficulties negotiating appropriate support. Negotiating adjustments can be complex and time consuming for students with mental health problems (Markoulakis, 2014) and students with disability employ scripts in order to downplay their needs and avoid potential negative judgements (Barnard-Brak, Lechtenberger, & Lan, 2010; McCarthy, 2007). Participants interviewed by Andrade (2015) described frequent experiences with mental health stigma from other students, and prior to commencing study, with one respondent likening their experience to being "subjected to a hate crime" (p. 82).

These student experiences point to the ongoing presence of negative attitudes towards mental illness in the academy. Lack of exposure to students with disability has been found to be associated with negative attitudes amongst graduate students, who are frequently employed as tutors (McAllister, Wynaden, Happell, Flynn, Walters, Duggan, Byrne, Heslop, & Gaskin, 2014). Negative faculty attitudes about the participation of students with mental health problems have been reported by Thomas (2015) who found that:

- 31.5% of staff felt uncomfortable dealing with a student exhibiting mental health symptoms in the classroom;
- 12.4% did not feel secure in these circumstances, and;
- 10.9% felt that these students were dangerous.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thomas' study was conducted in the United States of America, where portrayals of violence on campus have been reported to reinforce stereotypes by focussing on perpetrators' mental health status (Price, 2011). While Australia has lower levels of lethal violence on campus, incidents at Monash and Latrobe did lead to similar coverage and to Victorian universities adopting tribunal style processes for managing students with challenging mental health issues (Preiss, 2013).

Issues, Controversies, Problems: Social Work Students With Mental Health Problems

Social work students have been found to show elevated levels of depressive symptoms, with over 50% of students surveyed by Ting (2011) being over the cut off point for clinical levels of depression. Commenting on similar findings in social work and other caregiving professions, authors have posited that occupying such a role places professionals at higher risk for untreated distress (Pooler, 2008; Sherman, 1996; Strozier & Evans, 1998). A similar survey to Ting's in the United States by Horton, Diaz and Green (2009), found evidence of depression in 34% of respondents. Ting (2011) found that a mix of concerns about stigma, together with resource implications and a distrust of the mental health system, were contributing to low disclosure and treatment rates.

As a profession, social work influences and is influenced by mental health issues (Meacham, Tandy, Giddings, Vodde, Curington, Morris, & Holliman, 2004). Social workers play a pivotal role in mental health treatment systems and community support for underprivileged groups, including those with or at risk of mental health diagnoses (Scheyett, 2005). The profession's emphasis on the critical application of self as part of its signature process creates a situation where workers' unresolved personal difficulties can negatively affect clients (Collins, 2006; Gillis & Lewis, 2004; Watkinson & Chalmers, 2008).

In Australia, the profession employs three main devices to regulate professional conduct and the standard of graduating students; a code of conduct, accreditation standards for education programs and practice standards (AASW, 2010; AASW, 2012a; AASW, 2013). The Code of Ethics requires constructive and reflective practice and for students and professionals to seek adequate support when their performance may be impacted by personal factors, matters which may be impacted by mood disorders (AASW 2010). A search of the Education Standards and supporting documents reveals that the Association does not specify a direct requirement for programs to make adjustments for students with disability, except in the Guideline for Field Education Programs, where disability is treated an as 'extenuating circumstance' which may justify waiving the requirement for continuous five-day blocks of placement (AASW, 2012b, pp. 3-4). The lack of information about legal requirements to provide adjustments is extraordinary, given that bodies which accredit programs fall under the ambit of the DDA and DSE (Brett, 2014; DDA, 1992, S19; DSE s1.5(g)ii-iii). Social work must balance the imperative to ensure safe and effective practitioners with its historical commitments to social justice and inclusive practice without specific guidance from the professional accrediting body, the Australian Association of Social Workers (AASW), creating tensions for academics charged with responsibility for judging professional suitability (Adams, 2011; Sowbel, 2012).

The establishment of academic standards alone does not guarantee suitable graduates and significant attention has been devoted to how educators should manage issues of students' professional suitability. While some authors suggest that the primary site for gatekeeping should be within the application process (Collins, 2006; Tam & Coleman, 2009), application statements do not reliably predict future problems (Regehr, Stalker, Jacobs, & Pelech, 2001). These difficulties are illustrated by legal action in Canada

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

which resulted in damages against social work educators for an admission decision made on grounds of perceived suitability (Redmond & Bright, 2007). Once a student is admitted, social work programs tend to have low failure rates making the primary sites for screening out unsuitable students informal counselling and field practicums (Adams, 2011; Barlow & Coleman, 2003; Urwin, Soest, & Kretzschmar, 2006). It is logical to expect that statements of inherent requirements will be used within these processes to guide students and educators on the expected standards of the program with anecdotal reports suggesting this is happening (Adams, 2011; Elpers & FitzGerald, 2013; Mazza, 2015; McNaught, 2013).

While management of students with mental health problems is a common theme in social work's gatekeeping literature, discussion tends to be under-developed and problematic (Meacham, Tandy, Giddings, Vodde, Curington, Morris, & Holliman, 2004). It is common for articles to refer to errors with managing the impact of a student's mental health problem as a starting point for a discussion of gatekeeping issues, without providing any analysis of how shortcomings could have been addressed (Collins, 2006; Watkinson & Chalmers, 2008). When referring to legal issues, authors often devote considerable space to explaining the courts' traditional deference in matters of academic judgement without informing readers of rights and processes for making reasonable adjustments (Currer & Atherton, 2008; Wayne, 2004). Other articles report the development of gatekeeping policies without any specific discussion of disability rights (Barlow & Coleman, 2003; Urwin, Soest, & Kretzschmar, 2006). One notable exception is Valdosta State University whose social work program took the lack of clarity in the literature as a prompt for a sweeping review of their practice with students with disability (Meacham, Tandy, Giddings, Vodde, Curington, Morris, & Holliman, 2004).

Meacham commented that management of disability in practicum courses can be made more difficult by lack of knowledge and discriminatory attitudes amongst field supervisors and agencies (2004). This reflects a critique of social work by critical disability scholars and some faculty who contend that the profession has paid insufficient attention to disability rights (Dupre, 2013; Poole, Jivraj, Arslanian, Bellows, Chiasson, Hakimy, Pasini,& Reid, 2012). Acrey (2004) has documented social work scholarship's focus on medicalised models of mental health at the expense of empowerment and Scheyett (2005) notes that social work has made little contribution to the discussion of mental health stigma. Drawing these themes together, authors have begun to call for the discipline to thoroughly review its approach to mental health (Meekosha & Dowse, 2007; Poole, Jivraj, Arslanian, Bellows, Chiasson, Hakimy, Pasini,& Reid, 2012; Reid & Poole, 2013).

Social work has a significant role in mental health services and its current students have been demonstrated to have heightened risk of experiencing these problems. It has been the subject of justifiable criticism for its uncritical approach to the education and inclusion of students with mental health conditions. While professional standards apply these do not specifically address students with disability's rights. The discipline has a strong interest in screening out potentially unsuitable students and its approach to articulating inherent requirements will directly shape this practice. How social work programs frame their statements in regard to common hidden disabilities is therefore a critical issue for its currently enrolled students and requires further investigation.

SOLUTIONS AND RECOMMENDATIONS

Social work academy and professional accreditation bodies need to focus on the personal and political aspects related to inherent requirements. Disability rights are inherent in social work mission statements

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

on social justice and human rights and this includes the disability rights of prospective and current social work students. Prejudicial, often covert, attitudes and practices of academic staff regarding 'personal views on suitability for social work practice' need to be openly named – for discriminatory practices to be addressed so that students feel safe in the knowledge they will be provided with appropriate adjustments in a supportive and non-judgmental environment. Open discussion is required amongst social workers on what is a very contentious topic with strong views on either side. However, a sign of a truly mature profession is in its ability to engage with and openly discuss controversial topics particularly where issues of human rights and discrimination are involved. Education is a main facilitator of life opportunities leading to increased employment opportunities, affordable housing options and socialisation. If inherent requirements are to be adopted by universities and social work programs, it is imperative that these do not become another vehicle for discriminatory practice by social work academics and practitioners who believe that people with certain disabilities are more suited to client and not worker roles. Recent developments in the consumer movement with the co-design and co-production of mental health services, and the rapid growth of the peer mental health workforce, suggest that a focus needs to be on student's strengths and capabilities and not a narrow and limited view of disability from a deficits perspective.

FUTURE RESEARCH DIRECTIONS

Further research is required on the implementation and impacts of inherent requirements, particularly in relation to the health and human services disciplines. This includes impacts on student disclosure and help-seeking for initial entry into a degree program as well as when problems develop post enrolment. This is in relation to different mental health issues as stigma and discrimination vary according to diagnosis. Further research is required on discriminatory attitudes amongst staff and students toward students with disabilities and issues of social inclusion and exclusion in the university environment. Research that considers roles and responsibilities of universities, professional accreditation and registration bodies and practitioner communities in determining suitability for practice would be useful.

CONCLUSION

The introduction of inherent requirements in social work education requires careful consideration of the mission of social work and the personal and political aspects of the profession. Universities need to carefully consider whose responsibility it is to determine a person's suitability for enrolment to study in a particular discipline. The limits of such decisions need careful consideration. For instance, does a university simply decide on a person's capacity to effectively engage in and complete a program of study, or does this extend to deciding on a person's suitability to practice in a particular profession? Universities take a different view on this and in disciplines and countries, such as Australian social work, that do not have a professional registration body, pressure is placed on universities to be the gatekeepers for the profession. Any actions taken by universities need to uphold disability rights and to acknowledge the strengths and capabilities of students with mental health issues. Prejudicial attitudes and discriminatory practices need to be eliminated and staff held to account if students are to feel truly safe and supported and to have their rights upheld at university and in practice during field practicum.

Chapter 41
Healing Together:
The Lid Project

Kristine Vuocolo
Human Services Inc., USA

ABSTRACT

This chapter emphasizes several key concepts concerning mental illness in today's society. The author strongly believes that mental health recovery is possible and that it is an individualized journey. People struggling with mental health issues can find hope and healing through the use of artistic expression. This chapter is designed to encourage and inspire others to use everyday items and turn them into art. The author describes how collaboration can be a key ingredient to the success of the healing that takes place while doing art together.

INTRODUCTION

While trauma disorders are currently receiving significant attention, countless other mental health disorders often remain undiagnosed, ignored, and stigmatized. Statistically, 1 in 4 adults struggle with a mental illness in a year (Johns Hopkins Medicine). That is 1 out of every 4 people in a family, 1 out of every 4 coworkers, students, friends and neighbors. In other words, a quarter of the population is struggling with a mental illness at any given moment. Mental illness is non-discriminatory and crosses all cultural lines, age brackets, and economical statuses. So while communities and schools rush to become trauma-informed, it may be more poignant to acknowledge, educate, and respond to the extremely high percentage of people living with mental illnesses beyond those associated with trauma.

Fortunately, the benefits of art making do not discriminate either. Regardless of diagnosis, the arts have repeatedly demonstrated an ability to heal. Engaging in music correlated to a form of relaxation, a decrease of tension and anxiety, and control of chronic pain. Making art led to a reduction of the stress producing hormone cortisol, and also gave participants a sense of identity. The findings of movement expression and expressive writing are similar, but added findings of a boost in immune functioning, significant improvement in physical health, and an overall improvement in quality of life (Stuckey and Nobel, 2010).

Collaborative art projects seek to intertwine people traveling similar paths; building trust and connections in an effort to simultaneously decrease feelings of isolation while providing movement towards coping and healing. This chapter shares the story of The Lid Project, a collaborative art project set at Transitions, a psychiatric rehabilitation program. While the story may offer the reader a project to replicate, the more substantial takeaway is the richness of metaphor for the healing journey found within the story and the process of creating art together.

Collaborative Art Making

Strategically planned arts based experiences can play a very valuable role in healing for those living with mental illness. The arts have been shown to improve focus, mood, brain function, communication, and social skills, all of which are necessary for working toward healthy living and thinking (Nurrie-Stearns, 2013). The arts offer choice and opportunities to take control. For those who have experienced trauma or live with a mental health diagnosis, art making can promote skills to help regulate emotions, build confidence and self-esteem, and foster therapeutic communities and relationships through collaboration.

The shared experience of group art making in particular has many benefits. First it provides safety, which aids in building trust and stronger relationships among members of a group. The art maker is able to be vulnerable and understood by the group, without having to verbalize his experience, making it a safe form of communication and expression (Moon, 2010). Secondly, collaborative work lessens the pressure for one person to achieve an end goal successfully on their own. Both the individual and the community around him are empowered as they work together to achieve their goals (Moon, 2010). Finally, according to art therapist Dr. Bruce L. Moon (2010), "Making art in the presence of others is an expression of hope" (p. 8). When an individual is free to express and be understood by others through his artwork, he can begin to trust in something outside of, or greater than, himself. Ultimately, working collaboratively can move the participant away from feelings of isolation towards being part of a community (Rossetto, 2012).

Feelings of isolation are common among people who are in the midst of mental illness, addiction, grief and other traumatic experiences. These experiences may be difficult to talk about, which is why art making can be a valuable and effective method of therapy for many. Moon says, "In art-based group therapy we often witness creative expressions of feelings that are beyond the communicative abilities of conventional speech" (2010, p. 29). Making art within a group context allows people to share their stories without having to verbally articulate their experiences. This helps to establish an atmosphere of safety and trust, which is key to successful group therapies.

Artwork in any form (dance, music, painting, writing, etc.) can be considered a "partial self-portrait that metaphorically represents that artist's life" (Moon, 2010, p. 67). This makes one very vulnerable to the group when they share their work. However, when other group members are able to see and relate to the experience of the art maker, organic relationships begin to form, and the power of understanding that one is not alone in the world begins to establish feelings of hope. Moon says, "Acts of creating are invitations to relate. By making things, artists take images from within and give them visible form in the world" (2010, p. 4). Art making offers an alternative way for one to reconnect not only with himself, but with the world beyond.

When in a group, an individual is part of a collective whole working to achieve a common goal. This can set a participant at ease because he/she is not solely responsible for a final outcome of a project. The potential for creativity magnifies as ideas from one participant are able to expand off of ideas of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the other group members. Working through ideas with others changes isolation into connection (Moon, 2010), and gives group members choices about how they work together, and what they want to achieve as a collective whole. After that achievement is met, a sense of pride and ownership becomes evident, and group members find the confidence to continue trying new things and working together.

Description of Facility Program and Population

Psychiatric Rehabilitation (Psych Rehab) programs are designed to promote recovery, community integration, and an overall improvement in life for those diagnosed with a mental illness (Psychiatric Rehabilitation Association, n.d.). Transitions, located in Chester County, Pennsylvania, is a group-based model that utilizes evidence-based practices within a rotating twelve-week schedule. These groups vary based on the needs of the current membership and the goals they have set for themselves. Transitions serves adults who live with severe and persistent mental illness.

Upon arrival, new members are assigned a Primary Coach. These Psych Rehab workers are not therapists, but are there to support the client and assist them in achieving goals they set for themselves in areas such as living, learning, working, and socialization. The Primary Coach also helps to navigate the mental health system, which is vast and can be intimidating.

Participants

According to the Mayo Clinic's website, the definition of mental illness is, "disorders that affect your mood, thinking and behavior." Among the different diagnoses, the symptoms of mental illness are vast. Those who are accepted into the Transitions program exhibit characteristics associated with mental illness that can be nuanced or overt. Symptoms of schizophrenia, bipolar disorder and major depression disorder tend to be more widely recognized. However, symptoms associated with personality disorders, anxiety disorders, and trauma related disorders may not be so obvious.

Any and all mental health symptoms may cause those experiencing the symptoms to feel disconnected to friends and family or just as likely, have friends and family reject or turn away from them. Symptoms demonstrated by individuals with schizophrenia and bipolar disorder include depression and anxiety, hopelessness and thoughts of suicide, lack of social skills, and cognitive impairment. Those with bipolar disorder may also experience rapid mood swings, mania, or insomnia (Rodseth, 2011). Individuals diagnosed with major depressive disorders may demonstrate a lack of interest in activities, lack of energy and appetite, have trouble sleeping and may have suicidal thoughts or behaviors. Symptoms of anxiety disorders manifest as excessive worry, restlessness, irritability, and sleep disturbance (Smith, 2018). Trauma symptoms are similar to those of anxiety and depression and may include fear and anxiety, sleep disturbance, hypervigilance, difficulty concentrating, and problems controlling anger. Trauma survivors also struggle with feelings of safety and the ability to trust others (Setti & Argentero, 2014).

Many people facing mental illness find it very challenging to make friends, obtain jobs, and even complete simple tasks if these symptoms are not managed (NIMH, 2016). There are many reasons why adults struggling with mental health issues would come to Transitions: some are looking for people to whom they can relate; some need support going back to school, getting their driver's license and/or finding a job; others are there to learn a new skill set based on the impact of their mental illness symptoms.

From the inception of the Transitions program, there are a handful of groups that remain consistent in the different twelve-week schedules. Within these groups, participants develop coping skills for mental

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

health issues, relationship skills, job development skills, and artistic expression. The groups themselves have several goals including but not limited to building on skills, increasing natural supports, connection to community services, and building self-esteem. Through the use of art, it is possible to accomplish all of these.

Primary Coaches and Specialists

Psych Rehab workers or Primary Coaches along with Psych Rehab Specialists believe in the philosophy of mental health recovery. The term recovery has been historically linked to drugs and alcohol rehabilitation. However, the term recovery is also associated with mental illness. In 2005, the Pennsylvania Department of Mental Health and Substance Abuse Services released a publication titled, *A Call For Change: Toward A Recovery-Oriented Mental Health Service System for Adults.* This document was a proclamation of the Department's dedication to the Recovery Movement.

Certified Psychiatric Rehabilitation Specialists (CPRP) are professionals who have worked at least two years in the mental health field and have completed a minimum of 45 hours of training specific to "the treatment and/or rehabilitation of adults with serious mental illness" (PRA & PRF). After that time they are eligible to take the exam to become certified. CPRPs believe that people living with mental illness are first and foremost individuals. They believe that they have skills and talents unique to them, and recovery pulls on these strengths. Recovery is an individualized journey and different for everyone. They also work through the belief that recovery means people living with mental illness can find meaningful employment, stable housing, a supportive network and live a fulfilling life (PRA & PRF). It is this philosophical stance that guided the Lid Project.

The Creation of the Lid Project

The Transitions program is part of Human Services. Inc., which is a non-profit agency. As many staff of non-profits would attest, money for art can be tight or non-existent. When approaching this project the staff at Transitions began by working with the supplies they already had available to them: paints, paint brushes, and a large canvas they found tucked away in a closet. They also reached out to people in their network. During the daily morning meetings the Primary Coaches asked all of the Transitions' members to bring in lids of various shapes and sizes. They then approached other staff in the agency and local stakeholders to ask them to save lids as well. Rather quickly bags of lids started showing up. Peanut butter jar lids, soda lids, pickle jar lids, jam lids and so forth. No lid was too big or too small!

After the lids were gathered the project was officially started. Members were told that this was a group project and asked to decorate the lids. Staff presented the theme of mental health recovery and expressed that the lids were to represent what that means to them. Members asked about what the finished project would look like and the facilitator at the time was honest in saying that she wasn't sure what the end result would be. This actually excited the members! There was anticipation about what the lids would turn into.

During that first art group, some of the lids were painted. Members and staff worked side-by-side, each painting a lid or two. Some members were nervous because they hadn't really painted before. Yet, the staff watched as other members encouraged them, saying things like, "That's ok, just put some dots on them, or squiggly lines." This set the members who were nervous at ease and they joined in.

A few weeks went by and more people became involved in the lid project. There were times when the art room was buzzing with laughter and chatter. Other times music was heard up the halls. On some

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

lids words started to appear: hope, discovery, journey, etc. Other lids were painted in solid colors with a few accents. The colors ranged from loud primary colors to pastel tones. Each one was unique and symbolized a different artist.

As weeks passed something magical started to happen. The first was that as the members and staff painted, conversations unfolded about past experiences, the realities of mental illness, past traumas as well as fears mixed in with conversations of everyday life. Bonds started to form that didn't previously exist. Relationships between both staff and members became stronger. The members who participated were set at ease and went more in depth with sharing their stories. Around the program there was a genuine camaraderie that developed. Through spending time painting together the members found other members who had gone through similar experiences. They realized that others dealt with comparable mental health symptoms, and they began to share coping skills that had worked for them.

The second was that members started to become even more creative. The art room was a place that had a wall of storage closets. In these storage closets were unused art supplies of projects past. Members and staff alike started rummaging for items that could be glued to the lids. This was a surprising yet welcomed development!

At this point lids started taking on personalities all their own. Some had faces others had entire scenes painted on them, birds flying over grass and fish swimming in the ocean just to name a few. Then there were the more abstract pieces that were left to interpretation. Suddenly lids started appearing with feathers and beads on them and even mini dream catchers were attached for decoration. The creativity was contagious and this brought even more participation.

Approximately 100 lids later, the staff and members of Transitions thought it was time to look at the canvas and try to envision the final outcome.

What to do with the lids? At first the staff thought that they would just glue all of the lids on the canvas until the canvas was full. The canvas turned out to be bigger than they thought, and it was decided by the group that there might be too many lids. This is where members and staff started discussing some alternative options.

To get started they took some of the lids and arranged them on the canvas to see what it would look like with lid next to lid. It looked good, but it was observed during this process that pressing the lids up next to each other left gaps due to the different sizes of the lids. What to do with the gaps?

Again as a team they went back to the storage closets and, as luck would have it, found a bag of clear decorative glass gems. They fit perfectly in between the caps. This was the inspiration needed and a group went for exploration purposes to the dollar store. There they picked up more glass gems and some small round mirrors, which seemed like great options to glue onto the canvas as well.

It took a bit of dreaming, some more conversation between members and staff, and the vision finally emerged: "Journey of Recovery, River of Hope." Over the next few weeks staff and members jointly painted the canvas, and glued finished lids as well as glass gems and mirrors onto the canvas. The lids and gems became the bank of a river. Then a river was painted with lids lazily floating down it. Above that was a night sky with an artistic moon leaving a shadow reflecting off the river. Finally the mirrors were artistically positioned within the sky to reflect the onlooker. After a few months, good conversations, much laughter and some tears, the masterpiece was complete!

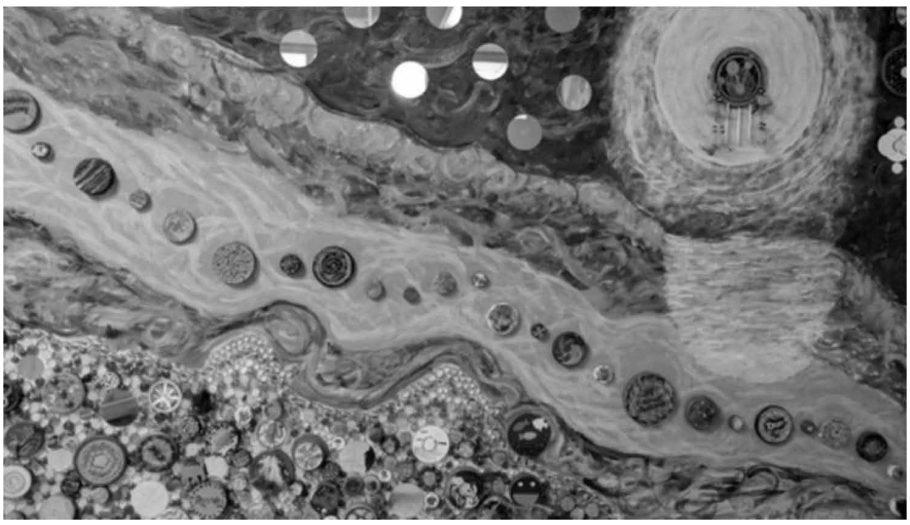
Healing Effects Observed



In the mental health field of today, employees at every level are being trained in trauma informed care. It is more commonly accepted that mental health issues can be connected with past traumas and vice versa. As facilitators, when approaching a group art project, it is important to remember that we do not know what traumatic experiences have impacted our participants, and it is impossible to know what might trigger the individuals we are working with. With that in mind, the Transitions Psych Rehab staff found that providing an activity with no specific end goal was more welcoming and safe than a more specific project. This allowed the project to focus on working collaboratively, providing choice and helping to set the participants at ease with making art. Even though no formal therapy was done during these sessions, healing effects were noticeable.

Members who participated felt pride in the finished project, and their confidence seemed to rise when they saw their painted cap(s) put into a collective project. When individuals who did not think that they could make art became involved, their self-esteem improved by being included.

Working on the same project as a group encouraged the development of meaningful relationships and natural supports within the group. New friendships developed through conversations that took place during the art groups. The Psych Rehab workers developed bonds with the participating members, leading to deeper therapeutic conversations that helped with breakthroughs and healing. Many of those participating in the project shared that the process was very therapeutic for them, and they began making art at home with everyday items. The shared experience helped build a sense of camaraderie among community members, and the continued openness with which they shared their experiences after the project was completed demonstrated the establishment of hope.

As the project progressed, more and more members took part in the art sessions. After The Lid Project was completed, more individuals participated in future art projects, and the walls of the Psych Rehab center are now covered with artistic expression. When visitors and new members arrive at Transitions, they stop at the mural and read the words associated with the journey of recovery. This has created an atmosphere of hope.

Figure 1. The completed lid mural

Metaphors Discovered in the Process

The destination is not always known at the onset of a journey

The Lid Project began as a way for the Primary Coaches to make art with their members as inexpensively as possible, but ended up being a very valuable journey. Through this process, participants learned to focus not on working towards something, but to trust in the process and be present in the moment. In recovery, this is a valuable lesson to learn. By focusing on neither the past or the future, participants can truly engage in the present moment, the present treatment method, and the present environment and community.

We can always reach deeper within to find new tools and resources.

As confidence and trust in the creative process and the project grew, participants began searching for more materials to use. They had become comfortable using the tools already on hand and were both prepared and excited to try new things. The supply closet became a treasure trove; providing creative materials once passed over or discarded as being useless. It was not until later in the process that the participants were able to recognize the value of what was on hand and how it could be incorporated into the artwork. In a similar fashion, as the healing process unfolds, with guidance and support participants are able to reach deeper into themselves to find more tools, untapped strength and energy, and deepened commitment to support further healing.

The small steps we take at the beginning still move us down the path.

The first few lids created were simple and unadorned. Yet, each simple, first lid moved the project forward towards the final 100 lids decorated and collected. The beginning of a treatment method or the beginning of a new program or even the beginning of a new relationship can feel overwhelming. It may seem at the start that every step must be completed simultaneously or that the first steps are so insignificant that they can not possibly be going anywhere. Those first lids helped to demonstrate the very opposite. Every small step, in any direction, is part of the journey and a valuable step towards healing.

CONCLUSION

Admittedly, at the start of this project, the Psych Rehab workers did not recognize the value of the journey they were about to embark on with their clients. They simply sought to build relationships using art in its most therapeutic form; to work through past traumas, build self-worth, and bring hope. A collaborative art project seemed like the best way to bridge the gap between someone who struggles with a mental illness and someone who wants to connect with him/her. The Lid Project accomplished all of these things and more.

Chapter 42
Healing Alex's Wound:
Application of MSJCC in Adlerian Play Therapy

Szu-Yu Chen
Palo Alto University, USA

EXECUTIVE SUMMARY

Multicultural and Social Justice Counseling Competencies (MSJCC) has emphasized the need to consider multicultural and social justice factors into all aspects of the counseling profession. Consistent with the MSJCC guideline, it is essential that counselors provide developmentally and culturally responsive interventions when working with children from diverse backgrounds. Adlerian play therapy is a unique approach in which counselors incorporate basic tenets of individual psychology and premise of play therapy to help children work through different types of emotional or behavioral issues. This chapter provides an overview of the effects of adverse childhood experiences (ACEs) on children's mental health, particularly the multitude of effects on Hispanic children. The author then illustrates the application of Adlerian play therapy from MSJCC's perspective to work with a Hispanic boy exposed to a high level of ACEs.

INTRODUCTION TO THE CASE

In this case study, to protect the child and his families' confidentiality and anonymity, pseudonyms are used. Alex was a 6-year-old Hispanic boy living with his grandparents, Mr. and Mrs. Garcia, two uncles, and a younger sister, Abby. Mr. and Mrs. Garcia were first generation immigrants in the United States and their children and grandchildren were born and raised in the United States. Mr. and Mrs. Garcia brought Alex to play therapy services because of Alex's increasingly aggressive behavior. Mr. and Mrs. Garcia reported that Alex's biological mother left the family when Alex was three years old due to the abusive relationship with Alex's father. Before living with Mr. and Mrs. Garcia, Alex and Abby had moved a lot with the father and his girlfriend, and Alex was asked to call the father's girlfriend "Mom".

Mr. and Mrs. Garcia reported that they called Child Protective Service (CPS) after finding out their grandchildren were victims of domestic violence by the father. They shared it was a hard decision for them to contact CPS because he was their son and they felt shame to reveal this incident to everyone. However, they wanted to protect their grandchildren and they think it was better for their grandchildren to leave their father. They noted that Alex's father was physically and emotionally abusive toward Alex and Abby when the father was angry or drunk. After CPS had been involved, they had removed Alex and Abby from the father's house. Alex and Abby had lived with their grandparents for about a half year since the removal. Although the father would visit the children once a week, Mr. and Mrs. Garcia reported that Alex would feel confused about why his father would come and go every week. They further reported that the father recently gave up the guardianship, so they had become legal guardian of their grandchildren. However, recently, the children's biological mother re-entered their lives and wanted guardianship of her children. Mr. and Mrs. Garcia were worried about losing their grandchildren. They shared the mother was not likely to get the guardianship back because she had not contacted the family since she left. Yet, it would be an ongoing issue in the family.

Mr. and Mrs. Garcia described that Alex would behave like his father when he got angry. For example, Alex would show anger outbursts, such as kicking, hitting, yelling, and threatening towards his grandparents and sister. However, his behavioral issues seemed to only occur at home. Alex's kindergarten teacher reported that Alex did not show any behavioral problems in the classroom and described Alex as a cooperative and polite child in the school setting. He seemed to get along with his peers well. However, the teacher commented that when Alex felt sad, he tended to hold his tears back from teachers and peers.

The grandparents reported feeling stressed and helpless about Alex's behavioral issues because they have tried different ways to discipline him, such as telling him not to hit people when angry, using timeout, or taking his toys or TV time away. However, their parenting methods did not seem to work. They were worried about Alex's aggressive behavior and their families' safety. They shared their hopes to decrease Alex's aggression and improve his relationships with his families.

ADVERSE CHILDHOOD EXPERIENCES IN HISPANIC CHILDREN

Adverse childhood experiences (ACEs) are chronic and traumatic experiences and events, ranging from abuse and neglect to parental separation or divorce, and may have negative, lasting effects on well-being in childhood or later in life (Sacks, Murphey, & Moore, 2014). A growing body of research has shown that ACEs are becoming a critical mental health issue (Sacks & Murphey, 2018). Adverse childhood experiences study was first conducted by Kaiser Permanente, a health insurance company in collaboration with the Center for Disease Control and Prevention (CDC) from 1995 to 1997. Over 17,000 middle-class adult participants completed the survey exploring their current physical health status, social functioning, and behavior along with questions related to their childhood maltreatment and family dysfunction. The questionnaire used in this study categorized ACEs into three groups: abuse, neglect, and family/household challenges. There are 10 ACE factors, including emotional, sexual, and physical abuse, emotional and physical neglect, substance abuse and mental illness within household, mother treated violently, parental separation or divorce, and incarcerated household member. Each factor weighs one point and the total score of the different categories of ACEs reported by participants was added up to assess cumulative childhood stress ranging from 0 to 10 points in which higher ACE scores indicate higher exposure to adversity events. The results indicated that almost two-thirds of study participants reported at least one

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ACE and more than one in five reported three or more ACEs (Centers for Disease Control and Prevention [CDC], 2016). The findings further revealed the greater exposure to ACEs is positively associated to the greater risk of behavioral and physical health across the lifespan (CDC, 2016). Numerous research studies have shown that children exposed to ACEs are more likely to develop physical, mental, behavioral, psychosocial, and/or cognitive issues into adolescence and adulthood, such as substance abuse, depression, poor academic and work performance, and risk for intimate partner and sexual violence (Burke, Hellman, Scott, Weems, & Carrion, 2011; Flaherty et al., 2013; Jimenez, Wade, Schwartz-Soicher, Lin, & Reichman, 2017; Kerker et al., 2015; Mersky, Topitzes, & Reynolds, 2013).

Hispanic children currently account for one-fourth of U.S. children and are projected to remain the largest ethnic minority group among children (Passel & Cohn, 2008). Hispanic children who are US-born or in the immigrant families (foreign-born children with at least one foreign-born parent, or US-born children with at least one foreign-born parent) are at high risk for mental health disorders stemming from poverty, exposure to trauma, acculturative stressors, and discrimination (Caballero et al., 2017). Sacks and Murphey (2018) examined the prevalence of ACEs among children using nationally representative data from the 2016 National Survey of Children's Health (NSCH). They found that 51 percent of Hispanic children have experienced at least one ACE, compared with 40 percent of white non-Hispanic children. Caballero, Johnson, Muñoz Buchanan, and DeCamp (2017) surveyed adverse childhood experiences among more than 12,000 Hispanic children from immigrant and U.S.-native families. The results indicated that about 30 percent of Hispanic children in U.S.-native families and 16 percent of children in immigrant families are in high ACE exposures (≥2 ACEs), including poverty, abuse, neglect, household dysfunction (e.g., parents' divorce, violence, and substance abuse, etc.). Specifically, economic hardship, the divorce or separation of a parent or guardian, living with an adult with a substance use problem, and parental incarceration are the most common ACEs reported for Hispanic children (Sacks & Murphey, 2018).

Childhood trauma exposure have been linked to an array of mental health issues, including externalizing and internalizing problems (Martinez, Gudiño, & Lau, 2013). Thus, children who have experienced ACEs often need mental health counseling services. Martinez et al. (2013) investigated the use of mental health services by children (N=1,600; 19.3% Hispanic) who had experienced some form of maltreatment and found that neither internalizing nor externalizing problems predicted the use of mental health service for the Hispanic children population. However, they indicated that cultural and family issues might discourage Hispanic parents to seek mental health services after their child's exposure to maltreatment. As a result, many mental health professionals have addressed a need to identify the predictors of mental health services among Hispanic children and enhance competencies to work with children using developmentally appropriate and culturally responsive interventions due to an increased concern about mental health for at-risk Hispanic children.

Play therapy has been identified as a developmentally appropriate approach to counseling children from age 3 to 10 because play is children's natural way to communicate and express their feelings and thoughts (Landreth, 2012; Ray, 2011). In play therapy, counselors utilize selected toys, art materials, and other play media, and build a safe and trusting relationship in which children can explore their world and express themselves more fully through the form of symbolic play (Landreth, 2012; Kottman & Meany-Walen, 2016). Meta-analytic results for play therapy outcome research have shown play therapy to be an effective intervention for children with a variety of presenting problems (LeBlanc & Ritchie, 1999; Bratton, Ray, Rhine, & Jones, 2005). There are different theoretical approaches to play therapy resulting in unique ways of counseling children and conceptualizing children's presenting issues.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Adlerian play therapy developed by Terry Kottman (1995) is a play therapy model based on the theoretical constructs of individual psychology (Adler, 1964) and is adapted to meet children's development level. Kottman and Meany-Walen (2016) indicated that therapists use Adlerian play therapy in clinics and school setting and the interventions are effective when working with children who exhibit a variety of presenting concerns. This approach has shown especially appropriate with children who have issues related to power and control, poor self-concepts, inadequate social skills, strained families relationships, and traumatic experiences (e.g., Kottman, 1999; Kottman, 2001; Kottman & Warlick, 1989; Meany-Walen, Bratton, & Kottman, 2014; Meany-Walen, Kottman, Bullis, & Dillman Taylor, 2015; Morrison, 2009; Rotter, Horak Jr., & Heidt, 1999; Snow, Buckley, & Williams, 1999).

To work effectively with diverse populations, the Multicultural Counseling Competencies Revisions Committee (2015) has developed the Multicultural and Social Justice Counseling Competencies (MSJCC) that serve as a conceptual framework for competent multicultural counseling practice. This framework signifies the need to focus on multiculturalism and social justice as the center of all aspects of the counseling profession. The core belief of MSJCC is that counselors and clients both bring to the therapeutic relationship various cultural values, beliefs, biases, and complex identities consisting of different race, ethnicity, gender, sexual orientation, socioeconomic status, religious/spirituality, and disability. Counselors, therefore, need to address how the interactions of power, privilege, and oppression influence the counseling relationship. Adlerians focus on an individual's subjective perspective and interpretation of an individual's world. By understanding an individual's experience, counselors can begin to understand the impact of culture may have on clients' values and perceptions. Thus, Adlerian play therapy may also work well with children from diverse cultures and ethnic groups (Kottman, Bryant, Alexander, & Kroger, 2009). In this chapter, the author shares her cultural identity and approach to counseling children. The author further illustrates the application of the MSJCC in Adlerian play therapy process with Alex and his families.

COUNSELOR BACKGROUND

Counselor's Cultural Background

I was born and raised in Taipei, Taiwan and immigrated to the United States approximately 12 years ago to pursue higher educations and trainings in clinical mental health counseling and play therapy and now being a counselor educator in a university setting. When I lived in Taiwan, I was aware of my power and privilege status, as I was raised in an upper-middle class family and in a capital city. I was able to receive many resources, such as education opportunities and financial supports to achieve my personal and professional goals and development. However, moving to the states, I become part of an ethnic minority for the first time in my life and have to think about my identity in a new way. In the U.S., I identity myself as an East Asian immigrant. Specifically, I am a heterosexual female counselor and counselor educator of color. I became aware of my transition to the marginalized group and the impact of my social status on my worldview, values, beliefs, and biases.

I have experienced various challenges during this acculturative process, including culture shocks, immigration status, acculturative stress, language barriers, limited support system, low self-efficacy, career concerns, discriminations, and oppression. Among these challenges, I reflected how my cultural values

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

have interfaced with the western culture and how my cultural background and acculturative process have impacted my identity as a counselor and a counselor educator.

Confucianism, Buddhism, and Taoism are the main cultural values that have profoundly influenced my view of myself, others, the world, and counseling relationships with clients. Confucianism defines family and society as hierarchical and authoritative where relationships are based upon moral principles, which reflect love, integrity, loyalty, sincerity, and benevolence (Jung, 1998). Buddhism indicates human beings are leading their own lives with guiding rules, refraining from evil and purifying own mind (Jung, 1998). Discovering harmony with the natural order of things as well as stressing themes of passivity, asceticism, and the search for immortality are the major tenets in Taoism (Jung, 1998). I believe that these philosophies, including collectivism, hierarchical structure in the family and society, well-defined social roles and norms, repression of the expression of emotions and problems, harmony, and indirect forms of communication (Sheu & Fukuyama, 2007) and my upbringing have shaped my worldview, interpersonal relationships, expectations of self and others, and communication styles.

Counselor's Counseling Approach

My counseling approach is based on Alfred Adler's individual psychology. Adlerian theory serves as my guiding theory because its underpinning philosophy is the most congruent with my beliefs about people and their personalities. I believe that people are socially embedded and striving for a sense of belonging and significance. I believe that people's behavior and beliefs are purposeful and they have the capacity and power to pursue a successful life. I also believe that people's family history and life experiences have influenced their personality and perception of the world. It is my fundamental belief that our experiences are not the cause of who we become but, rather, it is our personal understanding of our experiences that gives meaning to our lives. This personal understanding is essential to the way in which we develop relationships, pursue our life goals, and how we respond to adversity and challenges. Therefore, I endeavor to understand each client as a whole and unique individual with distinct attributes, personal values and strengths, and life purpose.

I view the therapeutic relationship as an imperative factor for growth and positive change to occur in the counseling process. Hence, I work with clients to identify their goals of counseling and I help clients recognize thoughts and behaviors that keep them from reaching their goals. Moreover, I support clients in recognizing solutions to their concerns. I expect through our collaborative effort that clients will grow and find new ways of seeing the world around them and create a more meaningful way of being in the world.

MSJCC IN ADLERIAN PLAY THERAPY

Historically, Adlerians have worked with children in the context of family and school in the form of family therapy, parent education and teacher consultation (Dreikurs, 1967). In Adler's view, children's play provides rich information about children's present situation as well as their future (Dreikurs). Adler considered children's play as an opportunity for counselors to view children's characteristic ways of behaving; hence, counselors may confirm their hypotheses of children's lifestyle by observing children's play behavior (Dreikurs). One of Adler's major assumptions was that an individual is guided by one's lifestyle that can be presented in every expression of the personality. Thus, counselors may observe

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and interpret children's lifestyle through their verbal and nonverbal behavior (Adler, 1956). Adler also believed people are socially embedded and considered social interest as a criterion for mental health (Mosak, 1989). Thus, Adler indicated that therapists could determine children's social feelings by observing children's group play and further provide an opportunity for children to develop their social interest as needed. It is obvious that play can give counselors clues to understand children's lifestyle, goals of behaviors, private logic, and interpersonal relationships.

Based on Adler's view of children, Terry Kottman (1995) integrated Adlerian theory with play therapy and developed Adlerian play therapy for working with children, parents, and teachers from a systematic approach. Kottman and Warlick (1989) posited that the concepts of individual psychology and various Adlerian therapy techniques could be incorporated with the premise of play therapy to create a model for helping children who exhibit various types of emotional or behavioral problems.

Theoretical Foundation of Adlerian Play Therapy

Adlerian play therapy exemplifies the tenets of individual psychology and applies them within a framework of how children view themselves, others, and the world. Adlerian play therapy may foster collaboration and purposeful movement, and help children master life tasks (Even & Armstrong, 2011; Kottman, 2003; Kottman & Warlick, 1989). Kottman (2003) defined play therapy as "an approach to communicating therapeutically with clients using toys, art materials, games, and other play media, giving clients a safe and nurturing relationship in which they can explore and express feelings, gain insight into their own motivation and into their interaction with others, and learn and practice socially appropriate behaviors" (p.1). Some primary theoretical tenets and constructs that Adlerian play therapy rests on are described below.

People are Socially Embedded

Adlerian play therapists work with children based on the beliefs that people are socially embedded, goal-directed, subjective, and creative human beings (Ansbacher & Ansbacher, 1956; Carlson & Slavik, 1997). One of the basic tenets of individual psychology is social interest and this is considered a criteria for mental health. Adler believed that people are born with an innate desire to develop social interests and connections with others, and strive for belongings and significance in their families, classrooms, communities, and other social groups (Ansbacher & Ansbacher, 1956; Carlson, Watts, & Maniacci, 2006).

As part of the development, children must form a secure attachment with their primary caretakers who are able to help them flourish their connections to the community at large (Kottman & Meany-Walen, 2016). Hence, Adlerian play therapists must investigate and understand how children build relationships and make connections with others. They accomplish this by observing their play in the playroom and discussing with parents and teachers the child's ways of interacting with others and seeking significance and belonging outside the playroom, such as schools and neighbors (Kottman & Meany-Walen). In addition, Adlerian play therapists want to assess children's level of social interest and try to increase children's social interest by modeling healthy ways to connect with others and maintain relationships, and fostering these abilities in children through encouragement (Kottman & Meany-Walen).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

People Behavior is Goal-Directed

Another tenet in Adlerian play therapy is that children's behavior is purposeful and goal-directed. As children interpret their environment, they make early decisions regarding the predictable way that they will behave to achieve that goal (Ansbacher & Ansbacher, 1956; Carlson et al., 2006). Kottman and Meany-Walen (2016) stated that Adlerian play therapists must help children recognize their goals of behavior and support them to strive toward constructive goals. Play therapists particularly focus on children's goals of misbehavior (Dreikurs & Soltz, 1964) and four crucial Cs: count, connect, capable, and courage (Bettner & Lew, 2005).

Lew and Bettner (1996) postulated that children strive toward these four crucial Cs and believed that children needed to perceive themselves as possessing attributes of the crucial Cs in order to grow and mature successfully in society. Adlerian play therapists make hypotheses about children's assets and limitations and the ways in which they approach life by assessing the crucial Cs (Kottman & Meany-Walen, 2016). Adlerian play therapists consider the crucial Cs on a continuum to observe how children connect with others, believe they are significant, believe they are capable of success, and they demonstrate courage to be imperfect and try new tasks (Kottman & Meany-Walen).

Dreikurs and Soltz (1964) posited four goals of children's misbehavior: attention, power, revenge, and proving inadequacy, and believed that children use these behaviors to meet their needs. Adlerians believe that when children feel discouraged and lack feelings of belonging and connecting with others, they may unconsciously use goals of misbehavior to meet their needs (Dreikurs, 1964). Hence, Adlerian play therapists aim to understand how children behave to meet their goals by observing children's play, consulting parents and teachers about children's behavior that upset them, examining reactions of adults, and observing children's reactions to corrections (Kottman & Meany-Walen, 2016). Once play therapists understand children's goals of misbehavior, they can help children strive for more positive goals, such as the crucial Cs.

In order to gain a better understanding of children and their dynamics, play therapists can use goals of misbehavior and crucial Cs as tools to conceptualize children's lifestyle and potential personality priorities, including superiority, control, pleasing, and comfort. Play therapists assess children's lifestyle by looking for patterns of behaviors, thoughts, attitudes, and relationships that help children navigate their life. Moreover, play therapists can apply these concepts to enhance their understanding of children's parents and teachers as well (Kottman & Meany-Walen).

Play therapists use play techniques to investigate children's lifestyle, help children examine their faulty assumptions, and help them draw more positive perceptions about self, others, and the world. When observing children exhibiting more socially appropriate goals, play therapists can encourage children's behavior to help them move toward the positive goals of behavior (Kottman & Meany-Walen).

People's Perspective is Subjective

Another central construct in individual psychology is that people view their life subjectively. They filter the reality through their subjective interpretation of facts based on their convictions in their lifestyle and perception of how they believe about self, others, and the world (Ansbacher & Ansbacher, 1956; Carlson et al., 2006). Children usually develop their lifestyle and perceptions about self, others, and the world before the age of eight by observing interactions and reactions, examining self-worth, and exploring best ways to gain belonging and significance (Kottman & Meany-Walen, 2016).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Some of these perceptions and conclusions about life and relationships are not accurate because children lack experiences and perception to accurately evaluate and interpret the situations and relationships, leading them to develop mistaken beliefs and private logic. Hence, Adlerian play therapists must be aware of each child's subjective interpretation of various issues. When play therapists gather information from parents or teachers, they also need to remind themselves that parents and teachers may have different views of the relationships and situations.

Striving for Superiority

Adlerians believe that children are born inferior and not yet having a place of belonging and significance in their social environment; thus, they are motivated to move from feelings of inferior to superiority in which they feel competent and significant (Ansbacher & Ansbacher, 1956; Carlson et al., 2006). A sense of inferior can result in discouragement. Adlerian play therapists believe that children who feel discouraged may feel overwhelmed and worthless, and thereby may experience maladjustment because of their mistaken beliefs about self, others, and the world (Kottman & Meany-Walen, 2016).

Encouragement is a distinguish feature of Adlerian play therapy and is a significant intervention strategy throughout the play therapy process (Kottman, 2003). Encouragement is essential for children to learn and feel significant in their social environment. Encouragement also fosters a sense of significance and responsibility for children (Kottman). Adlerian play therapists focus on children's assets, effort, and improvement of children, parents, and teachers to enhance everyone's self-efficacy and encouraged feelings. Therefore, play therapists encourage children, parents, and teachers by providing unconditional acceptance, showing faiths in their abilities, recognizing their efforts, focusing on their strengths and assets, focusing on the positive, modeling the courage to be imperfect, helping them learn from mistakes, and developing positive ways to gain a sense of belonging (Kottman).

ADLERIAN PLAY THERAPY PROCESS

Adlerian play therapists work with the children and primary caregivers through four phases: (a) building an egalitarian relationship, (b) exploring the child's lifestyle, (c) helping the child gain insight, and (d) reorienting and reeducating the child (Kottman & Meany-Walen, 2016). In the first stage, Adlerian play therapists establish an egalitarian relationship with the children through tracking children's play behavior, reflection of feelings and content, questioning strategies, encouragement, active interaction with the children, cleaning playroom collaboratively, and limit settings (Kottman & Meany-Walen).

During the phase of exploring the child's lifestyle, play therapists not only observe children's play behavior and actively interact with children, but also use other strategies, such as questioning techniques and art assessments to gather information about children's goals of behavior, the Crucial Cs, personality priorities, the family constellation, family atmosphere, early recollections, assets, and private logic (Kottman & Meany-Walen, 2016). Play therapists conceptualize children based on the information obtained from the play sessions and parent consultations and further develop treatment plans, including goals and strategies for children and parents (Kottman & Meany-Walen).

In the third stage of Adlerian play therapy, play therapists' goal is to help the children better understand the goals of their behavior, their convictions about self, others, and the world, and the behavior they uses to get a sense of significance and belonging. Play therapists make interpretations of the children's play

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in the form of hypothesis about the goals of their behavior and lifestyles, and use role playing, metaphor, art techniques, confrontation, immediacy, and humor to help the children reexamine their thoughts, feelings, perceptions, attitudes, and behavior (Kottman & Meany-Walen, 2016). When children gain insight into their lifestyles and clarify about the purposes of their behavior, they may decide which of these behaviors or attitudes they want to continue or they want to make some changes in their life (Kottman & Meany-Walen).

In the reorientation/reeducation phase, play therapists help children learn and practice new ways of viewing self, others, and the world, behaving in different situations, and connecting to others. Play therapists use brainstorming and problem-solving strategies to help children learn new constructive manners and interactional patterns while helping parents enhance their parenting skills (Kottman & Meany-Walen, 2016). Importantly, Kottman and Meany-Walen noted that these phases are not discrete. It is essential that play therapists continue to build relationships with children throughout the process. Play therapists also can flexibly combine the techniques to help the children gain insights into their private logic or mistaken beliefs during the investigation phase or choose to teach some new skills during the insight phase. In order to have effective outcomes, it is crucial to go through the four phases.

ROLE OF ADLERIAN PLAY THERAPIST

In Adlerian play therapy, counselors conceptualize children and their social environment from an Adlerian perspective (Kottman, 2003). Traditionally, Adlerian counselors are more active and directive to facilitate client's insight and encourage client's reorientation and growth. Adlerian play therapists generally follow the four phases of Adlerian therapy; however, the role of the therapist is rather fluid throughout the course of play therapy (Kottman, 2003).

Kottman and Meany-Walen (2016) indicated that in the first phase, Adlerian play therapists use a relatively non-directive approach to allow children to explore the playroom freely. In the second phase, play therapists tend to be more active and directive to gather children's and parents' lifestyle information, including attitude, perceptions, thoughts, feelings, and interpersonal relationships (Kottman & Meany-Walen). During the third phase, play therapists play a partner role to communicate essential information, including children's lifestyle, goals of misbehavior, and mistaken beliefs to children and parents (Kottman & Meany-Walen). Play therapists may challenge children's mistaken beliefs about self, others, and the world, support their decision making to changes and crucial Cs, and encourage increased social interest. In the final phase, play therapists actively educate and encourage children and their parents and possibly teachers to make necessary changes in attitudes, behaviors, and beliefs with the goal of reorienting the insight gained in the therapy. Play therapists provide opportunities to allow children and parents to practice various skills, such as communication skills, social skills, and parenting skills to enhance interactions and cope with situations (Kottman & Meany-Walen).

CONSULTING PRIMARY CAREGIVERS AND TEACHERS

Watts (2006) stated that effective counselors needed to be capable of providing consultation and educational services. Kottman (2003) indicated that consulting with children's primary caregivers and teachers is a critical component in Adlerian play therapy because these adults play significant roles in children's

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

life and bring important impact on children's lifestyle. In addition, primary caregivers and teachers can provide valuable information about children's developmental history, learning style, or interactional patterns. Importantly, they can provide support and encouragement for children's change throughout the therapy process. As children learn new ways to view themselves, others, and the world and develop new skills to practice socially appropriate behavior, primary caregivers and teachers can help children apply their new learning outside the playroom (Kottman).

Usually, primary caregivers and teachers also need play therapists' education to help them move in positive ways to interact with children (Kottman, 2003). Hence, having primary caregivers and teachers involvement is an imperative component of Adlerian play therapy. Alderian play therapists use basic counseling skills and teaching strategies to engage primary caregivers and teachers and tailor the consultations to meet individual needs of families and teachers (Kottman).

Caregiver Consultation

Caregiver consultations follow the same phases as Adlerian play therapy with a focus on investigating lifestyles of primary caregivers and children. The goals for consultations depend on the phase of play therapy (Kottman, 2003). During the first phase, play therapists work to build egalitarian relationships with parents. In the parent consultation, play therapists aim to explore parents' views about themselves as parents, their parenting styles, marital issues, and personal issues that may inhibit their ability to interact in a healthy manner with children. In the second phase, play therapists discuss the treatment plans with parents and outline strategies for working with parents based on their understanding of their children's needs (Kottman). In the third phase, play therapists simultaneously work with parents on helping them gain an understanding of lifestyles of parents and children with a goal of helping parents change their views and attitudes toward themselves and children (Kottman). In the reorientation/ reeducation phase, play therapists facilitate various strategies, such as modeling, brainstorming, problem solving, and teaching to help parents practice new strategies in their interactions with children (Kottman). Additionally, it is recommended that play therapists conduct a parenting training based on Adlerian principals, such as *Systematic Training for Effective Parenting (STEP)* program (Dinkmeyer & McKay, 1989) and *Positive Discipline* (Nelsen, 2006). Play therapists can also use a filial therapy model (Guerney, 1997) to train parents as therapeutic agents to enhance their relationships with children.

Teacher Consultation

Dinkmeyer (1987) indicated that during the therapeutic process, counselors needed to focus on their relationships with teachers as well. Kottman (2003) recommended that play therapists build relationships with teachers with a professional and collaborative manner. In order to get a holistic view of children's lifestyle, it is important for play therapists to gather information about children's interpersonal relationships at schools and children's view of self, others, and schools (Kottman, 2003). It is also helpful to investigate teachers' lifestyles, teaching styles, and their views toward children. Play therapists are encouraged to observe children at schools if permitted because play therapists can observe children's interactions with others and feel the atmosphere in the classrooms (Kottman, 2003). Some goals for teacher consultation are to share play therapists' information and insights about children's interactions with teachers and to help teachers gain a better understanding of the children's goals of behaviors and attitudes (Kottman, 2003). During the teacher consultation, play therapists provide some important information on Adlerian

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

principals, including crucial Cs, goals of misbehavior, logical consequences, encouragement, and techniques that are applicable in the classrooms (Dinkmeyer, Dinkmeyer, & Sperry, 1987; Kottman, 2003). Similarly, several resources are available for teachers to incorporate Adlerian principals in the classrooms, including *Positive Discipline in the Classroom: Developing Mutual Respect, Cooperation, and Responsibility in Your Classroom* (Nelson, Lott, & Glenn, 2013), and *Systematic Training for Effective Teaching (STET)* (Dinkmeyer, McKay, & Dinkmeyer, 1980). Kinder Training (White, Flynt, & Draper, 1997) is another teacher training model that can be helpful for teachers to apply basic play therapy skills and Adlerian constructs in the classrooms.

APPLICATION OF THE MSJCC IN ADLERIAN PLAY THERAPY PROCESS

The Adlerian play therapy process is consistent with the MSJCC's emphasis of seeing clients' issues from a culturally contextual framework and its recommendations for working with clients from individual and systems levels. The MSJCC expect counselors to understand the sociocultural system that influences clients' well-being and to address corresponding issues appropriately through counseling and advocacy interventions. Specifically, counselors are suggested to provide interventions and strategies at the interpersonal, intrapersonal, institutional, community, policy, and global levels (Ratts, Singh, Butler, Nassar-McMillan, & McCullough, 2015). Adlerians believe that people must be understood within their cultural or social experiences. Adler postulated that an individual's culture, climate in which an individual live, and perception of his or her community and society at large play a role in an individual's creation of lifestyle and beliefs of self, others, and the world (Oberst & Stewart, 2003).

The MSJCC note privileged and marginalized counselors must develop self-awareness by exploring their attitudes and beliefs, develop knowledge, skills, and action relative to their self-awareness and worldview. Kottman and Meany-Walen (2016) stressed the importance of examining one's beliefs and held biases about other cultures when working with diverse children and their families. For example, Adlerian play therapists are recommended to ask self "What are your beliefs about the work ethic or intelligence of low-income families?", "What are your beliefs about parenting and discipline styles of different ethnic families?", "What is your internal reaction when you learn that a child is being raised by grandparents, same-sex parents, or single parent?", and "What resources do you provide to families who speak different language than yours?" (Kottman & Meany-Walen, p.32).

Multicultural and social justice competent counselors take initiative to explore clients' relationships with families, friends, and their communities so that counselors are able to identify clients' obstacles to progress and help them develop their support systems (Ratts et al., 2015). Adlerian play therapists observe children's interactions with families inside and outside of the therapy, attend to children's play behavior in the playroom to explore children's subjective view of self, others, and the world, and conduct classroom observations to identify children's classroom behavior and relationships with peers and teachers.

Counselors are also recommended to facilitate open and genuine conversations with clients to discuss their own cultures and identities, gather information about their clients' experiences with microaggression, discrimination, and oppression, and explore how privileged and marginalized identities might enhance or impede the counseling relationship (Ratts et al., 2015). Counselors also want to explore clients' issues through societal lenses by considering the impact of cultural norms and values on clients' well-being. In the Adlerian play therapy process, it is important that counselors bring this discussion into parent and teacher consultations by exploring how cultural backgrounds and experiences affect their relationships

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

with child clients and counselors. Counselors also focus on discussing if children and their families think that society holds negative stereotypes or attitudes about their membership in a privileged or marginalized group. Counselors may utilize toys, art materials, games, and other play media to establish a trusting and working relationship so that children can explore and express their feelings and thoughts about their world. By using play media, children are able to gain awareness of their experiences and interaction with families and communities resulting in their interpersonal relationships and lifestyle.

In addition to focusing on individual changes, multicultural and social justice competent counselors also make efforts into community and institutional change (Ratts et al., 2015). Adlerian play therapists advocate for children by collaborating with children's families and school personnel to improve home and school environments that might inhibit children's well-being and growth. For example, Adlerian play therapists might advocate for children's emotional and behavioral needs by attending a school meeting to discuss inequity issues that are affecting children's learning environment. Counselors also provide teacher consultations and professional development trainings to help teachers gain a better understanding of children's needs and learn new ways of interacting with children.

CASE CONCEPTUALIZATION AND TREATMENT PROCESS

Lifestyle Conceptualization

From an Adlerian perspective, counselors can develop a picture of how children's lifestyles are reflected in their patterns of misbehaviors, thoughts, attitudes and relationships by considering the crucial Cs, the goals of misbehavior, and personality priorities (Kottman, 2003). Kottman indicated that in order to survive and flourish, children must master each of the crucial Cs, which are courage, connect, capable, and count. Based on my observation of Alex's play behavior and his report, Alex seemed to struggle with connect and count. Children who do not have the skills necessary to connect will feel isolated and insecure, where those who do not feel as though they count will feel insignificant (Kottman). In the playroom, Alex showed a play theme of relationship building as evidenced by his frequently saying "look, I did it" or "look what I got" and bringing all the toys in front of me and inviting me to join his play, indicating his desire to get attention from me. Alex also shared the need to protect his sister from bad people and he would play out wishing to have his own bedroom in the family dollhouse, indicating Alex's challenge of feeling counted in the family.

Given that Alex had been exposed to various ACEs, he appeared to seek connections with his family and me in order to feel that he has a sense of belonging in the playroom and with his family. Alex also seemed to possess low self-esteem and caution to answer the questions about his family when I explored his family atmosphere and relationships. He would look down or change play behavior when I reflected his emotions and thoughts about the family issues. Additionally, Alex seemed to feel no power or control in his life and to believe that he only counts if he protects his sister and takes care of his family.

In terms of personality priority, Dinkmeyer and Sperry (2000) described it is a pattern of behaviors and reactions that are based on a person's convictions about how he or she acquires belonging, significance, and a sense of mastery. Alex seemed to have developed control as his personality priority as evidenced by his attempt to control my reflections and behavior in the playroom. He was eager to get more attention from his grandparents and uncles through goals of misbehavior.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Alex's family atmosphere appears to be chaotic-conflictual, hopelessness, and inharmonious. Parents in this type of family atmosphere often discipline their children in an inconsistent manner and structure, depending on their mood and status of their marital conflict (Kottman & Meany-Walen, 2016). Having witnessed verbal or physical abuse between their parents, children from chaotic-conflictual families often develop an idea that having power and control is the only way interacting with others (Kottman & Meany-Walen). Therefore, Alex seemed to develop mistaken beliefs that by acting angry, he can control others, connect with them, and receive more attention. He also seemed to believe the need to protect his family, which is a typical characteristic of a first-born child in the family constellation. Mr. Garcia further shared that he told Alex to be brave and to protect his family because in Latino culture men are supposed to be strong and protect their families. Consequently, Alex's lifestyle is a method of expressing anger, frustration, and power in order to obtain a sense of significance, belonging, and to engage with others.

Due to the childhood trauma of abuse, domestic violence, and mother's absence, Alex had experienced fear, worry, insecurity, and sadness in his life. Impacted by his father, Alex seemed to tend to express his anger with physical aggressions toward his family and he often had bad dreams about monster's coming at night. Alex seemed to strive for a sense of belonging in the family as evidenced by his report that he did not have a room in grandparent's house and grandparent's report that Alex had moved from one house to another house with his father.

Treatment Goals and Therapy Process

Over the course of Adlerian play therapy, I conducted 22 weekly individual play therapy sessions with Alex and five caregiver consultation sessions to support Mr. and Mrs. Garcia. My overall treatment goals included (a) increasing Alex's positive goals of behavior and self-regulation skills, (b) helping Alex substitute positive convictions from mistaken beliefs, (c) enhancing Alex's grandparent's compassion toward Alex's behavior and needs by teaching Alex's grandparents basic play therapy skills and language, and (d) improving caregiver-child attachment. The following illustrates how I worked with Alex and his grandparents through Adlerian play therapy four phases using the MSJCC framework.

Prior to the first play session, I conducted a caregiver consultation session with Mr. and Mrs. Garcia and one of Alex's uncle to gather more information about Alex's background, presenting issues, and his family's goals of counseling. I was aware that Mr. and Mrs. Garcia's preferred language is Spanish, but they tried their best to communicate with me in English given that I am not a Spanish-speaking counselor. Alex's uncle would sometimes translate his parents' disclosure in the session. I observed Mr. and Mrs. Garcia's uncertainty of the counseling process and their tendency to see me as an expert. Therefore, I made efforts to foster an egalitarian relationship with them by sharing my professional background, clinical experiences, explaining my role in the play therapy process, and my expectations for their involvement in the treatment. I also shared how my cultural background may be very different from their values and beliefs and thus, I appreciate their sharing to help me gain a better understanding of Alex's and their needs. They all seemed appreciative of my genuineness and care about Alex's situation.

In the first play session, I observed Alex's interactions with his sister and grandparents in the waiting area. Alex looked cautious and nervous about going to the playroom when I met him in the waiting area. Being aware of his young age and his history of ACEs, I began the play therapy process by building a collaborative and egalitarian relationship with Alex. I communicated respect, unconditional acceptance, and trust in Alex's abilities in the playroom by means of tracking his play, reflecting feeling and content, consistent limits setting, and encouragement. After the first session, Alex seemed happier and less anxious

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

walking to the playroom. During the first several sessions, Alex looked hesitant to initiate the play and he did more exploratory play by looking around the room and playing briefly with different categories of toys. Gradually, Alex appeared to play more freely and had more interactions with me as evidenced by his increased verbal communication and invitation to his play after four play therapy sessions.

In the phase of exploring the child's life, I made efforts to gain a deeper understanding of Alex's lifestyle, personality priority, goals of behavior, and crucial Cs through his verbalization and play behavior in the playroom as well as consultation with Mr. and Mrs. Garcia. During one self-directed puppet show, Alex created a scene where an alligator puppet was fighting for a rabbit puppet. I observed that Alex was not completely comfortable sharing his feelings yet; therefore, I used metaphoric techniques to reflect my observation of the puppet's goals and emotions. Alex then reported that the rabbit is his sister and he had to protect his sister because he is always her brother and he had to protect grandparents, too. After the session of the puppet show, Alex's play themes of dominance, control, and need to take care of others became apparent. Alex had shown control as his personality priority as evidenced by his attempt to control my reflections and behavior. For example, he frequently told me what to do and say. He was also eager to show me his power through some aggressive play behavior and would feel upset or frustrated when things did not go the way he wanted to in the playroom. I reflected his need to correct my responses, feel powerful by maintaining a sense of control, and seek attention from me through metacommunications.

Based on my observation of Alex's play behavior and reports, he seemed to feel challenged with the crucial C's of connect and count causing Alex feelings of isolation, insecurity, and insignificance. Alex had developed a mistaken belief that he only counts if he shows others his power to protect his sister and taking care of his grandparents. Alex also constantly sought attention from his family and me in order to feel that he belongs in the playroom and to his family. In addition, Alex's exposure to adverse events caused his perception of the family atmosphere as a skewed dynamic of chaos and powerless. Consequently, Alex had also developed a conviction that only by acting out angrily and aggressively, he could build relationships with others and receive attentions from others. I concluded that Alex's lifestyle is a method of expressing anger and frustration in order to obtain power, control, and attachment. Due to the trauma of physical and emotional abuse and abandonment, Alex had experienced fear, worry, insecurity, and sadness in his life. Lacking a secure attachment and role model, Alex tended to express his emotions with aggressions toward his family as well.

In the insight phase, in order to help Alex gain awareness of his lifestyle and mistaken beliefs, I elected to use puppets, mutual storytelling, and other creative arts to communicate the value of building relationships, empathize Alex's feelings and beliefs about connecting, and teach him new ways of connecting with others. I conveyed my tentative hypothesis about his mistaken beliefs about himself, others, and the world. I also facilitated encouragement to help him know that he is significant and counts. Moreover, I reflected the purpose of his attention seeking behavior to facilitate his insight into his goal of misbehavior and to help him understand that he does not need to be the center of attention to gain a sense of belonging. Furthermore, I continuously provided a safe environment where he can be a child and enjoy playing and having fun. I aimed to convey the idea that he can feel safe without showing aggression and even when he cannot control situations.

Alex's play behavior in the final phase was considerably different from his play at the beginning of our counseling relationship. His play became more spontaneous and relaxed with a sense of pleasure. He no longer exhibited a need to control my behavior or responses and did not seek attention from me to approve his abilities or significance. Instead, he connected with me in positive ways and showed play

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

themes of mastery and resiliency. For example, during one session, he created a challenging situation where toy soldiers were in a battle. He was able to use different strategies to end the war and he was proud that no one was injured. In the earlier stage of therapy, I would sense his frustration and disturbance whenever he was in a chaotic and deconstructive play. This change indicated that Alex made improvements in increasing his self-regulation skills, healing his traumatic experiences, and overcoming his faulty assumptions of his perceived world. Mr. and Mrs. Garcia also reported observing significant improvements in Alex's aggressive behavior at home. He interacted and communicated better with his family.

Throughout the course of play therapy, I regularly conducted caregiver consultations. I began with assessing Mr. and Mrs. Garcia's lifestyle and supported their parenting roles in Alex's transition. I helped them understand Alex's lifestyle, mistaken beliefs, and goals of misbehavior. I discussed Alex's need for gaining a sense of control and belonging. I showed my respect toward their cultural value of patriarchal structure. However, I shared with them that Alex's childhood trauma influenced his sense of value and potentially affected Alex's perception of himself, others, and the world. They seemed to get a better understanding of Alex's underlying purpose of behavior. I collaborated with them to come up some ideas to help Alex feel safe, decrease his fear of abandonment, and seek healthy ways to seek power. Additionally, I taught them some basic play therapy skills, such as reflection of feelings, encouragement, limits setting, and choice giving to help them develop better relationships with Alex, feel capable of parenting, and help Alex feel significant and count. Mr. and Mrs. Garcia were very cooperative and willing to adapt new ways to interact with Alex. Alex's uncles were also supportive and understanding of Alex's situation. His uncles would take turns to attend the caregiver consultations with Mr. and Mrs. Garcia as well. Knowing that Alex missed a father figure in his life, the two uncles both wanted to show him a good role model.

In addition to conducting caregiver consultation, with caregivers' permission, I contacted Alex's schoolteacher over the phone to address the teacher's concerns. Although Alex's behavioral issues mostly were presented at home, I aimed to advocate for Alex's needs systematically. Thus, I encouraged the teacher to be aware of Alex's withdrawing behavior in the classroom and showed the teacher ways, such as active listening, to reflect Alex's behavioral and emotional needs. I also helped the teacher find creative ways to help Alex feel significant in the classroom, such as assigning him a special task to help peers so that he would increase his self-esteem and feel counted. The teacher shared her appreciation for me reaching out and helping her feel more prepared to address Alex's needs if necessary.

CONCLUSION

Research has indicated that adverse childhood experiences (ACEs) can cause negative outcomes on physical and mental health issues, including asthma, obesity, attention-deficit hyperactivity disorder, depression, and substance use over the lifespan (Caballero et al., 2017; Loria & Caughy, 2017). Hispanic immigrant children are the fastest-growing child population in the U.S. (Passel & Cohn, 2008). Hispanic children, including US-born and foreign-born children have shown a higher prevalence of ACEs exposures in the U.S. (Loria & Caughy, 2018). Children who have experienced ACEs are more likely to have emotional and behavioral challenges (Sacks & Murphey, 2018). Consequently, they may benefit from counseling services.

Adlerian play therapy developed by Terry Kottman (1995) is a play therapy model based on the theoretical constructs of individual psychology (Adler, 1964). It is a developmentally appropriate approach where counselors use play as a modality to work with children exhibiting a wide spectrum of social-emotional and behavioral issues (Kottman & Meany-Walen, 2016). Adlerian play therapy is also a culturally responsive intervention. It has shown its effectiveness to work with children from diverse cultures and ethnic groups (Kottman & Meany-Walen). Moreover, given Adlerian's focus on clients' subjective perception of self, others, and the world, counselors are able to understand how clients' views lead to their responses to ethnic values and perceptions.

Multicultural and social justice competencies have been considered as core values to work effectively with clients from diverse backgrounds. The Multicultural and Social Justice Counseling Competencies (MSJCC) developed by Ratts et al. (2015) has served as a conceptual framework for competent multicultural counseling practice. The central concern of MSJCC is that counselors and clients both bring to the counseling relationship a constellation of identities, social locations, cultural values, beliefs, and biases. It is important that counselors address how the interactions of power, privilege, and oppression influence the client in all aspects of the counseling profession.

The process of Adlerian play therapy is congruent with MSJCC framework. It addresses the complex of identities that counselors and clients bring to the therapeutic relationship. The ultimate goal in Adlerian play therapy is for counselors to use the therapeutic relationship with children and their families to help the family enhance their understanding of interpersonal and intrapersonal dynamics and to allow the family to use these insights to make necessary changes in their thoughts, feelings, behavior, and attitude (Kottman & Meany-Walen, 2016). To accomplish this goal, it is crucial that Adlerian play therapists develop self-awareness, knowledge, skills, and action related to their self-awareness and worldview. Adlerian play therapists are recommended to examine their beliefs and biases or prejudice about other cultures when working with diverse children and their families. Adlerian play therapists conceptualize children's presenting issues from a cultural and social context and work with them from individual and systems levels (Oberst & Stewart, 2003). Adlerian play therapists discuss children's experiences with power, privilege, and oppression during parent and teacher consultations by exploring how cultural backgrounds and experiences affect their relationships with child clients and counselors. During play therapy sessions, counselors utilize toys, art materials, games, and other play media to establish a trusting and working relationship with children and allow children to explore and express their feelings and thoughts about their world.

To help children develop their support system, Adlerian play therapists take initiative to observe children's interactions with families both inside and outside of the therapy, attend to children's play behavior in the playroom to explore children's subjective view of self, others, and the world, and conduct classroom observations to better understand children's school behavior and interpersonal relationships. Notably, Adlerian play therapists advocate for children's mental health by collaborating with children's families and school personnel to improve the social environment that might impede children's well-being and growth. The presented case example of Alex and his families illustrates how I, a marginalized counselor, worked with a marginalized child who has experienced ACEs. Utilizing MSJCC as a framework, I was aware of my power and privilege that may bring in our counseling relationship. Thus, I was mindful of my approach to involving Alex and his families in the therapy by understanding their needs in a cultural context. I was able to address barriers and create opportunities for advocacy when helping Alex heal his wound.

Chapter 43
Culturally Responsive Practices:
African American Youth and Mental Health

Tricia Crosby-Cooper
National University, USA

Natasha Ferrell
National University, USA

ABSTRACT

Achieving positive mental health is a worthy desire as positive mental health leads to better success in all aspects of life. Unfortunately, for some youth, achieving positive mental health is a struggle. African Americans demonstrate mental health difficulties approximately 20% more than their White counterparts. To address mental health concerns, schools have increasingly implemented multi-tiered supports to better identify and support students. Unfortunately, interventions implemented in schools have largely ignored the impact that race, culture, and behavioral expectations have on the mental health of African American youth. African American youth exhibit symptoms and behaviors of mental health similar to youth of other cultures and races, yet they experience lower levels of mental health services. To help African American youth experiencing mental health difficulties, stakeholders must implement culturally responsive, evidence-based interventions.

INTRODUCTION

What is mental health? Mental health is the bases for interaction between the individual and their community, family and friends. It is directly related to an individual's ability to be resilient and how she or he views their worth (Parekh, 2018). Mental health can affect how an individual acts, thinks, and feels, in addition to one's ability to cope with life stressors (mentalhealth.gov) which include emotional, behavioral, and cognitive functioning. Mental health difficulties can affect individuals in all life stages, from all races, cultures, ethnicities, SES, and religious affiliations. Mental health difficulties can also manifest as the result of trauma, life stressors, genetics, and a family history (mentalhealth.gov). Often the behavioral manifestations of mental health do not look the same across individuals, even if individuals

have the same diagnosis (NAMI.org). The National Institute of Mental Health (NIMH) estimates that millions of people are affected by mental health difficulties each year.

In 2004, the World Health Organization (WHO) defined mental health as an individual's well-being where the individual understands their own abilities, is able to cope with stressors in life, is able to be productive, and contributes to their community (WHO, 2004 as cited in Galderisi, Heinz, Kastrup, Beehold, & Satorius, 2015). This definition resulted in progress towards a more inclusive definition of mental health. For example, Bhugra, Till, and Sartorius (2013) state that mental health is an integral part of one's overall health and does not exist in isolation. They further note that the individual is able to maintain positive relationships and engage in social and cultural roles according to Bhugra et al., (2013).

The state of mental health implies that the individual has the ability to form and maintain affectionate relationships with others, to perform in the social roles usually played in their culture and to manage change, recognize, acknowledge and communicate positive actions and thoughts as well as to manage emotions such as sadness. Mental health gives an individual the feeling of worth, control and understanding of internal and external functioning. (p. 3).

Despite the definitional progression of mental health, Galderisi et. al., (2015) recognize that there may continue to be misunderstandings regarding "positive feelings and positive functioning as key factors for mental health" (p. 231). They note that individuals with positive mental health with a fully lived life can experience a variety of emotions including sadness, unhappiness, and anger. Moreover, these authors note that a focus on positive emotions as a determining factor for mental health "risks excluding most adolescents, many of whom are somewhat shy, those who fight against perceived injustice and inequalities or are discouraged from doing so after years of useless efforts, as well as migrants and minorities experiencing rejection and discrimination" (p. 231). It is this definition of mental health, that notes varied emotions as a part of life's experiences coupled with the inclusion of cultural factors that will be used for this chapter.

According to Bailey (nd), there are approximately 40 million people who identify as African American. This chapter will address mental health in relation to African American youth. Topics in this chapter will include prevalence, barriers, stigmas/perceptions, cultural expectations, culturally responsive evidence-based interventions, and school-based mental health practices. The terms adolescent and youth will be used interchangeably as both are being used to describe individuals ranging in age from 12 to 17.

Mental Health and African Americans

Historically, African American individuals have experienced significant challenges accessing mental health supports and services (mhanational.org.nd) that date back many years where the African American community was denied or treated differently by the mental health community. In order to address the lack of mental health services utilized by African Americans, one must look at the historical abuses experienced by African Americans in the mental health system. Briggs, et al., (2014) note that historically, the use of proper treatment for African American's experiencing mental health difficulties "was virtually nonexistent" (p.2). African American's suffering from mental health difficulties suffered abuses such as whippings, as a justified cure, and placement in poor houses or jail houses. Additionally, the authors note that debilitating labels, such as "negritude, a condition that was analogous to leprosy" (p. 2) continued to perpetuate the inhumane treatment African American's with mental health difficul-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ties suffered. African American's experiencing mental health difficulties continue to suffer from the historical perceptions of mental health in the African American community. Because of the historical abuses, there continues to be a level of skepticism and cultural mistrust "toward institutions, systems, and individuals that have exhibited harm in the past and the potential for future harm" (Breland-Noble, 2004, p. 536), thus affecting participation with mental health supports and services.. These perceptions also affect African American youth. According to Breland-Noble (2004),

...black adolescents and their families do not use a systematic method for identifying the disorder; that black adolescents and their parents consult different entities for help, and that blacks perceive mental health clinical care as a majority culture phenomenon for people with severe psychopathology, thereby making these services irrelevant for them (p. 537)

While mental health and depression can affect African American families from across the socioeconomic status (SES) spectrum, the literature regarding mental health and African American youth has focused on youth from lower SES backgrounds with limited mental health resources (Breland-Noble, 2013) thus leaving a void in research examining mental health difficulties with all youth who identify as African American.

Adolescents

For many, adolescent years can be a difficult time. There are issues related to educational transitions, phenotypical changes, and instability regarding self-esteem. Adolescents dealing with mental health difficulties can experience this developmental period with a heightened sense of negativity. Mental health difficulties can affect an adolescent's interpersonal relationships, daily behaviors, and productivity at work, home, and school. During this time, there is an increased desire for autonomy regarding their behavior, cognition, and emotions in relation to their social environment (Compas, Jaser, & Benson, 2009). Research has shown that African American youth experience mental health difficulties at rates higher than their White counterparts, and that adolescents experiencing mental health difficulties have a greater chance of experiencing severe mental health difficulties later in life (Hurd, Stoddard, and Zimmerman, 2013). During adolescence there are many behavioral, psychological, and emotional changes that take place, which can make it difficult to know which behaviors are normal typical developmental changes, and which behaviors are symptoms of mental health difficulties. While it is normal for young people to experience feelings of anxiety, fear, sadness, loss, and depression, when these feelings persist for long periods of time, there can be cause for concern. For most adolescents, "…mental health distress is episodic, not permanent…" (Youth.gov, nd). There are warning signs for individuals experiencing mental health difficulties, therefore, it is important to note these changes in behavior as they can last for weeks or months. Often, these behavior changes interfere with the adolescent's daily interactions with family, friends, and/or their school performance (NAMI, nd). Some symptoms are observable such as changes in sleeping patterns (sleeping more or sleeping less), changes in eating patterns (eating more or eating less), experiencing mood swings (including anger, sadness, crying), weight fluctuations, low energy level, changes in school performance and poor grades, and a lack of desire to spend time with friends. At the same time, there are internal signs that can include thoughts of wanting to harm her/himself, and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

thoughts of suicide (Youth.gov, nd; NAMI, nd). Some adolescents struggling with mental health concerns experience psychosomatic symptoms such as body pain and headaches. When adolescents express or display these behaviors, it is important to obtain mental health supports.

Prevalence

The National Institute of Mental Health (NIMH) estimates that mental health difficulties affect millions of people each year. Unfortunately, only approximately half of those affected by mental health difficulties receive treatment (nimh.gov). Approximately one out of five youth experience mental health concerns, yet a majority of youth affected by mental health difficulties do not receive the required supports and services (Kataoka, Zhang, & Wells, 2002). Mental health does not manifest the same for everyone. There are variations in severity and topography. The National Alliance of Mental Illness (NAMI, nd), notes that African Americans experience higher levels of disadvantages regarding access to mental health supports and services. The NAMI also notes that African Americans are more likely to receive incorrect mental health diagnoses.

While approximately 20% of youth suffer from mental health difficulties, the survey by the Substance Abuse and Mental Health Services Administration (SAMSHA, 2018) examined the number of youth under the age of 18 who received mental health supports. This survey disaggregated the data to demonstrate the prevalence of service at each age level. According to the survey 13.8% of 12-13-year old's, 15.1% of 14-15-year old's, and 15.6% of 16-17-year old's received mental health supports. This resulted in an overall total of 28.4% of 12-17-year old's experiencing mental health difficulties. Of the youth who received supports and services for mental health concerns, 58.9% percent reported feeling depressed, 33.5% had thoughts of killing oneself or had attempted to kill oneself, 33.2% reported feelings of anxiety, 23.5% noted problems at home or with family, and 19.7% reported problems at school. In general, the SAMSHA (2018) data showed that the mental health concerns noted most often by adolescents included depression, anxiety, and suicidal ideation. As such, this chapter will focus on these three areas- depression, anxiety, and suicidal ideation.

Depression

Depression is defined as a common mood disorder that is marked by difficulty concentrating, changes in sleeping and eating patterns, feelings of hopelessness and sadness, chronic pain, and a general loss of feeling joy or happiness. Individuals diagnosed with depression must exhibit these symptoms for a minimum of 2-weeks (American Psychiatric Association, nd). Depression is "…one of the most prevalent and incapacitating mental disorders…" (Kalibatseva & Leong, 2014, p. 433) and is the leading cause for youth to seek out and receive mental health services. The SAMSHA 2018 report notes that 59.7% of youth age 12 through 17 received mental health services due to depression. Historically, research regarding mental health, specifically for depression stemmed from a medical model, thus negating the expressed symptomatology of people from racially and ethnically diverse backgrounds (Ofonedu, Percy, Harris-Britt, & Belcher, 2013). The medical model consists of a systematic process of identifying internal struggles based on external manifestations in which a diagnosis is given without the inclusion of ecological variables. These external behaviors are tied to societal norms of how one would express

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

emotion or thought. The behavioral demonstration of African American youth suffering from depression can display behavior of sadness and low energy but also anger and irritability (Ofonedu et. al., 2013). It is these demonstrated behaviors of African American youth that can, and have, led to the misdiagnosis and underdiagnosis of mental health concerns.

Anxiety

Anxiety is the second leading reason for youth to receive mental health services. While feelings of anxiety are normal, according to the Mayo Clinic, individuals with anxiety disorders can experience frequent fears and worries regarding everyday situations. Common characteristics of anxiety include, rapid breathing, feelings of nervousness, trouble sleeping, feeling tired, trembling or shaking, and an inability to control the anxiety provoking thought (Mayo Clinic, nd). The SAMSHA (2018) report states that 33.2% of youth age 12 through 17 received supports for anxiety.

Suicidal Ideation

Suicidal ideation or attempts is the third leading cause for youth to receive supports and services for mental health difficulties. The SAMSHA (2018) report indicates that overall 32 percent of adolescents aged 12 to 17 had thoughts of or attempted to kill oneself. It is important to note that the percentage of youth receiving mental health services for suicide attempts or ideation increased 3.4 percent from 2016 to 2017. African American youth report feeling sad and helpless at rates higher than their white counterparts, but African American are less likely to die from suicide, though they have higher attempt rates (Bailey, nd).

PROTECTIVE AND RISK FACTORS

There are various factors that can contribute to adolescents experiencing mental health difficulties. These factors are called risk and protective factors. Risk and protective factors can emanate from the same entity, such as family, friends, and community.

Protective Factors

O'Connell, Boat, and Warner (2009) note the developmental progression of an individual is intertwined with various life interactions. Life interactions can help or hinder the mental health development of adolescents. Protective factors are typically associated with desirable behaviors and can include a high self-esteem, positive academic development, good problem-solving skills, and the engagement of social interactions through sports, peers, and/or religious affiliations (O'Connell et. al., 2009). Facilitators are also considered protective factors. Facilitators are events or individuals who assist in the receipt of information, services, and treatment (Planey et al, 2019). Mental health facilitators for African American youth include people who identify behavior changes and help the youth proactively seek help, provide assistance to the youth by accompanying the youth to an appointment, and having a positive and trusting relationship with the mental health service provider (Planey et al., 2019).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Risk Factors

The ability to identify risk factors can help match the evidence-based intervention and prevention strategies to support the adolescent appropriately. Risk factors are typically associated with negative or problematic behaviors, and can include being shy, having low self-esteem, experiencing symptoms of depression, poor social skills, and an increased need for external validation (O'Connell et. al., 2009). In general, African Americans experience increased risk factors such as poverty and classism which can affect their mental health. African American adolescents increased exposure to life stressors such as poverty, stereotypes, involvement in social service program - like foster care, racism, and violence can contribute to increased rates of risk factors associated with negative behavior and mental health concerns (Breland-Noble, 2004).

BIAS, STIGMAS, AND IDENTIFICATION

Access to mental health for African American youth is also mitigated based on perceptions and stigmas. Perceptions of care givers and friends, access to supports and services, and knowledge of how to obtain supports and services (Planey et. al., 2019; Lindsey, Barksdale, Lambert, Ialongo, & Lindsey, 2010) can impact stigmas associated with help seeking behaviors. African American youth are less likely to receive mental health service due to stigmas and negative perceptions (Lindsey, Chambers, Pohle, Beall, & Lucksted, 2013). Moreover, studies show that African American youth feel that they will be perceived negatively by friends and family if they disclose mental health concerns.

Barriers are obstacles that inhibit someone from accessing information obtaining supports, and receiving treatment (Planey et al., 2019). These barriers also result in African American youth suffering from mental health needs at rates higher than their White counterparts (Breland-Noble, 2004). Barriers for African American youth include access to mental health service providers, transportation, refusal to obtain help, prior negative mental health service experiences, a perception that mental health difficulties do not exist, lack of trust for the mental health service provider, and cultural aspects of self-reliance (Planey, et al., 2019). Another barrier that impacts African American mental health supports and services center around bias and identification.

Barriers such as negative perceptions, biases, and stigmas result in a decrease in African American youth seeking mental health services (Barksdale, Azur, & Leaf, 2010). "Overall, African American students and males are the most likely to be overrepresented as a result of teacher referral for mental health services" (Stiffler & Dever, 2015, p.32). Some of the issues regarding African American youth and mental health has stemmed from bias regarding assessment and intervention. Previous research has noted that African American youth are often misdiagnosed or underdiagnosed when dealing with mental health concerns (Breland-Noble, 2013). Much of the misdiagnosis and under-diagnosis can be attributed to the fact that depression symptoms and mental health topographies are typically defined by and based on the behavior of mainstream (White) youth (Castro-Olivio, 2017; Cokley et. al., 2014; Ofonedu, Percy, Harris, Britt, & Belcher, 2013).

As stated earlier in the chapter, African American youth depressive behaviors can consist of low energy and sadness, but they can also display behaviors of anger and irritability (Ofonedu et. al., 2013) whuch contributes to African American youth being identified as a behavior concern versus in need of mental health supports. While African American youth demonstrate mental health needs at an increase

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

rate compared to White youth, the behaviors of African American youth are overidentified for behavioral issues and under identified for mental health difficulties. The misdiagnosis and under-diagnosis of African American youth as can lead to increased mental health concerns due to a lack of supports and treatment. The lack of treatment and supports can manifest into an increase in mental health symptoms, behavioral concerns, academic difficulties, and violence which can lead to an "increased risk of juvenile justice" (Lindsey, et al., 2010, p. 367) encounters.

Issues regarding proper diagnosis can affect self-help behaviors. While there is a vast amount of information regarding mental health topics, identification, and access to mental health services, African American youth seek out mental health supports at lower rates than their White counterparts (Barksdale et. al., 2010). Data from the SAMSHA 2018 study showed that African American youth identified as receiving mental health supports was 11.7 percent compared to 16.9 percent for White youth. Approximately 14.7 percent of the adolescents received supports and services from school-based mental health providers (SAMSHA, 2018). At the same time, African American youth received .7 percent of their mental health supports from the juvenile justice system, while .1 percent of White youth received mental health supports from the juvenile justice system (SAMSHA, 2018). A 2019 study by SAMSHA conducting a National Mental Health Services Survey (N-MHSS), examined who was receiving mental health services and the types of facilities providing mental health services. This report states that youth age 17 or younger accounted for 26 percent of outpatient mental health services with 15 percent African American and 40 percent White (SAMSHA, 2019, figure 16 and 17). Additionally, youth under the age of 17 receiving mental health services through community mental health centers equated to 28 percent, with 16 percent African American and 55 percent White. While jail and prisons are not included in the SAMSHA (2019) report, many African American youth receive support for mental health and social-emotional disorders through entrance into the juvenile justice system or though involuntary methods via law enforcement (Breland-Noble, 2004; Cauce et al., 2002).

According to Snowden (2003), "One possible reason for disparities is that practitioners and mental health administrators make unwarranted judgements about people on the basis of race or ethnicity. Their inappropriate expectations lead to inappropriate decisions and actions" (p. 239). Cokley et al., (2014) examined the disproportionate rates of African American male youth being identified as emotionally and behaviorally disturbed at rates higher than their White counterparts noting that the"…pervasive negative stereotyping of blacks can bias teachers toward addressing externalizing symptoms (e.g., delinquent and aggressive behavior) rather than being sensitive to their underlying internalizing causes (e.g., depression and anxiety)" (p. 41). Because of disparities with mental health assessment/intervention, response, and support, African American youth have been systematically denied proper mental health supports due to exclusionary practices such as suspension and special education placement. It is vital that educators and service providers, "…work to understand what underlies the student's behavior rather than using [the students] misconduct to harshly judge students" (Cokley et. al., 2014, p.42).

CULTURAL RESPONSIVENESS

Cultural responsiveness incorporates the clients and mental health providers age, race, gender, sexual identity and language (Cabassa & Baumann, 2013). Though there are several barriers for African American youth to receive mental health supports, research has shown an increase of African American youth seeking out, and participating in, mental health services (Lindsey et. al., 2013). Increasing the mental

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

health participation of African American youth would require an increase in services being provided for families that have historically been under served. This would require the use of school-based mental health screenings and treatments in addition to culturally responsive practices. Evidence based practices have largely ignored the socioeconomic status, race, and culture of the individual (Castro-Olivo, 2017). This is problematic as Castro-Olivo (2017) notes that culture matters in the development of an adolescent.

Responding to the mental health needs of youth from diverse backgrounds has led to the increase of positive academic and behavioral performances (Schellengerg and Grothaus, 2011). To date, there are still issues around trust and stigma in the African American community. This is further exacerbated by the lack of culturally responsive mental health practices. Studies and researchers alike have stated that the lack of mental health service providers who are of color leads to a disconnect between the mental health provider and the individual (Briggs, Banks, and Briggs, 2014; Breland-Noble, 2004).

CULTURALLY RESPONSIVE EVIDENCE-BASED PRACTICES

Cognitive Behavioral Therapy

One type of evidence-based practice used to support adolescents dealing with mental health difficulties is Cognitive behavioral therapy (CBT). As noted earlier in this chapter, there is an increased number of individuals identifying as being culturally diverse. With the majority of school-based mental health service providers being primarily heterosexual, middle-class Caucasian women, this demographic disparity can and has led to issues regarding assessment, diagnosis, and appropriate interventions/services for people of color (Jones, Lee, Zigarelli & Nakagawa, (2017). The implementation of evidence-based therapies focuses, "… on the importance of implementation fidelity and efficacy of contextual aspects to mental health care… (Zigarelli, Mones, Palomino, & Kawamaura, 2016, p. 458). Ensuring that evidence-based interventions are culturally responsive is important.

The use of CBT was originated to help individuals with emotional difficulties such as anxiety and depression (Zigarelli, et. al., 2016,). Cognitive behavioral therapy is action-based psychotherapy that focuses both on the cognitive thoughts and demonstrated behaviors. Cognitive behavioral therapy does not address the origins of the thoughts or behaviors of concern, but rather focuses on changing the thought patterns, which would in turn change the exhibited behaviors (Ford-Martin, 2018). This form of therapy combines the cognitive therapy with behavior modification; thus, the individual is an active participant in the process. Additionally, CBT is conducted within a specified timeframe (Ford-Martin, 2018) with an established goal that is being worked toward. There are several CBT techniques that can be utilized. These techniques include conditioning, journaling, modeling, behavioral homework assignments, and systematic desensitization (Ford-Martin, 2018). The implementation of culturally responsive CBT takes into account ethnic and culture factors and fosters the interventions specifically for that individual (Zigarelli, et. al., 2016). Further, research has shown that including ethic and cultural variables into therapy sessions results in an increase in students' academic performance (Zigarelli, et. al., 2016).

Interpersonal Therapy

Interpersonal therapy is another culturally responsive evidence-based intervention that is typically used with individuals demonstrating depressive symptoms. Interpersonal therapy is a short-term therapy

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that examines the adolescent's mental health concerns (i.e., depression) in relation to the adolescent's relationships with people in their social network (Spurling, 2012). More specifically, individuals are assisted in understanding how their relationship with others are linked to their depressive symptoms, how to deal with those feelings, and how to "…improve the quality of their relationships" (Spurling, 2012 p. 233). This form of therapy can be adapted to incorporate the adolescent's depressive symptoms in relation to external cultural relationships. The symptomatology and stigma associated with depression, "…may be grounded within a cultural context…" that can be carefully explored through interpersonal therapy (Kalibatseva & Leong, 2014, p. 447). The implementation of "culturally adapted treatments for depression appear effective in symptom reduction…" as studies have shown that interpersonal therapy is effective for African Americans (Kalibatseva & Leong, 2014, p. 447).

MULTICULTURAL COUNSELING

Another evidence-based intervention is multicultural counseling. In multicultural counseling, the mental health support provider is aware of his/her own bias and works with the individual from their cultural perspective or lens (Zigarelli, et. al., 2016). Multicultural counseling has been found to be effective with individuals from various backgrounds as well as individuals with diverse sexual identities. According to Lee, Blondo, Mizelle, and Orzco (2010), when working through a multicultural lens the mental health provider should understand that adolescent's culture and what is considered aceptable within that cultural group. Additionally, the adolescent's behavior can be evaluated in relation to the cultural norms. "Behavior that is abnormal in one culture may be adaptive in another" (Lee, et. al., 2010, p. 2). The impact of the individual being able to express concerns and receive supports from a mental health service provider that is of the same culture, or at least someone who has cultural awareness, increases the effectiveness of the counseling. African American adolescents "…may be more likely to seek and stay in treatment if they consider the issues discussed in therapy relevant to their culture" (Kalibatseva & Leong, 2014, p. 447).

School-Based Mental Health Supports

Schools can be a vital component for the provision of supports and services for students experiencing mental health difficulties (Lindsey, et al., 2010). Schools are primed to provide early screening, identification, referral, and support. There is an increase of schools implementing "…multi-tiered levels of support [that] can help them better identify and treat children and adolescents in need of mental health" (Castro-Olivo, 2017, p. 177). Stiffler and Dever, (2015) note that "Schools are an optimal setting for service delivery" (p. 33). Utilizing school-aged mental health services can assist in facilitating mental health care for youth (Husky, Kanter, McGuire, and Olfson, 2012). According to SAMSHA (2018) of the 59.7 percent of the youth who received supports for depression, 45.3 percent of those youth received supports in a school-based setting. At the same time, of the 32.2 percent of youth who received supports for anxiety, 23 percent of those youth received supports in a school-based setting. Additionally, of the 32 percent of students who received supports for suicidal thoughts or attempts, 18.4 percent of those students received services in a school-based setting.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

For many African American youth, school based mental health services provide most of the received supports (Lindsey, et al., 2013). Mental health screenings are conducted in schools to more readily provide and improve the identification in students (Husky, et al., 2012). In a study conducted by Husky, et al., (2012) approximately 40 percent of African American students who were screened for mental health scored in the range of needing mental health supports. Additionally, the African American youth voluntarily participated in mental health services at rates higher than their white peers.

While school-based mental health services allow for quicker identification and consistency of supports and services, there is little diversity among mental health service providers. This can cause African American youth to have feelings of mistrust and fear of potential judgement from the service provider. These feelings of mistrust and judgement can reduce the number of African American youth who receive school-based mental health services. At the same time there is a difference between the prevalence of African American youth exhibiting mental health difficulties overall in comparison to African American students identified in the school setting. This indicates that African American youth are being underdiagnosed in schools. Unfortunately, African American youth demonstrating aggressive or deviant behaviors as a manifestation of their mental health difficulties receive harsh discipline consequences instead of appropriate mental health supports to address the specific needs of the youth (Hess, Pejic, and Castejon, 2014).

One way of being proactive with mental health identification is through the implementation of the problem-solving model which includes the response-to-intervention/multi-tiered systems of supports (RTI/MTSS) process. Many schools use the RTI/MTSS approach for the identification and treatment of students in need of mental health supports (Castro-Olivo, 2017). Though the use of RTI has not historically been implemented to assist students with mental health difficulties, this systematic process can be beneficial in determining the effectiveness of the intervention (Hess, et. al., 2014).

Problem-Solving Model

Froiland (2011), examined the possibility of addressing mental health issues through the problem-solving model. This research consisted of implementing mental health interventions. The use of RTI allows for the student to receive interventions that are monitored over a specified amount of time to determine the effectiveness of the intervention. The impetus of response-to-intervention is that the student receives evidence-based interventions in the general education setting, the teacher and the student receive supports upon the inception of RTI, and the potential identification of the student needing support for emotional or behavioral difficulties is not based on potential biased teacher referral, but rather based on the evaluation of the outcome data (Harris-Murri, King, & Rostenberg, 2006).

Response-to-intervention is a systematic method of solving problems. The use of the problem-solving model within the RTI framework allows for the "…application of the scientific method…" (Froiland, 2011, p. 36) through the four problem solving stages: problem identification, problem analysis, treatment implementation, and treatment analysis (Kratochwill & Bergan, 1990). The problem-solving model is based in behavioral consultation and is effective with both academic and behavioral difficulties.

The first stage in the problem-solving model is problem identification. This stage consists of obtaining a concrete definition of what the behavior is and what the behavior is not. The behavior is described in measurable observable terms that assist in determining if a problem exists. The potential existence of the problem is determined through observation and the students' performance. This step allows for the systematic process of collecting data regarding the student's difficulties demonstrated at school (Brown-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chidsey and Steege, 2010). The problem identification stage is completed when it is clearly established that, "…a discrepancy exists between the occurrence of the current and the desired levels…" of the behaviors of concern (Kratochwill and Bergan, 1990 p.35).

The second stage in the problem-solving model is problem analysis. Problem analysis consists of determining factors that may identify a solution to the concern and develop a plan to support the student and solve the problem (Kratochwill and Bergan, 1990). Emphasis is placed on environmental factors and social interactions of the adolescent (Kratochwill and Bergan, 1990). During the problem analysis phase a hypothesis is developed in an effort to determine why the student is demonstrating behaviors of concern. Through this information, student perceptions, as well as the perceptions of others, in addition to cultural variables are incorporated into the hypothesis. This information can be gathered through a Review, Interview, and Observe (RIO) process, or Instruction, Curriculum, Environment, and Learner (ICEL) process. Information from these processes analyze both the skill level of the student and also the ecological variables that may be contributing to the student's behaviors.

The third stage in the problem-solving process is treatment implementation. Treatment implementation consists of implementing an intervention or treatment to support the student in addition to monitoring the effectiveness of the intervention through progress monitoring (Brown-Chidsey and Steege, 2010; Kratochwill and Bergan, 1990). At the same time, this phase should incorporate the ecological variables as well as any cultural variables. It is vital that the intervention is implemented with fidelity to ensure that the intervention is carried out the way it was intended.

The fourth stage in the problem-solving model is treatment analysis. During this stage data is examined to determine the effectiveness of the intervention. With mental health concerns, the analysis would note changes in behavior and or thoughts in addition to the frequency of these behaviors or thoughts. If the intervention was not effective or the mental health concerns require a higher level of support and or treatment, multiple mental health providers may need to be brought in to help support the student and increase success (Brown-Chidsey & Steege, 2010). Essentially, treatment analysis consists of gathering the data from all three previous stages and determining the effectiveness of the intervention.

The utilization of the problem-solving model should take into consideration cultural responsiveness. This includes the students background, race/ethnicity, primary language, and potential bias for the initial referral (Harris-Murri, King, & Rostenberg, 2006). The number of students enrolled in public schools from diverse backgrounds are increasing (Kena, et. al., 2014). At the same time, the percentage of White students attending public schools has decreased from 28.7 million students to 25.6 million students, which results in an approximate 12 percent reduction of White students attending public schools. According to the U.S. Department of Education Schools and Staffing Survey, 82 percent of teachers in public schools identified as White in 2015, which is a 2 percent decrease from 84 percent of teachers in public school who identified as White in 2000 (U.S. DOE, 2016). Further, data from a national survey conducted in 2015 noted that 80 percent of teachers and principals in the public-school system identified as White (U.S. DOE, 2016).

There is a higher percentage of teachers who are White in relation to the percentage of students from non-white backgrounds in elementary and secondary schools (U.S. DOE, 2016). The racial discrepancy between teacher and student can create a cultural separation regarding academic and behavioral expectation (U.S. DOE, 2016). The cultural separation can be noted in expected academic performance, behavioral expectations, and discipline practices (Gregory & Roberts, 2017). When culturally responsive practices are not considered regarding discipline and instruction, the behavior and emotional well-being of students can be misinterpreted as a disorder (Harris-Murri, et al., 2006) instead of a skill-based or mental health

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

need. Research has shown that teachers of color add to the culture of the campus by representing as positive role models for all students. Having diversity among teachers assists in robust conversations and actions around culturally responsive teaching practices (U.S. DOE, 2016) and can assist in eliminating negative stereotypes for racial and ethnic groups.

Response-to-Intervention

While RTI was originally used for academic assessments, research has shown that this method can be used to identify students demonstrating an emotional disturbance (Stiffle & Dever, 2015; Froiland, 2011). The use of RTI resulted in a change in the way students were assessed. Instead of the identification process stemming from a "with-in" child perspective, RTI encompasses more of an ecological perspective and incorporates variables in the student's life that may be attributing to the behavior of concern. Response-to-Intervention places emphasis on evidence-based interventions prior to a referral for special education (Harris-Murri, King, & Rostenberg, 2006; Brown-Chidsey & Steege, 2010 and 2005). Using RTI to address mental health needs is something that school psychologists can do (Froiland, 2011). "School psychologists can utilize RTI to further consult with schools and families to develop potent interventions that foster students' mental health, social success, and resilience" (Froiland, 2011, p. 41).

Response-to-intervention (RTI) is an alternative method for identifying students who need additional supports. With RTI, all students are screened and monitored through a systematic objective data-based system that determines the needs of the student based on the student's response to the intervention (Brown-Chidsey & Steege, 2010; 2005). "Essentially, RTI is an objective examination of the cause-effect relationships(s) between academic or behavioral *intervention* and the student's *response* to the intervention" (Brown-Chidsey & Steege, 2005, p. 2). It is also essential that the systematic process is culturally responsive and connects different aspects of the youth life such as school, community, and home (Harris-Murri, et al., 2016). Response-to-Intervention can consist of 3 or 4 tiers. "Tier 1 is comprehensive and universal" (Brown-Chidsey & Steege, 2010, p. 4).

Tier I

In Tier I all students are screened and provided with evidence-based academic interventions in a general education setting. Culturally responsive behavioral practices promote general positive interactions and supports for students across the school, while noting any underlying factors that are contributing to the behaviors of concern (Hess, et al., 2014). Data obtained during screening and monitoring in Tier I can assist in determining if there are behavior patterns that result in disproportionate consequences or responses with certain ethic, racial, and/or cultural varied students. Data should be examined and disaggregated to note if there are any differences regarding office referrals, types of behavioral consequences, or inconsistent supports and follow up that would affect one group of students over a different group of students (Hess, Pejic, & Castejon 2014).

Unfortunately, despite some systematic Tier I interventions designed to support all students, evidence shows that there are still disproportionate disciplinary actions and consequence (Hess, et. al., 2014). These cultural response practices can be ameliorated through systematic reviews of data examining the referral of the student, and the consequence received by the student while monitoring the frequency of the represented cultural groups to note which cultural group receives the most disciplinary consequences and the type of disciplinary consequences (Hess, et al., 2014). Through systematic behavioral monitoring, most

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

students can be successful and receive the supports needed at Tier I through school-wide interventions. Students who demonstrate a need for additional supports after receiving Tier I supports, move to Tier II.

Tier II

Tier II consists of providing additional supports for the student while the student is still receiving Tier I interventions. Tier II adds on additional interventions versus replacing Tier I interventions with Tier II interventions. Approximately 20% of students will move from Tier I to Tier II. Interventions in Tier II include the implementation of small group supports that allow for additional learning and practice of the desired skill. Unfortunately, for students demonstrating mental health difficulties, the inclusion of small-group settings may not be appropriate as the inclusion of new students to the group can disrupt the current group (Hess, et al., 2014). Additionally, students may be more reluctant to share if the make-up of the group is not consistent. Intervention structures that are centered around the student being able to meet with or check-in with an adult mentor have proven successful. Students who continue to demonstrate a need for additional supports would receive intensive instruction, intervention, and possible assessment in Tier III (Brown-Chidsey & Steege, 2010 and 2005). "However, if culturally responsive academic and behavioral components are not integrated at each tier, these programs may not adequately address the needs of all students" (Hess, et al., 2014, p. 323). It is important that school staff who are from different cultural backgrounds, or who have knowledge of the various cultures on campus are a part of the problem-solving process when examining the behavioral concerns and developing the behavioral supports (Hess, et al., 2014).

Tier III

Tier III consists of providing small group instruction or supports to students who need additional supports at a level and frequency higher than Tier II. Approximately five percent of students within the RTI process will require supports and services at Tier III (Brown-Chidsey & Steege, 2010 and 2005). Typically, at Tier III, the student receives an in-depth evaluation consistent of a record review and data collected during Tier I and Tier II to determine needs and supports while receiving supports. During the evaluation, students continue to receive supports and services with increased frequency and duration (Hess, et al., 2014; Brown-Chidsey & Steege, 2010 and 2005).

CONCLUSION

With a culturally diverse population, mental health supports for adolescents must incorporate culturally responsive evidence-based interventions. African American adolescents experiencing mental health difficulties for depression, anxiety, and suicidal ideation should receive supports and services that are in conjunction with the cultural norms of behavior from a mental health provider who is aware of the cultural norms and can incorporate that information into a pro-active intervention strategy. Schools are a mecca of diversity, and the use of culturally responsive practices in schools is vital. Adolescents in need of supports and services for mental health concerns should be able to receive evidence-based interventions that are shown to be effective for a variation of cultures and backgrounds. African American adolescents should be free from bias and assumptions of symptomatology based on the behavioral expectations of the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

mainstream culture. Noting the various issues discussed in this chapter regarding stigmas, perceptions, and community supports, it is incumbent on the mental health system to ensure that African American youth are able to receive the mental health supports and services needed from a variety of mental health providers with demonstrated cultural awareness and responsiveness to the students symptomatology.

KEY TERMS AND DEFINITIONS

Cognitive Behavioral Therapy: A solution-focused therapy that focuses on current concerns to modify emotional and behavioral concerns.

Culturally Responsive: Being knowledgeable of, relating to, and incorporating other cultures and backgrounds.

Evidence-Based Interventions: Strategies and practices proven to be effective through systematic evaluation.

Interpersonal Therapy: Evidence-based therapy that focuses relationships the individual has with others in relation to the areas of concern

Multicultural Therapy: A form of therapy that takes into consideration the individuals cultural background in addition to other diverse experiences in addressing areas of concern.

Response-to-Intervention: A multi-tiered approach for identifying and supporting students with academic and behavioral needs.

This research was previously published in Implementing Culturally Responsive Practices in Education; pages 39-56, copyright year 2020 by Information Science Reference (an imprint of IGI Global).

ABSTRACT

There is limited evidence base regarding mental health issues in people with intellectual disability (ID), and hence, findings from the general population are often applied to ID groups. Available evidence suggests that individuals with ID experience higher rates of mental health disorders than the general population, although findings are mixed with regard to the determinants of this increased prevalence. Further, the consequences of this comorbidity for individuals, families, and the wider community are often overlooked including the multiple challenges in identifying and managing these concerns. Accurate diagnosis and effective intervention are currently hindered by factors including the applicability of standardized psychiatric classification systems, gaps in service delivery models and access to such services, as well as unmet training needs. It is critical that further research is carried out to examine the specific challenges facing individuals with ID along with facilitating appropriate mental health services to individuals with ID.

INTRODUCTION

Despite increased recognition of the prevalence and impact of psychiatric disorders among individuals with Intellectual Disability (ID), the early assessment and treatment of these concurrent comorbidities remains a significant societal challenge and affect the functional skills and intensity of daily support needed for those living with ID. Limitations in current assessment and diagnostic systems prevent the equitable access to services for people with ID in line with Article 25 of the United Nation's Convention on the Rights of Persons with Disabilities which outlines 'the right to the enjoyment of the highest attainable standard of health without discrimination on the basis of disability' (United Nations 2006; Stuart, 2012). Consequently it is critical to further develop and refine standardised diagnostic systems to achieve these aims. Furthermore, in order for intervention to be effective, it must address the multiple risk and resilience factors underlying ID and comorbid mental health problems. Therefore, from a public health perspective, rates of comorbid psychiatric disorders should be taken into account when planning for the equitable provision of services. Similarly, intervention research should consider the role of comorbidity in predicting outcomes and the nature of the barriers that prevent access to services, while basic science research would benefit from increasing understanding of these comorbidities by delineating possible heterogeneous aetiological and neurobiological determinants. This chapter will review and synthesise the literature on the prevalence, impact and determinants of the comorbidity of ID and psychiatric disorders, and discuss important considerations to improve accurate identification and effective management of these concerns.

Background

Intellectual Disability (ID) is characterised by deficits in both intellectual and adaptive functioning beginning during childhood or adolescence (APA, 2013). Adaptive behaviour includes conceptual skills (e.g., language, money and time concepts), social skills (e.g., interpersonal skills and social problem solving), and practical skills (e.g., activities of daily living and occupation) (Maulik, Mascarenhas, Mathers, Dua, & Saxena, 2011).

A comprehensive meta-analysis found that the overall global prevalence of ID was approximately 1%, with higher prevalence rates found in low- and middle-income countries, and among child and adolescent populations (Maulik et al., 2011). Social gradients and ethnic disparities have been reported in previous research on the prevalence of ID. Lower socio-economic status (SES) has been found to be associated with a marked increase in the prevalence of ID, particularly mild ID (Emerson, 2012; Leonard et al., 2005; Leonard & Wen, 2002; Roeleveld & Zielhuis, 1997; Stromme & Magnus, 2000), and higher rates of ID have been found among African-American and Indigenous Australian children (Croen, Grether, & Selvin, 2001; Leonard, Petterson, Bower, & Sanders, 2003; Leonard et al., 2005; Yeargin-Allsopp, Drews, Decouflé, & Murphy, 1995).In a recent epidemiological study it was estimated 5.9% of the Indigenous population lives with ID compared to 2.5% of the non-Indigenous Australian population(Statistics, 2015).

It has been proposed that socioeconomic disadvantage can contribute to both causation and severity of ID. (Durkin & Yeargin-Allsopp, 2018)For instance the etiology of some causes of intellectual disability, such as Down syndrome have been associated with environmental factors and stress that are linked to low SES. Additionally low SES families may not have the resources to provide the early socio-cognitive stimulation that is associated with improved outcomes in ID. Of particular concern is the evidence that an "inverse care law" applies, in that the greater number of risk factors a child may have for ID, the less

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

access they have to preventative and comprehensive health care (Woolfenden et al., 2013). This creates a vicious cycle whereby the risk factors that may predispose a child to ID are also the same risk factors that may mean they are likely to miss out on timely and effective identification and intervention.

CHALLENGES IN THE ASSESSMENT AND MANAGEMENT OF PSYCHIATRIC DISORDERS AMONG INDIVIDUALS WITH INTELLECTUAL DISABILITY

Prevalence of Psychiatric Disorders among Individuals with Intellectual Disability

In a comprehensive systematic review, Einfeld, Ellis, and Emerson (2011) found that between 30 and 50% of children and adolescents with ID had a comorbid mental disorder, and that the relative risk of mental disorder associated with ID, when compared to children and adolescents without ID, ranged from 2.8 to 4.5. Consistent with these findings, a secondary analysis of the 1999 and 2004 Office for National Statistics surveys of the mental health of British children and adolescents estimated that the 3% of British children with ID accounted for 14% of total child and adolescent psychiatric morbidity (Emerson & Hatton, 2007b). Comparing 641 children with ID and 17 774 children without ID, this research found that the prevalence of psychiatric disorders was observed to be 36% among children with ID and 8% among children without (Odds Ratio/OR=6.5). Increased prevalence among children with ID was particularly marked for autism spectrum disorder (OR=33.4), hyperkinesis (OR=8.4) and conduct disorders (OR=5.7). Furthermore, a cumulative effect was observed, with research suggesting that the greater the number of social or environmental risk factors a child with ID is exposed to (e.g., low SES, stressful life events, poor parental mental health), the higher their risk of having mental health problems such as emotional or conduct disorders (Emerson & Hatton, 2007b).

Other studies have also noted an increased relative risk for psychiatric disorders among children and adolescents with ID, and this has been found across a range of diagnoses including anxiety and mood disorders, behaviour disorders and attention deficit hyperactivity disorder (Dekker & Koot, 2003a,b; Emerson, 2003; Emerson & Hatton, 2007b). A secondary analysis of the 1999 Office for National Statistics survey of the mental health of children and adolescents in Great Britain found that the prevalence of any diagnosed ICD-10 disorder, as well as specific disorders such as conduct disorder, anxiety disorder, hyperkinesis and pervasive developmental disorders, was significantly greater among children with ID than among their non-ID peers(Emerson, 2003). A more recent examination of the mental health of adolescents with ID found that they were significantly more likely to report symptoms of anxiety than their peers without ID (King et al., 2019).

Longitudinal studies suggest that comorbid psychiatric disorders among children with ID persist through to adolescence and adulthood (Chadwick, Kusel, Cuddy, & Taylor, 2005; Einfeld et al., 2006; Richardson & Koller, 1996; Tonge & Einfeld, 2000). For example, in a 14-year longitudinal study of children with ID in Australia, high initial levels of behavioural and emotional disturbance decreased only slowly over time, with 31% of participants continuing to meet criteria for a psychiatric disorder in young adulthood (Einfeld et al., 2006). Greater decreases in psychopathology were found among males rather than females, and in participants with mild ID compared to those with severe or profound ID.

Overall findings with regard to rates of mental disorder among adults with ID have been somewhat inconsistent, partially due to differing methods for assessing psychiatric comorbidity. In their meta-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

analysis, Maulik et al. (2011) found that studies based on diagnosing psychiatric comorbidity using psychological assessments or scales showed higher prevalence compared to those using standard diagnostic systems and disability instruments. When ICD-10 or DSM criteria have been applied, reported rates of psychiatric disorder among adults with ID have been comparable to those found in the general population (Cooper, Smiley, Morrison, Williamson, & Allan, 2007; Deb, Thomas, & Bright, 2001); however, the utility of these criteria among individuals with ID has been questioned (Einfeld & Tonge, 1999; Sturmey, 1995). When psychiatric diagnoses were made by consultant psychiatrists on the basis of clinical interviews, Cooper et al. (2007) found that 41% of adults with ID met diagnostic criteria for at least one mental disorder. This is a significantly higher point prevalence rate than that observed in the general population, where rates have been estimated to be approximately 13.2% (Andrews, Henderson, & Hall, 2001). Indeed, reviews generally indicate a three to four-fold increased prevalence of psychiatric problems among individuals with ID compared to the general population (Harris, 2006; Munir, 2016). As for children and adolescents, a number of psychiatric disorders have been found to be more common among adults with ID than among the general population, including anxiety and affective disorders, psychotic disorders, and behavioural problems(S.-a. Cooper, 1997; Pallab K Maulik & Catherine K Harbour, 2010). Additionally recent cross sectional study of Scottish primary care practices found that people with ID were twice as likely to have one or more concurrent mental health conditions relative to people without ID (Cooper, 1997).

Impact of Psychiatric Disorders among Individuals with Intellectual Disability

Psychopathology associated with ID carries significant consequences for individuals with ID, their families and the wider community. For individuals themselves, for example, the dual disability of ID and psychiatric disorder is a major cause of failure of transition to school programs and community residential placements (Bruininks, Hill, & Morreau, 1988; Einfeld et al., 2006), leads to restricted participation in recreational and educational programs (Parmenter, Einfeld, Tonge, & Dempster, 1998), and is associated with reduced workplace opportunities following school (Anderson, Lakin, Hill, & Chen, 1992). Robust evidence indicates that a lack of early detection and intervention, including interventions directed at improving parental wellbeing, has significant implications for the future academic, behavioural and social functioning of children with ID (Bouras, 2011; Crnic, Neece, McIntyre, Blacher, & Baker, 2017).

Mental health challenges can also be exacerbated by the inaccessibility of services and resources to allow people with disabilities to achieve goals such as independence, to whatever extent possible, from the familial unit. For instance the lack of adequate support during the transition from school to adulthood including a lack of post-school opportunities, such as supported work placements and the inaccessibility of many workplaces for individuals with disabilities has also been identified as contributing to heightened(Young-Southward, Cooper, & Philo, 2017) anxiety and mental health difficulties among youth with ID and their parents. A lack of meaningful daytime activities in addition to negatively affecting mental health is also often associated with a loss of functional skills that had been previously gained and limited formation of socially supportive net words (Gauthier-Boudreault, Gallagher, & Couture, 2017).

Interactions between social environment, family, ID and mental health problems are complex and not unidirectional. It is known that families experiencing additional life stress prior to having children are more likely to have children with ID (Eapen, Al-Gazali, Bin-Othman, & Pramathan, 1998). This is particularly the case with respect to Indigenous families, those from culturally and linguistically diverse backgrounds, and those with a parent who has ID or a mental illness (Leonard et al., 2011; Leonard et

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2005; To et al., 2004). Hence, a vicious cycle of the development of ID and mental health problems can be seen at an individual level or in population groups experiencing adversity (Whitehouse, Durkin, Jaquet, & Ziatas, 2009; Whitehouse, Watt, Line, & Bishop, 2009). This confluence of factors generates a significant health burden for individuals, families, and communities, as well as inequity in child health resulting in significant health and economic impacts.

The long-term support of individuals with ID places a considerable burden on families and carers (Bourke et al., 2008; Crnic et al., 2017; DeRigne & Porterfield, 2017; Miodrag & Hodapp, 2010), and mothers in particular are at increased risk of mental health problems (Abbeduto et al., 2004; Gilson et al., 2018). Several studies have found that parents of children and adolescents with ID have higher levels of child-related stress and depression than parents of typically developing children (Browne & Bramston, 1998; Dyson, 1997; Olsson & Hwang, 2001; White & Hastings, 2004), and key short- and long-term outcomes for families of individuals with ID may be mediated, at least in part, by mental health difficulties (Eapen, 2014). For example, the mental wellbeing of parents of children and young adults with ID has been shown to be more strongly influenced by the severity of their child's comorbid mental health disorders including emotional and behavioural problems than by the severity of their ID (McIntyre, Blacher, & Baker, 2002; Tonge & Einfeld, 2003). Mental health problems among children and young adults with ID have also been shown to significantly predict parents' feelings of dissatisfaction with the family situation (Maes, Broekman, Došen, & Nauts, 2003), mothers' perceived negative impact of their child on the family, and the family's decision to seek out-of-home placement (Maes et al., 2003; McIntyre et al., 2002). It is interesting to note that stress did not account for significant additional variance in this decision-making (McIntyre et al., 2002), suggesting that mental health problems can significantly impact on the family's ability to care for a young person with ID without requiring out-of-home care arrangements. This adds to the social and financial burden of ID on families and societies, in conjunction with the economic impact of caregiving with mothers of children with ID earning significantly less over the course of their lifetimes than their peers with typically developing children(Parish, Seltzer, Greenberg, & Floyd, 2004). Overall, the inequities relating to the mental health of people with ID and their families relative to the general population has significant implications for service provision and policy development.

A recent meta-analysis based on studies published between 2010 and 2015 (n = 17) found the range of prevalence estimate to be 0.05 to 1.55%.(McKenzie, Milton, Smith, & Ouellette-Kuntz, 2016 ; McKenzie et al 2016). ID is also associated with reduced life expectancy and poorer quality of life (Begg et al., 2007), and high economic costs for governments and families (Doran et al., 2012). It ranks within the top 20 sources of burden of disease (Begg et al., 2007) and is among the 20 most costly disorders (Polder, Meerding, Bonneux, & Van Der Maas, 2002). This burden is compounded when ID is associated with a comorbid mental health disorder, leading to greater economic burden for provision of health care and education, in addition to further reductions in capacity for employment and earning.

Determinants of Mental Health Problems in Intellectual Disability

Given the high prevalence of mental health disorders among individuals with ID, and the impact of this dual diagnosis on individuals, families and the community, there has also been interest in examining specific variables that may influence this comorbidity.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Available evidence from the literature suggests that most variance in developmental vulnerability is associated with the social determinants of health and their interaction with an individual's innate biological susceptibility to adversity (Guralnick, 1997; Zeanah, Boris, & Larrieu, 1997). Cumulative exposure to risk factors over time in the absence of protective factor scan result in changes in neuronal circuitry with long-term consequences (Eapen, 2014).For example, there is evidence of altered brain architecture found in children exposed to abusive environments or who have a history of sensory deprivation, as well as an association between the impact of less extreme adverse environments on brain architecture linked with language and reading skills (Hackman, Farah, & Meaney, 2010; Marmot et al., 2010). Such risk and protective factors have their maximum effect during critical or sensitive periods, especially in the first five years of life (Maggi, Irwin, Siddiqi, & Hertzman, 2010; Siddiqi, Irwin, & Hertzman, 2007). While brain plasticity offers an opportunity for maximum gains with appropriate intervention during the early years, this becomes increasingly difficult the further we move away from childhood.

There is also emerging evidence of a transactional relationship between genes and the environment (A. E. Sameroff, 2009), suggesting that individuals with certain genetic profiles may be more sensitive to favourable and unfavourable environmental influences than those without such genetic makeups (Mitchell et al., 2013). In other instances the behavioural or mental health problem may be part of the behavioural phenotype of the underlying genetic condition as is the case with Lesch-Nyhan syndrome and self-injurious behaviours, Fragile X syndrome and disruptive behaviours, Williams syndrome and exceptional conversational verbal abilities and excessive empathy, Prader-Willi syndrome and temper tantrums and obsessive-compulsive features, and Angelman syndrome and happy affect and hyperactivity (Cassidy & Morris, 2001). Further, when the condition is associated with dysmorphic features or changes in physical appearance, such as short stature or excessive growth, or delayed sexual development or functioning, affected individuals can suffer from low self-esteem and this can, in turn, lead to secondary emotional or behavioural difficulties.

In a recent case-control study using data from the Intellectual Disability and Mental Health Assessing the Genomic Impact on Neurodevelopment (IMAGINE-ID) study, genotype to phenotype associations in children with copy number variants associated with a high risk of neurodevelopmental and psychiatric disorders (referred to as ND-CNVs) was examined. Among individuals with 13 ND-CNVs, a similar range of phenotypic expressions in neurodevelopmental adverse outcomes was observed although there were subtle quantitative and qualitative differences. The findings suggest that the genomic risk for neurodevelopmental and psychiatric disorders has pleiotropic effects involving varying processes and diverse neural circuitry involvement rather than specific or individual phenotypes (Chawner et al., 2019). Due to the transactional and inter-dependent relationship between these factors, developmental vulnerability should be understood, assessed and treated with consideration given to the cumulative impact of multiple factors, both risk and protective, including those related to the individual child, family, psychosocial status, neighbourhood, and service systems and policy (Eapen, 2014).The occurrence and nature of mental health comorbidity in children with ID is therefore influenced by the interaction between biological and environmental risk and protective factors, with the overall risk increasing as the number of risk factors increases (Eapen, 2014).

Exposure to a range of social and environmental risk factors such as poverty, living in a single-parent household, exposure to negative life events, low parental education, and poor maternal mental and physical health, has been found to be associated with increased prevalence of emotional and conduct disorders among children both with and without ID (Emerson & Hatton, 2007b). Importantly, however, exposure to these risk factors was found to be significantly higher among children with ID, with 46% of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

them having been exposed to three or more potential risk factors compared to 24% of children without ID. While there is limited evidence regarding the specific factors predicting the presence of mental health problems in individuals with ID (Costello & Bouras, 2006), these findings are consistent with the prevailing view that individuals with ID are more vulnerable to psychosocial stress than people without ID, and are therefore more likely to develop psychiatric symptomatology (Deb et al., 2001).

Similar findings were reported by Emerson (2003), who conducted a secondary analysis of data from 10 438 children aged between five and 15 years from the 1999 ONS survey of the Mental Health of Children and Adolescents in Great Britain (Meltzer, Gatward, Goodman, & Ford, 2000). Specific family characteristics were found to be associated with increased rates of particular psychiatric diagnoses, and children living in families belonging to lower social classes, and those from single-parent and lower-income households, were found to be at increased risk for a range of psychiatric disorders, including emotional disorders, anxiety disorders, depression and conduct disorders. A further study specifically examining the contribution of socioeconomic position to the health and mental health status of children and adolescents with ID, using the same sample, found that between-group differences in socioeconomic position and household composition accounted for 24% of the increased risk for poor health, 23% of the increased risk for conduct disorder and 37% of the increased risk for emotional disorder among children and adolescents with ID (Emerson & Hatton, 2007a). The authors concluded that socioeconomic disadvantage may account for a significant proportion of the increased risk for poorer physical and mental health among children and adolescents with ID. Another study, however, failed to find significant differences in the prevalence of psychiatric disorders between children classified as low SES and those classified as medium to high SES (Dekker & Koot, 2003a,b).

Factors related to parents, including parental mental health and parenting practices, have also been found to be an important determinant of mental health problems in children and adolescents with ID (Dekker & Koot, 2003a,b; Emerson, 2003). (Hazarika, Das, & Choudhury, 2017) in a study of parental attitude towards children and adolescents with ID found that while parents exhibited love and acceptance towards their children, there was also evidence of frustration, disappointment, and overprotection. This in turn had a negative impact on the children's adaptive functioning and independent skill development. Further, children whose primary carers reported more frequent use of punitive strategies and who had higher scores on the General Health Questionnaire (a measure assessing risk of developing psychiatric disorders) were more likely to have a range of psychiatric disorders, including an emotional disorder, an anxiety disorder, a conduct disorder and hyperkinesis (Emerson, 2003).

In a systematic review, Einfeld et al. (2011) discuss individual factors that have been associated with mental disorder in children and adolescents with ID. Factors that have been most commonly examined include age, gender and severity of ID, but findings have been largely inconsistent. With regard to age, some studies have found higher rates of psychiatric disorder in younger children when compared to teenagers(Molteno, Molteno, Finchilescu, & Dawes, 2001), but others studies have shown no significant relationships between age and overall rates of mental disorder (Einfeld & Tonge, 1996a, 1996b). Other studies have examined age effects for particular psychiatric disorders. Older children with ID (aged 11 – 16 years) have been found to be more likely to have an emotional disorder, including a depressive disorder, while younger children (aged 5 – 10 years) were more likely to have hyperactivity or a pervasive developmental disorder (Emerson, 2003; Emerson & Hatton, 2007b). Among adults with ID, increasing age has been found to be associated with a higher likelihood of psychiatric illness (S. A. Cooper, 1997; Deb et al., 2001).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Mixed findings have also been noted with regard to the association between gender and risk of mental disorders among children and adolescents with ID. Some studies have found no effect of gender on overall rates of mental disorder (Einfeld & Tonge, 1996a, 1996b; Molteno et al., 2001), but other studies have reported significantly higher overall rates of mental health problems among male children and adolescents with ID (Emerson, 2003; Stromme & Diseth, 2000). Further, some studies of children and adolescents with ID have found that males are significantly more likely to have conduct disorder and hyperactivity than females with ID (Emerson, 2003; Emerson & Hatton, 2007b), while others have shown no gender effects for anxiety, mood or disruptive disorders (Dekker & Koot, 2003a,b). In a study of adults with ID, female gender was associated with increased prevalence of psychiatric disorder (Cooper et al., 2007). In a study of older adults with ID, women with ID were more likely to have been diagnosed with affective disorders or dementia than men with ID and less likely to have been diagnosed with substance use related disorders (Axmon, Sandberg, & Ahlström, 2017). This study also found no gender differences were found for anxiety disorders or psychotic disorders. The research to date has not however been able to elucidate whether these gender differences are due to differences in prevalence, identification or treatment of mental health disorders among adults with ID.

The literature is also unclear about how the severity of ID affects an individual's vulnerability to developing different psychiatric disorders (Costello & Bouras, 2006). Among children and adolescents, several studies have reported no statistically significant association between severity of ID and risk of psychiatric disorder (Einfeld & Tonge, 1996a, 1996b; Stromme & Diseth, 2000), but one study found higher rates of mental disorder in participants with more severe ID (Molteno et al., 2001). Findings are also mixed in adults. Some studies have shown higher rates of psychiatric illness among people with severe ID (Cooper et al., 2007; Gostason, 1985; Lund, 1985), others among individuals with mild ID (Borthwick-Duffy & Eyman, 1990; Iverson & Fox, 1989), and others have found no evidence either way (Corbett, 1979). Intellectual functioning has also been examined, with findings suggesting that depressive feelings, anxiety and antisocial behaviours are more common among those with higher IQs, while psychotic, self-absorbed and autistic behaviours are more likely to be found in children with lower IQs (Dekker & Koot, 2003a,b). The impact of physical disability on psychiatric illness is also unclear. Some studies have found that physical disability is associated with an increased prevalence of mental disorder (Deb et al., 2001), while others report that the absence of severe physical disability and immobility is associated with greater prevalence of psychiatric illness (Cooper et al., 2007).

Challenges in Identification of Psychiatric Disorders among Individuals with Intellectual Disability

There are a number of obstacles to the valid and reliable identification of mental health problems in people with ID (Hatton, 2002). Firstly, standardised psychiatric classification systems are often adopted in studies of mental health problems in people with ID (Costello & Bouras, 2006); however, the applicability of these to this population is questionable. Two factors have been posited to influence the applicability of standardised psychiatric assessment criteria to individuals with ID: linguistic abilities and the presentation of mental health problems (Costello & Bouras, 2006).

Current diagnostic systems such as ICD-10 and DSM-5 rely upon verbal accounts of an individual's symptoms. The utility of these systems is therefore limited by the linguistic skills of the individual being assessed. As Costello and Bouras (2006) note, some features of psychiatric illness are complex, requiring a high level of verbal fluency to describe and differentiate between symptoms. Therefore, the use of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

these existing diagnostic symptoms may not be appropriate among people with ID, particularly those with severe ID who frequently have limited or no language skills. When examining mental health among individuals with ID, it is therefore necessary to assess the individual's non-verbal behaviour, in addition to gathering historical information and observations from other people such as family members or carers. Importantly, the validity of this information is also dependent on the particular psychiatric condition in question, with informants likely to be more aware of disorders with clear behavioural manifestations rather than subjectively experienced phenomena such as thought disorder or anxiety (Costello & Bouras, 2006).

In addition to concerns with regard to linguistic abilities, the use of standardised classification systems among individuals with ID assumes that mental health problems present in the same way in this population as they do in the general population; however, this may not be the case and may also depend on the severity of ID. For example, in a review of mood disorders among patients with ID, Hurley (2006) reported that individuals with mild ID had a fairly typical presentation and could be assessed using standard practices with minor accommodations. An atypical presentation of mood disorders, however, including increased behavioural problems such as aggression, was more frequent in individuals with moderate to profound ID. Due to limitations in the use of standardised diagnostic symptoms, various instruments (including both self- and informant-report measures) have been either designed specifically or adapted for use with individuals with ID (for a review, see Hatton, 2002).

Differential diagnosis between symptoms that may be an expression of underlying brain damage and those that are related to a psychiatric disorder may also be particularly important when working with individuals with ID (Costello & Bouras, 2006). Disturbances of emotion, attention, activity and thought, and associated behavioural problems, may occur as part of the ID and it is often difficult to ascertain whether these additional difficulties are due to a comorbid psychiatric disorder. For example, it is important to distinguish between ID and the negative symptoms of schizophrenia such as slowness of thought and poverty of speech (Clarke, Littlejohns, Corbett, & Joseph, 1989).

It is likely that many individuals with ID have mental health problems that remain undetected and therefore untreated (Taylor, Hatton, Dixon, & Douglas, 2004). Einfeld et al. (2006), for example, found that only 10% of young adults with ID and definite psychiatric disorder had received specialist mental health intervention. Insufficient numbers of professionals with appropriate training and necessary expertise may impede accurate diagnosis and the adequate provision of mental health services to people with ID (P.K. Maulik & C.K. Harbour, 2010; McCarthy & Boyd, 2002). Diagnostic overshadowing, where a clinician regards the ID as a sufficient explanation for an individual's presenting symptoms rather than attributing them to a psychiatric disorder and making a dual diagnosis, may be partly responsible for the under-recognition of dual disability in clinical settings (Mason & Scior, 2004; Tonge & Einfeld, 2000). Recent linkage of disability services and ambulatory mental health services data in the Australian state of New South Wales further found that people with an ID were more than twice as likely to receive an "unknown" diagnosis as those without ID (Howlett, Florio, Xu, & Trollor, 2015).Recognition of comorbid psychopathology requires detailed interviews using sensitive assessment techniques by specialist staff (P.K. Maulik & C.K. Harbour, 2010). It has been theorized that the rates of mental health disorders in people with ID may be both higher and untreated for longer periods of time than among the general population however no research to date has formally examined this notion(Munir, 2016) .

Furthermore, in the general population, identification of a mental health problem is often prompted by the failure of an individual to maintain social roles such as employment and parenting. In contrast, individuals with ID generally have fewer societal role expectations and the severity of their symptoms therefore does not necessarily relate to the degree of impairment in daily life(Costello & Bouras, 2006).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

This reduces the chances that mental health problems will be recognised by carers, and means that conditions such as anxiety and depression may cause significant distress to an individual yet remain undiagnosed(Whittle, Fisher, Reppermund, Lenroot, & Trollor, 2018)

The prevalence, persistence and consequences of comorbid mental health problems in individuals with ID necessitate improvements in the availability of early assessment and diagnostic services for these individuals and their families, for whom there are currently significant gaps in service provision urgently necessitating extensive further research and evaluation (McCarthy & Boyd, 2002; Whittle et al., 2018).

Challenges in Management of Psychiatric Disorders among Individuals with Intellectual Disability

The significant comorbidity between ID and mental health disorders poses considerable challenges to individuals with ID and their families, and for service providers (Eapen & Jairam, 2009), including not only significant barriers in the detection of mental health problems among individuals with ID but also the unique challenges in the management of these concerns. Some of the specific challenges in this regard include the lack of an interdisciplinary service model; lack of dedicated 'space' within mainstream mental health services for individuals with ID; lack of a clear transition model from childhood to adult services; and lack of staff training and expertise. Such deficiencies in service provision, and the associated cognitive, emotional and behavioral problems, combine to increase rates of unemployment, social isolation and depression in individuals with ID and their families, and the consequent healthcare burden for communities and governments.

Additionally as highlighted by a recent systematic review there is a dearth of quality evidence regarding the effectiveness of treatments designed to address the mental health needs of children and adults with severe ID (Vereenooghe et al., 2018). While the scope of this review was broad, only 5 studies were found that examined the mental health related experiences of people with ID and the findings of these studies were largely inconclusive due to small sample sizes, there were a total of 16 participants across the 5 studies examined. Concerningly this review found that the most recent study in the field was published in 1999 with many of the others employing pharmacotherapies that are no longer routinely prescribed. While there is more evidence for treatments that may be promising for adults with mild to moderate ID, the heterogeneity of study designs and the presence of underpowered trials make it difficult for clinicians to make decisions regarding effectiveness of many existing mental health interventions for their patients with ID(Koslowski et al., 2016). Given the limited available evidence, the findings of studies examining the broader population are often applied to manage mental health issues among people with ID. Given that these interventions may not address the specific needs of people with ID, there is an urgent need for further research in the area to facilitate adequate mental health services to children and adults with ID.

Thus, one of the primary targets of intervention when working with children with ID and their families should be to reduce stress and increase wellbeing among parents. This is also important because it is likely that parents of children with ID who report high levels of stress may engage in parenting behaviour that may negatively affect outcomes both in the child with ID and his or her siblings (Hastings & Beck, 2004), thus maintaining a vicious cycle. Indeed, it is likely that complex and multidirectional relationships exist between parents' wellbeing, psychological coping styles, parenting practices, and their child's behavioural problems, and comprehensive and effective intervention should aim to target these various factors.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Several factors have been found to explain stress among parents of children with ID. For example, research has suggested that child characteristics, such as the frequency or severity of behaviour problems, may lead to parental stress (Hassall, Rose, & McDonald, 2005; Hastings, 2002). For example, in a study of Australian children with a disability, the severity of children's behaviour was associated with parents' experience of greater stress in relation to their child, and their own personal wellbeing (Gavidia-Payne, Richdale, Francis, & Cotton, 1997). Thus, interventions that are successful at improving skills or reducing problem behaviours in children with ID also seem to benefit parental wellbeing (Gavidia-Payne & Hudson, 2002; Hastings & Beck, 2004). Other studies, however, have found that different factors are more important in predicting parental stress than child characteristics. For example, the way in which parents define their situation, and the resources available to them, have been found to predict significantly more variance in stress levels in mothers (29% and 42% respectively) and fathers (37% and 33% respectively) than any characteristics of the child, which accounted for only 2% of variance in maternal stress and 8% of variance in paternal stress (Saloviita, Itälinna, & Leinonen, 2003). Similarly, significant variance in mothers' parenting stress has been found to be explained by parental locus of control and parenting satisfaction (Hassall et al., 2005). These findings are encouraging, as changing parents' attitudes and perceptions may be an easier intervention target than ameliorating the child's disability and associated difficulties (Saloviita et al., 2003).

Recent reviews suggest that behavioural family interventions that train parents to respond contingently to child behaviour indicate positive results among both children with ID and their parents (Gavidia-Payne & Hudson, 2002; Hastings & Beck, 2004).For example, Stepping Stones Triple P (Sanders, Mazzecchelli, & Studman, 2003), an adaptation of the Triple P Positive Parenting Program for families of children with developmental disabilities, has been found to lead to fewer maternal-reported child behaviour problems, improved maternal and paternal parenting style, and decreased maternal stress, with gains maintained at the six-month follow-up(Roberts, Mazzucchelli, Studman, & Sanders, 2006). Similarly, parents of children with ID who have been trained in behavioural principles, such as limit setting and use of consequences and rewards, have been found to report increases in their self-efficacy in managing their child's behaviour, as well as lower levels of stress (Feldman & Werner, 2002). While parent training programs have been found to be beneficial, some research has suggested that families with additional psychosocial stressors such as lack of employment and poor marital adjustment may make the least gains (Baker, Landen, & Kashima, 1991). Additionally recent research has identified that parents of children with disabilities facing mental health problems also report greater difficulty in arranging appropriate childcare, financial difficulties and limited service provider availabilities as barriers to accessing treatment for their own psychiatric issues. (Osborn, Roberts, & Kneebone, 2019)

Hastings and Beck (2004) have also reviewed other interventions for stress reduction in parents of children with ID, including parent-to-parent interventions, and group interventions with parents. Although descriptions of various models have been published, strong evaluation data has rarely been reported for parent-to-parent interventions. One exception is a controlled trial of the Parent-to-Parent model (Singer et al., 1999), in which a parent who has experience caring for a child with a disability is paired with and provides emotional support and information to another parent of a child with ID. Although no measure of parental stress was used, the study found that parents' positive perceptions of their child and his or her impact on the family improved significantly in the treatment group, and parents' ratings of progress towards the resolution of their main need showed a clear improvement (Singer et al., 1999). Aside from the value of formal or informal networks of parents, research has also investigated the efficacy of group interventions for decreasing stress among parents of children with ID. Most group interventions have

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

involved elements of cognitive-behavioural therapy (CBT), and suggest a reasonable evidence base for the use of CBT techniques in improving the wellbeing of parents of children with ID (for a review, see Hastings & Beck, 2004). For example, mothers assigned to a Life Skills Training group where sessions focused on CBT techniques including coping and communication skills, problem solving and decision making, and skills to manage and control social networks, had reduced depression and stress and improved social support compared to mothers who were assigned to a non-directive parent support group (Kirkham & Schilling, 1990). Further, mothers in the Life Skills Training group maintained lower depression scores and higher levels of social support at a two-year follow-up (Kirkham, 1993). Furthermore, there is increasing evidence of the buffering role of informal support in the management of young people with ID and mental health problems and their families. For example, parents of adolescents with ID who perceived greater helpfulness from informal supports (e.g., spouse, extended family, friends) reported lower stress, anxiety and depression, even after controlling for child characteristics (White & Hastings, 2004). Typical appropriate supports provided by services for children with ID and their families such as respite services, case management and provision of key workers are also likely to contribute to reductions in parental stress (Hastings & Beck, 2004). Further, the establishment of early family-school partnerships is important in promoting positive outcomes among children with developmental delays and should not be overlooked as children transition to school (McIntyre, Blacher, & Baker, 2006).The importance of school-based intervention programs for mental health difficulties, including among children and adolescents with ID, has been recognised (Christensen et al., 2011). School-based interventions, such as the NSW School-Link initiative in NSW, Australia (NSW Ministry of Health, 2015), and targeted policies, such as the No Child Left Behind Act ("No Child Left Behind Act of 2001," 2002) are vital in ensuring effective intervention is provided to children and adolescents with comorbid mental disorders and ID.

There is also an acute need to be aware of the impact of ID and associated mental health difficulties not only on the individual, but also on the wellbeing of his or her family. Several studies have found that parents of children with ID report higher levels of child-related stress than parents of typically developing children (Browne & Bramston, 1998; Dyson, 1997; Patton, Ware, McPherson, Emerson, & Lennox, 2018), however this heightened stress has not been found to be the case across all causes of intellectual disability (Dabrowska & Pisula, 2010). Parental stress may result from life events that may impact on any family such as marital breakdown, but also from family life-cycle transitions that may be especially relevant to families of children with disabilities, such as the diagnosis of the child's disability, starting school, transition from child to adult services, and increasing age and infirmity of parents (Hastings & Beck, 2004). It has been assumed that the extra stress of caring for a child with disabilities places parents at an increased risk for depression. Indeed, mothers of children with ID have been found to have higher depression scores than mothers of typically developing children. (Olsson & Hwang, 2001). While no differences were reported in the wellbeing of fathers of children with ID in early studies (Olsson & Hwang, 2001), more recent studies have found significantly higher levels of depression and stress than normative data (Giallo et al., 2015).Similarly, having a brother or sister with ID is a risk factor for sibling adjustment problems (Rossiter & Sharpe, 2001). Within their families, siblings may experience extra caregiver burden, differential treatment, and an imbalance of family resources (Lobato & Kao, 2002). Outside their families, siblings may experience limited access to information about the child's condition, negative peer reactions, and disruptions in age-appropriate peer and family activities (Lobato & Kao, 2002). Thus, siblings of children with ID may also require formal support. Studies have investigated the efficacy of combined group interventions for siblings and parents of children with ID that are designed to increase the siblings' understanding of and adjustment to ID. These studies have found

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

significant improvements in siblings' knowledge of the child's disorder, siblings' self-competence, and sibling connectedness, and decreases in parent-reported behavioural problems among siblings (Lobato & Kao, 2002, 2005). Several of these improvements have been shown to be maintained at three-month follow-up (Lobato & Kao, 2002, 2005). Open communication and sharing age-appropriate information with siblings appears to be the best approach, as this reduces uncertainty and confusion, helps the development of family-centred problem solving skills, and allows siblings to support parents in the best way they can. If there are issues of risk to the sibling in terms of violent or aggressive behaviours, appropriate safety steps should also be taken.

Despite this range of interventions, there are significant challenges in providing a comprehensive and integrated service for those with ID and mental health problems. For example, studies from the UK have shown that young people with severe ID and mental health problems fall between a number of healthcare providers, including child and adolescent mental health services, specialist ID services and paediatricians (McCarthy & Boyd, 2002). Working with children with ID and their families likely necessitates a multidisciplinary approach, potentially involving physiotherapy for motor development and coordination, occupational therapy for proprioception and sensory integration, speech therapy for receptive, expressive and pragmatic communication, psychology for assistance with thoughts, feelings and behaviour including social interaction, and medical specialists for assistance with physical health difficulties, just to name a few. In this regard, it is worth noting that severity of ID is associated with an increase in associated medical conditions and complications, with the relationship being complex as they interact with one another and can result in secondary medical and behavioural complications (O'Brien, Barnard, Pearson, & Rippon, 2002). Collaboration and clear communication is also needed between families, health providers, and the various other agencies involved in the patient's care including education, housing and financial support services. Due to the multidisciplinary nature of services required for children with ID and their families, a model where one person works closely with the family and can mediate between the family and various services or professionals may lead to the most positive outcomes for parents (Hastings & Beck, 2004). However, there is often no collaboration or communication to enable a continuum of care. This is further compounded by the fact that different disciplines and agencies use different models of care ranging from patient-centred to those involving the family. Often there is no continuity between various services such as acute inpatient units, emergency departments, outpatient and community services, education services, vocational centres, the juvenile justice system and disability services. Families may be expected to go from one specialist to another, and navigating the complex health system is a significant challenge for both patients and their carers.

Hatton (2002)Reviewed the literature on psychosocial interventions for adults with ID and comorbid mental health problems. Individual and group intervention studies using modified CBT, including one small waiting list controlled trial (Rose, West, & Clifford, 2000), have found reductions in anger and aggressive behaviour among adults with ID. Adaptations of CBT have also shown reasonable outcomes in reducing depression and anxiety among adults with ID, but the reviewed research is limited to case studies and case series (Hatton, 2002). When implementing CBT with adults with ID, Hatton (2002) discusses the importance of assessing the individual's capacity to give informed consent. Wong, Clare, Holland, Watson, and Gunn (2000) found that people with ID and people with dementia were less able to make an informed consent decision than people with a chronic mental health problem or a comparison group. All participants benefited when the informed consent decision-making task was simplified by presenting information as separate elements and reducing the level of expressive verbal ability required to respond (Wong et al., 2000). These considerations may be particularly important when working with

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

adults with comorbid ID and mental health problems. Further, consideration must be given to the person's suitability to engage in CBT, including assessment of communication skills, cognitive aptitude, ability to identify emotions, and capacity to understand the CBT model (Hatton, 2002). Enhancing skills including communication, emotion recognition, problem solving and social skills can lead to increased independence and self-determination, which in turn can improve overall quality of life among individuals with ID (Nota, Ferrari, Soresi, & Wehmeyer, 2007). Assistance with housing, employment, social networks and independent living skills also deserve attention.

As such it is critical to facilitate the development of clinical tools for use by people with ID including those who are non-verbal to allow for better communication with clinicians regarding the nature of concurrent mental health issues in ID. Given the heterogeneous range of functional, behavioral and cognitive features among people with ID, the lack of consensus with regards to the tools to measure functional outcomes presents a significant challenge to health service provision. Once mental health problems have been identified however gaps in the integration and sharing of information between service providers of disability and mental health services, lack of appropriately targeted services and deficits in clinician knowledge act as barriers to access to appropriate health care(Whittle et al., 2018). Risk management is also important when working with individuals with comorbid ID and mental health problems. One particular area that warrants attention is the issue of behavioural change associated with sexual development, which can lead to sexualised behaviours and offending. Social stories appropriate to the mental age of the person with ID and sexual health education are critical in these situations. CBT has also been found to be successful in changing attitudes in sex offenders with ID (Hatton, 2002). Planning for emergencies and crisis situations is an important consideration of treatment, and having a safety plan with contact numbers of case workers or members of the treating team in case a crisis happens can put the mind at ease for both the patient and the family.

While randomised controlled trials concerning the effectiveness of psychotropic medications for people with ID and comorbid mental health problems are virtually absent (Hatton, 2002), psychopharmacology is a treatment option although this is also associated with challenges. It is to be noted that individuals with ID are often more at risk of developing side effects. One example of the potential complexities when treating people with ID who also have mental health problems is evident when these individuals are treated with second generation antipsychotics (SGAs) which considerably decrease the lifespan due to increased risk of weight gain, cardiometabolic changes, metabolic syndrome and related side effects of SGAs. Concerns have also been raised about the inappropriate use of antipsychotics in individuals with ID especially for behavioral problems without a diagnosed mental health condition(O'Dwyer et al., 2019).In this regard, a recent study examining the antipsychotic use in people with ID found that, of the 305 participants, 45.1% received antipsychotics with only 25.9% having evidence of a psychotic disorder with the rest being treated for problem behaviors. This highlights the need for careful consideration of the indication and the justification for the use of antipsychotics in individuals with ID. In either case, attention should also be given to an integrated and comprehensive physical health care plan for people with ID and mental health problems. While such a plan would be a policy direction to aspire to, research is needed in order to understand gaps in attitudes, awareness, and training of staff, resources, and service delivery options.

While various interventions have been found to show efficacy, Dosen (2007) argues that a monodisciplinary treatment approach to behavioural and psychiatric problems in persons with ID, such as psychotropic medication or behaviour modification alone, has yielded limited success. He argues for an integrative diagnostic and treatment approach consisting of four dimensions – biological, psychologi-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

cal, social and developmental – for people with ID and mental health problems, where the focus should not be primarily directed towards the symptoms of the disorder but towards restoring a person's mental wellbeing. For individuals with an established dual diagnosis of both ID and a psychiatric disorder, treatment goals should include preventing further disability, restoring premorbid functioning, and improving quality of life through restoration of functionality, independent living and rehabilitation.

SOLUTIONS, RECOMMENDATIONS AND FUTURE RESEARCH DIRECTIONS

A developmental-bio-psycho-social-cultural model of service delivery and training and education of professionals involved in the care of people with ID is critical for early identification and appropriate management of comorbid mental health problems. People with ID and mental health problems are some of the most vulnerable people in society and they are often let down by the health care system, funding and service delivery models. Efforts to intervene in a more coordinated and integrated way can significantly improve their outcomes. Further, both the patient and the family or caregiver would need support, advocacy and case management. This would require coordination rather than separate services across types of difficulty, age groups, treatment modalities and disciplines. This should include a focus on the individual in a family context and using skill building models for developmental gains and appropriate management of maladaptive behaviours through an integrated multidisciplinary and multiagency collaborative service.

In order to plan effective and comprehensive prevention and intervention strategies for young people with ID and mental health disorders, it is important that there is a better understanding of the complex interplay of both risk and protective factors at different levels, including individual child factors, family, neighbourhood and society, as well as services, systems and policies. It is also important to consider the perspectives of the family members and support persons and work collaboratively together. Differentiating between behavioural challenges and mental health co-morbidity is also important and in doing so information from multiple sources needs consideration and interpretation (Weise, Fisher, & Trollor, 2018; Weise et al 2018).Given that no factor acts in isolation, and that there is an interaction of these factors at multiple bio-ecological levels, and at multiple time points along the life course, it is essential to have rigorous and relevant epidemiological and statistical techniques that can apply a bio-ecological model using a life course approach(Woolfenden et al., 2014). A cumulative risk index, being the sum of individual risk factors, is one way of conceptualising how risk factors interact over a life course(A. J. Sameroff & Seifer, 1983), but in this model all risk factors are given an equal weight which is a significant disadvantage when compared to a regression model. Structural Equation Modelling and Multilevel Modelling techniques, on the other hand, are based on a proposed hypothesis and, using regression techniques, variables including time are grouped into hierarchical levels(Diez Roux, 2004), and measured to see which model fits best. Future research exploring risk factors should where possible use composite theoretical models, longitudinal study designs and multilevel modelling in order to tease apart risk factors at different levels including individual, family and neighbourhood as well as society, services, systems and policy factors, which might increase vulnerability of people with ID to develop mental health problems. In this context, it is noteworthy that the occurrence of mental health comorbidity in children with ID, and the nature and type of such comorbidity, is shaped by the interplay of biological and environmental risk and resilience factors, mediated by the life course issues as to when these factors are in operation in the child's life.Eapen (2014) has described such a model of a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Developmental Risk Index where appropriate weighted scoring is given to different microsystem (child's most immediate or proximal environment), mesosystem (reciprocal relationships and interconnections), exosystem (distal factors that indirectly impact on the child and their family) and macrosystem (societal, cultural and service or policy) factors. Future studies should also explore biological risk factors including genetic factors, perinatal events, trauma, toxins, infections and immunological factors. Research should also focus on early identification processes that accurately assess the nature and reasons behind behavioural and emotional problems encountered in the context of ID; for example challenging behaviours may be due to the underlying brain pathology, or due to speech and language difficulties resulting in communication problems, or due to lack of stimulation and opportunities resulting in poor quality of life. Such a comprehensive assessment would no doubt facilitate the development of an individualised multidisciplinary treatment model and better outcomes.

Regarding management of co-morbid ID and mental health disorders, a recent study examined a discrete choice experiment (DCE) for assessing care management preferences of parents for their children(N'Dri, Ross, Castillo, Reeves, & Butler, 2019; dos Reis et al 2019). Using mixed methods, this study tested six attributes of care management decisions by parents namely medication use, parental custody, time cost, social interactions, medication effects, and school placement. Among children with ID the common co-morbidities were autism spectrum disorder (55%) and attention-deficit/hyperactivity disorder (76%). The study found that the participants had a preference for using fewer medications and maintaining decision-making authority and that they considered medication effects on the child's mood to be more important than its effects on personality or body weight.

CONCLUSION

There are significant challenges in the detection and characterisation of comorbid mental health problems in the context of ID. For example, for those with limited language and cognitive abilities, can the same diagnostic criteria and measures be used? Identifying the nature and extent of mental health problems is further compounded by the lack of measures specific for ID. There are also difficulties in identifying the nature and extent of ID and the consequent impact on function (measurement of adaptive behavior), as there is considerable variability in the terms and definitions as well as the diagnostic criteria and assessments across settings and across the different parts of the globe. While some of these issues could be addressed through better training of professionals, there are also significant barriers in service delivery models and access to services. In this regard, there are significant gaps in the availability of evidence based intervention programs in general for children with ID and mental health problems. In particular, the needs of those with behavioural or mental health problems and chronic and complex health care problems are not met by mainstream services. There is an urgent need to have a consensus on a statement of minimum standards of care, with clear policy objectives, program outlines and comprehensive training of staff, followed by evaluation of its implementation. Family and support persons perspectives also need due consideration during the management planning and decision making process. Furthermore, improved longitudinal outcomes will only be possible for people with ID and psychiatric disorders if there are opportunities for access to integrated services including better identification and treatment models, and improved knowledge and awareness of health-related conditions for people with ID, enhanced parent or carer support, as well as changes within health and disability service systems to ensure universal coverage of quality services.

KEY TERMS AND DEFINITIONS

Cognitive-Behavioral Therapy: A type of psychotherapy that helps individuals to identify and teaches skills to modify unhelpful thinking patterns, feelings, and behaviors.

Indigenous Australians: The original inhabitants of the Australian continent and nearby islands, including Aboriginal people and Torres Strait Islanders.

Intellectual Disability: A disability characterized by significantly impaired intellectual and adaptive functioning, formerly known as mental retardation.

Multidisciplinary: Drawing on expertise from multiple disciplines to accurately define and manage complex situations including health concerns.

Chapter 45
Mental Health Issues, Wellbeing, and Related Issues Among Caregivers of Individuals With Intellectual Disability

Tanay Maiti
AIIMS Bhubaneswar, India

ABSTRACT

Caregivers are the important and integral part in the lives of people with intellectual disability. As caregiving is extensive and mostly lifelong for this population, the associated burden, stigma, and also wellbeing of the caregivers are also equally important as these are often very directly correlated with the wellbeing of the individuals with intellectual disability. The chapter focused on the issues and impacts of caregiving, mental health problems, wellbeing, and related issues of caregivers. The authors also discuss the various facets of stigma caregivers do face and ways to deal with the stigma.

INTRODUCTION

Care giving to individuals with disability is laborious and associated with many mental health issues and related problems. In a longitudinal study on the well-being of parents of individuals included in the Australian Rett Syndrome Database over the period from 2002 to 2011, Mori, Downs, Wong, & Leonard (2019) reported that poorer parental physical well-being was related with residential remoteness, the child being a teenager at baseline, having frequent sleep disturbances or behavioural problems, and being a single parent or on a low income was associated with later poorer physical well-being, while the child having enteral feeding was associated with later poorer emotional well-being. Laurvick, Msall, Silburn, Bower, de Klerk, & Leonard (2006) reported in a study on mothers (n = 135, age ranged from 21 to 60 years) of children with Rett syndrome (age between 3 and 27 years) that the most important predictors of maternal physical and emotional health are child behavior, caregiver demands, and family function. The scenario is not much different with caregivers of individual with intellectual disability.

Many researches focused on the management of individuals with intellectual disability, the mental health issues, stress and burden of the care givers of intellectually disabled individuals are equally important as indicated by the recent researches. In some cases, family members neglect the disabled individuals. Enoch, Mprah, Isaac & Joseph (2018) have reported in a study from Ghana that most parents refuse to visit their children with intellectual disability in school. However, due to deinstitutionalization and perspective of inclusion in to society, most of the intellectually disabled children, adults and older adults are taken care at home and at least one of the family members to be the primary care taker. Such scenario gives importance for the needs and difficulties for the caregiver. The chapter focused on the issues and impacts of care giving, mental health problems, wellbeing and related issues of caregiver.

Care giving and Mental Health Issues

The negative impact of caregiving on the mental health of caregivers is well documented in the literature. In a population based study, Schofield et al., (1998) found less life satisfaction, less positive affect, and more negative affect among caregivers compared with non caregivers regardless of age or marital status. Caregivers experienced depression, anxiety and stress symptoms and these symptoms were found to be significantly higher among caregivers of individuals with intellectual disability than those with Psychiatric illness (Panicker & Ramesh, 2019). Similar findings were reported in other studies too. For example, in a study on family burden in people with intellectual disability with or without mental disorders, higher levels of family burden were related to higher functional disability in all the areas, lower intelligence quotient, diagnosis of ID with mental disorders and presence of organic, affective, psychotic and behavioral disorders. Stepwise multiple regression showed that behavioral problems, affective and psychotic disorder, disability in participation in society, disability in personal care and presence of ID-MD explained more than 61% of the variance in family burden (Irazábal, Marsà, García, Gutiérrez-Recacha, Martorell, Salvador-Carulla, & Ochoa, 2012). In another study, higher family impact was found between caregivers to people with mental health disorders - intellectual disability. The interaction of both conditions (ID and mental health problems) results in a higher degree of burden on families (Martorell, Gutiérrez-Recacha, Irazábal, Marsà, & García, 2011).

Maternal depression in families having a child with a disability has been the subject of considerable research over four decades. Bailey, Golden, Roberts, Ford (2007) reviewed 42 articles on maternal depression and found that only eight were clinically diagnosed depression; most of them used a scale rating depressive symptoms. Across the studies, mothers of children with disabilities generally exhibited a higher than average rate of depressive symptoms and are more at risk for clinical depression, but the incidence may be lower than reported in previous literature. Child behavior problems, maternal stress, coping style, and support were consistently associated with depressive symptoms. The distinction between clinical depression and depressive symptoms may be important in conceptualizing how a child with a disability can influence family members and the nature of support that may need to be provided.

Many studies on mental health issues of caregivers of intellectually disabled individuals in different cultural settings consistently reported increased maternal distress and burden. Australian Bureau of Statistics (ABS) (1998) reported that, approximately 30% of caregivers reported that their well-being had been affected by caregiving, and that they were often worried or depressed. McConkey, Truesdale-Kennedy, Chang, & Jarrah, Shukri (2008) have studied 206 mothers with intellectually disabled children in three different countries and reported that mothers experienced poor mental health, increased levels of child-related stress and poorer family functioning. Their child's behaviour problems were a major factor

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in this. The impacts on mothers' well-being were not alleviated by access to professional supports or use of coping strategies. John (2012) assessed stress among mothers of young children with intellectual disabilities in urban India and examined the extent to which child functioning and maternal coping predict maternal stress. Three-fourths of the sample obtained a clinically significant stress score, and maternal coping emerged as a robust predictor of stress for mothers of boys with intellectual disabilities. Qualitative analyses indicated positive and negative maternal experiences related to self, child, family and community. In a study involved secondary analysis of data from the 2011 Survey on the Actual Conditions of Individuals with Developmental Disabilities, conducted by the Ministry of Health and Welfare of Korea reported that all components of caregiving burden and depression (effects of caregivers' characteristics, caregiving time and cost, and perceptions of time and cost, on depression) were significantly higher in the 1st grade, designating the most severe disabilities. Overall, caregiving burden tended to be higher in female caregivers, the unemployed, parents, co-residents, and people with health problems. Caregivers' characteristics such as spouse relationship, having health problems, and perception of caregiving time and cost were associated with depression (Nam & Park, 2017). Studies across the world confirming the fact that caregivers experience stress, burden and various mental health issues.

Gardiner, Miller & Lach (2018) have tried to identify functional predictors of perceived impact of childhood disability among families of children with neurodevelopmental disorders and disabilities. They examined the relationship between sub-domains of adaptive and problematic behaviour and perceived family impact, and whether the same sub-domains would emerge as significant after controlling for the impact of child diagnosis, including autism spectrum disorder, cerebral palsy and intellectual disability. Caregivers of 216 children and adolescents with neurodevelopmental disorder and disability completed measures of children's practical, conceptual and social skills (i.e. adaptive behaviour), behaviour problems and positive and negative family impact. Indices of child adaptive and problematic behaviour were only significantly associated with perceived negative family impact. Children's practical and social skills, as well as emotional symptoms, emerged as significant predictors of perceived negative family impact, with emotional symptoms accounting for greatest variance. The study findings suggest that it is not children's most impaired domains of functioning that are perceived as significantly impactful by the family. The findings highlight the importance of devoting consideration to the ways in which the functional limitations experienced by children with chronic developmental health conditions similarly impact family life and well-being, regardless of disorder designation. Future studies are required on this direction.

Care Giving and Wellbeing

The impact associated with long term care giving has been indicated that care givers are burned out with poor subjective well being, life satisfaction and social support. Gebeyehu, Sahile, & Ayalew (2019) reported in a study on level of burden, social support, and life satisfaction of seventy four caregivers (parents, grandparents, and siblings of the child) of children with intellectual disability that caregivers are experiencing much level of burden with inadequate social support and have pitiable satisfaction in their life. Burden is negatively correlated with social support and life satisfaction, but social support is positively correlated with satisfaction in life. The authors emphasized the need of result social support for caregivers in order to reduce the level of burden and enhance their satisfaction in life.

The impact of care giving and compound caregiving (i.e. multiple caregiving roles) on caregivers are different in many ways. Compared with the non-compound caregivers, the compound caregivers of adult children with intellectual disabilities had increased desire to place their care recipient into residential

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

care. They also spent an average of 12 additional hours per week undertaking the compound caregiving role. Overall findings indicated that caregivers reported giving more tangible and emotional support than they vii received, but considerable variability was evident. Relative disadvantage in tangible reciprocity was associated with increased depressive symptomatology, poorer mental health, and reduced desire for residential placement of the care recipient, but not with physical health or life satisfaction (Perkins, 2009).

In order to compensate for the disadvantages of caring, researches tried to identify factors associated to caregivers' subjective well-being (SWB). Hope is found to have significant impact on social self-care, mental health and conscientiousness of staff working with people with intellectual disabilities (Oliver, Revuelto, Fernández, Simó-Algado, & Galiana,2019).

Caregiver Impact on Management

Attitude and perception of the caregiver influence the service selection and outcome of management. The responsibility of choosing the kind of services to be provided to the disabled individuals is also related to the knowledge and attitude of the caregiver. Werner, Stern, Roth, & Tenenbaum (2019) have examined the roles of stigma and of enabling factors in help-seeking by parental caregivers of individuals with intellectual disabilities and dual diagnosis. Questionnaires were completed by 195 family caregivers. Lower family stigma was related to higher personal enabling factors (e.g. knowledge about services and previous experience in seeking help), which in turn was related to higher help-seeking behaviors. Higher professional enabling factors (e.g. attitude of the professional, services in the vicinity) were related to higher intentions to seek help, which were related to higher help-seeking behaviors. Professionals can help families achieve a greater sense of self-efficacy in their own help-seeking process by providing them with knowledge about services and facilitating a more positive experience in the process.

The involvement of caregiver in the intervention programs for intellectually disabled individuals could predict the success of the intervention. For example, many weight reduction programs fail to show positive and sustainable impacts due to not involving parents, who are usually unavailable to attend school-based health programs. The mHealth interactive interventions were carried out in September 2015-August 2016 by Lee, Brown, Leung, Chen, Louie, Chen, & Lee (2019), engaging carers to monitor and sustain their children's healthy lifestyle behaviours at home. Twenty family carers were recruited and four themes emerged such as improving family carer-child interactions and communications, gaining useful and practical health information from experts, supporting each other via an mHealth platform and appreciating the collaborative effort between school personnel and family carers. Family carers stressed the usefulness of the mHealth interactive interventions in monitoring and sustaining the children's healthy lifestyle behaviours at home. The mHealth interactive interventions for increasing family carers' involvement and monitoring were well received. The findings provide new insights into using mHealth interventions in future weight management programmes involving parental participation in the home environment.

Carer mental health literacy and help seeking are areas that are not well researched in the intellectual disability field. Man & Kangas (2019) aimed to explore the above including service utilization experiences of Australian parents with an offspring with an intellectual disabilityand a comorbid psychiatric disorder. Forty-one parents took part in an online survey assessing satisfaction and helpfulness ratings of received services. Twenty-six parents also completed items to assess mental health literacy and attitudinal barriers to help seeking. Parents showed good mental health literacy with depression and with challenging behaviour associated with autism and poorer literacy with mixed presentations. Parents

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

reported varied helpfulness and satisfaction ratings with disability and mental health services and they are capable of recognizing the need to seek professional help for their offspring.

The relationship between ethnicity, service use and perceptions of service effectiveness is inconclusive. The study examined differences in service use and perceptions of service effectiveness between Israeli Jewish (Jewish) and Israeli Arab (Arab) parental caregivers of individuals with intellectual disabilities and dual diagnosis of psychopathology. Arab parental caregivers perceived health services to be more accessible than did Jewish caregivers, but there was no difference between the two groups in the use of the services. Overall, greater enabling factors and accessibility were associated with higher use of education and social services. No differences were found between the groups in their perceptions of service effectiveness.Arab family caregivers use education and social services less than do their Jewish peers, possibly because they have fewer enabling resources. The finding that both groups reported similar use of health services may be explained by a shared perception that informal help may not be suitable for dealing with situations of psychopathology. The similar perceptions of service effectiveness may be explained by extensive services available in Israel, to the satisfaction of both groups, or by the fact that participants perceived these services as their only alternative, and therefore fear losing them (Werner, 2019).

Stigma and Caregivers

Stigma, can be understood as mark of social disgrace, where discrimination happens based on variable factors like disability, mental health problems, ethnicity etc. Both the individuals with intellectual disability and their respective caregivers do face significant amount of stigma and prejudices, resulting in added disability and obstacles restricting their human rights. Stigma can be conceptualized as an attitude or belief which lead people to reject or avoid others who are 'percieved' to be different. The word is greek in origin which initially meant a cut or burn mark in skin used as identification mark for slaves or criminals.

Among the various type of stigmas described; family, courtesy or associative stigma has been described for the people or caregivers associated with targeted individuals, who are subjected to stigmatization by common people. Both associative and affiliate stigma has been researched in details and Mak et al (Mak WWS et. J Appl Res Intellect Disabil 2008) has mentioned about three components of family stigma; i.e. affect, cognitions and behavioral responses whereas Mak & Cheung's Affiliate Stigma Scale(MakWWS et al 2008)measures the extent of self stigmatization with good predictive value on subjective burden, even after controlling the factors like extent of caregiving involvement and caregiving stress.

Researches from India has shown direct correlation of lower parental education belongingness to low socio economic strata and low paying high labouring job of the parents with the prevalence of intellectual disability, all of which definitely increases the burden of caregiving leading to a further vicious circle. (Naskar S, et al . Int J Med Sci Public Health 2016. In a country like india, with 21 million people living with disability(as per census 2011), of which nearly 75% staying in rural background, without basic resources and minimum facilities, the burden of caregiving is immense. Stigma certainly make things even worse. The legislation related to intellectual disability(PWD Act 1995, National Trust Act 1999, UNCRPD 2007), simplified procedure of issuing disability certificates, multiple educational facilities(acceptance of 'Child with Special Needs', CWSN into regular school, The Right of Children to Free and Compulsory Education (RTE) Act, 2009, under Article 21-A) along with employment ben-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

efits might have changed the Indian scenario partially, but the social stigma alone hindering access to maximum benefit to this population.

Other than legislation and policy making at the government level, village gatherings and support from community or religious leaders can turn very useful to deal these stigmas of caregivers in a developing country like India (McConkey et al 2016) McConkey proposed four key strategies to challenege the negative perception about intellectual disability, which include nurturing the child's development, inclusion in the society and also in the peer group, information about myths, superstitions and advocacy about their needs and rights. (McConkey, R., Kahonde, C., & McKenzie, J. 2016). Cross et al mentions about matrix of intervention plans which could be explained at various levels, like intrapersonal, interpersonal, organisational or at community level. For the first three level the labelling, stereotyping, status loss and discrimination out of it need to be dealt specifically however government lead policy and favourable legislation can change the scenario over time.

Stigma by now, is more than a belief. It's a social, cultural and moral process, whose complex interaction within the socio cultural environment affects not only the stigmatised individuals but also their caregivers, in multiple domains. The anthropological researches on stigma has emphasised about the moral standing of an individual determined by their local social world, and local social obligations and norms further maintains one's morality.

CONCLUSION

Understanding the disability impact on parenting and caregiving is important for intervention. Despite variations in coping pattern, both positive and negative coping strategies were observed in caregivers and positive coping does not rule out negative coping strategies (Kishore, 2011). Use of appropriate coping styles can reduce the negative impact of care giving. The factors positively associated with better maternal physical health were the mother working full-time or part-time outside the home, having some high school education, having private health insurance, the child not having breathing problems in the last 2 years, the child not having home-based structured therapy, and high scores on the Family Resource Scale (indicating adequacy of time resources for basic and family needs). The factors positively associated with better maternal mental health: were the mother working full-time or part-time outside the home, the child not having a fracture in the last 2 years, lesser reporting of facial stereotypes and involuntary facial movements, being in a well-adjusted marriage, and having low stress scores (Panicker & Ramesh(2019); Laurvick, Msall, Silburn, Bower, de Klerk &, Leonard (2006). The amount and quality of social support available to caregivers is an important factor in moderating the impact of caregiving and social support can be provided both informally, by family, friends, neighbours, social groups and so on, and formally, by professionals and agencies (Dunst, Trivette & Deal, 1988).

Factors such as the type of disability of the care recipient and where the caregiver is in the caregiving process will affect the impact caring has on the caregiver's mental health, and thus the type of supports most appropriate for the caregiver. The important role of moderators of the impact of caring, such as the caregiver's financial situation and coping strategies used, should also be considered by service providers when planning how to assist caregivers. Greater consideration of some of these factors may assist in more efficient use of the resources available to support caregivers. Attention should be paid to the individual situation of each caregiver. Careful assessment of caregivers' needs should consider the factors associated with a negative impact of caregiving and of the various mediators of this impact.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

It is also important to acknowledge the positive aspects of the caring role to ensure that these are not obstructed by interventions to assist caregivers. Global responses to the needs of all caregivers will not provide the most benefit to individuals (Sally Savage & Susan Bailey (2004).

It is important to give attention to various issues of caretaking and negative impact of care giving and to implement appropriate intervention strategies and policies to deal with such issues.

Chapter 46
Flying With Eddie:
Complicated Grief in the Military

Emeline Carol Eckart
University of Indianapolis, USA

EXECUTIVE SUMMARY

Over 2.4 million American service men and women were deployed overseas between 2001 to 2011. Families of these service members include over one million spouses and two million children under the age of 18. There is a growing need for counselors to understand the mental health needs of military service men and woman, and the unique aspects of military culture. This chapter will demonstrate how to practically apply the Multicultural and Social Justice Counseling Competencies (MSJCC) to counseling work with the military population through a case study.

INTRODUCTION TO THE CASE

Case Description

Eddie calls my private practice office for counseling, stating that he recently lost a friend in an accident and people are urging him to talk with someone. He states he is in the military and does not want to see a counselor on base because he does not want anyone to find out he is in counseling. He is tearful on the phone and asks for the first available time slot. I previously served fourteen years in the military as an aviator before becoming a counselor. I schedule him for an intake the very next day.

Eddie arrives promptly at the office in jeans and a collared shirt. He is groomed, though his eyes are swollen and red. He appears nervous as I invite him into the counseling space. When asked what brings him into counseling today, Eddie tears up. Eventually, he blurts out that his best friend, who was in the same aviation squadron as him, died. A week ago his friend was completing an annual flight evaluation in marginal weather, and Air Traffic Control lost radar on the airplane. Three days later the plane was found in the ocean underneath the area where the plane had been operating. Both pilots died in the incident.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Since that time Eddie reports difficulty sleeping and eating. He reports increased use of alcohol. He no longer drives his own car but instead drives his best friend's car around. He is in shock about the mishap and is angry the squadron has started to continue normal operations. Eddie states that he knows the squadron needs to continue workups before they leave on their six-month deployment in three weeks. He is not sure whether he can go on this deployment, whether it is safe for him to fly an aircraft under these circumstances. He is concerned that if he does not go on this deployment, it will impact his career. "I just can't get myself together!"

I utilize a biopsychosocial assessment during the intake session to assess the psychological, social, and cultural factors that impact Eddie. Eddie is from a middle-class background, in which his parents urged him to seek scholarship opportunities for college. Eddie is a white male who entered the Naval Academy after high school. Upon his graduation from the Naval Academy, he entered the pilot training program in the Navy and became a helicopter pilot. He has served as an active duty officer for five years and is currently on a tour of sea duty that is three years in duration. Eddie is 27 years old, identifies as Catholic, and is a Lieutenant (O-3) (Redmond et al., 2015) in the Navy. He is scheduled to leave for deployment onboard a ship in three weeks. He has been married for five years and has no children. He and his wife live off base. He states no family history of mental illness or substance use. Eddie reports this is the first time he has experienced a significant death in his life. Eddie reports that there are some negative aspects of the military, but overall, he enjoys his occupation and lifestyle.

Literature Review

The military as a social institution has a distinct culture, and within the larger culture, subcultures are based on an individual's affiliation with a specific branch of the military, such as the Navy, Air Force, or Army, etc. (Branson, 2017). In April 2019, the Navy reported a total force of 332, 507 active duty members and 101, 018 reserve members (www.navy.mil). Men and women who are part of the Navy are involved in various careers that include aviation, navy seals, search and rescue, medical, cryptology, meteorology, navigation, explosive ordinance disposal, etc. (www.navy.mil). A unique aspect of the Navy is the sailor's experience with "shipboard life" during their sea tour, which they rotate with a shore tour (Wilcove, Schwerin, & Kline, 2009, p. 446). During a sea tour a sailor typically leaves for a six-month deployment on board a US Fleet ship or submarine, and is forward deployed to strategic locations around the globe.

Redmond et al. (2015) summarized the structure and culture of the US military for those who may not have an understanding of that culture. Service members learn military cultural norms during their indoctrination training, which teaches military personnel how to think, communicate, and interact with each other. Individual thinking transforms from individualist to collectivist thinking that focuses on completing the mission. Service members learn a new communication style, which emphasizes professionalism in greetings (e.g., using *sir* or *ma'am*), and common military terms and acronyms (e.g., *galley* means *dining room*; *O-6* stands for *Captain*) (Redmond et al., 2015). Additionally, service members learn new ways of interacting, in which salutes replace handshakes. Rules of interaction focus on following a chain of command and maintaining professional relationships with coworkers.

Within the military culture, a member's social status depends on the subculture with which they identify. Subcultures include differences common to many groups of people such as gender, sexual orientation, social class, race, ethnicity, and age, but there are additional subcultures in the military (Branson, 2017). Each service branch has a distinct culture, and rivalries exist between services, as evidenced in

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the annual Army vs. Navy football game. An individual's rank identifies him or her as part of another subculture, comprised of officers or enlisted personnel (Gleeson & Hammer, 2014). Additional subcultures exist based on an individual's job duty assignment, for example, pilots, sailors, shipmates, and "grunts" (Redmond et al., 2015). Aspects of military culture common to most service members include a lack of control over assignments and deployment dates, exposure to combat or life-threatening situations, lack of sleep or rest during operations, and high expectations for performance (Branson, 2017).

An example of a specific subculture in the US Navy is the aviation component. Aviation service men and women deploy on the same ship as sailors, though identify as aviators and maintain a distinct identity from their shipboard peers. Movies such as *Top* Gun depict a culture of aviators with attitude who participate in dangerous operations (Simpson, Bruckheimer, & Scott, 1986). The risks inherent in the aviation duty assignment are discussed often. Aircraft mishaps are due to either mechanical or human error, with aircrew/human error explaining the majority of mishaps (Alkov & Gaynor, 1991). During deployment aviation missions occur primarily at night, causing fatigue and stress which can lead to degraded pilot performance (Neri & Sheppell, 1994). The Navy spends a considerable amount of time emphasizing aircrew coordination training in which pilots monitor each other for signs of work overload and stress, and readily admit the psychological or physical stressors that can impact an individual's ability to complete a mission (Alkov & Gaynor, 1991).

Military culture also impacts the families of service members. Often a military spouse hierarchy develops based on the rank of the active duty spouse (Redmond et al., 2015). The family might live in a certain geographic location based on the service member's current duty assignment (Russo & Fallon, 2015). Other cultural differences include whether the family lives on or off base, whether they utilize health care at a base or civilian medical facility, and what school the child attends (DeGraff, O'Neal, & Mancini, 2016). When they become adults, some military children refer to themselves as *military brats* to summarize their frequent relocation and inability to call one place home (Wertsch, 1991).

A unique aspect of military culture is the deployment cycle and how it impacts service members and their families (Redmond et al., 2015). The five stages of the deployment cycle include predeployment, deployment, sustainment, redeployment, and postdeployment (Pincus, House, Christenson, & Adler, 2007). Hicks, Lenard, and Brendle (2016) described each of these five stages of deployment in their research with military families. During predeployment, service members work long hours in preparation for leaving and experience tension and anxiety about leaving. The deployment phase occurs during the first month of separation and is characterized by feelings of anger, frustration, grief, and loneliness. During the deployment stage, the service member and family adjust to life without the service member present. The redeployment stage is filled with anticipation and expectations about the return home, and sometimes frustration due to high expectations of a positive return. In the last stage, postdeployment, emotional needs must be reconsidered as the service member reintegrates into civilian culture.

The values of military culture are summarized as a warrior mentality and extend into every aspect of a military member's life (Redomond et al., 2015). Military culture values physical and mental strength (O'Brien, Keith, & Shoemaker, 2015). Service members learn to adapt and overcome challenging situations and to think from a collectivist perspective that emphasizes group cohesion (Branson, 2017; Canfield & Weiss, 2015). "Obedience, discipline, self-sacrifice, trust, and courage" are key military values (Redmond et al., 2015, p. 14). Values such as mental toughness and self-reliance help service members tolerate difficulties and emotional distress. Individuals with problems are perceived as weak and may be rejected or viewed as a liability to completing the mission (Bryan, 2016).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Castro, Kintzle, & Hassan (2015) compiled a list of common thoughts, emotions, and behaviors of combat veterans from discussions with veterans or counselors. Thoughts include being proud of one's service, and "people will think I am weak if I ask for help…showing emotions is a sign of weakness" (Castro et al., 2015, p. 301). Emotions include being angry, sad, happy to be alive, and lonely. Common behaviors include not being able to sleep, constantly feeling on edge, and not being able to calm down. The authors recommended increasing service members' self-awareness of their thoughts, emotions, and behaviors so they can recognize when they might need the assistance of a mental health practitioner.

Many of the cultural values listed above are protective factors, however, they can also be risk factors for a service member's mental health. Mental toughness and self-reliance can lead to avoiding problems, not asking for help when it is needed, and rejecting social support (Bryan, 2016). Service members who discuss problems instead of solutions may be seen as unmotivated or complaining, and subsequently may be rejected by peers. Additionally, a social dominance orientation exists within the military, in which members of the dominant group stigmatize members of the out-group if they do not conform to the dominant mentality (Johnson, Rosenstein, Buhrke, & Haldeman, 2013). Many service members will not voluntarily seek counseling and will only attend counseling if ordered by their command or given an ultimatum by a family member (Canfield & Weiss, 2015).

Additional barriers to seeking mental health treatment for soldiers are: shortcomings in a counselors' understanding of military culture, career concerns, mental health concerns, and evaluation of mental health issues (Eckart & Dufrene, 2015). Service members become frustrated at having to explain basic aspects of the culture to therapists who have little knowledge of military culture. Service members are concerned that seeking mental health treatment might negatively impact their careers, in terms of duty assignments, confidentiality, and promotions. Concerns about mental health include a stigma against receiving help. Finally, mental health issues are often assessed incorrectly or inaccurately, so that those who seek help do not receive the treatment they need (Zinzow et al., 2013).

To effectively help clients that are service members, counselors need to understand military culture, subcultures, social norms, and values. A therapist can better understand a client's worldview by considering military service as an extension of an individual's identity (Strom et al., 2012). Strom et al. pointed out that a counselor's direct experience serving in the military would enhance cultural competence with clients. In a study assessing 89 health care providers for military cultural competence, the authors found that participants with military exposure had increased knowledge of military culture compared to participants with no military exposure (Meyer, Hall-Clark, Hamaoka, & Peterson, 2015). However, the authors warned that a counselor may also make false assumptions about a client when a counselor's culture is similar to a client's culture.

Other considerations for counseling military members center on the member's schedule. Once a service member enters counseling, it is important to consider interventions the service member can use while on deployment or during extended periods away from the counselor. These interventions might include journaling, books, teleconferencing, email contact, and long-term homework (Eckart & Dufrene, 2015). Other counselors implement *smart books* (Bryan, 2016, p. 167), small notepads that allow a service member to write down coping statements or lessons from therapy and carry them discreetly in a uniform. A therapist should continually modify and adapt treatment approaches to meet the needs of each client.

INTRODUCTION TO THE COUNSELOR

Cultural Background

My background includes growing up as a white female in U.S. culture and serving as an officer in the U.S. military. I am the middle child in a single-parent family raised in the Midwest. I received a Reserve Officer Training Corps (ROTC) scholarship to attend college and upon graduation was required to enter the military. Because I had a college degree, I entered the military as an officer, where I completed nine years of active duty service, four years of select reserve duty, and currently serve in an inactive reserve status. My husband is an active duty service member who currently resides in a separate geographic location from me and my daughter, because of his duty assignment and our future plans upon his retirement.

Being an aviator in the Navy opened my eyes widely to the privilege and oppression that exist in the United States of America and other parts of the world. In 2001, when I entered the military, restrictions placed on females precluded them from participating in combat operations, some job duty assignments (e.g., being assigned to a submarine), and some military occupational specialties (MOS). In January of 2013, the Department of Defense rescinded the direct combat exclusion rule that had been in place since 1994 (Segal, Smith, Segal, & Canuso, 2016). There were few females in the pilot training program, and an immense amount of pressure to meet the program's high expectations was both physically and mentally demanding.

I had the privilege of being an officer, but I also experienced oppressive acts such as sexual harassment and gender bias. During my first deployment in 2004, my assigned ship had recently become integrated, meaning females were allowed. At that time, females were only present in the officer ranks, and I was one of three females on the entire ship. On my second deployment, I was the only female in my helicopter detachment of 35 personnel, though there were other females present on that ship.

Visiting other countries while in the Navy, I realized the privilege that Americans have, even as one of a few females present. In Oman, American females were told they needed to have their heads and knees covered before going out in the town. In other countries, such as India, women sat backward on scooters, holding their babies while males zoomed down the street. I was shocked to see the sacrifice some individuals would make to find more privilege in life when we rescued boatloads of migrants trying to go to America with nothing but oranges and the clothes they were wearing. Most of them were women and children. Even as I conducted rescue operations during Hurricane Katrina, I saw the privilege and oppression that is present in US society.

Counseling Approach

My approach to counseling is first to form a therapeutic alliance with the client. Using a feminist approach, I form a therapeutic relationship that is egalitarian and addresses any imbalances, i.e., between the therapist as expert and the client (Otting & Prosek, 2016). Sessions start by asking the client, "how would you like to use your time today?" Intake sessions usually begin by asking clients if they can tell me a little bit about what brought them in. My theoretical orientation is solution-focused, so I focus on what the client is experiencing, how they are experiencing it, and what they would like the future to look like when the problem is no longer present (Froerer & Connie, 2016). During intake sessions, I will ask clients to "tell me more about that" if I need clarification. I want to know and understand clients' worldviews so I can empathize with them.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

My perspective that a session should be about the client's needs limits my level of self-disclosure with firm boundaries. I have received feedback that I can be very direct, yet still empathic. I believe some of these characteristics come from my military background. I learned a lot about boundaries through the division of officers and enlisted personnel. From my experience, it is easier to keep those boundaries if there is less self-disclosure. As a counselor and counselor educator, I begin a relationship with firm boundaries and limited self-disclosure, and those things can be relaxed at a later time if needed. Some clients ask about the military pictures in my office, and I answer by objectively telling them what I did in my previous career. The majority of clients who ask also have a military background or experience with someone in the military. In the case of Eddie, I feel it is important to disclose my military background as a way to let him know that I understand military culture, yet I also recognize that his worldview and experience in the military is different from mine.

CASE CONCEPTUALIZATION

The next section of this chapter focuses on case conceptualization of Eddie. Symptoms and presenting problems are used in case conceptualization to formulate a treatment plan. The symptoms the client describes and I observe are crying, trouble sleeping, trouble eating, and increased use of alcohol. The problems are grief and problems related to deployment. Thus, goals focus on decreasing symptoms and formulating solutions to the problems. At this time, Eddie appears to present with normal bereavement, though if his symptoms worsen, that may be changed to adjustment disorder (American Psychiatric Association, 2013).

Theory

When working with the military population, it is important for counselors to consider the amount of time they will have with a client to implement interventions and for clients to begin the process of change. Solution-focused therapy is a brief therapy with a concentration on client strengths, what the client would like to happen in the future, how things will be different when the problem no longer exists, and solution-oriented talk that does not focus on the problem (Seponski, 2016). Solution-focused brief therapy (SFBT) is collaborative, as the therapist believes the client has the solutions for his or her problem. Criticism of SFBT includes the theory being too simplistic and dismissive of client problems (Froerer & Connie, 2016).

In SFBT, interventions seek to increase client awareness and maintain a present and future focus. Solutions always come before the problems (De Shazer, 1988). For Eddie, the solution is to overcome his grief and join his squadron on deployment. If something is not working, the client is encouraged to try something different. Any time the client thinks about a past moment, it is to determine an exception when the problem was not present or when the client reacted differently (Cepeda & Davenport, 2006). The therapist focuses on what is working for the client. I want to ask about what is working, what has worked, and what might work. Acknowledging exceptions allows a client to recognize previous success in a given problem area and that solutions exist for a given problem. SFBT holds that small changes can lead to more significant changes. For Eddie, a small change in the impact of his grief will lead to more of his feelings changing related to the loss he recently experienced. As will be discussed later, Eddie acknowledges that not talking to his command about his grief is not helping him. Therapists emphasize

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that problems are caused by life transitions and do not indicate pathology. Considering the stigma against mental health treatment in the military (Eckart & Dufrene, 2015), it is important to normalize Eddie's experience of grief.

Therapists help clients achieve small changes by asking scaling questions (De Jong & Berg, 2013). When asking scaling questions Eddie can be asked how he rates his experience of grief (6 or 7), and what would need to happen for that to be a 5 instead. The *miracle question* is used to talk with clients about how things will be different when the problem no longer exists (Strong & Pyle, 2009). Conversation about the miracle question focuses on action and perceptions that help the client begin to create the solution to his or her problem, emphasizes behavioral descriptions of what that will look like (De Jong & Berg, 2013). I ask Eddie to describe how he will know he is no longer grieving his friend, what will be different, and how will he feel.

De Jong and Berg (2013) introduced a staged approach to forming solutions in SFBT. The stages are describing the problem, developing goals, finding exceptions, feedback, and evaluating client progress. These stages focus on the future and empower the client to resolve the problem. The language used in SFBT focuses on solution talk as opposed to problem talk. Thus, increased solution talk indicates progress in a client. Clients may shift their language from helplessness to taking control and becoming empowered to change things. Eddie can recognize areas in his life where he does have control in his life and can be empowered to make different choices, such as choosing to cope with alcohol or not. Compliments are given to the client on his or her progress toward a goal (De Jong & Berg, 2013). When a client is asked a scaling question, a change in number is another indication of progress. The stages of SFBT serve as a framework for the counseling session.

Multicultural and Social Justice Counseling Competencies (MSJCC)

Counselor/Client Intersectionality

Ratts et al. (2016) depicted a framework that indicates the privileged and oppressive statuses of counselor and client. When counseling Eddie, the quadrant that summarizes the therapeutic relationship is that of marginalized counselor–privileged client, given a male client receiving counseling from a female counselor. However, this interaction represents a snapshot in time, and it is possible for the counselor and client to consider themselves in more than one quadrant throughout the counseling session. For example, when discussing the military, both myself and Eddie experience privileged status due to our identities as officers, although a gender difference remains.

Developmental Domains and Competencies

The developmental domains in the MSJCC are: counselor self-awareness, client worldview, the therapeutic relationship, and counseling and advocacy interventions. Competencies within these domains are: attitudes and beliefs, knowledge, skills, and action (Ratts et al., 2016). By applying these domains and competencies, counselors are committing to a multicultural practice that includes the action of social justice when considering interventions for clients.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Counselor Self-Awareness

When working with Eddie, I must first consider my own attitudes, beliefs, and biases. I can examine my beliefs about being an individual who previously served in the military and the privilege of being an officer. I can also examine my beliefs about the oppression that occurred in the military due to my status as a female. When counseling Eddie, it is important for me to be aware of any feelings I have about the privilege white male officers experience. I can then explore how these beliefs impact my worldview. I acknowledge that other members of the military will have a different perspective than my own. In regard to action, I have spent a considerable amount of time immersed in military culture. I can be aware of how my military experience impacts my communication and how I talk with Eddie about his experience. *Counseling Military Families: What Mental Health Professionals Need to Know* (Hall, 2008) is a book I use a resource to separate my experiences in the military from the experience of my clients, and to review approaches to working with military members.

Client Worldview

To understand the client's worldview, I can understand the privilege and oppression the client experiences and how those experiences shape the client's attitudes and beliefs. Eddie is experiencing oppression for several reasons related to military culture. First, senior individuals in command make decisions that impact Eddie without his input, such as the decision to resume normal operations. Second, he is experiencing concerns about his career if he does not go on deployment. He has a loss of control over when he can leave on deployment and how that will impact his career, thus feels oppression. Additionally, he does not want anyone in the military to know that he is going to counseling, suggesting a stigma against mental health issues oppressing individuals who experience them.

To gain knowledge about Eddie's worldview, I can review research on mental health stigma in the military, and how career and confidentiality concerns may impact a client's decision to seek counseling (Eckart & Dufrene, 2015). I can use critical thinking and analysis to understand the oppressive force of power in the military and those senior to Eddie, and how that power impacts the client. The oppression this client feels contributes to his problems in several ways. First, the client is not reaching out to his military community for support but is coping by self-medicating with alcohol instead. Additionally, Eddie is not discussing his problems and loss with his command, so they are not aware of how much these events have impacted him. They are also not aware of his career concerns. If he discusses these concerns with them, there may be more solutions to choose from that will still allow him to meet his goals.

To better understand Eddie's worldview, I can stay current with the literature on counseling the military population. Prosek et al. (2018) developed competencies for counseling military populations that "offer a framework and foundational principles and practice for working with military-connected clients" (p. 88). These competencies are based on research and are considerations for counselors working with military clients.

Counseling Relationship

Counselor self-awareness and knowledge of the client's worldview can help me determine how the privileged and marginalized statuses of both Eddie and myself impact the therapeutic relationship. Thus, I ask the client things such as "tell me what being in the squadron is like for you" or "tell me what it would

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

be like to tell a senior officer your concerns about leaving for deployment." For example, one way in which the marginalized status of myself in the military could impact the counseling relationship is in a situation where I use therapeutic confrontation. I might not use therapeutic confrontation because of my experiences with males in the military. In order to manage this I can be aware of my attitudes and beliefs about confronting a client in the military and rely on the knowledge and skills I have used when working with other clients. Ratts et al. (2016) suggest counselors know when it is appropriate to discuss topics such as power and stereotypes. In the case of Eddie, one way to manage the privilege and oppression present in the therapeutic alliance is to acknowledge that Eddie and I had similar experiences in the military yet that differences also exist.

In terms of action, I can participate in continuing education that focuses on being accepting of clients. When working with Eddie, this means accepting his wish to maintain confidentiality due to the stigma about mental health. I can also collaborate with colleagues when I feel I am not remaining objective or accepting of the client's choices (Sheperis & Sheperis, 2015).

Counseling and Advocacy Interventions

Once I gain self-awareness about working with Eddie, acknowledge Eddie's worldview, and discuss power, privilege, and oppression as they impact the therapeutic relationship, I can suggest appropriate interventions that promote social justice. In this case, Eddie has three weeks before leaving on deployment. SFBT is an appropriate counseling theory to use, as well as interventions that can be completed during deployment, such as books, email contact, journaling, and teleconferences (Eckart & Dufrene, 2015). Advocacy interventions for Eddie focus on the oppression Eddie is experiencing and how that is impacting his ability to formulate realistic solutions. I might try to help Eddie reflect on his thoughts about leaving for deployment and what is hindering him from telling his senior officers about his concerns. I can also discuss how military culture might support Eddie during this time and influence his well-being, as the military family takes care of its members. It is appropriate for myself and Eddie to discuss goals in terms of how he can advocate for himself so that the military can give him some of the support he needs.

Competencies for Counseling Military Populations

In 2016, the Military and Government Counseling Association appointed a task force to develop the Competencies for Counseling Military Populations (CCMP). "The intention of the CCMP is to provide a research-based set of guidelines that represent military considerations through the lens of a counselor professional identity" (Prosek et al., 2018, p. 88). Seven core competencies serve as the framework for the CCMP: military culture, ethics, system features, assessment of presenting concerns, identity development, treatment, and advocacy. These fall within the MSJCC competencies as seen in Table 1.

Military Culture

"Military culture represents general information about the functioning and worldview of military service members and their families" (Prosek et al., 2018, p. 88). Specifically, in this component counselors are "aware that differences in experiences may exist between Veterans who previously served and Service members/Veterans who currently serve, as well as Veterans who served in different areas" (p. 88). In

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Eddie's case, it is important for me to recognize that my military experiences occurred almost ten years before counseling Eddie and may have been very different from his experiences. Additionally, counselors should be aware of differing worldviews between civilians and military members. I am currently in civilian employment outside the military, so I will naturally have a different current worldview than my client.

Table 1. Alignment of CCMP competencies within the MSJCC competencies (Prosek et al., 2018; Ratts et al., 2016)

Attitudes and Beliefs	Knowledge	Skills	Action
Ethics	Military Culture	Assessment of Presenting Concerns	Advocacy
	Identity Development	Treatment	
	Systems		

Identity Development

The identity development component "represents the whole person concept of military life including one's personal identity as a Service member and connection to mission and core values of working as a military Service member across the lifespan" (Prosek et al., 2018, p. 89). In counseling Eddie, I start to understand how Eddie's sense of self relates to his occupational role and how his military rank influences his sense of self. Additionally, he may tie his career progression to his identity. Therefore, concerns about his mental health status impacting his career might ultimately affect his sense of self.

Systems

The systems component "represents general information about how Service members' families, spouses, and children experience the nature and structure of the military lifestyle" (Prosek et al., 2018, p. 90). It includes deployment, long periods of separation, and consequences of injury. When counseling Eddie, I want to acknowledge the stress of leaving for deployment and how it impacts the client. I also consider the emotional demands of the military and the impact of a high-risk occupation on the individual and family members. I consider Eddie's sources of support, such as marital and family support. Additionally, with Eddie's concerns about leaving for deployment, it is important to consider how his absence will impact his family system. From an SFBT perspective, the client discusses how the family system has handled past deployments and what solutions the family will implement while he is away.

Assessment of Presenting Concerns

The next component lists common clinical concerns of military members seeking counseling services. The list includes military stigma against seeking mental health treatment, as well as TBIs, PTSD, secondary and vicarious trauma, substance use, suicidality, and military sexual trauma (Prosek et al., 2018). Since Eddie expresses concern about stigma against mental health, making it difficult for him to talk with his command about his recent loss, I can advocate for him by discussing how important it is for him to seek

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

mental health treatment and work toward addressing that stigma. Eddie also admits to increased alcohol use. Heavy drinking is often normalized within the military, therefore an individual might not recognize a substance use problem (Fuehrlein et al., 2016).

Treatment

The treatment component addresses unique concerns when treating military members, as well as research-based approaches to treatment and best practices. I understand how military care systems work and what services they may offer its members (Prosek et al., 2018), such as adjunctive services including talking with a chaplain, utilizing peer support, or incorporating physical therapy. I can help Eddie develop coping skills and continually assess social support and substance use. I determine Eddie's social support, including support from his command, and discuss his increased alcohol use and develop alternative coping strategies as well.

Ethics

The ethics component describes ethical considerations for counselors working with military members as well as counselors reflecting on their motivation to work with this population (Prosek et al., 2018). The task force recommends that counselors receive experiential training in working with military clients and learn the legal requirements for documentation and disclosure of records. Additionally, counselors who also identify as military members should assess for countertransference. I decide to seek additional supervision/peer consultation while working with Eddie, due to the possibility of countertransference. This section also discusses considering a community referral for military members if needed. In this case, Eddie felt more comfortable with a community counselor, so it is important that I maintain the confidentiality Eddie is requesting.

Advocacy

Finally, the advocacy component addresses "counselors' ability to understand and influence individual, system, and public policy efforts to increase access to mental health resources for military-connected clients and promote the role of counseling professionals working with military populations" (Prosek et al., 2018, p. 93). Counselors can advocate for approaches that use a wellness model and are strengths-based. Counselors support decreasing mental health stigma within the military and actively assist service members in self-advocacy strategies. Eddie feels self-advocacy is best in consideration of whether he is able to leave for deployment or not. Once Eddie has made this decision, I can help him advocate for himself to his command.

TREATMENT

Goals

In SFBT the counselor and client collaborate on treatment goals so the client can determine the best solutions for the problem. When formulating goals with Eddie, it is important to remember that he only

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

has three weeks before leaving on deployment. Therefore, goals need to be short-term. I ask what the future will be like when the problem is no longer present, and Eddie expects that he will no longer be so reactive to the tragic death of his friend. Therefore, the first goal is to process the feelings of grief and loss that are present. The second goal is to address Eddie's feelings about the upcoming deployment and advocate for the best solution with one member in his command in the next two weeks. The third goal is for Eddie to recognize how military culture affects how he is experiencing his problems and to list more effective coping skills. I use solution-talk and a future focus when communicating with Eddie about meeting these goals (Froerer & Connie, 2016).

Goal 1: Processing Grief

I choose to use psychoeducation to help Eddie process his feelings of grief and loss. Kubler-Ross proposed a grief model with five stages: denial, anger, bargaining, depression, and acceptance (Sheperis & Sheperis, 2015). Sharing this model with Eddie can help normalize some of the feelings he is currently experiencing and give him hope about the future stage of acceptance.

Worden (2008) emphasized that the space provided in counseling for processing bereavement is more important than an intervention. In many other areas of life, the client may be trying to hold it together to avoid being too emotional, trying to act a certain way, or trying to hide feelings. Eddie states that he has tried to do his best at work, but often when he gets into his car for lunch, he is overwhelmed and begins sobbing at the loss of his friend. He recognizes that by not talking to others in his command about how he is feeling, he is trying to hide his feelings. He wants to maintain the perception that he can handle this and still go on deployment so it will not impact his career. Eddie and I talk about the stages of grief, and Eddie views himself as currently being in the denial stage and at times the anger stages. I recommend that Eddie read *On Death and Dying* (Kubler-Ross, 1970) while he is on deployment and journal about his feelings to continue processing his grief while he is not attending bi-weekly counseling sessions.

Goal 2: Individual Advocacy

The stated goal is for Eddie to decide what is best for him in terms of leaving for deployment and then advocate for himself by discussing this with a senior member of his command. Scaling questions can be very insightful while discussing this goal. When asked how ready he feels to leave for deployment on a scale of one to ten, with one being not ready and ten being ready to leave tomorrow, Eddie states he is currently at a five. When asked what would need to happen to change that number to five and a half, Eddie states he wishes he had more time and is afraid that if he does not leave on time, it might impact his career.

I then ask Eddie for exceptions: "Does everyone always make the whole deployment?" and, "Are there any penalties for those that do not?" Eddie remembers that two pilots split a previous deployment and were still able to accrue enough flight hours to qualify as an aircraft commander or otherwise avoid impacting their careers. Eddie states that he has been planning for this deployment and would like to be a part of it, but he feels that he needs more time to prepare since this tragedy happened. He states that he feels the best solution would be to meet his squadron on deployment two to four weeks later than the scheduled date.

After identifying this solution, the next step is to discuss is how Eddie can advocate for himself. I ask Eddie if he has ever felt comfortable talking with anyone in the command about something like this.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Eddie identifies his department head as such a person and decides to ask his department head if he can join the squadron two to four weeks into the deployment because he is having some difficulty dealing with the mishap and needs a little more time to "get his head on straight" before he flies an aircraft overseas. Eddie and I also discuss how it is important for Eddie to discuss his career concerns and ask his department head how leaving late for deployment might impact his career. Eddie decides that he will do this before his next session.

Goal 3: Awareness of Military Culture

In this goal, I help Eddie explore how military culture might be hurting or helping with his current problem, including military cultural norms related to confidentiality and mental health stigma. He describes an environment in which service members handle their own problems and are mocked if they do not meet standards or act tough. He wishes he could be more courageous in managing his feelings about the mishap and that he could talk to others, but he does not want others to view him as too weak. The inability to do a job is a sign of weakness; asking for more time could be interpreted as not being part of the team.

I also discuss how military culture is helping Eddie with this problem and focus on his strengths. We discuss how other military members might be supportive of Eddie and help him get through this time as a team, despite his fears of being seen as weak. One of Eddie's strengths is the courage to seek help and to speak with his department head about leaving later for deployment. It also takes courage to recognize that it might not be safe to perform his job and to admit he fears retribution on his career. In many ways, Eddie is adapting to the situation and managing it. We also discuss self-reliance and how there are times in the military when one does need to talk with someone else.

Finally, I discuss Eddie's increase in alcohol use. Eddie states that he usually drinks at the end of the day when he is alone. I am aware that military culture promotes drinking, and alcohol misuse can be problematic (Ijamanta & Lasebikan, 2016). Alcohol use in military aviators is associated with an increased risk for safety (Gates, Duffy, Moore, Howell, & McDonald, 2007). For this reason, I decide to use the Alcohol Use Disorders Identification Test (AUDIT), to gather information on the quantity and frequency of alcohol consumption (Stevens & Smith, 2018). Eddie reports drinking every day since the mishap, and usually has three to four drinks, although occasionally he consumes more than that. Stevens and Smith (2018) recommend counselors utilize psychoeducation on the effects of alcohol which includes poor judgement, endangering self or others, and negative effects on cognitive functioning. Eddie and I identify some people that Eddie can reach out to for support during these times. We also talk about journaling and reminding himself about good times he shared with his friend. Eddie is able to identify that feeling alone is a trigger for his drinking, so we discuss alternative activities for his leisure time. Eddie mentions that he could also go running or watch a movie to keep his mind off being left alone without his friend. He also recognizes that it is important to spend time with his wife prior to leaving for deployment. I also talk with Eddie about the possibility of attending an Alcoholics Anonymous (AA) meeting. He does not wish to pursue an AA meeting at this time, but I do provide him a list of meeting times and locations.

Progress

Goal 1: Processing Grief

One measure of Eddie's progress is to look at his symptoms. During the intake session, Eddie reported having trouble sleeping and eating and also feelings of anger toward his squadron. As therapy continues, Eddie's physiological responses will hopefully subside so that he will be able to sleep and eat better and therefore will be able to meet some of his basic needs. Maslow (1954) proposed a hierarchy in which basic physiological needs (e.g., shelter, food) must be met before one can move up the hierarchy to safety and security, belongingness, esteem, and self-actualization. An individual is at a higher level of mental health when the basic needs are met.

Another measure of progress is forward movement through the stages of grief. However, this may be a long-term process, and it is common for clients to move forward and then revert to a previous stage (Sheperis & Sheperis, 2015). Journaling is an effective way to track the stages of grief.

Goal 2: Individual Advocacy

Progress on this goal depends on Eddie following through with his decision to talk with his department head about the possibility of leaving for deployment at a later time. Improved responses to the scaling question of how ready Eddie feels to leave on deployment also indicate progress. Eddie stated he is currently at a five. As the deployment approaches, I would expect this number to go up. If it does not, Eddie and I can discuss what is stopping him from being ready for deployment. We may need to reconsider the solution and try an alternative. In SFBT, if something is not working, it is time to try something else (Froerer & Connie, 2016).

Goal 3: Awareness of Military Culture

Progress in this goal is indicated by Eddie's awareness of how he is feeling and where those thoughts and values originate. Keeping a feelings journal should be very effective, in which Eddie writes down his feelings, reflects on the events that precipitated those feelings, and reflects on any cultural values that might influence how he is feeling. In this way, Eddie can separate his feelings from cultural factors that might be influencing them. He can learn to honor his feelings and recognize when he might be placing judgment on those feelings. Eddie can understand that military culture has some excellent values but also has some values and behaviors that are maladaptive. In this way, Eddie can begin to advocate for himself, allow for his feelings, and realize mental health issues need not be stigmatized. Progress on this goal would also be indicated by a decrease in the frequency and amount of alcohol consumed, and utilizing the alternative coping strategies that were discussed.

CONCLUSION

Ratts et al. (2016) discussed the importance for counselors to reflect on the intersecting identities of the counselor and client and how that impacts the process of therapy. This chapter specifically focuses on the intersecting identities of current and former members of the military. Military culture can serve

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

as a protective factor for military members, but it may also be a risk factor in terms of mental health (Bryan, 2016). The Competencies for Counseling Military Populations (CCMP) serve as a framework for counseling military clients (Prosek et al., 2018), and these competencies fall within the MSJCC and can help counselors reflect on the intersecting identities of counselor and client (Ratts et al., 2016). A case study illustrates the practical application of the CCMP and MSJCC.

Chapter 47
Organizational Prevention and Intervention Services:
Beyond the Early Intervention System

Jennifer Kelly
Independent Researcher, Haddonfield, USA

William D. Walsh
Voorhees Police Department, USA

ABSTRACT

Improving the opportunities for enhanced health and wellness in first responders has gained national attention in recent years. Employers and other stakeholders striving to improve employee utilization of available resources will need to increase transparency in the process and improve understanding between first responders and clinicians. One potential process, early warning systems (EWS) are primarily designed to alert management to an at-risk employee. However, the continuing goal of any effort should be to identify and remedy any employee issue before the employee exhibits the predetermined number of events that trigger an early warning alert. Although many organizations are adopting an EWS by either choice or mandate, they are largely separate and distinct from the agency's health and wellness programming. Administrators are not only unsure of what data to consider, but also what to do when an alert is activated. Ideally, agencies move toward early intervention systems that themselves are conceptualized within the larger framework of wellness programming.

ORGANIZATIONAL MENTAL HEALTH SERVICES

First responder organizations vary across disciplines, occupations, and jurisdictions in their handling of the health and wellness of employees. Prevention and response approaches may vary, even among different subdivisions or teams in the same organization. Standardizing prevention and intervention strategies for all first responders would be difficult, given differences in organizational cultures, geography, and individual experiences; however, basic elements of prevention and intervention programming

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

can remain consistent. For example, as a minimum, each organization's preventive measures should include resilience-building training for employees and their families, beginning before a first responder is deployed in the field, and training on improving mental and physical health in response to adversity and stress (Kelly & Hoban, 2016). Recent initiatives such as the President's Task Force on 21st Century Policing (COPS Office, 2015) and the Law Enforcement Mental Health and Wellness Act of 2017, have placed national attention on the need to make mental health a priority. As such, first responders require (a) continuing education, (b) stress management training including adaptive coping strategies throughout their careers, (c) early intervention systems (EISs) that focus on the whole employee (i.e., not just the behavior triggering an alert), (d) responses to early behavioral alerts that promote well-being, and (e) general intervention options to address mental health emergencies. Employee health and wellness and early warning/intervention systems should be designed with the employee, families, the organization, and the service population in mind.

Training and interventions developed to enhance the health and wellness of public safety employees should be evidence-based or at least integrate research findings. Those involved in the research, development, implementation, and assessment of employee health and wellness programs must be properly trained and vetted to ensure they will benefit employee and organizational health. They must also be able to deal with the sensitive nature and confidentiality requirements of this work. Attention must be paid to ensuring that intervention strategies listed in policies are operational, following the agency's plan, prior to any program rollout.

This chapter provides policy makers, researchers, administration and supervisory staff, and clinicians a framework to create policy that fosters prevention and intervention for mental health difficulties in first responders. It demonstrates the need for transparency and collaboration among stakeholders regarding prevention and intervention, discusses benefits of early alert systems, and presents examples of programming for first responders, not only as they begin their careers, but when they have experienced risk factors for impairment and for those exhibiting mental health difficulties.

EARLY WARNING SYSTEMS

Early Warning Systems (EWS) were originally created to detect and address problematic police officer conduct and enable intervention to correct it (Walker, Alpert, & Kenney, 2001). This concept was born out of the 1981 U.S. Commission of Civil Rights recommendation that police agencies create systems to identify "problem officers" that are frequently the subject of citizen complaints (DeCrescenzo, 2005). The original EWSs were designed primarily to alert management about at-risk employees (DeCrescenzo, 2005; Bertoia, 2008). EWSs are widely used in first responder organizations and are mandated in some locations (e.g., the authors' home state of New Jersey). Despite this, many stakeholders, both on the frontlines and in administrations, are still unsure what data to collect or how to respond appropriately.

Arguably, the original concept of an EWS should be reframed and redesigned more broadly to maintain healthy first responders and organizations, with indirect consequences that benefit their organizations and the communities they serve (Amendola & Davis, 2019). Collaboration with all stakeholders, including labor unions, administration, frontline personnel, and mental health professionals, would help to ensure EWSs are used as intended, to both prevent and address alerts, and not as a disciplinary tool. Union leaderships acknowledging the nonpunitive value of a properly administered EWS would promote

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

frontline personnel buy-in (DeCrescenzo, 2005). Any effort should continuously identify and remedy any employee issue before it triggers an early warning alert.

In 1999, at least 39 percent of county and local law enforcement organizations with service populations greater than 50,000 were using or working toward implementing an EWS (Walker et al., 2001). With increasing mandates to adopt such programs, it is safe to assume the agencies are increasing in number and more varied in size. EWS research has typically only measured the number of complaints against employees. It has been suggested that enhanced employee scrutiny could lead to reduced proactivity, which obviously could skew research (Macintyre, Prenzler, & Chapman, 2008). Formal exploration of the EWS' impact on the health and wellness of employees and the overall agency is needed. An EWS can serve as an additional layer of strategy to maintain a healthy and sound workforce. Little research addresses EWSs in public safety.

Weaknesses in the EWS

In the standard EWS, public safety agencies compile data and then wait until the number of events in a given period triggers an early warning alert for a supervisor to address a potential issue with an employee. Some EWSs are designed to treat the symptom and not the whole person, by offering limited interventions or lacking preventative strategies for employees. Underlying causes of symptoms that trigger EWS alerts are typically not explored or addressed, although doing so would help develop intervention strategies. A more proactive approach would benefit the organization as a whole by preventing, mitigating, or reducing the need to react to an early warning trigger.

Improving the EWS

Fortunately, public safety agency leaders and employees are increasingly acknowledging the need to help first responders cope with trauma and stress. The second author was personally affected by the suicides of two friends who were police officers in 2009 and has seen a quarter of his academy class leave police work since graduating from the police academy in 2004, due to injury, domestic violence, felony arrests, and drunk driving, while one member died of a heroin overdose (after being terminated). According to Chae and Boyle (2013), "at least five prominent themes emerged as content domains that were positively associated with police suicide: organizational stress, critical incident trauma, shift work and atypical work hours, relationship problems, and alcohol use and abuse" (p. 92). Along with bolstering support systems, a holistic approach to officer wellness will address, educate, and mitigate these factors. An EWS can help protect employees, since these stressors often present identifiable symptoms and patterns of conduct.

In addition to helping employees, public safety organizations must seek to prevent civil litigation, civil-rights violations, excessive force, accidents, workplace injury, negligence, suicides, substance use disorders, domestic violence, family crises, divorce, public relations crises, and employee turnover through resignations or terminations. An effective system must include education for employees, supervisors, and their families. So, the warning system concept evolved to offer interventions before more serious issues develop (Walker, 2003). A more holistic Early Intervention System (as opposed to an EWS) with comprehensive health and wellness programming embedded may reduce reliance upon formalized warning systems. According to Walker, Milligan, and Berke (2006), an employee's supervisor is the key to successful early interventions. The way the program is framed, and even its title, can positively

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

impact employee views toward it. Walker et al. (2006) elaborate upon the importance of using the proper terminology, along with the logic behind it:

It is important to get the terminology of EIS right. Supervisors must set the right tone from the beginning. When EISs first appeared about 25 years ago, they were usually called early warning systems. Many agencies still use that term, although it does not convey the right message. The word warning has a punitive, negative tone, implying that it is a precursor to discipline. The PERF (Police Executive Research Forum) study revealed that the best EIS emphasize assisting officers, not punishing them. These systems typically include a range of programs designed to help officers recognize and deal with their performance problems because, time and again, it was discovered that performance problems are rooted in stress and personal and family problems. As a result, the more positive term early intervention system is preferred. (Walker et al., 2006, p. 13)

CASE EXAMPLE: EWS MANDATE IN NEW JERSEY

New Jersey mandates EWSs in every law enforcement agency in the state. Although the directive is titled "Early Warning Systems," the explanation recommends that the EWS "assist officers through early intervention" (New Jersey Office of the Attorney General, 2018a). EWSs hold agencies accountable for their officers' ethical behavior and their wellness and ability to protect and serve their respective communities. The New Jersey Attorney General's Office provided the following explanation on the intention of the EWS in New Jersey:

Early warning systems are designed to monitor officer conduct using objective measures that indicate a potentially escalating risk of harm to the public, the agency, and/or the officer. They are intended to increase public safety and public confidence, while assisting officers through early intervention. . . .

Under Directive 2018-2, the following performance indicators are required to be included in all early warning systems:

1. *Internal affairs complaints against the officer, whether initiated by another officer or by a member of the public;*
2. *Civil actions filed against the officer;*
3. *Criminal investigations of or criminal complaints against the officer;*
4. *Any use of force by the officer that is formally determined or adjudicated (for example, by internal affairs or a grand jury) to have been excessive, unjustified, or unreasonable;*
5. *Domestic violence investigations in which the officer is an alleged subject;*
6. *An arrest of the officer, including on a driving under the influence charge;*
7. *Sexual harassment claims against the officer;*
8. *Vehicular collisions involving the officer that are formally determined to have been the fault of the officer;*
9. *A positive drug test by the officer;*
10. *Cases or arrests by the officer that are rejected or dismissed by a court;*
11. *Cases in which evidence obtained by an officer is suppressed by a court;*
12. *Insubordination by the officer;*
13. *Neglect of duty by the officer;*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

14. *Unexcused absences by the officer; and*
15. *Any other indicators, as determined by the agency's chief executive.*

(New Jersey Office of the Attorney General, 2018a)

New Jersey Attorney General Directive 2018-3 (2018b) offers more examples than most policies of potential remedial actions in response to an EWS alert. The list provided includes:

1. *Training or re-training*;
2. *Counseling*;
3. *Intensive supervision*;
4. *Fitness-for-duty examination*;
5. *Employee Assistance Program referral*; and
6. *Any other appropriate remedial or corrective action*.

(New Jersey Office of the Attorney General, 2018a, pp. 3–4)

In New Jersey, if an early warning alert is triggered based on the data maintained in the EWS, the officer's agency must notify the county prosecutor's office and provide all the data for review, including the intervention used in response to the alert. This mandate is designed for oversight, to ensure appropriate data collection and interventions in the agencies. In an investigation, the data could lead to adverse consequences for the organization or the employee, including remedial training, a change in employment status, and even an administrative or criminal investigation; agencies may face sanctions, audits, or increased oversight.

EIS BEST PRACTICES

Amedola and Davis (2019) offer an aspirational definition of EIS, which would provide employees with "resources and tools in order to prevent disciplinary action, and to promote officer safety, satisfaction and wellness." They also suggest going beyond the traditional data collection and evaluation followed by intervention, to include monitoring employees and supervisors. As they note, the EIS is designed to be "pre-disciplinary," which shows the primary objective must shift toward officer wellness, not reprimands.

According to Amedola and Davis (2019), this focus on pre-disciplinary interventions means a system should consider indicators beyond those that directly lead to discipline, such as excessive force complaints. An EIS that considers an employees' need for additional knowledge or training, life changes, personal problems, and mental health difficulties, might include indicators such as tardiness, risk-taking behavior, damage to vehicles, complaints by peers, and excessive overtime (indicating potential family or financial difficulties), etc. Best practices warrant thresholds relevant to each employee's position with potential variations depending on the unit, shift, etc. Absolute and comparative approaches to defining thresholds may more accurately reflect an individual employee's difficulties than a simple threshold of occurrences. This may include officers who are subthreshold across several categories of alert or ones who are approaching an alert threshold (Jackson et al., 2016). Reviewing the context of each alert to potentially rule out concern based on prior knowledge about the officer or unit could reduce false positive results. An EIS policy needs clear performance standards and thresholds in order to determine what training is necessary. Responses to alerts should be recorded, including detailed descriptions of the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

interventions taken and their outcomes. Maintaining historical data is likely to prove useful, not only for quality assurance of the system, but to monitor the success of the intervention as well as the performance of supervisors (Amendola & Davis, 2019).

Perceptions, Misconceptions, and the Need for Transparency

Some government organizations have taken the increased call for transparency in government to heart by publishing online their rules and regulations, reports on use-of-force data, and even body-worn-camera footage. However, government leaders tend to miss the importance of transparency within the organization, particularly in mental health.

Too much mystery and paranoia still surround mental health professionals and their role with first responders in our culture. The only interaction some first responders may have with a mental health professional is during their pre-employment psychological screening. They then spend roughly 25 years of their career trying to avoid being "on the couch" again. The reason? The only thing they know about coworkers going to see "the shrink" is that it never ends well for the employee, which is often a misconception. The first responder community sees fitness-for-duty examinations as career-ending events (Schlosser & Kudrick, Jr., 2019). The perception is that even if the person is cleared to return to duty, they are not promotable, nor will they be considered for any special assignments. Sadly, the same perception holds true for first responders who realize on their own, without an organizational intervention that they should talk with a mental health professional. The employees who do seek help will often do so by paying cash out of pocket and will proceed to their appointments with a cloak-and-dagger approach. Employees do not want the stigma of perceived weakness for speaking with a mental health professional or a diagnosis to follow them around for the rest of their careers.

Public safety personnel experience uncertainty, anxiety, or even fear of mental health professionals and the potential for a diagnosis due to health care coding requirements mandated for mental health clinicians. In consultation with mental health and human resource professionals, leaders of public safety organizations must work together to demystify the preconceived notions prevalent in the first responder community. This attention to internal transparency could send a positive message to agency members regarding the importance of employee health and wellness.

Bridging the Gap Between Employees and Wellness Services

More open dialogue and opportunities to embed the clinician in public safety activities can bridge the gap between first responders, administrations, and mental health clinicians. Some examples include mental health clinicians speaking at in-service training sessions, multidisciplinary police mental health working groups, and mental health professionals participating in ride-along programs with frontline and supervisory personnel. Integrating the mental health professional in this manner will provide an understanding of the culture of the organization the clinician is servicing, common sources of distress and anxiety among employees and their families, and perhaps ways the organization can reduce distress for their employees, all while taking care not to breach confidentiality. Once a person perceives a betrayal of trust, regaining that trust is typically difficult. Opportunities such as the examples listed above would enable first responders to get to know mental health professionals and perhaps break preconceived notions regarding those who choose to serve others through the practice of counseling and psychotherapy.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Standardized Training

In the absence of a closer relationship between first responder agencies and certified mental health clinicians, other (often well-meaning) people or organizations will fill that void. Problems arise when they do not have the appropriate education and experience or become complacent about evaluating new evidence or continuing their education.

Wellness is becoming a popular topic in both the public and the private sectors, with an increase in attention to wellness initiatives, grant availability, and expanding budgets may receive additional funding for health and wellness programs. Demand requires a supply of organizations and instructors offering their services in return for payment. Public safety administrators must use caution when vetting psychoeducational training curricula and instructors. It is wonderful that health and wellness, especially mental health, are finally getting the attention they demand.

However, public safety organizations must make sure not to cause harm in their well-intentioned attempts to address the issues facing our first responder populations. Establishing a standard for certification to provide instruction to first responder communities is something public safety leaders and mental health professionals can work on together, to ensure that what is taught helps first responders, rather than hurting them. This collaborative approach to reviewing and approving programs will further bridge the gap between the agency and trainer/clinician. A peer-reviewed and evidence-based training curriculum for each discipline could be standardized with input from police, corrections, fire, emergency medical services, and emergency-communications communities. At a minimum, the agency should consult with a licensed mental health professional to vet the qualifications of any instructors and the validity of their training programs.

Transparency in Early Interventions

Organizational responses to mental health emergencies should not be a surprise to employees or supervisors. If an employee comes to a supervisor and indicates thinking about suicide, a substance use disorder, or domestic issues, the supervisor should not have to dig out the policy manual. These revelations could even surface during a meeting between the supervisor and employee in response to an EIS alert. Everyone should know before the employee's personal or professional crisis arises how the organization responds and helps.

Internal transparency and collaborative relationships are both components of this topic. For example, the authors' experience in law enforcement is that employees often fear that the organization will take custody of the officer's firearm if the employee relays experiencing a mental health emergency. The likelihood of that scenario should be made clear to all. Effective resilience-building strategies made available to employees and accepted in the employee's life prior to the crisis should work to end the over-identification with title and foster more identification as a human being, so that the loss of symbols of authority does not increase psychological trauma to the already suffering employee. Public safety employees need to know that symbols of their authority are not symbols of their personal identity or humanity.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Common Interventions for Early Alerts

The typical response to an early intervention alert is one of two options: remedial training or counseling (DeCrescenzo, 2005; Walker et al., 2001; Bertoia, 2008). The supervisor or training staff of the agency often orchestrates remedial training and presents it in-house. This response may fail in the absence of formal lesson plans and learning objectives, because of the time constraints of the supervisor, employee, or both, or because an underlying catalyst to the behavior is left unexplored. The training may also take place by sending the employee to an external training course, with the potential drawback being the lack of feedback to the sending organization regarding the employee's reception and retention of the information provided. The focus could be on how to avoid unwanted attention at work, rather than on how to return things to their normal balance in the employee's life.

Counseling sounds like a huge step forward for the public safety community. Traditionally, public safety organizations have resisted mental health counseling or even involvement of mental health professionals with employees following pre-employment psychological screenings. Counseling in first responder jargon is not what it seems to readers coming from the psychological disciplines. The term *counseling* in the public safety realm deals with correcting a specific behavior through discussion and a plan to improve, diminish, or eradicate the flagged employee behavior. In a counseling session that a supervisor organizes, the employee is presented with the problematic behavior and research the supervisor has conducted into that employee's history. The supervisor seeks the employee's acknowledgment of the behavior and the adverse impact it has had or could have on the service population, the organization and its mission, and the employee. Together they try to formulate a performance improvement plan, establish benchmarks to measure improvements, and adopt a timeline for the changes (Walker et al., 2001; Walker et al., 2006). The present authors propose a clearer focus on the underlying difficulty, within both the alert mechanism and intervention, so that employees' mental health is best served.

An agency contemplating developing an EIS should consider consulting its employees and mental health professionals to see if they feel it would be beneficial to share these alerts with a departmentally sanctioned mental health professional. An oversight mechanism like this would help ensure the agency is responding with appropriate intervention strategies based upon the needs of both the organization and the individual employee. In essence, it is consulting with the agency's mental health professional to obtain feedback on potential avenues to best address underlying mental health issues.

The other standard intervention option in an EIS is the referral to an employee assistance program (EAP), whether in-house or contracted to an external provider. A noteworthy concern in this process relates to the level of training and experience the EAP staff have in assisting public safety personnel with their unique stressors and the impact of their careers on family members and support systems. A variation of the existing EIS referral to EAP would be a yet different type of psychological visit from pre-employment screening, annual wellness visit, or fitness-for-duty examination: An automatic EIS alert visit with a mental health professional who specializes in public safety treatment. Akin to the EAP referral, the latter may be much more effective if it precedes the two common traditional responses of remedial training and supervisory counseling in that it will potentially lead to the treatment of the underlying cause(s) of any behavior that triggers early alerts.

When behaviors leading to an early alert or other complaints are too severe or disruptive for the effective and safe provision of services to the community, the fitness-for-duty examination may be the most appropriate intervention. Although a fitness-for-duty examination is listed as a potential interven-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion strategy in the New Jersey Attorney General's Directive 2018-3 (2018b), it may not always be an appropriate response by a mental health professional. The following list includes potential clinically relevant intervention options once an employee has been identified by the EIS:

- Voluntary referral EAP
- Automatic referral to the department psychologist
- Peer support referral
- Occupational health referral
- Referral to rehabilitation facility
- Sleep specialist referral
- Anger management referral
- Fitness-for-duty examination

Family as an Early Intervention System

Taking the term *Early Intervention System* most literally, a first responder's family and personal support system is where changes and difficulties are first noticed, and training and participation in any meaningful program must not neglect that fact. In most instances, close family members or friends are more likely than a coworker or a supervisor to observe changes in mood, behavior, energy levels, optimism, faith, and happiness.

The first vital step to empowering the employee's family to act as an additional layer of protection involves a trained mental health professional conducting a seminar to educate first responder family members and support systems. There they could learn to recognize warning signs their loved ones may display, realize those signs could correlate with distress from work, and identify ways they can assist their loved one and/or find the resources available to them, should they need more assistance.

Both authors have conducted family education courses for police agencies and academies and have received overwhelmingly positive feedback and expressions of gratitude from those who have attended. Feedback often includes reports of a better understanding of their police officer family member's calling and the unique stressors that come with a career in service, including being under the constant microscope of the media and the general public. Employees must also take personal responsibility for realizing when they need help, seeking it themselves when they are able to do so, and accepting the help. Believing this before it becomes needed is the key. A major factor in ensuring that employees will trust the agency and the process is their knowledge of the steps involved in assisting them prior to their crisis surfacing.

Achieving Greater Buy-In

Public safety leaders must always be mindful of all stakeholders. If an organization has an employee-oversight system to detect potentially problematic behaviors or patterns of behaviors, that organization could be sending a message that it is only interested in sifting out the negative, unless the oversight system is complemented with an awards and recognition program, a health and wellness program, and the ability to offer valid interventions for employees when they are going through a crisis or triggering a confirmed early warning alert. If the organization offers proactive and preventative interventions in addition to a transparent EIS it may prove to be a more accepted management tool.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Transparency and *health and wellness* have recently become popular buzzwords in the public safety leadership community, although rarely, if ever, are these two terms used in the same conversation. Could separating them result in missing a vital link for sustainable health and wellness efforts? In the experience of the authors, the fear and mystery surrounding the mental health profession is real for most first responders. The authors are personally aware of first responders who have experienced substance use disorders or mental health, personal, or family crises and have paid out-of-pocket to see a mental health clinician due to an intense fear of a real or perceived stigma that comes with a diagnosis required to utilize one's health-insurance plan.

Achieving buy-in through education is the key to success in the implementation of effective and meaningful organizational strategies. An early intervention system could be a component of a more comprehensive plan to help the first responder community.

Critical Incident Interventions

While the EIS is meant to look at data sets over a period of time and alert supervisors to potential issues, a critical incident is a triggering event in its own category. A common intervention public safety agencies use is critical-incident stress debriefings that administrators and/or peers typically conduct. In some of the more traumatic cases, a one-on-one appointment would be made for the affected personnel with a licensed mental health clinician who specializes in treating public safety personnel. The lack of standardization and training on which resources to utilize and who decides what defines a true critical incident for a particular employee or group of employees would be an area worthy of further research and collaboration between public safety leaders, researchers, and the mental health community. Organizations must have an open dialogue when considering criteria that would gauge which incidents are traumatic enough to require a one-on-one consultation with a licensed mental health professional, with the possibility that this would best be done on a case-by-case basis. Subjectivity in these decisions and the selection process and decision-maker training or lack thereof are extremely problematic.

Wellness Options for Employees

A multidisciplinary approach to serving the needs of employees and their support systems requires working across paradigms. Integration could include all or some of the following: peer support, critical-incident stress-management teams, EAP staff, chaplains, and mental health clinicians. Each of these groups of professionals can work within the discipline or in concert with others to assist the first responder community in preparation for shiftwork, the disturbing situations and scenes they will encounter, moral injuries, potential shifts in their faith and idealism, dehumanization, gallows humor, and personal family disruptions. Those agencies would achieve this most effectively through resilience training, psychoeducation, early intervention systems, intervention options, and the inclusion of families and support systems in these initiatives. Agency leaders must be aware that individual employees may have different preferences regarding who makes them feel most comfortable in these dialogues. For some employees, a peer support team member may be preferable, others may choose to confide in a chaplain, and some may wish to speak only with a licensed mental health professional. The employee's preference may also vary according to his or her needs or stage in life. Ideally, policies and programs would be designed to allow the employee to control selections for personal counsel and support while ensuring that employees are

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

educated on the services and unique perspectives each discipline may provide. Employees must also be made aware of the confidentiality protections or lack thereof in working with each of these disciplines.

Employees may not always have the level of self-awareness or the ability to overcome obstacles, real or perceived, to seek help during a time of personal and/or professional crisis. Agencies may rely on supervisor or peer observations of changes in an employee's attitude, demeanor, behavior, or personal situation. EISs are one solution being utilized by public safety agencies to aid the organization in identifying employees who may need assistance through interventions.

Pre-Existing EWS Flags

Those in public safety circles commonly know that exposure to trauma, moral distress, moral injury (Papazoglou & Chopko, 2017), substance use disorder (Sack, 2017), post-traumatic stress disorder or injury, cardiac issues, digestive issues, hypertension, and sleep disorders are all prevalent dangers in first responder communities (Violanti, 2014) and should serve as a pre-existing flag for first responders. Action should focus on reducing the dangers associated with what is already known to be hurting or killing our first responders, in addition to causes such as felonious assaults, accidents, disease, and fires. Preventative strategies should be designed with input from mental health professionals, frontline personnel, labor union representatives, supervisors and administrators, and members of first responder families.

The responsibility for the health and wellness of our first responders should not rest solely upon the shoulders of the leaders of public safety organizations. Ideally, labor unions incorporate health and wellness when negotiating for their represented employees. There is a tendency for collective bargaining units to place emphasis on gaining increased salary for employees toward the end of their careers in public safety, in order to increase the take-home amount of their pension, to the exclusion of more present-focused concerns. Health and wellness bargaining items, such as fitness center memberships and/or incentives, more affordable health care plans, education incentives or tuition reimbursement, psychotherapy, maternity/paternity leave, and bereavement leave are often not typical concerns. Public safety leaders and union leaders are in a unique position to guide these conversations so that employees value thriving in the present equally to monthly pension payout calculations that are 30 years or more in the future. This shift in mindset could improve the quality of life for first responders and their families and support systems in the present.

Comfort With the Clinician

In order to ensure a comfortable relationship in which the public safety employee is open to sharing thoughts and feelings with a mental health professional, agencies may want to consider instituting a wellness check-up program with a licensed mental health clinician who specializes in treating the first responder community. Post-critical-incident visits may be the first time employees meet a mental health professional. Perhaps it is the second time, the first being a pre-employment screening, also an uncomfortable situation for a job candidate. The first author has partnered with several police departments in Burlington County, New Jersey, to facilitate annual wellness visits for agency employees. The officers meet to discuss anything they wish or simply to receive psychoeducation. Benefits to this approach include an opportunity for the employee to discuss with a professional in a secure environment the operational and organizational stressors, family difficulties, coping skills, critical-incident and cumulative stress, and any other topics that benefit their overall wellness. Other advantages include the opportunity for

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

individual education on resilience, coping skills, and self-care. One of the most beneficial aspects of this program is the familiarity between the officer and the clinician. The building of trust and rapport can be achieved early, which could greatly assist if the officer automatically attends a counseling session in response to a critical incident or an EIS alert.

Agency leaders, along with their respective organizations, would benefit greatly from familiarizing themselves with some of the resources currently being used, such as resource phone numbers, training programs, and critical-incident stress debriefings, and the research available on such programs. Critical-incident stress debriefings have contradictory or little evidence gleaned from studies. The studies that evaluated critical-incident stress debriefings did not specifically address a sample that was exclusively public safety personnel to prove efficacy in that population (Mitchell & Dorian, 2017). The selection of a critical-incident stress management (CISM) team to service the organization should be vetted with a mental health professional. There are numerous resource phone numbers available in the first responder community for employees to make a cold call for help. These services can be evaluated by offering anonymous surveys to first responders to determine how effective or detrimental the sources whose services they attempted to use were to their health and wellness.

FUTURE DIRECTIONS

Policies dictating responses to the needs of first responders' mental health would best be written with the counsel of mental health professionals to ensure the correct message is being sent to public safety personnel. A commonly discussed nuance in the language is the use of the word *mandatory* versus *automatic* intervention. The two terms may seem synonymous to a policy writer, but something as simple as word choice could make or break buy-in of a well-intentioned organizational intervention strategy. This example is just one of many that could be listed to illustrate the importance of multidisciplinary collaboration in policy and procedure development.

Organizational interventions for public safety agencies must be carefully planned with the assistance and counsel of mental health professionals, buy-in from the rank and file and administration, and support of the community served. The interventions should cover all phases and facets of the public safety employee's career and ensure support for their personal lives as well. An organization's opportunity to show the priority placed on health and wellness begins in the hiring process. Training programs in academies for both new employees and their family regarding critical-incident and cumulative stress, organizational stress, sleep disorders, resilience-building techniques, nutrition, physical fitness, financial wellness, spiritual wellness, and resources available to help the employee and the family in times of crisis are critical. These training sessions and face-to-face visits should not be a "checkbox" completed one time in a career of 30 years or more; rather, they should continue as an ongoing open dialogue between the employees and mental health professionals throughout an employee's entire career.

EIS conceptualization can be broadened to capture a greater variety of potentially problematic behaviors. In New Jersey, while the list of circumstances requiring documentation is extensive, it is focused on behavior suggestive of illegal or at the very least overly aggressive behavior. However, other circumstances could aid in monitoring the well-being of public safety personnel, such as a noticeable increase in overtime and secondary employment shifts, avoidance of going home after work or arriving for work extremely early, isolation from coworkers, complaints of pain, increased sick time usage, complaints of changes in sleeping habits or lack of sleep, unexplained weight gain or loss, changes in eating habits, or

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

changes in marital or family residence status. These suggested factors that a supervisor could monitor may not necessarily be part of a formal EIS; nonetheless, they could provide an early alert to trigger a supervisor's probing questions. They are likely not dissimilar from the facts that down the road would trigger an alert or employee assistance program referral. The best case scenario would result in helping an employee before a formal EIS alert mandates an intervention; the worst case scenario would be that nothing is wrong, and the employee perceives their supervisor's care for his or her welfare (given the conversation is framed appropriately)—obviously, a win-win situation. As such, the EIS needs to remain flexible and continually reviewed to ensure any policy changes are reflected.

In addition to training supervisors on the goal of the EIS and the manner in which to assess employees close to alert status or already flagged, organizational staff in other fields may also play a role. The agency's human resource professionals can further enlighten personnel about their available insurance and relevant health care plans, including any employee assistance programs available to them and their support systems. The human resources representative could also have conversations with employees regarding logistical issues, such as sick time, administrative leave, the Family and Medical Leave Act, temporary disability, and worker's compensation, to name a few.

Chapter 48
Application and Integration of Psychological First Aid in First Responder Organizations

ABSTRACT

First responders are exposed to many potentially traumatic events throughout their careers. Given the risk of adverse mental and physical health outcomes secondary to frequent trauma exposure, access to culturally-sensitive, evidence-informed early intervention is paramount. Critical Incident Stress Management (CISM) and components therein (e.g., Critical Incident Stress Debriefing, peer support) represent the most commonly utilized early interventions within first responder organizations. Limited research has evaluated these models, and evaluation of early interventions presents many challenges due to characteristics of first responder cultures and organizational demands and constraints. Psychological First Aid (PFA) is a widely endorsed and promising evidence-informed early intervention model grounded in research on trauma recovery and resilience. This chapter examines the theoretical underpinnings and core actions of PFA and describes the potentially diverse applications of PFA within first responder organizations and concludes by discussing recommendations and future directions.

INTRODUCTION

First responders are exposed to many critical incidents (e.g., Carlier, Voerman, & Gersons, 2000; Malcolm, Seaton, Perera, Sheehan, & Van Hasselt, 2005) or potentially traumatic events that "may cause a given individual's emotional resources to become over-taxed, resulting in a spectrum of reactions from exhaustion to increased and unrelenting mental health symptomology" (Maguen et al., 2009, p. 754). For example, research suggests police officers are exposed to an average of 166 – 188 critical incidents during their careers (Chopko, Palmieri, & Adams, 2015; Weiss et al., 2010). Not surprisingly, first responders are at elevated risk for PTSD, depression, and alcohol use disorders (Berger et al., 2012; Kleim & Westphal, 2011).

Given the potential for adverse mental health outcomes secondary to frequent trauma exposure, access to culturally-sensitive, evidence-informed early intervention is paramount. While definitions of early intervention vary, it has been viewed as secondary prevention efforts occurring in the immediate (0-48 hours) or acute (a few weeks later) phases following a potentially traumatic event (Litz, 2008). Current early interventions within first responder organizations often include elements of the multi-component Critical Incident Stress Management (CISM) model (Everly, Flannery, & Mitchell, 2000; Mitchell & Everly, 2001). However, CISM has not been rigorously evaluated, has not specifically been studied with first responders, and includes components (e.g., Critical Incident Stress Debriefing) that have been called into question (Bisson, McFarlane, Rose, Ruzek, Watson, 2009; Brucia, Cordova, & Ruzek, 2017; Bryant, 2007; Fox et al., 2012; Rose, Bisson, Churchill, & Wessely, 2002; Ruzek et al., 2007; Tuckey, 2007; Van Emmerik, Kamphuis, Hulsbosch, & Emmelkamp, 2002). Thus, evidence-based early interventions for first responders have not been established and there are realistic challenges to implementing standardized approaches in first responder organizations.

Psychological First Aid (PFA, Forbes et al., 2011) is a specified set of early post-trauma helping behaviors derived from research-based principles (Hobfoll et al., 2007). While multiple models exist, this chapter will focus on a PFA approach collaboratively developed by the Child Stress Traumatic Network and National Center for PTSD (Brymer et al., 2006). Although this model has great potential, it has yet to be empirically validated for use in first responder populations.

This chapter will initially discuss critical incident exposure and mental health sequelae in first responders and highlight first responder cultures as an important context in which support programs must be designed. Current critical incident and early intervention models will then be reviewed, followed by examination of the theoretical underpinnings and actions of PFA (Forbes et al., 2011) and descriptions of the potential diverse applications with first responders. The chapter will conclude by identifying methodological and organizational challenges in the development, implementation, and evaluation of PFA, and discuss future directions. While first responders (e.g., emergency medical services, fire, dispatch, law enforcement) at large will be considered there will be an emphasis on law enforcement personnel and organizations given the state of the literature.

TRAUMA EXPOSURE AND MENTAL HEALTH OUTCOMES

In the United States (U.S.), civilians' lifetime risk of trauma exposure ranges from 37-92% and the prevalence rate of PTSD is 6.8% (Kearns, Ressler, Zatzick, & Rothbaum, 2012; Litz, Gray, Bryant, & Adler, 2002). While psychological distress following trauma exposure will resolve naturally for most

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

individuals, those who continue to experience symptoms beyond 3 months are at increased risk for chronic conditions (Kessler, Sonnega, Bromet, Hughes, & Nelson, 1995; Litz et al., 2002). Identified risk factors for PTSD include perceived life threat during the traumatic event, peri-traumatic responses, previous trauma exposure, self and family psychiatric history, insecure attachment style, and limited social support (e.g., DiGangi et al., 2013; Kearns et al., 2012; Ogle, Rubin, & Siegler, 2015; Renaud, 2008; Woodhouse, Ayers, & Field, 2015). Female gender, younger age, and certain personality traits (e.g., neuroticism, hostility, trait anger, anxiety, and dissociation) are also associated with increased risk of PTSD (e.g., Brewin, Andrew, & Valentine, 2000; DiGangi et al., 2013; Litz et al., 2002; Maguen et al., 2009).

First responders are significantly more likely than the general public to be exposed to critical incidents. For example, research suggests the average 30-year police officer is exposed to between 166 – 188 critical incidents (Chopko et al., 2015; Weiss et al., 2010), and Marin (2012) posited that number may be as high as 250 critical incidents. Berger and colleagues' (2012) meta-analysis suggested that 10% of emergency service workers (e.g., police officers, firefighters, paramedics) worldwide have PTSD, with approximately 400,000 cases in the U.S. alone (Haugen et al., 2012). Prevalence rates of PTSD in police officers range from 4.7% to 19%, suggesting approximately 135,000 U.S. police officers have the condition; many more may experience subthreshold PTSD (Berger et al., 2012; Carlier, Lamberts, & Gersons, 1997; Komarovskaya et al., 2011; Marin, 2012; O'Hara, 2012). Risk factors for PTSD in first responders include cumulative trauma exposure, environmental and work stress, avoidant coping and difficulties problem solving, and poor social support (Beaton & Murphy, 1993; Brondolo, Wellington, Brady, Libby, & Brondolo, 2008; Evans, Pistrang, & Billings, 2013; Haugen et al., 2012; Kleim & Westphal, 2011; Maguen et al., 2009; Marchand, Nadeau, Beaulieu-Prevost, Boyer, & Martin, 2015; Marmar et al., 2006; Meyer, Zimering, Daly, Knight, Kamholz, & Gulliver, 2012; Phillips, LeardMann, Gumbs, & Smith, 2010; Royle, Keenan, & Farrell, 2009).

Beyond PTSD, the most commonly diagnosed psychiatric conditions in first responders are Alcohol Use Disorders and Major Depressive Disorder (MDD) (Kleim & Westphal, 2011). Sterud, Hem, Ekeberg, and Lau (2007) found that 17.7% of male and 9.1% of female Norwegian police officers ($N = 2{,}372$) endorsed hazardous alcohol use. Compared to the general American population (5.2%), rates of depressive symptoms are higher in female (12.5%) and male (6.1%) police officers (Violanti & Drylie, 2008). Stanley, Hom, and Joiner's (2016) systematic review of 63 studies on suicide in police, firefighters, and EMTs/paramedics identified elevated risk of suicidal thoughts and behaviors. Between 2008 – 2012, police officers were twice as likely to die by suicide than be killed in the line of duty (Marin, 2012).

FIRST RESPONDER CULTURES

While there are many first responder sub-cultures, police, fire, and emergency medical services personnel share common characteristics including unique indoctrination procedures, a strong sense of duty, discipline and compliance with rules and authority, and strong allegiance to their organizations, which have hierarchical command structures and long-standing traditions (Brauer, 2016; Cassan, 2010; Liedenbaum, 2011). Norms include working unusual schedules, exposure to inordinate amounts of danger, special privileges (e.g., arrest power), and the ability of superiors to cancel leave due to work demands (Brauer, 2016). Further cross-cutting first responder values and behaviors include communalism, separateness from civilians ("the thin blue line") and isolation from society, keeping work-related concerns in-house,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

caring for others before self ("mission-first," self-sacrifice), exhibition of physical and emotional strength, and compartmentalization and suppression of emotion (Kirschman, 2007).

Importantly, first responder cultures and beliefs about self, other, and the world may pose real and perceived barriers to seeking informal support and/or formal mental health treatment. Mental health issues are often stigmatized, particularly given that many community calls involve responding to mental health crises, and disclosure of emotional distress or mental health concerns may be viewed as weakness. (Kirschman, Kamena, & Fay, 2014). While these attitudes and coping strategies may be viewed as resilient and foster effective first responder work in the short-term, they may inhibit expression, detection, and treatment of mental health problems in this population (Haugen, McCrillis, Smid, & Nijdam, 2017; Kirschman et al., 2014; Wester, Arndt, Sedivy, & Arndt, 2010).

COMMON INTERVENTIONS FOR FIRST RESPONDERS

Given characteristics of first responder cultures and organizational demands and constraints, the development, implementation, and evaluation of critical incident interventions presents many challenges. In the 1990s, Mitchell and Everly (2001; Everly et al., 2000a) developed the multi-component Critical Incident Stress Management (CISM) model. CISM is a comprehensive stress management model utilized by some first responder organizations, with the primary aim to provide various types of mental health support to first responders, their families, and their organizations at various time points before and after a critical incident (Everly & Mitchell, 1999; Everly et al., 2000a; Everly, Lating, & Mitchell, 2000b). CISM includes pre-critical incident psychoeducation about stress reactions and stress management, and assessment of the needs of first responders during or immediately following a critical incident. The model further calls for a group defusing intervention to assess current needs within 12-hours post-critical incident, followed by a Critical Incident Stress Debriefing (CISD) in the subsequent days or weeks. CISM also includes peer support and chaplaincy services, consultation with organization and community administrators to tailor the model as appropriate for the setting, referrals for ongoing psychological distress, and debrief-the-debriefer sessions (Sheehan, Everly, & Langlieb, 2004).

Some meta-analytic studies have reviewed the effectiveness of CISM interventions. Everly, Flannery, and Eyler (2002) conducted a meta-analysis investigating the effectiveness of eight CISM interventions on outcomes, including PTSD symptoms. Results demonstrated large mean effect sizes, suggesting delivery of CISM interventions may mitigate adverse psychological outcomes of trauma. However, these naturalistic studies were not conducted with first responders, and contained many methodological limitations that limited generalizability and the ability to draw definite conclusions.

Within many first responder organizations, isolated CISM components are utilized as stand-alone interventions that are not embedded within the multi-component stress management model. Psychological debriefings are the longest-standing and most common critical incident intervention for first responders, though debriefing structures and content can vary dramatically between organizations and there is confusion in the literature about the definition of debriefings (Bisson et al., 2009; Brucia et al., 2017; Litz et al., 2002; Tuckey, 2007). First developed in the early 1980s, Critical Incident Stress Debriefing (CISD) is the most frequently utilized group critical incident intervention for first responders and is comprised of seven phases: Introduction, Fact, Thought, Reaction, Symptom, Teaching, and Re-entry (Malcolm et al., 2005; Mitchell, 1983). While very limited research has evaluated CISD delivered to first responders (e.g., Bohl, 1995; Carlier, Lamberts, Van Uchelen, & Gersons, 1998; Carlier et al., 2000), multiple meta-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

analytic studies concluded that both CISD and non-CISD stand-alone group psychological debriefings do not reduce psychological distress or prevent PTSD and may even exacerbate symptoms (Bisson, Jenkins, Alexander, & Bannister, 1997; Bisson et al., 2009; Brucia et al., 2017; Bryant, 2007; Carlier et al., 1998; Carlier et al., 2000; Fox et al., 2012; NIMH, 2002; Gene-Cos, 2006; Rose et al., 2002; Ruzek et al., 2007; Tuckey, 2007; Van Emmerik et al., 2002). Notably, the CISM manual explicitly states that CISD is not intended to be delivered as a stand-alone intervention.

In the U.S., Canada, and globally, there is a proliferation of peer support programs in emergency medical services, fire, and law enforcement organizations (Papazoglou & Tuttle, 2018). Although informal peer support has been an integrated part of police culture for decades, some police departments offer formal peer support programs as a way to support the psychological health of officers (Benner, 1982; Graf, 1986; Kamena, Gentz, Hays, Bohl-Penrod, & Greene, 2011; Waters & Ussery, 2007). To this end, the International Association of Chiefs of Police (IACP, 2016) developed Peer Support Guidelines, which provide guidance and flexible recommendations for creating and maintaining a formal peer support program within an organization. Peer support members are specially trained co-workers who serve to normalize and validate the range of decisions (e.g., tactical, emotional) made by officers (IACP, 2016; Kirschman et al., 2014). Peer support members may be particularly well-suited to identify officers in increased distress, and because of the peer relationship, distressed officers may be more amenable to sharing (M. Bloesch, 2018, personal communication; Kirschman et al., 2014). Peer support programs have numerous intended effects, including providing emotional, social, and practical support to those in distress due to personal and work-related issues, and helping officers navigate the challenges of policing (IACP, 2016). Peer support programs may protect against the adverse outcomes of trauma exposure, may reduce feelings of shame, embarrassment, abandonment, and rejection, and may increase help seeking behavior (Graf, 1986; Flannery, 2015; Kirschman et al., 2014).

Limited research has evaluated the effectiveness of peer support programs in reducing psychiatric morbidity (Brucia et al., 2017; Grauwiler, Barocas, & Mills, 2008). Berg, Hem, Lau, Haseth, and Ekeberg (2005) found greater work injuries and perceived job pressures in a nationwide sample of Norwegian police ($N = 3272$) who worked in districts lacking peer support programs and whose populations were greater than 50,000 people. These findings highlight the importance of peer involvement in early intervention programs.

Several support structures for first responders have emerged outside of the workplace. National peer-to-peer organizations have developed (e.g., The Badge of Life, 2018; Concerns of Police Survivors (C.O.P.S.), 2018; COPLINE) in an effort to increase awareness of mental health, support bereaved survivors of duty-related deaths, and prevent suicide (Samuels, 2018). Other innovative models of care include residential treatment programs (e.g., First Responder Support Network) for first responders with post-traumatic stress reactions (e.g., Brucia, 2018; Dunnigan, 2012; Fay, Kamena, Benner, & Buscho, 2006).

In some fashion, CISM model, CISD, and peer support all incorporate information about coping and fostering social connectedness in the immediate aftermath of a traumatic event. However, these interventions have limited empirical support, particularly with first responders. Given the complex organizational demands, diverse roles, and multiple critical incident exposures of first responders, flexible, empirically-informed, principle-based approaches to early intervention are needed.

CORE PRINCIPLES AND ACTIONS OF PSYCHOLOGICAL FIRST AID

Developed to be utilized in the immediate aftermath of a traumatic event and delivered by mental health and/or disaster response workers, Psychological First Aid (PFA) (Forbes et al., 2011) is an early intervention with primary goals of reducing acute distress and facilitating individual and community short- and long-term resilience, adaptive coping, and functioning (Brymer et al., 2006). The basic standards of PFA are consistent with research on trauma-related risk and resilience, practical for field settings (e.g., emergency departments, staging areas, feeding locations), appropriate for use in individuals across the developmental lifespan (e.g., children, adolescents, adults), and designed to be delivered in flexible and culturally sensitive ways (Forbes et al., 2011). PFA has multiple basic objectives identified as eight core actions: 1) contact and engagement, 2) safety and comfort, 3) stabilization, 4) information gathering regarding current needs and concerns, 5) practical assistance, 6) connection with social support, 7) information on coping, and 8) connection with appropriate services (Brymer et al., 2006; Ruzek et al., 2007; Uhernik & Husson, 2009). Importantly, PFA acknowledges that trauma survivors will experience a range of reactions, that not all survivors will experience chronic symptoms, and that natural recovery is common.

PFA emerged from five core theory-based principles that are rooted in empirical support and that highlight mechanisms of trauma recovery (Hobfoll et al., 2007). The five central intervention principles are promotion of safety, calming, self- and collective efficacy, connectedness, and hope. These principles can guide organizational responses to work-related trauma exposures at the individual, group, organizational, and community levels, including workforce education, peer support, specialist counseling, media communications, and organizational ceremonies and practices (Hobfoll et al., 2007). Further, the underlying principles of PFA are generative tenets that can be creatively applied in culturally appropriate, flexible ways. The following text will describe the five core theory-based principles underlying PFA and the core actions of PFA that map onto these principles; it will also discuss the particular relevance and application of these principles and actions for first responders. These broad principles and core actions are potentially applicable at multiple levels; mental health providers may provide PFA to first responders, and first responders may deliver PFA to each other and to those in the public they serve. Given that many PFA components are nested within multiple underlying principles and core actions, those most salient to each will be discussed.

Safety

Traumatic events threaten self and other physical and psychological safety. In the face of real or perceived on-going danger, the human body is hardwired to make biological and survival driven behavioral and cognitive adaptations (van der Kolk & Saporta, 1993). Bryant and colleagues (2007) posited that promotion of safety in both humans and animals is associated with regulating biological responses, such as the fight-flight-freeze response, that maintain anxiety and fear. Traumatic events also impact safety-related cognitions and threat appraisal such that the ability to realistically appraise threats can be compromised, increasing the likelihood that ambiguous and neutral stimuli will be experienced as real threats (Ehlers & Clark, 2000; Foa & Rothbaum, 1998). As such, beliefs about self- and other- safety and the dangerousness of community environments have important implications for trauma-related mental health sequelae.

Self and other safety concerns map onto two core actions of PFA. Contact and engagement, PFA's first core action, encourages those in response roles to develop non-intrusive and compassionate human

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

connections with trauma survivors (Forbes et al., 2011). Specifically, PFA recommends introducing oneself, explaining one's role, and inquiring about immediate needs while respecting confidentiality and upholding relevant ethical and legal standards. The second core action of PFA is focused on the promotion of immediate and ongoing physical and psychological safety and comfort (Forbes et al., 2011; Hobfoll et al., 2007). Re-establishing safety at multiple levels (i.e., individual, group, organization, and community) is emphasized, and ensuring immediate and ongoing physical safety is paramount. Depending on environmental circumstances and personal needs, this may include basic actions like removing sharp objects (e.g., broken glass), asking about the need for medications, eyeglasses, wheelchairs, or other mobility devices, or provision of blankets. It is also critical to assess for ongoing threats to self or others and to identify individuals who may be in shock and in need of immediate medical and/or psychiatric attention.

Given unique cultural factors and the significant risk of work-related trauma exposure in first responder populations, re-establishing physical and emotional safety in the immediate aftermath of a traumatic event may be challenging. Re-establishing physical and emotional safety is likely best delivered via bottom-up and top-down approaches. Immediate bottom-up approaches may include providing first responders with information about tactical response activities and available services, giving them the opportunity to ask questions about what may happen next, and providing support for acute stress and/or grief reactions. Top-down approaches may include dissemination of accurate, organized, and timely information by first responder administrators and other leaders (Shalev & Freedman, 2005). To create a more comfortable physical environment and promote social interactions with colleagues who are coping adequately, organizational leaders may designate a separate staging/recovery area in a safe area for respite, attention to practical needs (e.g., hunger, thirst), and social connection.

Safety-related beliefs are particularly salient for first responders and may present unique challenges to immediate and ongoing post-trauma interventions. First responder training and experiences may alter and/or reinforce prior beliefs and contribute to the development of new self, other, and world safety-related beliefs (Brucia, 2018; Kirschman, 2007; Kirschman et al., 2014; Terpstra & Schapp, 2013). Beginning in the academy, police officers are trained to be suspicious and skeptical of others and to view civilians as "suspects" and potential sources of danger. Research examining risk factors of PTSD in male firefighter cadets ($N = 82$) found that those with fewer negative and catastrophic beliefs prior to work-related trauma exposure were at decreased risk of PTSD one year later (Bryant & Guthrie, 2005). Later in their careers, self and other safety concerns may generalize to broader distrust of non-police individuals, politicians, command staff, and administrators, who may be perceived as unable to understand policing demands, experiences, and culture (Terpstra & Schapp, 2013). Many negative safety-related beliefs held by first responders may prove functionally adaptive in some aspects of the job, but may contribute to psychological distress and dysfunction in other work and non-work contexts. Providing psychoeducation (see below) about trauma reactions and coping on an ongoing basis, including at the onset of first responders' careers as well as in the immediate aftermath of traumatic events, may be one particularly useful way to protect against development of problematic beliefs about personal and community safety.

In the immediate aftermath of a traumatic event, individuals delivering PFA to first responders may encounter individuals whose self and other safety and trust-related beliefs inhibit engagement with mental health providers, and this may be compounded by self- and other-stigma as well as label avoidance (Corrigan, Watson, & Barr, 2006; Goldstein, 2005). Importantly, practical (e.g., duty-related responsibilities) and systemic barriers (e.g., organizational policies that prohibit interactions with others prior to evidence collection and formal statements) may further impede contact and engagement with first responders in need, and compound safety-related beliefs and stigma that contribute to reluctance to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

utilize social support and mental health services. A clear understanding of organizational policies and procedures as well as depth and breadth of knowledge of first responder culture is critical for otherwise well-intentioned mental health providers.

Calming

The second underlying principle of PFA is promotion of calming (Hobfoll et al., 2007). Increased emotionality, anxiety, and hypervigilance and/or affective detachment and numbing are common responses to traumatic events. However, if these symptoms are maintained over time they can interfere with basic needs, such as eating, sleeping, or hydration, and contribute to impairment in concentration, completion of routine tasks, and social connectedness (Goenjian, Karayan, Pynoos, Minassian, Najarian, Steinberg, et al., 1997; Goenjian, Walling, Steinberg, Karavan, Najarian, & Pynoos, 2005; Hobfoll et al., 2007). There is also a well-demonstrated relationship between stress and trauma and adverse physical health outcomes (e.g., cardiovascular, autoimmune disease, chronic pain, GI conditions), as well as increased utilization of healthcare services (Engelhard, van den Hout, Weerts, Hox, & van Doormen, 2009; Hoge, Terhakopian, Castro, Messer, & Engel 2007). Physical and emotional calming may be promoted via psychoeducation that identifies and normalizes early trauma responses, formal relaxation training methods (e.g., breathing, mindfulness, meditation), and relaxing activities that enable teams and individuals to find calm across their daily routines. Indeed, most evidence-based psychosocial post-trauma interventions include promotion of calming as a critical component (e.g., Bryant, Harvey, Dang, Sackville, & Basten, 1998; Foa & Rothbaum, 1998; Foa, Hembree, & Rothbaum, 2007), and an indicator of successful treatment completion is attainment of mastery and calming over the traumatic memory (Forbes et al., 2011).

Promotion of calming relates to the third and fourth core actions of PFA. Stabilization, the third core action, aims to calm and orient overwhelmed survivors who may be numb, unresponsive, confused, or incapacitated by anxiety and worry by engaging individuals in calming strategies. The fourth core action of PFA focuses on identification of current needs and concerns and gathering additional information (Forbes et al., 2011). While multiple factors in the field may limit what and how much information is gathered, PFA suggests asking questions in an effort to clarify the following: nature and severity of experiences during that trauma, death of and/or separation from colleagues and if relevant, family and loved ones, concerns about immediate or ongoing danger, history of exposure to trauma, physical illness and psychiatric conditions and need for medications, losses (e.g., home, neighborhood, property, business), strong feelings of guilt or shame, suicidality and homicidality, access to social support, and/or historical or current substance use. PFA also recommends enlisting nearby family members or friends to comfort the individual, engaging the individual in conversation about their current concerns, remaining calm and quiet, and providing orienting information (e.g., next steps) (Forbes et al., 2011).

Promotion of calming in first responders is vital given research demonstrating first responders are more frequently diagnosed with stress-related physical illnesses than the general population, though it may be challenging (Alkus & Padesky, 1983; Centre for Occupational and Environmental Health, 2000; Marin, 2012). Their training to suppress outward signs of physical and emotional stress enables effective action in response to victims but may reduce awareness and self-regulation of heightened internal states. That said, helping first responders learn to recognize their own distress and arousal and re-establish calm may be accomplished through a variety of strategies. Psychoeducation specific to common psychological, emotional, and physiological reactions during the stabilization phase may also serve to normalize and validate first responders' reactions and challenge negative safety-, doubt-, and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

stigma-related beliefs (e.g., "I'm losing it; I'm not safe because my reactions") and emotional distress, which may in turn foster increased coping self-efficacy. Referrals for professional mental health services may likely utilize cognitive-behavioral and exposure strategies to increase self-awareness of antecedents of anxious distress, gently challenge beliefs, and increase coping self-efficacy (see below). For example, in the immediate aftermath of a traumatic event, anxiety management techniques might include physical, mental, emotional, and self-soothing grounding strategies, such as diaphragmatic breathing and progressive muscle relaxation, which have been found to reduce anxiety and counter intense emotionality (Foa & Rothbaum, 1998; Somer et al., 2005).

Calming interventions for first responders are being implemented. Some police departments in the U.S. and Canada are creating "quiet" rooms for rest, relaxation, or meditation, furnished with comfortable recliners and televisions (McHugh, 2019; PoliceOne, 2017). Christopher and colleagues (2015) evaluated an 8-week Mindfulness-Based Resilience Training (MBRT) program for police officers ($N = 43$) and found significant improvements in self-reported mindfulness, physical and emotional health, perceived stress, burnout, emotion regulation (e.g., anger), resilience, sleep difficulties, and fatigue. These approaches reflect proactive, early organizational-level interventions that may foster calming coping strategies and restoration of homeostasis following critical incidents. In contrast, interventions such as CISD, which involve emotional processing and ventilation, may exacerbate disequilibrium at precisely the time when recently traumatized individuals are attempting to restore calmness (Bisson et al., 2009).

Gathering information about current concerns may guide tailored responses to first responders. For example, emotionally flooded first responders may benefit from immediate and ongoing use of grounding and calming strategies. Alternatively, individuals expressing intense negative self, other, and/or worldviews may benefit from immediate and ongoing use of cognitive interventions (e.g., reframing, gentle thought challenging, crafting more realistic/flexible beliefs). First responders may also present with culturally-unique concerns. For example, specific types of critical incidents (e.g., officer involved shootings) may initiate organizational policies that require an officer's duty weapon be removed from their possession. Approaching the function of firearms from a self-psychology perspective, Feldmann and Johnson (1992) suggested that weapons serve to combat feelings of powerlessness and vulnerability and maintain self-cohesion. As such, police officers who have their duty weapon removed from their possession following a critical incident may feel particularly uneasy and unsafe. To ease such concerns some departments ensure that a replacement weapon is available and provided to officers as appropriate (M. Bloesch, 2019, personal communication).

Self and Collective Efficacy

Promotion of self- and collective efficacy is the third principle underpinning PFA. Trauma can overwhelm one's coping resources and contribute to feelings of powerlessness and helplessness (Hobfoll et al., 2007). The concept of self-efficacy emerged from social cognitive theory (Bandura, 1997) and may be defined as beliefs that one can successfully implement a particular behavior and that one's "actions are likely to lead to generally positive outcomes, principally through self-regulation of thoughts, emotions, and behavior" (Hobfoll et al., 2007, p. 293). Most individuals draw from a broad array of learned adaptive and maladaptive coping strategies in an effort to self-regulate following trauma exposure. Research suggests that the development of trauma-specific adaptive coping self-efficacy is particularly beneficial for trauma recovery and resilience (Benight & Harper, 2002), and that those with greater coping self-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

efficacy may naturally select more adaptive, action-oriented strategies compared to those with lower self-efficacy (Luszcynska, Benight, & Cieslak, 2009).

Bandura (1997, p. 477) defined collective efficacy as "a group's shared belief in its conjoint capability to organize and execute the course of action required to produce given levels of attainment." Given the action-oriented nature of first responder careers, the development and maintenance of collective efficacy vital as it promotes action (Cicognani, Pietrantoni, Palestini, & Prati, 2009). Importantly, self-efficacy and collective efficacy are often interwoven; solving large-scale problems requires the collaboration of multiple people and systems.

Self- and collective efficacy are associated with the fifth core action of PFA, which consists of offering practical assistance, identifying and clarifying the most pertinent need(s), and discussing the action plan (Forbes et al., 2011). Accessing and retaining resources is associated with post-trauma recovery and may foster self- and collective efficacy (Forbes et al., 2011). For first responders, practical assistance may include organizational and peer support, religious activities, briefings, meetings, mourning rituals, and dissemination of information and resources (Benight, 2004; Cicognani et al., 2009; de Jong, 2002; Sampson, Raudenbush, & Earls, 1997). Providing and helping first responders maintain access to these resources may improve self-efficacy, contribute to restoration of dignity and empowerment, buffer against a loss of hope, and promote optimism, a sense of predictability, positive beliefs, and for some religious faith.

To cope with their complex job duties, responsibilities, and exposures, first responders need to be familiar with and confident in their ability to use a broad range of strategies. Learning and rehearsing strategies for problem-focused coping, sleep hygiene, managing media exposure, relaxation, and engagement in pleasurable activities that foster positive emotions such as joy, curiosity, humor, and love, may result in more effective coping (Hobfoll et al., 1991, 2007).

Some cultural norms underlie maladaptive coping. For example, first responder culture condones drinking as a coping strategy. High rates of problematic alcohol use in police officers have been documented and may have the unintended long-term effect of decreasing self-efficacy (Kirschman, 2007; Larson, Eyerman, Foster, & Grfoerer, 2007; Richmond, Wodak, Kehoe, & Heather, 1998).

Given the collaborative and interdependent nature of their work in high risk, stressful situations, first responders are likely to develop collective efficacy beliefs about situations they can master as a group (Cicognani et al., 2009). However, discrepancies may exist between their beliefs about the abilities of their frontline colleagues versus the abilities of command staff and organizational leadership. Further, positive outcome expectations may depend on a just world view (i.e., good things happen to good people, bad things happen to bad people). First responders may be at risk of lower collective efficacy due to past work-related stressors and trauma, organizational demands, childhood and civilian trauma exposure, and minority stress/trauma. Formal assessment and education about the impact of past learning experiences on individual and group beliefs, and training to identify and evaluate maladaptive beliefs and formulate more helpful thoughts may foster greater self- and collective efficacy.

Connectedness

The fourth principle of PFA is connectedness. Trauma can be isolating and alienating, and social support is one of the strongest post-trauma protective factors against PTSD and suicide (Bernert, Kim, Iwata, & Perlis, 2015; DiGangi et al., 2013; Ozer, Best, Lipsey, & Weiss, 2008; Vallieres, Azaiez, Moreau, LeBlanc, & Morin, 2014; Van Orden et al., 2010). Survivors often yearn for immediate connection to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

those with whom they have a strong relationship (e.g., family, close friends, clergy, colleagues), and social support immediately after a traumatic event serves multiple functions, including normalization and validation of emotional reactions and facilitation of problem-solving (Hobfoll et al., 2007). Talking with supportive others can help individuals process emotions and develop a coherent and realistic understanding of traumatic experiences (Lepore, 2001). In contrast, social constraints related to talking about trauma, whether objectively imposed by others' behavior or subjectively experienced due to one's expectations or perceptions, can inhibit trauma processing and pose obstacles to natural recovery (Lepore & Revenson, 2007; Belsher, Ruzek, Bongar & Cordova, 2012).

Establishing and connecting survivors with social support is the sixth core action of PFA. Social support may include emotional support, physical and material assistance, social connection, feeling valued and needed, reassurance of self-worth and that others are reliable, and advice and information. PFA advocates guiding those who are reluctant to seek social support to consider what type of support might be helpful and who they may feel comfortable approaching.

Social support is associated with reduced distress in a range of first responder populations. Specifically, among police officers, social support has been found to protect against mental health disorders, hopelessness, and suicide, and to increase recovery rates from PTSD, even in the absence of a formal treatment intervention (De Terte, Stephens, & Huddleston, 2014; Klimley, Van Hasselt, & Stripling, 2018; Marchand et al., 2015; Violanti et al., 2016). Stanley et al. (2018) found that among firefighters social support received from coworkers, supervisors, family, and friends buffered against the development of PTSD. Dispatchers displayed higher rates of burnout, stress, and anxiety when they perceived a lack of social support (Klimley et al., 2018; Burke, 1995; Kirmeyer & Dougherty, 1988). Regehr, Goldberg, Glancy, and Knott (2002) found that current social support was associated with paramedics' tendency to use mental health stress leave.

While families are often the primary source of support following a traumatic event, it is common for first responders, particularly police officers, to experience a decrease in social support from non-law enforcement family and friends as they progress through their careers (Gilmartin, 2002; Violanti & Drylie, 2008). This decline in support may be influenced by beliefs that "others can't understand me and my job," a desire to not burden family and friends with the stress of first responder work, substance use, emotional numbing and distancing, and feelings of isolation.

First responder peer support programs provide social support in a variety of situations and can be designed to integrate PFA principles and core actions. Although some organizational peer support programs incorporate chaplains as part of the CISM model, these programs tend to emphasize collegial peer support (Gillespie, 2017). In addition to work-related peer and spiritual support, encouraging connection with multiple sources of social support, including connecting first responders with their family members, non-first responder friends, and other community-based social, religious/spiritual, and recreational groups, is especially important. Further, departmental peer support programs may also implement programming specific to first responders' significant others, partners, children, and extended family.

Hope

Instilling hope is of central importance following a traumatic event. Trauma can shatter world-views and contribute to feelings of despair and hopelessness (Janoff-Bulman, 1992). Hope is commonly defined as a "positive, action-oriented expectation that a positive future goal or outcome is possible" (Haase, Britt, Coward, & Leidy, 1992). Hobfoll, Briggs- Phillips, and Stines (2003) note that this view of hope

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

may be more consistent with Western, upper-class, and white majority culture, and based on a notion of "rugged individualism" that overlooks realities of those who experience racism, poverty, and/or mass trauma. More inclusively, hope may be viewed as a sense of strength and optimism for recovery. Maintenance of hope is a resilience factor; optimism following a traumatic event is associated with a favorable outcome (Hobfoll et al., 2007).

The seventh core action consists of providing psychoeducation about common stress reactions and coping strategies, which may foster hopefulness about trauma recovery and resilience. As previously discussed, trauma survivors may be alarmed by their stress reactions and their baseline coping tools may be ineffective following trauma exposure. Providing reassurance about trauma responses and teaching a range of adaptive coping strategies may enhance a sense of self-efficacy and foster goal-oriented coping. These coping strategies may include seeking social support, accessing information and resources, engaging in distracting, enjoyable activities and physical exercise, maintaining a normal schedule to the extent possible, utilizing relaxation methods such as calming self-talk, journaling, and grounding. PFA also recommends identifying and modifying maladaptive coping strategies (e.g., substance use, overworking, excessive self/other blame, lack of self-care).

Referring survivors to additional services is the eighth core action of PFA. Providing information about professional support services may instill hope, contribute to calming, and foster a plan for action. Recommended referrals might include mental health care, medical treatment, social support services, and drug and alcohol support groups. When possible, PFA recommends warm hand-offs (i.e., provider-to-provider communication about survivors), which can ease the transition for survivors, increase sense of being cared for, and decrease the burden survivors may feel to "re-tell" their story to multiple providers.

Psychoeducation and referrals for first responders should be couched in terms that are consistent with first responder culture. Ideally, this would include education, during training/academy and then on an ongoing basis, about common trauma responses, the trajectory of and obstacles to natural recovery, the strengths and potential liabilities of first responder culture with regard to emotional and physical well-being (e.g., "it is not a sign of weakness to experience distress, even when it persists"), and adaptive and maladaptive coping. Education should also be provided regarding formal empirically-supported treatment options for post-trauma distress and their efficacy. Organizations should maintain a network of mental health professionals that have the cultural competence and evidence-based training to work effectively with first responders and should take steps to reduce stigma and barriers to initiating treatment (e.g., confidentiality of referrals, warm hand-offs when feasible, assurance that seeking treatment will not negatively influence job status or promotion).

In sum, promotion of safety, calming, connectedness, self- and collective efficacy, and hope are the core evidence-informed elements that guided the design of PFA and are integral components of many evidence-based treatments (Hobfoll et al., 2007). The underlying principles of PFA are interrelated; feeling physically and psychologically safe and calm may increase one's sense of coping self-efficacy and hope for recovery, which may increase likeliness of social connectedness, and positive outcomes of social support likely enhance a sense of individual and collective efficacy (de Jong, 1995; Hobfoll et al., 2007).

METHODOLOGICAL AND ORGANIZATIONAL CHALLENGES

Significant methodological and organizational challenges to evaluating and implementing PFA in first responder organizations exist. In general, conducting evaluations of PFA is difficult. Most broadly, PFA

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

is not a structured, one-size-fits-all approach. It is not surprising that there are no published RCTs of PFA given practical and ethical challenges of assessing pre-trauma functioning, randomizing trauma survivors to treatment modalities, delivering replicable interventions in the field, monitoring what is actually happening during those helping encounters (i.e., fidelity, replicability), retaining participants, and obtaining consistent follow-up data.

Evaluation of PFA will be especially challenging in first responder populations, particularly police officers. First, it is likely that PFA would be integrated as one of many components of a peer support program and would not exist as a stand-alone model. Second, although law enforcement peer support program guidelines exist (e.g., IACP, 2011), departments vary in their application of these guidelines. Third, the intended effects of peer support programs are conceptually unclear and may include outcomes both for those whom the first responder helps and interacts with and for first responder themselves. These might be as wide-ranging as detection of symptoms/impairment, prevention of chronic and impairing psychiatric conditions, receipt of professional support/treatment, maintenance of on-the-job functioning, prevention of adverse events, reduction of needed stress leave or workman's compensation cases, and improved employee retention. Fourth, it is ethically and functionally challenging to conduct RCTs, resulting in the self-selection of officers who choose and are selected to participate in peer-support programs. Fifth, it would be rare to obtain a true baseline level of functioning prior to a given critical incident and few psychological assessments have been normed and validated for police officers (Robinson & Mitchell, 1993; Malcolm et al., 2005). Thus, it is acknowledged that rigorous research evaluation of PFA outcomes faces complex obstacles.

Challenges in implementing PFA in first responder organizations are also anticipated. Strong leadership support is needed, and must be sustained across changes in personnel and organizational change. Effective training methods are required to ensure mastery of PFA skills and routine ongoing use in day-to-day practice. Optimal training in PFA would likely entail didactics, observed role-plays with feedback, and ongoing supervision and case consultation. Such continuing support is needed to help trainees continue to apply their skills and reach a level of familiarity and confidence that will lead to continued use. Should they be mastered, the new ways of helping included in PFA will need to negotiate cultural barriers, including previous ways of doing business and countervailing norms of behavior. It remains challenging to encourage openness and sharing of thoughts and feelings in organizations characterized by a commitment to placing others before self and norms of "emotional strength" (Kirschman, 2007). Finally, it may be necessary to alter staffing patterns, shift rotations, use of organizational space, and allocation of resources in order to make it possible for newly trained helpers to successfully deploy their skills. All these considerations mean that leaders intent on building effective PFA programs will need to think beyond simply adding training workshops to include planning for sustained use in the context of local factors and challenges of encouraging busy people to do things differently in busy organizations, where the focus on community service under emergency conditions may push to the side considerations of staff wellbeing. Additionally, ensuring the confidentiality of peer-to-peer supports and referrals for professional services is paramount given internalized stigma about mental health concerns among first responders.

RECOMMENDATIONS AND FUTURE DIRECTIONS

As demonstrated above, developing, implementing, and evaluating evidence-based or evidence-informed early interventions for first responders following trauma exposure poses many practical, methodological, and organizational challenges. There is an alarming paucity of research demonstrating that the historically implemented early intervention models (e.g., CISD/CISM, peer support programs) are effective at ameliorating acute psychological distress, preventing trauma- and stressor-related disorders, and promoting a natural recovery (Everly et al., 2000a; Everly et al., 2000b; Tuckey, 2007). Clearly, there is a need for innovative, integrative early intervention work-related stress management models that expand on the traditional CISM model or offer novel ideas; this would facilitate assessment of the centrality of critical incident exposure and its interaction with other stressors (e.g., poor relationship with supervisor, overall workplace functioning, family stressors). With high-stress, physically and emotionally taxing jobs, frequent exposure to potentially traumatic events, and higher rates of stress-related physical illnesses, depression, PTSD, alcohol use disorder, and suicide compared to the general population, there is an urgent need for flexible, adaptable, and evidence-based early interventions for first responders. PFA is a promising and widely endorsed evidence-informed model grounded in theories of trauma recovery and resilience. PFA may be particularly well-matched for first responders because it 1) expands on currently culturally accepted interventions (e.g., peer support programs), 2) can be delivered on both mental health provider to first responder and peer-to-peer bases, and 3) may enhance first responders' skill-sets when caring for those they serve. As such, PFA may be diversely utilized and integrated within first responder organizations for an array of purposes. More specifically, multi-component PFA interventions could include staff education and preparation for stressful aspects of the job, response to critical incidents, team-building/morale, peer response programs, specialized crisis counseling and/or treatment, and family programs.

Detailed below are several evidence-informed recommendations. First, the beginning of a first responder career should include comprehensive psychoeducation about common mental health issues, coping strategies, self-care, peer/social support, and resources, and this should be reinforced throughout their careers via continued training. Second, it is recommended that first responders be trained in PFA (Forbes et al., 2011), and that these interventions be utilized in the immediate aftermath of a critical incident and integrated into peer support programs. Such training would likely enhance first responders' knowledge and skill-set in supporting their colleagues and have the added benefit of enhancing their skill-sets when serving their constituents. For example, first responders are exposed to mass disaster and hostage situations, distressed survivors and family members, suicidal and homicidal suspects who may be armed and dangerous, and deaths of adults and children secondary to suicide, homicide, accidents, and natural causes (Golden, Jones, & Donlon, 2014; Kleim & Westphal, 2011). First responders additionally provide emergency medical care and engage in handling of human remains (Golden, Jones, & Donlon, 2014; Kleim & Westphal, 2011). As such, PFA training may facilitate their ability and self-efficacy to provide psychological and practical support to victims and may protect against the experience of a loss of coping ability. More specifically, PFA may provide a clear, organized mental template that first responders can use when tasked with providing psychological and practical support to trauma survivors in the immediate aftermath of a traumatic event. PFA also provides recommendations for death notifications and body identification, which may be particularly relevant for first responders tasked with this challenging role.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Third, it is recommended that first responder organizations develop peer support programs, particularly in light of research demonstrating social support as a primary protective factor of PTSD and related mental health sequelae. With regard to peer support, it is recommended that peer support programs follow the IACP Peer Support Guidelines (2016) and are confidential, provide ongoing monitoring and support as indicated, and utilize targeted and appropriate interventions for specific problems. For the field to advance, and to ensure that services are actually helping, there will be a need for conceptual clarity about the intended effects of peer support programs. Fourth, it is recommended that intentional efforts be undertaken to assimilate peer support programs as a culturally-normed component of first responder organizations.

Beyond PFA, there is also a need to develop evidence-based teaching interventions to train those who provide peer support, and to tailor these trainings to the variety of existing first responder subcultures. It is now well established that, by themselves, simple training workshops are unlikely to effectively add to staff skills and change routine practice. Instead, they need to be followed by a period of supervision and consultation as trainees try out the new skills and make them their own. A few preliminary yet promising interventions have emerged, including Marks and colleagues (2017) peer support training program titled Recognize, Evaluate, Advocate, Coordinate, and Track (REACT). This four-module training program was designed to promote psychological health and prevent stress injuries in first responders.

Internet and mobile technologies offer significant opportunities to innovation. Given recent technological advances and the potential value of integrating mobile-health into early intervention responses, PFA Mobile was developed and is available for download on iOS and Android operating systems. The mobile app is provides a broad and comprehensive overview of PFA, including the five evidence-informed principles and basic objectives, information about who should deliver PFA and where it should be used, PFA guidelines (e.g., how to engage survivors, recommended behaviors to avoid), and considerations for cultural/diversity factors and supporting at-risk populations. The mobile app contains sections about PFA in practice, the eight core actions, and common reactions across the lifespan (e.g., infants/toddlers, preschool-age, school-age, adolescents, adults). There is also a section within the app that allows for providers to create a survivor needs form as a quick and practical way to keep track of individuals with whom providers come into contact. Provider self-care is another component of the PFA mobile application, including a provider self-assessment and information about self-care before, during, and after relief work. Lastly, the PFA mobile app includes a resource section with direct links to SAMHSA's Disaster Distress Helpful, the National Suicide Prevention Hotline, FEMA, and National Center for PTSD and National Child Traumatic Stress Networks.

At present there is no published research evaluating PFA. While RCTs may not be tenable due to aforementioned methodological and organizational challenges, there is a need for program evaluation research of PFA that is generalizable to first responder cultures, although there are still many obstacles (e.g., funding, organizational support) to conducting this type of research. At present, little is known about whether programs (e.g., CISD/CISM) accomplish their intended objectives, so managers cannot adequately evaluate the cost-effectiveness of their initiatives and, most important, it remains unclear if these programs are effectively reducing individual distress. There is a need to evaluate PFA peer support programs on multiple outcomes such as PTSD, depression, substance/alcohol use, suicide, and social and occupational functioning, and quality of life (e.g., Wessely & Deahl, 2003), and to consider the role of stigma of mental health and broader organizational context in which peer support programs are developed, implemented, and evaluated.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perhaps most importantly, in order for leadership to manage effectively and for peer support and other procedures to benefit staff members, it is important that organizations conduct periodic assessments of staff well-being and areas for concern. This information can be gathered anonymously, to evaluate PFA programs and inform their improvement and redesign. Further, first responder organizations are likely to benefit from collaboration with academic partners in order to evaluate current models of support and to develop and investigate innovative and potentially more effective proactive, preventative interventions as well as posttraumatic early intervention models for first responders, who fulfill vital and complex roles in society.

Chapter 49
Media, Social Media, and the Securitization of Mental Health Problems in Nepal: Yama Buddha's Case Study

Sudeep Uprety
Tribhuvan University, Nepal

Rajesh Ghimire
Tribhuvan University, Nepal

ABSTRACT

This chapter attempts to unfold the trend and nature of mainstream and social media coverage on mental health issues in Nepal through suicide case of Yama Buddha, a popular musician. Using the securitization theory and concepts of threat construction and threat neutralization, major findings through content analysis and key informant interviews reveal reputed mainstream media following cautious route towards threat neutralization and therefore, maintaining a level of journalistic professionalism. However, especially in the other online media, blogs, and other social media, there were sensationalist words and tone used to attract the audience, triggering various sorts of emotional responses, thereby fulfilling the act of securitization. Major recommendations from this chapter include more awareness and understanding about the nature and type of mental health problems; capacity building of journalists and media professionals to better understand and report on mental health problems; development and proper implementation of media guidelines on reporting mental health issues.

INTRODUCTION

Anil Adhikari, popularly known as Yama Buddha, a celebrated Nepali rapper reportedly died of suicide at his residence in Ruislip, United Kingdom on January 14, 2017, leaving scores of his fans and followers in shock. This tragic incident triggered a wide attention about celebrity suicides, especially linking

to the dreaded late twenty's club of global celebrities such as Jimi Hendrix, Janis Joplin, Jim Morrison and Amy Winehouse. Extensive mainstream and social media coverage of Yama Buddha's suicide also led to the ongoing debates and thereby public discourses on rising cases of suicides and mental health problems in Nepal.

About 90 percent people living in Nepal are suffering from psychiatric problems and there is 'insignificant attention' given to this sector (Uprety & Lamichhane, 2016). Furthermore, the lack of proper knowledge and understanding about the subject matter, lack of mental health specialists; poor implementation of policies and guidelines and lack of adequate resource allocation for mental health sector has aggravated the stigma surrounding mental health in Nepal (Luitel, et al., 2015). This stigmatization has led to under-reporting of many mental health cases and lack of proper care and attention towards the issue.

This chapter attempts to unfold the trend and the nature of stories reported in mainstream and social media on mental health and suicides in Nepal, meticulously unfolding the media reporting about Yama Buddha's case and how different discourses on mental health, suicides and stigma have been developed as a result of the attention the celebrity's death gathered.

Events occurred in this world including suicides are a 'shared reality' held not only by individuals, but also institutionalized in everyday practices and public artifacts such as media coverage (Uchida et al, 2015). While communicating a certain message through media, stories present socio-cultural attitudes and values apart from presenting objective facts, consequently generating a collective perception. However, the story teller or the journalist brings in his/her individuality making stories more interesting. In that sense, media coverage is not just a collective or macro phenomenon, but also comprises of individual psychological facts.

Social media has added a new dimension in the era of communication. Social media sites such as Facebook and Twitter provide that space of inter-linkage where 'weak links' or connections could be established with another person or group without having any previous interaction or good understanding about such people and groups. The power of digital media is as such today that a celebrity suicide case could go viral in no time that such news can have both effects – positive in terms of building a discourse and bringing mental health issues into the mainstream of national health debates on one hand while on the other hand, the lack of understanding about mental health and suicide, in the lure for 'dying to be famous' thus promoting more number of suicides. The fact that the number of Facebook users in Nepal rose from 0.85 million to 4 million in the space of 4 years (2011 to 2014) goes to show the escalating figures of social media usage amongst Nepalese and the impact as well as vulnerabilities it brings along with growing number of users (Anil, 2014).

In that regard, the authors would like to analyze in depth about the type and nature of media reporting on mental health/suicide issues and whether and how the Nepalese media is 'securitizing' such issues. Furthermore, with the social media analysis, it would also be useful in drawing the nature of discourses on mental health issues carried out at the public level and how that is contributing to the construction or deconstruction of stigma surrounding mental health issues in Nepal.

For the purpose of this chapter, the authors collected primary data about Yama Buddha death stories from various mainstream electronic and print media published from January 14, 2017 until end of April, 2017. Ten Key Informant Interviews (KIIs) were also taken with mental health professionals, mainstream media and social media researchers to understand the broader context. Furthermore, relevant literature reviews were undertaken to gather more global and local evidence to gain an in-depth insight and understanding on the issue.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Some studies have attempted to analyze the media reports on suicide – in terms of sensationalizing them in a way to solve problems.

Instances of Securitization by Media

A fact sheet by Media Frame (Pirkis & Blood, 2010) illustrates how media reporting and framing leads to imitation or 'copycat' suicide: when there is repeated and prominent coverage (across multiple media sources and on front page); when the reader or viewer identifies with the person as either someone that is similar to themselves or someone they look up to such as a celebrity; when certain subgroups in the population (e.g. young people; people experiencing a mental illness) may be more vulnerable; and when there are explicit descriptions of the method or location.

Interestingly, there are evidences to illustrate that celebrity suicides had more of imitation/copycat effect than non-celebrity suicides. A comprehensive study covering meta-analysis of 419 findings from 55 studies revealed that studies based on celebrity suicides were 5.27 times more likely to report a copycat effect than studies based on non-celebrity suicides (Stack, 2005).

Of 13 studies of television news reports of suicides on at least two of three national TV networks in the USA, an increase in suicide rates was found after the reports in 10 of the studies. Five of these 'positive' studies were of teenage suicide rates and one was of suicide rates in elderly people. Of 10 further studies of news coverage of suicides in more than one news medium, an increase in suicide rates was found in six (Programme, 2003). In some there was clear evidence of the direct impact of the reports on subsequent suicides (e.g. following the suicide of a very popular Japanese pop singer and of Miss Hungary).

Celebrity suicides are clearly newsworthy, and reporting them is often regarded as being in the public interest. Reports of suicides by famous entertainers and political figures are particularly likely to influence the behavior of vulnerable individuals, because they are revered by the community. Glorifying a celebrity's death may suggest that society honors suicidal behavior (WHO, 2008).

A particular incidence of securitization of a celebrity suicide case using Twitter can be understood from a tweet by the Academy of Motion Pictures and Arts (Dewey, 2014) which tweeted an image of Robin William's death with the phrase, 'Genie, you are free'. The impact of this tweet was as such that almost 340,000 retweets were made, violating the ethical norms of talking about suicide using social media.

Likewise, a review about media reporting on mental health issues (Ma, How the media cover mental illnesses: a review, 2017) of more than four decades of published studies revealed that media portrayals of mental illness were consistently inaccurate and unfavorable; people with mental illness were labeled as inadequate, unlikable, and dangerous. The review further indicated that media portrayals of mental illness influenced people's knowledge and attitudes toward mental illness and that negative depictions could have an unfavorable impact on people's attitudes toward people with mental illness.

Similarly, some of the studies provided evidence that reporting of the graphic and disturbing details of suicides might act as a deterrent, putting people off suicide as a solution to their problems, and that in fact 'sanitizing' the reporting of suicides might encourage suicidal behavior. Although there is evidence to suggest that features which include graphic or disturbing images of suicide methods may inform the majority of the audience about the dangers of a particular method, those individuals who are most at risk may actually be attracted to or encouraged by the same graphic details (Programme, 2003).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, there have been numerous other empirical studies showing media's influence in negative portrayal of mental health problems. A study in 2005 found almost 40 percent of newspaper stories portrayed mental illness as dangerous and violent, and the stories often appeared in the front section. Likewise, reviews of the US media found rates of dangerousness of 85 percent in representations and particularly controversial reporting of schizophrenia. Similar trends have been identified in New Zealand and Australian studies, where identified dangerousness in 62 percent of 600 articles drawn from a four-week timeframe. In a particular review of representations in various media over a one-month period, using content analysis, themes of violence and dangerousness were identified in more than 60 percent of the 562 articles. Likewise, another study found significant negative reporting in 1035 articles over a one-year period, and 50 percent of reports depicting danger (Knifton & Quinn, 2008).

Instances of Desecuritization by Media

Although majority of media stories tend towards sensationalizing the mental health issues, especially celebrity suicide cases owing to various socio-political and economic context, there have also been some instances of media encouraging desecuritization or normalizing such suicide cases.

There have been instances of desecuritization through media to discourage such acts such as an Australian study of reporting of Kurt Cobain's suicide in a range of media found that rates of suicide among 15-24 year olds fell during the month following the reporting of Cobain's death as the media was highly critical of the musician's act (Pirkis & Blood, 2010).

A review of 41 empirical studies conducted in 12 years shows that although negative portrayals of mental illness still account for a large portion of the research findings, researchers also found the number of such stories is decreasing (Ma, 2017). In that review, a study revealed recovery about mental illness and advocacy action was beginning to be discussed in the media, and more stories focused on biological or environmental causes instead of personal or parental blame. The researchers claimed that this finding was good news because previous research suggested people tended to view people with mental illness as more responsible for their condition than those with other health disorders. Likewise, another study found a large proportion of articles on autism sampled from The New York Times and The Washington Post provided more solutions for autism than causes and more often used medical experts as the news sources, which could help normalize this disorder.

There have also been efforts to desecuritize mental health issues using various social platforms. One such is PatientsLikeMe.com where people suffering from an illness exchange information with others with the same condition, e.g. to find alternative treatment opportunities. Forums such as these promote a patient centered approach to discuss and share problems, experiences in disease control initiatives – including mental health.

Due to the greater influence of media to influence policies, there have also been some instances of mental health policy influence through media with the help of strong evidence. In Australia (Meurk, Whiteford, & Head, 2015), media have contributed to making mental health a national issue. This has been possible with the global attention towards mental health with the combined with the global reach of media to promote inter-cultural dialogue and bringing stakeholders together for required policy uptake.

The 'shock' and 'celebrity' factor appears to count higher in rating the newsworthiness of a suicidal event than broader issues (debt, depression, despair) that may have a greater resonance with readers/audiences lives (Trust, 2007). At the same time it is evident that media coverage of suicide and suicidal

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

behavior can and does highlight important social and societal issues, especially where time and space is given to examining context and considering policy implications.

Media Ethics on Reporting Mental Health Issues

BBC Editorial Guidelines (BBC, 2017) also provides various tips for journalists in reporting suicide cases such as: avoiding language which sensationalizes or normalizes suicide, or presents it as a solution to problems; avoiding prominent placement and undue repetition of stories about suicide; avoiding explicit description of the method used in a completed or attempted suicide; avoiding detailed information about the site of a completed or attempted suicide; wording headlines carefully; exercising caution in using photographs or video footage; taking particular care in reporting celebrity suicides; showing due consideration for people bereaved by suicide; providing information about where to seek help and recognizing that media professionals themselves may be affected by stories about suicide.

In specific country contexts, Media Guidelines prepared by Ministry of Health of New South Wales, Australia (Health, 2014) suggests the following considerations for reporting suicide:

1. **Volume and Prominence:** Positioning the story on the inside pages of a paper or magazines, or further down in the order of reports in TV and radio news
2. **Context:** Reporting the underlying causes of suicide (e.g. mental illness, drug-related illness or other familial or social risk factors) can help dispel myths and increase community understanding
3. **Method and Location:** Detailed descriptions of suicide methods can prompt some vulnerable people to copy the act. If it is important to the story, discuss the method in general terms only. Particular care should be taken not to promote locations as 'suicide spots' or 'hotspots'.
4. **Add Crisis Support Contacts:** Including phone numbers for 24 hour crisis support services to provide immediate support to those who may have been distressed, or prompted to act, by the story
5. **Language:** If the story is about a death, use the term 'suicide' sparingly and check the language you're using does not glamourize, sensationalize, or present suicide as a solution to problems.
6. **Celebrity Suicide:** Celebrity suicide is often reported where it is considered to be in the public interest. To minimize risk, ensure the story does not glamourize suicide or provide specific details about method or location of death.
7. **Interviewing the Bereaved:** The bereaved are often at risk of suicide themselves. Follow media codes of practice on privacy, grief and trauma when reporting personal tragedy.

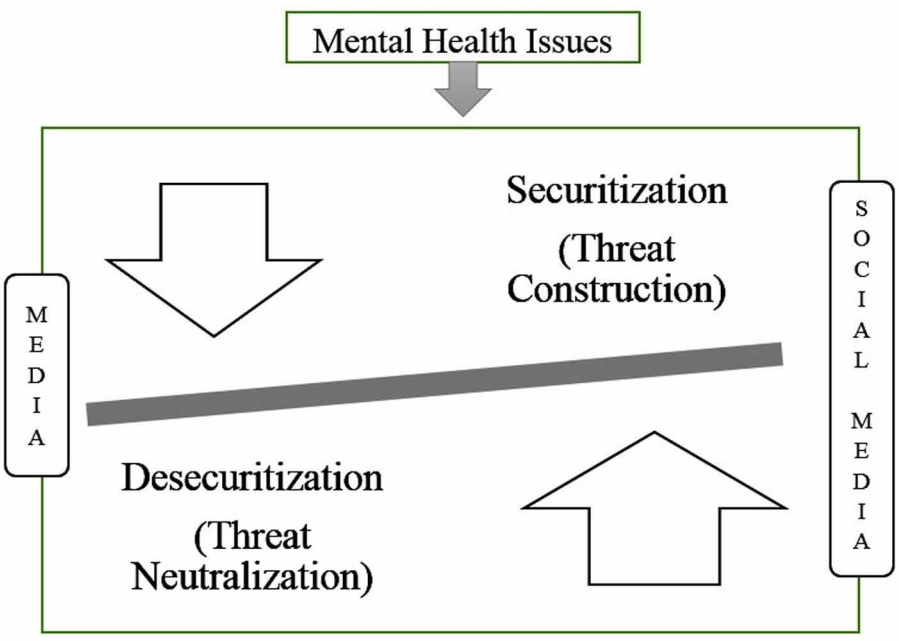
Likewise, in early 2009 the Canadian Psychiatric Association issued a position paper on safe media reporting (Medicine P., 2009). The paper urges reporters to avoid the following: giving details of the suicide method; using the term 'suicide' in the headline; including photos or admiration of the deceased; repetitive, excessive, or front page coverage; 'exciting' reporting; romanticized or simplistic reasons for the suicide; the idea that suicide is unexplainable; and approval of the suicide.

Theoretical Framework

Authors, through this chapter have used the Theory of Securitization (Buzan, Waever, & Wilde, 1997) first conceptualized in the mid-1990s. The basic notion of securitization is the positioning through speech acts of a particular issue as a threat to survival, which in turn enables emergency measures and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the suspension of 'normal politics' in dealing with that issue. The notion of securitization has also been closely linked with linguistics through scholars like Jacques Derrida. Derrida's theory of deconstruction, where his famous quote that "a text matters more for what it does than for what it says".



Authors have also aligned their analysis of the stories covered in mainstream and social media through the lens of Copenhagen School of Security Studies (Sulovic, 2010), conceptualizing security as a process of social construction of threats which includes securitizing actor, who declares certain matter as urgent and a posing threat for the survival of the referent object, that, once accepted with the audience, legitimizes the use of extraordinary measures for neutralization of the threat.

This sort of analysis is very important in the current context of the use of social media for developing and spreading fake news about suicides of certain celebrities that create a lot of fear, shock, anxiety and confusion among the public, thus contributing to the stigma surrounding mental health/suicide issues.

Therefore, for the sake of analysis of this case study, the term securitization has been defined as the process of sensationalizing the celebrity's death and his act of killing with the deliberate use of certain words and terminologies – thereby contributing to threat building with regards to suicidal tendencies. Likewise, the process of desecuritization has been linked with efforts by media to normalize the act of suicide and rather promote better education and awareness of mental health problems.

In a figurative presentation, the theoretical analysis of this chapter rests on analyzing the elements of securitization and desecuritization prevalent in reporting mental health issues by Nepalese mainstream and social media (see Figure 1).

Figure 1. Securitization and Desecuritization of Mental Health Issues

FINDINGS

Mainstream and Online Media Coverage

Republica (Sharma, 2017), covered this event of Yama Buddha's death with the title, 'Famous rapper Yama Buddha no more'. The choice of words in the title is mild with no negative connotations hinting at suicide or any mental health problem, therefore no direct association of securitization can be drawn directly from the title. The phrase 'no more' just suggest the rapper's death and the readers need to read through the content to get more details of the content.

As in the title, the content of the news also avoids any terminologies that securitizes the mental health issues or suicide incidents. The news agency attempts to put forward its event based reporting. Excerpts from the media story:

In an apparent suicide, famous Nepali rapper Anil Adhikari, widely known as Yama Buddha, has been found dead here on Saturday morning.

Quoting the family sources, journalist Bhagirath Yogi of BBC reported that the singer committed suicide in his residence in northern London.

Marhatta added that the cause for the death will be known only after the postmortem is conducted.

With lack of detailed information, the news agency does not give any suggestion or indication about the cause of his death. Professional ethics also seems to be maintained while the source of the death has been quoted (BBC) as well as mentioning the death of the rapper ('in an apparent suicide').

Some of the interesting reactions to the online version of the story are:

It is more important to not lose hope than winning. I am having a nightmare before sleep.

Damn, goose bumps as I read this!

My soul is dead hearing this.

These reactions suggest that shocking news that too of a suicide of a celebrated rapper could trigger grave responses from their fans and the reactions could be very pessimistic such as the ones mentioned above ('having a nightmare before sleep' and 'my soul is dead hearing this').

Daily Mail (Summers, 2017) chose a very long and provoking title: 'Nepal mourns its 'voice of a generation' after the mysterious death of the country's most famous rapper who was found hanged at his wife's parents' home in a west London suburb' of the event. The choice of words used by the news agency definitely has a securitization angle with description of the cause of death (found hanged at his wife's parents' home). Likewise, the phrase 'Nepal mourns its 'voice of a generation' also an attempt to trigger an overwhelming response especially from youth and music fraternity. The story is mentioned as 'exclusive' news in block letters, specifically highlighting that Yama Buddha had hanged himself in the bathroom.

The major content of the story provides a detailed description of the event such as:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

When his father-in-law went to use the bathroom at 6am he found he was unable to open the door and could not get an answer.

Eventually he forced his way in and found his son-in-law hanging from his belt in the bathroom.

The rapper had not left a note and friends and relatives are mystified why he would want to end his life.

Providing as detailed information as possible to the readers could be the motive behind publishing such content by the media agencies. However, these sorts of explicit descriptions may also lead to securitization and result in negative connotation of the news agency.

Some of the interesting reactions to the online version of the story are:

The disillusionment of many people in this world is reaching epidemic proportions. So sad to see this happen.

I am a Nepali and I am baffled by his suicide. He could get any sort of help from his fans if he had appealed or gave some signals. It feels so bad. Why?

Nepal is one of the poorest countries in the world and has spent several decades in severe political turmoil. After what they've been through I very much doubt if the country has been "thrown into mourning" by the death of a rapper.

Why would he kill himself when he got the world? There is more to it.

There have been mixed reactions to this story. While the fans of Yama Buddha were in despair, there was also desire to know more about the cause of his death. Likewise, the reactions also suggest the worry about the increasing trend of mental health problems. One of the interesting comment was also related to the title of the story – with the inclusion of the term 'thrown into mourning', clearly having the securitization element to gather attention to the readers while the situation might not have been so extreme.

The Himalayan Times (Times, 2017), a mainstream English news daily chooses a shorter self-explanatory title, 'Yama Buddha commits suicide' to cover the event. The title provides an enough detail for the readers regarding the cause of the rapper's death and moreover as debated by various mental health experts, deems the act as an offense with the term 'commits suicide'.

The Himalayan Times presents an event based reporting of the incident as per the available information, also quoting the source of information:

Famous rapper Yama Buddha has reportedly committed suicide. Anil Adhikari, popular as Yama Buddha, reportedly took his life at his residence in northern London on January 14, according to BBC Nepali Service. He was 29 years old. Quoting his family sources, BBC Nepali Service confirmed that his dead body was found in the bathroom.

There were no apparent reactions to this coverage by the news agency in the comments section.

A popular online website among non-resident Nepalese, Canada Nepal (Baral, 2017) also chooses a similar shorter self-explanatory title, 'Rapper Yama Buddha committed suicide'. Similar to the choice

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of words for the title by The Himalayan Times, Canada Nepal opts for usage of the term 'committed suicide' linking it as an act of offense.

Canada Nepal chooses to provide a rather detailed account of the event – not just informing about the death of the rapper but also additional detail of his death, stating that he was found dead in his bathroom. However, the tone of the story does not have an explicit securitization angle as it obtains its information from trusted sources (such as BBC and family members) and mentions that additional details about the cause of the death would be revealed after the post mortem report.

In an apparent suicide, famous Nepali rapper Anil Adhikari, widely known as Yama Buddha, has been found dead here on Saturday morning. Adhikari's brother-in-law Resh Marhatta confirmed the death talking to Republica Online. BBC Nepali Service said that the rapper is no more. Quoting the family sources, journalist Bhagirath Yogi of BBC reported that the singer committed suicide in his residence in northern London.

According to family sources, the singer was found dead in his bathroom at around 3 am. Adhikari, 29, had been living in London with his wife. The dead body has been kept at Northwick Park Hospital, Harrow. Source added that police have told the family members to contact them only on Monday. It is learnt that the postmortem will be conducted on Wednesday. Marhatta added that the cause for the death will be known only after the postmortem is conducted.

Another online Nepali portal XNepali.net (2017) does have a securitization component in its coverage. The title itself is attracting the audience when it says, 'Why Yama Buddha committed suicide?' for the audience to be interested to know the cause of its death.

The news agency put forward its arguments to its readers questioning the official report of the rapper's death that it was a suicide case.

This story also has many horrific pictures about the dead body of the rapper further securitizing the act of suicide.

An online portal, Habamoment.com (2017) explicitly mentions about the cause of the rapper's death and also associated with other celebrity suicides with the title, 'Yama Buddha and Three Other Nepali Celebrities Who Committed Suicide'.

The online portal discusses about how Yama Buddha's death 'has made all Nepali think about all high-profile suicides in Nepal'. The article has a negative tone filled with shock with the choice of words such as: "he had name, fame, money, and most importantly the love from his family, wife, and fans but who knew that he too had the courage to kill himself!"

The title of the story by another online portal Update Medicine (2017) attracts the audience in terms of asking the audience one pertinent question: 'The Case of Death: Suicide or Murder?' Through this title, the story gathers attention of the readers to unfold the mystery surrounding the rapper's death.

The story follows a negative tone, inclined towards a fan/follower's reaction towards his death. The story provides additional detail about the death of the rapper and some of the suspicions surrounding Yama Buddha's death:

His near ones say he had not been under any ongoing personal conflict with anybody. After hearing the news, some people in Nepal had some kind of suspicion (correlating to Rap & Hip Hop Culture) that Rapper abused some form of drug before it all had happened but it is said the post mortem examination

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

did not find evidence of drugs over his body. Rather it's been said that they found some traces of alcohol regarding which it said that he had drunk few sips of wine with his wife after returning from his work at Royal Mail that night.

The Guardian published an article the next day stating that rapper's father in law found him after his second attempt to open bathroom door with the next set of keys they had inside the house. On the other hand, other media sources state that it was another person living in the next floor of the same house who on an attempt to enter into bathroom that morning found the door locked from inside. He then opened the door with the next keys and found him hanging dead. The same question gives rise to next suspicion that how can a door be opened with the next key from outside when it was locked with the original set of key from inside.

It has also been reported that torn pieces of passport was found on the scene but the reason behind and its relation with his death still remains a mystery. There seems no other way to assume why Yama Buddha had done so. The absence of any reports regarding the footprints investigation has also become the matter of suspicion. Another mystery regarding this case is relevance of fractured lower molars (some sources report lower jaw) with hanging. It is still unclear if those got fractured before it all took place (due to some other incident) or the knot simply broke off after his death leading to that fracture.

The story had plenty of securitization elements especially with the big bold sub-headings such as 'Who saw the dead body first?' and 'The torn pieces of passport and the torn pieces of molars/jaw'.

Barun Ghimire, a Nepali blogger pays an emotional tribute through his blog (Ghimire, 2017) to the rapper as reflected in the title, 'Rest in Beats Yama Buddha'. Ghimire attempts to desecuritize the event with suggestions on more awareness about suicide and mental health issues.

We need to connect, communicate and care if we are to combat suicide. Let us work together towards suicide prevention and let people know them that they matter more than they think they do. We need to talk about suicide and create awareness in the underlying cause or at least we need to explain to everyone that suicide is not the ANSWER.

To those who want to express respect and tribute to Yama Buddha, I urge them to work towards suicide awareness and suicide prevention so we'd deal with actual killer. Let's talk about suicide and spread awareness. It is high time we do something about it.

Ghimire also expresses a strong message that 'suicide doesn't end the chances of life getting worse, it eliminates the possibility of it ever getting any better'.

Another attempt of desecuritization to this story was made by a blogger Shiva Neupane from Melbourne in his letter to The Himalayan Times (Neupane, 2017) emphasizing on more diffusion of academic knowledge and awareness on psychological studies especially to the younger generation as he writes:

We all have different level of capacities to resist suicidal tendencies. The capacities come from our deeper understanding of life, and the way we look at what it means to live. As long as we are mindful in what it takes to know the internal locus of control, then nothing would happen to us. However, it is

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

our independent mindset to contemplate the entwined fabric of our likes and dislikes about our own boundary of our personal life.

Surprisingly enough, we can see the national and international examples that even the celebrities who have name, fame and money commit suicide just because of their pseudo-views that may be logical for what they do in the first place. The society is the sole- reason why they commit suicide. Directly or indirectly society is culpable for blanketing the individual's framework of understanding about how they view life in which they are encapsulated.

What I personally perceive is the material gains may not fulfill our life. The singer lived in the sophisticated city of London. However, he committed suicide. This reflects the fact that it is not a conscientious decision to readily accept the fact that the people's class and status may not be the only yardstick to measure that they are living in harmony with peace of mind. When there is no peace of mind it doesn't matter how rich you are or how popular you are, death will steal you away in a matter of few minutes. We need psychological studies about mitigating and finding the root causes of this kind of incident.

Social Media Coverage

YouTube

A YouTube video by a channel, Efact TV (2017) has uploaded a video on January 15, 2017 explaining the reason why Yama Buddha committed suicide. The video as of April 11, 2017, 6 am Nepal time has reached 267,573 views with 1220 likes and 145 dislikes.

The title itself has a lot of securitization element with the choice of words, 'Why Yama Buddha hanged himself using belt?' drawing curiosity among readers in terms of not just the cause of the suicide but also the method used by the rapper to kill himself.

The video mentions that the rapper killed himself by hanging in his bathroom. The video also provides details of his hanging mentioning why he chose belt as the rod to hang clothes was located at some height and using belt was easier. The video also mentions that the reason behind his act of killing himself mainly was the gradual erosion of his popularity which sore in 2002/03 and then there was downfall which led him to prolonged depression.

Some of the viewers of the video have commented suspecting the details provided by the media that the rapper woke up from his bed at around 3:30 am and was inside the bathroom for more than 3 hours without his wife even noticing that while she was just sleeping beside him.

Another YouTube video by Thuloparda TV channel (2017) uploaded on January 28, 2017 shows the pathetic emotional condition of a father while his son's corpse was brought for cremation to Kathmandu. This video with images of his corpse surrounded by his family members and relatives along with scores of his fans and other commoners interested to take his photograph triggered a lot of rage amongst its readers. Some of the readers' comments were:

How insensitive people have become? In such a tragic moment, some people are finding it interesting to take photographs using mobiles while the poor parents are in such a shock.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

So sad to see that most people are concerned taking pictures only instead of offering prayers and condolences.

Likewise, this video also triggered some of the extreme reactions from the rapper's fans, thus fulfilling the securitization motive of the media agency:

Why is media all the time trying to prove that Yama Buddha committed suicide by assuming that he went into depression after being revealed publicly that the celebrated rapper was earning money by being a postman in the UK?

This life is such a waste! All the time we are worried about what we don't have and what others have. Ultimately, we all will be worthless one day!

Another YouTube channel NK TV goes further extreme in terms of choosing its title for covering the Yama Buddha story. The chosen title is 'True story behind Yama Buddha's death now revealed: the reason you hear will shake your heart'. The choice of words used in the title such as 'true story now revealed' and 'shake your heart' has securitization move. Consequently, this video had a high viewership (422, 307 views with 2161 likes and 243 dislikes as of April 11, 2017, 6:30 am Nepal Time).

This video without citing any source provides an elaborate description on why Yama Buddha killed himself mentioning that the rapper was in a state of worry with him residing in his in-law's house in the UK. Furthermore, the media states that he went into a state of depression having lost all his pride as a celebrated rapper in Nepal and having to work as a postman, delivering letters in the UK. He went into contemplating how could he earn his living just by singing rap songs? According to this channel, one incident really triggered Yama Buddha in killing himself. Once while he was delivering letter in one of the residences in UK, he met one of his fans. She was so excited to meet him. She called all her friends and took photographs with him. This incident went viral on social media and everybody came to know that a celebrated Nepali rapper was doing the 'menial job' of a postman in UK. Furthermore, sympathizing his condition, those people who knew him used to give him tips while delivering letters, which made him feel very uncomfortable. The media concluded that the rapper being fed up with his life, ultimately, committed suicide.

Another YouTube channel Nepal Reviews chooses the title, 'Yama Buddha suicide letter' with the strategic attempt to securitize the story and attract more viewership (Reviews, 2017). There is no mentioning of the suicide letter. Instead the video runs through some of the photographs of the rapper and the audio narration in the background explaining the reason (all based on assumptions and no quoting of the source) why the rapper killed himself. The channel claims that he had already had a fame but deep down he was frustrated. He was not able to make money and was also into drugs occasionally. He was struggling financially to keep up to his name.

With the choice of emotional words, the channel makes an attempt to securitize this story to his followers:

It might be true that good persons go to heaven earlier. He used to rock at live performances. The Almighty might also be interested in his live performances – so the God also might have been interested in his live performance.

Naya Naya News Nepal – another YouTube channel chooses to desecuritize the Yama Buddha case (2017). Published on January 30, 2017 (with 102, 069 views – 367 likes and 66 dislikes as of April 7, 2017 6:30 am Nepali time), with the title, 'Who is this Person who is revealing death secret of Yama Buddha?'

Rather than providing any first-hand detailed account of the rapper and its audience, this video is more of a commentary about the social, psychological and economic factors leading to the rapper's death:

Why competent youth go abroad? This trend needs to stop. This death teaches us a lesson how to manage our life effectively. There is a trend of Burger nationalism where competent youth go abroad and preach about how Nepal should develop. Yama Buddha wasted his time and competence by engaging in menial jobs such as that of a postman. Some people assumed that he was embarrassed and depressed after it was revealed in social media that he was working as a postman. Yama Buddha's weakness is not to feel proud about the work that he was doing. We should not do activities that embarrass us. Recently, another youngster committed suicide after his piracy scandal of Chakka Panja movie was revealed. Life is not synonymous to sadness and failures. Life should be spent with joy and happiness. He/She should do justice to the talent/skills he/she bears. There is an increasing trend of going abroad to earn money. Student visa has been misutilized not to study abroad but to work as laborers. Greater attention needs to be paid in terms of stopping from going abroad in the lure of earning dollars, getting depressed and committing suicide. There is no point of toiling hard in the abroad. Rather than that, it would have been worthwhile to work hard in own homeland and do something for the country.

Furthermore, the video also talks of various pertinent questions raised in the social media about his suicide such as:

In Britain, there wouldn't be appropriate place to hang oneself inside the bathroom.

Yama Buddha's wife who had slept with him – how could she not notice that her husband was in the bathroom for over 3 and half hours and the dead body was noticed by another member in the family only in the morning?

Yama Buddha's jaw was also broken. How did that happen?

How was the door of the bathroom unlocked?

Overall, the video makes a good effort to desecuritize the story and give a positive message to its viewers with these closing remarks:

These [assumptions made in the media] are all just unproven doubts and until they are proven, we should not be highlighting these issues in the media. We should not be assuming that this could have happened and that could have happened.

Rather we should support the family of the deceased at this time of need.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

A talented Yama Buddha – how he spent his life was a wrong message. Nepali youth should take a lesson from this tragic event.

Twitter

There has also been mixed reactions from Yama Buddha's fans and other general public reacting to his death. Some of the interesting tweets collected by the authors are as follows:

I feel ashamed to see the fake cheap videos on YouTube regarding Yama Buddha' death and people accusing his wife who isn't in right state of mind

And the irony is that it took the death of a celebrity for many Nepalese to understand that depression is deadly.

Let the poor soul, loved by everyone rest in peace. Dammit, don't use his death as earning source. Truth will find its way.

Please, stop putting up Yama Buddha's picture as you DP, it's unpleasant, the reminder of his mode of death.

We can't judge anyone as a coward unless we dun know the pain behind the suicide as their last way out.

With curiosity searched about Yama Buddha, ended up with Kurt Cobain's' suicide note

Couldn't tear out a single page of life, so decided to throw the whole book into the fire.

I wish all my books to do suicide like Yama Buddha

The demise of Anil Adhikari (Yama Buddha) Yama Buddha resembles Swiss cheese, lots and lots of holes. Does not sounds suicide to me.

I wish I could actively get involved in case of Yama Buddha's death/suicide conspiracy. I had few question to ask to his acquaintances.

Yama Buddha, you had the guts to commit suicide. There are several people who have no desire to live longer but are not able to kill themselves. You are great.

Yama Buddha is a legend in his own right. His death (reportedly suicide) bursts the bubble our newsrooms & society in general dwells in.

I also have an excuse to kill myself, but I these days I also seek to find excuses to live every day and defeat the death.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

People say that suicide is a permanent answer to a temporary problem, but sometimes that problem isn't so temporary.

If Yama Buddha had really committed suicide, then he must be a coward.

Thus, these reactions are filled with extreme love and support and at the same time hatred for the rapper as well as disappointment in his act. Some of the tweets do have desecuritization elements – with appeals to leave this case aside and not to blow this story out of proportion but rather analyze the contexts that lead to such acts and hopefully control such incidents in the future.

Facebook

Similar reactions were received on Facebook and with no word limitations as in Twitter, there have been elaborate discussions about the causes of his death and in general why people, especially celebrities end up killing themselves.

Anil Adhikari's (Yama Buddha) death by suicide is a sad news indeed as is hundreds of Nepalese who commit suicide every year. Mental illness is still such a stigmatized subject. It's about time we speak out about it and encourage people in need to seek support!

Am I the only one who wants to find out the actual reason behind the so called 'suicide' of Yama Buddha? What is written in Nepali news sites is so unclear. Hope to find out the reason soon. I still can't believe that he did suicide and he is with us no more) I am so confused.

I read somewhere, suicide is a temporary solution of a permanent problem. I don't know if you ever read that, but I'm sad to let you know that the problem that you thought you got rid of just got amplified by a larger scale. You thought that you had a valid reason to decide for yourself, but, do we really get to decide for ourselves?

If he had committed suicide there's no space for him on heaven.

Yama Buddha did not commit suicide because he was weak or out of options or in pain. He was just too fed up with these human structured unemotional machines. He only tried to escape them.

As illustrated above, some were in total shock and disbelief about the incident and blamed Nepali media for not providing clear information about his suicide. On the other hand, there were also attempts made to understand the real context that led him to such circumstances as well as appeals to discourage such acts by being sensible and attempting to address our problems rather than taking an escapist route.

Findings From Key Informant Interviews (KIIs)

Few mental health and media experts were also consulted through Key Informant Interviews to gather their perception and opinion about the media coverage of mental health issues in Nepal, particularly linking with celebrity suicides.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Limited Understanding of Mental Health Issues

Both mental health and media experts have pointed towards limited understanding of mental health issues in Nepal.

Mental health as a discipline is very broad subject in itself. However, due to very less proportion of mental health experts, wide misconceptions regarding mental health exists. It is therefore imperative that wider awareness, knowledge and understanding regarding mental health needs to be spread to the public. – Consultant Clinical Psychiatrist

As a mental health researcher, sometimes I am surprised that even the 'educated' and 'informed' citizens have very limited understanding of mental health. Major reasons for this could be limited academic orientation on the subject; lack of resources easily accessible about mental health through the media and social media; more focus on urban settlements – linking mental health issues more towards work related stress management, anger management, depression, among others. – Mental health researcher working in an NGO

As a journalist reporting for the past 9 years on health and social sector, as an honest confession, I admit that I have limited understanding of mental health issues. We have very few journalists (equal to none), who have academic background on health reporting in Nepal. – Journalist of a national daily

Capacity of Journalists to Report on Mental Health Issues

It is striking to notice that the media sector itself was skeptical of its capacity to understand and report mental health issues in a proper way.

The reality of media reporting needs to be taken into consideration. Media professionals are educated mostly on the theories and practical approaches to journalism and mass communication. Yes, we do have some academic training on development journalism, but in terms of mainstream media coverage, the principles of development journalism are not applied to a larger extent. Nowadays, as a positive sign, development agencies have started engaging media professionals on different issues such as health and education. Therefore, there are some opportunities for journalists through fellowships to learn and understand more about the health – including mental health sector. However, these efforts and initiatives are miniscule considering the wider network of commercial media and journalism sector. – Sub editor of a national daily

I have been reporting on health issues for the past seven years now and the basis of my reporting is self-exploration and consultation with mental health experts. The problem with us is that with various constraints for us to report on a regular basis – including time and resource factor for an investigative reporting, it should be admitted that our understanding on mental health issues is not adequate. Furthermore, we are not provided with adequate training and orientation on mental health issues for us to report better unless we take the initiative ourselves through self-learning. In simple terms, there is no institutionalized practice for capacity development of the journalists. – Journalist of a national daily

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Media's Role in Securitization on Mental Health Issues

There have been mixed reactions by the key informants when it comes to media's role in securitization of mental health issues.

A section of the key informants believed that at least in the Nepalese context, mental health issues have not been securitized to that extent through media, unless there was a major celebrity suicide or mental health disorder incident.

Frankly speaking, Nepali media sector has not matured enough to that extent where there is institutionalized practice or intention to securitize on 'soft issues' such as health and education. Yes, there have been some instances where there has been some 'over-reporting' or 'sensationalism' created over media reporting of celebrity suicides but, still to a great deal as securitization principle envisages of an existential threat. – Media researcher

As a nation, we are still yet to experience that kind of celebrity 'mania' or 'paparazzi' as experienced in the West or even in India. Nepali celebrities are found accessible to the commoners. In a way, this is a good thing as it limits general public to be idolizing or patronizing acts or deeds of celebrities. In real life incidents elsewhere, there have been many instances of 'copy-cat suicides' which hasn't been 'viral' yet in Nepal. – Clinical Psychiatrist

Whereas, some of the key informants also believed that there is increasing trend of securitizing acts on mental health issues in Nepal.

Yes, to some extent, we are heading towards it [securitization of mental health issues] and moreover, with the increasing growth of media agencies and social media use, the tendency to be interested in celebrity incidents such as suicide cases will increase. – Psychologist

As a media researcher and enthusiast, though I am excited about the staggering growth of media outlets and social media platforms, I am also equally cautious about the consequences of growth of this nature. This ultimately brings us to an interesting debate on media freedom and ethical reporting. It is not a hidden thing that the growth of social media has led to securitization of mental health problems, particularly celebrity suicides and Nepal is no exception. – Media researcher

On Securitization of Yama Buddha Suicide Case

As a reader, I was also confused initially with the nature of stories reported in the media about Yama Buddha's suicide story. The act of securitization really began when there were numerous story links posted in online and social media about horrific pictures of the rapper's dead body and his parents crying in shock, symbolic photographs about the rapper's act of hanging using belt, and various assumptions based coverage about why the rapper could have killed himself. This definitely had a negative impact upon the minds of his young followers. – Psychiatrist

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

As a close observer of the digital media activities in Nepal, I was well aware of the patterns and intentions of the media agencies in reporting Yama Buddha stories. During informal chats with the media agency owners, they have also revealed about the need for the 'masala' or 'spicy' content to increase their views and shares of their stories. Yama Buddha was a big name and an inspiration for the youth, with his followership growing. His most recent tweet, four days before his death declaring that his latest album was soon to be released had also contributed to his greater fan following. In other words, this is click bait journalism in simple sense. – Media researcher

On developing an interface between media and mental health professionals to improve reporting on mental health issues

Both media and mental health professionals appreciate that there has been a positive response towards improving the practice of media reporting on mental health issues in Nepal. However, they admit that it is more of a 'reactive' rather than a 'proactive' response:

Yes, there has been greater realization that mental health issues are sensitive to have a significant impact upon wider public due to media reporting and we have had discussions at the policy level to address this issue. However, no substantial steps have been taken to institutionalize this practice. – Mental health professional

What strikes me, at this point of time, as media professionals, is that, we do realize that an intermediary is required to strike a balance between a 'journalistic reporting' and policy uptake, may be more in the line of principles of development journalism. This realization has been there at all levels from a novice journalist to a seasoned editor. However, we haven't taken this to the next level, which I suppose is a strategic policy engagement by a civil society organization, a critical media group or similar structures.

Overall, the key informants have shared that the current journalistic practice and lack of adequate information and underlying misconceptions about mental health in Nepal definitely leads to securitization of mental health issues in the long run if the concerned agencies working in the field of media ethics and media education are not cautious enough at an early stage.

CONCLUSION AND RECOMMENDATIONS

This study attempted to understand the nature of media reporting on mental health issues in Nepal, particularly investigating the Yama Buddha suicide case and the extent of securitization applied by the mainstream and social media channels, while covering the story.

Though the Yama Buddha case might not be entirely sufficient to make a comprehensive conclusion, given the high mainstream media and social media attention the story gathered, certain conclusions can certainly be drawn.

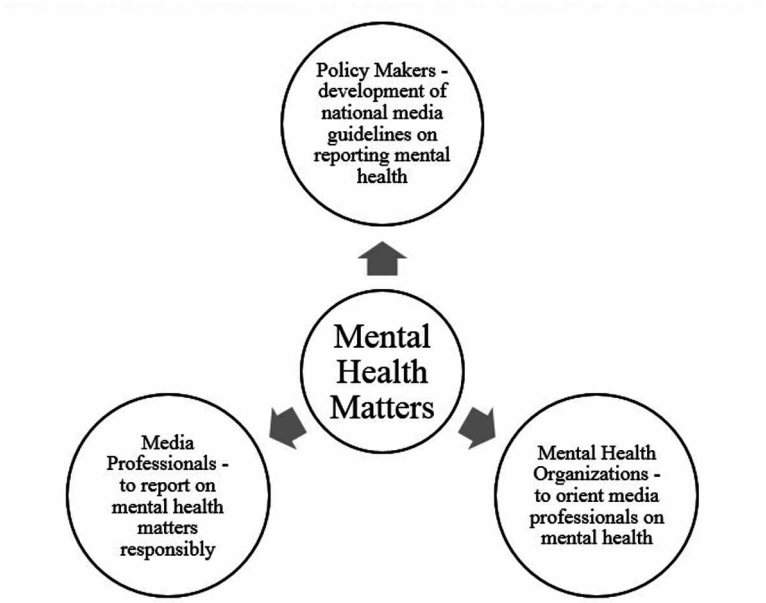
Reputed mainstream media outlets in general have chosen a cautious route towards threat neutralization. From the choice of words used for the title to the content, there was an attempt made to ensure that the followers/fans of the celebrity do not follow the path of 'copycat suicide'. In this regard, it can be deduced that a level of understanding and journalistic professionalism is maintained at least by mainstream media outlets.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, especially in the other online media, blogs and other social media, there were sensationalist words and tone used to attract the audience. This definitely drew the audiences towards such stories and triggered various sorts of emotional responses – thereby fulfilling the act of securitization. The suicide case of Yama Buddha, as a famous celebrity and his songs being widely popular, became a perfect story for click bait journalism for Nepali online media sites. This nature of click bait journalism, knowingly or unknowingly has resulted in mental health issues being 'over-reported' in the media as compared to, previously, even though through an individual case like that of Yama Buddha. Particularly, in the Youtube videos, the securitization element was prominent with titles suggesting explicit details of the rapper's suicide including the cause as well as method of killing himself while the content of such videos barely described such minute details. Some of those videos receiving almost half million views shows the extent of reach among his fans/followers.

Through the key information interviews, it was also revealed that the mushrooming of online and social media globally and in Nepal with increased competition and trend of click bait journalism, the securitization on sensitive issues such as celebrity suicides have also been justified in some occasions. However, this doesn't negate the fact that the capacity of journalists to report on mental health issues, especially suicide cases sensibly needs to be improved to a great extent. The context of story production – the tight deadlines, limited resources and the interest of media houses to capitalize on the celebrity coverage could also have triggered on the nature and extent of media reporting on such issues. Furthermore, with some level of realization and advocacy for the need for an 'intermediary' to take the initiative forward for evidence informed policy development exercise following the media reporting, some efforts have already been made such as a collaboration between Primary Health Care Revitalization Division (PHCRD) under the Ministry of Health and Health Research and Social Development Forum (HERD), a non-government organization to improve media reporting on urban health issues in Nepal (Uprety, McGrath, McNerney, Ghimire, & Baral, 2016).

More often, the triggers resulting in a response become more important than the response itself. When the mental health issues in Nepal are over-reported and in most cases, without substantial details or readers/viewers being misled, three major recommendations can be drawn from this study:



1. More awareness and understanding about the nature and type of mental health problems as well as the existing myths and misconceptions at the public level.
2. Capacity building of journalists and media professionals to better understand and report on mental health problems and consequences of securitization at the public level with over-reporting on suicide cases. This could be done in collaboration with organizations working on mental health.
3. Development and proper implementation of media guidelines on reporting suicide and other mental health issues.

Thus, these recommendations form a multi-sectoral coordination between policy makers, media agencies and mental health organizations promoting better reporting on mental health matters, as presented in Figure 2.

The authors, through this chapter, thus, advocate for the desecuritization of mental health issues in order to deconstruct the stigma and myth surrounding mental health in Nepal.

Chapter 50
Barriers to Practitioners' Endorsement of a Recovery Perspective:
Considering Attitudes Through a Schema Lens

Debra Kram-Fernandez
Empire State College (SUNY), USA

ABSTRACT

This chapter is concerned with the impact of practitioner biases on the experience of a meaningful life for individuals who live with serious mental illness (SMI). Professional biases, systemic biases that originate in societal fear and lack of knowledge, and internalized stigma taken on by the consumer affect life decisions. Following a history of treatment initiatives experienced by consumers as abusive, it is important to understand how a system envisioned to protect and treat was often experienced as harmful. In the 1980s a movement emerged to transform the nature of mental health treatment to a client-centered, recovery-oriented model. In 1999, the Surgeon General proclaimed that all agencies serving this population should be recovery oriented. Yet, the shift to this approach to understanding people with SMI has not been complete. While there are many explanations why practitioners may not fully embrace this perspective, this chapter introduces the concept of "schemas" from cognitive behavioral theory as a way of examining professional biases in the field of SMI.

INTRODUCTION

This chapter concerns the impact of professional biases on the ability of individuals with Serious Mental Illness (SMI) to experience a life of meaning and purpose in the same way as those who do not live with SMI. Due to the inherent power differential between patient and therapist, client and coach, or consumer and guide, professional biases can devastate the dreams of individuals who turn to the

mental-health system, voluntarily or involuntarily, for the purpose of learning strategies to manage life with SMI. Most studied is the impact on help-seeking behaviors of people with SMI due to public and professional stigmas (Hailamariam et al., 2017; Henderson et al., 2013). When professionals are not able to reflect on their own schemas, there is potential for a cyclical and damaging dynamic. This dynamic is one based on personal biases of the professional, systemic biases originating in societal fear and lack of knowledge, and subsequently the internalized stigma taken on by the consumer, can prevail (Beretta et al., 2005; Orbell & Henderson, 2016). In the face of obvious reservations on the part of their treating professional, rare is the individual who will have the courage to move forward in pursuit of a life course of their choosing (Mead & Copeland, 2000; Deegan, 1996).

The mental health system has a long history of offering interventions that were ineffective and sometimes barbaric. However, when professionals act on the science and data of the time, interventions are usually reasonable and calculated risks. Bloodletting, ice baths, and even frontal lobotomies most likely emerged in a genuine effort to effect healing. Yet, these treatments often continue long past the acquisition of evidence that they are ineffective and in fact harmful, and the realization of their effects. One explanation of how this happens might be the impact of professional stigma. At what point does the practitioner embrace an "us and them" attitude toward his or her charges? At what point is it easy to detach from empathizing with the other because the other has become somehow less human?

In 1999, the Surgeon General proclaimed that all agencies serving this population should be recovery oriented; yet, the shift to this more client-centered approach to helping people with SMI has not been seamless or complete. Many reasons impede greater embrace of this directive, including but not limited to lack of consistent and widely disseminated data that a Recovery Perspective is more effective; lack of understanding of the practices that make an agency recovery oriented; and misconceptions that suggest this orientation is cost-prohibitive. Thinking critically about the recovery perspective reveals that this "perspective" or "paradigm" is not an evidence-based practice. In fact, it is not so much a "practice" as it is a way of working with people—an ethical focus on an individual's right to self-determination, dignity, and respect. Therefore, failure to fully embrace these principles remains somewhat curious. This chapter will define the cognitive behavioral concept of schemas, and consider how a greater understanding of this psychological mechanism may be a way of examining professional biases and their impact on consumers in the field of SMI.

By the end of this chapter, readers should have a basic understanding of the Recovery Perspective in mental health, and areas of common ground as well as conflict when compared with the more traditional Medical Perspective. We discuss how this perspective offers a client/consumer-centered approach to services for people with SMI, and how attention to professional schemas may be a vehicle for understanding the perpetuation of stigma against the people with SMI by professionals in the field of mental health. In closing, the chapter will offer some possible directions for mitigating the inherent harm that can occur from unchecked schemas among mental-health professionals.

TYPES OF STIGMA AND THE PERSPECTIVES THAT MAY HELP DRIVE THEM

Understanding a number of key concepts can assist the reader in fully appreciating the impact that stigma and bias have had on the lives of adults with SMI. First, this chapter refers to individuals who utilize mental-health services as "consumers." The nomenclatures for this population and the terms by which they are identified have morphed with the emergence of new scholarly and political developments. The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

term "patient" gave way to "client" as many recognized that the original term promoted a sense of illness and a role or position of dependence upon a person with a title suggesting "expert" status. "Client" gave way to the term "consumer" in the 1990s. This coincided with the emergence of the recovery movement that quickly became a formidable component of the mental-health landscape. The title "consumer" emphasizes a shift in the understanding of the relationship between a person in need of services and a service provider. Rather than a person with a disability being acted upon, "consumer" connotes a sense of the system working for the person in need of service. The battle for adoption of this change has been hard-fought and the term remains in inconsistent usage. Other important concepts include the notion of personal biases among professionals, social and systemic bias among others in the society, and bias that consumers of mental-health services often internalize.

Personal bias among helping professionals is one type of stigma. Numerous factors influence the development of individual perspectives on SMI, and like lay people, professionals are not immune to these factors. Lessons learned from family of origin, school and community experiences, religious organizations and affiliations, the political climate, and everyday experiences impact expectations and assumptions about human beings with SMI. The inclination toward science and/or religion can have an impact on how people understand the world around them, and the influence of the media cannot be overstated. Images of SMI in popular culture, such as sound bites on television or radio news broadcasts, movies, sitcoms, miniseries, and even social media, can have a profound influence on a person's understanding of causes, prognoses, appropriate treatment alternatives, and implications for public safety.

Haller (2010) makes the argument many representations of disability in the media show a tendency toward distortion that betrays the "ableist" values so dear to society. "Ableist" values essentially promote the worth of physical and mental, and intimate that their lack may even be a reasonable excuse for suicide. Haller uses the notion of assisted suicide to make this argument. If it is understandable that under the circumstance of losing a physical or sensory ability, one should have a right to end one's own life, what message does this convey to a person who never had that sense or ability? In her content analysis of media images of disability, although she observes shifts in public consciousness that were promising, the theme of disability represented as weakness remains prevalent. In addition, the theme of disability deserving derision or ridicule continues to be a problem.

Science in and of itself can exhibit bias. While greater learning and science can challenge misconceptions and fallacies, the history of the treatment of people with SMI is plagued by interventions founded in science that ultimately proved ineffective, dangerous, or sometimes even downright barbaric. Azar, Benjet, Fuhrmann, and Cavallero (1995) emphasize that "scientific facts" are laden with personal values.

Personal values of professionals informed by beliefs and perceptions that stigmatize can be profoundly detrimental to life outcomes for individuals with SMI. A professional making a decision based on an unsubstantiated fear can exert tremendous and unfair power over the life choices of a consumer. Not all mental-health professionals are experts on the scholarly literature of mental illness and societal risk; however, all mental-health professionals influence decisions over the lives of others, which their unchecked personal views may govern.

History has played a role in professional bias—perhaps small, but nonetheless a definitive role in the perpetuation of personal biases held by many mental-health professionals and lay people. For instance, Emil Kraepelin was the first to distinguish a separate set of symptoms that could be associated with what is now called schizophrenia. Kraepelin (1919, cited in Warner, 2004) named this separate disorder Dementia Praecox, which translates in essence to an illness that begins in adolescence (praecox) and results in a dementia-like state. He proclaimed that what differentiated dementia praecox from other

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

forms of mental illness was its incurability. Thus, over a hundred years later and in spite of evidence to the contrary, diagnosis of a SMI, particularly a psychotic disorder such as schizophrenia, is often thought incurable. In fact, Kraepelin himself conducted numerous studies and found that a small percentage recovered from SMI (Kraepelin, as cited in Warner, 2004). Even today, many professionals believe recovery is hopeless with a diagnosis of schizophrenia.

A further historical blow came later in early 1900s when one of the greatest minds in psychiatric and psychological history, considering the diagnosis of schizophrenia, declared that psychotic illness falls on a continuum separate from the mental health of the average person. In his contemplations about varying types and levels of neurosis, Sigmund Freud (1911) in his work on dream interpretation expressed concerns about the ability of a person with damaged ego strength to delve into this material without exacerbating psychotic symptoms. Regardless of Freud's personal reckoning of the implications of that assertion, the message suggests that people with SMI were somehow less than capable of psychological growth and change.

Another factor in professional bias might be the influence of a theoretical framework to which a given professional subscribes. Freud was the father of psychoanalysis, and psychoanalytically oriented mental-health professionals understand the cause of mental-health issues to be rooted in unconscious conflicts, usually traceable from childhood. In other words, symptoms or behaviors for which a consumer might seek help from a professional are a result of these unconscious conflicts. Recovery is thus a cessation of symptoms that results from working through past traumas by putting them into words with affect. Particularly in classical psychoanalytic theory, the roles of analyst and patient were clearly delineated and hierarchical. The treatment was usually quite long term, with a belief in recovery. However, whether this type of treatment is appropriate for people with more serious disorders is still a question, suggesting that there is actually no strong belief in recovery from SMI. Even today, some professionals see psychodynamic treatment of serious mental illness such as schizophrenia as akin to malpractice (Fuller Torrey, 2006). The value in this theory is the idea that motivations and drives made conscious free the consumer to make choices of his or her own free will. Recovery is ultimately the moment when through complex psychodynamic processes, the consumer "internalizes" the therapist and is able to do this kind of detective work on his or her own.

Alternatively, cognitive behavioral theory (CBT) was a bold and radical shift that emerged at a time when the "unconscious" was a household word. Albert Ellis (1994) proposed the idea that perhaps rather than an unconscious that would require long-term detective work with an expert professional, the locus of why people behave and feel as they do lies in how they interpret cues from their environment. In other words, the thoughts that go through a person's head in a given situation will determine how they feel and then act, and then perhaps think, feel, and act again. Thoughts, feelings, and behaviors are cyclically related. However, with just a few sessions with a cognitive behavioral therapist, a person can learn to identify thought distortions and thus interrupt the unhelpful patterns. CBT is an active therapy, particularly for the consumer. While both theories require hard work, CBT requires specific homework assignments and activities. Therapist and consumer roles are more level, and the therapist is more of a coach. Therefore, after just a few sessions, the consumer will have the tools to coach him- or herself. There is once again an expectation that with this work, recovery is a possible outcome.

Sociocultural theory minimizes the impact of internal dialogue and unconscious conflicts on the functioning of an individual or group. On the contrary, this theory suggests that if we resolved societal inequities and injustices, people would not behave in symptomatic ways. This theory sees causality as related to social injustice, and therefore the cure lies in social change. The role of a helping professional

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

might be to stand side by side with a consumer at a march, painting a mural, lobbying legislators, and fighting together for social change.

Dividing theories into separate categories—biological, psychodynamic, cognitive, behavioral, family or systems, and sociocultural theories—is neat and organized. But in practice, varying degrees of each theory have an impact on the individual's emotional health in different and unique ways. Societal biases and systemic bias are crucial issues, and different consumers respond well to different approaches fueled by different theories. In sum, professional bias can be attributed to personal life experiences of the practitioner, to historical inaccuracies perpetuated over a century, and even to the theory that most resonates for the individual helping professional.

Internalized stigma is another level of presupposition that negatively affects the lives of consumers. People with SMI are members of the same social system as everyone else. The images they see of SMI are the same as the rest of the population sees. In addition, many have experienced a medical-model culture where calling an individual "a schizophrenic," "a borderline," or "a depressive" was standard nomenclature. This can be very demoralizing. The problem with this language is that once an identity becomes a label that entails lesser social and professional expectations for a meaningful life, only an extraordinary human being could overcome such expectations and thrive.

Expectations expressed by the professional community have a tremendous impact on people with SMI and greatly affect their expectations for themselves. In an editorial piece in *Schizophrenia Bulletin*, a family member explains that when the disease affects the brain, it is difficult to see where the disease ends and the person begins (Sundstrom, 2004). This difficulty is compounded when professionals in the field cannot make this distinction either.

The Recovery Perspective

Harry Stack Sullivan (1962), a renowned psychoanalytic theorist and practitioner in his own right, was a disciple of Sigmund Freud. Their paths diverged due to professional disagreements. One important difference in their understanding of mental health was that while Freud saw psychosis on a continuum separate from that of the rest of humanity, Sullivan saw humanity in SMI. On many points, he presaged innovations of the late 20th and early 21st centuries. Long before evidence-based practices were a celebrated initiative in mental health, Sullivan made the claim that any treatment offered to a person with a SMI requires study. He also understood that when a person with a SMI believes that the treatment provider considers the illness degenerative, the patient is at great risk of losing hope for the future. He also believed that an illness that affects the life of people as young as adolescents must be curable. Although his contributions were made before the onset of the recovery movement (and subsequently the recovery perspective), crossovers between his humanistic theory and the recovery perspective are noteworthy.

Although a large number of studies throughout the 20th century document recovery from the most serious mental disorders (see Warner, 2004; Calabrese & Corrigan, 2005), in 1987 Courtney Harding published an article on a study that she conducted, which also presaged aspects of the recovery movement. Not too distant history conjures up an image of SMI housed in a mental institution from which many people never were discharged. Images included restraints, screaming, electric-shock treatments, and lack of care such that human adults sat for interminable periods of time in soiled clothing. Harding (1987) wondered what the impact might be of a twofold intervention, the first being inpatient skills training, and the second a coordinated plan for support, from the same team that taught the inpatient skills, for patients reintegrating into the world-at-large. She led a team that provided this intervention,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and conducted a longitudinal analysis. Her findings were quite positive and became a turning point in the scholarly discourse around the notion of recovery from SMI. This skills-building and environmental-support model presaged the Psychiatric Rehabilitation Model that, in addition to sharing office space with proponents of the Recovery Perspective, is in many ways the operationalization of the Recovery Perspective.

While standing up for the dignity and appropriate treatment of people with SMI is not a late 20th-century phenomenon, (e.g., Dorothea Dix, Philipe Pinel), in the 1980s this movement developed leadership among consumers, their families, and professionals, which turned it into quite a formidable movement. Some leaders and advocates of this movement include individuals who identify with attributes of both scholars and consumers, including Patricia Deegan, Ph.D. (1988; 1996), Mead & Copeland, (2000), and Anthony (2000), to name a few.

In the 1980s, the recovery movement was born, and it would change the face of mental-health treatment. Two divergent forces were the impetus for this transformation. First, people with SMI began writing in large numbers, not only about their experiences with recovery, but also of abuse that they experienced in the mental-health system. Second was the development of the Psychiatric Rehabilitation Model, dovetails with the Recovery Perspective in that both are strengths-based models of care that recognize the value of peer support, encourage integration into the community-at-large, and maintain core values in understanding recovery from SMI.

Today's scholarly discourse about the definition of recovery from SMI considers what recovery means to those with serious mental illness. Up until the 1980s, recovery was essentially synonymous with cure, and thus meant a cessation of symptoms, cessation of hospitalizations, and the achievement of a "normal" level of functioning (Warner, 2004). This provided a measurable definition that would satisfy medical practitioners and quantitative researchers alike. This Medical Model perspective sees recovery from SMI as an endpoint that does allow for measuring recovery in a consistent and unbiased manner. On the other hand, recovery-oriented clinicians and consumers tend to view recovery as a non-linear process. Although from a Recovery Perspective there is variation in the way in which recovery is defined, certain key elements are present in most definitions, including the restoring of a sense of hope, a sense of meaning, and a sense of purpose in life (Noordsy et al., 2002). Other important elements of this newer definition include creating and/or maintaining a peer-support network outside the mental-health system (Davidson, 2006), taking responsibility for one's own recovery journey, and considering one's own understanding of spirituality (Anthony, 2000; Davidson, 2006 Noordsy et al., 2002). Measuring recovery by this definition is a greater challenge than examining the number of hospitalizations, symptoms, and defined levels of functioning, but there is tremendous value in the endeavor. This method of measuring recovery recognizes the identity of a person as more than an illness and a number, and instead as a multidimensional human being.

Mental illness is rarely an event from which recovery is linear. While measures and numbers are clear and concise, mental health is a grey and murky concept best envisioned as multilayered and inexact. All human beings are learning, growing, and changing in different aspects of their lives at any given time. Thus, envisioning recovery from serious mental illness as a process that evolves in stages rather than as an endpoint is compelling (Lieberman & Kopelowicz, 2002). Proponents of the recovery movement invest their energy in changing the way we provide services. Rather than being acted upon by a system of experts, recovery-oriented consumers strive to be equal partners in determining their course of treatment.

Although this philosophy resonates with the social work code of ethics, a code that specifically emphasizes a need to respect client self-determination and the dignity of a person (NASW, 2017), like

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

any organizational change, this paradigmatic transition has experienced some obstacles. In fact, the vast majority of agencies serving those with SMI may not be fully compliant with the Surgeon General's directive.

There is a real and critical need to address myths and assumptions on the part of professional helpers. In general, stigma creates an "us and them" environment that enables people to behave in inhumane ways towards others. This can become routine and acceptable. Germaine to the experience of people with SMI are numerous concrete examples of how stigma against people with SMI has resulted in harmful and inhumane treatment of this population. A right to participate in one's own treatment-plan development is a recent addition to consumer rights. Prior to this, once a person bore the label of SMI, the norm became being acted-upon with little if any of their input. Protections to ensure that people with SMI would be free to live in the least restrictive environment that could allow for both their personal safety and society's is also a new phenomenon. Providers are attempting to review the use of restraints, and further, to recognize the element of retraumatization inherent in many of these routine practices. Only recently have programs begun to examine the risks of abuse of power within programs for people with SMI, and to implement strategies to mitigate this potential. Although the notion of internalized stigma and the knowledge of how institutional care can foster this situation has been documented as far back as 1961 when Erving Goffman published *Asylums*, rigorous efforts to address internalized stigma are still in their infancy.

In many ways, the greatest and perhaps the most critical negative impact of stigma, for people with SMI in particular, has been the impact on the psychological concept of hope (Davidson, 2006). Having lost hope, a person has lost a sense of controlling his or her destiny. Without enabling a sense of hope for the possibility of change, for the possibility of something better, we greatly diminish a person's motivation to find any meaning or purpose in life. Consumers have documented numerous examples of mental-health services that demonstrate how the mental-health system perpetuates this state of hopelessness, due to stigmatization based on lack of understanding, experience, and knowledge about SMI. This undermining of hope for a positive future robs many of years of their lives.

Frequently when treatment does not appear to be yielding positive outcomes, clinicians blame the consumer. Linehan (1994) has argued that if the treatment is not working, it is the treatment at fault, not the person. This perspective can promote compassion and recognition that SMI is not a willful attempt to sabotage treatment interventions.

"Schemas" are semifixed and long-held beliefs that individuals often develop from childhood experiences, which drive how they organize data in their world and make decisions, and how they relate to one another. This concept of schemas may offer a way of looking at professional attitudes influenced by stigma, and an understanding of how providers maintain errant views.

SCHEMAS

A Manner of Understanding Professional Biases From the Cognitive Behavioral Theoreticians

Many initiatives have been geared toward helping people with mental illness find strategies to cope and even fully recover. The historian Gerald Grob (1994) has separated periods in the history of treatment for

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the mentally ill into four discrete eras. Each period represents a shift in the understanding of the cause of mental-health issues and a new direction for providing treatment.

The first of these periods he called the Asylum Period, which occurred from approximately the mid-1800s through the early 20th century. While members of society with mental illness and without economic privilege found themselves in asylums, others found themselves in "sanctuaries," removed from the stresses of everyday society. These patients received "moral treatment" offered in some of the state hospitals. The rationale was that disorders of the mind were a by-product of the chaos, greed, and sense of meaninglessness in society, and thus the cure was to remove the afflicted person from these social stressors. Providing a sanctuary promotes a peaceful environment designed around a routine of purposeful and structured activities, and healing occurs. In fact, this type of treatment did prove successful. The industrial revolution led to overcrowding in an overwhelmed system that provided custodial care at best, and at worst neglect and abuse.

The Mental Health Hygiene period began in the 1890s with the notion that cure of SMI could be an outcome of proper scientific approaches to treatment. The shift was to small hospitals that were associated with medical schools. The emphases were on early diagnosis and reenvisioning mental-health care as equivalent to medical care, and thus moving into the mainstream. However, this model also met its demise with a loss of funding and an increase in demand for services, which overwhelmed the system.

The shift in the mid-20th century to Community Mental Health Care grew out of a few important developments. First was the discovery in the 1950s of psychotropic medications that could be combined with other medications, resulting in a calming affect that made community reintegration a real possibility. In addition, societal awareness of the conditions in mental hospitals put pressure on government officials to take action. President Kennedy, with a personal interest in human beings with mental disabilities of varying kinds, both emotional and intellectual, was persuaded to sign into legislation the Mental Health Centers Act of 1963 (Community Mental Health Centers Construction Act, public law 88-164) (Clark, 1993). Deinstitutionalization was the outcome of this bill, but the results were not as anticipated. Moneys earmarked for community treatment centers that were unaccustomed to meeting the needs of this challenging population were used to provide treatment to higher-functioning clients, and mass numbers of people discharged from the psychiatric institutions became homeless and in danger.

The Community Support period began around 1975 and continues today. This period represents a shift in the understanding of causes of mental illness, and recognition of the importance of addressing the stigma of SMI. One shift was the emergence of the recovery movement, wherein consumers began disseminating anecdotal data about recovery from SMI. The understanding of what causes SMI shifted from faulty parenting to a neuroscientific perspective. The development of new technology that allowed for neuro-imaging of the brain greatly supported this shift. The shift from bad parents to neuroscience promoted two ideas: that recovery is possible, and that the biggest challenges to societal reintegration for people with SMI were attributable to social stigma, not the illness itself. Social stigma was used to block appropriate housing for people with SMI (ex. group homes, scattered site homes) from receiving permits in safe neighborhoods, as well as funding that could help to integrate people with SMI into the competitive workforce. Social stigma interacts with personal stigmas imposed by professionals, and stigmas internalized by those with SMI.

Studying cognitive behavioral theory requires that a thought, feeling, or behavior that seems intractable or impermeable to change be questioned as to what mechanisms are perpetuating the problem. Similar to the difficulty many people experience when attempting to break a habit or develop a new behavior,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

professionals and lay people who determine the care that will be provided to people with serious mental illness may be vulnerable to acting on schemas that might be outside of their completely conscious control.

The intractability of stigmatized thinking may be a by-product of the cognitive behavioral concept called "schema." Schemas are a fact of development; human beings develop schemas throughout life in order to help them to make sense of the world around them (Azar et al., 1995). Schemas emerge as children collect a repertoire of life experiences, and familial as well as social relationships and interactions can impact them. They are also developed as we observe images of popular culture including television, movies, books, games, and all sorts of social media. Schemas respond to social norms, cultural beliefs, and experiences from infancy to the present, with families, schools, community centers, religious affiliations, and more. Further, human beings develop role schemas (Azar et al., 1995), which allow them to conceive of expectations or definitions for mental fitness, competence, and essentially mental health. The experiences that enable people to develop these schemas also determine their understanding of how human beings should act when confronted with various social relationships. This can elicit preconceived ideas of how consumers should act in the presence of a mental-health professional. This has crucial implications for professional decision-making. There is an inherent power differential between a provider and a consumer. Providers can determine what services and opportunities are available to a consumer. Thus, providers have an ethical responsibility to make decisions not driven by stigma and bias.

Schemas are not necessarily a negative construct. Like any personal characteristic, schemas can be rigid or flexible, closed or permeable to new data. They can encompass a negative assessment or evaluation, or a positive one. Professionals making decisions guided by fixed and negative schemas have the capacity to detract from client self-determination in a powerful and negative way. For example, how a provider writes a biopsychosocial report for an application for independent housing can be the deciding factor as to whether or not a consumer obtains the housing he or she desires. Like unchecked biases, unchecked schemas can result in professionals taking full responsibility for the life situations of their charges. Every professional possesses his or her own set of schemas, and thus can positively or negatively affect the basic right to self-determination of consumers of mental-health services. Schemas can determine the roles and expectations that practitioners hold for their charges.

Azar et al. (1995) have used the concept of schemas to offer a compelling way of examining bias in child-welfare decisions about termination of parental rights. Likewise, this chapter uses the concept of schemas as a manner of examining bias in decision-making on the part of professionals in the field of mental health. One way of examining schema is to look at expectations of people within role relationships. Often without realizing it, we have predetermined expectations of how individuals should behave in their role as consumers, toward others in the role of practitioners. One dyadic role that might be somewhat commonplace is that of the compliant client. What is a compliant client, and what happens when that role is not satisfied?

The Compliant Client

Although most professionals today would probably agree that the hallmark of a successful treatment is not fostering compliance and dependence, but rather fostering critical thinking, self-advocacy, problem solving, and a wide repertoire of safe coping mechanisms, adherence to this philosophy can be complicated in practice. Reasons for this conundrum may be the history of mental-health professions, and the context of the world in which people today practice.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

From an historical perspective on the field of mental health, direct-service providers have struggled to enjoy respect as both professionals and scientists when their area of specialization is studies of the mind and behavior. Although psychiatrists were devalued by other medical doctors, many social workers made the choice to associate with both the medical and the psychiatric professions in an effort to enhance their professional status. This social work profession carries a past haunted by functioning as "friendly visitors" who, while largely pure of heart, practiced by imparting knowledge about what was moral, as keepers of the social order. Therefore, it is not surprising that when the profession arrives at the 1980s, working from a position of more or less "equal" status with patients could be perceived as a threat to the psychiatrist's or social worker's public image of professional and scientist.

In addition, there is no denying that society has become increasingly litigious and blaming. There are very real professional consequences at risk when promoting consumers' right to self-determination and the kind of risk-taking that promotes growth and learning that other citizens can take for granted. Should a consumer voice a desire for independent housing, and a professional assist in exploring wants and desires before making a global assessment of the consumer's overall functioning; and should that housing situation result in a loss of the apartment, and emotional stress and suffering, who would be held accountable? On the other hand, what percentage of the population without a diagnosis of SMI learns in the absence of experience? Is there really another way to learn the skills of living independently?

These tensions trouble a field that values strengths-based and client-centered approaches to treatment, and that honors the right to self-determination for all people and aim to empower all charges.

The Mentally Deranged

Another expectation of the role imposed on persons diagnosed with SMI is that they are a threat and dangerous to society. Until quite recently, film and television stories of individuals with mental illness have consistently portrayed people with mental illness as regressed, dangerous, and irrational. When struggling, stressed, and symptomatic, lack of a clear sense of reality can be a symptom of many with these afflictions, which can be frightening to observe. On the other hand, frightened people are not sufficient to support an assessment of dangerousness. In fact, studies support the idea that the vast majority of people with SMI are at much greater risk of victimization than of ever committing a violent crime.

When a news story begins with a report of a terrifying, distressing, and unconscionable mass shooting, immediately followed by reporting that indicates belief that SMI was a factor, it creates a specific social response. That the gunman unsuccessfully sought treatment twice in the week before the incident due to a shortage of staff would create a different story and result in a different public sentiment. It would be a story less about the danger of the SMI, but rather about the need to provide adequate supports to all citizens to enable them to participate in the world safely and successfully. A story beginning with: "The shooter had never been known by the mental-health system . . . " would communicate a different message. If there were a weekly segment on every news broadcast that showcased the contributions of a different people living in the world with SMI, fully contributing and functioning as valuable members of society, again we would have a different story.

Diagnosis, Stigma and Schema

Diagnosis is a wonderful tool for identifying a set of symptoms that respond well to certain interventions, and for securing funding to help consumers obtain the supports required for growth and development.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Diagnoses simply allow consumers access to various programs. Other than these uses, it is always a potentially dangerous practice to put a label on a human that can have far-reaching consequences with respect to how they view themselves, how they are seen by society, and even how the community of helping professionals sees them. Diagnoses result in expectations that can be a detriment to growth and change.

Cognitive behavioral theorists are interested not only in the schemas that drive our actions, but also in the conditions that maintain and perpetuate these thoughts, feelings, and actions. In other words, it is not enough simply to strive to change a behavior; one must understand what maintains that behavior. When individuals look for confirmations of their expectations, they can very often find them. There is an abundance of societal expectations for how someone with SMI will behave in a given situation. Retroactively, people can often find ways to interpret what they see in a manner that supports their expectations. When looking through the lens of one's own schemas, we interpret multiple layers of a situation accordingly. Thus to be mental health professionals who promote recovery rather than stand in its way, the field will need to identify improved methods of helping professionals to better identify, understand, and resist acting on their existing schemas about people with SMI.

There are numerous schemas held by lay people, people with SMI, and professionals in the field of mental health, which are based on feelings rather than facts. These schemas have a tremendous impact on consumers' rights to self- determination, a life of dignity, and living in the least restrictive environment that allows for their care and safety and the safety of others. Identifying ways to ensure that professionals make decisions and recommendations they base on accurate information, and not long-held schemas, is a necessary priority in deconstructing stigma around mental illness.

SOLUTIONS AND RECOMMENDATIONS

Failing to address professional schemas is unethical, and it causes genuine harm in a number of ways. One issue is the notion of a self-fulfilling prophecy. Orbell and Henderson (2016) discuss the findings of a study that suggest that we activate subliminally based on a schematic representation of illness. In other words, the messages that consumers receive might be automatically activating behaviors that we then document as symptoms.

Studies around the word also suggest that social expectations about SMI drive beliefs that this group needs or deserves fewer social comforts to survive. One study (Rayan & Obiadate, 2017) examined the impact of stigma and poverty on people with SMI in Arab countries, and found that they experienced significant differences in overall quality of life.

One consequence that receives considerable attention is the impact due to stigma on help-seeking behavior in people with SMI (Corrigan, Druss, & Perlick, 2014; Clement et al., 2015; and Natan, Drori, & Hochman, 2017). In examining how specifically professional stigma acts as a barrier to help-seeking behavior, Clement et al. (2015) identify fear of disclosure—i.e., of being revealed as a "mental patient"—as a strong factor that keeps people from seeking treatment. Corrigan et al. (2014) concur and note as a deterrent the lack of accurate information possessed by not only the consumer, but also families and communities.

A concerning finding is that consumers in a 2017 study identified power relations in mental-health care as a primary locus of stigmatized behaviors. Sercu & Bracke (2017) found that one in four experiences of stigma occur at mental-health facilities. Professionals communicate these attitudes to consumers when they infantilize consumers and take no interest in aspects of their humanity outside of the diagnosis. The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

presence of other power attributes such as class and social inequalities compound these effects. Another study found that poor quality of life for people with SMI in India was significantly greater due to poverty. People with SMI were unable to pay for treatment and received unreliable medications, particularly those that could reduce side effects of the primary medications. There was a lack of understanding about the potential long-term nature of the illness, and that made sustaining support and connections a challenge. There was also a lack of education, and therefore a lack of flexibility in methods of engagement when someone was actively delusional, or unwilling or unable to enter treatment options (Hailamariam, Fecadu, Prince, & Hanlon, 2017).

Disclosure of mental illness has been correlated with better outcomes for people in recovery who are reintegrating into society (Pahwah, Brekke, Rice, & Fulginiti, 2017). However, stigma from professionals and people in the society-at-large is a factor in dissuading people from disclosure. The issue here is that many of the professionals who should be providing community education and advocating against stigma are unaware of their own discomfort and tendency to stigmatize consumers. Other studies support this idea and state that the mistrust of mental-health professionals might not be unfounded (Zieger et al., 2017). Many studies are showing that there is little success in most of our initiatives to reduce stigma and its harmful effects (Clark et al., 2013).

Some studies demonstrate that anti stigma campaigns help. Musyimi, et al. (2017) reviewed a study that analyzed results of campaigns at numerous levels. The study looked at how anti stigma efforts affected the attitudes of children, social media, adults, social marketing, and community initiatives. Indications appeared that initial help-seeking among people with SMI increased, and stigma from friends, family, and even community members decreased. Unfortunately, there was no indication that stigma perceived by health professionals decreased, and it is unclear as to why that occurred. This may identify long-held schemas about mental health and mental illness. How do we work to change stigmatizing behaviors, bias, and schema that we are unaware we carry?

Unexpected Consequences

Interesting studies have found that negative cognitive self-schemas increase self-stigma (Shimotsu et al., 2014). Pedersen and Paves (2014) addressed a perplexing question: Since we know that perceived public stigma is a barrier to young adults seeking treatment, how does this relate to personal stigma? In other words, they wondered how people with SMI would view and treat others, and how would this compare with perceived public stigma? Interestingly, the majority of responders would not have thought less of someone who had SMI or sought help; yet they believed others would think less of them. Also perplexing is that for so many people around the world, having a quality life is less important than avoiding the pain of a stigmatizing label. Stigma diminishes self-esteem and robs people of opportunities (Corrigan, Druss & Perlick, 2014).

In the United States and Western European countries, Sontag & Sontag (1990) observes a relationship between campaigns to overcome illness and other psychosocial stressors. As we call for a war on poverty, on homelessness, on AIDS, we communicate that to have an illness or any psychosocial concern is weak, vulnerable, and unacceptable. We communicate this in such a manner that often the person is lost in the war against their illness.

What Is Important to Successful Treatment?

Engagement and ability to connect with a benevolent other is an important element in successful treatment. Beretta et al., 2005 suggest that the therapeutic alliance is associated with the patient's wish to be close, to perceive others as trustworthy and helpful. However, they found that people with low alliance, relates not to a wish to avoid, but to a patient's wish to be close impeded by perceptions of others' responses as negative, with diminished capacity for affiliation. This is further complicated by the reality that many professionals unwittingly communicate the same fears, low expectations, and stigmas to consumers as people in the general population.

For instance, another study found that while most medical doctors, primary-care nurses, psychiatrists, psychiatric nurses, and psychologists self-report respect for the dignity of their patients, follow-up exploration of a vignette reveals that most would not want to hire or be neighbors or friends of people with SMI (Smith, Mittal, Chekuri, Han, & Sullivan, 2017). Likewise, in Sweden a study explored whether professionals would hire, date, or let a person with SMI take care of young people. Responses were quite negative. Like public perceptions of SMI, professionals on some level fear that people with SMI are dangerous, unpredictable, and difficult in relationships. This stigmatizing view does not seem to change in spite of global efforts to challenge stigma (Hansson, Jormfeldt, Svedberg, & Swensson, 2011).

Schemas drive decision-making. If reading an article exposing facts could change practitioner behavior, this would be a simple solution and likely would have been accomplished long ago, eliminating decisions based on negative schemas. Mechanisms that retrigger long-held beliefs make challenging schemas difficult. A practitioner may be privy to reliable, trustworthy data indicating that the majority of people with SMI are not a danger to other people. Nonetheless, this may not be enough to change the deeply wired mindset that drives how the practitioner makes decisions related to his or her work with consumers.

In order to address unconscious schemas that may drive treatment decisions, new and innovative training to identify negative schemas must be sought. Finding ways not only to identify schemas held by mental-health professionals, but also to examine the myths upon which they are built, where they originated, and how they are perpetuated, and to challenge them in a safe environment in which the professionals can do this personal work, will be a challenge. Research utilizing structured conversations to assist mental-health professionals in examining the schemas they may have about individuals with SMI may be a place to begin. Small-group dialogue that surfaces schemas in a safe environment can help identify those that are negative and biased, and find adequate ways of challenging those beliefs in a rigorous, yet safe manner as a means of practitioner training.

What Reduces Stigma and Professional Stigma?

O'Reilly, Bell, and Chen (2012) suggest that fostering empathy is a major factor in decreasing stigma. Others have recommended a need to recognize the culture within which one hopes to campaign against the stigma of SMI (Pawluk & Zolezzi, 2017). For instance, in Qatar, health professionals shared that they supported efforts to decrease stigma but thought efforts should target school-age children to provide education about SMI and appropriate pathways to treatment. Others concur, stating that mental-health literacy may be more effective than challenging stigma once it is entrenched (Greenwood et al., 2016). In another study, strategies such as role-play were not found to be as effective as direct contact with a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

person with SMI, and indirect contact (e.g., through film). Even educational emails showed short-term positive impact on decreasing stigma (Stubbs, 2014).

There are four accepted paths to changing perceptions. First, people learn from training (Bedregal, O'Connell, & Davidson, 2006). Numerous studies have found that specifically training on the Recovery Perspective and its operational model, Psychiatric Rehabilitation, opens professionals to growth and learning. Second, people learn from meeting and having meaningful connections with real human beings who have SMI (Eack & Newhill, 2008). The implication of this path to change is that as trainings are re-envisioned to improve professionals' ability to monitor their own schemas, it is logical that consumer participation in structured discussions be included. Third, people learn from self-reflection and genuine openness to challenging their own misperceptions (Kadushin & Harkness, 2014). Fourth, people learn from open dialogue (Brown & Isaacs, 2005). A tenet of group therapy is trusting that a group of people can come together to support one another. People can come together for the purpose of solving social problems, particularly when all acknowledge that they do not have the single answer that needs to be imposed on others. When people can demonstrate a willingness to share and contemplate their own thoughts and ideas and those of others, a willingness to work towards learning, growth and consensus building, there is hope for finding ways to end stigma. People come together willing to ask deeper questions and trust that together they may be able to identify innovative and positive solutions to stigma within the field of mental health, even those notions of stigma held by professionals.

CONCLUSION

When reviewing moments and shifts in the history of treatment of people with SMI, one can come away with a sense that people who cared about and empathized with the plight of people with mental illness often initiated efforts to heal, which ultimately went awry. One can look at the role of stigma—in particular stigma emanating from mental-health professionals—and see harmful interventions that required Herculean efforts to eradicate. Cognitive behavioral theory, when a thought, feeling, or behavior is recurrent or difficult to change, may aid in attending to the schemas that drive that behavior, and provide a place to begin. Thoughts, feelings, behaviors, and attitudes can be difficult to change because environmental factors retrigger them. This chapter argues for understanding the concept of schemas and considering training alternatives to help mitigate the harm resulting from stigma on the part of mental-health professionals.

Social workers provide the majority of services to adults with SMI (Kirk, 2005). The Social Work Code of Ethics posits ideas about service provision that are very much in sync with the Recovery Perspective. Therefore, it is curious that this would not be a smooth, timely, and easy transition. Yet there have been barriers to professionals embracing this client-centered perspective.

Recovery-oriented care represents a paradigm shift that not only has implications for clients but also involves a rather formidable shift in the role of the professional and how services are provided. In the litigious and blame-oriented environment that surrounds current practice, social workers who may wish to fully embrace a Recovery Perspective would have considerable concerns. This perspective supports people with SMI taking risks—the same risks that people who are not diagnosed with SMI are able to take for granted. This perspective honors a consumer's expressed desire for an independent apartment, and seeks it without a global assessment of functioning. While this does not mean abdicating responsibility for assessing consumer safety and problem solving around potential skills deficits that can be

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

addressed, its premise is that in the absence of data suggesting the person is not competent, we can assume the ability to budget and/or learn from mistakes, as a person without a diagnosis would. To work from an assumption that people with SMI can learn these lessons, in the same way as their non-SMI counterparts can, is a shift that can be threatening to a professional who may be held accountable by families and/or systems when a worthwhile risk does not work out.

Another challenge is failure to accurately understand definitions of the Recovery Perspective and the Medical Perspective. Some professionals see the Recovery Perspective as an anti-medication movement. While many consumers and professionals do question whether medication is overprescribed, this is not a Recovery Perspective agenda. Similarly, some believe a Medical Perspective is solely about medication. This again is inaccurate, as evidenced by a longstanding and ongoing history of Medical Perspective practitioners diligently working to identify new and progressive methods of helping consumers, which go far beyond medication.

One key difference between the two models can be articulated in terms of the shifting role of the professional. Recovery-oriented professionals see their role more as a coach or guide on the journey of recovery, while the medical model assumes more of an expert stance. Another key difference is the very definition of what it means to recover. In practice, however, this is not always the case. Greater attention to the role of schema in professional decision-making is one recommendation.

KEY TERMS AND DEFINITIONS

Cognitive Behavioral Theory: A theory of cause of emotional or behavioral issues based on the once revelatory idea that rather than being driven by unconscious factors, we behave as we do due to how we interpret stimuli around us.

Cognitive Distortions: Types of distortions that most people have experienced at one time or another, which can be challenged and reframed. For instance, a person states, "I am going to fail this exam." When this thought, which often leads to anxiety, is based on data to the contrary, it can be challenged

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

by identifying the type of distortion—in this case, "predicting the future"—and then challenged with a more realistic statement/thought.

Consumer: Terms such as patient, client, consumer, and survivor have all been used to describe the role of the person receiving mental-health services. "Consumer" is the term associated with the recovery perspective.

Hope: A reason to continue to try to find purpose and meaning in life.

Internalized Stigma: Feelings of unworthiness and self-directed rage internalized from societal assumptions; essentially seeing oneself in the role of "an illness" as learned from experiences in society.

Medical Perspective: A traditional medical perspective in the field of mental health looks at decrease in symptoms, decrease in hospitalizations, and increase in functional behaviors as end points in achieving mental health. From this perspective the role of the professional is elevated and hierarchical in relation to the consumer.

Recovery Perspective: A recovery perspective in mental health understands a definition of recovery to encompass a reawakening of a sense of hope, meaning, and life purpose. It suggests a more equal or level playing field in the relationship between a mental health provider and a consumer of mental health services.

Schema: Strongly and long-held beliefs based on early experiences that are often experienced as facts, and consistently influence our behaviors. For example, "I must adhere to directives of people in authority."

Chapter 51
Fighting Stigma in the Community:
Bridging Ties Through Social Innovation Interventions

ABSTRACT

This chapter will discuss action research conducted in Tuscany to fight stigma surrounding mental illness. Public mental health services (PMHS) in Italy are perceived as ascribing a mentally ill label to individuals who utilize these programs. Local associations, especially sports associations, can be used to fight this stigma. This chapter will present key aspects and results of a community social innovation intervention jointly performed by a PMHS and the University of Florence. The research will explore perceptions surrounding the role and value of the community sports association, participants' perceived improvements, effects of sports participation, and the role of the sports association as an instrument to promote mental health. Results will show that the sports association is perceived as an agent of social capital to reduce social barriers emerging from mental illness. In addition, stigma is deconstructed through improvements to individual and social wellbeing.

INTRODUCTION

This chapter will describe the role of the *La Rugiada* sports association as a powerful instrument to deconstruct stigma in mental health. First, the chapter will summarize the theoretical background. Next, the context of the intervention and its main features will be presented. The chapter will share study results related to a local community's strategies to prevent stigma surrounding mental illness.

Stigma consists of a social dimension (or public stigma) and an individual dimension (or self-stigma). Both dimensions are capable of affecting an individual's recovery from mental illness and isolation (Andrews, Issakidis, & Carter, 2001). Through individual participation, sports and teams can create a sense of community (Soundy et al., 2015).

By exploring a sports association's role in well-being, services can be identified to fight the effects of stigma and promote community mental health. This chapter will describe the role of *La Rugiada* in rural Tuscany, Italy. It will consider interventions realized through a sports association's role as a social innovation strategy.

THEORETICAL FRAMEWORK

Stigma: Threat to Others and to Self

Although it has been 50 years since Goffman's opera (1963), its contributions continue to be widely used (Bos, Pryor, Reeder, & Stutterheim, 2013). "Stigma" identifies negative characteristics attributed to others. In addition, it devalues stigmatized people. The rise of social problems causes limited citizenship and social segregation, including disqualification from daily community life (Montero, 2010). Participation in community life increases emotional connections in the community. However, a lack of participation, which is associated with disadvantaged social groups, can cause disempowerment (Christens, Speer, & Peterson, 2011; Gaebel et al., 2014; Bosco et al., 2016).

Stigma is a relational process because it is realized in social groups (Hebl, Tickle, & Heatherton, 2000). Through an individual's aversions and discredit toward others, it induces dehumanization and depersonalization for the out-group member (Dovidio, Major, & Crocker, 2000; Tajfel, 1981).

Negative social stereotypes surrounding a social group can be associated with both positive and negative value responses, which can cause different responses of power. As reported by Link and Phelan (2001), the interconnectedness of stigma and power is due to stigma's allowance of the balance of a prevarication relationship. In a psychosocial perspective, stigma's prevarication function is recognized between people who are and who are not stigmatized (Phelan, Link, & Dovidio, 2008). This function favors an imbalance between the powerful and the powerless groups (Major & O'Brien, 2005; Lukes, 2005).

Negative impacts of stigma generate several consequences in people who are stigmatized, including social discrimination and a system of low expectations (Crandall & Eshleman, 2003; Kurzban & Leary, 2001). Moreover, membership in a low-status group can negatively affect the individual level because it can lead to the perception that one's social identity may be threatened (Steele & Aronson, 1995).

The social identity theory (SIT) recognizes cognitive, social, and emotional aspects related to a sense of belonging to a social group as identified by society (Tajfel, 1981). This process involves both individual and social levels (Anderson & Lowen, 2010; Walton & Cohen, 2003). Belonging to a social group establishes significant emotional bonds and impacts positive self-image (Haslam, Jetten, Postmes,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Haslam, 2009). On the contrary, belonging to a low-status group causes a negative self-categorization (Sellers & Shelton, 2003). According to Major and O'Brien (2005), when the social identity is stigmatized, people can perceived themselves as at major risk of discrimination.

Coping strategies are tools to handle stigma's effects. The first strategy focuses on the attribution of negative events to discriminatory behaviors in a social system. Using this strategy, individuals can defend their self-esteem and self-identity (Vogel, Heimerdinger-Edwards, Hammer, & Hubbard, 2011). The second strategy is strictly associated with social identity, in which being a part of a labeled group can lead to evaluate self-identity independent from the in-group or to defend the social group from the society. However, the sense of belonging to a social group, even if stigmatized, allows an individual to obtain social support. The last strategy is associated with social groups (Major & O'Brien, 2005). People suffering from mental illness cope with pathology and stigmatized status. As reported by Link, Mirotznik, and Cullen (1991) people may adopt three specific coping strategies to avoid social rejection:

- Maintaining secrecy about their unhealthy conditions
- Limiting social interaction to those who know their psychological problems
- Using *"preventing telling"* to obviate negative attitude from others

When people are stigmatized, they use both functional and dysfunctional strategies, which may affect the self-evaluation (Link et al., 1991).

PUBLIC STIGMA AND SELF-STIGMA: NEGATIVE IMPACTS ON MENTAL HEALTH

Stigma grows in individual, interpersonal, and societal levels. According to Corrigan and Matthews (2003), public stigma is defined in a social system and self-stigma is a redefinition of the self, based on negative characteristics recognized by society.

Public stigma is a loss of status that produces discriminatory behavior toward people with mental illness (Corrigan & Boyle, 2003). According to Parcesepe and Cabassa (2013), public stigma is based on beliefs and negative attitudes shared by the social system. It may generate fear and social exclusion toward people with mental illness.

Self-stigma is the harmful impact that results from internalizing prejudice leading to diminished self-esteem, lower self-efficacy, and a sense of 'why try' self-deprecation" (Corrigan et al., 2012, p. 65). Moreover, self-stigma can lead stigmatized people to be aware of their social devaluation because of their unhealthy condition (Bos et al., 2013).

Both public stigma and self-stigma have cognitive (stereotypes), emotional (prejudice), and behavioral (discrimination) components. In mental illness, cognitive components are associated with a lack of expertise attributed to others or to one's self (Brohan, Elgie, Sartorius, & Thornicroft, 2010). This is also the case for emotional reactions. For example, that statement that "all people with mental illness are violent" causes the reactive statement that "everybody scares me" (Link & Phelan, 2001). Finally, the discrimination component can be defined as a barrier in the achievement of personal goals (Pingani et al., 2012). This affects opportunities to benefit from life experiences and can lead to a negative redefinition of social status (Corrigan, Larson, & Rüsch, 2009). The interiorization of attributes affects psychological resources and leads to social isolation (Feldman & Crandall, 2007).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Corrigan and Watson (2002) defined "three As" of self-stigma: (1) agreement; (2) awareness; and (3) application. As reported by Watson, Corrigan, Larson and Sells (2007), group identification, awareness of negative stereotypes, agreement, and application to the self allows self-stigma to impact individual self-esteem and self-efficacy.

Self-stigma may generate an individual's powerless response (or "the why try effect") (Watson, Corrigan, Larson, & Sells 2007). Disempowered people may be affected by a lack of self-efficacy, express a negative personal evaluation, and use an internal locus of control in case of failure (Huang & Lin, 2015). Thus, self-stigma may reduce an individual's quality of life and coping strategies (Vogel, Wade, & Haake, 2006).

From a clinical perspective, self-stigma appears to be associated with a serious increase of positive and negative symptoms, depressive symptoms, and reduced social functioning in people with schizophrenia (Yanos, Roe, Markus, & Lysaker, 2008). Self-stigma causes negative feelings, particularly shame, and embarrassment for the unhealthy condition and the discredited attitude by the social system. Self-stigma leads to negative feelings about the self, which causes an individual to perceive themselves as inferior to other community members (Huang & Lin, 2015; Rickwood, Deane, Wilson, & Ciarrochi, 2005).

The deconstruction of stigma must consider individual and social dimensions (i.e., health professionals, formal and informal associations, users as citizens, and the community). In doing so, community-based interventions and resources will be identified to promote empowerment, improved mental health, and social change.

SOCIAL CAPITAL TO PROMOTE MENTAL HEALTH

Mental health recovery through social engagement increases social capital (Tew et al., 2012). Promotion of social capital may result in greater integration in society and more access to opportunities for people with mental illness (Zoppei et al., 2014).

Social capital is a complex and debated concept with multiple definitions (Morgan et al., 2007). Its core can be summarized with the idea that networks and social relationships are valuable community resources (Field, 2003). Social capital studies refer to various aspects of social life, including social networks, mutuality, and social participation (Zoppei et al., 2014). In a more theoretical definition, social capital was defined as an "investment in social relations with expected returns" (Lin, 1999, p. 30). More specifically, *A Dictionary of epidemiology* (Porta, 2014), identified the concept's twofold nature with characteristics linked to both individual and group dimensions. Social capital is also described as a resource available to members of social groups (e.g., trust, norms) and a resource embedded in an individuals' social networks (e.g., social support, social credentials; Forsman et al., 2013).

Therefore, social capital is conceptualized as both an individual and community attribute. There has been considerable interest as to whether social capital is a feature of individuals, groups, or both. However, the notion has been at the center of a significant academic and policy debate on how socioeconomic disadvantages impact mental health (Bertotti et al., 2013).

A definition of its dimensions is needed to better understand the practical implications of social capital. Studies have discussed several types of social capital, such as structural and cognitive social capital (McKenzie, Whitley, & Weich, 2002). According to Ehsan and De Silva (2015, p. 1021):

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

…structural (participatory) social capital refers to relationships, networks, membership, organisations, associations, and institutions that may link groups or individuals together. Cognitive (perceived) social capital refers to values, norms, attitudes, beliefs, civic responsibility, altruism, and reciprocity within a community.

In other words, the structural component could be considered the quantity of social capital. It examines the extent and intensity of links between individuals, their behaviour, and their participation in group activities (Bertotti et al., 2013). On the other hand, the cognitive component could be regarded as the quality of social capital as it focuses on the types of social interaction between individuals (Harpham, Grant, & Thomas, 2002).

The structural and cognitive components influence health in different ways. The cognitive component, including perceived social support, trust, and a sense of belonging, has been strongly associated with a range of mental health outcome measures across several countries at individual and ecological levels (Phongsavan et al., 2006; Tomita & Burns, 2013). The structural component, which derives from social contacts and social participation, appears to have a more complex relation with health.

Systematic reviews using cross-sectional or experimental data found that social capital may act as a protective factor in mental health problems (De Silva, McKenzie, Harpham, & Huttly, 2005). The most recent systematic review from Ehsan and De Silva (2015) confirmed that both individual and ecological cognitive social capital reduce risks of common mental disorders. This means that these forms of social capital protect against mental illness.

At the same time, weaker associations emerge surrounding the positive influence of structural social capital on mental health. According to studies, low-resource settings (and selectively in these conditions) can impact an individual's participation in civic activities. This can be associated with an unexpected increase to the risk of mental disorders (Forsman, Nordmyr, & Wahbeck, 2011). Similar results emerged from Bertotti et al. (2013). In this work, the effects of social networks and perception of neighbourhood quality, which are components of structural social capital, change the sense of the relations to mental health depending on the socioeconomic characteristics of the environment (ibidem). Clayton et al. (2013) found similar unexpected results in their longitudinal randomized controlled study focusing on citizenship to prevent mental illness and criminal justice involvement.

Evidence reported in this work highlights the importance of innovative interventions based on the ecological community approach, the use of creative instruments to improve social capital and prevent mental illness, and caring for relationships among patients and the community (Bosco, Petrini, Giaccherini, & Meringolo, 2014). Social innovation interventions can be useful because they are based on solidarity and reciprocity among citizens and the social system.

SPORTS TO FIGHT STIGMA

An increasing amount of research shows that sports intervention improves physical health in people with severe mental illness (Firth et al., 2015; Rosenbaum et al., 2014). People with serious mental disorders experience a premature mortality, approximately 15 to 20 years earlier with respect to the general population. This differential mortality gap has grown in recent decades (Saha, Chant, & McGrat, 2007). Two-thirds of these deaths are due to physical health risk factors from limited access to medical care,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

poor diet, reduced levels of physical exercise, and medication-induced weight gain. This risk particularly affects people with mental illness due to greater amounts of sedentary behavior (Stubbs et al., 2016).

Many of the physical health issues, which are related to modifiable risk factors, can be attenuated through lifestyle changes, including exercise (Curtis et al., 2016; McNamee, Mead, MacGillivrey, & Lawrie, 2013). Physical exercise programs are valuable to people with serious mental illness. Recent meta-analysis of randomized controlled trials demonstrated that physical exercise has a moderate to large effect size for individuals with depression disorders as compared to control groups (Krogh, Nordentolf, Sterne, & Lawlor, 2011; Retrhost, Wipfli, & Landers, 2009).

Research in adults with schizophrenia shows that exercise interventions reduce negative symptoms and cognitive deficit (Firth et al., 2016; Kimby et al., 2015). This also includes secondary symptoms like depression, low self-esteem, and social withdrawal (Faulkner & Biddle, 1999).

In the treatment of mental disorders, exercise may complement other interventions. It can be used as a stress management strategy to prevent recurrences and improve functional recovery, lifestyle practices, and overall health (Morgan, Parker, Alvarez-Jimenez, & Jorm, 2013).

Firth et al. (2015) found that the most prominent exercise barriers for people with mental illness is the lack of support. This was reported by 50% of those analyzed in the systematic review.

Within physical activities, sports are considered a type of leisure time (Howley, 2001). Thus, sports participation can be viewed as a pleasant way for people with mental illness to achieve physical activity recommendations (Bulut, Eren, & Halac, 2013; Howley, 2001; Vancampfort et al., 2012). Based on literature, sports participation has psychological and social benefits. As reported by Langle, Siemssen, and Hornberger (2000), sports participation can have positive psychological effects on an individual's mental health, including self-esteem, body awareness, social interactions, and time management.

Regarding individuals with schizophrenia, a recent study by Soundy et al. (2014) identified broader, more direct psychosocial benefits of sports participation. They highlighted self-initiated positive changes in behavior, increased confidence, pride in other settings, and a sense of purpose, meaning, and achievement. A sense of belonging, cohesion, and support are identified by Soundy et al. (2014) as benefits of sports participation.

In a meta-synthesis review on qualitative data, Soundy et al. (2015) emphasized the following themes associated with sports participation for individuals with mental illness:

1. Social Meaning of Sports in the Lives of Patients
    a. Positive social experiences to look forward to and be a part of
    b. Feelings of community and positive identity
    c. Activities to promote autonomous behavior and social engagement
2. Direct Benefits of Sports
    a. Places to go and things to do
    b. Normalized activities and opportunities to be in a positive group
    c. Distractions from typical worries, anxieties, or symptoms of mental health
3. Organization, Process, and Challenges of Sports
    a. Progression of tasks' difficulties and use of supported competitions
    b. Importance of environment and use of sports to foster a sense of belonging, identity, and interaction

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Functional Social Support
    a. Esteem support, encouragement, and positive feedback
    b. Emotional support from staff and peers

Thus, sports can offer positive opportunities for social engagement to people with mental disorders. Participation in sports-related activities is a social learning experience. It can be an opportunity to feel "normal" in front of others. Moreover, sports can provide access to new social levels, as well as create a distance from institutionalized settings and identities (Soundy et al., 2014).

Voluntary sports organizations represent the largest voluntary sector in the western countries. According to literature, volunteering and active participation in society are considered crucial elements to social capital (Baum & Ziersch, 2003; Hartmann; 2003). Sports and exercise interventions can be used by mental health services as instruments to fight stigma and social isolation. Moreover, sports and exercise interventions can promote social interaction and a sense of community and connectivity (Coaffee, 2008; Hartmann, 2003). Thus, social interventions based on sports activities can promote community mental health and social capital by engaging diverse audiences and providing avenues for social inclusion in communities (Sherry & O'May, 2013).

PMHS IN ITALY: INNOVATIVE INTERVENTIONS WITHIN THE COMMUNITY

Research reported in this work took place in Tuscany, Italy.

The Italian system of mental health is founded on the Law n.180, Basaglia Law, from the name of its promoter. Realized in 1978, this psychiatric reform signified the closing of all insane asylums within the national borders. It also introduced diagnosis and care psychiatric services into general hospitals.

Psychiatric reform generated an enormous cultural change for communities and people living with mental illness. Prior to the Basaglia Law, the psychiatric system was addressed to the custody and social control of the deviance. After its approval, people with mental illness received the civil right to be cured and cared for in their community.

In 1998, a new organization of PMHS was settled following the first national mental health project. In accordance with the project, small services were founded in local communities and territorial areas, aimed to care for people with mental illness. To meet this goal, they used therapeutic and rehabilitative interventions, promoted empowerment, and increased healthy communities by means of preventive strategies.

The connection between PMHS and communities allows for planned interventions to prevent the worsening of mental illness, establishes networks of people suffering with mental illness, and improves social capital. This process can be achieved by starting from resources in the territory, promoting empowered communities, and generating well-being and mental health. Civic participation and civic engagement are key features to this perspective (Arcidiacono, Gelli, & Putton, 1999; Ehsan & De Silva, 2015).

The Italian system of mental health is based on participation. Bridging health professionals, families, and patients of PMHS promotes a proactive attitude toward health (Bentall, 2003). On the other hand, it is possible to obtain positive effects on the quality of PMHS due to the added value derived from the participatory process (Crawford et al., 2002; Simpson & House, 2003). Social innovation interventions generated a new model of organizations based on collaborative relationship between social actors, including nonprofit organizations, users, and citizens.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

It is important to recognize interventions based on ecological approaches in the current Italian debate on mental health community care (Agnetti, 2007; Bosco et al., 2014; Re, 2005). The realization of social innovation interventions is required to achieve this recognition.

As reported by Stiglitz (2009,) social innovation can be defined as new responses to social problems, and as an instrument to improve individual and social well-being.

More specifically, the Bureau of European Policy Advisers (BEPA, 2011) defined social innovations as new ideas able to meet social needs, create new social relationships, and enhance society's capacity to act.

Considering the ecological community approach, social innovations can be a powerful strategy to promote positive effects on societies at both macro- and micro-levels. This empowers people by engaging them through participation as a model of intervention.

The sports associations for social integration was founded within this process. The group brings together PMHS and third sector organizations with mental illness users, their families, and their communities. Using sports to build social integration, they involve citizens in the management of activities to promote community wellness. Their purpose, which is based on the principles of welfare community and welfare mix, is to redefine the reciprocal relationship between individuals and communities as they bridge ties within the social system.

LA RUGIADA SPORTS ASSOCIATION FOR SOCIAL INTEGRATION

La Rugiada, a sports association, was founded in 1996 in partnership with a PMHS of Florence. It is situated in a rural area of 110,000 habitants. *La Rugiada* has 120 members, including people with mental illness, PMHS professionals, and volunteers. Football, volleyball, hiking, canoeing, and sailing are the main activities. The association promotes social integration for people suffering with mental illness. It maintains links between PMHS and the community.

La Rugiada was officially recognized in 1998 as a sports association for social integration. It earned formal autonomy in the improvement of sports activities, social projects, and management processes. An important evolutionary step of *La Rugiada* was the foundation of its sailing club in 2008. This represented true innovation. Figure 1 illustrates the principal steps of *La Rugiada*.

Figure 1. Steps of La Rugiada's evolution

The sailing activities are carried out in a small lake near the town. Community activities included families, children, youth, high schools, and citizens in the community and nearby territories. In 2016, 100 children participated in the summer activities. Three hundred young people were enrolled in sporting activities.

Members of the sailing club included individuals with mental illness, PMHS professionals, and volunteers who worked in the community. The principal innovative aspects were to:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Create a sailing club in Tuscany's hilly landscape (far from the sea or basins) as an attractive community resource
2. Establish recognize social roles for people with mental illness (e.g., patients are sailing activity instructors)
3. Consider the sailing club as an instrument to fight stigma in mental illness, promote participation, and enrich community wellness

These new activities generated an important cultural change in the territory. Prior to the sailing club's foundation, activities promoted by PMHS and *La Rugiada* focused on people with mental illness and their social reintegration. After its foundation, as comanaged by users of PMHS, activities refocused on the community to address of social well-being. In this process, PMHS users became community resources.

The present work explores *La Rugiada*'s potential as an agent of social capital to fight stigma. It studies *La Rugiada* as an instrument to promote sports' impact on mental health in the community.

RESEARCH

The present contribution describes action research carried out by the University of Florence and a PMHS in Tuscany. The studies discussed planned effective community strategies to prevent mental illness considering the role of stigma.

The increased number of young patients led PMHS to identify new instruments and methods to care for young people with mental illness and meet their psychological needs. When faced with psychological problems or mental health episodes, young people may be reluctant to seek PMHS help due to stigma. This reluctance, which is associated with an increase of mental health problems, may generate negative consequences to future health. Moreover, it can cause drop outs, social isolation, and marginalization. This study reviews *La Rugiada*'s experience using sports participation in PMHS and the community.

The first and second studies used qualitative methods to explore sports association in the community and the effects of sport participation on people with mental illness. The third study was action research in local high schools. It investigated the role of the sports association as an instrument to prevent and promote mental health in the youth population.

The exploratory investigation used both qualitative and quantitative methods. Qualitative studies explored the perceived role of *La Rugiada* in the community. It considered the points of view of professionals and patients of PMHS. The quantitative study detected changes in the high school prior to and after the sports intervention.

Study 1: *La Rugiada* as a Change Agent in the Community

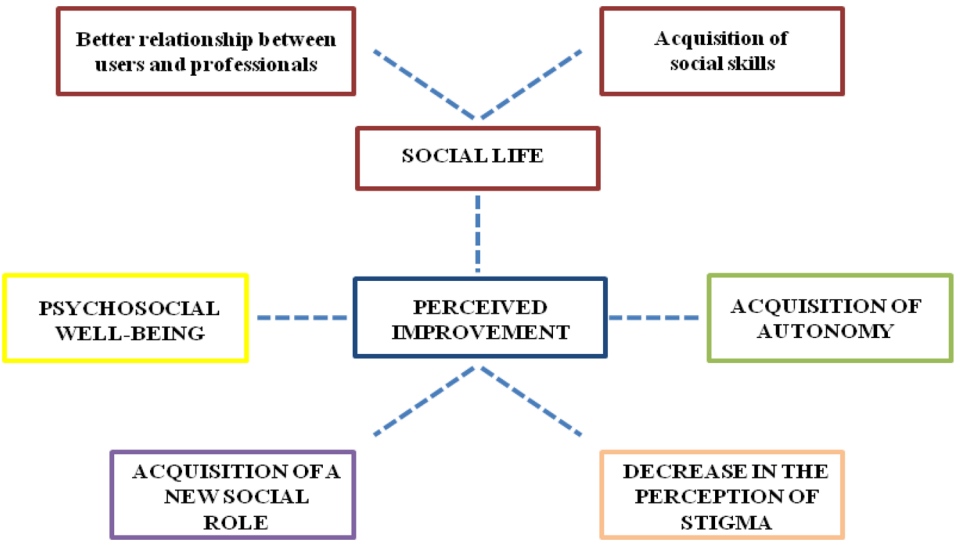
Aims

The exploratory qualitative research analyzed:

1. The perception of the role and value of the sports association in the community
2. Participants' perceived improvement from participation in the sports association

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Methods



- **Participants:** Twenty-three members of *La Rugiada* (users and professionals)
- **Instruments:** Semi-structured interviews.

Qualitative content analysis was inspired by Grounded Theory approach (Glaser & Strauss, 1967) and was performed using the qualitative data analysis software Atlas.ti.

Findings

Qualitative analysis shows that user-members who participated in sports activities experienced personal change (see Figure 2).

Figure2. Perceived improvement

Growth in personal and social knowledge by people with mental illness was perceived. In members' perceptions, sports participation by *La Rugiada* generated social responsibility, which positively impacted self-esteem:

I am starting to be more independent. Now I am more confidence. (user, male)

An increase of social networking and support between members was reported, which generates "weak ties" (Granovetter, 1983) between them:

Now I have friends. Before I was alone! We can meet also outside La Rugiada. (user, male)

Before [La Rugiada] I was very shy […] now I have another idea to stay with other people. (user, male)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sports participation promoted by *La Rugiada* offers socialization opportunities to people with mental illness.

It brings new social opportunities like participating at national events or on summer holiday. (user, male)

According to participants, *La Rugiada* promoted specific changes in the "autonomy area of life" for people with mental illness. In particular, *La Rugiada* acquired daily organizational skills and self-care tools. Through sports participation, members could:

learn with others and apply the game's rules in the social context. (user, male)

Being a part of *La Rugiada* was perceived as a protective element in case of stressor events.

The main change reported by PMHS professionals was members' peer relationships, including those with mental illness. Being a part of *La Rugiada* meant:

they were a part of the same group … members of the same association … with the same rights. (professional, female)

Social and professional roles were reduced in this setting. Sports activities allowed for more spontaneous and close relationships between professionals and users. Experiencing *La Rugiada* as PMHS professionals and members reduced biases related to mental illness.

Before this experience, I used to categorize 'us' and 'them.' I used social barriers as a form of psychological defense in the professional setting. After this experience I understand that there are not differences between us. (professional, male)

Sports participation appears to reduce prejudice and barriers caused by illness. Participation also generates *"a sense of sharing and belonging":*

Through participation in sports activities, it is possible to share memories, emotions, time, and difficulties. (professional, female)

Moreover, in the participants' perception, *La Rugiada* played a valuable role in the community as a *"central instrument to promote community mental health."* As was reported by one research participant, "*it was possible to connect PMHS and the local community."*

Finally, *La Rugiada* was perceived as a powerful instrument within the social system for people with mental illness. This was due to *"the strength of the weakness ties."*

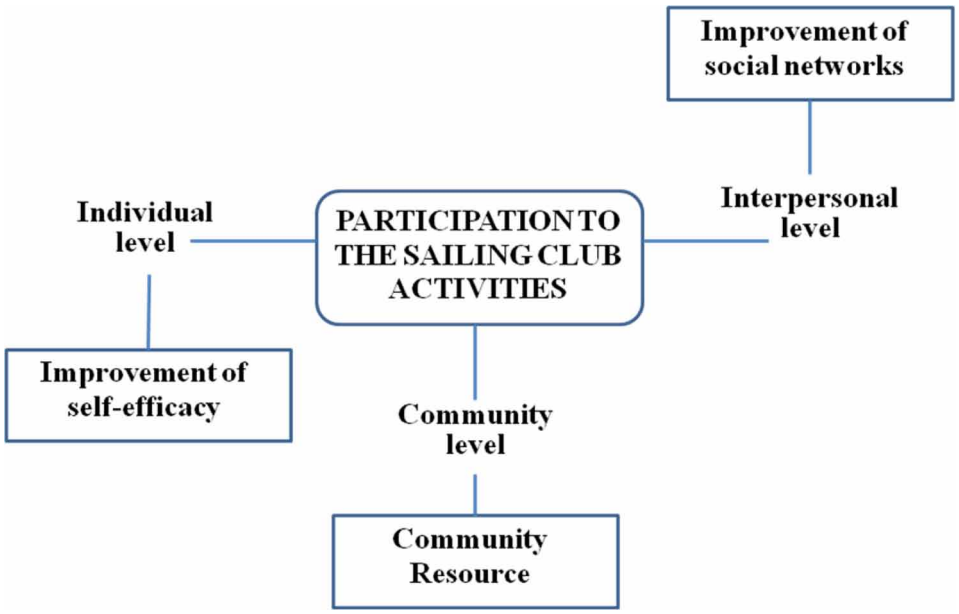
Through the participation, everyone connected with each other … it generated the opportunity to interact with other social groups in the local community. (user, female)

La Rugiada is a possibility to interact with others in a context where the social barriers are reduced … to create a new culture on mental health. (professional, female)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Study 2: Exploring Individual Perceptions on the Sailing Club as a Community Resource

The sailing club represents the most innovative activity promoted by *La Rugiada*. Members of the sailing club are people with mental illness, professionals of PMHS, and a great number of volunteers working together spreading their work into the community. The sports activities, sailing and canoeing, are addressed to all citizens (family, children, schools, et.)



While the first study focused on individual perceptions about the role and value of the *La Rugiada* sports association, a second study was carried out to investigate perceptions surrounding the sailing club and its peculiar function in bridging ties with the community.

- **Aims:** This study explored the effects of sports and association participation on individual well-being, as well as the value of the sailing club as a community resource.

Methods

- **Participants:** Seventeen stakeholders (directly and indirectly involved in sailing club activities)
- **Instruments:** Semi-structured interviews were analyzed using the Grounded Theory approach (Glaser & Strauss, 1967). Qualitative content analysis was performed using Atlas.ti.
- **Findings:** Data analysis showed a shared and coherent perception among stakeholders about objectives, health benefits, and community interests promoted by participation in the sailing club activities (see Figure 3).

Figure 3. Main effects of participation in the sailing club

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reduced social isolation and improved social networks appear to be an expected outcome for all stakeholders.

Before this experience, I was in a [therapeutic] community. I was just released and I did not know even where to go. My parents suggested the sailing club. (user, male)

Relationships require time. Here [in the sailing club], sports, dinners, and holidays are realized with others ... they are elements that can help to maintain contacts. People can discover positive aspects to stay with others. It is important to be part of a group. Here, I meet new people and I can spend time with people that I already know. (user, male)

According to professionals, sports participation fosters patient autonomy, improves self-efficacy, and assists in time management.

What I see is that they [user-members] are more responsible because the club also gives them responsibilities [...] there are timetables and they learn to manage the time themselves … they learn to do things they had never done. (professional, male)

The mutual help is a crucial dimension of the sailing club. This is recognized by all participants; they feel it reduces stigma surrounding mental illness:

When you join the club, there are no social differences. We are all equal; we are the same as a person! So, you cannot tell another 'you're problematic' or 'I have problems' and 'stay away.' On the contrary, 'I stay closer to you.' (volunteer, female)

Data suggests that the lack of competitiveness in this kind of sport could represent an added value for the recovery of people with mental illness:

This reality is special: it is not a football team or a volleyball team in which you are always with the sport team … where you train every week, do the weekly match, and you are sharing the aim of winning more than staying together […]. Sailing is an activity that you can do by yourself. (user, male)

The sailing club is perceived as an innovative community resource as underlined by all participants:

Sailing is an innovative activity in the community. La Rugiada promotes different sports activities, such as football and volleyball. But if you want to do sailing, you'll need to travel 90-100 km from the community. Thus, sailing is able to meet and respond to the needs of the territory. (volunteer, female)

Sailing generated a great curiosity between citizens. It generated the desire to perform sailing. There is a great interest about sailing in the community. (user, male)

The sailing activity is a very attractive sport activity, and it is perceived by participants as a *"shared dynamic movement between citizens."*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The sailing club is a place for everyone! We tried to create a place within the community. It is a sports association realized with people. So, the sailing club is an instrument and a resource for the community. (professional, female)

According to participants, another added value of the sailing club is its ability to generate relationships between members and citizens who are not involved in *La Rugiada* sports.

The sailing activity is performed by all the citizens - not only by members. This is an extraordinary wealth. (volunteer, male)

The sailing club is the spearhead of La Rugiada. It connects the community and PMHS. (professional, male)

Other institutions also perceive the sailing club as *"a resource for the community."* The social inclusion process for people with mental illness involves the community as a resource. Through interventions promoted by the sailing club, patients become resources for the territory. As reported by participants, *"this reverse of position has a strong value for the community."*

The sailing club is also perceived as a place to meet young people and an instrument to prevent mental disease:

the leisure time is important for young people. We have to take into account their needs considering that they use their extracurricular time at home or using the Internet. (user, male)

We have to include young people in the sailing club in order to realize activities able to reach their psychological needs. (professional, male)

Another important finding is the interest to spread knowledge about the sailing club. This enhances the social and solidarity dimensions, as well as characterizes the setting:

We have to stay in the community! We also have to organize meetings in the local schools. Then, students will talk with their parents, and so on. When people meet us [the sailing club], they discover a safe environment where people get involved thanks to their altruism. It's a wonderful thing that the sailing club is taken care of by all we meet. (volunteer, male)

Participants highlight their interest to work with young people. Their opinions are crucial when promoting a cultural change in the field of mental health.

We have to bring the sailing club into high schools because we need to educate youth on a culture founded on social inclusion and to change their beliefs about mental health. (professional, male)

Study 3: Preventing Mental Illness to Deconstruct Stigma

Findings from the qualitative research in the previous studies led to specific actions to prevent mental illness and promote mental health in the community. In addition, it focused on a specific setting and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

young people. To deconstruct stigma toward mental illness, action research was realized through *La Rugiada*'s sports activities involving Grade 12 high school students.

As reported, young people with psychological problems may avoid professional help due to prejudices toward PMHS. They may also fear receiving society's "mentally ill" label.

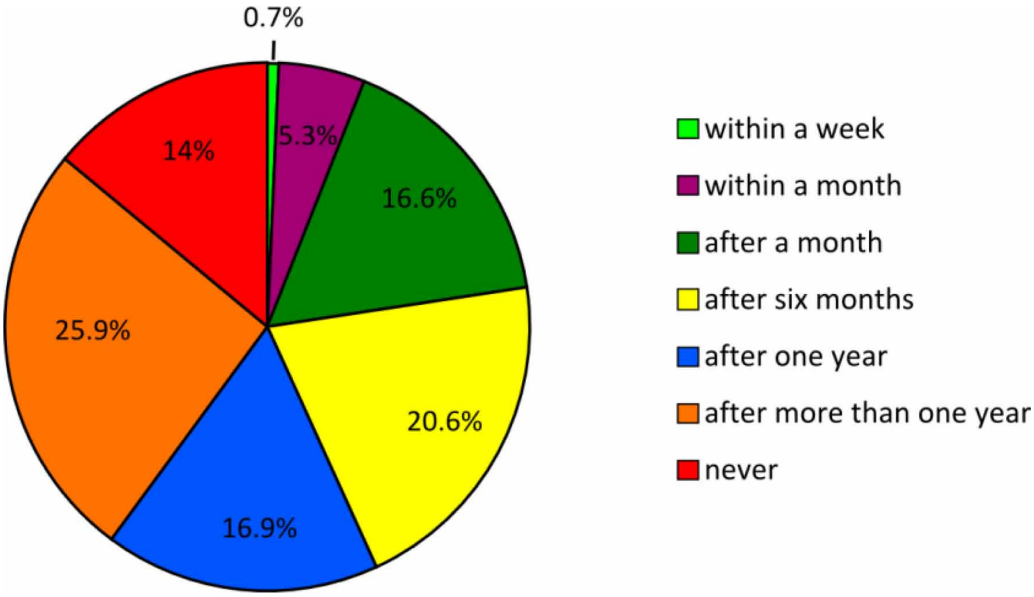
After considering the principal findings of the previous studies in this chapter, the third work aimed to increase knowledge about mental health. It studied how PMHS can use *La Rugiada* as an instrument of change.

- **Aims:** Action Research investigated beliefs surrounding mental illness, social and professional resources for youth with psychological problems, and the role of the sports association in promoting mental health. Moreover, the research aimed to verify if attending participatory sports activities can modify perceptions about mental illness.

Methods

- **Participants:** Three-hundred and fifty Grade 12 high school students (mean age = 17.46 years, SD = 0.66).
- **Instruments:** for each participant demographical information and data about the perception of seeking help have been collected. An ad hoc questionnaire was administered in order to explore their attitudes about mental illness and to assess perceived social support in case of psychological problems. The questionnaire had a 5-point scale ranging from 1 (strongly disagree) to 5 (strongly agree). Moreover, perceptions about the role of the sports association were collected and analyzed after the action.
- The Statistical Package for the Social Science (SPSS) was used to performed data analysis.
- **Descriptive Analysis:** One-hundred and sixty-three males (51.7%) and 152 females (48.3%).
- Almost all participants (96.8%) stated that their family had a mother and father. Participants reported that:
    - 40% of fathers held a high school diploma
    - 7.8% of fathers held a college degree
    - 45% of mothers held a high school diploma
    - 12.3% of mothers held a college degree

One-fifth of the participants (20.6%) stated that they repeated at least one school year. Of the participants, 41.5% experienced less severe educational difficulties.



Seventy-seven percent of the study participants had a friend with psychological problems. More than 53% suffered personal psychological problems. The most frequently reported issues were affective problems with partners or friends (36.4%), depression (32.6%), and anxiety (25.3%).

Among the participants, 57.6% sought help by speaking with friends for emotional support. Within the social system, participants used the social network to seek out health professionals (20.9%), peers (10.8%), and family (8.9%). Family doctors (4.1%) and teachers (2.8%) were perceived as potential helpers. The Internet was considered an instrument to seek help for 8.5% of participants. In fact, only 0.9% used social network forums for useful information.

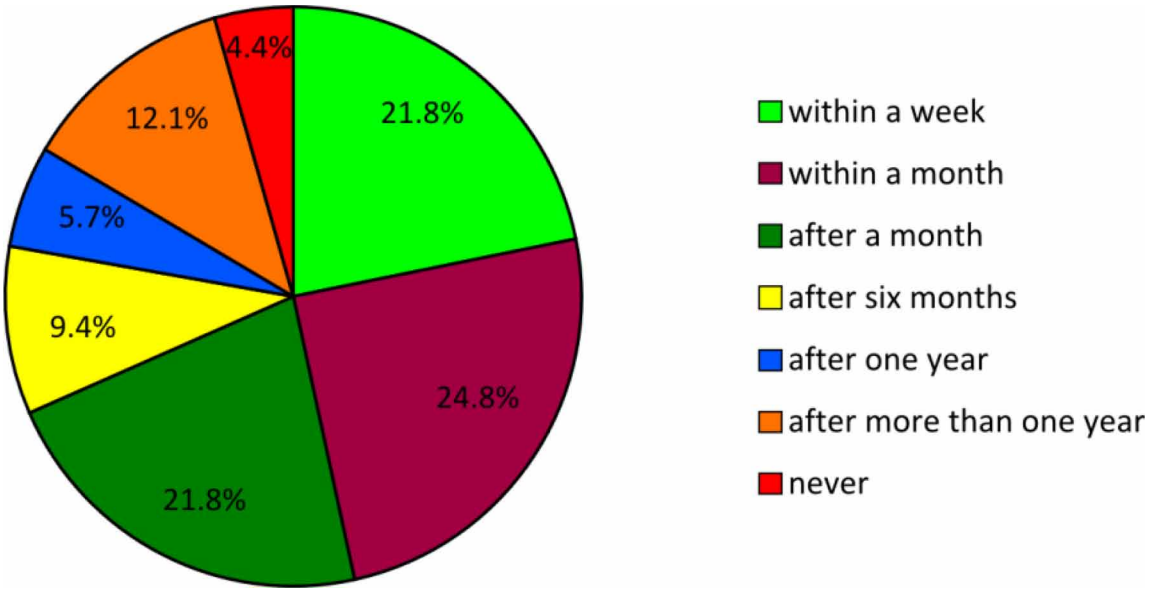
EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Participants were asked to identify the time between the arising of the first symptoms and the actions to seek help. More than a quarter of participants (25.9%) consider that young people seek help after more than one year; 16.9% seek help after one year; 20.6% seek help after six months; and 5.3% seek help in one month. A low percentage (0.7%) of participants report that youth seek help in one week; 14% will not seek help (see Figure 4).

Figure 4. Time before seeking help

Participants believe that response time before help can be received: one week (21.8%); one month (24.8%); after one month (21.8%); and after six months (9.4%). For 12.1% and 5.7% of participants, the response time can arrive after one year or several years (see Figure 5).

Some social beliefs are associated with mental illness. Of the participants, 42.4% believed that 1 out of 10 people will suffer mental illness during their life. Lazy or weak people are perceived to be at a greater risk for mental illness (75.9%). According to the study, 83.2% of participants believed that people with mental illness do not seek professional help. Only 3.8% of participants believed that it was impossible to help someone with mental illness.



During the study, 8.2% of participants felt that *"it is not possible to get better from mental illness.",* which was recognized as a cause of absenteeism (34.2%) and crime (45.6%).

Difficulties to seeking help with PMHS included prejudice (M=3.54; SD=1.23), lack of knowledge about services (M=3.37; SD=1.08), and low confidence in PMHS (M=2.85; SD=1.17). Participants reported poor motivation to seek help by young people (M=2.92; SD=1.03).

Despite difficulties perceived for young people, participants considered that seeking help through PMHS would solve psychological problems (M=3.36; SD=0.80). PMHS was perceived as a social resource in the community in which family members affected by psychological distress could seek help through professional services (M=3.24; SD=1.1).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Time before receiving help

However, seeking help through PMHS was regarded as a cause of a negative social response in the peer network (M=2.96; SD=1.18). Due to this reason, young people preferred to cope with the problem by relying on their own resources (M=2.85; SD=1.32).

Psychological problems led to feelings of shame (M=3.74; SD=0.82) and self-isolation (M=3.50; SD=0.88). Participants noted youngs with psychological problems received negative responses from peers (M=3.39; SD=0.95) and may be emarginated by them (M=3.20; SD=0.89). Hence, in the participants' opinion, young people can use social resources (M=2.85; SD=0.89) to receive useful help (M=2.55; SD=0.85).

Private professionals were perceived as more competent (M=3.75; SD=1.05). Peer networks (M=3.58; SD=0.92) and family (M=3.52; SD=1.01) were the principal sources of help related to psychological distress. Participants, in fact, reported that they sought help through friends (M=3.61; SD=1.16) and family members (M=3.36; SD=1.18).

Partners were also perceived as helpful (M=3.03; SD=1.02). Significant adults (M=2.77; SD=1.04), family doctors (M=2.49; SD=1.06), and teachers were perceived as less able to provide helpful actions (M=2.41; SD=1.0). In fact, in participants' personal experiences, teachers (M=1.75; SD=0.95), family doctors (M=1.51; SD=0.87), and PMHS (M=1.51; SD=1.03) were considered less able to give support to their own psychological problems.

- **Actions in High Schools:** High school students participated in a reflection process on mental health issues. This action was realized using sports activities as an instrument to promote mental health for the community and social inclusion for people with mental illness.

A volley match (see Figure 6) and a sailing boat tour (see Figure 7) promoted the interaction and connection between students and members of the *La Rugiada* sports association.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Analysis of the Intervention's Outcomes:** This study aimed to explore if participation promoted changes in participants. A paired sample t-test compared the mean scores for the same group of participants in two time frames (T1 = before the intervention; T2 = after the intervention).

Figure 6. Volley match with high school students

Table 1. Source of support before and after intervention

Source of Support	T1		T2		*t***
	M	SD	M	SD	
Parents	2.92	1.61	3.35	1.25	-3.42**
Partner	2.81	1.34	2.72	1.32	0.77
Friends	3.73	1.10	3.63	1.06	1.11
Teachers	1.79	0.94	1.94	0.95	-1.99*
Family Doctor	1.50	0.86	1.39	1.12	1.14
Significant Adults	1.95	1.08	2.08	1.13	-1.1
Private Professionals	1.94	1.36	2.22	1.43	-2.2*
PMHS	1.47	0.91	1.94	1.28	-3.3**

*: $p.< 0.05$, **: $p.< 0.01$

Table 1 shows that the intervention impacted student scores on the source of support. After the action, youth perceived parents (T1: M=2.92, SD=1.61; T2: M=3.35, SD=1.25; t=-3.41, p<.01) and teachers (T1: M=1.79, SD= 0.94; T2:M=1.94, SD=0.95; t=-1.99, p<.05) as more helpful in the case of psychological problems. Statistical differences were detected in the role of private professionals (T1: M=1.94, SD=1.36; T2: M= 2.22, SD=1.43; t=-2.20, p<.05) and PMHS (T1: M= 1.47, SD=0.90; T2: M=1.94, SD=1.28; t=-3.30, p<.01) as more effective in psychological distress after interventions.

A statistically significant change emerged in terms of difficulties perceived in a psychological problem. After the intervention, students had an increased awareness to negative attitudes and behaviors by the social system (T1: M=2.59, SD=0.96; T2:M=2.73, SD=0.94; t=-2.18, p<.05). After the intervention, students could identify adequately formal sources of support in the case of psychological problems (T1: M=2.13, SD=0.83; T2: M=2.25, SD=0.78; t=-1.94, p=0.054). They could also receive adequate help from these sources (T1: M=2.52, SD=0.84; T2: M=2.74, SD=0.89; t=-3.24, p<.01).

Reflections related to these experiences were collected. Many participants defined the association as an important *"source of help"*. A young male noted that he *"finally knew who and how to seek help in the future in my community."* Moreover, a young female defined the sports association as *"able to take care of the community and cure people with mental illness."* Another student (female) felt that the relationship built by the sports association was based on *"non-judging attitudes … this can really help people with an illness condition."*

Some participants found it difficult to seek help through PMHS because young people strongly recognize it as a place *"where crazy people go"*. However, the sports association is perceived as *"able to demolish prejudice that disease poses."(female)*

DISCUSSION AND CONCLUSION

La Rugiada experience is an innovative activity developed through the collaborative efforts of public organizations (a local PHMS and the University of Florence), a third sector association, users, and the community. These social actors strongly promoted a new culture of mental health founded on social inclusion for people with mental illness, and community wellness.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

This contribution shows an innovative social intervention to fight stigma in mental health, as well as prevent mental illness through sports participation. Two qualitative studies explored perceptions surrounding *La Rugiada* sports association. They looked at the effects of sports participation, specifically sailing. The third study by means of an action research investigated the role of sports as an instrument to prevent mental illness and promote mental health in youth.

One of the most interesting aspects of the experience was the capacity of the intervention in linking fundamental elements in the work of mental health.

Several actions have been realized through *La Rugiada* and the sailing club: fought stigma and implemented rehabilitation pathways for people with mental illness; prevented mental illness in young people; promoted well-being in the community.

Another important outcome of this intervention was the awareness that *La Rugiada* may be a community resource, and users became active members in this process.

Fighting Stigma and Implementing Rehabilitation

Sports participation as a rehabilitative program was a powerful strategy to improve people's mental health. Consistent with the literature, findings suggest that social interventions by sports participation improved both physical health and social responsibility in people with mental illness (Firth et al., 2015). It reduced isolation and social barriers between members, as well as improved social support (Morgan et al., 2007). Both professionals and patients considered sports participation as an instrument to promote socialization for people with mental illness (Rosenbaum et al., 2014; Sherry & O'May, 2013). Active roles and perceived skills positively affected self-esteem and self-efficacy. Participation generated a sense of reciprocity between PMHS, users (considered by the community as "citizens able to"), and the community. Sports participation reduced prejudice and barriers caused by mental illness. It created of a sense of belonging.

Preventing Mental Illness in Young People

Data emerging from the third study confirmed that stigma has a central role in the decisional process of seeking help. Among young people, reluctance to seek professional help may be explained by the lack of knowledge and prejudice surrounding local mental health services. These aspects were confirmed as relevant barriers by participants (Gaebel et al., 2014; Bosco et al., 2016).

Seeking help through PMHS was considered by young people as a cause of negative social reactions in the peer network. In their opinion, people with psychological problems are stigmatized by others in the society. This process may negatively affect the Self-evaluation (Corrigan et al., 2012; Parcesepe & Cabassa, 2013).

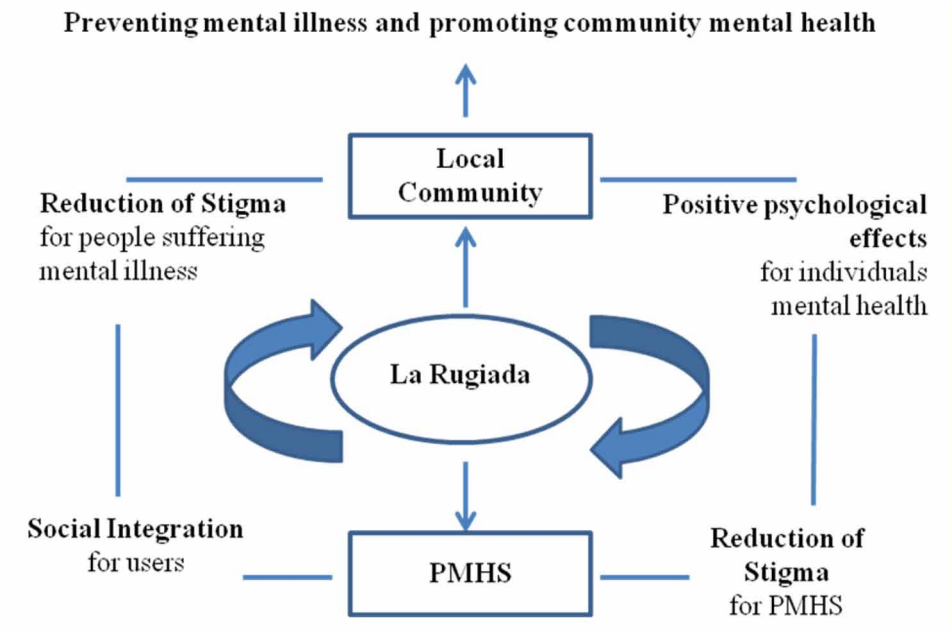
The negative attribution derived by the society (public stigma), may categorize them as members of a powerless and stigmatized group because of their unhealthy condition. Thus, in case of psychological problems, young people do not seek professional help to avoid the social rejection, and to protect themselves by feelings of shame, self-isolation (self-stigma), and discriminatory behavior acted by the peer group.

In the case of psychological problems suffered by a friend, emotional support was the principal action realized by participants. Young people would not seek help from formal resources event when the resources were perceived as more adequate (Rickwood et al., 2005).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Actions in local high schools fostered reflections on consequences experienced by people with mental health problems. Significant changes (before and after the intervention) have been detected, particularly related to increased awareness on the consequences of stigma (public stigma and self-stigma) in social life (Vogel et al., 2006). Following the sports participation intervention, significant differences were found about the source of the support. Participants perceived formal help seekers more adequate than informal help seekers (Anderson & Lowen, 2010). Moreover, significant adults, parents, and mental health professionals were perceived as more helpful than friends in the case of psychological problems.

The reluctance of young people to seek professional help, as well as their self-reliant attitude as preferred coping strategies, required a closer connection between PMHS and young people. The example of *La Rugiada* can be effective in connecting people and institutions through sport.



Sports participation generates a sense of belonging and creates significant relationships, which may include adults. We know that stigma negatively affects PMHS: therefore, mental health services must connect with the youth population through social innovation interventions for psychological needs. *La Rugiada* can be a significant resource to promote positive attitudes toward seeking help.

Promoting Community Well-Being

La Rugiada can be an innovative intervention. It generates mutual help, creates a sense of belonging to a sports team, and boosts members' confidence. These are crucial elements to meeting a community's psychological needs.

Results suggested relevant aspects to deconstruct stigma. *La Rugiada*, particularly its sailing club, may modify beliefs about mental illness. This activity allows people, including those with mental illness, to meet and connect. The community is considered a setting for everyone. People are assigned a new social role recognized by society.

Figure 8. Social role of La Rugiada

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Promising findings suggest that *La Rugiada* developed a powerful setting to link PMHS and the community. According to participants, the sports association functioned as an *"open workshop addressed to the whole community,* and *La Rugiada* is defined as a *"place of care"* for citizens. Thus, the intervention based on community setting and sports participation seem to be able to reduce stigma surrounding PMHS and mental illness (Soundy et al., 2015).

The social role and impact of *La Rugiada*, as suggested by results, are summarized in Figure 8.

La Rugiada may be an innovative experience to generate community participation. The capacity to promote positive change in various aspects of social life, including social networks, mutuality, and social participation (Zoppei et al., 2014), is the added value of the sailing club. It leads to consider this sports activity and *La Rugiada* as a bridging element of social capital.

As suggested by the results, *La Rugiada* connected citizens, formal and informal community networks, and the community. Thus, it can be viewed as a powerful instrument to promote healthy communities through destigmatizing strategies.

KEY TERMS AND DEFINITIONS

Basaglia Law: A legislative reform about psychiatric services that resulted in the closing down of all insane asylums in Italy.

La Rugiada: A sports association for social integration which promote well-being and mental health through sport.

PMHS: Public mental health service aimed to care and cure people with mental illness through therapeutic and rehabilitative interventions, and to promote community mental health.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social Capital: A social and/or individual dimension in which social networks, mutuality, and social participation are valuable resources.

Social Inclusion: A process to improve participation in the society for disadvantaged people.

Social Innovation Intervention: New strategies and/or services able to meet social needs and enhance individual and social wellbeing.

Stigma: A label attributed to others based on undesirable social characteristics.

ABSTRACT

The authors present the use of digital storytelling with two populations that have been consistently shown to be at increased risk for developing mental health disorders: veterans and firefighters. Despite efforts to increase access to evidence-based mental health programs, stigma remains a major barrier to care. AboutFace and Firefighters Helping Firefighters are two DST resources designed to help recognize the symptoms of posttraumatic stress disorder (PTSD) and related mental health symptoms, and to encourage help-seeking. These web-based video galleries introduce the viewer to 70+ peers who have experienced PTSD and have received formal treatment. These sites use the shared bonds of service to educate and help normalize common reactions that they may have due to the stressful nature of their occupations. Visitors to the site can "meet" peers and hear how mental illness has affected them through unscripted, authentic personal stories and can learn about common symptoms, struggles regarding decisions to seek care, and detailed descriptions of what treatment was like.

DIGITAL STORYTELLING: A PROMISING, SCALABLE APPROACH TO REDUCE MENTAL HEALTH STIGMA

Approximately 1 in 5 adults in the U.S. (43.8 million) will experience a mental health disorder in their lifetime, yet despite the availability of efficacious mental health interventions, fewer than half (45%) of individuals with a mental health problem seek treatment (Han et al., 2015; Hedden et al., 2015). Rates of treatment seeking for Posttraumatic Stress Disorder (PTSD) are similarly low. Several barriers to care have been examined, including financial, knowledge-related, logistical (e.g., transportation, scheduling), and attitudinal-barriers. Stigma consistently has been identified as a key barrier to mental health care (Corrigan, 2004). Feelings of weakness, shame, and fear of discrimination by others are reported reasons for not seeking or engaging in mental health treatment (Corrigan, 2004; Hoge et al., 2004; Kessler et al., 2001). Widely used strategies designed to reduce mental health stigma include training interventions and educational programs that address a range of audiences (e.g., health professionals, first responders, general public) and mass media campaigns (Bahora et al., 2008; Beltran et al., 2007; Corrigan, 2004, 2011). Whereas these have been found to be successful in improving attitudes toward mental health, most of these effects are short-lived (Corrigan and Gelb, 2006). In this chapter, we will provide an overview of how digital storytelling has been used to address mental health stigma and will present two digital-storytelling resources that can serve as a model for researchers seeking to develop and/or improve other web/smartphone-based DST resources to improve relevance, interest, and effectiveness in decreasing stigma.

Research consistently demonstrates that people are most responsive to advice or education when it comes from someone they consider similar to themselves (peer education). Indeed, mental illness stigma reduction has been found most effective when targeted toward specific populations, credible (using people from the targeted population to deliver the message), and when it involves contact with peers who have experienced mental health problems (Corrigan, 2011). More specifically, peers, especially those with the same psychiatric disorder or presentation of symptoms, can provide patients with accurate information (i.e., education) as well as personal contact with a similar peer that, in turn, can challenge perceptions about mental illness. A growing body of evidence supports the effectiveness of peer educators in reducing stigma and improving treatment seeking. For example, peer educators have been shown to improve knowledge, self-efficacy, and behavioral outcomes in people with HIV (Mahat et al., 2011; Medley et al., 2009), reduce drinking in college students (White et al., 2009), and reduce stigma in depressed older adults (Conner et al., 2015). However, this is a growing area of research and there is still much to be learned about the value of peer education in addressing mental health stigma. The National Alliance of Mental Illness program, *In our Own Voice (IOOV)*, is one such program that has shown success in reducing stigmatizing attitudes (Pinto-Foltz, Logsdon, and Myers, 2011). This program involves a 90-minute group interaction led by two facilitators who have successfully managed their mental illness. The group interaction consists of watching education videos, sharing of personal experiences by group facilitators, and open discussion. A major limitation of this, and other existing programs, is that they are delivered in-person, which does not address a number of noted barriers to service use, including transportation, time-commitments, scheduling difficulties, and worries about confidentiality. Moreover, costs associated with training peers and supporting their interactions with the target population limit the scalability of these approaches.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Web-based systems have effectively used this peer education approach to relay health related information to high-risk groups. Rapid growth in the use of smartphones (now used by roughly 80% of the adult US population) has strengthened the reach of these approaches and made them even more accessible and much more user-friendly. Peer education has been used effectively in online formats to address topics ranging from healthy lifestyles to severe medical illness. More recently, Naslund and colleagues (2016) proposed that online peer networks can improve access to treatment. These authors view online peer support networks as a mechanism to challenge stigma, increase consumer activation, and ultimately increase access to mental healthcare. This low-cost, highly sustainable and scalable approach to peer education may have particular value for populations with stigmatized conditions. Naslund and colleagues further suggest that people with PTSD may be motivated to access online peer interventions because they are struggling to deal with their PTSD symptoms, feel socially isolated and tend to avoid in-person interactions, and/or are afraid to reach out for traditional face-to-face help due to concerns about how others will perceive them or concerns about social or occupational repercussions to seeking help. These factors may encourage a person with PTSD to seek out online support, which is anonymous and less anxiety provoking. The decision to visit an online peer network provides opportunities to challenge stigma or other misperceptions that are preventing an individual from accessing needed mental healthcare. Additionally, peers may help people feel less isolated and alone in their illness, more empowered, and more hopeful. These interactions can motivate interest in learning more about PTSD and demystify the treatment process resulting in an increased likelihood that evidence-based care for PTSD will be accessed.

Overview of Digital Story-Telling Approaches to Address Mental Health Stigma

Peer education through digital storytelling (DST) is a particularly efficient way for everyday people to connect with others similar to themselves in a low-burdensome and sustainable way. DST features videos of individuals sharing aspects of their own personal stories (i.e., testimonials) through the use of recorded audio, video, graphics, and text that are disseminated electronically (e.g., via the Internet or DVDs) to a target population for a particular purpose (e.g., to train, instruct, educate, and motivate). This is accomplished through several storytelling modalities, including re-telling of historical events, informational or instructional videos, and/or personal narratives. DST has been used in a number of contexts and has traditionally been used in educational settings. For example, instruction-based and student-driven digital storytelling methods have led to positive learning effects in educational settings (Robin, 2008) and, when compared to basic technology-integrated instruction, DST leads to better achievement, critical thinking, and learning motivation (Yang & Wu, 2012). DST has been used with promising results in a number of mental health settings, such as development of trauma narratives in exposure therapy for PTSD (Anderson & Wallace, 2015), promoting stress reduction in female adolescents (Goodman & Newman, 2014), and encouraging positive health practices in patients with HIV (Medley et al., 2009). Despite positive findings for the role of DST as an educational and therapeutic tool, little is known about its value in decreasing mental health stigma and increasing treatment-seeking behavior. Because DST is a low-cost, scalable peer education approach, it may have tremendous value, particularly for individuals with stigmatized conditions such as PTSD, depression, alcohol and drug use, and other chronic diseases.

In the remaining sections of this chapter, we will present the use of digital storytelling with two populations that have high risk for developing mental health disorders, Veterans and firefighters. These individuals are frequently involved in life-threatening duties and occupational impacts with respect to posttraumatic stress disorder (PTSD), depression, substance abuse, and marital discord (Hoge et al.,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2006; Wagner et al., 2010). Yet, despite tremendous efforts from their respective organizations to develop and increase access to evidence-based mental health programs, misconceptions about mental health and treatment continue to be pervasive, and stigma remains a major barrier to care. *AboutFace* (http://www.ptsd.va.gov/apps/AboutFace/) and *Firefighters Helping Firefighters* (http://pocketpeer.org) are two DST resources designed to help visitors recognize the symptoms of PTSD and related mental health symptoms, and to motivate visitors to seek evidence-based assessment and treatment. These web-based video galleries introduce the viewer to a community of 100+ peers who have experienced symptoms of PTSD, depression, and/or other mental health and behavioral conditions and have received both formal treatment and other support mechanisms. These sites use the shared bonds of service to educate the user and to help normalize common reactions that they may have due to the stressful nature of their occupations. Consistent with this, visitors to the sites can "meet" peers and hear how mental illness has affected them through unscripted, authentic personal stories. Moreover, they can learn about common symptoms of PTSD and other behavioral problems, treatment opinions, struggles regarding decisions to seek care, and detailed descriptions of what treatment was like. Additional features include receiving advice from expert clinicians, hearing how PTSD can affect family members, and hearing from supervisors and other leadership the importance of seeking help.

AboutFace: A Veteran-to-Veteran Digital Storytelling Resource

Military operations frequently involve life-threatening duties, such as patrols and direct fire, witnessed violence and human suffering, and hostile responses from civilians (Hoge, Auchterlonie, & Milliken, 2006). Although the majority of Veterans are resilient and/or recover quickly, PTSD occurs in around 17% of Vietnam Veterans (Dohrenwend et al., 2006) and 13% of Veterans from Iraq and Afghanistan (Kok et al., 2012). PTSD is associated with other mental health problems such as depression and alcohol abuse (Blow et al., 2013; Cohen et al., 2010; Hoge et al., 2006; Hoge et al., 2004; Kim et al., 2010), and all of these disorders are in turn associated with high levels of distress, functional impairment, and morbidity and mortality. However, mental health treatment seeking among Veterans remains strikingly low; most Veterans with mental health problems do not seek mental health services (Han et al., 2015; Hoge et al., 2014). Stigma is frequently reported as a barrier to seeking treatment (see Clement et al., 2015; Gulliver et al., 2010 for two reviews). Stigma may be even more problematic among service members who perceive that disclosing a mental illness could negatively impact their military career. In one survey of four US combat infantry units, among those who met screening criteria for a psychiatric disorder, 65% were concerned that others would see them as weak, 63% were concerned that leadership would treat them differently, and 59% were concerned that members of their unit might have less confidence in them. Importantly, those most in need of care were also the ones most concerned about stigma (Hoge et al., 2004).

Developed by the National Center for PTSD, *AboutFace* is a web-based video gallery that introduces viewers to a community of 77 veterans, diverse with regard to military experience, age, gender, and race/ethnicity. The veterans have experienced PTSD and received treatment through the Veterans Health Administration (VHA). The site also contains testimonials from 23 family members and 22 clinicians. As such, it serves as an online peer network where Veterans can meet similar others and learn from them. *AboutFace* aims to use the shared bonds of military service to educate veterans and their families and help normalize common reactions that veterans may experience due to their military service or deployment experiences. Consistent with this, visitors to the site can "meet" veterans and hear how

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

PTSD has affected them through unscripted, authentic personal stories. Veterans are filmed in natural settings looking directly at the camera. *AboutFace* visitors to the site can challenge their stigmatizing beliefs by choosing to engage with the Veterans on the site with whom they most closely identify. They can view the clips that are most relevant to them and learn from others how they have handled similar situations. Veterans who access *AboutFace* can learn about other veterans' military histories, the common symptoms of PTSD, treatment options, and the struggles of other veterans regarding decisions to seek care. They can get detailed descriptions about what treatment was like for other Veterans. Real life examples provide corrective information to challenge misperceptions about PTSD or the treatment process for PTSD. There is even a section where Veterans give advice on what they think fellow Veterans with PTSD should know about seeking help. Thus, through honest and open testimonials, the Veterans of *AboutFace* serve as encouraging peer supports to other Veterans as they consider their own need for mental healthcare, what the process of PTSD treatment will look like, and how they can obtain and initiate needed services through the Veterans' Health Administration. This use of a peer-to-peer approach is innovative, relevant to a wide range of healthcare conditions, and has the potential to increase access to care through trusted narratives that promote hope in recovery. *AboutFace* has an open format that allows visitors to navigate the site freely based on their own user preferences (Bunnell et al., 2017). Visitors can learn about one Veteran's experience at a time by selecting that Veteran's image and then choosing from a series of statements that represent topics addressed by the Veteran (e.g., What is PTSD?, Am I ready for help?, What is treatment like?). Alternatively, the visitor can choose a specific topic and review video clips of all Veterans, who have addressed that topic. Veterans also can receive advice from expert clinicians and hear how PTSD can affect family members, via a separate component of the *AboutFace* site. Topics addressed in the brief (~1 minute) clips are included in Table 1. We recently conducted a two-stage evaluation of *AboutFace,* which included (1) a usability testing phase and (2) a pilot randomized controlled trial phase to explore the feasibility of incorporating *AboutFace* into a specialized outpatient clinic for PTSD (Hamblen et al., 2018). Twenty veterans participated in the usability testing phase in which they answered moderator posed questions regarding *About Face* while actively exploring the website. Sixty veterans participated in the pilot study after completing a PTSD clinic evaluation and were randomized to receive an educational booklet about PTSD treatment or to *AboutFace* prior to starting treatment. Stigma and attitudes about treatment seeking were assessed at baseline and two weeks later. Our results indicated that Veterans had positive attitudes about *AboutFace* and gave suggestions for improvement. Veterans in both conditions reported improved attitudes towards mental illness from baseline to the two-week follow-up. Future directions will include a large-scale randomized controlled trial to evaluate the efficacy and preliminary effectiveness of *AboutFace.*

Firefighters Helping Firefighters: A Digital Storytelling Resource for Firefighters

Based on the context of their job duties, firefighters are often faced with multiple and repeated life-threatening duties including direct fire, witnessed violence and human suffering, and sometimes death, which have significant impact on their physical and psychological well-being (Berninger et al., 2010; de Borros, Martins, Saitiz, Batos, & Ronzani, 2013; Mitani, Fujita, Nakata, & Shirakawa, 2006; Norwood & Rascati, 2012). Thus, firefighters are at elevated risk for trauma-related consequences such as PTSD, sleep disorders, suicide, depression and alcohol abuse (de Barros et al., 2013; Laposa & Alden, 2003; Stanley, Hom, Hagan, & Joiner, 2015); all of these disorders are in turn associated with high levels of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

distress, functional impairment, and morbidity and mortality. However, mental health treatment seeking among firefighters remains strikingly low; most firefighters with mental health problems do not seek mental health services (Gist et al., 2011). A primary hypothesis for this is stigma, which is frequently reported as a barrier to seeking treatment (see Clement et al., 2015; Gulliver et al., 2010 for two reviews), especially among firefighters (Del Ben et al., 2006). Specifically, firefighters report significant reluctance to discuss stress and mental health problems with coworkers, peers, and family members (Antonellis & Thompson, 2012; Norwood & Rascati, 2012), as they may be seen as a sign of weakness, vulnerability, and failure (Henderson, Van Hasselt, LeDuc, & Couwels, 2016). Further, stigma may be even more problematic among firefighters and other emergency response professionals who perceive that disclosing mental illness could negatively impact their fire service career.

Table 1. AboutFace video clips

CLIPS OF VETERANS	CLIPS OF CLINICIANS	CLIPS OF FAMILY MEMBERS
WHO I AM *Example: A.J., US Army (1978-1998), Germany/Korea/US*	**WHO I AM** *Example: Dr. Peter Tuerk, Clinical Psychologist, Director of PCT Clinic, Ralph H. Johnson VA Medical Center, Charleston, SC*	**WHO I AM** *Example: O.J., daughter of A.J.*
HOW I KNEW I HAD PTSD *I was waking up, sweating, [and I] couldn't go back to sleep…*	**WHAT PTSD IS** *A very, very lonely experience… People have thoughts and nightmares they experience alone. They want to isolate…*	**LIVING WITH SOMEONE WITH PTSD** *I didn't experience a childhood… I would give up going to a friend's house in case Dad needed me.*
HOW PTSD AFFECTS THE PEOPLE YOU LOVE *My daughter would ask, 'Mommy, why is Daddy crying?'*	**HOW TO KNOW YOU'RE READY FOR HELP** *Have the worst time sleeping, they isolate the most, have no relationships, extremely on edge all the time…*	**THE SIGNS THAT I SAW** *He wouldn't converse with me as much, he was a little distant, his temper…*
WHY I DIDN'T ASK FOR HELP RIGHT AWAY *I didn't think she [my therapist] could relate to what I had been exposed to…*	**WHAT TREATMENT IS LIKE** *People are asked to sort of get used to the things that are bothering them the most…*	**HOW PTSD AFFECTS A FAMILY** *When I got older, he would start isolating himself… I would talk "at him" without him saying anything.*
WHEN I KNEW I NEEDED HELP *I heard about Gulf War Vets not being able to sleep, etc. I thought "Wow, that's some of the symptoms I have."*	**WHAT TREATMENT CAN DO FOR YOU** *Set goals and target treatment to those goals. If Veteran wants to get rid of nightmares, use exposure…*	**THE HARDEST PART** *PTSD made him shelter me a lot…I couldn't go to the movies on the weekend or house parties*
WHAT TREATMENT WAS LIKE FOR ME *My homework was to go into the Walmart or crowded mall for 30-45 minutes.*	**QUESTIONS WE'VE BEEN ASKED** *Does my family have to be involved?*	**HOW TREATMENT CHANGED THINGS** *We don't argue as much. He's a different person, and I like it. He's happier and taking care of himself.*
HOW TREATMENT HELPS ME *I still have PTSD, but I'm in control of it now… I'm at peace with it, and I can talk about it [the trauma].*		
MY ADVICE TO YOU *They [the therapists] are waiting for Veterans like you and I. Try it. You won't regret it.*	**MY ADVICE TO YOU** *You really want a treatment that involves some type of exposure…*	**MY ADVICE TO YOU** *Support them [the family member] and let them know you're there for them. Most importantly - listen.*

Firefighters Helping Firefighters (FHF), is a video-storytelling resource that provides peer education through a video library of over 250 personal stories from firefighters and support personnel intended to reduce stigma and improve readiness to seek behavioral health care when needed. It was developed by the Technology Applications Center for Healthful Lifestyles and the National Crime Victims Research and Treatment Center at the Medical University of South Carolina, in partnership with the National Fallen Firefighters Foundation. *FHF* is committed to improving the lives of fire service members who are experiencing common behavioral health problems associated with occupational stress, such as symptoms of PTSD, depression, or anxiety. On this site, members of the fire service can learn about common behavioral health problems, discover treatment options, and hear firsthand from other fire service members as well as fire service supervisors. More specifically, *FHF* visitors have access to real life examples from fellow firefighters about the effects of stress on themselves as well as their families, various ways they tried to cope with this stress, how they knew it was time to ask for help and the types of help they considered, what getting help was like for them, and what advice and recommendations they have for other firefighters who are struggling, yet are reluctant to seek help. Similar to *AboutFace*, *FHF* has an open format that allows visitors to navigate the site freely by selecting what discussion topic they would like to hear and from which firefighter or support personnel. Topics addressed in the brief (~1 minute) clips are included in Table 2.

Table 2. Firefighters Helping Firefighters clips

CLIPS OF FIREFIGHTERS	CLIPS OF SUPERVISORS
WHAT IS THE MOST STRESSFUL PART OF YOUR JOB? *"You get comfortable in your job and then …something happens…Everything you see in the movies… flashbacks… it's all true"*	**WHAT UNIQUE STRESSORS DO FIREFIGHTERS FACE?** *"…having a lot of different calls. We call it the Big Four: any call involving children, a mass casualty, and threat of death or injury to themselves or another firefighter"*
ARE THERE ANY PARTICULAR STRESSFUL EXPERIENCES THAT STAND OUT TO YOU? *"I was trapped in a fire and I had to be pulled out. In that 5 minutes and 18 seconds, you know, you thought you were going to die"*	**HAVE FAMILIES OF FIREFIGHTER EVER REACHED OUT TO YOU IN REGARD TO SYMPTOMS?** *"I've had some family members reach out to me, especially after they know the symptoms of stress…we encourage firefighters to talk with their families..."*
HOW DO YOU KNOW WHEN YOU ARE STRESSED? *"When I lose sleep, I love to sleep, but when I know I'm waking up at night, my body lets me know through that …"*	**WHAT ARE SOME COMMON THINGS YOU HAVE SEEN FIREFIGHTERS DO WHEN THEY ARE STRESSED?** *"… A lot of times Firefighters withdraw from their families and fellow firefighters… become isolated and unfortunately go into depression sometimes…"*
HOW DOES STRESS AFFECT YOUR FRIENDS AND FAMILY? *"I would distance myself from my wife and kids… because I didn't want them to see me in that type of stress"*	**HOW DOES STRESS AFFECT THEIR FAMILY OR FRIENDS?** *"… .they feel left out, sometimes they feel anxious like they've done something wrong to affect the firefighter"*
HOW DID YOU KNOW YOU NEEDED HELP? *"After probably the third night without sleep, with all the flashbacks… I was taking it out on my wife and kids"*	**HOW DOES A FIREFIGHTER KNOW THAT THEY NEED HELP?** *"A lot of times the firefighter don't necessarily know … talking to someone is the best way to get help."*
WHAT TYPE OF HELP DID YOU CONSIDER GETTING? *"I went to a chief who was trapped in a fire one time and got burnt also … if it wasn't for him, I probably wouldn't be sitting here in front of you. He took me to [a program called] SAVE"*	**WHAT STEPS WOULD A FIREFIGHTER TAKE TO GET HELP?** *"Like a chain of command… go to that person that you trust… we have a support group we go to… have that person know not to be afraid to ask for help"*
WAS HELP WHAT YOU EXPECTED? *"It took time, but after a few sessions, it took that burden right off my shoulders"*	**WHAT CHANGES HAVE YOU SEEN AFTER PEOPLE SEEK HELP?** *"I've seen firefighters be reunited with their families in a whole sense… and see them grow back together as a family"*
WHAT WOULD YOU TELL OTHERS WHO ARE IN A SIMILAR SITUATION? *"I would tell them my story. Let them know that it's okay…we'll get help. It helped me and it will help you"*	**WHAT WOULD YOU RECOMMEND TO FIREFIGHTERS WHO ARE THINKING ABOUT SEEKING HELP?** *"To do it. Talk to somebody, reach out to peer, a family member, someone in your department that you trust, and talk."*

CONCLUSION

Individual and societal costs of stigmatized mental health disorders, such as PTSD, anxiety depression, suicidality, and alcohol abuse are enormous, and evidence based treatments are available to address these behavioral health problems. Benefits from career preservation, enhanced productivity, and improved quality of life are immeasurable if treatment can be accepted earlier and seen through to completion. Education may assist in addressing stigma (Dickstein et al., 2010; Finkelstein, Lapshin, & Wasserman, 2008), as well as knowledge, attitudes toward seeking mental health treatment, and service utilization (Corrigan, 2004; Pinfold et al., 2003). Education that is delivered by peers who give first-hand accounts of their experiences may be particularly effective in accomplishing these goals. Uniquely, peer education delivered via DST is a low-cost, scalable, and sustainable aid to such efforts. In this chapter, we presented two digital-storytelling resources that can serve as a model for researchers seeking to develop and/or improve other web/smartphone-based DST resources to improve relevance, interest, and effectiveness in decreasing stigma. Promisingly, this can be accomplished on both the disease (e.g., HIV, diabetes, obesity, and eating disorders) and demographic (e.g., Veterans, civilians, and first responders) level. The use of a peer-to-peer approach through digital storytelling is innovative, relevant to a wide range of healthcare conditions, and has the potential to increase access to care through trusted narratives that promote hope in recovery. Further research is needed to measure that short and long-term value of digital storytelling approaches toward addressing stigma and increasing motivation to initiate and follow-through with mental health treatment. If found valuable, DST is a scalable and sustainable approach for that can used with a wide range of traumatic stress populations (e.g., disaster victims, traumatic injury patients, first responders) to reduce attitudinal barriers and increase access to care.

ABSTRACT

Health literacy is a core element of patient-centered healthcare. Poor health literacy is a silent epidemic across the globe as it affects every aspect of health. Schools bear an important role in increasing health literacy. Improving health literacy in adolescence is supposed to improve the later life as adolescents are used to carry their modified behavior lifelong. Various school-based interventions covering physical and mental health have been studied and found to be effective. International bodies recommend incorporation of health-related tasks into school lessons and considered that teaching the young people will be a good investment for future. Multisectoral collaborations and locally proved effective strategies are the practical challenges. This chapter aims to focus on health literacy, global scenario of health literacy, measurement tools, role of school, interventions, limitations, and challenges of health literacy.

INTRODUCTION

In this contemporary and consumer driven world, education is considered as an important tool to increase income, reduce poverty, employ equality and justice, ensure sustainable growth and improve quality of health (United Nations General Assembly, 2015). Since 2000, preprimary education enrollment increased almost two third globally (UNESCO, 2015). According to UNESCO institute for statistics (2015), the youth literacy is 91% and adult rate is 85% around the globe (UNESCO, 2014). Health literacy is a domain which is directly connected to education. As a term "Health literacy" was mentioned first in 1974 in an article titled "Health Education as Social Policy" (Mancuso, 2008; Peerson & Saunders, 2009). In

past 30 years, more attention has been given to health literacy and it has gained popularity in most parts of the world (Berkman, Davis, & McCormack, 2010). But, still the definition of health literacy is yet to be unified and different authors, organizations, institutions, such as American Medical Association (AMA), WHO and Institute of Medicine (IOM) (Palumbo, 2015; Serper et al., 2014; Dickson-Swift, Kenny, Farmer, Gussy, & Larkins, 2014; Sørensen et al., 2012), defined it differently. Most widely used definition mentioned, health literacy as an "individual skills to obtain, process and understand health information and services necessary to make appropriate health decisions" (Dickson-Swift, Kenny, Farmer, Gussy, & Larkins, 2014; Sørensen et al., 2012). Dan Nutbeam preferred three typologies of health literacy mentioned as functional health literacy, interactive health literacy, and critical health literacy (Nutbeam, 2008; Nutbeam, 2000; Sørensen et al., 2012). For the better understanding about health literacy and school involvement in health issues, authors reviewed updated researches and documents. This chapter thoroughly described about global status of health literacy, measurement tools of health literacy, role of school in health literacy, interventions in school setting to improve health literacy, limitations & challenges of health literacy.

BACKGROUND

Health literacy (HL) is an important determinant of both public health as well as individual healthcare and is considered a core element of patient centered healthcare (Altin, Finke, Kautz-Freimuth, & Stock, 2014) where patients play a greater role in gaining and utilizing information about their health (Manganello, 2008). Although the concept prevailed before the term health literacy was coined first in 1974 in discussions regarding health education (Peerson & Saunders, 2009; Sørensen et al., 2012), since then its importance has increased as it is concerned with the individual's capacity to meet the complex health needs in this modern world (Sørensen et al., 2012). It covers the fields of health and education and builds an individual's ability to enjoy good health throughout the life span (Ghanbari, Ramezankhani, Montazeri, & Mehrabi, 2016).

Healthcare sector around the world rotates an ostensibly endless process of communicating health information clearly and tries to make sure that it is comprehended clearly. To provide safe and effective practice in the healthcare sector, the system is designed in such a way that structure, processes, tools and techniques should be in place for proper delivery of health information. Health care system should include and provide facilities related to health literacy (Osborne, 2012). It has been considered as a key determinant of health (Watson, 2011; Kickbusch, 2001) and its improvement is a practical approach to implement preventive strategies among the general population (Diemer et al, 2017). Recent evidence suggests that, health literacy has gained increased importance in public health, health promotion and clinical care (Liu, Liu, Li, & Chen, 2015). It is closely linked with knowledge, motivation, competency to access, understand, appraise and apply information to form and to make decisions related to healthcare (Sørenson, 2013). For adults with limited literacy or numeracy skills and with reduced functional skills, health literacy is viewed as a contemporary effort to foster adults' ability to manage their health (Marks, 2012).

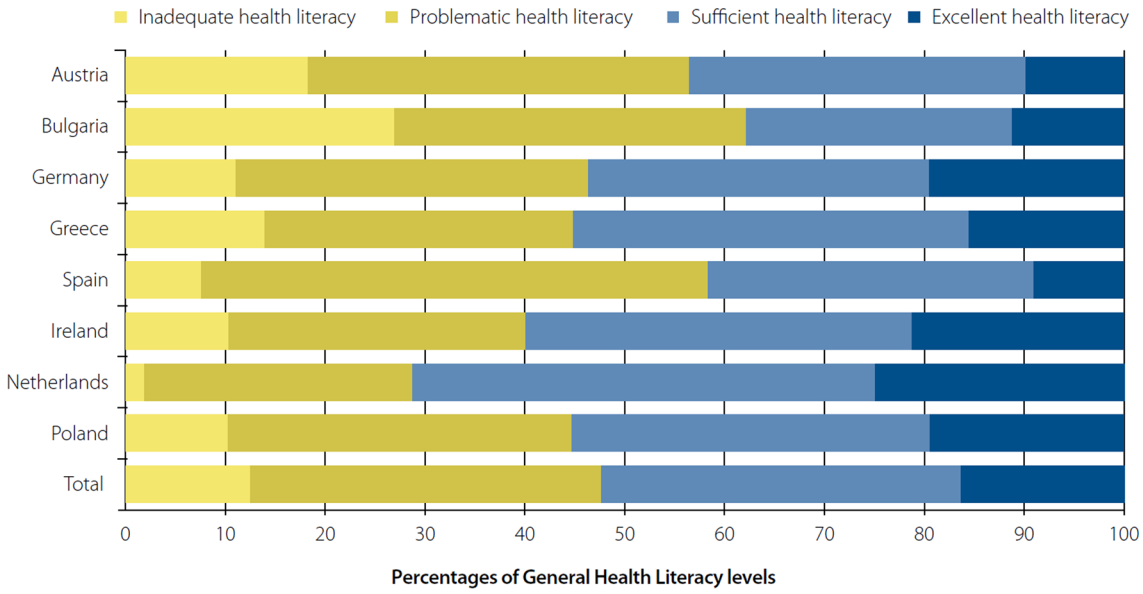
HEALTH LITERACY

Global Scenario



Currently optimum health literacy is a prime concern globally and poor literacy in health is a silent epidemic that is threatening the health service across the globe (Palumbo, 2015; Sørensen et al., 2012; Parker & Ratzan, 2010). Inadequate health literacy is a concerning problem both in developed and developing countries and the portion with poor health literacy ranges from a quarter to a third of the population (How, 2011). In United States National Assessment of Adult Literacy (NAAL) in 2003 revealed only 12% of US adults were found to have proficient health literacy (Koh et al., 2012), 52% were found to have intermediate health literacy, 22% were found to have basic percent, 14% were found to have below basic health literacy (Vernon, Trujillo, Rosenbaum, & Debuono, 2007), & approximately 90 million (Safeer & Keenan, 2005) of adult American peoples have below basic or basic health literacy (Koh et al., 2012; Bailey et al., 2014; Cajita, Cajita, & Han, 2016; McCaffery et al., 2013; Vernon, Trujillo, Rosenbaum, & Debuono, 2007; How, 2011; Muscat et al., 2016). The proportion was found more in Australia, where it was about 60% (Muscat et al., 2016). A comparative report on health literacy in eight European Union state members revealed that 12% of all respondents have inadequate general health literacy and 35% have problematic health literacy. Therefore, limited health literacy in Europe is a significant burden which does not affect a minority of the population. However, there are marked differences between different countries as demonstrated by the European Health Literacy Survey (HLS-EU) which was conducted in 2011 in eight European countries (Fig 1) (HLS-EU Consortium, 2012). In Asia, research in health literacy is not a priority. In India, a study was conducted to see dental health literacy among patients and it revealed that, 60.4% having low health literacy score (D'Cruz, & Aradhya, 2013). In Bangladesh, the literacy rate and the enrollment in the schools are increasing day by day but the health literacy is still untapped (Arafat & Ahmed, 2017). Moreover, there prevails multiple misconceptions those direct the people to pursue abnormal health seeking behaviors such as attending the traditional healers instead of registered physicians even in the major illnesses (Arafat, 2017a). Inadequate health literacy is much worse in case of older persons. Previous studies in different cultures revealed majority of patients older than 60 years found to have the lowest levels of literacy, and 80 percent were found to have limited skills to fill out forms when they were asked even in the waiting rooms (Safeer & Keenan, 2005). One of the major effects to poor health literacy is failure to take medications results in approximately 125,000 deaths annually in US, that costs from $106 to $238 billion yearly (Bailey et al., 2014; How, 2011).

Importance in Relation to Health Outcome

People with poor health literacy often perceive poor self-efficiency in regards to deal with their health conditions (Palumbo, 2015; Serper et al., 2014; Andrus & Roth, 2002); usually are not willing to take part in the health care services appropriately; associated with inadequate in management of chronic health conditions and diseases, prone to greater risk of hospital admission and increased mortality (Palumbo, 2015; Serper et al., 2014; Koh et al., 2012; Cajita, Cajita, & Han, 2016; Andrus & Roth, 2002; Vernon, Trujillo, Rosenbaum, & Debuono, 2007; Berkman, Sheridan, Donahue, Halpern, & Crotty, 2011; Muscat et al., 2016). Limited health literacy is also likely to exhibit impairment in recalling the provided health information (Palumbo, 2015; Cajita, Cajita, & Han, 2016; DeWalt & Hink, 2009; Manganello, 2008). People with lower HL, are less efficacious in understanding the prescription as well as taking medications

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. European Health Literacy Survey (HLS-EU): Levels of general health literacy index in selected European countries (Source: Sorensen et al., 2015)

as per direction, unable to implement appropriate strategy to improve the compliance (DeWalt & Hink, 2009; Andrus & Roth, 2002; Cajita, Cajita, & Han, 2016; Palumbo, 2015; Koh et al., 2012); usually show serious medication errors repeatedly (Palumbo, 2015; Koh et al., 2012; Safeer & Keenan, 2005; Manganello, 2008; Vernon, Trujillo, Rosenbaum, & Debuono, 2007) that ultimately tolls high medical expenses (Palumbo, 2015; DeWalt & Hink, 2009; Manganello, 2008; Vernon, Trujillo, Rosenbaum, & Debuono, 2007; Muscat et al., 2016). Low health literacy is associated with poor knowledge in health, unhealthy behavioral pattern, lower preventive health services utilization (Vernon, Trujillo, Rosenbaum, & Debuono, 2007; Dickson-Swift, Kenny, Farmer, Gussy, & Larkins, 2014) ultimately acts as a strong barrier to access health care services (Palumbo, 2015; Kabir & Khan, 2013); as a catalyst of poor health and high hospitalization (Dickson-Swift, Kenny, Farmer, Gussy, & Larkins, 2014; Cajita, Cajita, & Han, 2016; Safeer & Keenan, 2005; Andrus & Roth, 2002; Vernon, Trujillo, Rosenbaum, & Debuono, 2007). Importantly poor health literacy affects three points as mentioned in access and utilization of health care, interaction with services provider and self-care (Osborn, Paasche-Orlow, Bailey, & Wolf, 2011; Sørensen et al., 2012) and negatively influence the motivation of the patient, problem solving ability, self-efficacy, appropriate self-care behavior (Osborn, Paasche-Orlow, Bailey, & Wolf, 2011). It is troublesome to process health information for the people with low health literacy those affects reading, understanding the medication labels, making appointments as well as understand the appointment slips, comprehending the verbal communications with health care services providers, understand and follow the educational and self-care materials to adapt the preventive services (Cajita, Cajita, & Han, 2016). Better or improved status of health literacy leads to improved health status, lowered health expense, shorter hospital stay, less frequent hospitalization, less utilization of the health resources (Sørensen et al., 2012; Safeer & Keenan, 2005). Adequate functional health literacy enables to understand the risks and related health services, improved compliance; adequate interactive health literacy enables to improve individual motivation, self-reliant capacities, as well as to be self-sufficient; adequately critical health literacy enables to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

be resilient to surrounding adversities such as social and economic (Sørensen et al., 2012). Along with the enormous personal benefits adequate health literacy ensures very impactful community and social benefits. Adequate functional health literacy increases the participation in community health programs; interactive health literacy accelerates influencing capacity of an individual to affect the social norms and more interactions between the surrounding societies; critical health literacy enhances community based empowerment and enables to act as social and economic determinants of health (Sørensen et al., 2012). Low, inadequate, poor health literacy substantially affects treatment compliance, self-control for chronic diseases and ultimately the treatment costs (Safeer & Keenan, 2005). Previous studies revealed a significant difference in health outcome between the highest and lowest health literacy groups and the finding recommended to improve the health literacy of lower group (How, 2011). Even poorly literate people are unable to pick up the benefits aimed from media campaigns, interventions, and educational programs (Manganello, 2008). With this increasing importance previous authors like to consider health literacy as the sixth vital sign along with other traditional vital signs mentioned as temperature, pulse, respirations, blood pressure, and pain and it should be assessed in the same way other vital signs are assessed (Heinrich, 2012).

Health Literacy and Economic Growth of a Nation

Key international declarations considered literacy as a right, both for children and adults. The Hamburg Declaration conceived literacy "as the basic knowledge and skills needed by all in a rapidly changing world, is a fundamental human right" (UNESCO, 1997). Everyone should have 'the same opportunities for access to programs of continuing education, including adult and functional literacy programs'. Literacy skills provide a number of benefits to individual e.g. informed decision-making, personal empowerment, participation in social activities etc.

Link Between General Literacy and Health

The impact of education or general literacy on population and public health, especially women's health, is a well-researched (Kickbusch, 2001) and it was demonstrated that literacy program also has a greater impact on health. Many studies reported the positive impact of education and literacy on population health, in particular women's' health and the health of children (Bledsoe, Casterline, Jonson-Kuhn, & Haaga, 1999; Sen, 1999; Nussbaum, 2000). Female literacy rate is considered to be one of the 10 key indicators to assess 'women's well-being' (Save the Children, 2000; Kabir, Rahman, Monte-Serrat, & Arafat, 2017). In a study in Nicaragua, lower infant mortality was recorded among mothers who had participated in an adult literacy campaign than those who had not (Sandiford et al., 1995). Other studies showed literacy and basic education programs (Burchfield et al., 2002a), and radio broadcasts and other health interventions (Burchfield et al., 2002b) improved health-related knowledge and health seeking behavior of the women.

Impact of Low Health Literacy on Health Development

Health literacy is increasingly becoming important area to support people to utilize the opportunities available in the healthcare to improve and manage their own health. The Center for Health Care Strategies Inc. (Center for Health Care Strategies, 2013) used a simple definition of health literacy: "the degree

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions." Health literacy helps people to "obtain, process, and understand basic health information and services needed to make appropriate health decisions" (U.S. Department of Health and Human Services, 2000). The relationship between literacy and health is complex and widely studied area. It represents a group of skills required for public and patients to understand and interpreted healthcare information and take necessary action in a health care environment when necessary. These skills include interpretation, print literacy, numeracy, and oral literacy (Agency for Health Care Research and Quality, 2011). So, health literacy is more than reading which also encompasses writing, numeracy, listening, speaking, and conceptual knowledge. Effective communication is critical to successful health care. Low health literacy is linked to poorer health status, higher morbidity, mortality, lack of medical care knowledge, more hospital visits and hospitalization, lack of knowledge about medical conditions, utilization of expensive services (e.g. emergency care and inpatient admissions), non-utilization of health promotion services, low self-reported health profile, poorer compliance rates with treatment modalities, and increased health care costs (Andrus & Roth, 2002; IOM, 2004; Agency for Health Care Research and Quality, 2011). Low health literacy can result in: medication errors; low rates of treatment compliance due to poor communication between providers and patients; reduced use of preventive services and unnecessary emergency room visits; ineffective management of chronic conditions, due to inadequate self-care skills; longer hospital stays and increased hospital re-admissions; poor responsiveness to public health emergencies; and higher mortality (Berkman, et al, 2004). Improving health literacy reduces health care costs and increases the quality of health care. It is now well-established that there is a relationship between educational attainment, literacy skills and economic growth (Coulombe, Tremblay, & Marchand, 2004).

Economic Implications of Health Illiteracy

Health care sectors in both developed and developing countries deal with limited resources. Healthcare activities, especially in developed countries, consume a large portion of economic resources. Healthcare spending has grown from 13.2% of GDP in 2000 to 17% in 2010. Low health literacy has a huge impact on a country and it is one of the important causes of economic inefficiency. The average annual health care costs of persons with very low literacy were found to be four times greater than for the general population (Weiss et al., 1994). It was found that adults with low health literacy experience 6% more hospital visits, 1.5 times more physician visit, 3 times more prescriptions and 2 day-longer hospital stays in comparison to those with proficient health literacy (The Ohio State University-Office of Outreach & Engagement, 2008). All these unintended activities as a result of low health literacy cost the U.S. economy up to $236 billion every year which represents between 7-17% of all personal health care expenditures (Vernon et al., 2007). As a whole, low functional literacy causes 3 to 6% greater health care expenditures (The Ohio State University-Office of Outreach & Engagement, 2008). This is a real blow for other sectors of the economy not only in the USA, the picture is the same for all developed and developing countries. This situation places health care system and the economy of a country at risk. The combination of low health literacy, demographic and epidemiological shifts, technological advances, and patients' high expectations places additional financial burden on the health care system and in a long run hinders economic growth of country.

Health literacy is also becoming increasingly important public health issue and found to contribute to social, economic and health development of a nation (Kickbusch, 2001). Health literacy enables

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

individuals to protect themselves, their family and their community from various disasters and able them to take control of their health. It is evident that people with higher levels of health literacy are more likely to adopt healthier behaviors and decrease the undue utilization of healthcare. Moreover, they are far more able to understand available health-related information and would be empowered to make healthier choices. Benefits can be achieved across the life course and inter-generationally and the saved resources can be utilized to support priority health issues or can be channeled to other sectors for positive economic growth (WHO, 2016).

Access to reliable health information and usable health services are fundamental for the economic growth of a nation (Adams & Corrigan, 2003). The promises of medical research, health technology and healthcare delivery can only be implemented when a national action plan has been designed. The action plan needs to have specific steps connected to this direction. No single action will be sufficient. Actions should include partnerships among all levels of educators, health care providers, public and private healthcare institutions and government; should be based on feasibility, effectiveness and suitability; should evaluate the short and long-term effects of the efforts; and should involve continued public education, law and other policies to support health literacy (U.S. Department of Health and Human Services, Office of Disease Prevention and Health Promotion, 2010).

MEASUREMENTS OF HEALTH LITERACY

There are many measures globally which can qualify and quantify the status of health literacy. The tools aim to detect physical health literacy are: Rapid Estimate of Adult Literacy in Medicine (*REALM*) (Safeer & Keenan, 2005), Test of functional literacy in Adult (*TOFHLA*) (Baker, 2006), Wide Range Achievement Test-Revised (*WRAT-R*) (Bass, Wilson, & Griffith, 2003), Medical Achievement Reading Test (*MART*) (Hanson-Divers, 1997), Slosson Oral Reading Test (*SORT-R*), Peabody Individual Achievement Test Revised (*PIAT-R*) (Ojio, 2015), Instrument for Diagnosis of Reading (*IDL*) (Vernon, Trujillo, Rosenbaum, & Pfizer, 2007), Newest Vital Sign (*NVS*) (Peerson & Saunders, 2009), European health literacy questionnaire (*HLS-EU-Q47*) (Duong et al., 2017), High Blood Pressure-Health Literacy Scale (*HBP-HLS*) (Zhang et al., 2016), Health Literacy on Social Determinants of Health Questionnaire (*HL-SDHQ*) (Matsumoto & Nakayama, 2017), The Health Literacy Questionnaire (*HLQ*) (Nolte et al., 2017), The Eastern-Middle Eastern Adult Health Literacy (*EMAHL13*) (Nair, Satish, Sreedharan, & Ibrahim, 2016) etc.

Many reading cognition tools to assess patient's knowledge about health care terminologies are available and among them *REALM* is one of the most widely used instrument that can measure functional health literacy within 2 to 3 minutes by nurse or other staff (Safeer & Keenan, 2005). *TOFHLA* measures reading literacy, consists of 50 items assessing prose reading and 17 items assessing capacity to read and understand actual hospital documents and labeled prescription vials (Baker, 2006). The *WRAT-R* is a 57-item test that requires 3 to 5 minutes to respond and can measure reading, spelling and arithmetic (Bass et al., 2003). *MART* is designed to resemble a prescription label with its use of small print size, glossy cover, and medical terminology. This design allows practitioners and researchers to assess patients' inability to read the test (Hanson-Divers, 1997). *PIAT-R* is an individually administered tool measure six domain like: General information, Reading recognition, Reading comprehension, Mathematics, Spelling and Written expression (Ojio, 2015). Instrument for Diagnosis of Reading (*IDL*) is a reading comprehension bilingual (English-Spanish) tool for all ages. Subjects given time to read text

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of their own and then examiner asks series of questions of various difficulties (Andrus & Roth, 2002). Health literacy survey questionnaire (*HLS-EU Q47*) consists of 47 items that assess the capability to deal with health information like: access or obtain, understand, appraise, judge or evaluate, and apply or use health information) in three domains: health care, disease prevention, and health promotion (Duong et al., 2017). High Blood Pressure-Health Literacy Scale (*HBP-HLS*) is the only available hypertension specific HL instrument consists of 43 items assess knowledge about hypertension and its management (Zhang et al., 2016). *HLSDHQ* consists of 33 items clarifies 10 social determinants of health (Matsumoto & Nakayama, 2017). Health Literacy Questionnaire (*HLQ*) composed of 44 items which can assess nine distinct domains of health literacy like: support of health care providers, having adequate information for managing health, active management of health, social support for health, appraisal of health information, active engagement with health care providers, navigating health care system, ability to find good health information and understanding health information well enough to know what to do (Nolte et al., 2017). Eastern-Middle Eastern Adult Health Literacy (*EMAHL 13*) is brief screening tool can assess patient's ability to distinguish health and non-health related items (Nair et al., 2016).

In addition, regarding mental health literacy, a recent systemic review by Kutcher et al found 16 different tools in 17 studies mentioning mental health literacy tool (Wei, McGrath, Hayden, & Kutcher, 2016). The tools that measures knowledge about schizophrenia are: Knowledge About Schizophrenia Questionnaire (*KASQ*), Knowledge Questionnaire on Homecare of Schizophrenia (*KQHS*) and Knowledge about Schizophrenia Test (*KAST*). To detect literacy about overall mental health and illness there are few tools and these are: Multiple-Choice Knowledge of Mental Illnesses Test (*MC-KOMIT*), Mental Health Knowledge Schedule (*MAKS*), Mental Health Literacy Scale (*MHLS*), Journey of Hope (*JOH*) Outcome Survey, Knowledge of Mental Disorders (*KMD*), Mental Health Disorder Recognition questionnaire (*MDRQ*), Mental Health Knowledge Questionnaire (*MHKQ*). Others tools to detect knowledge about depression, anxiety and ADHD are: Depression Multiple Choice Question (*DMCQ*), Depression Literacy (*D-Lit*), Knowledge about Depression and Mania Inventory (*KDMI*), Adolescent Depression Knowledge Questionnaire (*ADKQ*), Anxiety Literacy Questionnaire (*A-Lit*), Test of Knowledge About ADHD (*KADD*). (Wei, McGrath, Hayden, & Kutcher, 2016).

KASQ consists of 25 multiple choice questions, *KQHS* contains 32 item multiple choice questionnaire on four aspects and *KAST* is 21 multiple choice questions on knowledge of schizophrenia. and *MC-KOMIT* is 33 multiple-choice items on knowledge of common mental illnesses, *MAKS* is 6-point Likert scale on 12 items of stigma knowledge of mental illness. *DMCQ* is 27 multiple-choice items, D-Lit is 22 true/false items, *ADKQ* is a tool consists of 13 dichotomous and 2 fill-in-the- blank questions and *KDM* is consists of 44 true false questions. *MC-KOMIT, MAKS, MHLS* tool containing multiple choice on 35 items regarding knowledge and attitudes about help-seeking, and ability to recognize disorders, *JOH* is a 4-point Likert scale on 15 items on mental health, *KMD* is tool having "Yes, "No", and "I don't know" responses to assess knowledge on the name and characteristics of mental disorders and ability to distinguish them from somatic illnesses, *MDRQ* is a 7-point Likert scale on 20 statements of mental illness descriptions in which 15 are real and 5 are false, *MHKQ* is tool having "yes", and "no" responses to 20 general mental health knowledge questions. *KDD* is tool containing 22 error-choice items to assess knowledge and attitudes toward students with ADHD. Among the measuring tools having good internal consistency are *DMCQ, KDD, JOH, KMD* and *ADKQ*. The tools having good to excellent content validity are: *KQHS, KAST, MC KOMIT, MAKS, KDM,* and *MHLS*. *KAST* and *KDM* are the two tools having fair criteria validity (Wei, McGrath, Hayden, & Kutcher, 2016).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ROLE OF SCHOOL IN HEALTH LITERACY

In 1986, WHO declared the Ottawa Charter and applauded the health promotion concept as health promotion is more than the disease prevention (Arafat, 2017b). Schools can have a very important role in health promotion and development of the future of the nation as well as the globe. Health literacy is a concept that can be extensively embraced by schools (St Leger, 2001). Schools across the world can play an important role in facilitating the achievements of health literacy as a public health goal along with the other educational commitments (Nutbeam, 2000). Nutbeam (2000) proposed a three-level hierarchy in health literacy. This would include: a) basic/functional literacy, b) through communication/ interactive literacy and c) critical literacy. Critical literacy is generally defined as a set of skills that enable people to obtain, understand and use information to improve their health and is something that can be developed, thus; it should be an important goal of school education (Chinn, 2011). Although school may play an important role, in health literacy, it is important to be pointed that their core business is education, whilst the level of expertise in health issues is limited. Children are supposed to spend about 80% of their waking hours in school (Wang, Li, Siahpush, Chen, & Huberty, 2017) and they are also engaged in different school related tasks before and after school (Karczewski, Carter, & DeCator, 2016). Moreover, large numbers of adolescents work with childrenin schools to get them engaged (Demissie & Brener, 2017). In addition, schools are responsible for social and emotional knowledge along with the academic education (Weisman, Kia-Keating, Lippincott, Taylor, & Zheng, 2016). With the gradual physical and mental development adolescents are involved with their health care, interact with the health system and like to have access to health information (Manganello, 2008) as they pose both the responsibility and freedom. Addressing the health literacy positively at early age can have global improvement in aspects of interactions with the health system that ultimately drives to positive health outcome across life (Manganello, 2008). Schools can empower the youths by promoting health literacy (Hagell, Rigby, & Perrow, 2015). Schools can provide an excellent opportunity and critical facility in which many agencies can work together for the betterment of the youths as well as the economy. Schools play a facilitative role to bring the societal components together in which children act members of families, peers, schools, and communities (Valois & Hoyle, 2005). Like a silent epidemic, appropriate educational programs are necessary even before the assessment of health literacy in the clinical settings and schools can be most appropriate point to start (Heinrich, 2012). Moreover, adolescence is usually the starting point of different chronic diseases such as asthma, diabetes, cystic fibrosis and mental illness between the age ranging from 0–17 years (Manganello, 2008). Usually with the increase spread of internet, teenagers are more interested in seeking information regarding the management of their illness and health service providers consider the habit as an important one for the youths with chronic illness to have adequate health literacy skills to perceive the right meanings (Manganello, 2008). With physical, emotional, cognitive change, greater freedom and autonomy, improved reasoning and abstract thinking adolescence is to begin thinking about health literacy interventions (Gray, Klein, Noyce, Sesselberg, & Cantrill, 2005; Ghanbari, Ramezankhani, Montazeri, & Mehrabi, 2016; Manganello, 2008). Working on health literacy in adolescence would improve health literacy in later life and adolescents are used to carry their modified behavior across the life as they transition into adulthood (Manganello, 2008). IOM proposed to incorporate health-related tasks into lesson plans of schools and recommended that teaching the young people will be a good investment for future population health (Gray, Klein, Noyce, Sesselberg, & Cantrill, 2005; Manganello, 2008). Previous literature has shown that there is a strong relation between good health and educational achievement (World Bank, 1993; WHO, 1996). Therefore, a perception has

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

been developed by schools and educators that if health and social issues will be addressed in schools, the learning outcomes will also be maximized (Cameron and McBride, 1995). St Leger and Nutbeam (2000) suggested that the health promoting school contributes to four main school-related outcomes: (i) lifelong learning skills; (ii) competencies and behaviors; (iii) specific cognate knowledge and skills; and (iv) self-attributes. Of course, these four school-related health/education outcomes are closely related to the three-level hierarchy in health literacy proposed by Nutbeam (2000) provided that they have been achieved by the students.

The effectiveness of school health and its outcomes has been reported by several reports and meta-analyses (Peters and Paulussen, 1994). Overall, the role of school in health literacy should include the following characteristics (adopted by St Leger, 2001):

1. Focusing on cognitive and social outcomes in conjunction with behavior change within an educational framework;
2. Occurring over several years and be relevant to young people's social and cognitive development;
3. Be adequately resourced;
4. Provision of significant professional development for teachers;
5. Be holistic in addressing strategic combinations of the curriculum, the school's physical environment, the school's social environment, health services, partnerships with parents and the local community and school policies;
6. Be based on effective learning theories; and recognize the limitations and opportunities of schools in bringing about substantial health improvements.

INTERVENTIONS IN SCHOOL TO IMPROVE THE HEALTH LITERACY

General Interventions

Some authors suggested a focus on the formal educational systems across the years such as elementary schools, high schools, junior schools, colleges and universities (Freedman et al., 2009). The approach should focus to prepare the students to address the public health concerns in from multiple perspectives rather to build them as public health specialist (Freedman et al., 2009). Educational materials distribution to the youths by health providers, schools and intervention programs can effective but further attention is needed regarding the readability of materials should be evaluated and sometimes it might be difficult for the youths to guide their choices about health behavior if they fail to understand the provided materials (Manganello, 2008). However, previous research revealed that school newsletters are being underutilized as a source of health promotion and health literacy in the school community (Merga & Hu, 2016).

Judicious use of media for the adolescents is a crucial part of health literacy as media is an important source of information nowadays. Past research revealed that youths aged 8–18 spend almost 6.5 hours per day with some type of media and their physical, social, mental, moral development is influenced by media. Educational television has been found to be linked with advances in literacy. Moreover, media is linked to development of health behavior and health literacy. So, justified use of media is an important area to improve health literacy in schools (Manganello, 2008) and limited abilities of using media should also be considered (Ghanbari, Ramezankhani, Montazeri, & Mehrabi, 2016). Educational programs implemented in schools or conducted via the mass media, can teach adolescents about health issues though

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the success of the interventions is dependent on their target group having the ability to understand the provided messages (Manganello, 2008). Creating a health promoting school environment is not just the focusing on the youths but also focusing the entire work force and a holistic approach involving every part is the best way to combat (Hagell, Rigby, & Perrow, 2015).

In this 21st century internet plays an important role in health, literacy, health literacy as well as internet has also a threatening role in regard to the novelty & validity of the available information (Ghanbari, Ramezankhani, Montazeri, & Mehrabi, 2016). Recent studies revealed respondents aged 15–24 years surfed internet for their expected information and they surfed several regular topics such sexual health, mental health, weight change, cancer, diabetes (Gray, Klein, Noyce, Sesselberg, & Cantrill, 2005). Limited internet facility, limited search abilities, low literacy skills affect the outcome and make difficult for adolescents to find, perceive the quality information. If there is nothing in the school health curriculum the adolescents would not achieve adequate health literacy (Ghanbari, Ramezankhani, Montazeri, & Mehrabi, 2016).

Specific Interventions

There are various school based interventions related to health literacy including physical and mental health. Specifically addressed areas are regarding: Obesity, Oral health, HIV, Fruit and vegetables intake, Nutrition, Bully behavior, Food literacy, Hand washing, Physical exercise, Adolescent dating violence, School based health centers (*SBHC*), Evidence based curriculum, Health Promotion School (*HPS*), School based health education, Physical education, Mental health teachers curriculum etc.

Interventions for Physical Health

High prevalence of childhood obesity predisposes children to various morbidities like insulin resistance, hypertension, dyslipidemia and liver disorders and risk of developing type 2 diabetes and cardiovascular diseases (Levy, Saenger, Steffes, & Delvin, 2017). In a study, school based health promotion program through scheduled extra school-day physical activities result increased habit of doing more aerobic activity among school children. "*KidMinutes*" is an easy measure that evaluates school activity program (Cluss et al., 2016). However, School-based intervention including counseling is not effective in reducing BMI or key obesogenic behaviors (Pbert et al., 2016). School based obesity prevention program is an effective approach to influence BMI among students (Karczewski, Carter, & DeCator, 2016). Academic lessons regarding physical activity has positive effect on BMI (de Greeff et al., 2016). The HealthCorps program is an effective health literacy program which significantly increases students' knowledge and behavior on issues like: nutrition, physical activity and mental health (Moonseong et al., 2016). It is evident that schools having Physical Exercise Lesson (*PEL*) program result more Physical Activity (PA) in both boys and girls (Frömel, Svozil, Chmelík, Jakubec, & Groffik, 2016). A Physical Activity program focusing school teachers is effective to increase PA and also improves early literacy (Kirk & Kirk, 2016). Go Wild with Fruits and Veggies (*GWWFV*) and fruit and vegetables snack program (FFVSP) is another curriculum based school program that increases the fruit and vegetables intake among students. Building a Healthy Me (*BHM*) is an effective nutrition intervention for classroom and family (Larsen et al., 2017). Team Nutriathlon is another school based program that can raise vegetables, fruits and dairy product consumption (Loosier et al., 2016; Drapeau, V. Savard, BA. Gallant, A. Nadeau, L. Gagnon, 2016). Brighter Bites is a school based intervention that includes three components like: fresh produce

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

deliveries, recipe demonstration and nutrition education. The intervention helps to learn some crucial lessons like: importance of leveraging existing infrastructure of food banks and engagement of parent, school and staff (Sharma et al., 2017). There is a discrepancy in the knowledge and comprehension about oral health differs from dental professional to students. In a study researcher used mouth drawing as tool of measuring health literacy among students prior and after health education. The study finds that 72.8% students answered better after the health education then they answered about the health education queries prior education (Ueno et al., 2014). Over the last 10 years, the Health Promoting School (*HPS*) concept developed and provided positive outcomes. HIV risk is not proportionate among sexual and gender minority (SGM) youth. School can play a valuable role for educating young students regarding primary prevention measures regarding such issue (Rose & Friedman, 2017).

Interventions for Mental Health

There are many specific interventions or programs focusing mainly on student's mental health. The Guide mental health literacy curriculum for school students is an effective way in raising mental health literacy. An MHL resource from Canada (*The Guide*) is the curriculum contains basic understanding of mental health, mental disorders and treatment in brief, about stigma, about help seeking behavior (Mcluckie, Kutcher, Wei, & Weaver, 2014). Teen Mental Health First Aid (*teen MHFA*) is training program for students effective to raise mental health literacy (Hart, Mason, Kelly, Cvetkovski, & Jorm, 2016). "Mental health education program", "Mental health for everyone" are the similar approaches to raise mental health literacy among students (Ojio, 2015; Mcluckie, Kutcher, Wei, & Weaver, 2014). To assess the status of knowledge and attitude about mental health and improving that issue can be solved by Focus Group Discussion (*FGD*) (Okello, Abbo, Muhwezi, Akello, & Ovuga, 2014). Other than these intervention, school based interventions were tried previously in different ways. Among them intervention for bully prevention reduces bully behavior among students (Educational Intervention Using the Integrated Model for Behavior Change, 2016), community based dating violence prevention program reduces dating violence behavior in adolescent school students (Joppa, Rizzo, Nieves, & Brown, 2016). In a review, it was found that sexual abuse among children age group occurs frequently in family setting and abuse victims are often bullied and isolated in school. In order to prevent serious mental health problems, teachers and school counsellors play an important role in identifying and offering help (Sawyerr & Bagley, 2017). A good portion of adult mental health and substance use (MH& SU) disorders starts in adolescent age. In another review it was found that, along with other intervention school can take part a significant role in prevention program (Dunne et al., 2016). Continuing innovation, adaptation and evaluation of programs is now required, especially in low-income countries, to integrate mental health promotion in the public health agenda of countries worldwide (Herrman & Jané-llopis, n.d.). Suicide is the second leading cause of death for adolescents. Whereas school-based prevention programs are effective, obtaining active consent for youth participation in public health programming concerning sensitive topics is challenging. The current authors explored several active consent procedures for improving participation rates. Although passive consent produces the highest student participation, these methods are not always appropriate for programs addressing sensitive topics in schools. In-person active consent procedures may be the best option when prioritizing balance between parental awareness and successful student recruitment ("Procedures for School Programming: Addressing the Sensitive Topic of Suicide," 2017). Differences in the use of school-based behavioral health services (autism, attention deficit hyperactivity disorder [ADHD], conduct/oppositional defiant disorder, and ''other'') by racial and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ethnic groups suggest the need for culturally appropriate outreach and tailoring of services to improve service utilization (Locke et al., 2017). Findings suggest that school engagement is a potentially modifiable target for interventions aiming to ameliorate the negative influence of mental health problems on school functioning for adolescent girls with histories of abuse or neglect (Threlfall, Auslander, Gerke, Mcginnis, & Myers, 2017).This study tested the influence of a training intervention to improve teachers' ability to accurately identify preschool children's emotional and behavioral problems in 24 schools in Addis Ababa, Ethiopia. Sensitivity and specificity of teacher identification, and overall agreement with an established measurement criterion (*Strengths and Difficulties Questionnaire*) were examined 2 years following training compared to pre- intervention baseline, and a non-intervention control group of 12 schools. Results indicate that the teacher training was significantly associated with more accurate identification of children's problem (Desta et al., 2017). Depression and anxiety often emerge for the first time during youth. The school environment provides an ideal context to deliver prevention programs, with potential to offset the trajectory towards disorder. These results suggest that the refinement of school-based prevention programs have the potential to reduce mental health burden and advance public health outcomes (Newby & Christensen, 2016).

CONTROVERSIES IN HEALTH LITERACY

In recent years, the volume of research on health literacy has grown. However, the definition of health literacy is yet to be universal. Moreover, few authors compare the concept as a repackaged form of health promotion (Sørensen et al., 2012; Nutbeam, 2000; Tones, 2002; Chinn, 2011). Some authors, clinicians and scholars like to consider health literacy as an individual responsibility and consider that itis the personal fault of the patient to have low health literacy (Koh et al., 2012; Serper et al., 2014). On the other hand, others consider health literacy as a dynamic & complex issue this reflects the available health information and service availability (Koh et al., 2012). IOM recommended it as a shared function of the society and the individual (Sørensen et al., 2012). IOM explains the source of relationship is the interaction of individual's skills and the sociomiety system demands. Health literacy is generated in the society as a whole but it can also be originated in an individual context based on different programs such as educational learning in the family setting, health promotion in the school, patient education programs, different patient self-management programs (Eichler, Wieser, & Brügger, 2009). WHO, IOM as well as different other professional societies mentioned repeatedly that poor health literacy is the result of low education, poor opportunity and limited healthcare access (Bailey et al., 2015). In addition, as mentioned in previous chapters, although schools may play an important role, in health literacy, it is important to be pointed that their expertise includes general education, whilst the level of expertise in health issues is limited (Chinn, 2011). Literature shows that educational programs particularly in schools, can promote the increase of the literacy levels of health care through a health curriculum however; at the moment there is no agreement on what a healthcare school curriculum design should include, probably because of the long-term nature of these educational programs (Parker and Kreps, 2004). Another limitation of school but also of other health literacy educational programs is that they focus solely on reading, writing, speaking, and listening skills and not on the larger set of communication strategies that consumers need to get the most out of the modern health care system (Cegala, 2003; Jones, Kreps & Cresskill, 1995).

RECOMMENDATIONS

Educators, school administrators and policy makers need to be well informed about the strengths and limitations of the current database on the effectiveness of currently available health literacy programs in schools (Schachter et al., 2008). Effectiveness of school-based health literacy programs will help establish strong foundation for addressing health promotion, prevention and intervention among adolescents in school establishments. Provider (teacher) health literacy is as important as student health literacy and taking full advantage of provider-student relationship in child and adolescent health promotion helps the preparation of the teacher (Peterson et al, 2001) and to achieve them teachers needed to adopt, learn and practice about new concepts such as critical health literacy and successive changes required in school structure to achieve beneficial outcomes which heavily depends on funding (St. Leger, 2001).

However, applications of interventions not know to be effective could be a waste of the limited public funds (Wei et al., 2013). According to AMA four areas should be further explored for research such as screening of the health literacy, communication improvement focusing the low literacy patients, expenses and outcome of inadequate health literacy, and causal relationship of low health literacy and health (Sørensen et al., 2012). Authors recommended that schools can act as a vehicle for promoting health literacy as well as overall health though there is limited evidence to support any specific level of school such as primary or secondary (Hagell, Rigby, & Perrow, 2015). Health promoting school concept is recommended to be embraced to initiate and sustain the positive changes (Valois & Hoyle, 2005). As schools influence directly both the education and development of the youths, IOM highlighted the need for playing important role in improving the health literacy (Manganello, 2008). WHO recommends few things after reassessment of the effectiveness of Health Promoting Schools such as curriculum modification with inputting the issues, changing the school ethos and further engagement of the families and communities (Hagell, Rigby, & Perrow, 2015).Parents play an important role in the lives of students and teachers should engage parents during the process delivery of health education which is a great part of family life (Begoray et al, 2009).

CONCLUSION

Health literacy is a global concern of this century. Although healthcare is moving towards the patient-centered approach poor health literacy is still a silent epidemic that affects health outcomes holistically. School is a potential area to improve the health literacy nationally and globally. Different measures are available to assess literacy. As schools influence directly both the education and development of the youths, IOM highlighted the need for playing important role in improving the health literacy. After reassessment of the effectiveness of Health Promoting Schools, the WHO recommends curriculum modification with inputting the issues, changing the school ethos and further engagement of the families and communities. Multiple interventions are implemented across the globe. Educational programs particularly in schools, can promote the increase of the literacy levels of healthcare through a health curriculum however; at the moment there is no agreement on what a healthcare school curriculum design should include, probably because of the long-term nature of these educational programs. Moreover, health literacy educational programs focus solely on reading, writing, speaking, and listening skills and not on the larger set of communication strategies that consumers need to get the most out of the modern healthcare system.

Multisectoral collaboration such as health, education, finance, media, communication; and locally proved effective strategies should be considered as a priority.

Chapter 54
Understanding and Addressing the Stigma in Mental Health Within the Asian and Asian-American Culture

Ben Tran
Alliant International University, USA

ABSTRACT

Mental health stigma can be defined as the display of negative attitudes, based on prejudice and misinformation, in response to a marker of illness. Stigma creates mental distress for individuals, which furthers stigmatizing attitudes, thereby making it a relentless force and as incompetent in achieving life goals such as living independently or having a good job. Over the years, researchers have consistently highlighted the problem of mental health service underutilization within the Asians and Asian-Americans communities. As such, understanding the cultural contexts that facilitate good outcomes may offer a lever or stigma reduction. Thus, the purpose of this chapter is to understand and address the sociocultural and psychological paradigms of the stigma in mental health within Asians and Asian-Americans. This chapter will cover the history of stigma within the Asian culture, Asian's mental health, mental health services utilization within the Asian culture, and methods of addressing the stigma within the Asian culture to promote the utilization of mental health services.

INTRODUCTION

Mental health stigma can be defined as the display of negative attitudes, based on prejudice and misinformation, in response to a marker of illness (Sartorius, 2007). Link and Phelan (2001) describe four characteristics that distinguishes mental health stigma from other social phenomena: (1) it is fundamentally a label of an out-group; (2) the labelled differences are negative; (3) the differences separate the 'normal' from the out-group, and (4) label and separation leads to discrimination. Stigma creates mental distress for individuals, which furthers stigmatize attitudes, thereby making it a relentless force (See-

man, Tang, Brown, & Ing, 2016). Nevertheless, it is widely acknowledged that psychiatric diagnoses are stigmatized, and associated with negative public attitudes (Angermeyer & Matschinger, 2003). Hence, social cognitive models pin point stigma as a relationship between stigma signals (cues), stereotypes (attitudes), and behaviors (discrimination) (Corrigan, 2000), stemming from socialization (Abdullah & Brown, 2011). People with mental illness are perceived as dangerous and unpredictable, incompetent at achieving life goals such as living independently or having a good job (Angermeyer & Dietrich, 2006), and often blamed for their own illlnesses. Prejudice arises when people endorse such stereotypes and discrimination is the behavioral result of prejudice (Corrigan, Druss, & Perlick, 2014; Jenks, 2011).

On a macrosocial level, institutional policies endorse mental health stigma by restricting opportunities for people with mental illness (Corrigan, Markowitz, & Watson, 2004). According to the Global Burden of Disease Study (Murry & Lopez, 1996), stigma lies in the world-wide impact of mental illness on overall health and productivity. Profoundly under-recognized, mental illness constitutes 11% of the global burden of disease, with major depression alone currently ranking fourth and expected to rise to second by 2020. In some regions of the world, mental disorders already represent the largest contributor to the total disease burden, and there is great concern with the *morality crisis* related to mental illness in Eastern Europe (Rutz, 2001). In the face of these concerns, the World Health Organization's (WHO) International Pilot Study of Schizophrenia (IPSoS), the International Study of Schizophrenia (ISoS), and the Study of the Determinants of Outcomes of Severe Mental Disorders (DOSMD), have all documented enormous heterogeneity in the outcomes of mental illness within and across countries (Hopper & Wanderling, 2000; Kulhara & Chakrabarti, 2001; Sartorius, Gulbinat, Harrison, Laska, & Siegel, 1996; Sartorius, Jabensky, & Shapiro, 1978). While it is generally agreed that the reasons for these differences are "far from clear" (Kulhara & Chakrabarti, 2001), one predominant explanation revolves around culturally defined processes.

Scholars and policymakers suggest that stigma may be the reason behind such findings and lies at the root of recovery from mental illness (Remschmidt, Nurcombe, Belfer, Sartorius, & Okasha, 2007). As such, understanding the cultural contexts that facilitate positive outcomes may offer stigma reduction. In particular, whether individuals and others around them recognize mental illness, stigmatize these conditions and support seeking care is critical, since each represent key aspects of culture that can influence the outcome of mental illness (Pescosolido, 1991; 2006). The purpose of this chapter is to understand and address the sociocultural and psychological paradigms of stigma in mental health within Asian culture. For the purpose of this chapter, within the focus of Asians, emphasis will be on Chinese and Chinese Americans. This chapter will cover the history of stigma within the Asian culture, Asian's mental health, mental health services utilization within the Asian culture, and methods of addressing the stigma within the Asian culture to promote the utilization of mental health services.

ASIANS: THE CHINESE

Based on U.S. Census information from 2011, according to Ali (2014), it is estimated that 18.2 million persons of Asian descent living in the United States, and that Asians comprise approximately 5.8% of the total population (Pew Research, 2012; United States Census, 2013a) and growing. Of the 50 states in the United States, California and New York have the largest numbers of Asians in 2010 (United States Census, 2013a). Asians were the fastest growing racial group with the largest proportional population increase between the 2000 and 2010 census, even compared to Hispanic and Latinos, which was one of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the largest increase in population (United States Census, 2013a; United States Census, 2013b). Among Asians of Chinese descent, followed by Filipino Americans, Indian Americans, Vietnamese Americans, Korean Americans, and then by Japanese Americans (United States Census, 2013a). Not surprisingly, after English and Spanish, Chinese is the third most widely spoken language in homes in the United States. While Asians are making tremendous strides in acculturation since the first Chinese and Japanese immigrants came to the United States in the mid 1800's, Asians are still largely a population made up of immigrants, with 74% of Asian adults having been in another country (Pew Research, 2012).

Among Asians, 28% live in a multigenerational family, defined by having at least two adult generations in the same household, which is higher than Whites, Blacks, and Hispanic Americans (Pew Research, 2012). On the whole, Asians have a relatively high educational status, with approximately 85% of adults over age 25 having attained a high school diploma, 49% of Asian adults over age 25 are college graduates, compared to 28% of the general population. However, there is a disparity in the percentage of college graduates in different Asians ethnic groups. For example, according to Ali (2014), only 26% of Vietnamese Americans over age 25 are college graduates, which is lower than the general population. Approximately half of Korean, Chinese, Japanese, and Filipino Americans over age 25 are college graduates. Indian Americans have a much higher percentage of college graduates over age 25 (70%). These interethnic differences may reflect different immigration patterns from the countries of origin. While the median income of an Asian household is $66,000, and higher than the national median, 12.5% of Asians lived in poverty in 2009 and 17.2% were without health insurance (United States Census, 2013a). Additionally, Asians households are often larger than those of other ethnic groups. While these facts and figures do not reflect the diversity of the Asians population, they help to provide a broad characterization of the group (Ali, 2014).

Brief Immigration History: The Chinese

The first Asian category of immigrant to the United States arrived from Japan in 1843 and were soon followed by Chinese men who came in 1850s and 1860s to work on the trans-continental railroad, gold mines, and in agriculture (Takaki, 1998, pp. 80-98; United States Census, 2013a). The Chinese Exclusion Act of 1882, which put an end to all immigration from China, was a reflection of the opposition to Asians immigrating to the United States and becoming permanent residents. The Asian Exclusion Act of 1924 was a continued response to concern about Asian immigration, which limited the new immigrants per year from East Asia, Southeast Asia, and South Asia (Pew Research, 2012). Asian immigrants were thought to be unable to assimilate into the U.S. population due to phenotypic differences in appearance, unlike European immigrants. A Supreme Court case in 1923 of U.S. vs. Bhagat Singh Third denied an Indian immigrant the ability to apply for citizenship citing this concern in the official decision (Takaki, 1998, pp. 80-98). The doubt about the allegiance of those of Asian origin to the United States lasted well into the middle of the twentieth century. During World War II, over 80,000 U.S.-born citizens of Japanese origins were held in concentration camps by the government (Takaki, 1998, pp. 80-98).

Immigration from Asia radically changed over the course of the twentieth century with different ethnic subgroups greatly increasing as a response to the loosening of governmental restrictions and quotas. For example, according to Ali (2014), in the middle of the 20th century, naturalization and immigration of the war brides of U.S. soldiers from Japan, Korea, and Vietnam became permissible (Cottrell, 1990; Lopez & Yamazato, 2003; Takaki, 1998, pp. 80-98). In 1965, the Immigration and Nationality Act ended quotas with regard to Asian immigrants from Asia. This act also changed the ethnic landscape of Asian

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

immigrants, who until that time had largely been from Japan, China, and the Philippines. In the 1970s, there was an influx of refugees from war-torn Laos and Cambodia (Tseng & Strelzer, 2001). Currently, Asian immigrants are most likely to come to the United States with work visas, but also come through student visas, temporary visas, and unauthorized status (Pew Research, 2012).

Moving forward, as a result of the varied historical waves of immigration, there is tremendous diversity among the immigration and acculturation experiences among Asians. The term Asian captures the breadth of experience of an elderly Japanese American man whose family has been in the United States for many generations and the 18-year-old female refugee from Myanmar who recently arrived to the United States. Despite their age gap, the Japanese American man whose grandparents immigrated in one of the early waves of immigration will likely be more acculturated than the 18-year-old who arrives to resettle in a very foreign culture. As the chapter's focus turns toward mental health in Asians, specifically the Chinese, it will be important to continue to consider each patient or family's immigration history as it informs aspects of who they are and what issues may arise when they present themselves to mental health professionals.

Brief History of the Prevalence of Mental Health Disorders in Asians and the Utilization of Mental Health Services

According to Ali (2014), the Surgeon General's Report on Mental Health in 2001, now well over 15 years old, there was little adequate data about the prevalence of mental health disorders in Asians. One of the larger studies mentioned in this report, the CAPES study, demonstrated that Chinese Americans in the Los Angeles area had a moderate rate of depression, with 7% of the studied participants endorsing having experienced depression in their lifetime and 3% in the prior year (U.S. Center for Mental Health Services, 2001; U.S. National Institute of Mental Health, 2001; U.S. Office of the Surgeon General, 2001; United States Substance Abuse and Mental Health Services Administration, 2001). Studies in the 1980s and early 1990s that assessed symptoms of depression rather than the diagnosis of depression in the Asian population found higher rates of depressive symptoms in Japanese American, Korean Americans, Filipino Americans, and Chinese Americans in various major cities in the United States (U.S. Center for Mental Health Services, 2001; U.S. National Institute of Mental Health, 2001; U.S. Office of the Surgeon General, 2001; United States Substance Abuse and Mental Health Services Administration, 2001). One of the concerns underscored in the Surgeon General's report is the lack of adequate data about DSM diagnoses in the Asian population and the report questioned whether or not Asians truly have lower rates of psychiatric disorders compared to other populations. Due to the potential cultural bias in the reporting of and asking about symptoms, it was unclear whether or not accurate data about mental health conditions in Asians were captured by numerous studies. Culturally informed ways of expressing symptoms, prevalence of somatization, and culture-bound syndromes were all raised as possible confounding factors. The report clearly states that there were inadequate data about the prevalence of disorders in Asians who did not report mental health concerns and did not see mental health professionals. Rather than demonstrating that Asians were a resilient model minority group (Tran, 2016, 2017), the report showed that the scope of mental health problems of Asians were not adequately detected. Without perceiving a realistic mental health need, treatment could not occur, except for high-acuity populations, like Southeast Asian refugees with post-traumatic stress disorder, whose need was more evident (U.S. Center for Mental Health Services, 2001; U.S. National Institute

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of Mental Health, 2001; U.S. Office of the Surgeon General, 2001; United States Substance Abuse and Mental Health Services Administration, 2001).

Moving forward, large-scale studies have yielded more useful data about the prevalence of mental health diagnoses in Asian Americans and utilization of mental health services. However, diagnosis-specific studies have focused only on ethnic subgroups of Asians and there is no reliable data on the prevalence of psychiatric diagnoses in Asians as a whole. One of the large-scale studies is the National Latino and Asian American Study (NLAA) that reflects the prevalence of psychiatric diagnoses to be 0.8%. This study was designed to assess the 12-month prevalence of mental health disorders from 2002 to 2003 among Asians and Latinos, to assess the psychosocial context of the emergence of the disorders, and to determine how often mental health services were sought, in comparison with White, Hispanic, and Black populations (Alegría, Takeuchi, Canino, Duan, Shrout, Meng, Vega, Zane, Vila, Woo, Vera, Guarnaccia, Aguilar-Gaxiola, Sue, Escobar, Lin, & Gong, 2004). In one analysis by Dr. Jennifer Abe-Kim of the NLAAS data, 8.6% of the population surveyed sought mental health treatment compared to 17.9% of the general population when assessed in other large-scale studies (Abe-Kim, Takeuchi, Hong, Zane, Sue, Spencer, Appel, Nicdao, & Alegría, 2007). In the general population, 41.1% of persons with a probable DSM-IV diagnosis sought psychiatric treatment compared to 34.1% of Asians. Additionally, the propensity to use mental health services was inversely correlated to generation of immigration, such that second generation immigrants were more likely to use mental health services than immigrants, and third generation immigrants were more likely to use mental health services than second generation immigrants at a rate more similar to the general population (Abe-Kim et al., 2007).

In the NLAAS study, the prevalence of lifetime suicidal ideation in Asian populations were found to be 8.8% and the prevalence of suicide attempts were found to be 2.5%. Factors that were positively correlated with suicidal ideation and attempts include being female, conflict with family, a history of depression or anxiety, and perception of discrimination. Stronger identification and sense of belonging with one's ethnic group was negatively correlated with suicidal ideation and attempts (Cheng, Fancher, Ratanasen, Conner, Duberstein, Sue, & Takeuchi, 2010). The 2010 National Drug Use Survey on Health by the Substance Abuse and Mental Health Services Administration (SAMHSA), a large-scale survey on mental health and alcohol, tobacco and drug use patterns among over 60,000 responders over 12 years old, showered that the rate of illicit drug use was 3.5% in the month prior, lower than Whites, Native Americans, Blacks, or Hispanics. Among the 38.4% of Asian Americans who endorsed alcohol use in the month prior, 8.8% were binge drinkers and 2.4% were heavy drinkers of alcohol (The 2010 National Drug Use and Survey on Health, 2012). Rates of substance abuse or dependence were lower among Asians at 4.1% compared to other ethnic groups, which is consistent with what others studies have found (The 2010 National Drug Use and Survey on Health, 2012).

Smaller scale studies in specific ethnic populations of Asians have identified prevalence rates in these subgroups, but conclusions from these studies do not necessarily generalize to the heterogeneous group of Asians. For example, according to Ali (2014), Yeung, Chan, Mischoulon, Sonawalla, Wong, Nierenberg, and Fava (2004) found the prevalence of major depressive disorder among Chinese Americans in a primary care setting in Boston to be 19.6%, much higher than the estimate from the CAPES study in Los Angeles described earlier (Yeung et al., 2004). Another study from 2000 found that the prevalence of panic disorder in Cambodian refugees being treated at a psychiatric clinic disorders in Asians based on data from NLAAS study and found overall low prevalence of eating disorders in Asians, less than 1% for anorexia and bulimia. Women had a higher lifetime prevalence of binge eating disorder than men, 2.67% compared to 1.35% (Nicadao, Hong, & Takeuchi, 2007). The author believes that it is difficult

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to draw conclusions about a particular individual based on these heterogeneous data. One interpretation of these data is that mental health professional should expect that refugees from Asia will likely exhibit symptoms of anxiety disorders. However, with less high-acuity populations, the mental health professional should be more vigilant for mental health symptoms, which may be underrepresented or may manifest in different ways.

The Surgeon General's Report in 2001, according to Ali (2014), in addition to emphasizing the need for better epidemiological data on mental health conditions, also highlighted the low utilization of mental health services by Asians compared to other minority groups, which has continued to be true when compared to Whites, Blacks, and Hispanics (Sue, Yan-Cheng, Saad, & Chu, 2012; U.S. Center for Mental Health Services, 2001; U.S. National Institute of Mental Health, 2001; U.S. Office of the Surgeon General, 2001; United States Substance Abuse and Mental Health Services Administration, 2001). Since that time, many studies have examined this question with differing results, because barriers for the individual Asian patient may include any of the following: cultural bias in how the patient describes his symptoms, bias in how the clinician or researcher assesses the symptoms, decreased perception of need for treatment, stigma, foreign-born status, wishing to save face, initial use of family support and traditional healing methods, focus on somatic symptoms, length of time in the United States, lack of culturally appropriate services, lack of language appropriate services, and lack of health insurance (Abe-Kim et al., 2007; Lu, 2010; Sue, et al., 2012; U.S. Center for Mental Health Services, 2001; U.S. National Institute of Mental Health, 2001; U.S. Office of the Surgeon General, 2001; United States Substance Abuse and Mental Health Services Administration, 2001). According to Ali (2014), for every 100,000 Asian and Pacific Islanders, there are 70 Asian and Pacific Islander mental health care providers, which is less than half of the number of providers for Whites. Also, Asians may have difficulty accessing the U.S. health care system in general, as suggested by the fact that Asians who are Medicaid eligible are much less likely to have Medicaid than their White counterpart (Lu, 2010). While it is not possible to review all of the nuances of the methodological difficulties in assessing the prevalence of mental health disorders in Asians and the disparity in their treatment, excellent reviews are provided elsewhere (Lu, 2010; Sue et al., 2012).

There have been calls for systematic, comparable studies of stigma within and across social and cultural contexts in order to understand its origins, meanings and consequences (Aggarwal, Cedeño, Guarnaccia, Kleinman, & Lewis-Fernández, 2016; Caracci & Mezzich, 2001; Hopper & Wanderling, 2000; Ng, 1997; Rutz, 2001; Slu, 1989). Despite these calls and findings that document the pervasive existence and impact of stigma in different countries (Crisp, Gelder, Rix, Meltzer, & Rowlands, 2000; Fabrega, 1991; Pescosolido, Martin, Link, Kikuzawa, Burgos, & Swindle, 2000; Stuart & Arboleda-Flórez, 2001; Wahl, 1999), relatively little about the cross-cultural distribution of stigma. Researchers across the global have collected data on stigma, but differences in samples and instrumentation make it difficult, if not impossible, to compare findings. Thus, questions about whether and how the social reaction to mental illness varies across countries, whether the underlying operative processes are similar, and whether it maps onto the distribution of outcome heterogeneity remain unanswered. Thus, the important question of whether these differences can offer a wedge into decreasing stigma's negative impacts, also remains unanswered. In sum, while the influence of cultural context on health and well-being is widely acknowledged, the empirical literature on the cross cultural nature of stigma remains underdeveloped (Aggarwal et al., 2016; National Research Council and Institute of Medicine, 2000). The World Psychiatric Association's (WPA) Global Programme Against Stigma and Discrimination because of Schizophrenia (Sartorius, 1997) has encouraged the developed the development of a comparative catalogue of informa-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion and, to date there have been only a few large-scale studies. Even recent cross-national effort, while springing from and being influenced by the WPA initiative, have not been linked in practice, making inference about comparative influence difficult. Moreover, according to Pescosolido, Olafsdottir, Martin, and Long (2008), there has never been a methodologically coordinated attempt to understand the extent to which mental illness is understood and stigmatized across countries (Townsend, 1975).

Mental Health Disorders and Stigma: Asians

The concepts of stigma and shame play an important role in Asians' low services use (Chu & Sue, 2011). According to Chu and Sue (2011), *Haji* among Japanese, *Hiya* among Filipinos, *Mianzi* among Chinese, and *Chaemyun* among Koreans are terms that reveal concerns over the process of shame or the *loss of face* (Sue, 1994). Many Asians tend to avoid the juvenile justice or legal system, mental health agencies, health services, and welfare agencies, because the utilization of services for certain problems is a tacit admission of the existence of these problems and may result in public knowledge of these familial difficulties. Older adult Korean Americans, for example, report greater misconceptions and stigmatizations about mental health as a weakness that would bring shame to a family if one were to reveal their mental illness by seeking treatment (Jan, Chiriboga, & Okazaki, 2009). Other studies have confirmed that greater personal stigma and lower stigma tolerance predicts a lower likelihood to seek help among Asian students, and that stigma about mental illness is higher among Asians (Eisenberg, Downs, Golberstein, & Zivin, 2009; Ting & Hwang, 2009).

System-level and care process factors also contribute to the considerable problem of mental health care disparities in Asians. Higher rates of poverty and rates of being uninsured or underinsured, particularly among Southeast Asians like the Cambodians, Hmong, or Laotians, can prevent access to needed mental health services (Reeves & Bennett, 2204). Compounding this problem of financial resources is the dearth of available language-appropriate and culturally-appropriate services for many Asian individuals. Beyond the need to increase the availability of Asian-language clinicians, research has pointed to the need for culturally-competent providers who are able to understand and deliver mental health treatments with similar worldviews and cognitive styles to that of Asian clients (Aggarwal et al., 2016; Zane, Sue, Chang, Huang, Huang, Lowe, Srinivasan, Chun, Kurasaki, & Lee, 2005). Asians who make the difficult decision to initiate contact with mental health providers may be more likely to stay in treatment if they encounter these culturally-congruent aspects of the care process (Aggarwal et al., 2016; Ivey, Ivey, & Simek-Morgan, 1997; Sue & Sue, 1999).

ASIANS: MENTAL HEALTH

Asians in the United States are comprised of many subgroups including Cambodians, Chinese, Japanese, Filipinos, Koreans, Laotians, Asian Indians, Vietnamese, etc. who speak over thirty languages. Asian comprise 58% of the U.S. population but 60% of the world's population (Chu & Sue, 2011). Despite the fact that Asian groups are heterogeneous, researchers have often studied the subpopulations as an aggregate group because Asians often show similar cultural values that are in contrast to Westerners (Chu & Sue, 2011). Despite the high prevalence of mental health-related problems, mental health is commonly overlooked in Asian communities, and cultural barriers have been identified as the most imperative

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

factor (Aggarwal et al., 2016; Lee, Juon, Martinez, Hsu, Robinson, Bawa, & Ma, 2009). Nguyen and Anderson (2005) stated that some Asians hold the belief that individuals who have mental illness may be possessed by supernatural entities such as demons or spirits. Therefore, mental illness is highly stigmatized in many Asian cultures, and the root of mental illness stigma can be found in Asians' cultural beliefs toward mental health (Kung, 2004; Lee et al., 2009; Masuda, Anderson, Twohig, Feinstein, Chou, Wendell, Stormo, 2009; Nguyen & Anderson, 2005). Indeed, among Asian immigrants, extra-familial intervention is often considered shameful, as it indicates the inadequacy of family members and causes them to *lose face* within their community (Chu & Sue, 2011).

Consequently, instead of seeking professional help, Asians may try to change this behavior through self-control and willpower or may try to keep out bad thoughts by keeping busy (Zhang, Snowden, & Sue, 1998). When these attempts fail, they may choose to address problems and needs first, within the family system (Hsu, Davies, & Hansen, 2004). External help is sought only after all other resources are exhausted or when legal or social services force the issue. Even when seeking mental health services, many Asians might first seek medical services or traditional resources such as herbalists, acupuncturists, fortunetellers, or religious/spiritual leaders for help, which are less stigmatized sources of help (Nguyen & Anderson, 2005). Depending on the severity of their illness, they may then seek a mental health professional (Kung, 2004). If the Asian culture and stigma play a significant role in help-seeking behaviors, given the interconnected nature of culture, stigma, and the acculturation process among ethnic minorities (Hsu, Davies, & Hansen, 2004), it follows that acculturation might predict help-seeking behaviors.

MENTAL HEALTH SERVICES UTILIZATION WITHIN THE ASIAN CULTURE: ACCULTURATION, PREFERENCE FOR COUNSELORS, AND HELP-SEEKING BEHAVIORS

In the Asian culture, empirical studies have shown that the identification, express and acknowledgement of psychiatric problems are influenced by culture. According to Han and Pong (2015), studies show that many Asians believe that emotional anguish is seen as the consequence of bad thoughts, a lack of will power and self-control, and personality weakness, and therefore disclosing that one has mental illness is considered to be shameful (Kung, 2004; Lee et al., 2009). These beliefs may deter individuals from seeking help for their symptoms. Furthermore, in Asian cultures, mental illness often is not considered as an individual problem. Rather, mental illness potentially represents a negative reflection on the immediate family as well as their ancestors. For Asian immigrants, stigma attached to mental illness is a multifaceted phenomenon which is related to loss of face and status that us beyond the individual level (Chu & Sue, 2011). It is likely that such an intense and complex stigma attached to mental health issues further exacerbates disparities in mental health service utilization. Indeed, among Asian immigrants, extra-familial intervention is often considered shameful, as it indicates the inadequacy of family members and causes them to *lose face* with their community (Chu & Sue, 2011). Consequently, instead of seeking professional help, Asians may try to change this behavior through self-control and willpower or may try to keep out bad thoughts by keeping busy (Zhang, Snowden, & Suc, 1998). When these attempts fail, they may choose to address problems and needs first within the family system, such as immediate nuclear family, then extended family (Hsu, Davies, & Hansen, 2004). External help is sought only after all other resources are exhausted or when legal or social services force the issue.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Another cultural-bound contributor to low mental health service utilization is one's level of acculturation. Acculturation is a process of changing one's culture by incorporating elements of another culture and entails a mutual blending of culture, both psychologically and behaviorally (Berry, 1997). Thus, acculturation reflects the extent to which individuals learn the psychological and behavioral aspects of the dominant culture (Zane & Mak, 2002). Thus, Asians' reluctance to seek professional help and their lack of acceptance of Western psychotherapy, based on their level of acculturation, is known as a contributor to barriers in seeking mental health services (Wong, Marshall, Schell, Elliott, Hambarsoomians, Berthold, & Chun, 2006). Furthermore, studies also show that many Asians, in addition to the cultural factors such as stigma and acculturation, do not feel comfortable speaking to a mental health professional who does not share their same ethnic background, primarily due to cultural/language difference (Lee et al., 2009).

Mental Health Services Utilization Within the Asian Culture: Characteristics and Professional Mental Health Help-Seeking Behavior

Most existing studies have emphasized the cultural contextual factors in Asians' professional mental-health-seeking behavior. Previous research has shown that demographic characteristics seem to play a role in the willingness to seek professional help among Asians (Takayama, 2010). According to Han and Pong (2015), Asian females tend to have more positive attitudes toward seeking help than do Asian males (Leong & Zachar, 1999; Yoo, Goh, & Yoon, 2005). Also, while some studies have not found any relationship between age and seeking formal psychological help (Abe-Kim, Takeuchi, & Hwang, 2002; Abe-Kim et al., 2007; Shea & Yeh, 2008), some argue that younger Asians, especially those who ae male, may be less traditional, which results in a positive view of psychological help-seeking behavior (Solberg Ritsma, Davism Tata, & Jolly, 1994).

Cultural-Bound Syndromes

Culture-bound syndromes are repeated clusters of symptoms and behaviors specific to a geographic region which can cause both physical and mental distress in an individual and may result in impairment of functioning and help seeking behavior. The symptoms may include somatic symptoms as well as symptoms that may or may not overlap with a psychiatric disorder classified in the DSM (Task Force on DSM-IV, 2000). Various culture-bound syndromes are associated with particular Asian populations and are a continued area of study as psychiatric researchers and clinicians alike determine how best to approach their diagnosis and treatment. Identification and management of culture-bound syndromes is a continued controversial area of inquiry. A recent review challenged the notion of this being only a culture-bound syndromes given the more frequent episodes of violence and aggressive behavior in Western countries as well as Asian countries, by people of Asian descent and non-Asian descent (Saint Martin, 1999). The prevalence of culture-bound syndromes may also continue shift. In Lee and Kleinman's study (2007), reviewing the history and prevalence of neurasthenia in China, Lee and Kleinman (2007) postulate that the worldwide impact of the DSM has made it less likely that Chinese psychiatrists use the diagnosis of neurasthenia in China (Lee & Kleinman, 2007). Culture-bound syndromes continue to evolve over time, particularly as technology and communication continue to impact cross-cultural exchange of information and ways of understanding illness.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Shame and Stigma

According to Wynaden, Chapman, Orb, McGowan, Zeeman, and Yeak (2005), Asians reported that their communities stigmatized people who had a mental illness and that the ill person experienced feelings of shame. Several Chinese elaborated that for the community, the meaning of *shame* had a very intense and profound meaning. Wynaden et al. (2005, p. 90) found it difficult to describe in English the intensity of the expression of the feeling of *shame* that a person with a mental illness would feel: "The [Chinese] feel shame, the meaning of shame is [non-Chinese people] can't understand the meaning of shame. For Chinese people shame is very deep meaning. It means that you can't go out and face other people (p. 3)". Thus, shame and stigma prevented people from seeking help from mainstream mental health services. According to Wynaden et al., (2005, p. 91), the family tried to manage the problem and isolated themselves from the community to prevent knowledge of the family member's illness from becoming public: "They [family] don't want to accept it and those that do [they feel that they] will be stigmatized and bring bad onto the family…migrants that live in Australia still often live in their own culture…They know that there is a problem but they do not want to accept it (p. 5)". A person with a mental illness, according to Wynaden et al., (2005, p. 91), and his/her family isolated themselves because they believed that they would be labelled as different by their community and viewed negatively: "I think that they [people who are ill] are very sensitive to being labelled being seen as different. You know they are very sensitive to people looking at you in a strange way that you have a mental problem. In Chinese it [a mental problem] is mad! (p. 3)".

Causes of Mental Illness

Asians stated that knowledge about the cause of mental illness depended on the person's: (1) level of education; (2) country of origin; and (3) age According to Wynaden et al. (2005). People who had migrated from countries such as Singapore, with a western lifestyle, were more open to the western concepts of education and scientific information regarding the causes of mental illness. Educated people were also better informed and viewed mental illness as having a genetic/hereditary link. They understood disorder such as depression and schizophrenia. In contrast, migrants from more remote villages who were less educated and elderly migrants held more traditional beliefs. Hence, religion, and in particular Buddhism and Taoism, was reported to be important in determining the health beliefs of community members. According to Wynaden et al. (2005, p. 91), Buddhists believed in reincarnation and, inherent in this belief is, the philosophy of karma. Karma, the law of cause and effect in eastern spirituality, emphasizes that there is a consequence for every action. Therefore, positive actions result in positive reactions and negative actions result in negative reactions in a later reincarnation. Subsequently, people who produced a child who had a mental illness were perceived as being punished for their conduct in their past lives: "Traditionally they [parent] feel they may have done something wrong for this [mental illness] to happen. What you did in your past lives reincarnation [(前 世) the previous life]. You have not done anything right in your previous life. It is a sin very simply (p. 3)".

Other beliefs, according to Wynaden et al. (2005, p. 91), about the cause of mental illness are linked to the person being possessed by evil spirits: "When you are unwell, people will try to treat you with a witch doctor or spiritual leader…They relate psychiatric problems to spiritual causes (p. 10)". Traditional beliefs were also reported to have a sociological base. This belief was associated with the concept of *bad blood*: "In the old times they thought it was some bad blood in your family that caused it [mental

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

illness]. Sometimes if the child has this problem [mental illness] then it must be the mother's fault, not the father. The mother brought all this to the family. It has a lot to do with the sociological thinking at that time society how they see women and men's roles (p. 6)". Furthermore, refugees from China were identified as an extremely vulnerable population because of the traditional beliefs they held. Many of the customs among this group did not facilitate resolution of problems associated with mental illness. According to Wynaden (2005, p. 91), the family may not attend funerals of a member who had committed suicide: "The refugee group from China…this is the group of people that are really very isolated and have nobody and no support at all…They don't know how to deal with it…Language is a problem culture is another major problem in fact I came across quite a few refugee families and they have a huge problem to adjust to the way of life (p. 6)".

Family and Reputation

According to Wynaden et al. (2005, p. 91), the need to maintain family reputation was reported by all Asians and Asian Americans and were not dependent on people's level of education or country of origin: "They are reluctant to talk about it [mental illness] even if you [a general practitioner] ask them questions. It is something to be ashamed of it is a weakness and there is a stigma attached to it. You will be branded (p. 9)". Maintaining family reputation was particularly important if the problem was viewed as having a hereditary cause. It was reported that many Asian migrants have high expectations for their children. If these children succeeded it gave a good impression for the family. However, if the child developed a mental illness the family's reputation was disgraced (Wynaden et al., 2005, p. 91).

Hiding Up

According to Wynaden et al. (2005, p. 92), hiding up involved keeping the mental illness hidden from the community and/or not doing anything about the ill person's behavior: "There is still a large group of people who hide their [mentally ill] children away. They refuse to believe that they have a history of mental illness…They hide them [the child] they let them stay in the house and they do not let them leave the house (p. 2)". Hiding up meant that the family would not actively look for treatment and they would hide the ill person away hiding that as the child matured the problem would go away. The family would not bring people into their home, they would keep to themselves: "A lot of Chinese families [with a family member with a mental illness] hide up, they do not come out and they do not feel comfortable n going out…If you get an illness like a mental illness you do not understand and it has connotations and there is a lot of pressure to keep it hidden. If a family has mental illness they never want to talk to it. Only the family people know about the illness (p. 3)".

Seeking Help

Seeking help was a difficult process and it was usually left until the ill person's behavior was so bad that it could not be managed any longer within the family: "People who get treatment do it as the last resort (p. 5)". Generally, Asians do not voluntarily seek help from mainstream health services. Instead, they prefer to use prayer and visit temples and churches. Taoism was an important religion as it provided direction about the cause and treatment of mental illness. The family sought help when they were not able to manage the ill person. Some accessed help from a general practitioners (GP) from their country

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of origin because they believed that the GP would be more likely to understand. Other went to a non-Asian GP to maintain family confidentiality and prevent the risk of information being leaked to their community. Furthermore, language barriers were experienced by people accessing non-Asian doctors, and the use of interpreters was costly.

Lack of Collaboration

Asians explained that health professional had to reach into the community to access people if they wanted to demystify mental illness. According to Wynaden et al. (2005, p. 92), one way was to make contact with spiritual/religious leaders as places of worship played a very important role in determining the health belief of these communities. Health professionals need to understand the impact of mental illness on the family: "[Health professionals need to] develop more understanding of how Asian people feel about having a family member with a mental illness. If they can understand the traditional thinking, how people think about it. Health professionals can support them and let them know that they are not different…You need to make them feel that they are not disrespected (p. 3)". Health professional have to act with compassion, establish rapport and maintain confidentiality (p. 8)".

FUTURE RESEARCH AND RECOMMENDATIONS

Asians may have needs for certain resources that are not reflected in lower service utilization patterns. Experts have criticized the mental health services currently available within the US mental health system as disjointed, culturally mismatched with the treatment preferences of ethnic minority clients, and non-representative of cultural ideas about illness and health (Aggarwal et al., 2016; President's New Freedom Commission on Mental Health, 2003; United States Department of Health and Human Services, 2001). In recent years, culturally-specific service options have emerged to improved fit with the mental health needs of Asians. Cultural treatment adaptations, for example, refer to the process by which evidence-based practices (EBPs) validated in mainstream populations are tested and modified for the specific cultural needs of ethnic minorities like Asians. Culturally-adapted EBPs systematically consider language, culture, and contextual issues consistent with client's cultural values, beliefs, and practices, and have demonstrated beneficial outcomes in diverse populations (Bernal, Jiménez-Chafey, & Rodríguez, 2009; Griner & Smith, 2006; Pan, Huey, & Hernandez, 2011; Sue, Zane, Hall, & Berger, 2009). Several of these culturally-adapted treatment options have emerged as viable options for Asian individuals, including Problem Solving Therapy for depressed Chinese older adults (Chu, Huynh, & Arean, 2012), a culturally-adapted one-session treatment for Asians with phobia (Pan et al., 2011), a culturally-adapted cognitive behavioral intervention to accommodate the somatic symptoms that accompany PTSD in Cambodian refugees (Hinton, Pich, Chhean, Safren, & Pollack, 2006), and a Cantonese language CBT for depressed Hong Kong immigrants in Vancouver Canada (Shen, Alden, Söchting, & Tsang, 2006).

As a relatively new field of study, the science of cultural adaptation has shown recent advances with strides in guideline for when, how, and to what extent treatments should be adapted for a cultural population without significantly compromising fidelity to essential treatment components (Castro Barrera, & Holleran-Steiker, 2010). In fact, several models for the cultural adaptation process have been offered, such as the ecological validity framework (Bernal, Bonilla, & Bellido, 1995), cultural accommodation model (Leong & Lee, 2006). Most of these models recommend variations around four basic adaptation phases:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

information gathering, developing of initial adaptation design, pilot testing, and additional refinement (Barrera & Castro, 2006). These culturally-adapted treatments show considerable promise to provide treatment options that are congruent with the cultural preferences, coping and interpersonal styles, and psychopathology expressions of Asian clients. Continued work is needed to further develop and refine culturally-adapted treatments, and translational implementation efforts are sorely needed to transport such treatments from research to applied community settings. Unique challenges for the validity of mental disorder research arise from the heterogeneity of Asians populations, cultural biases in reporting style, and cultural idioms of distress. First, the nature of the Asian population is that it is small, diverse, and ever-changing. Second, cultural variations in response style, particularly on self-report rating scales, present important challenges for researchers and mental health professionals in the interpretation and cross-cultural validity of questionnaires. Third, Asians choose to express their distress is that of language terms utilized on research instruments (Chu & Sue, 2011).

CONCLUSION

Over the years, researchers have consistently highlighted the problem of mental health service underutilization within the Asians communities (Abe-Kim, Takeuchi, Hong, Zane, Sue, Spencer, Appel, Nicdao, & Alegría, 2007; Cheung & Snowden, 1990; Sue, Yan-Cheng, Saad, & Chu, 2012; Sue & McKinney, 1975). This mental health disparity manifests in a multifaceted manner, such as lower services utilization rates relatives to Whites (Matsuoka, Breaux, & Ryujin, 1997), presenting for professional help with more severe symptoms compared to other races (Chen, Sullivan, Lu, & Shibusawa, 2003), and a preference for receiving help from sources outside of professional mental health services (Ruzek, Nguyen, & Herzog, 2011). What is especially troubling is the recent evidence based on national data indicating that Asians continue to lag behind other groups (African Americans, Hispanics, and non-Hispanic Whites) in mental health service utilization, even while factoring in rates of distress (Sue, Cheng, Saad, & Chu, 2012). Therefore, a continued effort among researchers to unpack the contributing factors behind this mental health disparity is needed. That said, Kim and Kendall's (2015) study confirmed the recent and powerful data presented by Sue et al. (2012), indicating that the Asians underutilization trend still holds, even after taking into account psychopathology, only serve to further underscore the need for more research addressing this mental health disparity. Such that, the nuanced understanding of when an explanatory mechanism of help-seeking [Asian values → help-seeking attitudes → willingness to see a counselor] is attenuated, is when spiritual and biological etiology beliefs are strongly endorsed

Religion, Philosophy, and Health Beliefs

Many values and beliefs common among Asian populations have underpinnings in Asian religions and philosophy. These value systems are comprehensive, describing the integration of the body and the mind as well and an approach to managing both one's internal and external world. Asians and Asian Americans are an extremely diverse group, and while all Asians and Asian Americans will not uphold these beliefs, it is useful to briefly review them here as they inform the conceptualization of mental health and illness as well as general cultural values in many Asian cultures. That being said, much of Eastern philosophy is based on principles in Confucianism, Taoism, Hinduism, and Buddhism. Confucian thought brought order to Chinese civilization by emphasizing concepts such as interpersonal harmony, acceptance of a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

person's place in society, hierarchy within the family with older adults and males in higher positions, unconditional obligation toward the family, and orientation toward the group rather than the individual (Uba, 1994; Yang, Narayanasamy, & & Chang, 2011). Taoism emphasizes the importance of maintaining balance and harmony both internally and with the larger world, respecting nature, and maintain personal qualities of humility and receptivity (Stevenson, 1996; Yang, Narayanasamy, & Chang, 2011).

In Buddhism, the individual cultivates compassion for the suffering of others, acceptance of one's fate, or karma as a result of acts in a past life, and an acceptance of the ephemeral nature of life, as well as emphasis on non-attachment to aspects of the self (Hinton, Tran, Tran, & Hinton, 2008; Plakum, 2008). Elements of animism, belief in the existence of spirits, gods, and ghosts and the belief in a larger spirit would infused in natural inanimate and animate objects, has informed elements of Asian philosophy from Taoism, Confucianism, and Buddhism that include respect or worship for ancestors as a virtue (Hinton, Tran, Tran, & Hinton, 2008). Hinduism and Islam are the most common religions in South Asian nations. Aspects of Hindu beliefs have overlap with Buddhism such as the values of knowledge of life, emotional regulation, control-over-desire, the value of humility, and the importance of societal duty (Jeste & Vahia, 2008). Muslims also have a strong belief in destiny or fate, similar to karma, in that events occur because of the will of God, and similar ideas of sin to Judeo Christian religions. Many Muslims also believe in the spirit world of the jinn and some may have supernatural beliefs about the evil eye (Walpole, McMillan, House, Cottrell, & Ghazala, 2013). Hence, for example, a Chinese patient may believe that his low energy and mood are the result of an imbalance of yin and yang and may wish to take traditional herbs from a root doctor along with the antidepressant recommended by his psychiatrist (Castillo, 2002). Understanding traditional beliefs may also help mental health clinicians, researchers, and educators gain insight into a family's approach to managing a particular condition in a family member and the challenges that may arise. The breadth of religious and philosophies upheld by Asians was briefly reviewed here, but the mental health clinician can improve their understanding of the individual Asian patient's approach to his/her mental health by learning more about his/her particular belief systems.

Asian American Family Culture

Based on the deeply ingrained idea of filial piety in the vast majority of Asian cultures, the family is the unit on which society is based. Filial piety is a core value based on Confucian principles. It emphasizes the importance of family throughout the life cycle of the individual. The interdependence of family, members among Asians manifests itself in various ways, one of which is when Asians contemplate making major life decisions. In surveys of Asian adults with children over age 18, 68% felt that parents should have some influence in determining what career their child pursues, and in the same group, approximately 66% felt that parents should have at least some influence in their child's choice of spouse (Pew Research, 2012). On the other hand, behavior against the family or cultural values, such as delinquent behavior, a suicide attempt, being gay or lesbian, or taking a partner from a different religion or ethnic background, may be viewed as bringing shame to the family, or causing the family to *lose face*, and lead to conflict within the family (Rho & Rho, 2009; Walpole et al., 2013). Cultural values of displaying more tempered emotions, and family harmony may lead to more indirect or restrained communication between family members than in non-Asian families (Rho & Rho, 2009; Uba, 1994). Additionally, the emphasis placed on respect and obedience to parental authority can also decrease the likelihood of open communication between different generations as detailed in immigrant families. Acculturation and enculturation are related concepts. Both reflect aspects of the process of change an individual undergoes when one moves to a new culture.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Acculturation and Families

Connections among family members undergo transition as immigrants move to a new culture and attempt to adapt to the culture. In a process known as acculturation, the individual adapts with regard to identity, beliefs, and values in relation to the new dominant culture (Kim, Ahn, & Lam, 2009). Enculturation, a related concept, functions in the opposite manner and is a process in which a person strengthens their ties to social norms and values of their culture of origin (Kim, Ahn, & Lam, 2009). Hwang (2007) has referred to the term as acculturation family distancing (AFD) to combine the parent and child generation in immigrant households may acculturate at different rates, leading to a difference in values and also difficulties in communication (Hwang, 2007; Uba, 1994). Other researchers have referred to this phenomenon as dissonant acculturation and suspect that this is particularly relevant in conflict between parents who may struggle to maintain ties to the older culture and children who because of their age and desire to connect with peers may have greater exposure to the new culture (Kim, Ahn, & Lam, 2009). According to Ali (2014), this acculturation gap can also occur between elderly relatives that are coming from the country of origin, to live in the United States with their children. Grandparents may be brought to the United States with the idea that they can benefit from better health care or provide childcare for the family. Immigration is often alienating for older immigrants, who likely face greater functional limitations and language limitations than younger generations (Baker & Takshita, 2002; Uba, 1994). It is also more challenging for the elderly to establish a peer group and a grandparent new to the United States may experience an acculturation gap with their children and an even greater one with their grandchildren. Acculturation is part of the process of making a cultural and geographic transition and can lead to significant intergenerational conflict in Asian families.

Hence, in previous section, existing evidence of the breadth and depth of stigma across countries and provocative cross-national findings in what empirical work exists. Thus, while stigma is seen as *cross culturally ubiquitous* (Dovidio, Major, & Crocker, 2000; Neuberg, Smith, & Asher, 2000), the earliest work (Goffman, 1963) to the most recent (Dovidio, Major, & Crocker, 2000; Fabrega, 1991) conceptualizes stigma as a phenomenon shaped by cultural and historical forces. Early on, anthropologists described the different ways that cultures shape how individuals with mental illness are viewed and treated (Benedict, 1934; Townsend, 1975). Lefley (1990) contends that chronicity, itself, is a cultural artifact based, at least in part, on differing worldviews, religious traditions, the role of alternative healing systems, and difference in the cultural value of interdependence. Even studies that have documented differences in outcomes for persons with mental illness across countries point to and call for further investigations across cultural contexts (Dovidio, Major, & Crocker, 2000; Ng, 1997). These studies suggest that future research must identify the collective properties of social, cultural, economic and physical environments that influence health and disease outcomes. For example, according to Pescosolido et al. (2008), Sartorius (1998) reports that the ratio of psychiatrists to the population ranges from 1:1,000-5,000 in the more developed societies to 1:50,000-100,000 in the developing world to only 1:5,000,000 in some African countries. Of course, this is not independent of the availability of economic capital in a society which needs to be considered as well, because the World Health Organization (WHO) reports that countries in Western Pacific Region devote less than 5% of their small health budgets to mental health and neurological disorders (World Health Organization, 2005, p. 121). Thus, existing research suggests that researchers and practitioners in the field of mental health need to examine cross-cultural issues directly, rather than making assumptions about their correlation with broad categories.

ACKNOWLEDGMENT

I would like to dedicate this chapter to William Marc Weisman, M.S. (Marc Weisman), at the State of California, Department of Rehabilitation (DOR), in San Francisco, California. Marc is a team manager that I have the pleasure to work under and an opportunity to being mentored by, who demonstrates the behavior and definition of servant leadership, and practices the act of servant leadership. Marc continuously demonstrates the behavior of servant leadership, and practices the act of servant leadership, through the implementation of his knowledge, skills, abilities, wisdom, charm, humor, and charism. Marc exemplifies his managerial skills and (servant) leadership qualities through his actions with how efficiently he is able to handle and resolve situations at hand.

I am a certified bilingual [Cantonese and English (and not certified Mandarin)] Senior Vocational Rehabilitation Counselor, Qualified Rehabilitation Professional (SVRC-QRP) with DOR. I am currently the top performing SVRC-QRP, among 36 counselors in 6 teams in the San Francisco District with the State of California, Department of Rehabilitation. I single-handedly manage the RAMS/Hire-Ability mental health contract, and achieved a 97% successful rate (66/68). The first time since the contract tenure with DOR (approximately 20 years). I am also the only bilingual liaison with the Disabled Students Programs and Services (DSPS) Department for Chinatown North Beach Campus at City College of San Francisco (CCSF) for DOR.

Hire-Ability is non-profit vocational services program partnered with San Francisco Department of Public Health and California State Department of Rehabilitation which serves the San Francisco Bay Area community by connecting employers with trained, assessed and pre-qualified employees. Hire-Ability specializes in providing employers with a pool of employees that reflect the diverse and multicultural population of the region. Specifically, Hire-Ability assists employers in achieving their diversity goals by matching them with qualified individuals with disabilities. Hire-Ability Vocational Services is a division of RAMS, Inc. (Richmond Area Multi-Services, Inc.), which was established in 1974 and has over 30 different community programs that operate in the San Francisco Area. RAMS, Inc. is a private, non-profit mental health agency that is committed to advocating for and providing community based, culturally-competent, and consumer-guided comprehensive services, with an emphasis on serving Asian & Pacific Islander Americans. Founded in San Francisco's Richmond District in 1974, our agency offers comprehensive services that aim to meet the behavioral health, social, vocational, and educational needs of the diverse community of the San Francisco Area with special focus on the Asian & Pacific Islander American and Russian-speaking populations.

KEY TERMS AND DEFINITIONS

Asian Americans (Americans of Asian Descent): The term refers to a panethnic group that includes diverse populations who have ancestral origins in East Asia, Southeast Asia, or South Asia, as defined by the U.S. Census Bureau. This includes people who indicate their race(s) on the census as Asian or reported entries such as Asian Indian, Chinese, Filipino, Korean, Japanese, Vietnamese, and Other Asian.

Asian Exclusion Act of 1924: A continued response to concern about Asian immigration, which limited the new immigrants per year from East Asia, Southeast Asia, and South Asia.

Diagnostic and Statistical Manual of Mental Disorders (DSM-5): Used by clinicians and researchers to Diagnose and classify mental disorders.

Hiding Up: Involved keeping the mental illness hidden from the community and/or not doing anything about the ill person's behavior.

Karma: The law of cause and effect in eastern spirituality, emphasizes that there is a consequence for every action.

Mianzi: Refers to one's own sense of dignity or prestige in social contexts. It is a strategy that protects self-respect and individual identity.

Multigenerational Family: Having at least two adult generations in the same household.

Stigma: Stigma can be defined as the display of negative attitudes, based on prejudice and misinformation, in response to a marker of illness.

This research was previously published in Deconstructing Stigma in Mental Health; pages 70-107, copyright year 2018 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 55
Religious Coping Among Muslims With Mental and Medical Health Concerns

ABSTRACT

Studies suggest that a lack of understanding and sensitivity around religious issues by healthcare professionals may be a noteworthy barrier for Muslims seeking treatment. One way to help bridge the gap between Muslims' healthcare needs and healthcare utilization rates may be through fostering awareness and sensitivity about the influence of Islam on how Muslims cope with their illness experience. Using a biopsychosocial-spiritual theoretical framework, a main aim of this chapter is to consider a variety of ways that Muslims use religion to cope with physical and mental health challenges. Religious coping can take a variety of forms: Positive religious coping involves making use of Islam in beneficial manners. Negative religious coping, referred to here as r/s struggles, often involves tension or conflict regarding matters of religion. Understanding the role that religion/spirituality can play in how Muslims cope with their physical or mental illness may help to foster higher quality, more culturally sensitive care. Recommendations and limitations are discussed.

INTRODUCTION

A growing body of literature suggests that people often turn to their spirituality and/or religious beliefs when coping with a stressful life event (e.g., Ano & Vasconcelles, 2005; Jim et al., 2015; Pargament, 1997). This may be particularly true among individuals who identify religion and/or spirituality as a salient component of their identity (Pargament, Tarakeshwar, Ellison, & Wulff, 2001). As most research

on religious coping has been conducted among Christians in the United States, there is a dearth of scholarly work that examines the important role that Islam may play for U.S. Muslims dealing with a mental health or medical illness. Thus, the primary purpose of this chapter is to consider the variety of ways that Muslims may use religion to cope with physical and mental health challenges.

Muslims constitute nearly one-fourth of the world's population and form the second largest religion in the world (Hackett & McClendon, 2017). Despite the current and projected rapid growth (Lipka & Hackett, 2017) of this population, Muslims continue to represent an understudied and underserved heterogeneous group of individuals. This is particularly true in the field of healthcare (Tackett et al., 2018). For example, researchers examining breast cancer screening practices among South Asian and Middle Eastern Muslim women found that only 52% of the participants indicated utilization of mammography services (Hasnain, Menon, Ferrans, & Szalacha, 2014), a percentage that is substantially lower than recent data gathered from a national health survey suggesting that about 72% of women in the United States received a mammogram within the past two years (Hall et al., 2018). Such results from the United States are comparable to findings from places around the world where Muslims may be in similar minority status (Gyimah, Takyi, & Addai, 2006).

In terms of mental health, researchers conducting a study among Somali, Palestinian, and Egyptian community members and college residents ($N = 276$) found that about 90% of the participants reported no utilization of mental health services in the past three years (Aloud & Rather, 2009). Likewise, Muslim immigrants with Obsessive-Compulsive Disorder (OCD) reported between 5-13 years between symptom onset and seeking professional help (Mahintorabi, Jones, & Harris, 2017).

A number of factors may influence and contribute to the low rates of healthcare seeking behaviors among Muslims not only in the United States but also in other places around the world where Muslims are a minority group (e.g,.Gyimah et al., 2006). First and foremost, Muslims may lack understanding and familiarity with the healthcare system (Hasnain, Connell, Menon, & Tranmer, 2011) or lack trust towards providers (Hasnain et al., 2011). Furthermore, both qualitative and quantitative studies suggest that many Muslims report feelings of perceived discrimination in healthcare (Martin, 2015; Vermette, Shetgiri, Al Zuheiri, & Flores, 2015). The lack of same-gender providers (McClean et al., 2012; Padela & del Pozo, 2011) and stigma associated with seeking help (Youssef & Deane, 2006) have also been proposed as factors that reduce health service utilization by Muslims. On a similar note, qualitative responses regarding cervical cancer screening suggest that Muslims' values may often differ from traditional values of Western medicine (Matin & LeBaron, 2004). Specifically, feelings of discomfort surrounding modesty concerns have been found to be associated with delayed healthcare seeking (Vu, Azmat, Radejko, & Padela, 2016).

Above all, multiple studies have suggested a lack of understanding, sensitivity, and competency regarding cultural and religious issues to be a noteworthy barrier in seeking medical and mental health treatment among Muslims (e.g., Hasnain et al., 2011; Padela & Zaidi, 2018; Weatherhead & Daiches, 2010). For example, a semi-structured interview with a heterogeneous Muslim sample revealed the inclusion of religious and cultural values to be an important component of the therapeutic discourse and relationship not only to better understand the individual but also for the provider to ask well-informed questions (Weatherhead & Daiches, 2010). Likewise, Muslim women have reported feeling misunderstood by healthcare practitioners regarding their religious needs, which can be a barrier to maternity health care services (Reitmanova & Gustafson, 2008).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, perceptions of being labeled as "ignorant" or having "abusive" spouses have also been reported among Muslims as examples of religious and cultural barriers in healthcare settings (Shah, Ayash, Pharaon, & Gany, 2008). Researchers have found that more than half of Muslim Americans report perceptions of being "ignored or excluded," and about one-third of Muslim Americans describe experiencing offensive or insensitive remarks (Martin, 2015) within the healthcare setting. Similarly, in a study conducted among Pakistani Muslim adults with chronic conditions in the UK, participants reported they were less likely to reveal how their religious beliefs influenced their health behaviors due to a fear of being misunderstood or having their values being undermined by clinicians (Mir & Sheikh, 2010).

Despite underutilization of healthcare services, Muslims continue to experience mental and medical health-related concerns. Although research on prevalence rates remains scarce, available data suggest that Muslims in the United States are most likely to experience adjustment disorders followed by anxiety, obsessive-compulsive, and posttraumatic stress disorders (Basit & Hamid, 2010). Likewise, Muslims may also experience mental health concerns stemming from experienced or perceived discrimination; in a nationally representative survey, 60% of Muslims reported experiencing some degree of discrimination due to their religious beliefs, which is significantly greater than the levels of religious discrimination reported by Jews (38%) and Catholics (11%) in the United States (Mogahed & Chouhoud, 2017).

With respect to physical health, in a recent study examining cardiovascular disease risk factors, about 43% of the Muslim sample met criteria for being overweight (Budhwani, Borgstede, Palomares, Johnson, & Hearld, 2018), and physical inactivity rates have been found to be higher in Muslim countries compared to non-Muslim countries (Kahan, 2015). Along similar lines, a study conducted among Arab Americans in Michigan found that diabetes and hypertension rates were of high prevalence (Aswad, 2001).

Bridging the gap between Muslims' healthcare needs and healthcare utilization relies to a great degree on clinicians within helping professions fostering awareness and sensitivity towards the influence of Islam on health. Similar to gender, ethnicity, sexual orientation, and/or race, religion can also be considered a dimension of diversity that shapes both one's psychosocial (Vieten et al., 2016) and physical functioning (Carroll et al., 2007). Thus, when working with Muslim patients, culturally sensitive care involves the acknowledgement and appreciation of the role that Islamic religiousness and spirituality may play in how Muslims interpret and respond to their illness experience (Padela & Curlin, 2013).

Essentially, providing sensitive care entails not only understanding the basic tenets of Islam but also knowing how Muslims make use of their religion/spirituality in coping with their physical and mental health issues. Accordingly, a primary purpose of the current chapter is to inform Muslim and non-Muslim clinical providers about how Muslims may use religion to cope with mental and physical illnesses, including positive religious coping and religious and/or spiritual (r/s) struggles (also termed negative religious coping). We will first briefly provide a theoretical framework for the inclusion of religion and spirituality in healthcare, followed by a discussion on positive religious coping and r/s struggles. We conclude by offering some tentative recommendations for practitioners.

BACKGROUND

Theoretical Framework

The biomedical model posits a pure biological explanation of diseases and defines health as the absence of disease (Brannon & Feist, 2009). A biomedical conceptualization of illness and health has been the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

traditional approach in mainstream Western medicine. Although such an approach has historically been effective for infectious diseases, researchers and clinicians began to question the effectiveness of the biomedical model in the treatment of chronic illnesses (Brannon & Feist, 2009). Thus, over the past several decades a biopsychosocial model has been proposed as an alternative way of understanding and treating diverse mental health and chronic medical conditions (e.g., Barker, Gumley, Schwannauer, & Lawrie, 2015; Day et al., 2016). A biopsychosocial model considers the biological, psychological, and social dimensions of an illness (Borrell-Carrió, Suchman, & Epstein, 2004). Within this model, however, religion and spirituality are often overlooked as factors playing a role in the understanding and treatment of illnesses. Overlooking these factors can particularly be an issue of concern when considering demographics surrounding religion/spirituality in the United States. According to a national survey conducted in 2014 by the Pew Research Center, about 80% of Americans report a belief in God and 77% of Americans find religion to be either very important or somewhat important in their lives. Similarly, more than half of the survey participants endorsed feeling "spiritual peace and well-being" at least once a week (Pew, 2014).

Results for Muslims are similar: In the same national survey, 96% of Muslims reported having a belief in God and about 88% viewed religion to be very or somewhat important in their lives. Moreover, approximately 70% of Muslim participants endorsed praying at least daily (Pew, 2014). Specific Muslim groups may endorse even a greater sense of religious importance. For example, among Saudi patients undergoing dialysis, 85% reported experiencing the presence of God in their everyday lives and 80% endorsed that their religious beliefs were the foundation to approaching life experiences (Al Zaben et al., 2015). Given the vital role that religion may play in Muslims' lives, the addition of a religious and spiritual dimension to the biopsychosocial model could be a crucial part of competent and holistic care. Over the past two decades, researchers have now proposed the biopsychosocial-spiritual model (e.g., Sulmasy, 2002; Taylor, Stotts, Humphreys, Treadwell, & Miaskowski, 2013) to better understand how religion and spirituality shape well-being. Within a biopsychosocial-spiritual model, healing involves not only biological, cognitive, emotional, and social components, but also a spiritual component. The biopsychosocial-spiritual model of healthcare is particularly pertinent within the context of Islam, which supports a holistic view of health in which the mind, body, and spirit all play a role in the healing process (Saniotis, 2018).

Studies have revealed that religious variables are associated with both mental and physical health outcomes (Cohen & Koenig, 2003). For example, a review of studies examining church attendance revealed that weekly involvement in religious services played a protective factor against cardiovascular disease (Powell, Shahabi, & Thoresen, 2003). Similarly, greater involvement in religious or spiritual (r/s) activities has been associated with lower blood pressure, heart disease, hypertension, and even lower levels of mortality (Koenig, King, & Carson, 2012). Higher levels of religion/spirituality have also been linked to lower levels of depression (Baetz, Griffin, Bowen, Koenig, & Marcoux, 2004; Hirsch, Nsamenang, Chang, Kaslow, 2014) and anxiety (McCoubrie & Davies, 2005).

Similarly, in times of distress, religion and spirituality (r/s) are often a major means through which people cope with negative emotion (Pargament, Smith, Koenig & Perez, 1998). This may particularly be true for Muslims. For example, in a study conducted among diverse religious groups on a university campus, Muslim participants reported the highest levels of belief in the effectiveness of all forms of religious coping, such as faith in God, prayer, and engaging in religious practice, in addressing their depression (Loewenthal, Cinnirella, Evdoka, & Murphy, 2001). Similarly, in a recent qualitative study conducted among Moroccan Muslim women, Islamic beliefs and turning to God played a critical role

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in how participants responded to their illness (Ahaddour & Broeckaert, 2018). Thus, the available evidence provides preliminary support for a biopsychosocial-spiritual model in which the r/s domain is acknowledged as a clinically relevant dimension of life.

RELIGIOUS COPING

When facing stressful situations such as physical or mental health disorders, individuals may turn to their r/s beliefs in order to cope. Religious coping can serve key functions by providing a sense of meaning, intimacy, and comfort (Pargament, Koenig, & Perez, 2000; Pargament, Falb, Ano, & Wachholtz, 2013). Researchers have suggested two overarching forms of religious coping: positive religious coping and religious and/or spiritual (r/s) struggles, which are also referred to as negative religious coping (Pargament et al., 2013; Exline, Pargament, Grubbs, & Yali, 2014). Both forms of religious coping have been associated with health outcomes (e.g. Trevino et al., 2010; Ellison & Lee, 2010). The following sections will discuss both positive religious coping and r/s struggles among Muslims. Specifically, we will discuss the unique role that Islam may play as a source of comfort and guidance or as a source of distress and tension among Muslims coping with stressful medical or mental health experiences.

Positive Religious Coping

Positive forms of religious coping often reflect a secure relationship with God, a spiritual connection with others, and a greater sense of meaning in life (Pargament et al., 2000). For example, positive religious coping may involve looking towards religion to discover a new direction in life, asking for prayer and support from faith leaders, or building a relationship with the transcendent (Pargament et al., 2000). Positive religious coping methods have been found to be associated with indicators of good mental health such as greater well-being (Tarakeshwar et al., 2006), life satisfaction (Trevino et al., 2010), spiritual growth (Pargament, Koenig, Tarakeshwar, & Hahn; 2004), and posttraumatic growth (Abu-Raiya, Pargament, & Mahoney, 2011). Likewise, positive religious coping has also been linked with better physical health (for a review, see Koenig et al., 2012).

Researchers investigating religious coping among Muslims have found that positive religious coping is associated with greater optimism (Ai, Peterson, & Huang, 2003) and purpose in life (Abu-Raiya, Pargament, Mahoney, & Stein, 2008). Several studies have revealed that Muslims endorse positive forms of religious coping significantly more than negative forms of religious coping (e.g., Ai et al., 2003; Abu-Raiya et al., 2011; Ghorbani, Watson, Hajirasouliha, & Chen, 2016). Positive r/s coping has been found to relate to Muslims' health in positive ways. For example, among Iranian Muslim patients undergoing hemodialysis, researchers found that religious coping factors contributed to about 40% of the variance in quality of life and about 25% of variance in participants' health status (Saffari, Pakpour, Naderi, Koenig, Baldacchino, & Piper, 2013). Furthermore, an Islamic religious coping mindset among immigrant Muslims in New Zealand was related to greater life satisfaction, regardless of participants' stress levels (Adam & Ward, 2016). Greater Islamic religious beliefs and practices have also been found to be associated with greater psychological functioning, lower depression levels, less smoking, and greater physical functioning despite greater severity in illness status in comparison to participants with lower levels of Islamic religious beliefs (Al Zaben et al., 2015).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Positive forms of religious coping can take place in a variety of ways among Muslims. For many Muslims, Islam may provide a framework for coping with major life events. An Islamic understanding of health promotes an interplay between turning both to medicine and to God (Khan, 1986; Ypinazar & Margolis, 2006; Ahaddour & Broeckaert, 2018). Thus, Muslims may often engage in a collaborative form of religious coping in which they may view both themselves and God playing a role in the healing process. For example, in a sample of older Muslim adults with good and poor health conditions, participants reported believing that God is the ultimate controller and creator of one's of body, health, and life, and that both illnesses and cures are created with God's permission (*bi-idni Allah*) (Ahaddour & Broeckaert, 2018).

Along similar lines, Muslims may engage in putting their full trust in God, referred to as *tawakkul*, which is an essential component of belief and faith in Islam (Al- Khattab, 1997). However, at the same time, participants report recognizing their own role in the illness and healing process (Ahaddour & Broeckaert, 2018). Researchers have found that Muslims describe actively seeking treatment to be one's religious obligation as the body God has given them is a trust (*amanah*) that they must take care of even in cases of terminal illness (Ahaddour & Broeckaert, 2018). For example, qualitative research suggests that Muslims might not only engage in seeking help from God but also adhere to their medication regimen or educate themselves on the illness to make progress in the treatment (Eltaiba & Harries, 2015).

When afflicted by a mental or physical illness, many Muslims may share the belief that their illness is a trial in life. Qualitative responses from Muslims emphasize the belief that illnesses are a test from God (Ahaddour & Broeckaert, 2018). Specifically, Muslim participants report Prophetic examples of suffering such as the story of Prophet Ayyub (Job) and state that God inflicts illness to the ones he loves the most (Ahaddour & Broeckaert, 2018). Similarly, Muslims have described their conditions as a trial sent by God that is part of their destiny (Eltaiba & Harries, 2015). Muslims may also appraise the situation as a means through which an individual becomes purified from their sins, as evidenced by the *Hadith* (sayings of the Prophet): "Never a believer is stricken with a discomfort, an illness, an anxiety, a grief or mental worry or even the pricking of a thorn but Allah will expiate his sins on account of his patience" (Al-Bukhari, 1990).

Physical and psychological illnesses may be viewed as God's mercy, as the affliction results in not only moral purification but also an eternal reward of entering paradise in the afterlife (Ahaddour & Broeckaert, 2018). Muslims may also turn to Qur'anic scripts or Prophetic traditions in order to seek guidance and comfort. For example, the saying of Prophet Muhammad "There is no disease that Allah has created, except that He also has created its remedy" (Al-Bukhari, 1990) suggests not only to put trust in God but also fosters a hopeful stance towards illnesses. This is in line with research conducted among Muslim physicians who described the influence of Islam as providing a hopeful state of mind among patients (Al-Yousefi, 2012). Thus, Muslims may incorporate a hopeful mindset that God may ultimately provide recovery from their mental or physical illness.

The role of virtue development in coping with physical and psychological illnesses is also promoted in the Qur'an and *Sunnah* (actions of the Prophet). Specifically, gratitude (*shukr*) and patience (*sabr*) are two virtues that has been proposed to form and reflects one's faith *(iman)* (Al- Khattab, 1997). Verses from the Qur'an such as "O you who have believed, seek help through patience and prayer. Indeed, Allah is with the patient" (2:153) and "And We will surely test you with something of fear and hunger and a loss of wealth and lives and fruits, but give good tidings to the patient" (2:155) highlight for Muslims the role of cultivating patience in times of distress. During times of hardships, Prophet Muhammad displayed gratefulness and stated, "The believer is fine whatever the situation; even when his soul is being pulled

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

from his body and he praises Allah, the Mighty and Sublime" (Ibn 'Abbas, 1843). Likewise, the Arabic word "al-hamdulillah" which translates as "Praise be to God" is presented 38 times in the Qur'an and is a word that suggests expressing gratitude towards God under *all* circumstances as He is Praise-worthy both in times of ease and prosperity and in times of distress and challenge.

The emphasis on patience and gratitude in Islam may encourage Muslims to practice such virtues when coping with an illness. For example, Muslim elderly adults with diverse health conditions such as hypertension, arthritis and headaches expressed gratitude towards God for their health status in qualitative interviews; participants also viewed their health condition as *ni'ma* (blessing) from God (Ahaddour & Broeckaert, 2018). Similarly, in a study of Arab American immigrant community participants, responses from all of the Muslim females involved a sense of gratitude towards God, specifically when discussing positive health outcomes (Shah et al., 2008). Muslims have also been found to present with a mindset of patience towards suffering and a belief that God was with those who displayed patience (Ahaddour & Broeckaert, 2018). Moreover, Muslims may cope with life stressors through a *dhikr* ritual, which involves the continuous utterance and remembrance of God. Muslims may engage in a *dhikr* ritual for various purposes such as wanting to feel closer to God, expressing gratitude, connecting with the transcendent, obtaining God's forgiveness and mercy, or fostering humility (Hamsyah & Subandi, 2017).

Researchers have suggested that Muslims may seek help from Allah by uttering specific *dhikrs* to eliminate or decrease mental and physical health-related concerns (e.g., Suryani, 2013). Notably, researchers have found *dhikr* to explain about 34% of unique variance in Muslims' subjective well-being (Hamsyah & Subandi, 2017). An examination of qualitative responses from Indonesian Muslim Sufi participants revealed that *dhikr* was reported to be associated with increased optimism, positive emotions, and mental stability in the face of life's problems (Hamsyah & Subandi, 2017). Muslims can also hold the belief that their recovery can be achieved through maintaining a close relationship with God (Eltaiba & Harries, 2015). Thus, prayer (*dua*) may be a way in which Muslims strengthen their relationship with the Divine (e.g., Loewenthal et al. 2001; Heidari et al., 2017).

A focus on one's relationship with God as a form of coping has also been reported among Muslim youth who describe being able to overcome adversity through incorporating a "God-conscious" mindset (Mitha, & Adatia, 2016). Muslims may also deal with distress by increasing their religious involvement. For example, Muslims may increase their mosque attendance or take part in their religious community activities in order to alleviate symptoms of depression and anxiety. Among young Australian Muslims the majority of which were experiencing mental health stressors, researchers found that participants reported feeling a sense of community, strength, and belonging when taking part in their faith community (Mitha, & Adatia, 2016).

Religious and Spiritual Struggles

While religion/spirituality can be a source of comfort and guidance, religion/spirituality can also be a source of distress when coping with life stressors. R/s struggles or negative forms of religious coping often reflect tension, conflict, or questioning related to supernatural, intrapersonal, and/or interpersonal matters of religion/spirituality (e.g., Exline et al., 2014; for reviews, see Exline, 2013; Exline & Rose, 2013). Certain forms of religious coping may be more dysfunctional or ineffective when dealing with stressful situations. Specifically, researchers have proposed various types of r/s struggles. Divine struggles may involve negative thoughts or feelings focused on God (Exline et al., 2014), which might include questioning God's love, fears of divine punishment, or anger towards God (see also Exline, Park, Smyth,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Carey, 2011). Demonic struggles may reflect feeling attacked by supernatural forces that are evil in nature, such as the devil or demons (Exline & Rose, 2005; Exline et al., 2014). Interpersonal struggles arise when an individual experiences conflict with religious individuals or institutions (Pargament, Murray-Swank, Magyar, & Ano, 2005; Exline et al. 2014). Moral struggles often reflect guilt or worry associated with following ones' moral principles (Exline, Yali, & Sanderson, 2000; Exline et al., 2014). Finally, doubt-related struggles pertain to questioning one's beliefs, whereas ultimate meaning struggles involve distress about perceptions that one's life lacks deep meaning (Exline et al. 2014). Although positive forms of religious coping are generally endorsed much more than r/s struggles, research has shown that many Muslims do indeed experience r/s struggles (Abu-Raiya, Exline, Pargament, & Agbaria, 2015; Saritoprak & Exline, 2016).

Researchers examining r/s struggles among U.S. adults have found that Muslims report greater overall r/s struggles in comparison to Christian, Jews, Buddhist, agnostics, and atheists (Saritopak, Exline, & Stauner, 2016). Specifically, Muslims appear to endorse moral, interpersonal, and ultimate meaning-related struggles the most in comparison to other forms of struggles (Abu-Raiya et al., 2015; Saritoprak & Exline, 2016). Prevalence rates of r/s struggles have ranged between 1% (divine) - 40% (supernatural) among an Israeli-Palestinian Muslim sample (Abu-Raiya et al., 2015). Reviews of r/s struggles have revealed significant links between struggles and health (e.g., Cummings & Pargament, 2010; Exline & Rose, 2013). Studies have shown links between struggles (usually labeled as negative religious coping) and a lack of social support (e.g., Tarakeshwar et al., 2006), greater pain experience (Sherman, Simonton, Latif, Spohn, & Tricot, 2005), lower quality of life (Lee, Nezu, & Nezu, 2014), and even mortality risk (Pargament, Koenig, Tarakeshwar, & Hahn, 2001). Likewise, Muslims experiencing interpersonal and ultimate meaning struggles endorsed lower life satisfaction and more symptoms of depression and anxiety (Abu-Raiya et al., 2015).

At the same time, r/s struggles have also been associated with positive, growth-oriented outcomes (Desai & Pargament, 2015). Specifically, researchers are suggesting that perhaps the response to struggles-such as an attempt to collaborate with God-may predict spiritual growth more than struggle itself does (Exline, Pargament, Hall, & Harriott, 2017). Specifically, in our prior work, we have proposed the notion of responding to r/s struggles with an Islamic growth-oriented mindset referred to as *spiritual jihad* (Saritoprak, Exline, & Stauner, 2018; Saritoprak & Exline, in press). Muslims with a spiritual jihad mindset may display a conscious effort in struggling against life's trials for the sake of God; despite experiencing hardships, they may engage in thoughts and behaviors that foster a closer relationship with God. Thus, for example, in the face of distressing moral struggles, Muslims may view their struggle as a temptation of their *nafs* that is brought as a test from God, and that a positive response may draw them closer to God; or they may believe that there is some good (*khair)* in the struggle because there is *khair* in all works of God (Saritoprak et al., 2018). Endorsing a *spiritual jihad* mindset in response to r/s struggles has been found to be associated with reports of greater spiritual and post-traumatic growth (Saritoprak et al., 2018).

Although limited, research on specific ways in which Muslims cope with r/s struggles suggests that some Muslims may view their illness experience as a punishment from God, perhaps for past sins or wrongdoings (Ahaddour & Broeckaert, 2018). Likewise, in a semi-structured interview conducted among five Muslim women with OCD symptoms, all participants reported washing their hands for fear of punishment such as going to hell (Mahintorabi, Jones, & Harris, 2017). Similarly, Islamic religiosity has been found to be associated with greater perceived discrimination among Muslim immigrants in

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the United States (Ghaffari & Çiftçi, 2010), which may potentially lead to greater general psychological distress and ultimately r/s struggles, especially interpersonal struggles.

It is important to keep in mind that r/s struggles can be considered a sensitive topic among Muslims. This may particularly be influenced by the core value of *submission* in Islam, as the Arabic word Muslim translates to *the one who submits*; thus, Muslims may perceive or fear that any expressed tension, conflict, or distress related to God or other matters of religion in the face of an illness to be a transgression against God's Will, which would go against a fundamental belief of their faith. However, more research is necessary to confirm such speculations.

LIMITATIONS OF THE EXISTING LITERATURE

There were several limitations in the presented research that should be noted. First, most studies presented in this chapter employed qualitative approaches to data collection such as conducting semi-structured interviews. These methods provide rich descriptive information, but due to small sample sizes, they can lead to some biases in results and may make the data less representative of the broader Muslim population. Lastly, the samples in the mentioned research studies generally endorsed high levels of religiousness and spirituality, which prevent the results from being generalized to Muslims who are non-practicing or who report low levels of religiousness and spirituality. Future research may benefit from examining larger sample sizes which include a greater range of diversity in terms subjective religiousness as well as cultural background. Finally, it would also be helpful to introduce more quantitative studies with larger number of participants, both to help with the process of identifying consistent patterns and to provide greater odds of generalizability to the broader Muslim population.

TENTATIVE RECOMMENDATIONS

Given the prevalence and importance of religion/spirituality in the coping process in addition to the associated health and well-being outcomes, medical or mental health providers working with Muslim patients may consider the following recommendations.

First and foremost, understanding and becoming informed on how patients make use of Islam in dealing with their psychological or physical issues is crucial in developing a culturally sensitive case formulation (Rassool & Gemaey, 2014; Rassool, 2015). One way that this can be initiated is through inquiring about how the patient historically has incorporated and currently incorporates religious beliefs and practices in their illness experience. Clinicians may ask about the role that God (or other supernatural agents) may play in making sense of hardships or what methods of religious and/or spiritual coping responses have worked (or not worked) in the past.

Furthermore, providers can ask specific questions such as "How is your religion and spirituality related to your symptoms?" "Is Islam relevant to your treatment?" or "Do you think your religious beliefs or practices are associated with your condition?" (Rosmarin, 2018). Perhaps clinicians may also consider administering subscales from the Religious Coping Questionnaire (RCOPE) (Pargament et al., 1998; Pargament et al., 2000) or Religious and Spiritual Struggles (RSS) Scale (Exline et al., 2014) to initiate a conversation related to r/s. Asking questions and having a discussion surrounding Islam may not only foster greater quality of care but also help improve the quality of communication between the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

patient and clinician, which has been shown to mediate the relationship between religiousness and mental health symptoms among Muslim ICU patients (Bashar et al., 2018). Clinicians working closely with Muslim patients may develop a list of Qur'anic scripture and stories of the Prophet regarding health and illness and discuss what patients may find helpful in coping with their concerns. Moreover, providers and patients may work together in implementing spiritual interventions such as finding ways to promote patience and gratitude or practicing specific *dhikrs* or prayers.

Likewise, being respectful and mindful of religious issues may foster greater comfort among Muslims within the healthcare setting and potentially result in greater treatment adherence. For example, simply asking Muslim patients if they wish for a prayer area and, if so, providing a place for prayer may put some Muslims more at ease. Furthermore, providers may facilitate connecting Muslims with resources such as chaplain services within the healthcare setting or an Imam within the community, both of which may help Muslims to feel a sense of spiritual support or provide them with an opportunity to process their illness within an Islamic framework

At the same time, Muslims may present with more negative forms of religious coping and experience r/s struggles. In such cases, clinicians may help patients by providing a nonjudgmental, supportive stance. Prior studies among largely Christian samples have shown that many people see certain r/s struggles, such as anger toward God, as morally wrong (Exline, Kaplan, & Grubbs, 2012), and can benefit greatly from having these struggles normalized (Exline & Grubbs, 2011). As such, Muslim clients may benefit from being reminded that many people, including Muslims (e.g., Saritoprak & Exline, 2016), experience r/s struggles (e.g., Abu-Raiya, Pargament, Krause, & Ironson, 2015) and by framing such struggles not only as acceptable but as possible avenues for growth.

Clinicians may also work with Muslims in processing and framing struggles within an Islamic framework to cultivate meaning. For example, providers may integrate Islamic sources into their clinical work and consider addressing the struggles through referencing Qur'anic scriptures that promote hope and trust in God such as "..indeed, with hardship will be ease" (94:5) or scriptures that promote God's mercy despite perceived transgressions, such as in the verse "…who have transgressed against themselves by sinning, do not despair of the mercy of Allah. Indeed, Allah forgives all sins. Indeed, it is He who is the Forgiving, the Merciful" (39:53). Clinicians can also explore stories of the Prophets in Islam and process the struggles and difficulties they experienced despite being the chosen loved ones of God. Patients may identify with the belief that God tests the ones He loves in this world.

A failure to recognize and/or incorporate Muslims' religious beliefs and practices within clinical practice may contribute to increased feelings of bias, discrimination, or a lack of feeling understood among Muslim patients (See Haque, Tubbs, Kahumoku-Fessler, & Brown, 2019 for specific client-centered recommendations on coping with discrimination). Such negative experiences can not only lessen Muslims' likelihood of utilizing healthcare services but may also increase Muslims' vigilance and suspicion (Rippy & Newman, 2006), lack of willingness to engage in activities (Livengood, & Stodolska, 2004), and symptoms of depression (Hodge, Zidan, & Husain, 2015). Thus, addressing r/s may play a vital role in fostering higher quality and more culturally sensitive care.

CONCLUSION

As the Muslim population continues to grow around the globe, understanding and addressing the gaps in healthcare service will be of even more importance. Currently, research suggests low rates of healthcare

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

utilization among Muslims, specifically in places where Muslims are of a minority status. There may be several factors that influence Muslims' healthcare utilization such as a sense of mistrust, perceived discrimination, and stigma associated with seeking help. Notably, several studies conducted among Muslims suggest that a lack of sensitivity and understanding of religious beliefs and values by providers to potentially be a barrier to seeking healthcare services and thereby contribute to Muslims' low rates of healthcare utilization; this may particularly be true for Muslims who express making use of Islam in their recovery process. Thus, an attempt to close the gap can be initiated through helping professions developing awareness and sensitivity towards the influence of Islam on health.

A biopsychosocial-spiritual model approach to healthcare is particularly pertinent to Muslims, as Islam fosters a holistic view of health which involves the mind, body, and spirit. Given Muslims' perceived importance of religion, many Muslims are likely to make use of r/s beliefs in coping with their physical or psychological concerns. Although much of the religious coping by Muslims appears to be positive, many do report some level of r/s struggles as well. Given the potential for both positive and negative religious coping among Muslims, it is important for clinicians to be able to do assessments and interventions related to religious beliefs and coping strategies in ways that are sensitive to Muslim belief and experience. For example, recommendations such as developing a culturally-sensitive case formulation, connecting Muslims with religious resources, and implementing spiritual interventions may not only increase utilization rates and provide better quality service to Muslims, but also potentially improve healthcare outcomes.

KEY TERMS AND DEFINITIONS

Dhikr: A form of ritual which involves the utterance and remembrance of God.

Dua: A prayer of supplication to God.

Hadith: Sayings of the Prophet Muhammad.

Islam: Submission and peace; also, refers to the second-largest religion in the world.

Qur'an: The sacred book of Islam revealed to the Prophet Muhammad and is believed to be the direct word of God.

Religious Coping: Methods grounded in religion and spirituality that are utilized when coping with a stressor.

Sunnah: Customs and practices of the Prophet Muhammad.

Tawakkul: Trust; reliance.

Chapter 56
Violence:
Mental Health, Family, and Media Reporting

Samuel Teague
Swinburne University, Australia

Peter Robinson
Swinburne University, Australia

ABSTRACT

This chapter explores the extent to which journalists draw on long-standing mental health narratives when telling their stories about the "mentally ill" and, in particular, their tendency to depict the mentally ill as violent and dangerous. The chapter is divided into three sub-categories based on the perpetrators of violent crime committed against members of their immediate family. These were "fathers," of which 24 articles were dedicated to the stories of 11 men; "mothers," where 22 articles documented the stories of 24 mothers who harmed their children; and finally, "progeny," where 58 articles presented 17 cases of sons or daughters who killed, or planned to kill, one or both of their parents. Despite differences in the way Australian journalists explain the violence depicted in these stories, particularly when the perpetrator was a female, they continually drew on mental health as an explanatory device to account for how and why these crimes took place. This provides evidence for a continuation of the confinement narrative presented in Chapter 1.

INTRODUCTION

The stories told in this chapter represent a continuation of the history of confining the mentally ill person, albeit in an invisible form presented in Chapter 1 of this text. In the years preceding the fifteenth century, the mentally ill were placed on boats and dumped on foreign lands. The seventeenth century saw institutions formerly built for lepers come to house the mentally ill and any other minority that threatened enlightened progress. The twentieth century witnessed the four-walls confinement of the asylum overtaken by the segregation of the doctor-patient relationship and medicalization. This chapter

illustrates the emergence of a complementary form of confinement – that of the stigmatized identity – reinforced through the telling of stories that use mental illness as an explanation for violent crime in the media. The purpose of this chapter is to assess the extent to which journalists draw on historically-derived mental health narratives when telling their stories about the mentally ill, and in particular, their tendency to depict the mentally ill as violent and dangerous. It is therefore a broad study focused on all types of mental disorder. Three cases involving fathers are presented followed by two cases involving mothers and four cases involving progeny. The chapter adopts Mindframe's guidelines for mental health reporting that recommend using language that separates an individual from their experience of mental illness (Hunter Institute of Mental Health, 2014). For example, describing a person as "having been diagnosed and treated for paranoid schizophrenia" is a more sensitive description than using the description "a paranoid schizophrenic". The authors have chosen to preserve the use of the phrase "the mentally ill" when it has been used by the journalist whose reporting is the subject of examination.

BACKGROUND

Author and journalist Sonya Voumard (2016) wrote about the intricacies of constructing news stories in her work entitled *The Media and the Massacre*. She wrote the following in regard to how journalists can use accounts provided by interviewees:

As a journalist you want something out of a subject: good quotes, insights, preferably controversial material. You must strike a rapport, conversationally win over the subject … Back at the office, the reality hits that journalism is an inexact science with great limitations. Variables like space, time, objectivity, editors and other points of view mean you can never guarantee that you will tell the exact story the subject wants told … you reject what you don't want, select and prioritize what you do.

Voumard's argument offers insight into the reality of assembling newspaper articles for print or online publication. Most revealing is the statement "you reject what you don't want, select and prioritize what you do". The analysis presented in this chapter offers support for this practice, evidenced in the way the mental health explanatory narrative was used differently across the mothers and fathers samples. It is remarkable how often journalists chose to select and prioritize mental illness in stories of violent crime and murder, and this was most evident in those articles devoted to mothers who killed their children.

This chapter is about storytelling, and in particular, the extent to which Australian journalists draw on mental health narratives when they tell their stories about the mentally ill. As explained in Chapter One, these narratives have changed over time, but still operate today in both subtle and overt ways. The authors conduct an analysis of the way journalists draw on and inform these narratives using discourse and narrative analysis techniques. The articles included in the analysis were collected from eight hard-copy Australian newspapers sourced through Factiva. Factiva was used to source articles published between November 2000 and May 2015. The analysis sourced those pieces containing both search terms "mental illness" and "mentally ill". Hard copy was chosen as it is considered a "trusted" source of news compared with online news mediums.

FATHERS

Case 1: Bribie Island, Queensland, Australia

The fathers sample contains eleven individual cases, three of which are addressed in this section. Five articles published between January 2008 and April 2009 told the story of a 39-year-old unemployed man who moved his family into a holiday home on Bribie Island and within days raped and murdered his 10-year-old daughter. Three of these articles were published in *The Courier-Mail* (Jan. 2008, Apl. 2009) and two in *The Australian* (Jan. 2008). The broad focus of this sub-sample was on a neglected health system and most representative of this narrative was Margaret Wenham's (2009) article entitled "System failure – warnings ignored before man raped and killed daughter". Wenham summarized the crime as follows:

The state's largest hospital was warned, so were police and a doctor, but no one stopped a mentally ill man from taking a family holiday which ended with him raping and killing his 10-year-old daughter.

Wenham reported that the unnamed father had been sole custodian of his four children since 2004 before he "ritualistically killed his daughter and spared her three younger siblings". Details of the graphic nature of this crime were a central component in the five articles that reported on this case, along with frequent mention of a "communications breakdown within the public sector" and persistent "underfunding"; descriptions which portrayed the rape and murder as the result of a neglected health system, one that failed to control a violent individual.

Co-authors Margaret Wenham and Janelle Mills argued in *The Courier-Mail* on 25 April 2009 that even an improved Queensland health system would not prevent a similar event from occurring again. This argument had been presented previously in an editorial published in *The Australian* in January 2008, which argued that "no system, however watertight, can prevent some dysfunctional individuals in fraught situations from harming those around them". The editors argued in this piece that "the frequent connection between mental health and violent crime [needs] to be addressed", and this statement was reinforced in four of the five articles that reported on the Bribie Island murder. While these articles explored some aspects of the broader social context that contributed to the murder of a 10-year-old girl, the journalists framed this broader context as relevant only in its ability to control a mentally ill man, who, without medication and/or involuntary admission to a mental health triage center, would be violent. Just one article addressed the reality of the link between mental illness and violence:

Crime and mental illness do not automatically go together. And anyone who does suffer from mental illness of whatever description has every right to be treated with compassion and sensitivity. (The Courier-Mail, 2008)

The effect of this statement is to remind the reader that while the crime was abhorrent, the case may not necessarily reflect the broader experience of mental illness. Short statements like this help to reduce the spread of stereotypes surrounding individuals with mental illness and their tendency to engage in violent criminal behaviour.

The editorial published in *The Australian* on 4 January 2008, entitled "Lessons must come from tragedy", shifted the focus from the publication's belief that a neglected health system led to this crime,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to the safety of children who have mentally ill parents, and this relates to the principal argument of this section concerning the tendency for journalists to report abhorrent cases, and frame them as representative of broader social problems. The editors presented the Bribie Island murder alongside a number of other violent crimes, and in doing so, portrayed them as mental health cases. They wrote that "a report tabled in Queensland parliament in November [2007] revealed that 57 children known to the Department of Child Safety died in 2006-2007". It is unclear how many of these deaths were at the hands of parents being treated for mental illness. This detail was not mentioned and instead the editors continued with a discussion of how the problem was one that extended beyond Queensland's borders:

In Victoria in 2006, serial rapist William Craig Forde told a prison psychologist before he was released from jail that he would rape again. Three months later he took a young Ballarat mother captive at knife-point and raped her repeatedly during a 29-hour ordeal.

It is not clear how the actions of "serial rapist" William Craig Forde relate to the Bribie Island murder. Because the Bribie Island story is framed as a case of a mentally ill father raping and killing his daughter, one must assume that the additional stories and statistics presented by the editors are also related to mental illness and have been included to strengthen the claim that mental illness can help to explain violence. This point was not stated explicitly in the article, but was implied when the authors stated that "Prime Minister Kevin Rudd [would] inevitably need to look at care for the mentally ill". It is not unreasonable for a journalist to argue that a health system has been neglected, or an underfunded sector needs reform. But it harms the public's image of those being treated for mental illness to conflate mental illness and violence without an appreciation for the broader social context within which these crimes take place. Without consideration of other possible explanations for violent crime, the mental health narrative can continue to foster a belief in society, among lawyers, judges, journalists, academics, and the general public, that mental illness explains violent crime in domestic settings.

Case 2: Tyabb, Victoria, Australia

The second case that involved a father killing one or more of his children was no less graphic than the Bribie Island murder. In a summary of the death of 11-year-old Luke Batty, John Silvester portrayed Luke's father, Greg Anderson, as a man with motive. Silvester reported in *The Age* (2014) that after leaving his Frankston accommodation on 12 February 2014, Anderson "told fellow residents he would not be coming back". He concealed a knife in his backpack, caught public transport to Tyabb Recreation Reserve, and "it was there the mentally ill Anderson killed his son".

Silvester outlined some of the broader social circumstances involved in this case. He described Greg Anderson as "alone", "unemployed", and "unemployable". According to Silvester's account, jobs had dried up, Anderson's marriage to Rosie Batty had ended, and "he knew he would never be granted shared custody of his son or even allowed overnight visits". These details are important as they offer the reader a picture of the circumstances of Luke Batty's death, and, perhaps, the father's state of mind. Yet despite consistent reference to the social stressors involved, Silvester still asserted that the young boy's death was an outcome of mental illness. He explained that Anderson's plan was "borne from madness … he knew his tenuous links to his son were fraying [and] through the fog of his mental illness he saw it as the only possible release for both of them".

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Silvester also portrayed Batty's death as reflective of a broader social problem concerning "the mentally ill", a method used by journalists who reported on the Bribie Island murder. Where the actions of the Bribie Island father were portrayed as the result of a neglected health system, John Silvester presented Greg Anderson as representative of other violent mentally ill individuals. He assumed a similar link between mental illness and violence as was assumed by the writers of *The Australian* when they tried to account for the Bribie Island murder:

The real issue is our inability to deal with the mentally ill, and the problem is getting worse. It is a massive problem, so much so that all police are being retrained to deal with the deeply disturbed. In 2009 the police dealt with 4798 people so disturbed they were taken to a mental health triage center.

By including these statistics, where 4798 individuals were involved in incidents so problematic they required intervention from law enforcement, Silvester implied that there is a casual link between mental illness and violence. Of the 4798 "deeply disturbed" individuals mentioned above, one could assume that their stories offer a deeper complexity than could be explained by a diagnosis of mental illness. Some individuals may be homeless, some addicted to illicit substances, some mentally ill, and any of these three in isolation would be incapable of explaining the malicious crime depicted in these articles. This lack of complexity illustrates the dangers present in relying on police testimony and court transcripts to construct stories for newspapers. While police have an important and often difficult role to play in incidents like the one that took place at Tyabb Recreation Reserve, where Luke Batty was murdered, they are not trained in diagnosing mental illness, and their appreciation for the broader contexts involved in crime often appears to be obscured by their tendency to make a layman's judgement about the mental state of male perpetrators of violent crime in domestic settings.

A similar pattern where journalists described an abhorrent event and portrayed it as representative of a broader social problem was present in *The Age* editorial published in February 2014, entitled "A bereft mother's insightful message". Its purpose was to commend Rosie Batty, who spoke to media less than 24 hours after the death of her son to explain that "no one loved Luke more than his father … I want to tell everybody that family violence happens to everybody, no matter how nice your house is, no matter how intelligent you are". If the editors had followed Rosie Batty's narrative, this article would have focused on the problem of family violence, yet two sub-sections, one that outlined family violence statistics and the other that paired these statistics with mental illness, dominated the 637-word editorial. In one paragraph, the authors explained that "family violence was involved in 80 per cent of child deaths … in 2013, up from 62 per cent in 2010". The following paragraph stated that "this year, 4 million Australians will have mental health problems … half of us will encounter such difficulty at some stage in our lives". The placement of these statistics can again have the effect of reinforcing a causal relationship between mental illness and family violence. The significance of this relationship, however, is dubious at best. While a large portion of Australians will deal with a personal experience of mental illness across their lifetime, the vast majority of this group will never engage in family violence. Is it not conceivable that the small percentage that do, do so for reasons beyond their mental illness? The murder of Luke Batty at the hands of his father might represent an intersection of family violence and mental illness, but the extent to which this story is reflective of most cases of family violence is questionable, and to reinforce the "mental illness-family violence" relationship is to offer an explanation to all perpetrators of abuse.

Case 3: Melbourne, Victoria, Australia

At 9.15am on 29 January 2009, Arthur Freeman threw his daughter Darcey from Melbourne's West Gate Bridge. The sample contained four articles which addressed varying aspects of this event (*The Age*, Mar. and May 2011, Aug. 2014; *The Herald Sun*, June 2010). In 2011, Andrea Petrie was the Supreme Court reporter for *The Age*. Her piece was a 1636-word summary of Darcey's death, and the discussion that took place in the Supreme Court two years later. Petrie's emotive opening sets the tone for the rest of the piece:

The only thing cold on the morning of January 29, 2009, was the heart of Arthur Phillip Freeman. But the nation felt a chill of horror when news broke that a little girl had been thrown off Melbourne's West Gate Bridge. Dozens of people in peak-hour traffic at 9.15am saw her tossed over the railing "like a rag doll". It was such a long way to fall: 58 meters. She sustained massive internal injuries and ultimately drowned.

In contrast with the sample that reported on mothers who took the lives of their children, explored in the following section of this chapter, Petrie's article represents an inclination of some reporters to provide multiple explanations for murders that are committed by fathers against their children. Where it appears unfathomable that a mother would knowingly and intentionally take the life of her child, Petrie presented an image of Freeman as possibly mentally ill, but more likely "cold" and "motivated by spousal revenge". This narrative is exclusive to the fathers sample.

Petrie began her analysis by quoting defence lawyer David Brustman, who asked in court whether Freeman was "mad" or "bad", and then argued that the father's actions were unintentional, unconscious, involuntary, and the result of a "highly disordered mind, a mind suffering mental illness". Petrie then contrasted this observation with the prosecution's claim that Freeman was "angry at his ex-wife" and "deliberately threw his daughter off the bridge because he was motivated by spousal revenge". The article underpinned this view with a quote from a relative of Arthur Freeman, who asked to remain unnamed:

A relative of Freeman's … has told The Age of a comment the father-of-three made at a family dinner at the height of his custody concerns in 2008. "We were discussing the custody of his children, and Arthur said 'She [his ex-wife] would regret it if he lost custody of the children' … it was only later that the comment began to play over and over in my mind".

This comment was representative of a broader stance the author took in this article. While even weight was given to all aspects of the trial, Petrie was transparent in her belief that Freeman acted knowingly when killing his daughter. This is significant as it contrasts with the central argument of this chapter; that mental illness is used as a default explanatory device to explain abhorrent events when no clear explanation is available to the journalist or the reader. In the case of Arthur Freeman, the presence of a mental illness was debated, and its relevance to the crime committed was obscured by a focus on "spousal revenge".

An interesting narrative that ran through the four articles that dealt with this case was the reputation of Professor Graham Burrows, described by Andrea Petrie as "the only one of six psychiatrists to conclude Freeman did not know what he was doing was wrong". According to Petrie, Professor Burrows had testified that the perpetrator "was suffering from a major depressive disorder at the time of the crime …

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

was psychotic, out of touch with reality and was in a dissociative state". Yet the reputation of Burrows was questioned and then attacked in the next two articles, one published in *The Age* on 12 May 2011 and the other in *The Herald Sun* on 23 June 2011. *The Age* journalist Selma Milovanovic reported that a Liberal MP "accused Professor Graham Burrows of giving concocted evidence at the trial of Arthur Freeman". This article was titled "Expert witness in Freeman case should be sacked: MP". *The Herald Sun* provided additional evidence one month later, compounding this attack on Burrows. Lucie Van den Berg reported:

The Medical Board is monitoring allegations made by patients against high profile psychiatrist Professor Graham Burrows to determine what action may be necessary to protect the public. A Seven News Investigation raised a list of allegations against the doctor including over-medication of drugs, consultations of 30 seconds and a conflict of interest involving pharmaceutical companies.

The effect of these two articles, alongside Petrie's commentary on the event and the subsequent court case, was to discredit the defence witness in the Arthur Freeman trial. In contrast with the articles explored in the following section, there was an apparent reluctance on the part of the journalist to attribute Freeman's actions to mental illness. This is significant in its distinction with the rest of the sample, where consistently Australian journalists tend to draw on the mental health narrative as a means to explain abhorrent or abnormal behaviour. It would appear that in cases like that of Arthur Freeman, where a father has taken the life of a child, other explanations are likely to be explored and/or offered, and the mental illness explanation is not so readily the "default' stance". In the following section this trend is contrasted with 22 articles that reported on mothers who took the lives of their children.

MOTHERS

The articles that reported on mothers who killed their children are best considered in light of research relating to our constructed understanding of women and their role in western culture. American sociologist Arlie Hochschild's (1979) term for the unpaid domestic labour that falls predominantly on the shoulders of women is "emotion work", and George Levinger (1964) argued in his study on social behaviour in marriage that this work, which includes maintenance of family emotions and interpersonal relationships, has been an aspect of married life in the west since the middle of the twentieth century. Where this relationship has long been interpreted as a product of the "male breadwinner-female nurturer" model, today, women who are engaged in full time paid employment still take on the bulk of routine housework and childcare.

Rebecca Erickson (2005) argues that it is the socio-cultural construction of gender roles that informs this unequal division, meaning we generally come to see being an emotional caretaker as "something women *are* rather than something women *do*" (p. 349). A woman's performance in the household is interpreted as a "natural" expression of her love for her partner and her children, and Erickson (2005) explains that some women are driving this understanding:

Women themselves often discount the time and effort involved in caring work not only because it is expected to be a spontaneous expression of love but also because the illusion of effortlessness is part of doing the work well. (p. 338)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

For many women, performing household labour with ease has become a core aspect of their identity construction. One must also consider the weight of traditional beliefs and theories of socialization that assert women continue to perform most of the work associated with "being female" because it is to these tasks that they are most suited (Erikson, 2005, p. 340). While this perspective is supremely archaic, some of this sentiment persists in the west.

It is in this context that 22 articles were examined, which documented the stories of 24 mothers who harmed their children. This is more than double the number of stories dedicated to fathers who killed their kids, of which there were eleven men in total. This group contained nine articles where mothers heard voices and/or messages from God compelling them to harm their children, while in all but three of the 22 articles the crime was murder. This section examines the reporting identified as unique to this sub-sample of articles that reported on mothers who murdered their children, and in particular, the tendency for journalists to portray mothers as psychotic and delusional, and to be more sympathetic to the plight of mentally ill mothers than fathers. Following is an analysis of those nine articles that involved mothers who reportedly heard voices that compelled them to kill their children.

Case 1: Houston, Texas, United States of America

On 20 June 2001, Andrea Yates drowned her five children in the bathtub of their home in Houston, Texas. The story gained national prominence across North America, and was overshadowed only briefly by the attacks on the World Trade Centre in New York City and the Pentagon in Washington on 9 September 2001. Journalist Andrew Cohen wrote in 2012 that a hearing to determine Yates's competency to stand trial for the murder of her five children was cancelled on September 11 because of the attacks. Two articles from the sample of eight east-coast Australian newspapers documented her crime (*The Australian*, 6 Dec. 2001; *The Herald Sun*, 20 Mar. 2002). *The Australian* ran the headline "Mama's deadly state of mind", and described the case as follows:

What police found inside the Yates's modest home shocked the nation. Neatly lined up under a sheet on a bed were the still-wet bodies of the couple's four youngest children: Mary, 6 months, Luke, 2, Paul, 3, and John, 5. Their eldest child, Noah, 7, was still in the bathtub in which Yates had drowned her children. Seeing what was happening to his siblings, Noah tried to run – but Yates chased and caught him.

Yates was described by the editors of *The Australian* as having suffered from "a bout of post-partum depression so devastating, so mind-altering, that she was incapable of judging right from wrong". She told psychologist Steven Rubenzer in one of eight interviews in Houston's Harris County Jail – where she was held and treated with anti-psychotic medication following her arrest – that she believed she was "Satan … George Bush will kill Satan", in the belief that the President at that time was still the governor of her home state. The editors portrayed Yates's actions as irrational, delusional, and the result of mental illness, and claimed "few would disagree that Yates is mentally ill. Her 1000-page medical record chronicles … a history of severe depression marked by delusional episodes". They then drew on statistics from "health experts" to support the link they were wanting to make between mental illness and the death of Yates's five children:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Health experts estimate about 40 per cent of women experience mood swings after having a baby ... However about two women in every 1000 ... can become delusional, have visions and hear voices urging them to harm themselves or their babies.

The Diagnostic and Statistical Manual of Mental Disorders (DSM-V) (APA, 2013) notes that depressive episodes that include psychotic features during pregnancy or following the birth of a child occur in 'from 1 in 500 to 1 in 1000 deliveries' (cited in Stone, 2013) and may be more common for women having their first child. Even though the statistics the editors cited were at odds with those from the DSM-V, they still portrayed the case as rare, and this appeared to be one moment in the article where the authors had the opportunity to emphasize and reiterate the extraordinary nature of Yates's crime in the broader story of mental illness. That Yates was severely mentally ill appears to be beyond dispute, but again, the fact is, the majority of severely mentally ill people would never contemplate a crime of this magnitude, and in the case of women who give birth, this story is exceptionally rare.

The editors that documented Yates's crime used mental illness as a default explanation for violence. The editorial published in *The Australian* in 2001 quoted Dianne Clements, from a Texas-based victims' rights group known as Justice For All, who argued that we "just can't conceive of someone in their right mind doing what [Yates] did". The previous analysis of the fathers sample showed that journalists can conceive of fathers committing the same acts in their "right mind". They seem to find it easier to imagine a father committing a similar act of violence deliberately and knowingly against his own children. Arthur Freeman, for example, was portrayed as someone "motivated by spousal revenge" when he threw his daughter Darcey off the West Gate Bridge. And journalist John Silvester framed Greg Anderson's "descent into homicidal madness" as calculated and deliberate. Anderson told fellow residents at his Frankston accommodation house that he "would not be coming back", and then took his son's life with a knife he had stowed in his backpack. Even the story of Robert Farquharson (Garner, 2014), the man who drove his three children into a dam between Geelong and Winchelsea on Father's Day in 2005, while not a mental health story in this sample, was still portrayed as a deliberate murderous act by an embittered and estranged father. Mothers from this sample, like Andrea Yates, are defined by contrast as psychotic, hearing voices, and out of control, and mental illness is presented as the only plausible explanation for their actions.

Case 2: Sydney, New South Wales, Australia

Shan Shan Xu was another mother who reportedly heard voices that compelled her to harm her child. She drowned her four-year-old son in 2003 and was later found not guilty by reason of mental impairment. John Stapleton followed Xu's trial in the NSW Supreme Court, and reported in *The Australian* on 19 February 2005 that after making suicide threats in 2002, Xu was admitted to the Caritas Centre, an acute-psychiatric unit in NSW. It was here that the hospital noted she had "thoughts of killing herself and her son … and sees nothing wrong with this". An interesting aspect of this article is the way Stapleton presented evidence he sourced from the NSW Supreme Court trial. He portrayed Xu as having acted in a calculated manner when she drowned her son, and then overlooked any further discussion on the perpetrator's mental culpability in committing this crime. Stapleton (2005) reported that:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

[Xu left] a note for her mother that said they would not be returning home to their western Sydney unit. "We are not coming back home. Please look after yourself. Just treat it as if we'd had an accident. I've really had enough", the note said.

Stapleton reported that Justice David Kirby oversaw this trial and accepted the evidence of two forensic psychiatrists that Xu "was suffering [from] a major depressive illness" at the time of the murder. This conclusion was reported by Stapleton but not given the subsequent analysis and discussion it deserved, and that I suspect it would have received had the perpetrator been a father. Instead of a debate about the mental health of the perpetrator, as was present in the case of Arthur Freeman, Stapleton concluded by using mental illness as an explanation for the crime. Stapleton did not point out that these sorts of crimes are extremely rare, and occur in roughly one in a thousand births. He also overlooked evidence that suggests when mothers do kill their children in circumstances like that presented in the cases of Andrea Yates, Christine Gifford, and Dena Schlosser, they often experience acute psychotic symptoms (Wondemaghen, 2013). One could argue that the scarcity of discussion presented in Stapleton's article reflects the Australian legal system's understanding of the killing of children by their parents. Section 6 of the Crimes Act (1958) (FindLaw Australia, 2017) defines infanticide as follows:

If a woman carries out conduct that causes the death of her child in circumstances that would constitute murder and, at the time of carrying out the conduct, the balance of her mind was disturbed because of: (a) her not having fully recovered from the effect of giving birth to that child within the preceding 2 years, or; (b) a disorder consequent on her giving birth to that child within the preceding 2 years.

This definition is significant because it provides for a defence of infanticide only in cases involving mothers. This suggests the disparate discussions surrounding mental culpability for mothers and fathers who kill their children could be reflective of the understandings of these crimes as they are presented in court.

While there were differences in the way journalists reported on mothers and fathers who took the lives of their children, some common reporting methods were evident across these two categories. The analysis showed that journalists who write about either mothers or fathers who have killed their children tend to use additional examples of what they perceive are cases of mental-health-related violence as a means of adding interesting or valuable content/context to an article. Andrea Yates's case is not used as an exemplar, or as evidence of a broader problem involving the mentally ill, but the authors of the editorial published in *The Australian* in 2001 did document other cases where mothers and/or spouses "got off" using a "not guilty by reason of mental impairment" defence. The editors reported:

Lorena Bobbitt, who cut off her husband's penis, got off. Susan Smith, who drowned her two sons by strapping them into the back seat of her car and rolling it into a lake, did not.

This technique was common across many articles in the family violence sample, with these stories seemingly used as a means to sensationalize and dramatize a story. Their purpose appears to be not to inform the reader, but to excite and incite (Uribe & Gunter, 2007).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Gendered Reporting

This analysis of cases where mothers heard voices that compelled them to harm or kill their children illustrates a clear distinction between two types of reporting: one involving fathers who murder their children, and the other involving mothers. While mental illness was the "default" position most frequently used by journalists to explain violent crime, the tendency to use this explanation was dependent on the identity of the perpetrator of the violent act. The notion of spousal revenge, preferable in cases involving fathers, was never used in the 22 articles that are the subject of this section of the chapter on mothers, as women were instead portrayed as generally psychotic, hearing voices, and in touch with a God who compelled them to kill their children. One could contextualize these reporting trends in the context of concrete social phenomena: first, that men are incapable of experiencing postpartum psychosis, and second, that men are more likely to be motivated by spousal revenge because they are more often rejected in their quests for custody of their children. But as feminist and writer Elaine Showalter (1987) argued in *The Female Malady*, attributing types of mental illness to some form of gendered psychology is a dangerous practice, one that has been common for many centuries and has disadvantaged women through the reinforcement of an "hysterical" woman narrative. What an analysis of this sample has shown is that journalists have overemphasized a very rare form of psychotic disorder, one that affects women giving birth at a rate somewhere between one in five hundred and one in one thousand. One could safely assume that the percentage of these mothers who act on voices that command them to harm their children is even more rare. Slightly less than half of the mothers sample accounted for women who heard voices. While these articles were accurate in their coverage of events, no piece contained a clear statement referring to the rarity of the case in question, or how it failed to reflect the broader reality of mental illness.

Mad or Bad

Concluding this section on mothers is an analysis of three newspaper articles that told the story of 31-year-old Louise Scotchmer, who killed her two-week-old son Shane in 1994 and 13-month-old daughter Melissa in 1996. Scotchmer was not charged with these murders until 2001, after she "drunkenly confessed" the crime to her husband. The three articles that reported on this crime were published in March 2003, two in *The Australian* and one in *The Herald Sun.* An account of this story contrasts with previous articles examined in this chapter, because while the three articles stated that Scotchmer committed the murders while in a "disassociated trance-like state", they explored the broader social circumstances involved in the crime, and so framed the killer as a victim.

Vanda Carson wrote in *The Australian* in March 2003 that Scotchmer's brother and husband planned to continue supporting the 31-year-old perpetrator because she had experienced "a horrible life and needed more support from mental health professionals". Scotchmer's younger brother, Anthony Gordon, was a central figure in both articles published in *The Australian*, and Carson used Gordon's commentary to structure a large portion of the piece:

Mr Gordon said the prison system had not been able to provide appropriate treatment for his sister's mental illness since she was detained in September last year [2002]. He said Scotchmer had been physically and sexually abused as a child and had been let down by the mental health system since her first counselling session as a five-year-old.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Vanda Carson also wrote the second article published in *The Australian*. The failing health system was the focus of this article, as the headline read: "Mental health system 'failed' mother jailed for killing babies". *The Herald Sun* focused on Scotchmer's husband in the same way *The Australian* made use of Scotchmer's brother, Anthony Gordon.

Mr Scotchmer, 49, said the sentence was unfair and he would support his wife, who engaged in acts of self-harm and was "quite fragile mentally". He said he was able to forgive her "because I don't believe she was in a normal frame of mind when she committed those acts". Mr Scotchmer said the surviving child, Jamie, visited his mother every fortnight.

The analysis presented here considers these three articles as an interwoven mosaic. The backdrop is the research presented to open this section concerning emotion work and traditional interpretations of women's "natural" role as nurturers and carers. These three articles, and their framing of the Scotchmer case, are placed within the context of that literature. It is difficult to comprehend a mother killing her children, but the framing in these articles is such that the mother, the killer, has become the only victim. A quantitative analysis of the type of language used in these three pieces showed that a total of 26 words were dedicated to the two children who died, two-week-old son Shane and 13-month-old daughter Melissa. This is a fraction of the 1055 words devoted to this story. We hear virtually nothing about the children and learn little of their short lives. The overwhelming majority of the content presented to the reader is instead devoted to Scotchmer's treatment, the support her family has and continues to provide her, her own history of physical and sexual trauma, and the fact she is "mentally fragile" and engaging in acts of self-harm.

In cases where a parent takes the life of his/her child, there are multiple victims, yet in the three articles examined above, Scotchmer appears as the sole victim, and the perpetrator is her mental illness. The children Scotchmer killed are mentioned infrequently and are secondary in the framing of this story. This contrasts with those pieces presented in the fathers sample, where the deceased are central figures, and they are remembered: Luke Batty, Darcey Freeman. The fathers are portrayed as lonely, unemployed, mentally ill, and often revenge-driven men with motive. The antithesis of a victim. In contrast, mental illness in women appears as tragic, and this would perhaps explain the "victim status" some have received in the articles explored in this chapter. The question "Was she mad or bad?" is rarely raised because our socio-cultural understanding of women and mothers tells us that no woman in her "right mind" could take the life of her child. This was most evident in the Scotchmer case, and also John Stapleton's account of Shan Shan Xu, who left a note for her family explaining that she would not return home as she intended to drown herself and her four-year-old son. The intention and calculation evident in this act did not prevent Stapleton from concluding that Shan Shan Xu was mentally ill at the time of the killing, and that this explains the crime. In men, mental illness is more appalling. Fathers are still described as mentally ill, but are portrayed as colder and more calculated killers, and are more often defined as "bad".

PROGENY

The final section of this chapter examines 58 articles that presented accounts of sons or daughters who killed their parents. A total of thirty-three articles from this progeny group were dedicated to four individual murder cases, suggesting that while this sub-sample is much larger than the fathers and mothers groups examined earlier in this chapter, its size is reflective of a more pronounced coverage of these four particular stories in Australian newspapers. These four cases are explored in this section,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and they include the stories of Mark Briscoe, a "criminally insane killer" who took the life of his father "with a cane knife" and five years later escaped from a Brisbane mental health facility; Kylie Fitter, the 15-year-old girl who helped her older brother and father kill her mother in the New South Wales town of Glossodia in October 2001; Malcolm Robert Potts, a "paranoid schizophrenic" who killed his father following an argument over a birthday present; and Anthony Waterlow, another person reported as a "paranoid schizophrenic", who killed both his father and his sister.

Case 1: Brisbane, Queensland, Australia

Between January 2002 and February 2003, eight articles reported on "criminally insane killer" Mark Briscoe and his escape from a Brisbane mental health facility, with seven of these published in *The Courier-Mail*, and one in *The Australian*. Mark Briscoe went missing on 18 January 2002 for a total of 83 hours after being last seen eating lunch at Wolston Park mental health facility in Brisbane. Slightly short of a non-event, Briscoe never left the grounds of the facility. Wayne Smith reported for *The Courier-Mail* on 24 January 2002 that Briscoe appeared to have taken refuge in a cricket pavilion before he was found:

A fellow patient saw him there and telephoned The Hub … where two registered nurses and an enrolled nurse were on duty. They immediately called the three rostered security staff who quickly made their way to Jacaranda House. Not finding Briscoe there, they looked outside and saw him about 100m away on a grassed area … "Mark, where are you going?" one of them called. Briscoe stopped, turned, and then came over to them. There was no violence used by or against him and he walked meekly with nurses and security staff to the vehicle that took him to the high security unit. He told staff he was sorry he had caused them any concern but had wanted to spend some time alone.

Briscoe never left the 320 hectares hospital grounds, yet the coverage in response to this event was alarmist and fear inducing. Three articles published in the days following his "escape" and "recapture" described Briscoe as a "criminally insane killer", three as a "mentally ill killer", and two as "a paranoid schizophrenic", descriptions in stark contrast with *Mindframe's* guidelines for mental health reporting. To compound this prescribed identity were the descriptions of the crime committed by Briscoe in 1997, which lead to his admission to Wolston Park. Two articles published in *The Courier-Mail* in 2002 reported that "he beheaded his father with a cane knife", Chris Jones described Briscoe as "a paranoid schizophrenic who hacked off his clergyman father's head", while *The Australian* stated more plainly that "[Briscoe] killed his father with a cane knife". A cane knife is similar to a machete, and to be beheaded is to have one's head completely separated from his/her body. The effect of the language used by journalists reporting on this case is to convey a barbaric and brutal image of Briscoe's crime. A description of the brutality of the crime solidifies the legitimacy of the community safety narrative being presented in these articles; the more dangerous the man who committed the murder, the more reason to fear for public safety. The language used by journalists who reported on this case reinforced the supposed danger Briscoe posed to the general public.

And so, upon the descriptive foundations of a barbaric murder that took place five years earlier, the journalists framed their articles on Briscoe's escape from a Brisbane mental health facility around the issue of public safety. *The Courier-Mail* noted that "understandably, the community was alarmed by Briscoe's disappearance". Chris Jones drew on Premier Peter Beattie's response to the event, and framed his comments in the context of concerns for public safety, saying "Mr Beattie conceded there was no

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

way to guarantee another criminally insane killer would not escape". Paula Doneman's response in *The Courier-Mail* (2002) mirrored Jones's:

While the Beattie Government has been using the soon-to-be implemented Mental Health Act as a shield to fend off criticism over the escapes, the truth is these provisions will not stop another determined killer from absconding.

This fear of determined killers undermining a neglected health system was drawn on and reinforced in articles examined earlier in this chapter, particularly in the cases of the unnamed Bribie Island father, who raped and murdered his daughter, and Greg Anderson, who killed his son. Wayne Smith's article published in *The Courier-Mail* in January 2002 reported that "from the community's viewpoint, the primary issue is not how such patients are returned but how they come to be in a position to go missing". The tone of all of these articles, coupled with descriptions of Briscoe's act as an "escape" and "recapture" situation, create a sense of an animal on the loose, one with the capability of inflicting indiscriminant violence on an unsuspecting public. The reality of this case is that Briscoe never left the grounds of Wolston Park. He was not violent, posed no threat, and hid in a cricket pavilion for the 83 hours he "went missing". Journalists took this event and turned it into a broader story about a crisis in Queensland, involving "determined killers" absconding from mental health facilities, and the danger they pose to an unsuspecting public.

Case 2: Sydney, New South Wales, Australia

The second case explored in this section of the chapter illustrates again how journalists tend to use mental illness to explain brutal crimes, even when this explanation appears insufficient. It also sheds light on the challenges journalists can face when constrained by sub-judice law. A particular crime is considered sub-judice when it is "before a judge", and sub-judice law is in place to prevent journalists publishing material that prejudices a fair trial, with punishment ranging from small fines to imprisonment (Pearson & Polden, 2011). In England and Wales, sub-judice law is applied when a case is "imminent", so when a crime has been committed but the suspect has not been apprehended, while in Australia the threshold is "pending", meaning that until an individual has been charged, journalists can report on a case and any relevant details without consequence. So, in the days before the apprehension of a suspect, journalists are free to document background information regarding the alleged offender and any additional details, such as criminal history or mental health status, identified as in the public's interest. As soon as that individual is charged, sub-judice law applies and journalists are restricted to documenting the facts of the case as they are presented in court.

If a case is before a judge, the journalist is restricted to reporting only on the facts presented within the courtroom. This constrains a journalist from engaging in deeper discussion and speculation about possible motives and likely causes of a crime. It restricts one from discussing the mental health history of an alleged killer if this is not a matter raised in court proceedings. It also allows for the identification of the accused as mentally ill, but then restricts the journalist from providing additional content if it was not raised before a jury.

The one newspaper article (*The Daily Telegraph,* 2 June 2001) that detailed the case of Malcolm Robert Potts contained similar reporting techniques to those that were described in the analysis of the Mark Briscoe case. Brad Clifton reported for *The Daily Telegraph* in 2002 that "an argument over a

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

son's failure to buy his father a worthwhile birthday present ended with one of the men being stabbed to death". The accused, Malcolm Robert Potts, was described by Clifton as a "paranoid schizophrenic". After giving his father an unsatisfactory birthday present, and being insulted for doing so, Potts "threw a shopping trolley at [him]" and sprayed him with a can of insecticide.

The language used in this particular article published in *The Daily Telegraph* was detailed and unambiguous. The purpose of describing the shopping trolley and can of insecticide as weapons is unclear, but the effect was to dramatize the event that took place. The fact the argument preceding the murder was based on a birthday present trivializes the death of the father, encouraging the reader to view the event as abnormal and exceedingly violent given the circumstances. The assertion is that the killer must have been insane. The article concludes that "the jury would be satisfied that Mr Potts [the perpetrator] was suffering from an abnormality of mind at the time of the killing". Mr Potts took the life of his father and was clearly very angry, potentially psychotic. But whether he suffered from a mental illness at the time of the killing, and whether his story is representative of the broader experience of most mentally ill Australians, must certainly be questioned.

What is clear from the article is that more information about the circumstances surrounding the murder is required. As was evident in the articles detailing the murders of Luke Batty and Darcey Freeman, the inclusion of one alleged diagnosis of mental illness does little to explain the extreme events that took place. In the case of Mr Potts, Brad Clifton offers a description of the trigger for the event – a disappointing birthday present – and two of the weapons involved in the attack, these being a shopping trolley and a can of insecticide. What these details suggest is a complex and tempestuous relationship between a father and his son, perhaps living on the margins of society. Certainly, the presence of a shopping trolley in the family home indicates some issues within the relationship that may have class origins. More contextual information is required, and this is something lacking in Clifton's account, one suspects as a result of the restrictions placed on journalists by sub-judice law. Clifton quoted Crown Prosecutor Terry Thorpe, who stated "Malcolm Potts is mentally ill … and has been since 1985". The presence of a mental illness that had persisted since 1985 is insufficient to explain the death of a father at the hand of his son.

The story of Malcolm Robert Potts illustrates both the need for improvement in some reporting methods, but also the constraints that are placed on journalists telling mental health stories that are also the subject of criminal proceedings in courts. Clifton's description of Potts as a paranoid schizophrenic reinforces the public's misunderstanding of mental illness as a life sentence. A more suitable choice of words might have been to describe Potts as "an individual being treated for, or diagnosed with, paranoid schizophrenia"; a description that separates the individual from their illness. Setting aside these concerns with language, Brad Clifton was clearly restricted in reporting only those facts that were subject to scrutiny within the court. Sub-judice law constrained Clifton's ability to provide these additional details and explore this case in-depth. While the article was still sensationalized, and the focus on a birthday present trivialized the murder of a father by his son, Clifton reported the facts of the case as they were presented in court.

Case 3: Glossodia, New South Wales, Australia

The third progeny case explored in this section is detailed in six articles published between August 2002 and March 2009 describing the murder of Fiona Fitter by her "estranged husband and two teenaged children". Two of these articles were published in 2002 in the months immediately following the killing, while the other four articles were published between 2006 and 2009, and shifted the focus from

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the circumstances surrounding the crime to the rights of Fiona's daughter, Kylie, who was involved in the murder and had been a resident of a mental health facility since her mother's death.

Fiona Fitter's death took place in the town of Glossodia in New South Wales on 16 October 2001. Both articles published in 2002, in the months immediately following the killing, presented mental illness as an explanation for the violent crime. Lorna Knowles's description of the event, published in *The Daily Telegraph*, is representative of both articles:

The victim came home from work. Neighbours said they saw her run screaming across the road, with her son in pursuit. She sought refuge in a neighbour's house but the two men – her son holding two carving knives in the shape of a cross – kicked the front door in and chased her outside. Witnesses said they saw the trio kick her on the ground … the daughter held both her mother's legs, while the husband and son bashed and stabbed her.

Knowles explained that the mother was killed because her husband and two children "believed she was a devil-worshipping witch", and all three would later plead not guilty "by reason of mental illness" in the NSW Supreme Court. The husband was described as a 40-year-old "cannabis dependent paranoid schizophrenic", his son, 18 years of age, "had attention deficit hyperactivity disorder and drug-induced psychosis", and his daughter "had learning difficulties and suffered depression".

It is unclear how relevant or reliable these diagnoses are. In considering the unnamed daughter's contribution to her mother's death, depression and learning difficulties are entirely insufficient to explain such actions. One has to wonder the effect of the association of this crime with the diagnoses offered by Knowles on those who suffer from clinical depression. For the victim's son, a diagnosis of attention deficit hyperactivity disorder could never legitimately explain or justify an individual's propensity for violence, and yet mental illness was still used by Knowles to explain the murder. The last line of the 384-word piece reads "the hearing will continue on Thursday", suggesting Knowles faced the same restriction as was faced by Brad Clifton, who reported on the murder committed by Malcolm Robert Potts, described in the previous section. This is a clear example of the restrictions of sub-judice law hindering a journalist from exploring the broader social circumstances involved in a crime. Knowles alludes to the fact that both the father and the son had been abusing drugs and that this could have induced a psychosis that led to the killing.

Like those journalists who reported on the Mark Briscoe case, Lorna Knowles made the decision to include details of the murder weapons and how they were used by the perpetrators in the murder. These were a "large carving knife" held by the son in the shape of a cross, and "a pair of surgical scissors", which were inserted up the victim's nose and "into her brain". How useful these details are for the reader's understanding of the event is unclear and their inclusion has only added to the sense of horror and terror that this story conveys. The four articles published between April 2006 and March 2009 shift the focus away from the horrific murder, and focus on the rights of Kylie Fitter, the 20-year-old daughter of the deceased victim. All four of these pieces were published in *The Sydney Morning Herald*, with three written by Adele Horin and one by health reporter Louise Hall. Unrestrained by the sub-judice restrictions faced by Lorna Knowles when she reported on this case in 2002, Horin's three articles described some of the broader circumstances involved in Fiona Fitter's murder, and campaigned for the rights of one of her killers, her youngest daughter. Two of Horin's articles were significant in length; one was 1162 words and the other was 2506. Both described Kylie Fitter as a "prisoner", both of her "past" and of "the state". They also portrayed the young woman as a victim:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Kylie was as much a victim as her beloved mother. A victim three times over: of an upbringing that made her unfit for the world, of a psychotic father and brother, and now of political expediency.

Throughout the article, Horin provided the details that Knowles was unable to offer when she reported on this case during the Supreme Court trial in 2002. She explained that Kylie Fitter's father was the primary source of her anguished upbringing, and had filled "her head with extreme Christian beliefs". He was described by Horin as "passionate about God and his family", and had "suffered mild psychosis" at different points during his life. Unrestrained by sub-judice restrictions, Horin was then able to present a fuller account of the challenges Kylie faced as a child:

Both Kylie's parents suffered abuse as children. Out of love for their children, they kept them close and fiercely protected. They moved a lot; there were several schools, and charismatic churches. By 13 Kylie was on Prozac. She left school at 14, a social misfit, believing she was stupid, and in isolation filled her days with computer games. Her brother was spiraling into schizophrenia, hearing "demons' voices" and becoming fixated on harming his mother.

A significant portion of the article was also dedicated to the challenges faced by Kylie's father, who was portrayed as having the greatest responsibility for the murder of Fiona Fitter, his former wife. Horin explained that the unnamed father lost his job in 1999 because of a back injury and that the resulting pain lead to him self-medicating with the use of cannabis. Horin stated that "for a devout Christian his heavy drug use was bizarre and it triggered outlandish behavior". He was known to share joints in the back shed of their home with his son, and he began to collect knives (though for what purpose is not made clear by the journalist). To consolidate the portrayal of Kylie as another victim of this crime, Horin concluded that "there were good days and bad … [Kylie's] father and brother lived in their shared world of demons, angels and paranoid delusions".

In a shorter piece, she wrote for *The Sydney Morning Herald* on 18 September 2006, Horin described Fitter as being "held prisoner by politics", and gave attention in the article to Ms Fitter's advocate, Bob Johnston, who stated that "Kylie is a virtual political prisoner because of the minister's concern that releasing her would damage the Government in the [upcoming] election". In March 2009, Louise Hall reported for *The Sydney Morning Herald* that the laws surrounding this issue had changed, and that "people who are declared unfit for trial or not guilty because of mental illness will no longer be detained or released 'at the Governor's pleasure', following widespread concern that patients' detention was being continued unfairly for populist or political reasons". Adele Horin interviewed Kylie and described her in an article published on 29 April 2006 in *The Sydney Morning Herald* as follows:

She is so gentle and polite as she offers tea and biscuits in a child-like voice that it defies imagination Kylie Fitter helped kill her mother in a crime of biblical proportions. Seated in the living room of an inner-city terrace, the willowy, 20-year-old spun-sugar blonde, sweetness itself, is out on weekend leave from jail. But in the view of her many supporters, Kylie is a political prisoner.

Remember that in later descriptions of the brother and father, also published by Horin in 2006, the two "lived in a shared world of demons, angels and paranoid delusions". According to Adele Horin, Kylie "lost capacity for rational thought and came to share the delusions of her father and brother" who

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

believed Fiona Fitter was evil, and that she "drank babies' blood". Kylie was presented in these articles as separate to her delusional brother and father, and the victim of their paranoid thinking.

The purpose of this analysis has been two-fold. First, it offers insight into the potentially negative consequences of the constraints placed on journalists by sub-judice law. In contrast, the four articles published between 2006 and 2009 were not constrained by sub-judice law, and so engaged in broader questioning of the social circumstances that lead to Fiona Fitter's murder, in particular, the links between religion, the abuse of illicit drugs and alcohol, and paranoid and delusional thinking. While the articles still described the perpetrators as mentally ill, the reader was presented with a more complex (and more thorough) account of how such a horrific murder could take place. Second, the four articles published between 2006 and 2009 portray Kylie Fitter as a victim of multiple circumstances: a victim of her father's delusional thinking, a victim of her upbringing, and a victim of the state. This reinforces a pattern identified earlier in the chapter, where mental illness in women is portrayed as tragic, whereas in men it is abhorrent and despicable. Certainly, Fiona Fitter's son and father are portrayed as psychotic, drug dependent, paranoid schizophrenics who acted coldly and brutally. Kylie Fitter is presented as the 15-year-old who was seduced and hypnotized by their delusional thinking.

Case 4: Sydney, New South Wales, Australia

On 9 November 2009, Sydney-based curator, gallery director, and academic Nick Waterlow was killed by his son Anthony, described as a 43-year-old man "suffering from paranoid schizophrenia". A total of eighteen newspaper articles reported on this case and were published between 12 November 2009 and 7 November 2014; eleven in *The Sydney Morning Herald*, four in *The Australian*, two in *The Daily Telegraph*, and one in *The Courier-Mail*. This is the fourth case explored in this section of the chapter and the purpose of the analysis that follows is to explore the tendency for journalists to document explanations for violent crime that reside outside the individual. I examine the case of Anthony Waterlow and the eighteen newspaper articles devoted to the murders he committed in 2009, and assess the extent to which journalists were willing or able to explore some of the broader social circumstances involved in violent crime committed by individuals described as mentally ill.

Jodie Minus presented a full account of the two murders committed by Anthony Waterlow in a piece published in *The Australian* on 13 April 2011. Minus explained that despite the son killing both his father and sister, there was love in the Waterlow family, and a deep care for the suffering Anthony that persisted "to the very end":

Just moments before his mentally ill son came lunging at him with a 34cm kitchen knife, the 68-year-old cried out "I love you". Anthony, suffering from paranoid schizophrenia, then turned the knife towards his sister, Chloe, who pleaded, "No, don't – stop," as her three young children screamed and cried. Silence descended on the Randwick house, in Sydney's east, for a brief spell as Waterlow, his shirt soaked in blood, walked out the front door … leaving Nick and 37-year-old Chloe on the floor.

A piece published just three days after the killings, at a time when Nick Waterlow had still not been apprehended by police, and so sub-judice restrictions were not applicable, sought to reduce mental health stigma by making it clear that there are no inherent links between violence and mental illness. Rick Feneley reported for *The Sydney Morning Herald* that the revelation that Waterlow "is a schizophrenic has raised concerns that people with mental illness will be demonized". Feneley explored some of the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

structural factors involved in the murders, and so looked beyond a simple explanatory link between mental illness and violence common to many of the articles explored in this chapter. He drew on SANE Australia's deputy director at the time, Paul Morgan, who explained that "when tragic cases do occur, it perhaps leads people to a mistaken impression that people with mental illness are more violent than they are". Feneley noted that males aged between 18 and 25 are the most violent group in Australia today, "but people [do] not live in fear of every young man".

That Feneley drew on the views of Paul Morgan is significant. SANE Australia is a mental health charity aimed at helping Australians affected by mental illness, both personally and through family, to lead a better life. A significant focus of their campaigning is the reduction of stigma. By including Morgan's expertise and insight, Feneley helped to balance and moderate the obviously horrific crime and its associations with mental illness. Feneley used Morgan's expertise most significantly when he placed emphasis on some of the structural factors involved in the murder:

Mr Morgan said … there was a "very small by significant" correlation between schizophrenia and an increased risk of violence. "But that is concentrated in people who are generally younger males, who may have a propensity to violence anyway … who are not getting treatment, and especially if they are mixed up in drugs and alcohol". Anthony Waterlow has a history of drug and alcohol abuse, and violence.

An article written by three authors, David Barrett, Rhett Watson, and Gemma Jones, published in *The Daily Telegraph* on 14 November 2009, explained that Anthony Waterlow was a "loner" who lived in "a lonely world". Barrett, Watson, and Jones explored some of the broader issues involved in the crime, looking beyond Waterlow's battle with mental illness. They documented a history of physical violence by Waterlow against his family that was compounded and exacerbated by his refusal to take anti-psychotic medication. They explained that as a young man he was officially diagnosed with paranoid schizophrenia, "but friends say he refused to take medication … [and] bursts of violence against family members as the delusions gripped him eventually led to court-ordered apprehension violence orders". His sister, Chloe, who he would later kill after murdering his father, "had already made it known to others that she feared for the safety of her family" and that he had "once attacked her in a hotel". The three journalists documented more cases of violence:

In 2007 he twice appeared in court. Once for bashing friend and prominent jewelery designer Bridie Lander. He also tried to smash down two doors of neighbours in an Elizabeth Bay block of flats … Even those who have previously been victims of Anthony's violence are loathe to blame him. Instead, there is a feeling that, like too many of the mentally ill, he fell through the cracks.

The purpose of this article, as it was in Feneley's piece, was to explore some of the broader social circumstances involved in the murders committed by Anthony Waterlow. The explanatory narrative so often reinforced in articles explored in this chapter was also tempered, with more attention given by Barrett, Watson, and Jones to Waterlow's history of violence, and reluctance to take anti-psychotic medication. This drew emphasis away from a simple cause-effect explanation between mental illness and violence. Anthony Waterlow was instead portrayed as someone who suffered greatly, and perhaps was as much a victim of this story as the deceased family members he killed. The three journalists consolidated this view when they concluded that he had fallen "through the cracks" of the mental health system.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

SOLUTIONS, RECOMMENDATIONS

As was the case in accounts of fathers, mothers, and progeny, nearly all cases involved murder, and journalists used mental illness more frequently than any other explanatory device to account for how and why these crimes took place. Further research and scrutiny of media reporting guidelines is required on the reporting of violence, separate to further research on fair and accurate reporting related to mental health, so that journalists do not inadvertently cause harm and increase stigmatizing attitudes and discriminatory practices toward people experiencing mental health issues.

CONCLUSION

This chapter was divided into three sections based on the perpetrators of acts of violence that took place in the family setting. Categories were fathers, of which there were 24 articles dedicated to the stories of eleven separate men; mothers, where 22 articles reported on the stories of 24 mothers who harmed their children; and finally, progeny, where a total of 58 articles presented 17 cases of sons or daughter who killed, or planned to kill, one or both of their parents. The argument that unites these three sections is that in cases where violence occurred in the family setting, whether the perpetrator was a father, a mother, or their sons and/or daughters, Australian journalists used mental illness to explain how and why these crimes took place. But the analysis presented in this chapter has shown that the explanatory mental health narrative, while used in the vast majority of newspaper reports on family violence, was not employed uniformly across all three categories. This analysis offers support for an argument presented in chapter one of this text relating to the construction of mental health reporting for publication in newspapers. The analysis presented in this chapter yielded three additional findings that were common across all three categories. The first was the tendency for journalists to portray abhorrent murders as reflective of broader social problems, the second was the use of additional examples of violence as a means for sensationalizing news stories, and the third was the restrictions placed on journalists by sub-judice law and the effect these constraints had on the construction of news stories.

Chapter 57
Finding Strength in the Struggle:
Addressing the Mental Health Needs of Children and Families Living in Rural Poverty

Loni Crumb
East Carolina University, USA

Madeline Clark
The University of Toledo, USA

Susan M. Long
The University of Toledo, USA

ABSTRACT

Poverty is an intersectional issue, as children; women; men; people of color; people who identify as lesbian, gay, or transgender; and immigrant groups are all prone to experience the multifaceted impact of poverty. People who live in rural poverty are likely to experience more severe and persistent mental health disorders. This chapter provides an overview of how rural poverty impacts the mental health and wellbeing of diverse children and families. The authors discuss issues faced by residents living in rural poverty and provide multiple strength-based strategies that behavioral service providers can use to provide culturally relevant mental healthcare in impoverished rural communities. Lastly, the authors offer suggestions for future research.

INTRODUCTION

"I don't see class." This claim echoes the more popular statement "I don't see color," which is a faulty claim made by individuals who want to ignore issues of structural power, privilege, and other topics related to race (Burke, 2019). Like the phenomenon of colorblindness, being class-blind dismisses the reality of social class differences and lessens one's ability to recognize and discern how to provide equitable resources and services to those who experience poverty. Over 40 million Americans live in poverty, with the most concentrated areas of poverty in non-metro, rural locales (United States Department of Agriculture [USDA] Economic Research Service, 2019). While poverty is commonly considered to be an urban issue, persons in rural areas experience poverty in higher rates (USDA Economic Research Service, 2019), with 16.4% living in rural areas versus 12.9% in metropolitan areas. The physical and psychosocial stressors attributed to poverty, such as malnutrition, increased morbidity, and homelessness are detrimental to the wellbeing of children and families (Zalaquett & Chambers, 2017). Therefore, scholars, policymakers, and the public must acknowledge the chronic life stressors that adversely impact the mental health and wellbeing of individuals living in rural poverty as well as identify protective factors that promote their healthy development and resilience.

In order to address the mental health-related concerns of children and families living in rural poverty, it is vital that professionals recognize the challenges residents face while simultaneously noting the strengths present in these communities. Individuals living in rural poverty possess remarkable assets that help them to overcome environmental and personal stressors (Williams, Bryan, Morrison, & Scott, 2017). However, in order to recognize the capacities (i.e., potential to withstand adversity) of individuals living in rural poverty, scholars from multiple disciplines (mental health, education, and allied professionals) suggest a need to shift from a deficit-oriented ideology to a culturally responsive, strength-based framework when providing services in these communities (Crumb, Haskins, & Brown, 2019; Harms Smith, 2017). Strengths based frameworks focus on the empowerment of people living in poverty and the acknowledgement of their capabilities (Harms Smith, 2017).

The objective of this chapter is to help readers develop an understanding of the mental health needs of children and families living in economically disadvantaged, rural communities. The authors provide strategies that providers of rural mental and behavioral healthcare services can use to address the concerns extant in impoverished communities using strength-based approaches. The authors outline ways that providers can alter services to address the unique mental health concerns of residents living in rural poverty and methods providers can use to engage in individual and systems-level advocacy interventions to promote equity and positive systemic changes in rural communities. The chapter concludes with recommendations for how mental healthcare providers can collaborate with schools, local organizations, and faith communities to improve mental healthcare for residents living in rural poverty.

DEFINING POVERTY

Poverty is a complex sociopolitical phenomenon that presents in various ways. Consequently, there are multiple poverty definitions, including: (a) absolute poverty, (b) relative poverty, and (c) income poverty (UNESCO, 2019). *Absolute poverty* is commonly understood to mean "poverty in relation to the amount of money necessary to meet basic needs such as food, clothing, and shelter" (UNESCO, 2019, p. 1). This definition is limited to the basic needs and resources that a person needs to survive. *Relative poverty* is

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

a more commonly used definition of impoverished experiences in the United States (U.S.) and is understood as poverty in which "people are 'poor' if they fall below prevailing standards of living in a given societal context" (UNESCO, 2019, p. 1). Meanwhile, *income poverty* is the metric used to determine if individuals or families meet standards to qualify for government assistance (UNESCO, 2019). In the U.S., this is represented by the Federal Poverty Level (FPL). While these measures of income poverty are important sociopolitical definitions, they do not take into account the relational or social aspects of impoverished experiences (relational poverty). If individuals earn slightly more income than the FPL, they will not meet the federal definition of poverty, and thus have less access to Federal Safety Net programs serving low-income persons (e.g., Temporary Assistance for Needy Families; Women, Infants, and Children; Supplemental Nutritional Assistance Program).

In addition to the resource and income definitions of poverty, poverty experiences can also vary by time and circumstance, leading to episodic, chronic, or generational poverty (Portland State University [PSU], 2019). It is critical to examine the differences in chronological poverty experiences, as time spent experiencing poverty will have a different impact on individuals' experiences with access to various resources, such as food, housing, healthcare, education, and employment. *Episodic poverty* lasts for less than two months; an example of episodic poverty may be when a parent loses a job and a family experiences a significant financial loss for a period of time, but when that parent returns to work, the family no longer experiences the financial strain and poverty. *Chronic poverty* is defined as poverty that is experienced by a person or group of people for four years or longer (PSU, 2019). In addition to chronic poverty, poverty can be conceptualized as generational in that it is something that families have experienced for two or more generations (PSU, 2019). *Generational poverty* can be characterized in some cases as families who have never owned property, do not have family members who have engaged in or benefitted from higher education, and have very little or no employment mobility (PSU, 2019).

THE FACES OF RURAL POVERTY

In 2017, 13.7% of U.S. residents experienced poverty, with an individual yearly income below $12,060 (Bishaw & Benson, 2018). While 13.7% represents the poverty rate of all Americans, poverty is an intersectional issue - children, women, people of color, and people who identify as lesbian, gay, bisexual, or transgender all experience higher rates of poverty than persons occupying non-marginalized statuses (Bishaw & Benson, 2018). Poverty is an important issue for families, especially those with women heads of household, which are more apt to experience poverty than households headed by men or those with multiple parents. Furthermore, children living in the U.S. experience higher poverty rates than adults (Bishaw & Benson, 2018). Racial and ethnic minorities experience poverty at increased rates in rural areas, as they do in urban areas and overall (USDA Economic Research Service, 2019). Coupled with the mental stress associated with financial concerns, many persons with historically marginalized identities also experience racism, sexism, homophobia, and transphobia. These experiences can lead to multiple minority stress and adverse physical and mental health outcomes associated with multiple oppressions (Bockting, Miner, Swinburne-Romine, Hamilton, & Coleman, 2013; Meyer, 2003; Wong, Schrager, Holloway, Meyer, & Kipke, 2014).

Regardless of identity status(es), persons experiencing poverty are more likely to experience mental health concerns and psychological disorders (Weissman et al., 2015; World Health Organization [WHO], 2007). Mortality, chronic physical illness, developmental delays, violence, and barriers to health care

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and housing are all risks associated with poverty experiences (Kaminski et al., 2013; Krieger, Chen, Waterman, Rehkopf, & Subramanian, 2005). Persons in poverty may have difficulty finding and maintaining employment, causing further mental distress (Weissman et al., 2015; WHO, 2010). These mental, financial, and physical stressors deepen the adverse experiences of poverty.

While experiencing poverty is not a direct cause of negative outcomes, the lack of access to economic and other resources significantly impacts an individual's daily life, health, and overall wellness (Kaminski et al., 2013). Beyond the specific physical, mental, and educational effects, persons experiencing poverty are also likely to live in overcrowded or poor-quality housing (Anakwenze & Zuberi, 2013; Goodman, Pugach, Skolnik, & Smith, 2012), to be exposed to community or interpersonal violence (Anakwenze & Zuberi, 2013; Goodman et al., 2012; Logan, Walker, Cole, Ratliff, & Leukefeld, 2003), and to experience food insecurity, relational instability, underemployment, and higher rates of incarceration (Goodman et al., 2012; Myers & Gill, 2004; WHO, 2007). Overall, children and families living in rural poverty are likely to have little to no access to health care, mental health services, or adequate educational opportunities (Goodman et al., 2012; Myers & Gill, 2004; WHO, 2007).

The noted issues highlight a need to conceptualize rural poverty from a socioecological perceptive (Bronfenbrenner, (1986) considering how individuals are impacted on the micro (individual level), meso (community level), and macro levels (society as a whole). A socioecological perceptive takes into account the broader social, political, and economic forces that impact an individual's wellbeing. Notably, individuals living in rural poverty are affected by systemic concerns and policies that do not contribute to equitable education, safe environments and housing, economic development, access to healthy foods, and employment (Thornton et al., 2016). Policymakers play an integral role in overall functioning and progression of these communities. Disparity-reducing policy interventions targeted at education, healthcare, and rural community development and employment are warranted.

MENTAL HEALTH AND RURAL POVERTY

Mental health, a component of overall health, is a measure of an individual's overall mental status, psychological health, and wellness (WHO, 2004). Mental health can be measured on a continuum from well to ill with every individual having a unique mental health status (WHO, 2004). Mental illness is commonly understood as the psychological state of experienced mental distress or a diagnosed mental disorder (as per the Diagnostic and Statistical Manual [DSM-5], American Psychiatric Association [APA], 2013). These mental health diagnoses include neurodevelopmental disorders such as Attention Deficit Hyperactivity Disorder [ADHD], depression, anxiety, psychotic disorders, trauma, and stress-related disorders (APA, 2013). The relationship between poverty experiences and mental health is well documented, and persons living in poverty are more likely to experience mental health disorders as well as more severe and persistent mental health disorders such as schizophrenia (Mickelson & Hazlett, 2014; Weissman et al., 2015; WHO, 2007).

Experiencing poverty is frequently associated with higher incidences of mental illness (Hanandita & Tampubolon, 2014; Lund et al., 2010; Mickelson & Hazlett, 2014; Weissman et al., 2015; WHO, 2007) just as higher incomes are linked to lower levels of psychological distress (Weissman et al., 2015). Persons living in poverty often report higher levels of depression, post-traumatic stress disorder (PTSD), and substance use (Bryant-Davis, Ullman, Tsong, Tillman, & Smith, 2010; Mickelson & Hazlett, 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The relationship between poverty and mental illness is not only correlated, it is cyclical and bi-directional (Weissman et al., 2015; WHO, 2007, 2010). With an increased risk for mental illness, a person is also more likely to experience poverty, as mental illness often makes engaging in sustainable work or educational/training programs challenging if not impossible (Anakwenze & Zuberi, 2013; Hanandita & Tampubolon, 2014; Lund et al., 2010; Mickelson & Hazlett, 2014; Weissman et al., 2015; WHO, 2007, 2010). For example, persons with a severe and persistent mental illness like schizophrenia are four times as likely to be unemployed (WHO, 2007). In sum, poverty experiences and mental illness can be mutually reinforcing.

These challenges can be even more difficult to navigate as many persons experiencing poverty have great difficulty accessing mental health treatment (Goodman et al., 2012; Weissman et al., 2015). Persons in poverty are less likely to receive mental health treatment, often due to systemic barriers such as unaffordability or lack of insurance coverage (Goodman et al., 2012; Nadeem, Lange, & Miranda, 2008; Weissman et al., 2015; WHO, 2010). Beyond these financial obstacles, simply finding a means of transportation to and from appointments can be a significant barrier to accessing care for many persons experiencing poverty (Goodman et al., 2012; Myers & Gill, 2004).

Rural Mental Health Needs

People living in rural communities face unique difficulties related to poverty and mental health beyond those presented above. There are higher incidences of deep poverty in rural locations (USDA Economic Research Service, 2019). Specifically, rural poverty rates are highest in the south, Appalachia, and Native American lands (USDA Economic Research Service, 2019).

Persons living in rural areas are often at a greater risk for mental health and substance use and have a greater need for mental health services than persons in metropolitan areas (Substance Abuse and Mental Health Services Administration [SAMHSA], 2019). Despite this, there is a shortage of mental health service providers in rural areas (Rural Health Information Hub, 2019). Because of this shortage, people in rural areas are often forced to travel to metropolitan areas for mental health services, which for persons experiencing poverty may be incredibly difficult beyond the distance traveled. It requires having access to a personal means of transportation. Moreover, finding funds for gasoline, maintenance, and auto insurance, being able to take time off from work, and arranging childcare all present significant barriers.

CLASSISM AND RURAL POVERTY

Classism is a form of prejudice due to which marginalization, ostracism, and oppression occur in response to an individual's social class (Liu, 2013). Classism is both individual (i.e., individuals can hold classist beliefs and use them to stereotype and discriminate against others) and systemic (i.e., structural inequalities exist to privilege those in upper social classes and oppress those in lower social classes; Liu, 2013, Lott, 2002, 2012; Smith & Redington, 2010). The prevalence of classism often stems from the idea that success is based on merit, and social class barriers such as poverty are due to an individual's deficits, such as laziness or lack of intelligence (Liu, 2013; Lott, 2002; Smith, 2005). Classism can further oppress those already impacted by the barriers of poverty via separation from "mainstream" culture, causing social isolation in housing, employment, and education as well as in other areas (Liu, 2001; Lott, 2002; Smith, 2005). Research has shown that significant classist biases exist towards persons who experience

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

poverty and that many people believe experiencing poverty is an individual's fault (Cozzarelli, Wilkinson, & Tagler, 2001; Hunt, 1996). Beyond the general population, even mental health providers have been found to have negative beliefs about persons experiencing poverty (Schnitzer, 1996; Smith, Mao, Perkins, & Ampuero, 2011; Toporek & Pope-Davis, 2005; Weiss-Gal, Benyamini, Ginzburg, Savaya, & Peled, 2009). Persons living in rural poverty who experience classist exchanges with mental health providers are unlikely to return for necessary mental healthcare due to fear of discrimination and judgment.

MAIN CONCERNS OF MENTAL HEALTH IN RURAL POVERTY

Mental healthcare disparities in impoverished rural areas is a four-part problem related to the (a) acceptability, (b) accessibility, (c) availability, and (d) affordability of mental health services (Smalley, Warren, & Rainer, 2012). The majority of persistently poor rural communities are designated as Mental Health Professional Shortage Areas, signifying a dearth of mental healthcare professionals and resources in these locations. The professional and resource shortage may lead to the underutilization of mental healthcare services as well as inadequacies in the quality of mental health treatment provided to residents living in rural poverty (Smalley et al., 2012).

In terms of acceptability, mental illness stigma is one of the most common reasons why residents living in rural poverty are apprehensive about seeking mental healthcare services (Crumb, Mingo, & Crowe, 2019; Stewart, Jamison, & Curtin, 2015). Mental illness stigma denotes the labeling and devaluing of a person based on negative beliefs, attitudes, and perceptions about mental health issues that result in status loss, stereotyping, or discrimination (Crowe, Averett, & Glass, 2016). Mental illness stigma is further designated as self-stigma, public stigma, and stigma by association. *Self-stigma* occurs when a person internalizes the negative attitudes of others about mental health issues, resulting in lowered self-esteem and self-worth (Crowe et al., 2016). *Public stigma* represents disdain toward those who have a mental illness from the general public (Crowe et al., 2016) and *stigma by association* occurs when a person is stigmatized by virtue of association with a person who has a mental illness (e.g., negative attitudes towards parents from school administrators regarding their child's mental health concerns).

All forms of stigma deter children and families living in rural poverty from seeking mental healthcare services (Heflinger, Wallston, Mukolo, & Brannan, 2014). For example, Crumb et al. (2019) conducted a qualitative analysis to examine the mental health treatment experiences of low-income adults living in rural areas across the United States. Participants were candid in reporting experiences of stigma, stating that they were reluctant to seek services because their relatives would perceive them as "weak" for having a mental illness. Similarly, Polaha, Williams, Heflinger, and Studts (2015) surveyed rural parents' experiences of seeking mental healthcare services for their children. The researchers found that stigma by association (i.e., stigmatizing attitudes from teachers and school administrators) deterred parents from seeking treatment for their children in school settings (Polaha et al., 2015). The findings from this study are alarming because schools are essential for children's access to mental healthcare services in impoverished rural communities, with school-based services circumventing common mental health treatment barriers such as transportation difficulties and parents' time constraints (Nichols, Goforth, Sacra, & Ahlers, 2017). Due to issues related to the acceptability of mental illnesses in impoverished rural communities, residents who experience mental health-related concerns postpone seeking professional services and often require more intensive treatment when concerns arise (Smalley et al., 2012).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The accessibility of mental healthcare services is also a significant problem in rural areas. Issues such as long distances to treatment facilities and a lack of transportation present barriers for children and families in need of mental healthcare. As a result of accessibility issues, rural children and families often forego timely mental health treatment (Nichols et al., 2017). Rural residents typically seek mental health services only after their symptoms have progressed, necessitating more extensive treatment, which is often unavailable in rural areas and too costly for persons of limited economic means (Gore, Sheppard, Waters, Jackson, & Brubaker, 2016). Furthermore, although rural youth may have professional school counselors who can help them access mental health services, the utilization of these services is still dependent upon parental consent and participation in the treatment process.

Likewise, the availability of treatment in impoverished rural areas is fragmented due to the shortage of service providers in these communities. The provider shortage is primarily attributed to the difficulty in recruiting and retaining mental healthcare professionals in such communities. Additionally, many providers have a limited understanding of cultural norms and effective interventions for addressing the mental health-related concerns of this particular group (Fifield & Oliver, 2016). Most impoverished rural communities do not have mental healthcare professionals, and if one is present, this person is often the sole provider. Moreover, mental healthcare providers practicing in these areas are paid less, have larger caseloads and fewer resources and support networks, and face personal and professional issues related to burnout (Reed & Smith, 2014). Rural providers also face ethical dilemmas, such as maintaining confidentiality and navigating multiple roles (Bowen & Caron, 2016). Furthermore, researchers have suggested that rural providers are not often well-trained in specialty areas of mental healthcare (e.g., substance abuse, trauma-informed care; Fifield & Oliver, 2016). Consequently, rural residents often depend on informal, nonprofessional sources to address mental health concerns such as friends, clergy, or other affiliates in faith-based organizations (Bryant, Moore, Willis, & Hadden, 2015).

Finally, the affordability of mental healthcare services is an ongoing concern, as most uninsured children and families are those living in rural poverty (Foutz, Artiga, & Garfield, 2017). Adults living in rural areas with concentrated poverty are more likely to work for small businesses that do not provide health insurance coverage, which is often necessary to receive adequate treatment for acute mental health concerns (Zalquett & Chambers, 2017). Furthermore, when low-income adults have access to government-supported health coverage such as Medicaid, they often need professional assistance to stay abreast of the ongoing changes to criteria that must be met to qualify for these services (Crumb et al., 2019). Consequently, individuals living in rural poverty may ignore the prevalence of mental health symptomology altogether.

MENTAL HEALTH LITERACY

In addition to issues related to acceptability, accessibly, availability, and affordability, mental health literacy is also important to consider in relation to impoverished rural communities. *Mental health literacy* is the knowledge and beliefs about disorders that assist in the recognition, prevention, or management of mental health concerns (Jorm, 2012). Individuals living in rural poverty are less aware of mental health symptomology and have less ability to appraise the level of symptom severity (Smith, Li, Dykema, Hamlet, & Shellman, 2013). For example, a study using focus groups to examine the perspectives of mental health problems among rural African Americans found that most participants did not know how to recognize mental illnesses and would, therefore, not understand when treatment was needed (Sullivan

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2017). These results convey the difficulty those living in rural poverty may have in appropriately assessing whether treatment is necessary or when to seek help.

Mental health literacy is associated with overall mental, physical, and social wellbeing (Cheng, Wang, McDermott, Kridel, & Rislin, 2018; Coles & Coleman, 2010; Kelly, Jorm, & Wright, 2007). Individuals who are aware of their personal mental health needs are more likely to seek treatment in a timely fashion and are more likely to recommend professional help to others (Coles & Coleman, 2010). However, limited levels of mental health literacy may cause individuals to delay seeking mental health services—if they seek services at all—ultimately exacerbating mental health conditions (Crumb, Haskins, & Brown, 2019; Kelly et al., 2007). Individuals with both limited mental health literacy and a lack of social and financial resources are especially vulnerable (El-Amin, Anderson, Leider, Satorius, & Knudson, 2018).

Individuals with limited mental health literacy living in rural poverty generally have poorer health outcomes, including smoking, alcoholism, nutritional deficiencies, lack of physical activity, and premature death (El-Amin et al., 2018; Hartley, 2004). Furthermore, mental health literacy, coupled with perceived stigma, may affect help-seeking attitudes for residents living in rural poverty (Cheng et al., 2018; El-Amin et al., 2018). While high levels of mental health literacy are positively associated with help-seeking, high levels of stigma, including self-stigma, negatively affect this relationship (Cheng et al., 2018; El-Amin et al., 2018). In some rural communities, discussing mental health concerns is considered to be inappropriate, embarrassing, and a violation of privacy, and may even be perceived as an insult (El-Amin et al., 2018; Polaha et al., 2015). These issues present significant barriers to the utilization of mental healthcare services in impoverished rural communities.

TRANSFORMING DEFICIT-BASED PERSPECTIVES OF RURAL POVERTY

Unfortunately, much of what is said about the rural poor is largely negative or grounded in deficit-based ideology. Deficit ideology proposes that: (a) people from poor rural communities are fully at fault for issues related to their living circumstances; (b) individuals do not have the capacity or motivation to change their circumstances; (c) children and parents do not value employment or educational endeavors; and (d) the cultural background, home environment, beliefs, and value systems of individuals living in poor rural communities are substandard (Smith, 2010). The use of a deficit approach weakens a practitioner's or researcher's ability to identify the strengths and positive experiences of children and families living in impoverished rural communities. Focusing only on the negative attributes of impoverished rural communities perpetuates classism, discrimination, prejudices, and stigma toward residents. Moreover, deficit-based ideology further increases the invisibility of the poor and stymies the allocation of various resources that may enhance fiscal restoration in these areas, both of which represent social and economic injustice.

Scholars (Cook & O'Hara, 2019; Reed & Smith, 2014) have called for increased research and interventions that focus on the assets and strengths amongst individuals living in impoverished rural communities. As an example, Williams et al. (2017) used a strength-based framework to explore the educational experiences of low-income middle school students. Instead of focusing on barriers to student success, the researchers investigated protective factors and processes that contribute to their academic success. Results from the study indicated that low-income students had a plethora of intrinsic and extrinsic factors that influenced their academic success, such as peer social capital, caring teachers, and family and community assets. Likewise, Crumb, Haskins, and Brown (2019) conducted a qualitative study

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to intentional capture the positive experiences of mental health counselors practicing in rural poverty. Counselors in the study reported that they showed appreciation for their clients' worldviews by learning about their family structure, leading with curiosity, and displaying cultural humility, which allowed them to acknowledge that their clients were resourceful, motivated to change, and capable of finding solutions to mental health-related issues. Moreover, due to the close relationship developed with their clients and their clients' families, counselors in the study were more readily willing to immerse themselves in the rural community and engage in social justice advocacy initiatives with and on behalf of their clients.

Additionally, increased training in poverty and multicultural counseling competence also has a significant impact on poverty beliefs (Clark, Moe, & Hays 2017; Greene & Manner, 2019). In a quantitative study examining the relationship between multicultural counseling competence and poverty beliefs using a sample of 251 counselors, Clark et al. (2017) found that higher levels of multicultural competence and training decreased poverty biases and helped counselors to understand the structural causes of poverty.

STRENGTH-BASED SOLUTIONS AND RECOMMENDATIONS

Mental health professionals have an ethical responsibility to support the overall wellbeing of children and families living in rural poverty through widespread interventions and advocacy efforts on the micro, meso, and macro levels (American Counseling Association, [ACA], 2014). The following section outlines ways in which professionals may positively impact the personal and social development of all persons living in rural poverty.

INCREASING MENTAL HEALTH LITERACY

Improving mental health literacy is important for empowering and reducing health disparities among vulnerable groups (El-Amin et al., 2018; Kelly et al., 2007). Early recognition and intervention of mental health conditions promote holistic health and wellbeing (Coles & Coleman, 2010; Kelly et al., 2007). Several interventions aim to improve mental health literacy, including mental health first aid, peer support groups, family-focused programming, school-based programs, and bibliotherapy (El-Amin et al., 2018; Rural Health Information Hub, 2018).

Mental health first aid is an especially useful strategy for increasing mental health literacy in rural communities (Rural Health Hub, 2018). Rural mental health first aid is a way to increase knowledge about mental health, substance use, and the stigma associated with mental health conditions (Rural Health Hub, 2018). This training can be applied on the micro, meso, and macro levels (Bronfenbrenner, 1986) such as with individuals, families, law enforcement, first responders, school personnel, policymakers, and the public to provide knowledge and skills related to mental illness, crisis intervention, and available referral sources within the community (Rural Health Hub, 2018).

Additional interventions that may improve mental health literacy include whole-of-community campaigns that aim to distribute information about mental health and available resources via pamphlets, posters, print media, and educational videos (Kelly et al., 2007). Community and school-based interventions may include teaching help-seeking skills, mental health literacy interventions, resiliency building, and crisis intervention training. School counselors or mental health professionals may facilitate these types of training (Kelly et al., 2007). Mental health professionals must take a socioecological approach

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Bronfenbrenner, 1986) when conceptualizing the issues and concerns faced by those living in rural poverty, such as helping clients to specifically identify and discuss how rurality and poverty influences family dynamics, occupational choices, and environmental resources or the lack thereof considering the influence of community norms, and public policy.

BUILDING COMMUNITY PARTNERSHIPS

It is imperative for mental health professionals within rural communities to build connections with community partners, including religious organizations, schools, law enforcement, social service agencies, and medical service providers (Rollins, 2010; Rural Health Hub, 2019c). Community partnerships such as these help to alleviate health disparities in rural communities, where health resources are limited (Rural Health Hub, 2019c). Establishing community relationships is also a means to combat stigma and promote the utilization of mental health services in impoverished rural communities. The close-knit nature of rural communities is a strength and can help facilitate help-seeking for mental health concerns (Polaha et al., 2015; Rural Health Hub, 2018).

Partnering With Faith-Based Organizations

Individuals living in rural poverty with mental health concerns frequently rely on their religious beliefs, prayer, or spirituality to cope with mental illness (Crumb et al., 2019). Thus, faith leaders and pastors may serve as liaisons in connecting community residents to professional services (Avent, Cashwell, & Brown, 2015). Mental health professionals could meet with members of the pastoral community to provide psychoeducational workshops, distribute mental health information, or serve as consultants when mental illness concerns arise. Building connections with the pastoral community may also serve to build rapport and trust between mental health professionals and parishioners, who may be uncomfortable seeking services on their own (Avent et al., 2015). Ultimately, appreciating and integrating the values and culture of the rural community (e.g., spirituality, family, and interdependence) is essential to bridging the gap and engaging with rural families in making decisions that influence their mental health (Rollins, 2010; Rural Health Hub, 2018).

School-Based Mental Healthcare

School-based mental healthcare improves access to services for children in rural areas by providing onsite care within the school and community (Rural Health Hub, 2018). School counselors are uniquely situated to serve rural communities. School counselors in rural communities are considered role models and can provide guidance related to legal issues, domestic problems, and sexual abuse (Breen & Drew, 2012). Because of their ability to serve as examples and foster close-knit relationships within rural communities, they are a useful resource for connecting students and families to mental health resources (Breen & Drew, 2012; Rural Health Hub, 2018). Also, school counselors can support mental health efforts through screening for mental, behavioral, and developmental disorders; wellness examinations; medication management; individualized education plans; and referral services (Rural Health Hub, 2018). School counselors should advocate for the needs of students and families and collaborate with mental health providers in order to provide comprehensive care. Furthermore, school counselors can equip teachers on

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

how to identify and handle mental health concerns observed in the classroom through practical hands-on training and classroom demonstrations. In cases in which school-based mental health professionals are not accessible or allowed, families can consider alternative options such as home-based counseling or seeking services from community mental healthcare providers; educators can ascertain trainings in mental health from online sources. It is important to note that managing mental health in schools is not the sole responsibility of the school counselors, as some rural schools may not have a counselor on staff.

Integrated Behavioral Healthcare

Resource scarcity, structural barriers, and stigma hinder rural families from seeking mental health services (El-Amin et al., 2018; SAMSHA, 2013). Integrated behavioral healthcare can increase access for rural communities, reduce stigma, and streamline services and collaboration among professionals by offering holistic healthcare in one facility (SAMSHA, 2013). There are three categories of integration between behavioral and primary healthcare (SAMSHA, 2013). The first level of integration is *coordinated care,* which involves minimal collaboration among professionals, who interact from a distance; separate systems and facilities are maintained. The second level of integration is *co-located care,* which includes close collaboration on site. *Integrated care* is the third level of integration and involves full collaboration and merging of services between providers in one facility. It is crucial to determine the level of integration that is most appropriate for a community and the availability of specialists and providers within the region (SAMSHA, 2013). Rural communities may consider implementing integrated behavioral healthcare in other settings such as schools and nursing homes and through the use of technology in order to increase access in cases where professionals are not able to adopt an integrated model (SAMSHA, 2013).

In addition, collaboration with other helping professionals working in impoverished rural communities (e.g., medical doctors, social workers, school counselors, case management providers) may increase the utilization of services by enhancing the visibility of mental healthcare through education and advocacy (Crumb et al., 2019; Crumb, Larkin, Johnson, Smith, & Howard, 2018; Polaha et al., 2015). This can be achieved if helping professionals provide brief screenings for mental health conditions in their respective offices, or if professionals provide psychoeducational pamphlets about mental health to the individual and families they serve. If mental illness is indicated, the professionals can then easily refer the person to mental health service providers within the community. Furthermore, helping professionals could establish interdisciplinary mental health and wellness coalitions within their communities to exchange resources and discuss ways to support rural families. This coalition should include community residents as collective partners to amplify community voice and focus on the needs of the families and the community at large.

ASSET MAPPING

Asset mapping is a method of cataloging a community's strengths and resources in a systematic way (Rural Health Hub, 2019a). Asset maps are developed from the strengths and capacities of a community rather than focusing on deficits (Dorfman, 1998). Assets may include individual skills (e.g., youth, older adults, parents, students, entrepreneurs), organizational resources (e.g., charitable groups, nonprofits, schools, universities, hospitals, and social service agencies), and local resources (e.g., business associa-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tions, merchants, banks, foundations; Dorfman, 1998; Rural Health Hub, 2019a). Asset mapping generally adheres to the following principles:

Every person has talents, skills, and gifts important to a community. Each time individuals use these abilities, the community in which they live is strengthened and these people feel a sense of empowerment. Strong communities are places where the capacities of local individuals are identified, valued, and used. The development of the community is built upon the talents and resources of its members. (Beaulieu, 2002, p. 5)

Asset mapping also requires an assessment of a community's physical spaces (e.g., gardens, parks, forests, and bike paths; Dorfman, 1998; Rural Health Hub, 2019a). Furthermore, asset mapping shows the interconnection of assets in order to network and establish interconnections among community assets to support the needs of the community (Dorfman, 1998, Rural Health Hub, 2019a).

There are several approaches to developing a community asset map; however, the Asset Mapping Model is a straightforward framework for creating one (Dorfman, 1998; Beaulieu, 2002). The Asset Mapping Model is a five-step process that has been applied to rural communities for economic growth although, theoretically, this same approach may be applied more broadly (Dorfman, 1998; Beaulieu, 2002). The first step involves mapping the assets of the community by completing an inventory of the skills and assets of local residents, emerging leaders of the community, local institutions, and existing community leaders who are committed to building the wellbeing of the community and its residents (Beaulieu, 2002). Next, the model builds relationships and broadens local leadership by including strategies for the long-term success of the community.

Then, skills and resources are mobilized by building upon what already exists within a community in addition to developing the resources and services that are needed (Beaulieu, 2002). The fourth step involves convening the community to develop a vision for a sustainable future; this can be achieved by establishing a dialogue with community residents about what they wish to see for their community in the next 5 to 10 years and beyond (Beaulieu, 2002). This team approach to community building helps to support long term initiatives and ensures the wellbeing of residents in rural communities. The final step is utilizing resources outside of the community by establishing partnerships and making use of them to support community priorities (Beaulieu, 2002). These steps can assist in strengthening the health and wellbeing of individuals, families, and the overall community (Dorfman, 1998; Beaulieu, 2002).

NON-TRADITIONAL MENTAL HEALTH SERVICE DELIVERY AND OPTIONS

Home-Based Counseling

Rural communities may benefit from services delivered in non-traditional formats, including home-based counseling and technology-based counseling (Freidman, 2012; Polaha et al., 2015). Home-based counseling is grounded in an ecological approach that considers the individual and family in the context of their system. It is also beneficial in monitoring how the family system operates (Freidman, 2012). Home-based counseling services may be particularly useful for rural communities due to barriers to mental health treatment such as a lack of transportation (Friedman, 2012). In addition, home-based counseling may be

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

culturally congruent for rural families who value connectedness and sense of community as this allows professionals to develop deeper relationships with them (Freidman, 2012).

Telehealth

Structural barriers exist for communities living in rural poverty, including limited transportation, a lack of mental health specialists, the cost of services, and poor access to healthcare (Orlowski et al., 2016; Polaha et al., 2015). Technology-supported mental health or telehealth provides rural communities with access to services that they might otherwise not receive and may mitigate the health disparities faced by families living in rural poverty (American Telemedicine Association [ATA], 2017; Gloff, LeNoue, Novins, & Myers, 2015; Orlowski et al., 2016; Polaha et al., 2015). Telehealth refers to "using internet and communication technologies (ICTs), such as videoconferencing, chat, and text messaging to provide health information and treatments in real time" (SAMSHA, 2016, p. 1). In addition, telehealth includes sending information and delivering services asynchronously through secure email, webinars, and video-recording (SAMSHA, 2016).

Telehealth programs increase access to mental health care in regions with limited resources, provide treatment, and improve adherence to medication regimens (ATA, 2017; Rural Health Hub, 2019b; SAMSHA, 2016). Technology-supported health care functions within four primary applications: (1) information provision, (2) screening, (3) assessment, and (4) monitoring (Orlowski et al., 2016). Additionally, telehealth is a vehicle for providing mental and behavioral health services through evaluation, diagnosis, case consultation, treatment, medication management, continuity of care, and education (ATA, 2017; Rural Health Hub, 2019b). The use of technology has been shown to increase rates of disclosure to mental health professionals by rural communities; however, barriers for engaging in technology-based services are important to consider (Orlowski et al., 2016).

Barriers for telehealth in rural communities include internet infrastructure, limited access to smartphones, credentialing and licensing, interoperability, lack of insurance coverage for telehealth services and reimbursement, technological challenges (e.g., transmission interruptions and connectivity), confidentiality and privacy concerns, and a lack of trust in healthcare and technology (Rural Health Information Hub, 2019a; SAMSHA, 2016). While technology-based mental health may increase access, significant barriers to wide implementation exist and must be addressed (Rural Health Information Hub, 2019a). Mental health professionals should be prepared to engage in advocacy efforts to increase access for telehealth services for rural and impoverished communities.

ONGOING PROFESSIONAL DEVELOPMENT

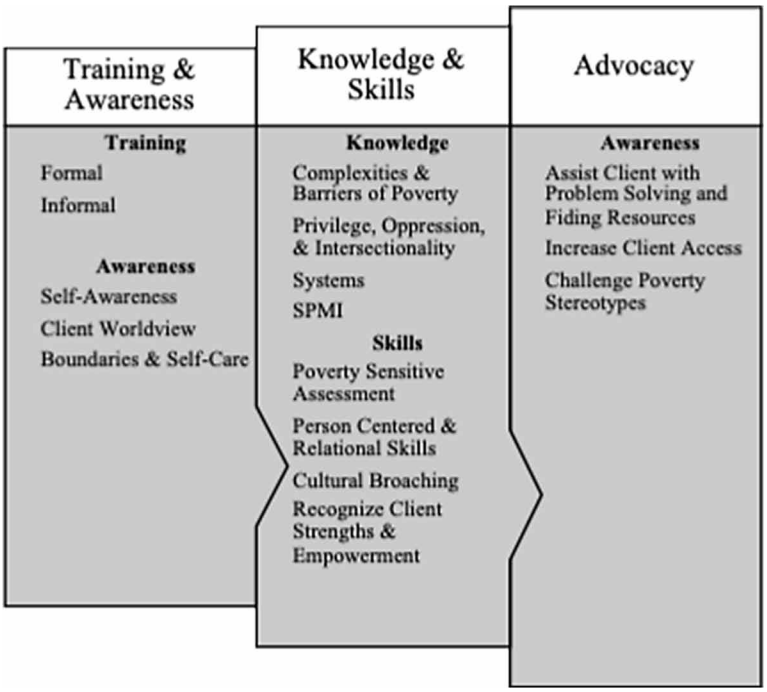
All behavioral health service providers working in rural poverty should seek opportunities for professional development. Furthermore, professionals working with vulnerable populations must be prepared to address systems of discrimination, oppression, and marginalization for individuals and families living in rural poverty (Crumb et al., 2019; Ratts, Singh, Nassar-McMillan, Butler, & McCullough, 2016). The ACA *Code of Ethics* and the *Multicultural and Social Justice Competencies* (MSJCCs) call for mental health professionals to examine their worldviews and those of their clients, be knowledgeable and aware of multicultural issues, and employ culturally appropriate counseling and advocacy interventions (ACA, 2014; Ratts et al., 2016).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Addressing Personal Biases and Stereotypes

Mental health professionals must be aware of their own biases, assumptions, and stereotypes in relation to rural poverty. Mental health professionals should engage in self-reflection as it relates to their unique beliefs and assumptions about poverty and rurality as this is congruent with multicultural and social justice praxis (Ratts et al., 2016). It is recommended that mental health professionals seek opportunities to engage with communities in which they work in order to gain a deeper understanding of the culture. Immersion experiences are vital for professionals to advocate and support rural communities with consideration of distinctive cultural values.

Integrating Social Justice Advocacy



Mental health professionals working with children and families living in rural poverty must demonstrate multicultural competence in order to provide both ethical and culturally responsive counseling to this population. The MSJCCs (Ratts et al., 2016) provides a framework for mental health professionals to examine their biases, skills, and their privileged and marginalized identities. The MSJCCs can also assist professionals in acknowledging the intersecting identities of clients as they relate to power, privilege, and oppression as children and families living in rural poverty (Ratts et al., 2016).

Mental health professionals must prepare to intervene with and on behalf of clients on multiple levels of advocacy, including intrapersonal, interpersonal, institutional, community, public policy, and global levels (Ratts et al., 2016). Advocacy efforts should occur in systems such as housing, school systems, social services, and the criminal justice system (Crumb et al., 2019). At the local and state level, counselors should advocate for policies and programming to alleviate resource hardship and increase access to community amenities for rural communities (Centers for Disease Control and Prevention, [CDC], 2019). Additional efforts on the meso level include collaboration with school systems and primary care settings to deliver mental and behavioral healthcare (CDC, 2019). Increasing parental and caregiver support programs, and screening families for mental health conditions and coordination of resources is essential in promoting the health and wellbeing of impoverished rural communities (CDC, 2019). Macro-level advocacy efforts include writing to national policymakers regarding funding (e.g., Medicaid) and policies that benefit residents living in rural poverty (Crumb et al., 2019). Individual- and systems-level advocacy efforts are critical in promoting equity and systemic changes that directly influence the wellness of this marginalized group. Therefore, mental health professionals must practice from a social justice framework in order to provide effective and ethical services to families in rural poverty.

Counseling scholars have developed specific competencies that help practitioners and researchers develop culturally responsive, advocacy-oriented counseling practices when working with economically disadvantaged populations (See Figure 1 for Poverty Competencies). These poverty competencies (Clark et al., in press) help to enhance the training, awareness, knowledge, skills, and advocacy capability of researchers and practitioners. Respecting clients' worldviews, understanding the complexities of poverty, and recognizing the intersectionality of clients' identities (e.g., people of color or individuals who identify as lesbian, gay, bisexual, or transgender and living in rural poverty) allow them to demonstrate to their awareness of the systemic issues that contribute to poverty (Clark et al., in press).

Figure 1. Poverty competencies

Specialized Training for Rural Mental Health Providers

Graduate courses specifically focused on rural populations could assist counselors in training (CITs) in elevating their understanding of culture and counseling practice in rural settings (Crumb et al., 2019; Rollins, 2010). CITS must have an understanding of poverty and its barriers for individuals and families. The importance of an understanding of the intersections of poverty and rurality cannot be overstated as it is critical to providing culturally responsive counseling (Ratts et al., 2016). CITs must also have an understanding of the nuances of boundaries between counselor and clients within a rural community and how they may ethically navigate those experiences (Breen & Drew, 2012).

Strategies for enhancing CITs' learning about rural communities can include specific coursework, group work, individual assignments, role plays, and field experiences focused on impoverished rural populations. Counselor educators should discuss the specific needs, barriers, and strengths of this population and have focused conversations about rural life and implications for professional praxis, including coverage of topics related to intersectionality, power, privilege, and social class (Breen & Drew, 2012). CITs need to have a rich understanding of rural culture. CITs must explore, understand, and appreciate rural cultural values in order to provide ethical and quality services to rural families (ACA, 2014; Breen & Drew, 2012).

Counselor educators could require CITs to complete their professional field experiences (e.g., practicum or internship) in rural communities as an immersion experience. Counselor educators could also require CITs to interview a counselor practicing in a rural community to gain a deeper understanding of the roles, culture, and implications of counseling within a rural context (Breen & Drew, 2012). Most counseling programs are focused on urban populations and exclude rural areas from classroom conver-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

sations; this is preventing CITs from gaining a broad understanding of counseling in various settings, cultures, and values (Breen & Drew, 2012; Rollins, 2010).

In addition, CITs should engage in reflective experiences that require them to examine their biases and assumptions related to social class and rurality. One way to achieve this is by asking CITs to engage in self-study in order to better understand their worldview and enhance their skills when counseling communities in rural poverty; this is a component of a multicultural and social justice framework (Ratts et al., 2016; Rollins, 2010). Self-study questions may include: "In what ways does the rural setting help your counseling practice?", "In what ways does it challenge your practice?", and "How does it change your concept of the role of a counselor?" (Rollins, 2010, n.p.). Lastly, supplemental materials such as readings, trainings, and audiovisual materials related to rurality, social class, and family may assist CITs in understanding the lived experiences of impoverished rural communities.

Professional Consultation and Supervision

Due to the limited resources and remoteness of impoverished rural areas, professional support is vital for mitigating frustrations related to consistently seeing poor, rural clients navigate difficult life circumstances. It is recommended that rural mental health professionals seek both informal and formal professional support such as consultations and ongoing supervision with other mental health professionals to help examine prejudicial beliefs, prevent the development of biases, and explore other areas of vulnerability and skills deficiencies (Crumb et al., 2019). However, it is important to note that professionals may face various challenges when seeking professional support. Foremost, supervision can be time consuming and costly (Breen & Drew, 2012). In addition, acquiring supervision in rural areas may require professionals to miss a day of work to seek supervision (Breen & Drew, 2012). Mental health professionals working in a rural community can consider alternative methods for supervision. For example, distance or online supervision may be a valuable tool for counselors, enabling them to receive supervision without sacrificing an entire day of work (Breen & Drew, 2012; Rollins, 2010). Mental health professionals and supervisors can also consider conducting conference calls for supervision when practicing in impoverished rural areas. Finally, rural service providers may connect with other professionals via listservs, face-to-face meetings, or the use of other technologies. This would help facilitate support for counselors working with impoverished rural communities in providing best practices for clients (Breen & Drew, 2012).

FUTURE RESEARCH DIRECTIONS

There are emerging opportunities for addressing the mental healthcare needs of highly underserved rural populations, despite the noted disparities. The content of this chapter presents various possibilities for future research. First, there is an ongoing need to increase the utilization of mental health services in impoverished rural communities. One strategy that has received attention is the use of telemental health services. Researchers can further explore how the use of technology can help children and families living in impoverished rural communities communicate with mental health providers and allow providers to integrate traditional office-based interventions online. Second, fostering the mental wellness of children and families living in impoverished rural communities require collaborative approaches (Williams et al., 2017; Reardon & Leonard, 2018). Researchers across disciplines (e.g., counseling, teacher education, educational leadership) can use multiple designs to explore the effectiveness of whole-school, whole-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

child approaches or examine if family-community-school-university partnerships can increase social capital and resources in these communities and contribute the resilience of children and families living in rural poverty. Researchers can frame these studies using strengths-based ideology. Furthermore, there is a need for policy analysis at the macro level to create interventions that target inequities in education, healthcare, housing, and rural community development.

Finally, there is a continued need to explore the efficacy of training received by mental health providers, teachers, and other professionals who work in impoverished rural communities as the recognition of social class as a critical component of multiculturalism is developing slowly. Thus, studies are needed to evaluate whether university educators are comfortable and competent in teaching topics related to poverty, rurality, and classism. Researchers could use surveys and focus groups to investigate if university educators recognize social class and rurality as important components of cultural identity and how often topics related to economic disadvantage are reflected in the curriculum.

CONCLUSION

Poverty and poverty experiences are complex and have a distinct impact on a variety of diverse groups, including women, children, families, people of color, and LGBTQ persons (Bishaw & Benson, 2018; PSU, 2019; UNESCO, 2019). Poverty is more prevalent in and complicated by rurality (USDA Economic Research Service, 2019). Persons who experience poverty are at risk of a variety of health (Kaminski et al., 2013) and mental health issues (Weissman et al., 2015) that can impact wellbeing; these health and mental health issues are complicated and often worsened by the obstacles individuals may face in engaging in work and educational experiences (WHO, 2010). In addition to these increased mental health risks, persons experiencing rural poverty are less likely to have access to services, either because of a lack of providers or due to stigma (Crowe et al., 2016; USDA Economic Research Service, 2019).

Mental health professionals should stay abreast to the current issues, needs, and dynamics of impoverished rural families and communities (Ratts et al., 2016). For many providers, this will require adjustment of service delivery to include community connections, advocacy, and a focus on strengths-based approaches (Clark et al., in press; Dorfman, 1998; Ratts et al., 2015; Rollins, 2010; Rural Health Hub, 2019c). These community partnerships may include integrated care models that involve working with medical professionals and case managers, school-based mental health services, and faith-based organizations (Crumb et al., 2019; Avent, Cashwell, & Brown, 2015). Beyond these partnerships, providers can also consider ways in which they can modify their service delivery methods to serve rural families in poverty, including home-based services (Freidman, 2012; Polaha et al., 2015) and telemental health (American Telemedicine Association [ATA], 2017; Gloff, LeNoue, Novins, & Myers, 2015; Orlowski et al., 2016; Polaha et al., 2015). In addition to these logistical adjustments, providers must address their own capabilities to work with rural families in poverty, including their own multicultural and social justice competence (Ratts et al., 2015), and utilize strengths-based interventions like asset mapping to focus on client strengths and abilities, not deficits (Dorfman, 1998).

KEY TERMS AND DEFINITIONS

Integrated Healthcare: The coordination of behavioral health services with primary care settings in order to attend to the overall healthcare needs of those seeking services.

Mental Health: A measure of an individual's overall mental status, psychological health, and wellness.

Mental Health Literacy: The ability to accurately identify mental illnesses, attributions of mental disorders, and the knowledge and beliefs about risk factors related to mental health disorders.

Resiliency: The capacity to withstand significant challenges that threaten stability, viability, or personal development.

Social Class: An economically and socially stratified group who share similar norms, values, and cultural experiences.

Social Justice: Awareness and actions related to changing social institutions, and political and economic systems that perpetuate unfair practices in terms of accessibility, resource distribution, and human rights in an effort to enhance the academic, career, and personal/social development of individuals and groups.

Strength-Based Ideology: A perspective that allows one to explore and identify people's strengths and integrate these strengths to build resiliency, competencies, and resources.

Chapter 58
Advocating for the Mental Health Needs of Children Living in Rural Poverty

Denise Lenares-Solomon
Augusta University, USA

Christina Conti
Augusta University, USA

Christina George
Augusta University, USA

ABSTRACT

A person's mental health involves their social, psychological, and emotional wellness, all of which are important to their development. Lack of resources and access to effective mental health services can have a negative impact on the mental health of children residing in poverty-stricken rural communities. In advocating for this population, the authors have highlighted five factors that work as barriers in the mental health of children living in rural poverty. These factors were identified as early development, healthcare accessibility, parental/caretaker's educational level, educational system, and mental health stigma and stress. Furthermore, the authors presented a multi-layered approach for addressing these barriers. The components of the multi-layered approach include school-based resources, community-based resources, medical-based resources, and government-based resources. A case illustration is used to demonstrate the practical application of one aspect of the multi-layered approach – the school-based resources. Lastly, the authors stated that more research is needed for this population in regard to the effects of rural poverty on the mental health of children.

INTRODUCTION

A snapshot of a mental health update across the United States found that one in five Americans (46.6 million) have a current mental illness. It has been reported that mental illness is not only the main cause of disability in youth but has also resulted in more deaths than any other health condition (Sawyer et. al, 2012 & World Health Organization [WHO], 2014). Reports like these highlight the importance of addressing mental health issues especially in younger populations (Petruzzelli, 2018). Mental health involves an individual's social, psychological, and emotional well-being (MentalHealth.gov, n.d.). In 2018, approximately 38.1 million Americans lived in poverty (Semega, Kollar, Creamer, & Mohanty, 2019) with people under the age of 18 representing 31.1% of these individuals. One out of every five children living in a rural area are considered to be living below the poverty line (Mammen, Dolan, & Seiling, 2015). Those who live in poverty face several stressors that impact their quality of life, one being access to mental health care (Fifield & Oliver, 2016; Hill, Cantrell, Edwards, & Dalton, 2016). The mental health concerns of families and individuals living in rural and poor communities are often overlooked and under-researched (Tickamyer, Sherman, & Warlick, 2017). Not only are their mental health concerns overlooked, but individuals living in rural communities are less likely to seek help for psychological distress than their urban counterparts (Cheesmond, Davies, & Inder, 2019).

Rural poverty can negatively affect the mental health of children. It is the opinion of the authors of this chapter that leaders and advocates of this population need to understand the mental health issues affecting these children. Consequently, the authors of this chapter will discuss the various barriers that affects the mental health of children and families living in rural poverty and present a multi-layered approach that will provide leaders and advocates with means in which they can address these barriers. The specific barriers that will be discussed are early development, healthcare, parental/caretaker's education, the education system, and mental health stigma and stress.

BACKGROUND

The United States government defines poverty as a state of living below the federal poverty line or earning less than $24,000 a year for a family of four (Kena et al., 2015). In 2013, approximately 21% of school-age children were living in households considered to be in poverty (Kena et al., 2015). A child in poverty can be negatively affected by a variety of environmental and situational factors ranging from lack of proper nutrition, differing parental level of education, stress, and lack of care, both physically and mentally (Conger, Conger, & Martin, 2010). These factors affect a child's ability to learn, regulate their emotions, and fight against hopelessness (Evans, 2016). A deficiency in these skills negatively influences the child's mental health. Mental health skills from early childhood and adolescence are vital to a person's success later in life.

According to the American Psychiatric Association (2019), experiencing healthy relationships, adapting in the face of change and adversity, and engaging in productive activities all allude to mental health. Mental illness can also occur when one experiences problems and/or dysfunction in family, social, or work relationships (American Psychiatric Association, 2019). Mental illness is a treatable medical condition. Unfortunately, Americans residing in rural environments face higher rates of mental illness, depression, and suicide compared to those residing in urban areas (American Psychiatric Association, 2019). Despite discrepancies such as these, rural residents are less likely to receive or seek mental health services than

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

urban residents (Carpenter-Song & Snell-Rood, 2017). Furthermore, rural poverty can be seen to have a more significant effect on mental health compared to urban poverty due to the lack of care, proper mental health education, and counseling services (Valluri, Mammen, & Lass, 2015). As stated earlier in the text, one out of five children residing in rural areas, live below the poverty line (Mammen et al., 2015). Poverty not only affects younger children, but it continues to affect these children as they mature into adulthood. Poverty is often seen as a never-ending cycle of low income, inadequate education, and lack of resources (Sigelman & Rider, 2015). Comeau and Boyle (2018) found an association between exposure to chronic poverty in children's early years and lower levels of mental health. This association was only found to increase as the child aged (Comeau & Boyle, 2018). Disorders such as learning problems, attention-deficit/hyperactivity disorder (ADHD) and anxiety often start in early childhood and can affect a person's well-being and life-long health (Centers for Disease Control and Prevention, 2019). According to the Centers for Disease Control and Prevention or CDC (2019), about one in seven American children between the ages of two and eight have been reported by a parent to have a mental disorder. Research has demonstrated that children with mental disorders and their families experience financial and personal challenges more often than those without mental health disorders (Centers for Disease Control and Prevention, 2019). It was further stated that the type of community, rural versus urban, may increase these challenges. Consequently, there has been a call from some researchers to examine how social inequality in rural America has affected the experiences of mental illnesses in rural communities (Carpenter-Song & Snell-Rood, 2017).

MAIN FOCUS OF THE CHAPTER

In response to the call of addressing the many influences that affect the mental health needs of children living in rural poverty, the authors of this chapter have proposed a multi-layered approach. The integration of family, community, and school-based resources is the key to providing mental health care services to children regardless of socio-economic status and can be especially effective for children living in rural poverty (Bullock, Zolkoski, & Estes, 2015). Consequently, the authors of this chapter have posited that advocacy has to be delivered in a multi-layered approach. This multi-layered approach includes school-based resources, community-based resources, medical-based resources, and government-based resources. However, before this approach is explored, it is important for leaders and advocates to have a comprehensive understanding of some of the influences that impact the mental health of children living in rural poverty. Following is an examination of the following influences: early development, healthcare accessibility, parental/caretaker's education, the education system, and mental health stigma and stress.

Influences on the Mental Health of Children Living in Rural Poverty

Early Development

Mental disorders and intellectual disabilities are significant public health concerns in America (Linn, Chuaqui, Wilson, & Arredondo, 2019). Two circumstances that threaten the emotional and social development of young children is a lack of resources and poor supplemental care settings (Fitzgerald, Weatherston, & Mann, 2011). Children are constantly learning and developing through their interactions and experiences with their environment and the people around them. Learning begins early, as babies have

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

been found to remember certain sounds such as their mother's voice before birth (Sigelman & Rider, 2015). How then does poverty affect early development? In a study analyzing the brain development of 77 children between five months and four years old, researchers observed that there were changes in the brain growth of the participants as they were exposed to poverty (Hanson et al., 2013). Researchers found differences in cortical gray matter in infants within their first beginning months of life. Hanson et al. (2013) measured the averages of total gray matter volumes in infants across a variety of socioeconomic backgrounds and races and found that children from poverty and low-income households had significantly lower average total gray matter volumes. These children were also found to have significantly lower average frontal and parietal gray matter volumes (Hanson et al., 2013). Gray matter is known to play a role in memory, language, reading and comprehension, and thought processing (Ruitenberg & Cassady, 2019). Researchers have further concluded that "Contemporary developmental sciences have linked interpersonal relationships to brain development…" (Fitzgerald et al., pg. 181, 2011). Brain development is negatively affected by poverty and poverty is often associated with disruptive behavioral problems (Hanson et al., 2013).

Healthcare Accessibility

It is important for parents to seek the help of a healthcare or mental health professional trained to diagnose and treat mental disorders if they suspect that their child is experiencing a mental disorder (Linn et al., 2019). Unfortunately, specialized professionals are scarce in rural areas, especially mental health professionals. Access to healthcare is especially important because in addition to the increase in the amount of stress in a child's life, there are also other medical disadvantages to living in rural poverty. Individuals living in rural poverty have been found to be more likely than their urban counterparts to die from five causes: cancer, heart disease, chronic lower respiratory disease, stroke, and accidental injuries (Weeks, 2018). Even though these causes of death are mostly preventable, people living in rural poverty do not have access to care compared to their counterparts living in urban poverty (Weeks, 2018). Many researchers have looked into the cause of this disparity. Weeks (2018) attributes this disparity to stress, hopelessness, bleak job markets, family dysfunction, poor social support, and addiction which causes individuals to turn to other forms of coping such as food, alcohol, tobacco, opiates, and suicide. As mentioned previously, the lack of medical professionals in rural areas plays a role. One-fifth of Americans live in rural areas while only one-tenth of physicians practice in rural areas (Weeks, 2018). Since 2010, 83 hospitals in rural areas have closed due to lack of funding and physicians (Weeks, 2018).

Along with lack of resources and financial concerns, transportation is a major issue. The public transportation infrastructure does not exist in most rural areas of the United States which further limits a person's ability to access mental health resources that are available in larger populated areas. Transportation is not only an individual issue but a community-wide issue because even when public modes of transportation do exist, they are often not flexible enough to meet individual needs (Pullman, VanHooser, Hoffman, & Heflinger, 2010; Blackstock, Chae, Mauk, & McDonald, 2018).

Healthcare Providers' Competency

Even if medical providers are located in rural areas, the providers might not be trained to help individuals suffering with mental illnesses. After interviewing medical providers in rural areas, Matsea, Ryke, and Weyers (2018) found that 43% of their population of medical professionals hadn't attended training on

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

mental illnesses or mental health related issues in the past 12 months. Mental illness is just as prevalent in urban areas as it is in rural areas, but rural areas cannot provide residents with adequate services in order to treat those who are living with mental illnesses (Matsea et al., 2018). Researchers discussed a few reasons for the lack of adequate care in rural areas which include lack of comprehensive service providers, lack of accessibility to available services, and poor quality of service.

It is imperative for healthcare providers, especially mental healthcare providers, to seek out training and become competent in specific mental health issues impacting children living in rural poverty. This competence is important because parents, unless taught by professionals, are unaware that a concern exists in regards to their child's mental health. How can we expect parents who are not aware of mental health concerns to be aware of the resources available to support them (Handley, Lewin, Perkins, & Kelly, 2018). Poor mental health literacy hinders mental health service use and can be seen as a barrier to adequate care (Handley, Lewin, Perkins, & Kelly, 2018). Mental health literacy is seen as knowledge about mental disorders (Bullock et al., 2015; Chambers, Murphy, & Keeley, 2015).

Parental/Caretaker's Educational Level

Effects of Poverty

A child's health, both physical and emotional, is influenced by their parent's lifestyle choices and socioeconomic status (Sigelman & Rider, 2015). Due to the lack of employment opportunities, high cost of life's necessities, and legislative measures, many families living in rural poverty are stuck in a never-ending cycle of poverty (Annie E. Casey Foundation, 2004). This results in the child being directly impacted by the parent's income, motivation, and perception of higher education (Sigelman & Rider, 2015). Maslow's Hierarchy of Needs states that a person must meet certain innate physical needs such as breathing, food, water, shelter, clothing, and sleep before they can progress up the hierarchy to higher order needs such as self-actualization (Maslow, 1943). Some people believe that these needs are accessible and available to everyone, yet those living in poverty struggle with meeting these basic foundational survival needs daily. A child who is hungry and living on the streets cannot meet higher level needs, such as achievement and acceptance (Noltemeyer, Bush, Patton, & Bergen, 2012). This might explain why 30% of children living in poverty do not complete high school (Johnson, Lawrence, Perales, Baxter, & Zubrick, 2019; Kerns, Newschaffer, Berkowitz, & Lee, 2017).

Taylor (2005) found that children that qualified for free lunches scored lower than students who did not qualify for free lunches on educational assessments. This pattern starts in middle school and continues into high school. Even Scholastic Aptitude Test (SAT) scores have been found to correlate with a family's income (Taylor, 2005). Children living in poverty not only achieve lower test scores than their more affluent peers, but they also drop out of school at higher rates (Taylor, 2005). Nogurea and Wells (2011) explain how poverty affects children's performance at school through a limited access to academic and social support, the influence of negative conditions on a child's health and well-being, and lack of social structures leading to adverse conditions. This never-ending cycle is nearly impossible to overcome due to situations out of the individual's control such as recessions and lack of employee benefits (Mammen et al., 2015).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Effects of Low Educational Level

Research from a study by Noble et al. (2015) found that for each additional year of education an individual had an increased amount of cortical surface area in the areas related to language, reading, and self-regulation. A groundbreaking study by Hart and Risley (2003) found 86% to 98% of the words used by children by the age of three were from their parent's vocabulary. Due to this finding, researchers were able to identify a difference in the number of words a child could speak that correlated to socio-economic status. Children from lower socio-economic households were found to hear about 616 words per hour from their parents while the children from middle and upper socioeconomic levels heard anywhere from 1,251 to 2,153 words per hour (Hart & Risley, 2003). Not only was there a difference in the number of words heard, but a difference in the content of the words was also identified. Children from higher-income families tended to hear more words of praise and admiration compared to children from lower-income families who tended to receive more negative reinforcement from their parents (Hart & Risley, 2003).

Educational System

School Mental Health

It has already been established that resources in poverty-stricken rural regions are scarce which translates to scarce resources in those local schools (O'Malley, Wendt, & Pate, 2018). These limited resources are not sufficient to address the care of students who are struggling with poor mental health. Additional constraints faced by rural schools are the lack of trained community and school-based mental health personnel. There is a gap between the increasing mental health needs of youth and the resources available to them at school (O'Mallley et. al., 2018). As a result of these limited resources, education agencies need to efficiently allocate resources by utilizing innovative public health models. A study focused on the school principals' perspectives identified that mental health was one of the greatest needs among teachers, school staff, and students (Iachini, Pitner, Morgan, & Rhodes, 2016). This finding is similar to a growing view of educational priorities emphasizing that school improvement models should be expanded to include mental health support. Principals have found that these models improve student learning (Iachini et. al., 2016). School mental health is an increasing priority across the United States for policy-makers and principals have highlighted that it is crucial to address the mental health needs in schools (Frabutt & Speach, 2012; & Iachini et. al., 2016).

Achievement Gaps

Another issue experienced by students from low-income families is what is known as the achievement gap. The achievement gap is the difference between the test scores of minority and/or low-income students compared to their more affluent peers (Von Stumm, 2017). Achievement gaps are present from preschool all the way through high school and into college (Kena et al., 2015). Standardized tests such as college admissions tests provide researchers with data that outlines a gap in achievement across socioeconomic statuses (Von Stumm, 2017). Thirty percent of children living in poverty do not complete high school (Clotfelter, Ladd, & Vigdor, 2006) and those children are also more likely to have lower scores on tests compared to children from wealthier households (Clotfelter, Ladd, & Vigdor, 2006). According to Williams, Bryan, Morrison, and Scott (2017), the income-related achievement gap is the reason that children entering kindergarten who are from families living in a higher socioeconomic status score 60% higher than children from lower socioeconomic households on cognitive tests.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In conclusion, school-based mental health programs are important because there is increasing interest and acknowledgement in the role that mental health plays in promoting positive early learning experiences which will help in closing the gaps between children in varying socioeconomic status households (O'Connor, O'Connor, Gray, & Goldfeld, 2018).

Mental Health Stigma and Stress

Stigma

A low level of mental health is an ongoing concern in rural areas and is only compounded by factors such as low rates of seeking help and utilizing professional care than urban areas (Caldwell, Jorm, & Dear, 2004; Hilton, Scheurer, Sheridan, Cleary, & Whiteford, 2010). Poor mental health literacy has been found to contribute to the lack of mental health service use in rural areas (Handley, Lewin, Perkins, & Kelly, 2018).

There is a stigma that is attached to seeking care for mental illnesses, especially in rural communities (Johansson et al., 2019). While mental health is a universally applicable concern, people living in rural communities have unique fears of stigma. Although mental illness stigma has been extensively researched, limited studies have investigated youth perspective and how they respond to it (Haug, 2019). Furthermore, fear of stigma as a belief consists of three separate components: trust, stigma, and attitude (Blackstock et al., 2018). The lack of trust for a mental health professional, who is often an "outsider" in rural communities, makes parents less likely to seek out or follow through seeking help for mental health. Attitude feeds into stigma. In rural communities, the pervasive attitude is that people should be stoic and self-reliant, neither of which bode well when someone needs mental health treatment (Blackstock et al., 2018). This type of attitude only serves to isolate and shame those who do need help, for instance, rural children. For youth and children experiencing a mental health issue, mental illness stigma is a serious concern for not only them but also their immediate family (Liegghio, 2016).

Stress

While stress is something everyone experiences, it is more common among low-income households. Studies measure the effect of poverty on a child's mental health and overall functioning with results confirming that poverty increases the amount of stress placed on a child (Evans, 2016). Evans (2016) found that children who grew up in poverty had a diminished ability to recall patterns compared to children who did not grow up in poverty. This finding is important since short-term memory affects other aspects related to basic cognitive skills and achievement, ultimately affecting educational success. Evans (2016) also measured the feeling of helplessness among these groups and found that adults who grew up in low-income homes were eight times more likely to give up on tasks than adults who did not grow up in poverty. This feeling of helplessness was present even with those adults who were able to escape the cycle of poverty (Evans 2016). Kim et al. (2013) found an association between childhood poverty and an adult's neural activity during attempts to regulate their emotions.

Stress has a significant impact on physical, mental, and emotional health (Kim et al., 2013). Stress affects a person's feelings and has also been found to affect certain areas of the brain; specifically, the amygdala and prefrontal cortex (Kim et al., 2013). The amygdala is responsible for perceiving and feeling the emotions of others, such as fear, sadness, and happiness (Sigelman & Rider, 2015). The prefrontal cortex makes up 10% of the brain's total volume; therefore, it is responsible for many tasks. Studies have

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

found that the prefrontal cortex plays a critical role in executive functions, memory, language, visual search, and gaze control as well as cognition and decision making (Sigelman & Rider, 2015). Researchers have also identified certain disorders that are associated with damage to the prefrontal cortex such as depression, anxiety, schizophrenia, as well as ADHD, ASD, and conduct disorders (Siddique, Chatterjee, Kumar, Siddique, & Nishant, 2008).

The Family Stress Model, first introduced in 1994, predicts that economic hardships contribute to the deterioration of marital relationships and therefore an increase in the amount of stress in the household (Conger et al., 2010). Since its introduction, researchers have not only found that stress affects the marital relationship, but it also affects a child's development (Neppl, Senia, & Donnellan, 2016). Neppl, et. al. (2016) found this to be true through their study, where connections between marital stress, harsh parenting, and child externalizing behaviors were tested with the family stress model. Researchers found that economic pressure, emotional distress, and couple conflict were associated with harsh parenting and therefore, may contribute to externalizing problems for children as they age. Economic pressure was related to emotional distress, which was associated with higher levels of harsh parenting. In conclusion, stress affects parents and children, both directly and indirectly (Neppl, et. al., & Donnellan, 2016).

CONCLUSION

All children experience stressors and difficult times in their lives (Padmore, 2016). In this chapter, the authors focus on the mental health of children living in rural poverty. The barriers discussed in this chapter, based on a study of research literature, were early development, healthcare, parental/caretaker education, the education system, and mental health stigma and stress on barriers to mental. Understanding the influences presented in this chapter will inform leaders and advocates on the pressing need to address these issues. Detection, early intervention, and support for children and their parents are crucial in building resiliency in this population (Padmore, 2016) These problems reduce the chance of academic and social success and increase the risk of substance abuse and misuse, self-harm, and suicide (Padmore, 2016). Consequently, a multi-layered approach is detailed next with the goal of ensuring that the mental health needs of children living in rural poverty are addressed.

Multi-Layered Approach Addressing the Mental Health for Children Living in Rural Poverty

Research is on-going into how meta-systems across the United States can more effectively address mental health concerns of children and adolescents living in rural poverty (Kazak, Hoagwood, Weisz, Hood, Kratochwill, Vargas, & Banez, 2010). This research has pointed to a need for a systemic overhaul that encourages cross-organizational collaboration as seen in states like New York, Hawaii, Tennessee, and California (Kazak et al., 2010). Although systemic change is shown as necessary to have a long-standing impact, research also stated a multi-layered approach of integrating family, community, and school-based resources is the current key to providing mental health care services to children regardless of socio-economic status. Collaborative efforts among parents/caregivers, schools, primary care managers, and community programs are essential. Implementing all of these resources lessens or even eliminates the negative impact of barriers parents face when finding and helping their children through prevention and treatment of mental health issues. These barriers could be a lack of availability of resources, insur-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ance limitations (financial cost), transportation challenges, lack of knowledge of resources, and fear of stigma (Searcey van Vulpen, Habegar, & Simmons, 2018). Previously in this chapter, early development, healthcare, parental/caretaker education, educational system, and mental health stigma and stress were addressed that impact the mental health of children living in rural poverty.

The authors of this chapter have posited that there are opportunities in a multi-layered approach for leaders and advocates to be effective in addressing rural poverty children's mental health. When informed on effective resources, individuals will be able to seek leadership and advocacy opportunities to address the influences that affect the mental health of children living in rural poverty. The following is a review of this multi-layered approach that includes school-based resources, community-based resources, medical-based resources, and government-based resources. A case illustration is used to demonstrate the practical application of the first element of the multi-layered approach - the school-based resources.

Case Illustration Overview

The following is a retrospective case analysis used for educational purposes. This case involves a 7th grader Caucasian male who resides in a low SES south-east region rural community. His school implements Positive Behavioral Interventions and Supports (PBIS) and Social Emotional Learning (SEL). He receives free and reduced lunch and was referred to the school counselor by his math teacher. The math teacher referred him as a result of poor academic performance and disruptive behavior in class. His teacher's school counseling referral reported that he would often disrupt class by engaging his classmates in conversation rather than do his work. The teacher also stated that she worries that he may have low self-esteem. He was very excited to see the school counselor and the attention given to him. The student appeared inappropriately dressed for the weather- wore a T-shirt and shorts in cold weather. He also had an odor. After the second session with the school counselor the student shared with the counselor that he found math "hard" and did not understand the work so he preferred to be sent to In-school suspension. In order to further understand the living conditions of the student the counselor rode his bus to see the area. The counselor discovered that he lived in a single-wide older trailer with compromised roof and shingles, no other houses were visible, and no heat and hot water. The student was referred to the social worker.

School-Based Resources

School-Based Mental Health Programs

To address the challenges faced by families living in rural poverty, SBMH programs, such as Positive Behavioral Interventions and Supports (PBIS) and Social Emotional Learning (SEL), help provide resources, increase knowledge of services, reduce or eliminate parent financial costs and transportation issues, and help reduce fear of stigma with parent and caregiver-centered psychoeducational training sessions (Bullock et al., 2015; Searcey van Vulpen et al., 2018). Schools are key resources because, even though the exact cut-off age varies by state, federal law mandates school attendance across the country (National Center for Educational Statistics, 2019). Infrastructure is already in place to transport students to schools which helps remove the transportation barrier; consequently, schools are able to directly impact a child's life through SBMH programs. The National Alliance on Mental Illness (2019) explained that evidence-based practices include "integrated expert opinions, observable scientific evidence, and client/patient experience" to gauge whether a program is successful (para. 2). Research has shown that SBMH

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

programs such as PBIS and SEL are integral evidence-based practices in the fight against mental health issues in poverty stricken rural areas. In addition to PBIS and SEL, school-based mental health programs also provide psychoeducational opportunities to the community via school personnel. Following is a discussion of how SBMH can assist in addressing the mental health of children living in rural poverty.

Positive Behavioral Interventions and Supports

Funded by the U.S. Department of Education's Office of Special Education Programs (OSEP) and the Office of Elementary and Secondary Education (OESE), the Technical Assistance Center on PBIS provides systemic support to schools, districts, and states to build systems capacity for implementing a multi-tiered approach to social, emotional and behavior support (OSEP Technical Assistance Center Positive Behavioral Interventions & Supports, 2019). According to the Technical Assistance Center on PBIS (2019), integrating PBIS in the school setting incorporates behavior as a part of the curriculum. Each school develops three to five behavioral expectations with standards that are clearly stated, easily measurable, and consistent throughout all areas of the school (para 1). Time is built into the school's beginning of the year calendar to teach and set these behavioral standards (para 5). Part of this process includes a consistent discipline referral matrix. This matrix delineates exactly what types of deviations from the behavioral standards are handled at what level of administration; certain behavior deviations are handled in the classroom and certain behavior deviations are handled by the front office (para 6).

The core principles of PBIS are as follows:

1. We can effectively teach appropriate behavior to all children.
2. Intervene early.
3. Use of a multi-tier model of service delivery.
4. Use research-based, scientifically validated interventions to the extent available.
5. Monitor student progress to inform interventions.
6. Use data to make decisions.
7. Use assessment for three different purposes. (OSEP Technical Assistance Center Positive Behavioral Interventions & Supports, 2019)

PBIS uses a 3-tiered approach to intervention: Tier 1 is universal for ALL students, Tier 2 is targeted group support for SOME students, and Tier 3 is individual support for a FEW student (https://www.pbis.org/school/tier2supports, 2019). For more information regarding how PBIS is integrated into schools, visit www.pbis.org.

Application of Case Illustration

Based on established PBIS program guidelines, the middle school set the following PBIS expectations:

1. Responsible for our actions
2. Organized and ready to learn
3. Achieving at our highest level
4. Respectful towards ourselves, others, and property.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

These expectations were displayed throughout the school on posters in the hallways, classrooms, cafeteria, and all common areas. These expectations were introduced the first few days of school with examples of how to demonstrate these expectations. For example, a student demonstrates "Responsible for our actions" in the classroom by following directions the first time they are given. Teachers often referred back to these expectations. For minor deviations from these expectations, the following progressive discipline steps were used.

In the case of our student, the math teacher noticed poor academic performance and disruptive behavior during class. Instead of paying attention and completing his work, the student would talk to his peers and distract them. This student was clearly deviating from all four of the behavioral expectations but in a minor way. The math teacher began with Step 1 of the Progressive Discipline chart above, but the student kept up the disruptive behavior. Using Step 2, the math teacher sat down for a conference with the student. This is when the math teacher realized that the student needed more support than he could give. The school counselor's office was a well-established place to get more support resources. The math teacher referred the student to the school counselor's office which is a Tier 2 level support.

In the initial session with the school counselor, the student presented as excited to be in the office which the counselor identified as a need/want for attention. The counselor also observed that the student was inappropriately dressed for the season and cold. The student had an unkempt appearance and an unwashed odor. After discussing the reason, the student was referred to the counselor, the student admitted struggling to understand the work in the classroom. The student had hoped his behavior would result in In-School Suspension (ISS) and ultimately a way to escape from the situation. Instead of escaping to ISS and further falling behind in academics, the student was now able to get the support he needed. The school counselor helped the student admit that he needed math tutoring. Together with the math teacher, the counselor made arrangements for extra intervention time during the student's daily school schedule. In order to monitor progress and to follow up on other noted concerns, the school counselor met with the student the following week.

During the second session with the school counselor, the student said what a help the extra intervention time had been, and the counselor shared positive comments from the math teacher regarding classroom behavior improvement. Even though this intervention went well, the counselor still noticed the same issues from the previous session of inappropriate dress for the season and an unkempt appearance. By asking a few direct questions about the student's home life, the counselor learned that this student lived in a single-wide trailer on a dirt road without heat or hot water. This information, combined with the student's current appearance, warranted a referral to the school social worker. The school counselor knew that the school social worker could help make contact with the family and provide them with resources to improve their living conditions.

By following the PBIS program, the school administration was able to intervene in constructive ways to better serve this student before punitive discipline such as in school suspension was used. The root of the child's issue was discovered, and steps were taken to assist based on the PBIS steps.

Social Emotional Learning

The Collaborative for Academic, Social, and Emotional Learning (CASEL) defines SEL as "the process through which children and adults understand and manage emotions, set and achieve positive goals, feel and show empathy for others, establish and maintain positive relationships, and make responsible decisions" (The Collaborative for Academic, Social, and Emotional Learning, 2019). CASEL uses 5 core

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

competencies to teach children and adults: 1) self-awareness, 2) self-management, 3) social awareness, 4) relationship skills, and 5) responsible decision-making (The Collaborative for Academic, Social, and Emotional Learning, 2019). Research has proven that incorporating these skills into a child's daily life helps them develop skills that serve to fight against the conditions leading to poor mental health.

Organizations such as CASEL (casel.org) and the Substance Abuse and Mental Health Services Administration's (samhsa.org) National Registry of Evidence-Based Programs and Practices (NREPP) provide a variety of SEL curriculums that can be implemented in a school setting. For more information regarding these programs, visit the referenced websites.

Application of Case Illustration

The student in our illustrated case study attends a school that employs Collaborative for Academic, Social, and Emotional Learning (CASEL). Utilizing this approach in this case, the teacher along with the school counselor utilizes social emotional learning (SEL) with the goal being to ensure that this student develops integral life skills that go beyond academics. SEL can be applied in the classroom and school. In the classroom, utilizing the following activities, the teacher will provide the student with the ability to work toward academic goals; consequently, improving his self-esteem. In this case, the goal is to improve in math. Two strategies the teacher applied were 'daily check-ins' and 'work buddy'. Check-ins were applied since the student responds positively to personal individual attention. This will allow the teacher to make a personal connection with the student at the start of every class. In using a 'work buddy' will enable the student to utilize social skills when the teacher will place the student with an assigned partner to work on class assignments. The goal is to strengthen the student's math skills while learning how to appropriately socialize with others. Along with the school counselor, the teacher will work with both students to apply rules to having a productive working buddy. Some examples of the rules are: to focus only on the class assignment, listen to each other, ask the teacher questions when the assignments are not clear, and complement each other. The school counselor will ensure that the student understands that the school counselor's office is a safe place he can use as a refuge when he is frustrated or upset. The school counselor also works with the student to understand emotions and how to properly convey them. Furthermore, the school counselor will work with the student on improving his self-esteem.

School Personnel and SBMH

Psychoeducational opportunities are also presented to the community via school personnel. SBMH programs are implemented as a part of the learning environment for every student which not only builds resilience skills for the community but also helps to educate the community regarding overall mental health wellness models. This psychoeducation reduces the fear of stigma associated with mental health in general, as well as reduces the fear of seeking help from outside resources. With collaboration between community and school resources such as school counselors, licensed professional counselors and social workers, more extensive mental health treatment can be offered at the schools. The school faculty and staff spend countless hours with students each week which gives them the opportunity to identify certain mental health needs above and beyond basic SEL (Bullock et al., 2015). With minimal additional training, basic mental health screening can be used by school faculty and staff such as teachers and nurses.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Application of Case Illustration

In our case, the student was referred to the counselor by his math teacher. If this teacher had not noticed that the child was having difficulties in class, he might not have received the care he needed. Unfortunately, counselors are not able to have individual time with students each day. There is not enough time for them to notice inconsistencies in children's behavior or assess for their needs, unless they are referred by either the teacher or a parent. Teachers are able to recognize if a student is in need due to a high rate of absenteeism, behavioral issues, and their academic record. Because the teacher referred the student in our case due to his poor academic performance and disruptive behavior, the counselor was able to look at the child holistically and determine if his needs were being met. It is imperative that teachers take the time to notice their students and are aware when a student is in need. If this teacher had not noticed and had instead dismissed the child in our case, they might not have received the help and support they needed from the counselor and social worker. The child in our case lacked the basic needs to live such as hot water, heat, and proper clothing for the weather. He was living in rural poverty and it wasn't until the counselor in our case drove by where he lived did she realize that his living situation lacked basic needs. Had the counselor not driven out, she would have not been able to empathize as much with the child, as he did not directly tell her about his living situation. The counselor was able to refer the student to a social worker in order to help him and his family gain access to basic necessities.

For rural areas, it is also important for SBMH programs to focus on healthy self-care, depression screening, and anti-bullying programs (Searcey van Vulpen et al., 2018). School counselors play an integral role in SBMH programs in their respective schools with the buy-in from parents/caregivers, administration and faculty. This means that counselors must find ways to empathize with the worldview of people living in rural poverty in their communities because it will help identify the needs of that population (Crumb, Haskins, & Brown, 2019). School counselors are also a source for parents, school, and community members by maintaining a mental health services resource lists and contacts in the community and by distributing this information through flyers and pamphlets to parents and caregivers (Searcey van Vulpen et al., 2018).

SBMH programs exist and have proven effective; however, it is important for leaders and advocates to ensure that rural schools are implementing these programs. Collaborating with rural schools will also ensure that the specific needs of communities are addressed. Programs should not forget to address cultural concerns in the lives of its families (Yohannan, Carlson, Shepherd, & Batsche-McKenzie, 2017). These multi-layered approaches have to be as diverse as the populations they serve (Hefflinger, Shaw, Higa-McMillan, Lunn, and Brannan, 2015).

Community-Based Resources

In a qualitative study eliciting views from rural patient and family members', participants did not identify community-level solutions that addressed mental health problems (Robinson et. al., 2012). Furthermore, they stated that mental health problems in the community were handled as a legal and law enforcement issue. Following are some community-based resources that are available in rural communities to help address the mental health of children and families living in poverty.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Community Centers

The United States Department of Agriculture (USDA): Rural Development provide affordable funding opportunities to develop essential rural community facilities (United States Department of Agriculture, n.d.). The USDA defines essential community facility as a place that provides a crucial service to the local community in a town, townships, villages, and cities with no more than 20,000 residents. Health care facilities, child care centers, telemedicine, and food pantries and banks have been identified as essential community facilities. As has been demonstrated by the research literature presented in this chapter, a mental health facility for children and families residing in rural communities would qualify as an essential service. Community leaders and advocates are encouraged to take advantage of such a program as priorities are given to low-income communities (USDA, n.d.). Further information can be found at the USDA: Rural Development website.

Non-Profit Organizations

Organizations that offer rural children the opportunity to engage in social and physical activities are important. According to Sigelman and Rider (2015), the benefits associated with exercise go beyond physical fitness for physical activities enhances psychological functioning. Some organizations that are available in rural areas are:

- 4-H: 4-H provides youth to engage in civic, healthy living, and science programs that results in these young people building confidence and life skills like resiliency and leadership (4-H, n.d.). 4-H programs are available in every parish and county in the United States. Information on programs available in rural areas can be found at the local 4-H office or online at https://4-h.org/find/.
- Boy Scouts of America: An organization for boys and girls, kids are given fun hands-on achievement and learning opportunities that prepare them for today and for life (Boy Scouts of America, n.d.). Information on programs available in rural areas can be found at the local Scouts office or online at https://beascout.scouting.org/?utm_source=scouting&utm_medium=FSYA_welcome&utm_campaign=ongoing.
- Girl Scouts: This organization prepare every girl for a lifetime of leadership. Some activities experienced by the girls are night-time hiking, lobbying city council, or running her a cookie business (Girl Scouts, n.d.). Information on programs available in rural areas can be found at the local Girl Scouts office or online at https://www.girlscouts.org/en/about-girl-scouts/the-girl-scout-difference.html

Medical-Based Resources

Access

Affordability and Transportation

Rural poverty is often associated with a lack of access to health care and proper education (Mammen et al., 2015). This never-ending cycle of poverty is real and makes it difficult for those born into poverty to escape from it (Mammen et al., 2015). People living in rural poverty are at a disadvantage when needing to access medical services (Valluri et al., 2015). Individuals living in rural poverty are more likely

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

to report a lack of medical services. Detrimentally, there is a lack of insurance for mothers (Valluri et al., 2015). Nearly one-quarter of individuals living in rural poverty under the age of 65 are uninsured (Annie F. Casey Foundation, 2004).

The Centers for Disease Control (2019) has recommended that some opportunities for mental and behavioral health care services to be available to rural children and parents can be through school systems. By integrating these services into systems that are already accessible – schools – children will be able to receive care. A detailed school based mental health system has been discussed earlier in this chapter. Utilizing options available via the internet has been discussed as another option for those living in rural areas to access mental health services (Carpenter-Song, & Snell-Rood, 2017). According to their study analyzing the he impact of rural social change on mental health these researchers have proposed the use of utilizing mental health-related information to this population via the widely available internet. They further discussed telepsychiatry as an option to mitigate the barriers in accessing mental health treatment options in rural areas. The American Psychological Association has defined telepsychiatry as providing health care through technology such as videoconferencing (American Psychological Association, n.d.). Video-based telpsychiatry not only helps to meet the mental health needs of patients, but also provides readily-accessible and affordable services.

Competency

In order to allow for culturally sensitive programs, it is imperative that the services of these multi-layered programs remain flexible and include local community programs and primary medical care providers (Yohann et al., 2017). Without having ever lived through the same experiences related to racism or suffering from poverty themselves, counselors cannot begin to provide effective help to the people they serve (Crumb et al., 2019). Consequently, primary medical and mental care providers need to be culturally competent to the unique mental health needs of children and families in rural communities.

Culturally competent mental and medical providers ensure that they address the specific needs of rural children living in poverty. These are included in the professional ethics and cultural competency guidelines for these professions. The ethics of the different medical and mental professions dictate that providers consider and respect the needs of clients, ensuring that social justice is applied. These cultural competence guidelines for the different professions encourage them to provide multicultural competent services (APA, n.d.). Some examples of different professions' cultural competency guidelines are:

- The American Psychological Association's Multicultural Guidelines: An Ecological Approach to Context, Identity, and Intersectionality. This version was adopted in August of 2017
- The American Counseling Association's Multicultural and Social Justice Counseling Competencies. This version was endorsed in July 2015.
- Association of American Medical Colleges' Cultural Competence Education. This version was published 2005.

According to the Centers for Disease Control (2019) another consideration for primary care clinicians in effectively assisting rural communities address mental health issues is by connecting families with early learning programs, parenting and caregiver support programs, and mental and behavioral health care (Centers for Disease Control, 2019). Further assistance can be provided by screening parents for mental health problems and then help them connect with the appropriate resources.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Continuing Education

In a focus group of rural mental health patients and families, they stated that they believed that they received inadequate medical interventions and that primary care providers did not have the proficiency to effectively treat mental health issues (Robinson et. al., 2012). The American Psychological Association website provides resources for continuing education that focuses on rural mental health issues. Two such research and publications are:

- Journal on Rural Mental Health, this is a publication of APA and the National Association for Rural Mental Health, and
- RHIhub: Rural Health Information Hub, a national clearinghouse on rural health issues (American Psychological Association, n.d.).

Government-Based Resources

As has been previously stated in this chapter, there are multiple barriers that prevent those residing in poverty rural areas from accessing mental health services. It is important to be knowledgeable about resources available through federal, state and local government to assist in addressing these concerns. For instance, in recognizing the importance of improving access to health care services to rural communities, the United States Department of Agriculture (USDA) invested more than $1 billion to this initiative (U.S. Department of Agriculture, 2017). There are several policy-oriented research that provides crucial data on rural health (Sigounas, 2018). This information is essential in understanding the unique challenges faced by those residing in rural communities and how these areas can be impacted by government policies in areas such as population health, health insurance, and access to healthcare. The following are some governmental organizations that can provide mental health service assistance to children and families living rural poverty.

- Federal Government
- United States Department of Agriculture
- State Government
- Department of Education
    - Department of Family and Children Services
    - Public Health Department
- Local Government
- City Government
    - Law Enforcement

FUTURE RESEARCH DIRECTIONS

Those living in rural poverty are faced with stressors as a result of their environment (Fifield & Oliver, 2016; Hill et al., 2016). One such stressor is being unable to access adequate mental health care. This in turns impacts their quality of life. Despite these concerns, the extent of the mental health needs of those residing in poor rural communities have remained overlooked and under-researched (Tickamyer

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2017). More research is warranted on the needs of this population. Focusing on the mental health needs of children in rural poverty will enable leaders and advocates to be informed and foster economic and social justice.

CONCLUSION

Despite an increase in mental health literacy, mental illness is often still under recognized (Handley, Lewin, Perkins, & Kelly, 2018). This is especially applicable to those residing in rural poverty. This chapter presented an overview of rural poverty and its effects on the mental health of children. Five influences were discussed: early development, healthcare, parental/caretaker's educational level, educational system, and mental health stigma and stress. Furthermore, the authors introduced a multi-layered approach for addressing these barriers. The components of the multi-layered approach include school-based resources, community-based resources, medical-based resources, and government-based resources. A case illustration was used to demonstrate the practical application of school-based resources to aide in the improvement of mental health of rural poverty children. A call to action is for leaders and advocates to expand the scope of understanding regarding the mental health needs of this population by encouraging further research and applying some of the resources outlined in the multi-layered approach

KEY TERMS AND DEFINITIONS

Mental Health: A person's emotional and psychological wellbeing.

Mental Health Competency: Mental and medical healthcare provider's understanding and recognition of the effect of a client's environment on their health.

Mental Health Literacy: The understanding of mental health wellbeing information.

Mental Health Stigma: The negative belief or attitude towards mental illness and someone suffering from mental illness.

Mental Illness: Medical conditions that affect behavior, thinking, or emotion.

Multi-Layered Approach: Utilizing several pathways to address a problem.

Positive Behavioral Interventions and Support: Strategies that are used to assist students who are displaying behaviors that are preventing them from learning.

School-Based Mental Health Programs: Initiatives used in schools that provide early intervention and prevention to improve the emotional and social development of students.

Social Emotional Learning: The means by which people manage and understand their emotions.

Chapter 59
Syrian Youth, War, and Community Approach to Stigma Surrounding Psychological Intervention

Adnan Mouhiddin
University of Surrey, UK

ABSTRACT

This chapter will discuss why countries that emerge from prolonged civil wars need to provide their citizens with adequate mental health services and make a reference to Syria as a case study. It will demonstrate an association between mental disorders and violence which threatens the stability, national security, and the aspired recovery of the country. The chapter will refer to young people as they are the future in process and the makers of the future change in Syria. However, rather than listing or discussing solutions, the chapter will take a community approach to stigma and discuss how a shift in the way the Syrian society views and approaches mental illness is necessary to alleviate stigma and its impact. The chapter will also show how minority groups among the Syrian youth are subject to an aggravated level of stigma. In doing so, the chapter will address various social concepts such as youth, masculinity, community, and society.

INTRODUCTION

Although a global phenomenon, stigma impacts societies on various levels and in different ways. Stigma surrounding mental illness and psychological interventions is discussed in this chapter. It will address why mental illness is stigmatised and how this may discourage individuals with mental illness to seek help and support. The chapter will discuss how this situation may amount to disorder and deviance in societies that were and are hit by wars and conflicts. This chapter will discuss why countries that emerge from prolonged civil wars need to provide their citizens with adequate mental health services and make a reference to Syria as a case-study. It will demonstrate an association between mental disorders and

violence which threatens the stability, national security and the aspired recovery of the country. The chapter will refer to young people as they are the future in process and the makers of the future change in Syria. However, rather than listing or discussing solutions, the chapter will take a community approach to stigma and discuss how a shift in the way the Syrian society view and approach mental illness is necessary to alleviate stigma and its impact. It will also show how minority groups among the Syrian youth are subject to an aggravated level of stigma. In doing so, the chapter will address various social concepts such as youth, masculinity, community and society.

Stigma as a Global Issue

According to the World Health Organization (WHO), mental illness precedes any other health issue in the world. It estimates that 450 million people worldwide suffer from mental health conditions, whereby 60% do not receive any form of care. It also reports that 90% of people in developing countries are receiving no form of care. Those labelled as mentally ill are subject to more severe stigma than individuals with other forms of non-mental illnesses (Corrigan et al., 2000). With the concealable nature of mental illnesses, impacted individuals may decide to circumvent treatment and psychological intervention to avoid stigma surrounding it (Corrigan & Matthews, 2003). Hence stigma has been identified as one of the reasons that prevent people from receiving the necessary care and support they need. It manifests itself in social distancing, whereby people with mental issues feel isolated and labelled. Among many reasons, stigma originates from personal, social and family sources. It is further augmented by social factors such as lack of awareness, lack of education, lack of perception, and the nature and complications of the mental illness manifested in the individual.

Gaining increased awareness of the long-term impact of mental illness and the way it shapes the present and future of mentally ill individuals, many societies have taken robust measures to alleviate its impact. This is done by various means on both official and public levels. Many campaigns have taken to the media to address mental health, with the aim of breaking through the barriers that prevent people from seeking the help they need. This involved celebrities who shared their experiences and how about they sought help and support. This, arguably, might have contributed to individuals with past or present mental disorders, increasingly stepping forward and sharing their experience.

However, as it appears to be the case, raising awareness is not enough. Whether the response action commensurate with the seriousness of mental health and its impact on both global and international levels is disputed matter. While the capacity of national health systems to accommodate and provide services that deal with mental illness varies across countries and nations, stigma remains an issue that hinders a lot of people with mental illness to receive the support appropriate to their situation.

What is noteworthy here is that stigma is a common concept across the globe. One of the most cited definitions of stigma is that of Goffman who referred to it as ‘an attribute that is deeply discrediting’ (Goffman 1963: 13). Further definitions that developed over times indicate a lack of consensus among scholars about the definition of stigma. The World Health Organisation defines stigma as ‘a mark of shame, disgrace or disapproval which results in an individual being rejected, discriminated against, and excluded from participating in a number of different areas of society’ (WHO, 2001). It is composed of interpersonal or public stigma and intrapersonal or self-stigma. The role of stigma as a barrier to seek psychological support emerges when individuals endorse and internalise negative attitudes and opinions about mental illness and intervention means (Sewilam et al., 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Contrary to the common belief, stigma is identified as a more significant barrier in high-income countries than in low-income countries (WHO, 2005). Although it is a common factor observed across the globe, stigma is dependent on social and cultural contexts and hence may vary as a result of different cultural norms (Pescosolido et al., 2008) and its role in the help-seeking process can vary across cultural groups. For instance, unlike other illnesses, mental illness is still considered to be a sign of weakness, as well as a source of shame and disgrace in Middle Eastern countries (Sewilam et al., 2014).

With the ongoing conflicts in Syria, Iraq, Afghanistan and Yemen, the need for mental health awareness interventions that are not hindered by stigma is even greater. The impact of mental illness resulting from war experience is unmeasurable and its impact may be sensed for decades if not treated and approached. As early as 1921, Oliver established a link in his thesis 'Emotional States and Illegal Acts' between the emotional and mental distress experienced during war and crime in the post-war society (Oliver, 1921). More recent research in this field also indicates an interlink between traumatic experiences and criminal and violent behaviour (Jakupcak et al., 2007) revealing that offenders present a higher prevalence of Post-Traumatic Stress Disorder (PTSD). It also suggests that that criminal and violent conduct could be both more widespread and more extensive among mentally ill individuals (Levy & Sidel, 2008), which is likely to be a significant challenge faced by many people scarred by wars and conflicts.

The accumulated evidence indicates that mental illness is one of the post-war features found in civilians and combatants. Violence, exploitation, displacement and deprivation are all unfortunate factors that fundamentally affect the well-being of the individual subject to them (Brick et al., 2017). For instance, 799 adult household members aged 15 and above were surveyed in Afghanistan in 2014. Symptoms of depression were found in 67.7% of respondents, symptoms of anxiety in 72.2%, and PTSD in 42% (Murthy and Lakshminarayana, 2006). Such exposure to the violence of the war does not only amount to social and mental dysfunction, (in addition to the depression and PTSD) among civilians (Ardino, 2012), but also among combatants (Orth & Wieland, 2006). These dysfunctions manifest themselves in both family and community contexts creating 'a link between experiences of violence as victims and later experiences of violence as a perpetrator' (Garbarino, 2002). Moreover, a considerable body of literature has documented the relationship between trauma and child abuse and subsequent aggressive and criminal acts. The abuse of children during the armed conflict, their poverty and witnessing of violence are the most common risk factors for causing future aggressive and antisocial behaviour (Finkelhor, 2008).

Having said that, the relationship between mental disorders and crime should be approached with caution. While not every person with mental illness is a project of a violent person, the importance of the traumatic event here is not whether it is a determining factor towards violence, but identifying it as a risk factor. On a larger scheme, the central point here is that mental illness in conflict countries could threaten the aspired post-conflict stability and hinders peacebuilding, recovery and reconstruction. Rather than taking steps to build a better future, people become caught in the cycle of violence. This becomes even more cause for concern if we consider the level of devastation which the health sector and its infrastructure has endured during the conflict.

Syria: Stigma and Youth

In January 2011, and following a series of events that has later become better known as the 'Arab Spring', the Syrian president Bashar al Assad dismissed the opinion saying that the wind of the Arab Spring will eventually reach Syria. Apparently, his prophecy proved wrong and the domino effect of the Arab Spring reached Syria two months later, resulting in the country becoming 'the worst man-made disaster since

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

World War II' according to Zeid bin Ra'ad, the United Nations High Commissioner for Human Rights, as (Collins, 2017). What began as peaceful protests in the city of Dar'aa in response to the detention and torture of school children who wrote 'It is your turn, doctor'[1] on their school's wall (Sterling, 2015), gradually turned into armed clashes in September 2011 and escalated to an armed conflict (civil war) in July 2012 (UNHCR, 2012).

The destruction, devastation and atrocities in this war are unprecedented. In 2017, the United Nations Development Programme reported that 'many basic infrastructure systems including provision of water, electricity and sanitation, in addition to social infrastructure such as schools and healthcare centres, have been damaged or destroyed, eroding the living conditions of people in affected communities' (UNDP, 2017). Beside the basic infrastructure which has been severely damaged, the impact of the ongoing war will affect the Syrian community for generations to come. The war has seen the death of half a million people and has resulted in four million refugees and around seven million internally displaced people, resulting in wide scale human devastation. In addition, millions of children and young Syrians have been deprived of education, displaced from their domiciles and neighbourhoods and/or recruited as soldiers in the course of the conflict. Their extensive involvement in the war, whether as a participant, a witness or a victim, has resulted in war associated mental illnesses such as PTSD and exposed them to risks of dysfunctional behaviours and serious criminal conduct (Save the Children, 2017).

While dealing with mental illness in conflict societies, the society and its role, including all age categories, should be considered. However, this chapter attaches particular importance to young people since youth are the future in process and the hope for the aspired recovery and the reconstruction of Syria. The hope and resilience in the Syrian society in general, and among the youth in particular, for a better future for the country is evident. They have shown a high level or resilience (Underwood, 2018), which is a promising factor to invest in for the future of the country.

The important role of the youth in their societies has recently received an international acknowledgement. In a solid recognition of their vital role in the prevention and resolution of conflicts, the United Nations Security Council culminated that attention by adopting unanimously Resolution 2250 in 2015 concerning the role of the youth in maintaining the peace and security in their societies. The resolution has also recognised the role of the young people in contributing to 'lasting peace and economic prosperity if inclusive policies are in place' (UNSC, 2015, p. 2). The resolution also urges the Member States to 'facilitate an inclusive and enabling environment in which youth actors, including youth from different backgrounds, are recognised and provided with adequate support to implement violence prevention activities and support social cohesion' (UNSC, 2015, p. 2). It also highlighted the political, financial, technical and logistical needs of the youth in conflict and post-conflict societies by inviting the member states to provide the necessary assistance in that regard.

The role of the youth is evident in the development of conflict and post conflict countries. As such, the role of the youth in the future of Syria, its development, stability and security manifests itself in various way. The Syrian demography is predominantly young (Dawlati, 2016). The latest figures reported by the Central Bureau of Statistics in 2011 estimates that 34.9% of the Syrian population is between 15 and 34 years of age. It also reveals that 20.2% are between 15 and 24 years of age (CBS, 2011). This could also suggest that the youth will be a vital force to bring about the aspired change in Syria. Their presence in the early protests in 2011 (Haj Saleh, 2017) testifies to that end.

There is no clear definition in the Syrian society as to what constitute a 'young person'. The relationship between youth and age varies with different social factors and events. For instance, Syrians refer to those in their 20s as young. Yet, when someone passes away in their 40s they too are referred to as 'hav-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing died quite young'. In the absence of an official indicator as to what is meant by 'young' and 'youth' in Syria, this chapter will opt for the age range between 15 and 24. This is for various reasons. Social scientists often consider 24 to be the age of childhood transition to adulthood (Altschuler et al., 2009; Crone & Corbin, 2010). Having said that, the 'completion of developmental tasks', cultural, upbringing and environmental factors should be taken in consideration while deciding where the transition happens (Thomson, 2013). The United Nations Educational, Scientific and Cultural Organisation observed that definition of youth perhaps changes with circumstances, especially with the changes in demographic, financial, economic and socio-cultural settings (UNESCO, 2018). Moreover, including the Syrian youth between 15-24 years of age does not only mean that we have included 20.2% of the Syrian population (according to the 2011 figures of the CBS), but will also captured those who are recruited in the Syrian army as well as those who are dismissed from the service with all the struggles they encounter while they aim to integrate in the civil life again.

Millions of young Syrians were and are involved in the war, or exposed to its impact in one way or another and have subsequently been deprived of education, displaced from their homes and, or recruited as soldiers during the conflict (Dawlati, 2016). In 2015, the United Nations High Commissioner for Refugees (UNHCR) reported that the 'the most prevalent and most significant clinical problems among Syrians are emotional disorders, such as: depression, prolonged grief disorder, Post-Traumatic Stress Disorder and various forms of anxiety disorders' (UNHCR, 2015, p. 15). Once the war is over, those groups will not only pose a serious challenge to Syrian society, but also raises significant challenges to their life opportunities and well-being. It is still unclear how the Syrian government and society will confront this issue. It is often the case that countries that emerge from prolonged civil-wars place different priorities. Their immediate concern is establishing order and security while running vital services become secondary issue (O'Connor & Rausch, 2007).

The present level of mental health care in Syria does not correspond to its ancient past, whereby Damascus was the home to one of the first psychiatric hospitals in the world in 1270 AD, along with Baghdad in 705 AD and Cairo in 800 AD (Okasha et al., 2012). While current reports from humanitarian organisations suggest that the crippling effect of the conflict on the health sector across the country, mental health services were already inadequate prior to the war. In 2008, Syria's residential mental health services comprised two mental hospitals in Aleppo and Damascus, with the latter hosting an addiction treatment center (Assalman et al, 2008). In addition to these, community health centers could be found in major cities as well private clinics. However, the ratio of practitioners to the population is 1 to 100,000, which is drastically low. Very few of these practitioners have specialty in child and adolescent mental health. Shortly after the eruption of the conflict, Okasha et al. (2012) reported that Syria is among other conflict countries (such as Iraq, Libya, Somalia, Sudan, and Yemen), which have less than 0.5 psychiatrists for 100,000 population.

In March 2017, the World Health Organisation estimated that more than half of the Syrian population is in need of mental health support and psychological intervention. Later in August, Mr. Ramadan Mahfouri, the head of the mental health department in the Ministry of Health, estimated that the war in Syria resulted in 300,000 individuals in need of psychological treatment (Al-Saleh, 2017). However, in February 2018, Mr. Mahfouri increased the number of Syrians suffering from severe psychological disorders to one million. He attributed this rise to destruction caused by the conflict and suffered by the health sector in general, and mental health services in particular, which are unable to cope with increased numbers of service users and lack of practitioners who fled the country (Al-Saleh, 2018). Such arbitrary statements, coming from the highest authority concerning itself with the mental wellbeing of the Syrians,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

are deeply regrettable. This, if anything, shows the arbitrary attitude of the Syrian government toward the statistical and scientific approach to a serious issue such as the society mental health. It also shows the incredibility of the governmental data related to the mental health in Syria and the absence of present and an effective mental health policy.

Now some law provisions in Syria recognise mental illness among young people. For instance, dealing with the juvenile delinquents is entrusted with the Juvenile Delinquents Act 1974 (and its 2003 amendments). Article 5 invites the court to apply rehabilitative measures in the light of the social and psychological conditions of the juvenile. Should the juvenile commit their offence due to an identified mental disorder, they will be placed in an appropriate mental asylum (Article 16). The practice, however, seems quite different. In 2010, the United Nations Development Programme, in cooperation with the Syrian Government, assessed the juvenile justice system in Syria with a view to enhance the juvenile justice in Syria as well as the juvenile reform institutions in Syria (UNDP, 2010). The assessment noted the lack of familiarity within the court system in Syria on juvenile issues. It also found that there is 'a lack of judges specialised in dealing with juvenile crime in Syria', although Article 34 of the Juvenile Delinquents Act 1974 clearly states that the juvenile judges must be selected based on their experience in the juvenile affairs. The assessment then provides some examples which indicate shortcomings in the juvenile justice system. For example, the assessment revealed that 'juvenile offenders between the ages of 15-18 are transported to the courts and back to the holding prisons with adult prisoners, exposing them to mental and physical abuse from older and more seasoned criminals' (UNDP, 2010:4).

Should an effective mental health policy be in place, and should mental health services be available and function efficiently, it is questionable whether Syrians with mental illness shall resort to them for support. Syrians, like their fellow Middle Easterners, consider religion, traditional practices and cultural beliefs as important factors while discussing mental illness and well-being in general (Ahmad & Dardas 2015). This often leads to certain prejudicial beliefs about mental illness that are shared globally and is found across cultures, although to different degrees (UNHCR, 2015). As we have seen earlier in this chapter, mental disorders are one of the tragic outcomes of the war. Such disorders will greatly benefit from psychological interventions that seek healing and wellbeing for the concerned youth. However, some Syrian communities might be adamant in their refusal to accept psychological care treatment. To appreciate why this might be the case, it is important to examine the factors under which stigma is socially constructed. In other words, whether psychological interventions will work or not, depends on how the Syrian society, as well as young people, the potential subscribers to these interventions, understand the reality of mental illnesses (Orlikowski & Baroudi, 1991) and the impact of producing local solutions, interventions and means (Alexander et al., 2008).

In Syria, religion and social norms are fundamentally intertwined (UNHCR, 2015). In this sense, certain social dynamics contribute to shaping the views of Syrians of the person and their relationship with their society and the world around them. Religion, ethnicity, tradition and history are the chief forces. Not only on social level where concepts are formed and shaped, but these forces also contribute to the individual identity and the place the individual inhabits within their community. This needs to be beard in mind while we approach stigma surrounding mental health of young Syrians. Mental disorders are often viewed by Muslim communities as shameful (Aloud & Rathur, 2009) and a punishment from God (Abu-Ras et al., 2008). Dr. Zaher Sahloul, a Syrian doctor and the past president of the Syrian American Medical Association, noted during his relief work in Syria that mental illness remains a taboo in Syria (Sahloul, 2018). Similar to Dr Sahloul's findings, Germany has reported some difficulties in promoting psychological therapy among the new Syrian refugees on its soil due to stigmas surrounding

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the psychological interventions (Rubin, 2016). Religion, however, is not always the reason. Traditional beliefs in the curative powers of black magic and spells as well as their ability to provide healing to mentally ill people remain central belief among a wide sector of the Syrian society. Many Syrians, from all religious and ethnical backgrounds, resort to this practice rather than subscribing to or visiting a mental health service. Since mental illness is regarded as a shame, these traditional practices ensure secrecy and privacy whereby the case remain between the "service" provider and their patient.

The complexity of understanding the reality of mental illness exceeds that of the personal belief, reaching to other sectors such as media and other influential platforms. In December 2017, Mr. Humam Hout, the host of 'The Scenario', a Syrian talk show and satire television programme discussed the character of Hassan Nasrallah, the chief of Hezbollah, a Lebanese terrorist group, by referring to the character of the 'scoundrel boy'. He said:

It is said that each family has a sewer. This sewer is often the scoundrel boy. He is out and about in the streets all the time…That kid is creative in being harmful… He set the street rubbish bin on fire... He punctures the cars tyres. He hates his school and his family… This scoundrel is a target for every gang's master, drugs dealer or a pimp, for he has all the qualification of being a bastard. Crime runs in his blood. All he needs is someone to adopt him and turn him unto a real criminal. Today I will introduce you to one sample of these scoundrels… Hasan Nasrallah. (Hout, 2017)

The image of the scoundrel boy is not the creation of Mr. Hout's imagination. The 'It is said' at the beginning of the quote is in fact the stereotyped image made by the Syrian society of the young children with difficult childhood and upbringing. Mr. Hout has simply used it to make a political inference. Such an opinion, coming from supposedly a media person who devoted a big part of his life (and continues to do so) to promote social justice, freedom and institutional reform through theatre plays and recently his TV show, is deeply regrettable. It also draws various questions as to whether Syrians have the culture of tolerance, understanding and rehabilitation. A rehabilitative culture is where all the aspects of a given culture supports the efforts of rehabilitation (Mann et al., 2018). The resilience of the Syrian communities in the face of the tragic outcomes of the war is evident, as well as their hope for a better future. However, the belief of the Syrian society in its understanding of the seriousness of the issue beforehand, that is to say the mental wellbeing of young Syrians, will be vital for destigmatising psychological intervention.

On global level, media could play a significant role in forging a better understanding of mental illness. Rather, it continues to misrepresent and portray individuals with mental illness as dangerous to society and a source of violence and disorder (Clement et al., 2013). Hurtful representations of the person with mental illness, discrediting them and treating them as being different from others all are attributes of social stigma (Dardas & Simmons, 2015). Although the portrayal above has taken place on a media platform in Syria, it nevertheless coincides with a global phenomenon where adults stigmatise children with ADHS and depression more than adults suffering from similar mental illnesses (Pescosolido, 2007). Stigma's impact in Syria is even more significant among young vulnerable groups, such as the LGBTQ community, survivals of sexual abuse and young people with existing disabilities (Fraser, 2019). These community members face an elevated risk of stigma. Male and female victims of sexual abuse neither report these incidents nor seek treatment because of shame and their fear of how society will stigmatise them (HRW, 2015). An LGBTQ young individual in Syria faces two kinds of stigma. The first is imposed on their sexual orientation. Syrian society continues to foster a hostile environment against gay people in general, including youth based on cultural and religious grounds. Article 520 of the penal code of 1949

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

prohibits 'carnal relations against the order of nature', and provides for up to three years imprisonment. Now should young people seek psychological support for emotional and mental distress resulting from such intense level of harassment and threat, they encounter the second stigma surrounding mental illness.

Community Approach to Stigma

Dealing with the mental health of Syrian youth and stigma surrounding it at an early stage will be vital for the future of the country, its security, order and development. However, this is not going to be an easy task for various reasons. The country has just started its long journey to recover from a fierce civil war that devastated it at every level and sector. The needs for innovative and culturally sensitive interventions are necessary to meet the need of post conflict mentally ill population. But before discussing plans and roadmaps, the Syrian society should probably question its approach to stigma as a concept since it is socially constructed.

An effective approach will have to consider a long list of societal factors. Among these are the socio-economic difference between urban and rural areas, strong belief in traditions, and the stark social gap between males and females. The Syrian conflict, the Syrian Centre for Policy Research reports, had 'caused huge differences between individuals and communities regarding shared values and visions of the future, at both local and national levels' (SCPR, 2017, p. 10). Therefore, we probably should adopt a short-term plan, and a longer one. The former should aim at reducing the impact of stigma and familiarise Syrian communities with the benefits of psychological intervention, while the latter should be a long-term campaign to eliminate stigma altogether from the Syrian society. This strategy will be about changing people's mentality towards psychological treatment and challenge certain cultural perceptions. However, before working on community level, it is important to distinguish between society and community.

The term 'community', according to the United Nations may refer to 'small neighbourhoods, areas within a city, or small villages or towns, or in some cases groups of citizens with particular concerns' (UNODC, 2010, p. 13). In his book 'Community and Association', Tonnies (1955) noted that association in the community is conceived as real and organic life, whereas the concept of society bases itself on imaginary and mechanical structure. Therefore, society members are separated despite all uniting factors while community members remain united despite all separating factor. He further highlighted that social co-existence in community is familiar and comfortable because people in community associate based on their free will, whereas the latter is rational in societies. Drawing from Tonnies, Willimot (1987) named three categories of communities. He argued that first there is territorial community (the group of people living in a particular area), second, those who have common factors that go beyond the limitation of geography and may be identified as the 'interest community', and finally the people who have a sense of a belonging to a place and fall under the 'attachment community'. However, Willmot is cautious not to limit our understanding of a community to one of these categories. He asserts that a community's experience may comprise of one, two or all of them. Similarly, Cohen invites us to understand a community 'by seeking to capture members' experience of it' and 'what does it appear to mean to its members' (Cohen, 1985, p. 20). Dismissing the structural forms to identify a community, he argues that the latter 'lies in the mind, in the meanings which people attach to them, not in their structural forms' (Cohen, 1985, p. 98). Mooney and Neal (2009) breaks down these meanings to subjects such as: language, food, dress, religion and faith-based custom (Mooney and Neal, 2009). These common themes are present in every Syrian city and village; a diverse country that remains as such even during the war (Atasi, 2015).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Stacey (1969), on the other hand, adopts a cautious approach, in that the word community falls short from accommodating the complexity of social organization and practices. We could also question here how could community be the source of stigma, yet be the solution? Rose (1999) advocates for a community that becomes an 'antidote to social ills' (p. 175). He argues that communities are increasingly being 'transformed and programmed into an expert discourse and professional vocation' (p. 187). In the same vein, the significance and the vital role which community played in the life of the individual is put beautifully and succinctly by Bauman in that community is like a 'fireplace at which we warm ours hands on a frosty day' (2001, p. 1). Probably less poetic, but Mooney and Neal provides us with a similar description of what community is. To them, community is about social bonds which have an emotional dimension that goes beyond the word 'group' (Mooney & Neal, 2009); Community is 'connected groups of people who care about and for each other' (Mooney & Neal, 2009, p. 2). In fact, community could be the centre of norms and moral values (Aspin & Chapman, 2007). It could also be, 'both the source of problems and the means of solving them' whereby 'proper communities deliver solutions, whereas dysfunctional communities work to reinforce and reproduce failure' (Cochrane and Newman, 2009, p. 44).

Therefore, a shift in how Syrian communities (subsequently the society) approach mental illnesses is vital. They also need to take into consideration the close and intimate connection between young people and their communities. This relationship exceeds the sentimental link to dependency. In 2007, a research entitled 'Youth Exclusion in Syria' (Kabbani & Kamel, 2007) reported a significant reliance among the Syrian youth (between the age of 15 and 24) on family and community connections to secure employment, marriage and housing whereby 90% identified 'family, relatives and friends' as the source for job search. Placing the young people's interest as a priority will require the society to take a lead in creating an environment of development, opportunities and community. Cantillon et al. (2003) found that a sense of belonging to their community could compensate for the outcomes of young people growing in disadvantaged community.

A research conducted by 'International Alert' in 2016 revealed not only the significant role of the family in the decision process of youth joining armed groups, but also pulling them back to the community. The role model and religion were also noted in the research. Another study conducted by 'Dawlati' noted that young people's perception of what constitutes crime is affected by the existing stigma fused in their society and communities' views (Dawlati, 2016). This suggests a significant role that could be played by the communities in Syria to integrate psychological support and intervention for young people with mental illness, in their overall efforts to recover from the aftermath of the conflict. It also suggests the influence which communities may have over young people when challenging certain conceptions and understanding is appropriate. Challenging stigma probably start from both the school and the family simultaneously. Existing evidence suggests that schools could play an effective role in reducing stigma toward mental illness (Watson et al., 2004). Clerics and priest could use their position and platforms to promote mental health and wellbeing and encourage those who are mentally ill among their congregations to seek help. This could also be advocated and promoted by community leaders, actors and actresses, media and societal personalities. In doing so, they will also challenge certain conceptions such as 'boys don't cry'; an expression that has probably been heard by the vast majority of Syrian children and young boys. As the young man grows, the 'boys don't cry' is then transformed into 'man up'. It will be vital that young boys and children learn that vulnerability is not weakness, and to seek help and ask for it when they need it.

This approach will probably clash with the general conceptual understanding of masculinity in the Syrian culture. Syria is patriarchal social structure where men still consider themselves to be the fam-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ily provider. Connell (1995) defined hegemonic masculinity as 'the configuration of gender practice which embodies the currently accepted answer to the problem of the legitimacy of patriarchy, which guarantees (or is taken to guarantee) the dominant position of men and the subordination of women (p. 77). Masculinity is Syria is related to everyday life, to the domestic and public life, to economics and history, social class, ethnicity, family relations, sexuality and culture. It is also related to symbolism. Daoud (2018) observed how the moustache represents to the ordinary Muslim man the maleness in its full sense. He also noted that 'a luxurious moustache was a boundless treasure, given that a single hair would suffice as surety for a loan or a promise' (p. 60). It is from these perspectives that masculinity in Syria needs to be approached and analyzed. This is important because traditional masculinity norms are determining factors in whether men with mental illness seek help or not (Yousaf et al., 2015). Existing research found that the endorsement of dominant masculinity corresponds to higher levels of self-stigma and less favourable attitudes toward seeking help (Vogel et al., 2011; Heath et al., 2017).

To increase seeking help opportunities, the World Health Organisation promotes community mental health services. It notes that they are more accessible to individuals living with severe mental disabilities and are more effective than mental hospitals (WHO, 2007). Thornicroft et al., (2011) identified Community Mental Health (CMH) as a 'population-based approach to promote mental health and prevent mental disorders'. They argue that such initiative will need to address the needs of the community in accessible and acceptable manner. It will also capitalize on the experience of people who experienced mental illness, which will enable CMH to promote its services and support it has the capacity to provide. The aim, as UNHCR (2015) highlights, should be 'providing safe, non-stigmatizing and supportive services with trained specialized staff'. This is even more needed when these services deal with victims of sexual and gender-based violence. Ensuring a confidential and appropriate manner will not only put these victims at ease to disclose and access services, but it will also establish trust and connection with the community members who will feel confident enough to step forward either to share their experience, or ask for help and support. Furthermore, UNHCR (2015) recommends that mitigating difficult living conditions is vital for community-based protection mechanisms. It also recommends navigating through 'models and sources of help that may include the formal and informal medical system, as well as religious, community, family and individual resources' (p. 40).

Through the Mental Health Gap Action Programme, the World Health Organisation has been able to provide mental health services across Syria despite the challenges and difficulties caused by the ongoing war. The Organisation reported in 2017 that more Syrians than ever have used its 150 primary and secondary health centres in 11 governorates (WHO, 2017). To fill gaps in qualified staff, the World Health Organisation has also reported that mental health services are provided by non-specialist general practitioners that it trained, under the supervision of national specialists. As Syria emerges from a long conflict with devastated infrastructure and stagnant economy, foreign expertise will be welcomed and approbated. Syria may also consider visiting the experience of other countries which survived an internal conflict and successfully installed programs that addressed and dealt with mental illness of their population. However, the international support should not replace the domestic experience which informed by its own social and cultural background. Any international initiatives will need to complement and empower rather than replace and install.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

It should be clear by now that this chapter does not attempt to address stigma from a medical angle. Rather, it reflected on whether mental illness and dealing with stigma that surround it should be approached on a community level. It also made the case that communities should have approach this issue based on their needs, social capital, circumstances and their own vision. A good starting point is probably the values embedded in the community that are embraced by its members. This is not to suggest that the mental health of young people in general, and those coming from conflict zones should are merely a domestic issue that need to be death with on domestic level. Rather, this should be of a global concern.

Whether in Syria or on a global level, stigma and its impact is an area that is still developing and being informed by research. A lot of concepts still need unpacking. Any suggested roadmap that aim to overcome stigma should listen to people with mental illness who avoid mental health services because they fear stigma, and practitioners. Syria still has a long way to go. However, it is important to start this conversation on national level both publicly and officially. While it may not provide immediate responses and solution, community approach to mental illness that challenges stigma is and will be needed on long terms.

Chapter 60
Mental Health Access Issues by People of Refugee Backgrounds in Australia

Ndungi wa Mungai
Charles Sturt University, Australia

Jeanette Ninnis
Service for Treatment and Rehabilitation of Torture and Trauma Survivors, Australia

Ruth (Isobel) Bailey
Charles Sturt University, Australia

ABSTRACT

This chapter presents a critical discussion on the understanding and access of mental health services by people from diverse refugee backgrounds delivered in a Western cultural setting. Mental health services are heavily influenced by a biomedical approach, but there is a growing understanding of the importance of culture and biopsychosocial approaches. This chapter highlights some of the institutional and cultural issues that need to be addressed for the services to be effective. Practical approaches that have worked in different places are explored and critically discussed. A recovery-oriented model that recognizes that the individual is part of the community and the importance of spirituality are canvassed.

INTRODUCTION

Mental health work with migrant and refugee communities settling in developed countries like Australia is both challenging and rewarding for the wide range of professionals involved. While all the professional knowledge in mental health is important, the biggest challenges are presented by the diversity of cultures, diversity of prior experiences, settlement challenges, social and political dynamics and the negotiation of divergent worldviews. While cross-cultural mental health work would include working with a wide range of cultures, in this chapter only migrants and refugees are considered, while other cultural groups

such as Indigenous people or Lesbian, Gay, Bisexual, Transgender, Queer and Inquiring (LGBTQI) are not considered except in passing where necessary.

Regular migrants and forced migrants including refugees, asylum seekers and undocumented migrants, have radically different issues on arriving at their destination. However, they also face similar issues such as displacement and dislocation, discrimination and a desire to rebuild disrupted lives. A study of migrants in Europe identified eight types of problems: language-based problems, lack of health insurance cover, poverty and trauma experience, lack of knowledge about services, divergent notions of diseases and treatment, unhelpful attitudes among both migrants and staff and missing medical history (Priebe, Sandhu, Dias, Gaddini, Greacen, Loannidis, … Bogic, 2011). Weiss (2015) has noted that in Switzerland migration worsens physical and mental health risks because migrants encounter cultural barriers. At the same time clinicians also experience challenges related to the complicated circumstances of their patients. Considering this is important due to the rapidly growing numbers involved in international migration. The number of international migrants globally reached 244 million in 2015, an increase of 41 per cent compared to 2000, and includes 20 million refugees (UN Sustainable Development Goals, 2016). The main direction is from developing to developed countries but there is also movement of refugees from developing to developing countries; indeed, most refugees are located in developing countries like Pakistan, Lebanon and Uganda. Turkey is the exception, as a European country with very high numbers of refugees.

In Australia, a wide range of disciplines including social workers, psychologists, nurses and psychiatrists assist patients suffering from mental health disorders. For that reason, the dynamics could be described as both multidiscipline and multicultural interaction. Experience with clients of ethnic Arabic people has shown that mental health services may be viewed by migrants with mistrust and suspicion and because of the stigma associated with mental illness, mental health services may be viewed negatively and therefore underused (Al-Krenawi & Graham, 2000). Building trust in this situation is a high priority. Defining mental illness and what is normal or abnormal varies between cultures and a cultural understanding is therefore critical in any mental health intervention (Kleinman, 1988; Weiss, 2015). Migration is stressful and migrants have been reported to be at higher risk of developing mental health disorders. Cultural factors, for example, affect the care-seeking behaviours and attitudes of older Iranian migrants in the United States (Martin, 2009). These older Iranians are reported to mistrust prescribed medication, hold a holistic view about mind body and spirit and their conceptualisation of mental health, including the language used, is at variance with that of service providers.

A recovery-oriented framework is currently supported by the government in Australia. The *National Standards for Mental Health Services* (2010) defines the principles of recovery oriented mental health practice and notes:

From the perspective of the individual with mental illness, recovery means gaining and retaining hope, understanding of one's abilities and disabilities, engagement in an active life, personal autonomy, social identity, meaning and purpose of life, and a positive sense of self. (State of Victoria Department of Health, 2013, p. 7)

Recovery is not the same as cure but rather puts the recovering person at the centre of what they want in life. The framework recognises the importance of partnerships between different professionals in supporting the recovering person to achieve their goals.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The aim of this chapter is to critically discuss the challenges of working with refugee groups experiencing mental health problems. It highlights the important role played by social workers and advocates a strength-based community development approach that forms a recovery partnership with people with refugee backgrounds. The barriers that stand in the way of such partnership such as individualism and boundaries set by codes of ethics are explored. The strength-perspective based on acceptance of the cultural worldviews of people from non-Western backgrounds are noted as important starting points.

SOCIAL WORK ROLE IN CROSS-CULTURAL MENTAL HEALTH

In the multidisciplinary care for people experiencing a mental health disorder, social work plays a fundamental role in engaging, motivating, advocating, counselling and supporting individuals, families and communities. This is consistent with the internationally agreed definition of the role of social work:

The social work profession promotes social change, problem solving in human relationships and empowerment and liberation of people to enhance wellbeing. Utilising theories of human behaviour and social systems, social work intervenes at the point where people interact with their environments. Principles of human rights and social justice are fundamental to social work. (Australian Association of Social Workers [AASW], 2010, p. 7)

Given the vulnerability of people experiencing mental health disorders, the ethical commitment to human rights and social justice is critical and all professionals are expected to operate in an ethical manner and uphold human rights. World Health Organisation (WHO) defines mental health as 'a state of wellbeing in which every individual realizes his or her own potential, can cope with normal stresses of life, can work fruitfully and productively, and be able to make a contribution to her or his community' (WHO, 2017, para. 1). This broad view is consistent with WHO constitution definition of health that is considered wellbeing and not just merely absence of disease: 'health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity' (WHO, 2017, para. 2). These definitions show clearly that social work is philosophically well positioned to play a key role in both physical and mental health and underscores the bio-psychosocial dimensions in the ideal approach to mental health. It is well documented that in Western countries gender and power relations are rooted deeply within the dynamics of medical and mental health and are systemic in nature. Social workers often experience ethical strain in balancing the biomedical view of psychiatry against their commitment to non-hierarchical and genuinely collaborative processes, culturally informed and respectful practices and human rights perspectives (Probst, 2012). But social workers ought to develop, refine and use their collaborative skills and standpoint to bring these issues to the table in the interdisciplinary context of the medical and mental health care of migrants and refugees, rather than capitulating to or avoiding their effects. Social workers in mental health care have a responsibility to meaningfully collaborate, with integrity and a clear purpose, with other health professionals as well as other service providers and networks to ensure the wellbeing of their clients:

The purpose of practice is to promote recovery, restore individual and family wellbeing, to enhance the development of each individual's self-determination and to advance principles of social justice. (AASW, 2014)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Among the allies in achieving these goals are the cross-cultural psychiatrists who also realise the limitations of a biomedical modal in meeting the mental health needs of multicultural communities, or anyone else for that matter.

Cross-Cultural Psychiatry

Cross-cultural psychiatry is also known as transcultural psychiatry or cultural psychiatry and refers to psychiatry that is concerned with the cultural context of mental health. What is considered as 'new transcultural psychiatry' is traced back 40 years ago in the work of Arthur Kleinman (Kleinman, 1977; Krimayer, 2006). The approach demonstrated clearly the critical cultural dimension of mental health. Krimayer identifies some key features for ongoing development in transcultural psychiatry: that it is multidisciplinary and integrative and views culture as a key feature of human biological theory; psychological processes are important in understanding the individual but social factors are equally fundamental; and, local and global systems of knowledge need to be critically examined in the context of a globalizing world (Krimayer, 2006). In practical terms psychiatrists engage their migrant patients in an open way about their understanding of their problem in order to understand the meaning the problem has to the patient and how they might have approached it in their cultural setting (Weiss, 2015).

The increasing number of refugees and migrants in Western countries has renewed an interest in cross cultural and cultural psychiatry. It is considered that being able to appreciate the patient's background and develop rapport with patients and their families or communities will enhance the treatment and recovery (Bracken, Thomas, Timimi, Asen, Behr, Beuster, ... & Downer, 2012; Bracken & Thomas, 2001; Double, 2002; Wintrob, 2010). A study with Chinese migrants in Australia found that communication about mental health was hampered by lack of understanding of cultural norms and values and this affected diagnosis (Blignault, Ponzio, Rong, & Eisenbruch, 2008). Communication, however, was only one aspect affecting awareness and access to services, as stigma, quality of services and lack of trust are also factors. A focus on the social context avoids the pitfall of a narrow view of mental health and brings to the fore important but complex social problems that demand political, social and economic solutions (Krimayer, 2006).

The challenge remains then for psychiatrists and other professionals as to how they apply diagnostic tools like the DSM V to people from other cultures who may not conform to the Western formulation of mental health symptoms. How symptoms are perceived and manifested is governed by both culture and context (Fried, Bockting, Ajard, Borsboom, Amshoff, Cramer, … Carr, 2015; Krimayer, Gomez-Carrillo & Veissiére, 2017). This concept challenges the notion of a universal human biology and argues for an understanding of the dynamic interaction between culture and biology. Simply adding the extra observed symptoms to a diagnostic manual is not considered good enough, as a completely different approach is called for:

Unfortunately, simply adding more symptoms to the ontological category does not rid the process of Western cultural bias and might make it worse by over-extending the category to include syndromes or patterns of distress that are better conceptualized in other terms. (Krimayer, Gomez-Carrillo, & Veissiére, 2017, p. 167)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

A biopsychosocial approach in mental health takes into consideration the wide range of issues that contribute to wellbeing including biological and social factors. A variety of approaches then that take into consideration cultural and community factors would be preferable to a narrow focus on a specific disorder (Fried, Bockting, Ajard, Borsboom, Amshoff, Cramer, … Carr, 2015; Jordans, Tol, Komproe & de Jong, 2009; Krimayer, Gomez-Carrillo, & Veissiére, 2017). This would also be consistent with a social work approach to mental health.

COMMUNITY DEVELOPMENT AND CROSS-CULTURAL MENTAL HEALTH

The concept of individual autonomy pervades Western thinking and approaches and informs the biomedical model of mental health. The biomedical model of mental health is the dominant approach to mental health and is based on the belief that mental disorders are brain diseases that are treatable through pharmacological interventions to correct specific biological abnormalities (Deacon, 2013). The biopsychosocial alternative is less established and regarded as not evidence-based to the same level as the biomedical or biological model. The biopsychosocial model has been in development over the last four decades and suggests that biological, psychological processes are integrated and how the processes interact is important in understanding both physical and mental health (Suls & Rothman, 2004; Wade & Halligan, 2017). That mental health involves more than chemical imbalances in the brain is gaining more acceptance in the west and hopefully moving closer to the more holistic view in traditional societies.

Traditional societies tend to view the individual as part of a larger group rather than a solitary and autonomous unit. Many non-Western communities prefer to seek solutions to mental health within the family, extended family or community rather than focusing on the individual autonomy favoured in the West. That is claimed to be the case within Arabic communities for example, where it is noted that:

Contrary to a Western therapeutic emphasis on the individual, all interventions with Arab clients need to be couched in the context of the family, extended family, community, or tribal background (Al-Krenawi & Graham, 2000, p. 13).

The African communities also identify with this communal approach as the best way to address problems faced by members of their communities. This communal approach is underpinned by the concept of Ubuntu that posits that individuals exist within a web of interconnection with others and the world and the wellness of one is dependent on the wellness of the whole (Mungai, 2017). The community development approach has been used by Foundation House trauma counsellors to address the issues of torture and trauma within the Sudanese community resettled in Melbourne (Mungai, 2014; Mitchell, Kaplan & Crowe, 2007). Kenny (2011) supports the community development approach with communities with collectivist cultures because group and individual decisions tend to be made in consultation with the group. Failure to recognise this process can be detrimental to social work intervention as well as psychiatric treatment.

The WHO comprehensive mental health action plan 2013-2020 clearly shows the broad view necessary in addressing metal health through 'six cross-cutting principles' identified as: universal health coverage, human rights, evidence-based practice, life course approach, multisectoral approach and empowerment of persons with mental disorders (WHO, 2013). This broad approach is consistent with a community development approach. Empowerment in particular aligns with a community development approach and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

it calls for involvement of people with mental disorders in advocacy, and all possible activities relating to research, policy and services delivery that affect them. Ife (2010) argues that community development is intricately associated with human rights and identifies seven dimensions underpinning community development as: social development, economic development, political development, cultural development, environmental development, spiritual development and survival-based development. At different times, and for different programs, these dimensions would apply rather than assuming that they would all be there in every community development program.

Mental illness is often accompanied by multiple problems including stigma and isolation. WHO (2013) points out that mental disorders put people at risk of poverty and homelessness, imprisonment and other forms of vulnerability. A community development approach would be a suitable way to address the issues of marginalisation, isolation and stigma while promoting a sense of belonging (Francis, Pulla & Goel, 2014). Communities may be people who share a common identity such as nationality, ethnicity or religion or live in a common geographical area (Kenny, 2011). Community development is therefore appropriate to address mental health disorder issues given the major implications for the lives of individuals and their families and communities. Medication alone could never address all the implicated social and biological issues adequately. Focusing on the strengths of the individual and community is regarded as the starting point in recovery and rebuilding lives that are affected by mental health disorder (Francis, Pulla, & Goel, 2014).

Community development is not the answer to all problems related to mental disorder but an important part of the response. There are people who may not identify with a particular community or even family and would prefer to be treated as individuals and that has to be respected. Communities can be wonderful and nurturing but can also be a source of stress when they impose conformity. Traditional cultures cannot be assumed by virtue of people's ethnicity as other influences including religion, education, globalisation, colonisation, migration and the media have their impact on these cultures. Experiences such as war, systematic state based violence and insecurity during refugee displacement can rupture community trust bonds and cultural norms. It has also been argued that both past and current indigenous knowledge concepts could be hard to ascertain as history is contested and the indigenous knowledge that is unaltered by modernity could be an illusion (Bar-On, 1999). The Africans, for example, have a culture that has been described as based on a triple heritage: indigenous cultures; European capitalism and religions imposed through colonialism; and, Islam imposed through jihad and evangelism (Mazrui, 1986). This diversity underscores the importance of allowing people to define themselves and the best way to work with them. Williams (2018) notes the importance of checking the relevance of culture to the issue at hand and suggests letting people determine their cultural identity and what it means to them should be standard practice.

Community Trauma

A model of healing communities after trauma suggests that linking individuals, families and communities to rediscover their resilience and collective resources, is far more effective than working with individuals. It also argues that the resilience of families and communities is inseparable and therefore the role of the worker or therapist is to assist in rekindling this connectedness that is disrupted by grief, loss, trauma and other stressors that negatively impact on individuals, families and communities. This model known as LINC and developed by Linking Human Systems LLC trains communities to help themselves:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The LINC Model as a means of extending social support systems to help empower individuals, families, and communities to bind their own wounds by leveraging their collective power to overcome adversity and sustain long-term change with minimum of time and effort on the part of outside professionals (Landau, 2007; Landau-Stanton, 1986). (Landau, 2010, p. 517)

The model has evolved from Transitional Family Therapy and focuses on strengths, rather than deficits, of families and communities. It is a whole system approach focused on change and elimination of guilt and shame while mobilising resources for the healing process. The model has been applied with good results in: Buenos Aires, Argentina in a province afflicted with violence and HIV/AIDS; in Kosovo after the war with a whole country focus on general health and mental health including trauma, grief and loss; and, a Romanian border village with child welfare, gang violence-related issues and social inequalities (Landau, 2010). The outside professionals do not impose their culture. They start by identifying the cultural strengths in the community and train and resource the local people that the communities can trust and are seen as the key to success of the programs.

True to its origin in family therapy, the LINC model is based on the importance of connection to the family and community. In Kosovo, the connection to the family and culture of origin has been found to be correlated with reduced risk-taking behaviour, sexual risk-taking and a reduction in a range of mental health disorders (Agani, Landau & Agani, 2010). Agani and colleagues (2010) found that closeness to the family, whether, emotional, physical or spiritual (shared stories), was beneficial while distance was detrimental. An effective community-wide intervention then had to involve all the systems and have the people design the content and priorities that would contribute to trauma recovery, healing and resilience.

FRIENDS AND PROFESSIONALS DILEMMA

The concept of 'professionals' can sometimes be alien to people from non-Western backgrounds who are used to seeking help from friends and relatives. It can be confusing enough in Western cultures too but in cross-cultural contexts it can be more complex. In some professions like medicine it is easier to identify the boundaries of friendship and professional relationship than in social work where establishing good rapport is critical to the helping process. In medicine, the idea of the physician as friend can be traced back to ancient Greece but the consensus now is that friendship can help in the healing process but there are also ethical, practical and institutional barriers that suggest a healing relationship is the better option (Davis, 2000). In social work the concept of setting boundaries is emphasised in codes of ethics for legal and practical reasons but there is a need to review the impact this has on social work and cross-cultural social work in particular (O'Leary, Tsui & Ruch, 2013).

It can be confusing as to where one draws the line between friendship and professional engagement with the objective to help. Summers (2010) suggests that there is a clear distinction between professional relationships and friendship. One notable distinction is that the professional has a formal legal and ethical relationship with the client while friends generally have informal relationships and could be intimate and could also involve exchanging gifts. This still does not show where the clear boundaries are, as a worker and a client could still exchange small gifts, for example. One way of understanding boundaries is considering situations where the worker may have interests that are outside the working relations and is hence considered to have 'dual relationships'. However, even that may be unavoidable in small communities where interaction between a worker and a client in multiple roles is unavoidable

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

as the client could be the worker's child's school teacher or both worker and client sing in the church choir. The main boundary issue then would be whether there is anything harmful or illegal occurring between the worker and client:

Boundary crossings are harmful when the dual relationship has negative consequences for the social worker's client or colleague and, possibly for the social worker as well. For example, a clinical social worker who discloses to a client personal, intimate details about his or her own life, ostensibly to be helpful to the client, ultimately may confuse and compromise the client's mental health because of complicated transference issues produced by the social worker's self-disclosure. (Reamer, 2003, p. 123)

O'Leary and colleagues (2013) argue that the notion of boundaries in the social work relationship is derived from a situation that has relevance for professions such as medicine and law, but has a restrictive application for social work relationships, where aspects of the relationship share many of the qualities of friendship (Beresford, Croft, & Adshead, 2008; Doel, Allmark, Conway, Cowburn, Flynn, Nelson, & Tod, 2010). Commonly, effective social work relationships are built through the practitioner's expertise and skills in establishing connection through informal conversations and contacts. Very often, these relationships establish an atmosphere in which highly personal information and feelings are shared (O'Leary, Tsui, & Ruch, 2013). The realities and philosophy of social work practice demands connection rather than separation, mutuality rather than hierarchy, and Western conventions and understandings of a professional boundary create restrictive artificial barriers that are not in keeping with the profession's values (O'Leary, Tsui, & Ruch, 2013).

There can be no argument against avoiding anything that could be harmful to the client, if that can be predicted. The problem here is predicting the outcome as even self-disclosure could be therapeutically helpful if applied properly and could help normalise the client-worker relationship (Reamer, 2001). The literature and codes of ethics clearly suggest having an awareness of the boundaries and workers should avoid clear issues such as intimate relationships, criminal activities or other exploitative relationships (Reamer, 2003; 2001). There are also grey areas on issues such as touching, hugging, accepting gifts, accepting food or drinks and friendship after ending therapeutic relationships.

When working with clients from diverse refugee backgrounds, there are many situations where friendship is assumed or expected in the helping relationship. Many social workers are asked to be friends in real life or in social media. Food is also offered during home visits and refusal could be regarded as rude and could potentially ruin the relationship. The worker then has to consider the issues that could enhance or threaten trust. A fundamental virtue is therefore creating an environment of trust – trusting self, client, institutions and clients – and reflective practice (O'Donovan, 2000). Making an effort to understand the client's cultural expectation and the worker also explaining their expectation is one way of minimising the risk of misunderstanding. Reflection is therefore needed both at the individual level and discipline level on the ontological basis of practice in order to establish relevance to clients served by social work (Bell, 2012). Acknowledging that boundaries can become walls between social workers and clients and clarifying what the clients mean when they want to be friends with the social workers is a starting point.

To be a friend may also mean more than a personal friend to one client in a collective culture but being accepted and trusted by the community. In this situation, to reach the individual the social worker has to reach the community. This is well known by workers with Aboriginal Australians but it is also suggested as the case with ethnic Arab communities:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Individual's interests unite with those of their group of allegiance, and the general good supersedes the personal. Individual problems draw the members of the group in common pursuit of solutions. Individuals in trouble do not choose, in isolation from others among the alternative courses of action. (Al-Krenawi, 2000, p. 13)

This can make the work frustratingly slow but it is important to take the time to understand what works best for the individual client and the community. It is equally important to bear in mind the diversity between and within ethnic communities and even within one family. Factors like age, education, religion, acculturation, size of the community, gender and migration status have significant impact on the culture of origin. Recognising this heterogeneity is important to avoid oppression through stereotyping and generalising:

The practitioner's lens must be clear to recognise heterogeneity among groups, patterns that may be responses to years of indifference or oppression, and other underlying factors that impact perceptions. It is through the sensitivity of the ethnic lens that barriers associated with ethnicity can be removed. (Cox & Ephross, 1998, p. 158)

Appreciating the common issues faced by ethnic groups and at the same time taking time to understand the specific individuals and communities with their particular lived experience, background, history and culture, makes for effective practice. This is achieved through respect and genuine curiosity. In addition, the principles of inclusion, participation and building credibility and trust between the worker and the client as well as the community and institutions.

The ideal to the question of friendship or professionalism remains ambiguous in social work and other professional codes of ethics. Schiele (1996) suggests, from an Afrocentric perspective, to do away with boundaries between the helper and the helped and practice engaged relationships for an emotional, trusting and transformative connection. This radical approach assumes that the worker identifies with the client's problem and collaborates to find a solution as equal interested parties.

Challenges of Serving Own Community

There is not much literature on social workers working in their own ethnic communities. There can be both advantages and disadvantages. Cox and Ephross (1998) suggest that families with ethnic identities may prefer workers from their own ethnic group but competence may be valued more and, at the other extreme, members of the same ethnicity may be mistrusted. Ethnicity alone is clearly not enough for one to be accepted. However, for those who are accepted and can be regarded as part of the community they can be integral part of their community's endeavours at self-help in addressing a wide range of issues such as mental health and housing. This is articulated in the Afrocentric paradigm that notes that:

Black self-help from an Afrocentric perspective is politically and economically necessary to guard African Americans against both the planned and capricious forces of continued racism and Eurocentric oppression (Karenga, 1993; Shujaa, 1994; Wilson, 1993). (Schiele, 2000, p. 148).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

There is therefore a need to decolonise social work and therapeutic practices so that non-European clients are not seen through Eurocentric perspectives. Akinyela (2014) calls for cultural democracy in therapeutic work. That means moving beyond multiculturalism and inclusion to actually having knowledge produced by non-Western cultural groups. Attempting to fit non-Western cultural groups into therapies produced within a Eurocentric worldview only entrenches the domination over the 'other'. What is needed, then, is that 'other voices are being identified as world communities speak on behalf of their own healing in their own cultural languages with their own cultural meanings' (Akinyela, 2014, p. 49). This will mean that Indigenous healing practices from around the world can speak between themselves and with Western practices as equals and learn from each other.

Social workers use anti-oppressive practices to address oppression experienced by their clients. Anti-oppressive practice acknowledges the diverse forms of oppression within societies and the harmful effects of inequality (Connolly & Healy, 2013). In this sense, social work takes a political position against oppression and rejects such oppressive practices as sexism, racism and ageism and other generalisations that lead to stereotypes and oppression. Schiele (1996) argues that while these practices raise awareness about the problems faced by minority groups, they fall short of embracing their worldview and cultural values.

THE ROLE OF CULTURAL RITUALS AND DANCES IN HEALING

The biological basis of mental health problems like depression are well understood in the Western cultures and the treatments that include both medication and counselling are well-established. How other cultures understand and treat depression is far less understood. Solomon (2001) has reported that other cultures have different ways and the rituals and community-approach in Senegal, West Africa, are examples of the different approaches. The Senegalese, despite the Islamic faith, exhibited a belief in sprits and the role of blood rituals and communal dancing movements to exorcise the spirits that caused depression. Solomon notes that different practices were also found in Rwanda (Solomon, 2015). It was clear from the experience in Rwanda that if Western-trained practitioners did not take the cultural differences into consideration they could be ineffective or rejected in Rwanda as an informant suggested to Solomon in regard to Western therapists after the genocide:

Their practice did not involve being outside in the sun, like you're describing, which is, after all, where you begin to feel better. There was no music or drumming to get your blood flowing again when you are depressed, and you're low, and you need to have your blood flowing. There was no sense that everyone had taken the day off so that the entire community could come together to try to lift you up and bring you back to joy. There was no acknowledgment that the depression is something invasive and external that could actually be cast out of you again.

Instead they would take people one at a time into these dingy little rooms and have them sit around for an hour or so and talk about bad things that had happened to them. We had to get them to leave the country. (Solomon, 2015, p. 41)

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Not all communities in Africa continue to perform these rituals as the major religions have tended to discourage cultural practices which they see as satanic and contrary to modern religions and enlightenment-inspired science. Nevertheless, it would be worthwhile checking what people's beliefs are and how they interpret the causes of their illness. It is not unusual for people to be educated, Christian or Muslim and still use traditional healers alongside Western medicine. Western practices, including medication and counselling, can play a role but they have to be adapted to the cultures of the people.

Culture as a Strength

Where people are able to reconnect with their culture, they can begin to regain their self-esteem and rediscover their strengths. Successful programs that have helped people to reconnect with their culture also help them to find their strength even after the program ends. Work with American Indian and Alaska Native (AI/AN) has demonstrated this view in a culturally grounded program that also focused on skills to address problems of substance abuse among the tribal youth (Donovan, Thomas, Sigo, Price, Lonczak, … Bagley, 2015). This educational program grounded on cultural practices demonstrated the effectiveness of the approach to increase connection to the tribe and prevent important issues such as suicide, substance abuse and behavioural health issues:

Community-derived, culturally grounded prevention curricula represent promising practices. Integrating evidence-based components of positive youth development and tribal-specific culture, traditions, and values, the curricula have the potential of reducing substance use; increasing hope, optimism, and self-efficacy; and facilitating cultural identity. (Donovan, Thomas, Sigo, Price, Lonczak, … Bagley, 2015, p. 67)

The challenge is taking time to work with the concerned people and identifying what is significant to them, what can be adapted to address the problem being experienced and making it work positively for the people. The canoe journey in this case was based on long traditions that people could easily identify with so the community participation, the dancing and the celebrations reconnected people to those traditions and rekindled pride in their heritage and the motivation to live better and purposeful lives.

Dance, songs and storytelling are part of the important cultural expressions that communities use to promote cohesion and explore culturally appropriate ways of healing. A good example of this is the native dance called Danza Azteca in the United States as practised by the Chicanos/Mexicans. Yañez (2014) found that the dance was a powerful means of reclaiming political space, spiritual awakening and healing from colonisation trauma that was the root cause of many mental health issues:

At its most fundamental level enacting "your culture" and promoting community cohesion is a political act because it disrupts narratives that have been essential to the nation-state and Euro-American values such as the idealization of individuality verses community well-being and the accumulation of capital and resources with little regard for communities of color, group cohesion, or spiritual wellness. (Yañez, 2014, pp. 36-37)

The role of the social worker is assisting people to identify what cultural activity would be ideal in their healing process. It is empowering for the participants to get involved in the selection of activities that work well for them and the worker can assist in accessing the resources needed and how to embed

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the intervention into the activities. Where people might not have a cultural identity to fall back on they could choose to have modern dances like rap or opt for sporting activities like soccer matches. These activities can go a long way in addressing issues like isolation and break the barriers between the worker and the clients. Crafts and gardening are other activities that are possible and could have other benefits like generating income or food.

Hip Hop and Rap

The health benefits of music and dance for mental health and general wellbeing are well established. A relatively new area of interest is using rap music particularly with youth who are marginalised. Rap music in therapy has been used for listening, performing, composition and improvising. Hip hop is a culture that young people identify with as their own and is particularly identified with young African Americans.

Hip hop as an urban culture evolved in the streets of the Bronx, New York, in the 1960s and early 1970s. Its roots are the oral expression traditions from Africa maintained and promoted by poor black youth but has since become part of a popular global youth urban culture and a visible subset of it is rap music (Price, 2006). Rap represents a powerful form of storytelling. Its power arises from the Bantu notion of Nommo, the African belief in the power of the spoken word to change and reconstruct reality. Stories are formed by reality and they also form and shape reality (Yancy & Hadley, 2011). Crooke and Travis (2017) note it is now being taught in mainstream universities, such as Melbourne University, as a therapeutic tool for healing when working with young people. They suggest it is important to recognise more than the profanity in some rap music and note the core of it is a struggle for social justice, peace, respect, self-esteem, community and simply a good time. There are genres that range from feminist to anti-drugs and violence and reject homophobia (Rine, 2013). In Brazil, hip hop is regarded as an artistic movement of social protest to claim recognition and social citizenship (Alves, Oliveira & Chaves, 2016). Rap music has been found to be an effective culturally specific form of therapeutic individual and group intervention with vulnerable or at-risk young people (Tyson, 2011; Yancy & Hadley, 2011).

Religion and Spirituality

Religion and spirituality are very fundamental to the way people understand the world and in particular how they understand mental health. The importance here is for social workers to pay attention to how the individual or community interpret their reality. The workers also need to have an awareness of their own religious beliefs including not having any. Minority groups, like Muslims, have experienced problems in the Western counrties and these may make them wary of the workers. There is a history of 'Christian West' and 'Muslim East' being in conflict dating back to the crusades, the holy wars between the Christians and Muslims starting about 900 years ago. But the more relevant history is the current issues with terrorism that is associated with a small but violent radical group within the Muslim faith that destroyed some buildings in America on 11 September 2011 (or 9/11):

Next to the people who lost their life [sic], Muslims were the worst sufferers of the 9/11 attack on the Twin Towers. Although some Muslim fanatics accomplished the terrible task of destroying the towers, the entire Muslim community had to suffer for this. They suffered immediately from the hate-crimes and discrimination although these were initially sporadic. Later, because of the US government's social, local

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and foreign policy, the Muslim community started to suffer from what can be labelled as "institutional discrimination." (Abdullah, 2015, p. 58)

What this demonstrates is that even though faith and spirituality can be regarded as personal issues, there are also political, social, identity and even economic implications. Given the implication of discrimination on oppression and mental health, workers cannot afford to ignore the role religion plays in people's lives and life-chances. Religious beliefs can also be a source of strength as conveyed in the word the Muslims use when committing to a future action, inshallah, meaning if Allah wills or God willing.

In traditional African and Eastern traditional belief systems, spirituality is not separate from mind and body or even the material world, as it is in the Western empiricist view of the world. In the Eastern traditions, everything and every aspect of life is linked to spirituality which is the web that links all beings. Religion and spirituality in African traditions is inseparable from other aspects of life such that "religion permeates into all departments of life so fully that it is not easy or possible to isolate it" (Mbiti, 1989). Spirituality in traditional societies is also linked to morality and ethics and it has been argued that in social work this can have a role in addressing problems such as mental health problems, alienation, drug use and violence (Belgrave, Cherry, Cunningham, Walwyn, Letlaka-Rennert, & Phillips, 1994; Schiele, 2000). Social workers therefore need to take these spiritual factors into consideration:

The spiritual factors for social workers will involve the notion of identity and the sense of being. There will be consideration of hope and optimism, consideration of the sense of aesthetics, consideration of the sense of purpose, understanding of religion and consideration of ontological and existential issues. The social worker ought to have a well-considered position on these issues. (Pawar & Anscombe, 2015, p. 53)

Spirituality is not emphasised in social work, but Hay (2012) suggest that it would be beneficial to have a spiritual component in the social work curriculum. Even when a social worker does not believe in the existence of a spiritual dimension, they need to understand the significance of the spirit world and its influence on the people they work with. For the people who believe in the spirit world then there could be symbolic ways of appeasing the spirits. When something is considered evil or taboo, it is considered a threat, not only to the individual but to the entire community, so some ritual cleansing is important for the stability of the community and avoidance of shame (Ekeke, 2011). The Igbo people of Nigeria, for example, had a substitute for the community in the form of an animal or a human being dragged through the polluted places in the community so they could symbolically absorb the uncleanliness, then the soiled victim is thrown away (Ikenga-Metuh, 1985).

The healing power of rituals is important for those who subscribe to it and this is consistent with the ethical basis of social work, which respects people's belief systems. Research has shown that Congolese and Somalis settled in the United States turn to traditional healers and religious leaders in times of distress before they consider accessing western mental health services (Piwowarczyk, Bishop, Yusuf, Mudymba & Raj, 2014). This in part could explain the low utilization of mental health services among different African refugee groups, despite rates of posttraumatic stress disorder that are higher than the general population (Kinzie, 2006; Piwowarczyk, Bishop, Yusuf, Mudymba, & Raj, 2014). The traditional and religious rituals approach to mental health are based on a worldview that accepts the existence of a spirit world. Complications could arise where the rituals to address mental health may contradict the laws for example, in terms of cruelty to people or animals and where the human rights of others may be

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

impinged upon. The duty of the social workers then is to explain to the individual or community why there might be objections to their practises outside of their place of origin.

CONCLUSION

This critical review of cross-cultural social work in mental health has demonstrated the challenges that social workers and other professionals working in the field face. The authors have underlined that awareness of own culture and making effort to understand the cultural worldview of the mental health service user is important for engagement. Understanding of seemingly ordinary issues such as friendship and what that means in other cultures, may prevent misunderstanding. While codes of ethics and organisational codes of practice may have good reasons for proscribing against expression of friendship, it is important to review the implications for the helping professions.

The important aspects of culture like collective orientation and spirituality have been identified as critical in understanding why people with refugee backgrounds may not utilise services even when their symptoms suggest such services are needed. Respecting how people define their understanding of mental health is consistent with a recovery-oriented framework that the Australian government promotes. While there are inevitable generalizations in the discussion, it is important to understand the unique situations for individuals and communities and hence the importance of maintaining a genuine curiosity and an open mind at all times. There is need for research to continue informing how mental health services can be made more responsive to people from minority cultures.

KEY TERMS AND DEFINITIONS

Afrocentricity: This refers to scholarship on African people and people of African descent that treats them as subjects, rather than objects. African history, culture, and philosophy is put at the center while a Eurocentric approach, by contrast, would use a European lens that marginalizes the African people.

Hip Hop: Hip hop or hip-hop refers to the African American urban culture that evolved in the streets of Bronx, New York, in the 1960s and early 1970 and the practices within that culture. Rap music and its sub-genres are one component of that hip hop culture that has now spread around the world. In therapy, it is used to engage young people who identify with that culture or art form.

Nommo: *Nommo* comes from Bantu languages in Africa and represents the power of the spoken word to create harmony and balance. This is power of the spoken word suggests that language is important for the community and change and healing can be generated from speaking if it is done well.

Chapter 61
Facebook Depression or Facebook Contentment: The Relation Between Facebook Use and Well-Being

Jessica J. Joseph
Mount Royal University, Canada

Malinda Desjarlais
Mount Royal University, Canada

Lucijana Herceg
Mount Royal University, Canada

ABSTRACT

Within the literature, Facebook has received much attention in order to understand the potential positive and negative effects associated with using the social networking site. The current chapter provides a discussion of the empirical support for the differential outcomes associated with actively posting and chatting on Facebook vs. passively browsing Facebook, as well as the underlying mechanisms for the effects. Specifically, the current chapter will discuss two perspectives related to the differential effects of active and passive Facebook use: Facebook contentment (a wellbeing enhancing effect) and Facebook depression (a wellbeing diminishing effect). The authors also discuss the extension of the results to other social media platforms and provide suggestions for future research.

INTRODUCTION

Social networking sites are rapidly changing the way that people interact with one another, and have the potential to influence psychosocial functioning and emotional distress. Of the variety of social networking sites that exist, Facebook has rapidly gained popularity since its induction to the general public in 2005. Facebook users create online profiles containing personal information about the self that are

broadcasted to other online users, which can be updated with additional information at the discretion of the profile owner. The information shared is also open to the reception of quantitative or qualitative feedback from Facebook friends.

Subjective well-being is a phenomenon that is comprised of people's personal evaluations of their lives, including emotional responses to life events, as well as a personal assessment of one's overall satisfaction with life (Diener, Suh, Lucus, & Smith, 1999). Research on the social aspects of well-being has revealed that interpersonal relationships and social engagement are associated with positive affect and enhancements in subjective well-being (see Diener, Suh, Lucas, & Smith, 1999 for review). With the opportunity to stay connected with others online, Facebook may benefit subjective well-being, resulting in a potential for "Facebook Contentment". However, not all aspects of being social enhance subjective well-being; for example, if a person compares him/herself to others who are doing better off than he/she is, then subjective well-being is reduced (Michalos, 1985). Similar emotional distress may arise when negative feedback is received for information about oneself that is shared on Facebook. In either case, Facebook users are at risk of "Facebook Depression".

Overall, this chapter will synthesize the current literature regarding Facebook and its relation to psychosocial functioning, which may aid in the advancement of research, increase in public awareness, policy development, and clinical applications. The chapter is divided into the following sections. First, the chapter will summarize statistics about the frequency of Facebook's use and its most popular users. Second, the authors will synthesize the literature examining the relationship for active and passive Facebook use separately with subjective well-being and present theoretical background to explain these associations to support the potential for Facebook Contentment and Facebook Depression, respectively. Third, a summary of the literature regarding the effects of posting selfies will be provided, and the authors will present an evidence-based argument that active Facebook use is not always positive when considering selfie-posting behavior. Fourth, the authors will evaluate the uniqueness of the findings related to Facebook in comparison to offline interactions and other social networking sites, which highlights the real but rather small magnitude of effect Facebook has on social interactions and mental health. Finally, the gaps in the literature will be discussed and future research suggested.

AN OVERVIEW OF FACEBOOK USE AND USERS

Internationally, over 1.7 billion people visit Facebook every month, with over 1.2 billion visits every day, and 85% of the logins occurring outside of North America (Stats, 2016). In relation to North American use, in November of 2016, the Pew Research Centre reported that Facebook remains the most popular social networking platform in the United States by an overwhelming margin (Greenwood, Perrin, & Duggan, 2016). Furthermore, in a 2015 study conducted by Forum Research on social media usage, Facebook remained the top social network in Canada, with 59% of respondents indicating they use Facebook and visit about nine times each week (McKinnon, 2015). On average, Facebook users are comprised of young adults between the ages of 18 and 39, with female users being slightly more common than male users (Greenwood, Perrin, & Duggan, 2016).

While on Facebook, users are able to create a personal profile, known as the Facebook 'Timeline' that contains an amalgamation of image and text-based information about the user, which can then be shared with the user's Facebook 'friends'. In the context of Facebook, 'friends' consist of a combination of close friends and acquaintances met offline, and family members, for which the average ranges from

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

around 150 (Ellison, Steinfield, & Lampe, 2007) to over 400 friends (Manago, Taylor, & Greenfield, 2012). Young adults often turn to Facebook to aid in the maintenance of their relationships (e.g., to post or send messages, stay in touch with friends), to pass time, or for entertainment purposes (e.g., to see other people's pictures and read their profiles; Davis, 2012; Sheldon, 2008; Smith, 2011). Therefore, users can interact with Facebook in a passive or active fashion. First, Facebook is often used to *observe* Facebook friends by anonymously scrolling through the newsfeed, or browsing friends' photos/timelines, without any form of direct communication with their Facebook friends. This type of Facebook behaviour is regarded as passive Facebook use or surveillance (Ryan & Xenos, 2011). Second, during active use, individuals communicate with others by *sharing* text-based information or photos when directly messaging friends, posting status updates, sharing memories, posting on timelines, or reacting to others' posts.

The taking and sharing of selfies, a specific type of image shared on Facebook (Weiser, 2015), falls under the umbrella of active Facebook use. A selfie consists of a photograph of one's self alone or with others that is taken with a camera held at arm's length or pointed at a mirror (Sorokowski, Sorokowska, Oleszkiewicz, Frackowiak, Huk, & Pisanski, 2015). Selfies are shared as a means for communication, to attract attention from others, for entertainment, and to archive memories (Sung, Lee, Kim, & Choi, 2016). According to American surveys of 18 to 24 year old participants, 98% took selfies, 46% had shared selfies within the past day, and 69% tended to share selfies three to 20 times daily (Katz & Crocker, 2015). There are mixed findings regarding who frequently posts selfies. On the one hand, there is some support that frequent selfie-posters tend to be those who score high on narcissism (Moon, Lee, Lee, Choi, & Sung, 2016; Weiser, 2015) or extroversion (Kim & Chock, 2017; Sorokowska, Oleszkiewicz, Frackowiak, Pisanski, Chmiel, & Sorokowski, 2016), as well as adolescents and younger adults (Dhir, Pallesen, Torsheim, & Andreassen, 2016). On the other hand, researchers have also reported no such relationships between behaviour and characteristics of the poster (Barry, Doucette, Loflin, Rivera-Hudson, & Herrington, 2017; Sung, Lee, Kim, & Choi, 2016). Given the increasing popularity of selfies, it is important to consider the effect of this Facebook activity on its own.

Taking into account how and why Facebook is being used, there are potential consequences for subjective well-being. The following sections present an overview of subjective well-being, and outlines why active (including selfie posting behaviour) and passive Facebook use may influence well-being in a positive (Facebook Contentment) or negative (Facebook Depression) way.

FACEBOOK USE AND SUBJECTIVE WELL-BEING

Facebook provides opportunities for users to disclose personal information about themselves, to receive reactions from others, and to compare how they are doing relative to their Facebook friends. These activities have the potential to contribute to subjective well-being by influencing feelings of social connectedness and self-esteem. Social connectedness is characterized as the feelings of belonging and staying in touch with ongoing social relationships (Van Baren, IJsselsteijn, Markopoulos, Romero, & De Ruyter, 2004). Self-esteem is considered as the level of value you place on yourself, which is influenced by the reactions of and comparison with others (Argyle, 2008). The popularity of Facebook has given rise to a body of research investigating the association between Facebook use and well-being or one of its related constructs (e.g., depression, life satisfaction, and loneliness), which has uncovered inconsistent results. On the one hand, spending more time on Facebook was associated with increases in depressive symptoms (Steers, Wickham, & Acitelli, 2014), as well as feeling lonely (Lou, Yan, Nickerson, &

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

McMorris, 2012), ostracized from their friends (Tobin, Vanman, Verreynne, & Saeri, 2015), and less satisfied in their own lives (Blachnio, Przepiorka, & Pantic, 2016; Valenzuela, Halpern, & Katz, 2014). In fact, when Facebook users take a break from using the social networking site, it enhances both the cognitive and emotional aspects of subjective well-being (Tromholt, 2016). On the other hand, research also supports that more time spent on Facebook enhances life satisfaction (Valenzuela, Park, & Kee, 2009), self-esteem (Burke, Kraut, & Marlow, 2011), and psychological well-being (Burke & Kraut, 2016; Liu & Yu, 2013). Still, others report no relationship between time spent on Facebook and depressive symptoms (Jelenchick, Eickhoff, & Moreno, 2013), or life satisfaction (Glynn, Huge, & Hoffman, 2012). The challenge with measuring Facebook use as a single dimension is that it may cancel out the effects associated with different activities. While activities directed at the sharing of information may enhance social connectedness and has the potential for Facebook Contentment, the viewing of others' posts may elicit negative feelings because of social comparison, which increases the risk for Facebook Depression. Therefore, the following sections present a synthesis of the literature for active and passive Facebook use and explains their unique association with subjective well-being.

Facebook Contentment and Active Facebook Use

Active Facebook use is characterized by making social contributions while on Facebook, including broadcasting information about one's self and writing what's on a person's mind (through posting photos, status updates, or sharing links, memories, or memes), communicating with others (by writing on friends' timelines, and sending messages on Facebook), and providing feedback to others [by liking, commenting, and reacting to friends' Facebook posts (Burke, Kraut, & Marlow, 2011; Verduyn, Lee, Park, Shablack, Orvell, Bayer, & Kross, 2015). It should be noted that social networking activities usually involve the sharing of authentic information and content without malicious intent (Fox & Moreland, 2015; Reinecke & Trepte, 2014), and thus a discussion of false identities and cyberbullying or similar contexts are considered beyond the scope of the chapter. Typical active Facebook use has the potential then for Facebook Contentment, a phenomenon suggested by the authors that emphasizes the positive consequences for psychosocial functioning associated with the use of Facebook (and other social networking sites). In other words, active Facebook use results in enhanced subjective well-being and related constructs. In support of this principle, active use is typically associated with heightened subjective well-being (Kim & Lee, 2011). Greater active use is also correlated with enhancements in social well-being (Burke, Marlow, & Lento, 2010), and self-esteem (Csepeli & Nagyfi, 2014), as well as decreases in depression (Frison & Eggermont, 2016), and loneliness (Ryan & Xenos, 2011).

Social connectedness, a key underlying mechanism for enhanced mental health in general (Baumeister & Leary, 1995), has been put forward as the variable that links active Facebook use and subjective well-being. When considering social connectedness in the context of traditional offline interactions, those with greater subjective well-being also report greater levels of social connectedness (Baumeister & Leary, 1995), and social support (Helliwell, Huang, & Harris, 2009). In a three-year longitudinal study of over 1700 adolescents, researchers found that youth who reported higher levels of social connectedness would subsequently report higher well-being, but there was no support for a reciprocal relation (Jose, Ryan, & Pryor, 2012). These benefits of social connectedness also extend to online social interactions. In particular, individuals who are more active on Facebook report greater social connectedness (Köbler, Riedl, Vetter, Leimeister, & Krcmar, 2010), social capital (Burke, Kraut, & Marlow, 2011), and social support (Wright, Rosenberg, Egbert, Ploeger, Bernard, & King, 2013). In addition, when researchers test

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the features that fall under the classification of active Facebook separately, only certain active behaviours enhance users' life satisfaction. In a longitudinal study, Wenninger, Krasnova, and Buxmann (2014) measured each active component separately (i.e., posting, chatting, liking, and commenting), as well as users' life satisfaction over the course of one week. Posting on and chatting with friends via Facebook were associated with increases in users' life satisfaction over the course of one week, while liking and commenting on friends' posts were not related to life satisfaction. Therefore, only the specific Facebook features that enabled users to make social contributions, that are required for enhancements in subjective well-being, actually contributed to life satisfaction.

There is also direct empirical support for social connectedness as a mediating factor that explains the positive association between actively posting on Facebook and users' subjective well-being. Correlational studies indicate that the feelings of social connectedness that occur when actively using Facebook are associated with decreases in depressive symptoms (Grieve, Indian, Witteveen, Tolan, & Marrington, 2013). Similarly, Frison and Eggermont (2016) identified that for females, actively interacting with friends either publicly or privately while on Facebook led to the perception of being supported by friends, which then decreased depressive mood. Since correlational studies can only support a relationship between variables, and cannot distinguish the directionality of the effect between Facebook use and social connectedness, Deters and Mehl (2013) conducted an experimental study to investigate the proposed directional effect that Facebook use leads to increases in feelings of connectedness. In their study, participants in the experimental condition were asked to post on Facebook more frequently than they typically would, while their control counterparts were instructed to use Facebook as usual over the course of one week. The results indicated that the Facebook users in the experimental (active) condition experienced decreases in loneliness, which was attributed to feeling more connected to their friends.

In sum, the findings from the research centered on active Facebook use provides overwhelming support for Facebook Contentment. More specifically, the studies suggest the following two principles: (1) the phenomenon of Facebook Contentment is an accurate depiction of what users experience when they are engaging in active behaviour on Facebook; and (2) social connectedness is the causal link between active use and subjective well-being. It can then be inferred that when users log onto Facebook and utilize the features that enable them to make active social contributions such as sharing information about themselves, or communicating with friends, the feelings of social connectedness that result resemble feelings that occur during traditional offline interactions, and consequently so do the enhancements in subjective well-being.

Facebook Depression and Passive Facebook Use

In general, researchers and society have become concerned with the potential harmful effects elicited by Facebook use. This has led to the introduction of Facebook Depression. In the current literature, Facebook Depression refers to a phenomenon where users experience increases in depression and loneliness, and decreases in self-esteem and psychological well-being as a result of spending too much time on Facebook (Kross, Verduyn, Demiralp, Park, Lee, Lin, … Ybarra, 2013; O'Keeffe & Clarke-Pearson, 2011). Facebook Depression is not an overarching result of Facebook use; rather, the negative effects of Facebook have been associated only with passive use. Passively observing friends on Facebook is negatively associated with several constructs that are related to subjective well-being, including increased loneliness (Ryan & Xenos, 2011), and depression (Frison & Eggermont, 2016), as well as decreased social well-being (Burke, Marlow, & Lento, 2010), and life satisfaction (Wenninger, Krasnova, & Buxmann,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

2014). In fact, in an experimental study by Verduyn et al. (2015), participants in the passive experimental condition were asked to use Facebook solely passively (i.e., scrolling through Facebook with no posting or interacting) for 10 consecutive minutes. Although there was no change in well-being immediately following Facebook use, participants reported decreases in affective well-being at the end of the day. Even after controlling for the changes in affective well-being that occurred via passive use, the reverse path (affective well-being resulting in higher levels of passive use) was not significant.

What is it about passive Facebook use that would be detrimental to subjective well-being? Social comparisons are a rather automatic consequence of being social (Festinger, 1954). Festinger's (1954) social comparison theory postulates that individuals engage in self-evaluation by comparing themselves to those who are similar. Social comparison provides individuals with the ability to gather information to evaluate their own capacities and characteristics so they can develop stable and accurate evaluations about the self. During social comparison, individuals gain social information, think about social information and then react to the comparative information (Diener, Suh, Lucas, & Smith, 1999). Building on social comparison theory, Suls, Martin, and Wheeler (2002) argued that social comparison can be both upward and downward, and that there are differences in the outcomes of social comparison depending on whether the evaluator is engaging in upward or downward social comparison. Upward social comparisons (aka negative social comparison) refer to instances where the targets of social comparison are doing better than oneself (Suls, Martin, & Wheeler, 2002). Michalos (1985) postulated that a person's subjective well-being depends on the discrepancy between a person's current life circumstances compared to a standard set by comparing him/herself to others' current life circumstances. If the target(s) that a person compares him/herself with is perceived to be more successful, happier, wealthier, more attractive than him/herself, then there is a tendency to develop a negative self-image and exhibit decreases in subjective well-being (Michalos, 1985). On the other hand, a person can also compare him/herself to a target who appears to be worse off. This downward social comparison (aka positive social comparison) is typically associated with a more positive self-image and increased subjective well-being (Suls, Martin, & Wheeler, 2002).

Facebook users do compare themselves to their Facebook friends (Feinstein, Hershenberg, Bhatia, Latack, Meuwly, & Davila, 2013; Joseph & Desjarlais, 2017; Vogel, Rose, Roberts, & Eckles, 2014). And, the more time users spend on Facebook, the more likely they are to negatively compare themselves to others, which often leaves users feeling as though their friends are doing better off in life than they are (Chou & Edge, 2012; de Vries & Kühne, 2015). Similar to offline contexts, the act of negatively socially comparing while on Facebook is associated with increases in depressive symptoms (Nesi & Prinstein, 2015; Steers, Wickham, & Acitelli, 2014). The challenges associated with negative social comparison online are only evident for passive Facebook use. Scrolling through Facebook has been associated with increases in negative social comparison and thus decreases in users' self-esteem (Vogel, Rose, Roberts, & Eckles, 2014), and increases in feelings of envy (Appel, Crusius, & Gerlach, 2015; Krasnova, Wenninger, Widjaja, & Buxmann, 2013). Furthermore, passive use is not related to users' depressive symptoms unless the browsing Facebook has led to feelings of envy (Tandoc, Ferrucci, & Duffy, 2015).

Negative social comparison in the context of Facebook is especially troublesome because when people are comparing themselves to others on Facebook, they may not actually be comparing themselves to a realistic target. In general, people are concerned about the way they are perceived by others (Goffman, 1959), and thus attempt to manage the impressions others on Facebook form and their evaluations by presenting oneself to others in a positive and socially desirable way (Zhao, Grasmuck, & Martin, 2008). Applications that enable users to touch up their photographs with filters, thus promoting users to hide their flaws (Walther, 2007), have become increasingly popular (Lup, Trub, & Rosenthal, 2015). As such,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the information visible while scrolling through Facebook probably is comprised of images and statements that represent users' idealized selves (Manago, Graham, Greenfield, & Salimkhan, 2008). Thus, if social comparison occurs while passively using Facebook, and the information posted on Facebook sets a standard for a level of unrealistic perfection, then users find themselves comparing to an unrealistic target. It is not surprising then that users feel as though they do not measure up to their friends.

In conclusion, the literature regarding passive use support a real risk for Facebook Depression. Consistent with social comparison theory, negatively comparing one's self to Facebook friends, and the feelings of envy that ensue, appear to be driving the negative association between passive Facebook use and subjective well-being. Due to selective presentation and impression management strategies common on Facebook, users need to be cautious they do not get wrapped up in a fantasy where everyone else's lives are near perfection.

SELFIES: THE POTENTIAL FOR FACEBOOK CONTENTMENT AND FACEBOOK DEPRESSION

As aforementioned, active Facebook use is positively associated with subjective well-being and related constructs. However, within the literature on the psychological effects of Facebook use, a specific type of active behavior has not received attention - that is, the posting of a specific type of photo, the selfie. Unlike active Facebook activities in general or other specific active behaviors (posting and instant messaging), sharing selfies has disparate effects on subjective well-being. Selfie-posting behavior may lead to enhanced subjective well-being through self-disclosure and positive reactions from others. On the other hand, sharing selfies can deflate self-esteem when the photos receive negative attention. Since there is limited research explicitly investigating the link between selfie-posting behavior and subjective well-being, the authors can only postulate the potential for Facebook Contentment and Facebook Depression.

Facebook Contentment: Selfies Facilitate Connections With Others

Intimate friendships have implications for adolescent psychosocial adjustment and the quality of future relationships. For example, a lack of close friends has been associated with feelings of loneliness, alienation, depression and low self-esteem among adolescents (Buhrmester, 1990; Cohen & Willis, 1985), as well as life satisfaction during adulthood (Marion, Laursen, Zettergren, & Bergman, 2013). Learning to maintain close relationships prepares adolescents for adult intimate relationships (Sullivan, 1953), such that high-quality adolescent friendships are related to greater adult romantic relationship commitment (De Goede, Branje, van Duin, VanderValk, & Meeus, 2012). Self-disclosure, or the sharing of personal thoughts, feelings, and experiences, is an important feature of adolescent and adult intimate friendships (Berndt, 1989).

Social networking sites are providing users with the ability to meet these social needs. Valkenburg and Peter (2009; 2011) formulated the Internet-enhanced self-disclosure hypothesis, which postulates that online interactions stimulate online self-disclosure and in turn enhances closeness with friends. Therefore, Facebook may offer users a comfortable environment for sharing information, including anonymity, accessibility, asynchrony, and the absence of nonverbal cues. In direct support of the Internet-enhanced self-disclosure hypothesis, Valkenburg and Peter (2009) found that the relationship between online communication and friendship quality was fully mediated by self-disclosure. Other studies have

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

also provided support for portions of the hypothesis. Specifically, more frequent use has been associated with greater online self-disclosure (Desjarlais & Joseph, 2017). Moreover, online disclosure consistently has been associated with increases in friendship quality (see Desjarlais, Gilmour, Sinclair, Howell & West, 2015 for a review), which then enhances users' well-being (Valkenburg & Peter, 2007, 2009).

When asking about people's motivations for posting selfies, they do indicate that some selfies are shared as a means to communicate with others. Instead of posting notes that one is starting a new job, is on a vacation, or feeling upset, the poster can share a selfie of him/herself in her new uniform, sitting on a beach relaxing in the sun, or visually crying. As a snapshot of one's life, selfies offer a medium to express emotions and reveal insights (Wortham, 2013). In this context, the intention for posting the selfie is not to present the best polished self, but rather to share honest information, natural insights, and emotions with friends, family, and acquaintances in an effort to build intimacy (Choi, Sung, Lee, & Choi, 2017; Diefenbach & Christoforakos, 2017). Group selfies also provide information about the poster through social cues, such as relationships with others and behaviour in a group (Wang, Yang, & Haigh, 2017). In terms of the outcomes of such disclosure activities, results suggest that self-disclosure through selfies may open the line of communication, earn sympathy, and result in positive emotional experiences for posters (Diefenbach & Christoforakos, 2017). Therefore, it is reasonable to postulate that the selfie contributes to connections made with friends and family, supporting the Facebook Contentment perspective.

Facebook Depression: Selfies May Deflate Self-Esteem

In general, people are concerned about the way they are perceived by others, and as such, their reactions can raise or deflate self-esteem (Goffman, 1959). Compliments, praise, and indications of liking serve to enhance self-esteem, whereas criticism and rejection deflate it. In order to elicit esteem-enhancing reactions, people attempt to manage the impressions others form and their evaluations by presenting oneself to others in a positive and socially desirable way both offline (Walther, 2007) and online (Hart, 2017). People often put work into selfies in order to present the best image of themselves. They have worked on finding the right angle, and will edit the pictures before posting in order to present one's ideal self (Hart, 2017). In interviews regarding social media use, adolescent girls indicated that editing photographs and making oneself look good on social media has become a necessity (Chua & Chang, 2016). All admitted to using filters and editing photos with software to, for example, brighten the skin, conceal facial imperfections, and enhance colors. One-third of the girls went so far as to change their facial features, including modifying their face line, and altering the size of their eyes and noses. According to one teen, the purpose of putting so much effort into perfecting the selfie is so posters can share pictures that meet the standard and to impress their friends (Chua & Chang, 2016). Consistent with this, attention seeking has been acknowledged as a driving motivation behind the taking and sharing of selfies. People post selfies with a desire to attract attention, to be acknowledged by others, to gain self-confidence from others' reactions, and to receive affirmation from others (Sung, Lee, Kim, & Choi, 2016).

Individuals seem to place high importance on the number of likes and followers they receive, believing that the numbers are more important than comments, and that the numbers serve as an indication of peer attention, benchmark against peers, and their position in their peer group (Chua & Chang, 2016). By manipulating the number of likes individuals receive, Burrow and Rainone (2017) examined the extent to which self-esteem was sensitive to the number of likes received on selfies posted to a mock Facebook site, and if this depended on individuals' sense of purpose. They did find that for those reporting a lower

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

sense of purpose in life, the number of likes was positively associated with self-esteem; whereas, there was no relationship between the number of likes and self-esteem among those with a greater sense of purpose. Other researchers have argued that frequent likes may affirm the ideal self that one presented in a selfie and make an individual feel good about him/herself, thereby increasing self-esteem (Bazarova & Choi, 2014; Shin, Kim, Im, & Chong, 2017). On the positive side, selfies do generate a high number of likes compared to natural pictures (Souza, de Las Casas, Flores, Youn, Cha, Quercia, & Almeida, 2015). So long as selfies receive a high number of likes, self-esteem may be boosted.

However, other research regarding selfie-posting does not suggest such esteem-enhancing effects, which is particularly concerning for girls and women given that they exhibit higher selfie-posting frequency as compared to males (Dhir, Pallesen, Torsheim, & Andreassen, 2016; Sorokowska, Frackowiak, Karwowski, Rusicka, & Oleszkiewicz, 2016; Weiser, 2015). With the exception of a few studies (Barry, Doucette, H., Loflin, Rivera-Hudson, & Herrington, 2017; McCain, Borg, Rothenberg, Churillo, Weiler, & Campbell, 2016), research tends to suggest a negative association between selfies and self-esteem for the profile owner. In an experimental study, participants who took selfies, whether they were saved or posted to social media, showed decreases in self-esteem (Shin, Kim, Im, & Chong, 2017). In general, selective self-enhancement is negatively related to self-esteem and well-being (Robins & Beer, 2001), and instead, it is the honest self-presentation that enhances perceived social support and thereby has positive implications for subjective well-being (Kim & Lee, 2011). Adolescent girls believe that insecurity and low self-esteem are the root of the need to edit photographs to perfection (Chua & Chang, 2016). Furthermore, there is also increasing support for a link between selfies and self-esteem related to body image. For adolescent girls, sharing selfies correlated with over-evaluation of shape and weight, body dissatisfaction, and thin idealization (McLean, Paxton, Wertheim, & Masters, 2015).

Shin and colleagues (2017) argued that taking and sharing selfies may hinder self-esteem because of heightened self-awareness that one does not meet social standards. Specifically, according to objective self-awareness theory (proposed by Duval & Wicklund, 1972), self-awareness increases when individuals view images of themselves, which leads people to become more anxious about others' judgments about themselves, and make social standards and norms more salient. Since people often think they do not meet social standards when self-awareness is heightened (Gonzales & Hancock, 2011), there is the possibility that taking selfies would lower self-esteem. In fact, in one experiment, participants were instructed to take a selfie or a picture of an object using their own smartphone and then either post it on social media or save it (Shin, Kim, Im, & Chong, 2017). Those who were instructed to take a selfie, especially those who also posted it, showed heightened concern for other people's judgments and reactions to themselves compared to those instructed to take a picture of an object. This supports the objective self-awareness theory, suggesting that people became more socially sensitive after taking a selfie.

Although selfies do grab the attention of viewers over other types of photographs on social media sites (Ford, 2016; Souza, de Las Casas, Flores, Youn, Cha, Quercia, & Almeida, 2015), the attention may not be as positive as one hoped. Placing importance on the reactions of others may be detrimental to subjective well-being, given that selfies are not perceived in the best light. There is a clear preference for non-selfie, natural pictures of the self over selfies (Diefenbach & Christoforakos, 2017). Furthermore, the negative perceptions that people have of those who post selfies may translate into the quantitative and qualitative feedback selfies receive, and thereby influence one's self-esteem. In a study of perceived positive and negative aspects, people indicated that selfies are fake, a threat to self-esteem through the receipt of negative reactions, and result in negative impressions by others (Diefenbach & Christoforakos, 2017). Selfies are regarded as an inauthentic way of showing off (Lobinger & Branter, 2015). Consis-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

tently, selfie-posters are judged as being narcissistic, with males judged more harshly than females, and external raters assume posters are motivated to seek attention (Diefenbach & Christoforakos, 2017; Krämer, Feurstein, Kluck, Meier, Rother, & Winter, 2017; Re, Wang, He, & Rule, 2016; Sung, Lee, Kim, & Choi, 2016). Even though these comments come from people who post their own selfies, they justify their own selfie-posting behavior with the belief that their self-portraits are more authentic and self-ironic (i.e., selfie-bias; Diefenbach & Christoforakos, 2017).

In conclusion, on the one hand selfies may have positive implications for subjective well-being by establishing and maintaining relationships online. Alternatively, there is much more support for the risk of decreasing self-esteem, and thus for Facebook Depression, simply by taking selfies. The negative perceptions the public holds for selfie posters in general can translate to negative reactions posted online for all Facebook friends to see. In effect, the attempt to manage others' impressions and evaluations may be to no avail.

IS FACEBOOK UNIQUE?

Facebook facilitates communication with friends and family, social comparisons, and feedback from others, resulting in both positive and negative consequences for users' subjective well-being. These social factors and the associated ramifications, however, are not novel to Facebook. That is, Facebook is not the only setting in which people are able to acquire information about their friends and broadcast information about oneself; instead, individuals may socialize within a multitude of social networking sites as well as offline settings. In a study by the Pew Research Center (2017), the most-widely used of the major social media platforms after Facebook were Instagram, LinkedIn, and Twitter, with just under a third of Americans using each of these sites. In addition, roughly half of Instagram users and 40% of Twitter users visit these sites at least once a day. Also considered among the most popular social media sites is Snapchat (Duggan, 2015). The following provides an overview of the unique features and audiences for three other popular social media platforms - Twitter, Instagram, and Snapchat.

Twitter is a micro-blogging social media platform that restricts users' posts (known as tweets) to 140 characters. Users can and do typically follow other individuals with whom they do not have a relationship, such as celebrities, politicians, and organizations (Jin & Phua, 2014). On Instagram, users are also likely to interact with others they do not know in real life, but to a lesser degree than Twitter. Instagram provides users with a platform to take photos, edit them using a series of filters, and share them to their profile instantaneously (Ting, Wong, de Run, & Lau, 2015). Other users have the ability to follow individuals on Instagram, which allows the follower to view the owner's profile and photos, and for recently uploaded pictures to appear in the follower's Instagram newsfeed. Unlike Facebook where friending gives both partners access to each other's profiles, the action of following someone on Instagram does not automatically result in reciprocal following. Having followers as opposed to friends creates more acceptability and opportunity to view strangers' posts. In contrast, Snapchat is a photo-sharing application where users can send snaps (i.e., pictures and short videos that can include text and drawings) with friends that dissolve after a few seconds (Vaterlaus, Barnett, Roche, & Young, 2016). Therefore, in contrast to Facebook where posts are long lasting and often visible to a large audience, information shared on Snapchat is transitory and relatively private and thereby reducing the need to self-censor. In effect, communication via snaps has been viewed as more intimate (Utz, Muscanell, & Khalid, 2015).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are relatively few studies investigating the psychosocial outcomes of Twitter, Instagram, or Snapchat use. Of the research that is available, these social media platforms do appear to have similar outcomes as Facebook. It is argued that people do use Twitter to connect with others by staying updated about the lives of friends and acquaintances (Boyd, 2009), and that Twitter activity may be related to decreases in loneliness (Pittman, 2015) and increased feelings of camaraderie (Chen, 2011). Moreover, the multitude and variety of people being followed can increase social capital (Phua, Jin, & Kim, 2017). Similarly, social interaction is a key motivation for using Instagram (Lee, Lee, Moon, & Sung, 2015), and Instagram activity has been associated with positive effects for social capital (Phua, Jin, & Kim, 2017) and happiness (Pittman & Reich, 2016). However, there is a potential for negative effects on self-esteem when using Instagram that mirror Facebook. The combination of frequent selfie-posting by users (Hu, Manikonda, & Kambhampati, 2014), the ubiquitous selective self-presentation (Lee, Lee, Moon, & Sung, 2015; Ridgway & Clayton, 2016), and the frequent use for surveillance purposes (Sheldon & Bryant, 2016) may give rise to negative social comparison and decreased self-esteem. In contrast, Snapchat may offer the most positive outcomes of the social media platforms when considering social connectedness. From interviews of young adults for perceptions of how Snapchat behaviors influenced their interpersonal relationships, it was clear that Snapchat was praised for being a valuable communication tool (Vaterlaus, Barnett, Roche, & Young, 2016). Users felt that the ability to present messages using a combination of picture and text allowed for better understanding of the emotional context of the conversation (i.e., emotion can be shown in a picture and attached with a text message). Young adults indicated that Snapchat provided a way to remain close with their most important friends.

In addition to social networking sites, Facebook users still do interact with their friends face-to-face. Adolescents use social media predominantly to supplement rather than replace offline interactions with friends (Valkenburg & Peter, 2011). Social connections, social support, and social comparison are all associated with face-to-face social interactions in the same fashion as was discussed in the context of Facebook (Berkman & Glass, 2000). The socialization that occurs on Facebook, and other social networking sites, mirror those in offline settings. Thus, the increases and decreases in subjective well-being associated with sharing information, social connectedness, and social comparison are something that people experience regularly, and regardless of whether they use Facebook or any other social networking sites. What is different when face-to-face however, is the presence of verbal cues and body language. So although someone may present only the most positive and socially desirable information, his/her body language, clothing, tone of voice, eye contact, and so on when face-to-face may inadvertently reveal the truth. It may be then that the ability to selectively present and filter personal information posted on social networking sites make the negative effects in subjective well-being more salient online compared to offline interactions.

FUTURE RESEARCH DIRECTIONS

This chapter presented a review of the literature pertaining to Facebook, its features, and subjective well-being. The vast majority of research reviewed in the current chapter is cross-sectional and correlational. While this research can reveal the relationship between variables (e.g., passive use and poorer subjective well-being, or selfie-posting frequency and decreased self-esteem), the directionality and causal links among variables are speculative. Facebook Contentment and Facebook Depression present the perspective that Facebook use leads to increases and decreases for subjective well-being, respectively. However,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

it is equally plausible that those with already strong connections with friends turn to Facebook to share information. Alternatively, people with emotional distress may be inclined to view others' successes in Facebook without posting their own feelings of failures, which results in negative social comparison. Although there have been a few longitudinal studies that examined the directional effects of Facebook use, they were at the end of day (Verduyn, Lee, Park, Shablack, Orvell, Bayer, & Kross, 2015) or end of the week (Deters & Mehl, 2013). Examining relationships over a greater span of time would provide information on the long-term effects of Facebook use and provide perspective on just how detrimental or facilitating activities are for subjective well-being. In addition, a few studies have involved experimental manipulations of activity engagement to investigate causal implications (Deters & Mehl, 2013; Shin, Kim, Im, & Chong, 2017; Verduyn, Lee, Park, Shablack, Orvell, Bayer, & Kross, 2015). Similar research is needed to assess the relationship between selfies and subjective well-being. Specifically, it is relatively unknown whether the negative perceptions associated with selfie posting translate into the quantitative or qualitative feedback that a selfie poster receives, and whether this information has any meaningful long-term effects for the target.

Longitudinal studies are also necessary to evaluate the practical significance of the relation between Facebook activity engagement and subjective well-being, or related constructs. Although passive Facebook use and selfie-posting are correlated with decreased subjective well-being and self-esteem, respectively, there is no evidence to suggest a major concern for users. On the other hand, however, Facebook use may have additive effects over time, ultimately resulting in decreases in subjective well-being to levels that would significantly affect an individual's psychosocial functioning. The questions that arise then are: Does passive Facebook use or sharing selfies over time lead to depression at a clinical level? Moreover, does this effect exist after controlling for overall mental health? Therefore, longitudinal research would be valuable for understanding any reciprocal relationships between use and psychosocial functioning as well as additive effects.

Furthermore, research investigating who is most affected by using Facebook and posting selfies is scarce. While some studies suggest that females may be most at risk (Dhir, Pallesen, Torsheim, & Andreassen, 2016; Weiser, 2015), there are other factors that also need attention. For instance, given the fact that cultural values and expectations are important factors that influence subjective well-being (Diener, Oishi, & Lucas, 2003) and social relationships (Kim, Sherman, & Taylor, 2008), it may be that the effects for subjective well-being derived from using Facebook and posting selfies are culturally dependent. In addition, researchers have identified that individuals who are shy or socially anxious may exhibit benefits from online interactions in general (social compensation hypothesis; Valkenburg & Peter, 2007). Last, people who have particular expectations of their Facebook friends regarding the content and frequency of feedback to postings may also exhibit the largest effects to self-esteem. Although Facebook users typically report receiving the amount of feedback they expect (Joseph, 2017), there is evidence that sharing information online without receiving a response leads to feeling ostracized (Smith & Williams, 2004). Thus, it is plausible that how using Facebook and posting selfies affect subjective well-being depends on cultural values, current level of shyness, or expectations of other users.

CONCLUSION

What is clear across the current Facebook literature is that Facebook serves as a double-edged sword - a communication medium that could lead to feelings of inadequacy and envy, but at the same time facilitate

social relationships. Offering support for the Facebook Contentment perspective, active Facebook use often correlated with enhancements in subjective well-being through feelings of social connectedness. This was true for active use in general and when examining activities that resulted in some level of self-disclosure. In contrast, selfie-posting behavior, when driven by attention seeking motives, presents consequences that are more negative. Similarly, passive Facebook use typically was associated with emotional distress as a function of negative social comparison, which supports the risk for Facebook Depression. It should be noted that the mediating factors in the associations between active and passive Facebook use with subjective well-being (i.e., self-disclosure, jealousy, negative social comparison, feedback from others, and selective presentation) are not unique to Facebook. People engaged in these social activities prior to the advent of the Internet and social media, and will continue to engage in these when they move on to the next popular social media platform. Therefore, more longitudinal and experimental studies are required to truly understand the significance of active and passive Facebook (or any other social media) use for long-term changes in mental health.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

KEY TERMS AND DEFINITIONS

Active Facebook Use: An approach by which Facebook users interact with other users through sharing textual and pictorial information, sending messages, and reacting to others' posts.

Facebook Contentment: A phenomenon related to Facebook use that is characterized by positive outcomes for psychological functioning and wellbeing.

Facebook Depression: A phenomenon related to Facebook use that is characterized by negative outcomes for psychological functioning and wellbeing.

Negative Social Comparison: Instances where the targets of social comparison appear to be doing better than oneself.

Passive Facebook Use: An approach by which Facebook users surveil others through scrolling the newsfeed, and browsing timelines.

Positive Social Comparison: Instances where the targets of social comparison appear to be doing worse than oneself.

Self-Esteem: A global self-evaluation of one's own self-worth or value.

Selfie: A photograph of oneself, alone or with others, taken with a smartphone held at arm's length or pointed at a mirror.

Social Connectedness: Feelings of belonging and staying in touch with ongoing social relationships.

Subjective Wellbeing: The evaluation of one's own life including an assessment of overall life satisfaction and emotional responses to life events.

Chapter 62
From Medical Student to Medical Resident:
Graduate Medical Education and Mental Health in the United States

Warren G. McDonald
Methoodist University, USA

Matt Martin

Lenard D. Salzberg
Southern Regional Area Health Education Center, USA

ABSTRACT

The transition from medical school to board-certified medical practice includes a period of intense, practical training known as medical residency. Medical residents are at risk for greater mental health distress than the general population. Interns, which are first year residents, are most at risk for, at worst, depression and suicidal ideation, and, at best, negative outlooks on the medical profession. Risk factors include role transition, decreased sleep, relocation, isolation, stigma toward mental health problems and treatment, and health care industry changes. Untreated mental health problems can lead to burnout later during a physician's career. Residents thrive on social and organisational support which can include systematic screening and treatment of mental health problems. Although research regarding best practices for addressing mental health problems during residency is limited, we offer four core strategies for preventing and addressing mental health problems in medical residents: education, screening, treatment, and support.

INTRODUCTION

The purpose of graduate medical education (i.e., medical residency) is to cultivate competency, enthusiasm, and confidence within new medical school graduates and prepare these newly minted physicians for a rewarding and successful career in medicine. Residency training in the United States is primarily distinct from medical school education. Residents, unlike medical students, are fully responsible for the treatment of large panels of patients which means they order laboratory and diagnostic tests, perform surgical procedures, make referrals, and design treatment plans. In addition, residents spend long hours during inpatient and outpatient shifts including night rotations and on-call hours. This particular training is necessary for physicians to develop the skills and temperament required for medical practice. However, such training also exposes residents to isolation, role transition, fatigue, and stress.

While it is clear that residents are at greater risk for depression and suicidal ideation than the general population, researchers have not yet identified the best practises for addressing resident mental health (de Oliveira et al., 2013; Goldman, Shah, & Bernstein, 2015; Govardhan, Pinelli, & Schnatz, 2012). Some qualitative data shows that social support is crucial (Mata, Ramos, Kim, Guille, & Sen, 2016). The medical school literature shows promising results for physical activity, organisational changes and support (e.g., pass/fail grading, faculty advisors, and student retreats), and mindfulness training (Drolet & Rodgers, 2010; Kötter, Tautphäus, Obst, Voltmer, & Scherer, 2016; Slavin & Chibnall, 2016). In this chapter, the authors will describe the transition from medical school to residency training, the relationship between residency training and resident mental health, the effect of chronic stress on resident wellbeing, and a four-part programme for supporting resident mental health.

BACKGROUND

Residency selection is a long and cost-intensive process. During the fourth year of medical school in the United States, students apply to multiple residency programmes devoting significant money and time. Concurrently, residency directors and coordinators spend substantial resources recruiting and interviewing students for a limited number of slots. After interviews conclude, faculty members meet and rank all applicants according to programme fit and quality. Osteopathic students match to their respective residency programmes at the beginning of February while allopathic student match in the middle of March. Residency selection is a long and arduous process for both sides. New residents report to their programmes in June or July, complete orientation, and begin their first rotations.

First-year residents (interns) hit the ground running. Even during orientation, interns are signing medical orders and patients charts. They assume responsibility of continuity patients from recently graduated residents and make treatment decisions at the hospital. With a limited patient panel and under the watchful supervision of attending physicians, interns act like fully-functioning physicians. During the first three months of residency, incidences of depression can increase from 4% to 27% while suicidal ideation can increased nearly 400% (Sen et al., 2010).

In an effort to curb resident fatigue and distress, the Accreditation Council for Graduate Medical Education (ACGME) mandated resident duty hour reforms which, among several requirements, capped residents' weekly duty hours at 80 per week (Bolster & Rourke, 2015). There is no doubt that residents work long and hard hours; yet, it is unclear if limiting resident hours is beneficial to patient care and resident well-being (Bolster & Rourke, 2015; Lin, Lin, Auditore, & Fanning, 2016). Under long periods

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of duress, residents can experience allostatic load (i.e., chronic stress) which puts them at risk for mental health problems like depression (McEwen, 2003). Chronic stress can lead to feelings of isolation and helplessness, social withdrawal, and impaired immunity function. In addition to stress, residents also grapple with mental health stigma and poor work-life balance (Billings, Lazarus, Wenrich, Curtis, & Engelberg, 2011; Mata et al., 2016). These experiences can create negative frameworks of patients and medical practice and lead to future burnout.

Transition From Medical School to Medical Residency

The mental health of residents is partially understood when examining the experience of medical school and the transition to graduate medical education. Life transitions, such as those experienced by new medical students, are times of high stress. The impact of stressors is reduced when people have high levels of mastery, high self-esteem, and/or have social support (Thoits, 2010).

Medical school curricula vary. In most U.S. medical schools, the initial two years of school are taught in the classroom, a familiar setting for students who have recently completed four years of undergraduate education following twelve years of primary education. The structure of medical school is such that there is a high level of social support built into the first two years. All first year students take the same courses together. Synchronised schedules give students time off concurrently, creating an opportunity to socialize, celebrate, and commiserate together. The large medical school class is frequently divided into smaller work groups (e.g. a group of four that share a cadaver; groups of eight to twelve that meet for problem-based learning) that naturally form social networks. These social networks and social support help medical students cope with the increased stresses inherent in medical school.

Medical school is a time of high stress (MacLean, Booza, & Balon, 2016). The pace of medical school is much faster than anything students experienced during college. Prior to medical school most students are the best or brightest in their class. In medical school, these students are surrounded by others who have achieved as much as they have, and are in competition with other high achievers for grades if they desire the most coveted residency positions.

By the end of the second year of medical school, students are required to pass the first of three parts of the United States Medical Licensing Examination (USMLE). The USMLE is designed to assess a physician's ability to apply knowledge, concepts and principles to demonstrate fundamental patient-centered skills. The first step tests classroom knowledge. This test generates anxiety: If students do not pass, they are not promoted to the next year of medical school and may not graduate. If students pass but do not excel, they may not be considered for residency spots in highly competitive medical specialties (e.g. dermatology, ophthalmology, radiology).

During the initial two years of medical school, there is a gradual introduction to patient care. In some U.S. schools, students are first exposed to patients during a physical diagnosis course taught in the latter half of the second year of school. In other schools there is longitudinal exposure to patients beginning in the first year. This controlled exposure to patient care is used to prepare students for the final two years of medical school, the clinical clerkship years. During the third and fourth year of medical school (the clerkship years) students interact with patients in hospitals and in physicians' offices.

The clerkship years bring new stressors. Beginning in the third year of medical school, students are no longer in a single large cohort. Due to the limited ability to provide teaching/learning activities for all the students at once, students rotate through the different clinical disciplines at different times. Each students' peer support group grows much smaller as schedules are no longer synchronised.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The clerkship years are frequently the first-time students are exposed to death and dying (MacLean et al., 2016). There is usually not time to process these new experiences and there is typically no guide or structure to do so. Medical students may not know what to do with their feelings, and may be encouraged to ignore them or bury them, leading to increased stress.

During the preclinical years, students typically have learned that there is a 'right answer' or a 'wrong answer' to questions that are posed regarding medication choice, test ordering, and diagnosis. Once in the clerkship years, students see that there are multiple possible answers to every clinical question. This can be frightening to the learner and can lead to a feeling of lack of control (MacLean et al., 2016). It can be stressful to the learner who does not know if the reason there is no clear answer is because they are inadequate or if there truly is no answer.

Medical Residency Training

Changing roles from medical student to physician is a major life stressor. After spending 20 years as students receiving financial and other support from parents and others, the new resident physician may now be facing life issues for the first time (Coates, Spector, & Uijtdehaage, 2012). College students and medical students typically accrue debt. Once they are graduates, residents are now members of the adult work-force, many for the first time in their lives. While in school the burden of debt felt theoretical; now that loans have started to come due, the debt is real. Financial concerns are atop the list of stress producing situations for new residents (Coates et al., 2012).

For those residents who never held full-time employment prior to residency the reality of work is shocking. Resident hours are long and inflexible. Residents work on weekends, holidays, and special occasions (e.g. birthdays). Calling in sick is not an easy option. Lateness is not excused or overlooked.

The biggest stress for new residents is assuming responsibility for patients' lives. Medical schools give students the opportunity to observe and participate in patient care, but at no point are medical students solely responsible for patient care decisions. They may suggest a diagnostic test or medication, or list potential diagnoses, but ultimately the resident and attending physicians are responsible for making decisions. No medical student orders are taken off the chart unless cosigned in hospitals, and no prescriptions solely signed by a medical student can be filled at a pharmacy. From the first day of residency, residents are given the responsibility of responding to pages, writing patients' prescriptions, writing orders, and making clinical decisions. The realisation that every decision needs to be made and that each of these decisions have implications for patients' wellbeing can be harrowing to the new resident (Abuhusain, Chotirmall, Hamid, & O'Neill, 2009).

When medical students graduate medical school, they are no longer students; they are now 'doctors'. This title change alters perceptions. Faculty, peers, and even family members look at these newly minted physicians as professionals who have sworn an oath to put patients' needs above their own. From day one in residency, these doctors are responsible for their patients' care, and will be held to the same standards as physicians in practice for twenty years. Patients in the hospital and in the office do not distinguish between a resident starting her first day and a resident who has completed her training. Patients look at these new physicians as competent professionals, even if the resident does not feel competent. A new resident can feel like an imposter.

Residents in training are given progressive responsibility. From day one, residents are responsible for their own panel of patients. As they progress through residency training, the size of the resident's panel grows. Early in training residents are directly supervised. As they develop competence and confidence,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the residents are directly observed less frequently, and instead report to a preceptor during each patient encounter. During this report, the preceptor gives the resident feedback on presentation skills, thinking and organization, and patient care. Residents are asked to make assessments and plans which are reviewed by the preceptor. The resident-preceptor relationship is integral for developing confidence and competency.

Second year and third year residents have fewer required rotations and more elective rotations. As they progress through training they have increased responsibility in the inpatient and outpatient settings. In outpatient care, their patient panel grows dramatically at the conclusion of their first year. By the end of third year, residents see patients at a pace similar to community physicians. Residents are required to precept all patient encounters during their first year of residency. After successful completion of their first year in residency, residents are no longer required to universally precept, and subsequently have less time allotted into their schedule to see each patient.

In addition to office and hospital-based experiential learning, residents are taught in longitudinal seminar series. Humanism and professionalism are taught by example but also through readings and discussion. Practice management, likewise, is taught by example and through didactics. As residents grow in medical knowledge and develop a professional identity, they develop a sense of mastery which helps to mitigate residency distress. Residents are required to teach themselves, alongside faculty instruction, in order to obtain this competency.

Residency training challenges new physicians on a variety of personal and professional skills. Program directors identify a lack of medical knowledge as only one of the common struggles interns face. Lack of self-reflection and improvement, poor organisational skills, and underdeveloped professionalism were identified as deficits in a study of thirty residency program directors across ten specialties (Lyss-Lerman et al., 2009). These deficits are developmentally appropriate and expected for young residents and can lead to frustration and undue distress when not addressed by the resident and supporting faculty.

Residents are evaluated on each rotation (with both formative, mid-rotation evaluations and summative, end-of-rotation evaluations) and longitudinally. Evaluations allow faculty to measure the progress of residents and identify any deficits in patient care or professionalism. Knowledge is evaluated during rotations and by standardised exams administered annually. Physicians in practise are required to maintain certification once they have been specialty board certified. Residents are introduced to this process during residency and complete certification modules during each of their three years of training.

As residents progress through the training their patient care ability matures. They are treated more as colleagues when they are PGY-3 residents than they were when they were PGY-1 residents. By the time they are allowed to graduate, residents are ready to be independent practitioners.

Medical Residency and Mental Health

Mental health is the combined emotional, psychological, and social well-being of an individual and determines how that individual handles stress, relates to others, and makes choices. Burnout is a state of chronic stress that leads to physical and emotional exhaustion, cynicism and detachment, and feelings of ineffectiveness and lack of accomplishment. Burnout is more common among physicians than other US workers (Shanafelt et al., 2012). Over the past several years, physician burnout has increased with one estimate that more than half of US physicians are experiencing professional burnout (Shanafelt et al., 2015). Mental health support and treatment can help medical residents develop resiliency and alleviate the effects of stress from graduate medical education.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The purpose of graduate medical education (i.e., medical residency) is to cultivate competency, enthusiasm, and confidence within new medical school graduates and prepare these newly minted physicians for a rewarding and successful career in medicine. The process by which residents grow and develop is purposefully intense and, consequently, places residents at risk for experiencing poorer mental health. Compared to the general US population, medical residents are at greater risk for poorer mental health (Dyrbye et al., 2014). The importance of addressing resident mental health cannot be overstated. Untreated mental health can undermine residents' professional development, negatively affect patient care, and lead to mental illness and suicidal ideation (Dyrbye & Shanafelt, 2016).

It not entirely clear why residents are at risk for poorer mental health due to a lack of large, prospective studies. However, it seems that factors within the learning and work environment, rather than individual attributes, are the main drivers of mental health problems (Dyrbye & Shanafelt, 2016). Moreover, resident distress does not seem to be the result of poor medical knowledge and suboptimal clinical performance (Beckman, Reed, Shanafelt, & West, 2012). Rather, it seems that unmitigated burnout and distress lead to increased medical errors (Fahrenkopf et al., 2008; West, Tan, Habermann, Sloan, & Shanafelt, 2009), decreased empathy (West et al., 2006), and unprofessional conduct. One common result of burnout is depersonalisation which causes physicians to act callous or detached towards patients (Dyrbye et al., 2008; Shanafelt, Bradley, Wipf, & Back, 2002).

Risk and Protective Factors

There are several risk factors that can lead to poorer mental health outcomes for medical residents: prior history of mental illness, poor work-life balance, organisational stressors, and health care industry change. The first three apply to all US workers while the latter is unique to physicians. Whether due to family genetics, adverse childhood events, or ineffective coping strategies, residents with a history of depression, anxiety, trauma-related disorders, or serious mental illness (e.g., bipolar disorder, schizophrenia) are at greater risk for poorer mental health during residency training. Mental health stigma in the medical profession can discourage residents from recognising their own mental illness and seeking support and treatment. Some may minimize or veil their personal struggle with mental illness in order to be accepted into and complete residency training (Cooley-Wilder, 2016).

Work-life balance is the sense that one's work schedule allows time for personal and family activities. Dissatisfaction with this balance is a symptom of either an overburdening employer or a resident who does not schedule time for activities outside of work. Most residents are young adults with limited life experience and few if any robust coping strategies for stress. In addition, graduate medical education places residents in a variety of new health care systems with long hours and heavy responsibilities. When not directly taking care of patients, residents spend time completing medical charts, preparing for examinations, and other residency requirements. Residents with a poor work-life balance may not engage in physical activity, nutritious eating, good sleep hygiene, and social and community activities.

Organisational stressors include chronic high workload, lack of training and support, and unclear roles and responsibilities (Kapinos, Fitzgerald, Greer, & Rutks, 2012). The workload of a resident depends on the rotation and medical setting. For example, a resident on a hospital medicine rotation will work long shifts for several days in a row treating very sick patients. Meanwhile, a resident on an outpatient clinic rotation will work a shorter shift and have more time to rest. A high workload is normal in residency training and is offset by the change in responsibilities and stress. For example, the resident who completes a demanding rotation with long hours may then start a new rotation with a lighter load. This oscillation

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of schedules allows residents to recover and build stamina over time. Chronically high workloads do not allow residents to recover and lead to distress and burnout.

Residents need orientation training (e.g., didactics, shadowing, training modules) to learn electronic medical record systems, clinical policies and protocol, organisational hierarchies, academic requirements, building layouts, and more. Residents also need peer and faculty support to recover from stress, answer questions, and receive feedback. Residents who relocate from far away for residency training may especially need social support. A lack of training and support is a sign that a residency programme has few resources, is disorganised, or is not invested in resident mental health.

The third organisational stressor, unclear roles and responsibilities, is a direct consequence of the second stressor (WHO, 2003). Residents work in multiple health care systems with multiple providers during their training. When residents consider their role and responsibilities as unclear, they feel a lack of control with their environment and experience distress. For example, a resident who does not know which patients are under her responsibility and which attending physician to report to will experience distress. A resident who covers hospital admissions at night but does not know the protocol will experience distress as well. Most residents will quickly learn how to work in various systems but residents who are constantly confused about their place in a system will flounder.

Most of the risk factors listed thus far are not unique to residency training; most individuals are at risk for poorer mental health with mental illness, poor work-life balance, and little social and organisational support (World Health Organisation, 2012). A risk factor that is unique to residents is the constant change in the US health care industry. Residents are beginning a medical profession at a time of massive change and regulation in US health care including pressure from government, payers, and patients. Since the passing of the Affordable Care Act in 2010, physician burnout has increased by 10% compared to the US working population, even after controlling for other factors like number of hours worked, age, sex, and relationship status (Shanafelt et al., 2015). Some medical specialties report burnout rates of well over 50%. This is a concerning trend which may influence medical students to choose medical specialties that are less stressful but sorely needed.

In a large review of nearly 400 meta-analyses, researchers identified three major risk factors as genetic (e.g., multiple gene polymorphisms, gene networks), psychological (e.g., self-esteem, emotional intelligence, learning disabilities, mental health history), and physiological and health (e.g., physiological vulnerabilities and strengths, illness and disability, obstetrical and perinatal factors) (Furber, Leach, Guy, & Segal, 2016). These findings fit with a World Health Organisation report that states, in addition to individual characteristics, mental health is influenced by social circumstances and environment across the life span (World Health Organization, 2012). The worst outcome of resident mental illness is suicide. Residents are at greater risk for suicidal ideation than the general population (Sen et al., 2010). It is not clear how many residency programs screen for depression and suicide much less talk about it as well. Mental health treatment is effective and can help those residents struggling with feelings of hopelessness and helplessness. Residency programmes can even go further by investing in preventive services to help residents manage stress and avoid a journey toward burnout and possible mental illness.

Protective factors for residents include wellness activities that benefit virtually all human beings. Residents need social and organisational support to mitigate the effects of stress and orient themselves to new health care systems. Residents also benefit from a work-life balance that includes activities of self-care like physical activity, restful sleep, and healthy eating habits. Mindfulness training can specifically help residents alleviate the effects of burnout (Krasner et al., 2009).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

One of the most significant changes in 21st century graduate medical education is resident duty hour restrictions (DHR). Historically, residents would complete 30 hour shifts and then rest. In 2002 the Accreditation Council for Graduate Medical Education (ACGME) mandated that intern resident shifts be restricted to 16 hour shifts, and a maximum of 80 hours per week (Philibert, Friedmann, & Williams, 2002). In 2011, the ACGME revised the 2002 rules and added more extensive guidelines for resident supervision and patient handoffs. Since the inaugural restructuring, DHRs have remained a source of controversy and empirical inquiry. Despite the numerous publications on the subject, studies on the impact of DHRs suffer from limitations.

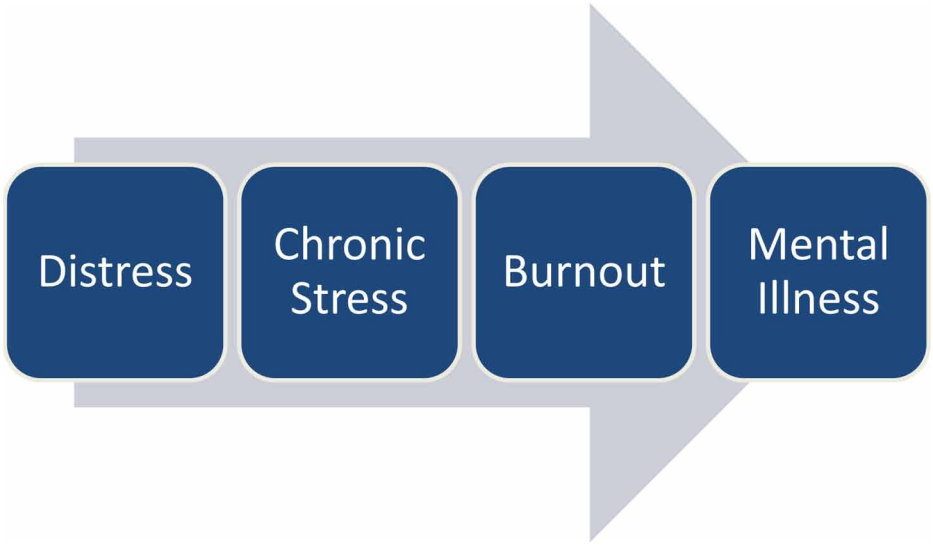
It is not clear if DHRs are good or bad for residents (Bolster & Rourke, 2015; Lin et al., 2016). Obviously, the field needs large, prospective studies of interventions over a long period of time to further distil trends. The current research suggests that DHRs have not delivered on their promise for significantly improving resident wellness. Some reforms like night float have the opposite intended result. This suggests that DHRs are not the main strategy for preventing poor mental health outcomes among residents. Indeed, some may intuit that residents need lighter workloads and shorter shifts when perhaps the most effective strategy is an organised programme of resident wellness and support in tandem with a demanding education experience.

The Spectre and Spectrum of Stress

Sound mental health does not equal the absence of stress. Stress is a natural phenomenon and provides the functional benefit of recognizing physical and psychological reactions to external stimuli. This operational view of stress is counterintuitive to many clinicians and to society as a whole who typically perceive stress as a 'killer' that requires elimination. It is impossible to eliminate stress and research shows that a negative perception of stress is harmful. In a large study of nearly 30,000 U.S. adults, 34% of survey respondents perceived that stress affected their health a lot or to some extent (Keller et al., 2012). This negative perception of stress increased the likelihood of worse medical and mental health outcomes. Those who reported high stress and believed stress affected their health a lot had a 43% increased risk of premature death.

There are two implications of this study on resident mental health. First, residents can benefit from a holistic perception of stress as signals that the body is energised and ready to meet a challenge. Residents who perceive stress as a sign of incompetence or failure do not understand the correct role of stress in their lives as well as the nature of residency training. Such residents may attempt to remove or diminish stress using avoidance behaviours (e.g., not collaborating with peers and attending physicians, not seeking feedback and instruction) or creating unrealistic expectations for themselves (e.g., 'I should not feel stress'). Stress is undoubtedly uncomfortable and when experienced at high levels and for long periods of time is detrimental (Schneiderman, Ironson, & Siegel, 2005). Research indicates that a stress-as-enhancing mindset moderates cortisol reactivity and induces a desire for performance feedback (Crum, Salovey, & Achor, 2013).

The second implication is that faculty can teach residents to recognise stress and respond in a healthy manner. Faculty can also set the example by effectively managing their own stress and creating a residency culture that allows safe discussions on stress and wellness. Residents are acutely observant of faculty behaviour and what is known as the 'hidden curriculum' which are unintended messages conveyed by faculty, staff, and senior residents (Billings et al., 2011). A hidden curriculum condones certain behaviours and results in creating a residency culture that may not be intended by the faculty. For example,



EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

faculty who disrespect others in front of residents passively excuse such behaviour. Faculty who have a poor work-life balance and complain about work convey unintended messages of poor stress identification and management.

Stress is not a spectre that residents and faculty should fear. Through education, residents can see stress as a vital alert system that connects them to the inherent wisdom of their bodies. This alert system developed over eons of times. From an evolutionary standpoint, the primitive ancestors of the human race who survived the jungles and savannahs of the past were the ones with an effective stress response that alerted them to dangers. Humans today carry that same alert system in relatively safe towns and cities of the modern era. In addition, the cardiovascular response to stress includes an increase in heart rate and blood vessel constriction which is similar to the physiological state of positive emotions like joy and courage. People who view their stress as helpful still experience increased heart rates but without the constriction of blood vessels which is a risk factor for cardiovascular problems. This stress-as-enhancing mindset does not always fit neatly with American ideals like rugged individualism. Through teaching and leading by example, residents can learn to see stress as an ancient ally and not a spectre.

One helpful tool for teaching residents is the spectrum of stress which includes distress, chronic stress, burnout, and mental illness (McEwen, 2003, 2004; see Figure 1). Each stage represents not only the accumulated level of stress but the response of the individual as well. The first stage, distress, is a common experience caused by a sense of real or implied threat that activates involuntary mechanisms (e.g., elevated heart and respiratory rates, increased alertness). The sympathetic nervous system becomes active and primes the body for attention and action by increasing the flow of oxygen to vital areas of the body like the brain.

Figure 1. Spectrum of Stress

Consider the following example: a resident is paged for a possible hospital admission and upon meeting the patient recognises several distressing personal medical symptoms. Her physiological response to the situation provides energy and focus for the task at hand. As she completes the admission, her

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

parasympathetic system returns her body to a state of rest until the next activation. If the resident feels inadequate to address the patient's health status and does not have peer or supervisory support, then the resident's distress level will increase in both time and intensity. Even this uncomfortable situation has a functional role in that the resident's body is alerting her to the lack of knowledge and support. The resident can actively address the medical knowledge deficit or develop a strategy for collaborating more effectively with peers and supervisors. If the resident does not address the knowledge deficit or avoids collaboration, then the distress can become a prolonged experience and increase the chance of repeating in the future (Gross & Levenson, 1997).

Residents can cope with distress when it comes in short episodes followed by periods of rest. This allows for physical and psychological resources to replenish. Chronic or prolonged states of arousal and alertness can lead to fatigue, burnout, and even mental illness, especially when the individual perceives the stress as bad. The accumulation of stress over time is usually gradual and can include small stresses that combine into a generalized or continuous feeling of distress. Accumulated stress, however, is not the sole cause for chronic stress. The resident's reaction to the daily stress is just as important, if not more so, as the amount of stress (Crum, Salovey, & Achor, 2013). For example, a resident who works in a low income, urban area with a very sick patient population and with few resources may experience daily distress with little alleviation. If the resident has strong social and organisational support and begins a new rotation in a less stressful setting, then he will likely return to a state of respite. If instead he worries about his ability to care for very sick patients, begins avoiding similar patients in the future, and does not disclose his feelings to peers and supervisors, he may begin to experience chronic distress over the issue. His avoidance reaction exacerbates and extends a normal stress experience (Gross & Levenson, 1997).

Chronic stress affects all systems in the body. When the body is stressed, muscles tense to protect the body from injury and pain. Long-term musculoskeletal tension can lead to other problems like headaches and physical pain. Prolonged periods of stress can contribute to cardiovascular problems possibly due to the inflammation of coronary arteries. Cholesterol levels can rise as people develop a sedentary lifestyle and unhealthy eating habits in response to stress. When stress hormones (e.g., cortisol, epinephrine) are released, the liver produces more glucose for energy. People with diabetes are at risk for complications when extra glucose is released due to stress. Chronic stress also affects the gastrointestinal system leading to stomach pain, diarrhoea, and constipation. All of these bodily changes contribute to an overall state of exhaustion as the nervous system is constantly aroused. Residents and faculty can attend to these physical symptoms and prevent chronic stress from developing into burnout and even mental illness (Drolet & Rodgers, 2010).

Burnout is a syndrome of emotional exhaustion, loss of meaning in work, feelings of ineffectiveness, and a tendency to view people as objects rather than as human beings (Maslach, Jackson, & Leiter, 1996). Burnout affects physicians and their families, impacts patient care, and contributes to physician turnover. One study estimates that over half of all US physicians are currently experiencing burnout (Shanafelt et al., 2015).

In regard to residents, one study of 47 Dutch residents found 31% met the criteria for burnout which was significantly associated with work-family conflict, work-related autonomy (amount of control over work activities), and work-engagement (level of vigour, dedication, and absorption at work) (Ringrose, Houterman, Koops, & Oei, 2009). A study of anaesthesiology residents found 41% met burnout criteria (de Oliveira et al., 2013). Risk factors for burnout included working over 70 hours a week, consuming more than five drinks with alcohol a week, and female gender. One large study of over 1,700 residents found a 60% burnout rate, higher than medical students and early career physicians (Dyrbye et al., 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

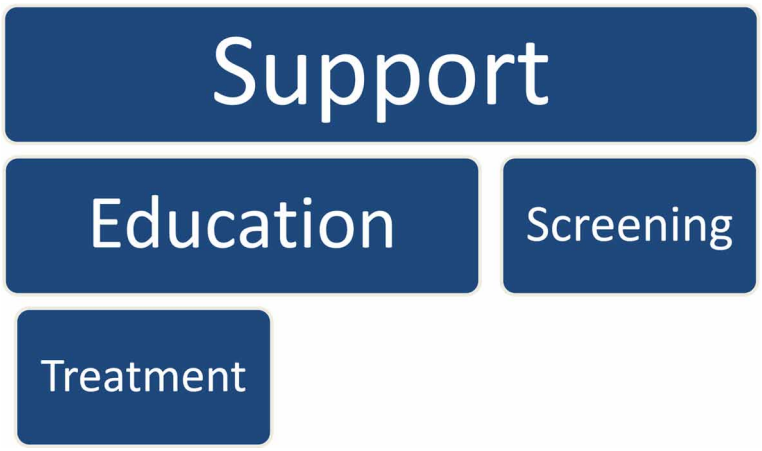
Residents were more likely to report high levels of depersonalisation (50%) than medical students (37%) and early career physicians (37%).

Burnout is the result of working with difficult patients or being exposed to patient suffering for extended periods of time without adequate opportunities for recuperation. Physicians can feel a sense of psychological numbness, a disconnection from others, and apathy to the suffering of others. This is similar to symptoms found in trauma-related disorders like post-traumatic stress disorder in which people survive highly stressful events and then experience a debilitation of adaptive abilities.

The most common measure for physician burnout is the Maslach Burnout Inventory (MBI; (Maslach et al., 1996). There are three domains within the MBI: emotional exhaustion, depersonalisation, and personal achievement. Emotional exhaustion includes items like 'I feel emotionally drained from my work' and 'I feel used up at the end of the workday'; depersonalisation includes items like 'I feel I have become more callous toward people'. One major limitation of the MBI is that it was normed for physicians and other US workers, not for residents who are under supervision and moving to and from various medical settings. This raises serious questions about the validity of the MBI in measuring resident burnout. Yet the vast majority of studies on resident burnout use the MBI (Dyrbye & Shanafelt, 2016). Futures studies should develop an inventory normed to the unique experience of graduate medical education.

Another limitation for any burnout inventory is that it does not focus on resilience which is the ability to adapt in the face of significant adversity, past or present. Burnout denotes pathology and deficits in positive adaptability and subtly minimises ways in which residents successfully cope with difficult tasks. Resilience is a resident's ability to struggle well during his or her training. It includes multiple individual and environmental factors that provide a protective benefit to the resident. Resilience incudes periods of accumulation and maintenance and does not necessarily mean that the resident accomplishes every single goal. Rather, resilience helps the resident to persevere even when temporarily failing. Resilience can be taught but must be practised. Resilience can help a resident to recover from burnout and avoid developing a mental health disorder.

Resident mental illness has received national attention in the past few years. In the first two months of the 2014-2015 academic year two medical interns in New York City died from two separate suicides. Soon thereafter, an intern from Yale School of Medicine wrote an op-ed in the *New York Times* about the effects of medical training on mental health (Sinha, 2014). Rates of depression can increase sevenfold for medical interns during the first three months of training while rates of suicidal ideation can increase by 370% (Sen et al., 2010). In one study of paediatric residents, 20% met criteria for depression and were six times more likely to commit medical errors (Fahrenkopf et al., 2008). It is not clear how many residents seek mental health treatment. In one study of 385 medical students, 34% who reported depression or anxiety sought mental health counselling (MacLean et al., 2016).



Whereas burnout is emotional exhaustion from working in a highly stressful environment, mental illness refers to specific diagnosable health conditions in which an individual's capacity to think, behave, and interact with others is affected. Mental illness is correlated with increased rates of morbidity and mortality (Walker, McGee, & Druss, 2015). There is no current literature on pathways between physician burnout and mental illness. Moreover, the genesis of mental health problems for any individual is multiple and varied.

Mental Health Programme for Medical Residents

The goal of a mental health programme for medical residents is to train residents in self-awareness and self-care and develop a culture of wellness and support. Programme directors and faculty play a vital role in ensuring residents are equipped for thriving during residency training. The authors offer a four-part template that residency programmes can use for tailoring their own distinctive programme (see Figure 2).

Figure 2. Mental Health Wellness Program

Support

The most significant mental health benefit a residency programme can offer is a culture of wellness and support which requires a concerted and intentional effort by all faculty, staff, and residents. Organisational support does not happen spontaneously. Residency leaders must diligently structure wellness activities and nurture key relationships between faculty and residents to generate any mental health benefits. The authors offer four ways to give organisational support.

First, nurture relationships between faculty members and residents. In a highly supportive residency culture, faculty advisors and supervisors take a genuine interest in the lives of their residents, including their experience in residency training and what happens outside of medicine. The same advisors are assigned to residents throughout their entire training and advocate for their wellbeing, including asking direct questions about mental health. Advisors and preceptors give direct, effective feedback and help residents clearly understand what they are doing well and what needs improvement. This feedback is both formative and summative and does not require a request from the resident. Continuous feedback instils confidence and trust between the faculty and the residents.

Second, identify and buffer stress points. Stress is a natural part of graduate medical education. In a highly supportive programme, faculty and staff identify time periods in which residents will experience high levels of stress (e.g., intern year, examinations, demanding rotations, life transitions) and design activities that alleviate the stress as much as possible. For example, a long period of orientation helps interns to fully understand the residency culture, their roles and responsibilities, and resources for sup-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

port. Orientation helps interns to quickly develop relationships with faculty and upper-level residents. In another example, faculty use weekly didactics during examination periods to prepare residents for upcoming exams (e.g., question banks, exam topics) which supplements the residents' personal study. Finally, faculty assist residents who are experiencing a life event or transition (e.g., marriage, loss of loved one, new-born) to create a rotation schedule that fits the resident's current needs. Programmes that anticipate and acknowledge stressful time periods will more effectively manage the unanticipated events (e.g., faculty departure).

Third, include resident leadership in designing and implementing a mental health programme. Supportive programs include residents in designing activities that promote wellness (e.g., residency retreat, lunch meetings, walking groups, and movie and dinner clubs). Residents feel part of the organisation and believe that their ideas matter. Supportive programmes ask chief residents to regularly report any concerns about residents and even consider assigning upper-level residents as peer-support to incoming interns to help with housing options, orientation, schedules, and more. Faculty request ongoing feedback from residents about the residency culture using online surveys, informal focus groups, and advisor meetings. Residents have the advantage of being newcomers to a residency culture and can provide a fresh perspective on strengths, weaknesses, opportunities, and threats.

Fourth, design formal and informal wellness activities. Supportive programme design formal activities like residency retreats, lunch meetings, and didactics that are fun, engaging, and informative. The benefit of formal activities is that they can be scheduled during normal residency hours which protects the time residents have for themselves. Informal activities can include dinner groups at the home of a faculty member or resident, movie clubs, coffee meetings, and volunteer service projects. Some residents will form social groups and events on their own while other, more reserved residents will benefit from faculty-supported activities.

Volunteer service helps residents to become involved in the community, meet new people, develop empathy for vulnerable populations, and reflect on their own personal and professional values. Service has a stress-buffering effect on health, especially for residents who value the service (Poulin, 2014). Supportive programmes create opportunities outside of residency requirements for residents to serve in the community (e.g., homeless shelter, soup kitchen, school tutoring, sports events, natural disaster relief, free medical clinics, and health fairs). Faculty members lead by example in serving the community and invite residents but do not require they join them.

Education

The second most important mental health benefit a residency program can offer is to educate residents about the spectrum of stress and the importance of self-care. It is ideal that a mental health professional (e.g., psychiatrist, psychologist, or counsellor) use curricular time (e.g., grand rounds, didactic conferences, or small meetings) to discuss signs and symptoms of stress as well as the pathway from distress to burnout to mental illness. Residents learn how unmitigated stress affects themselves and their patients and different types of effective coping strategies. The instructor normalises the experience of stress and explains the functional role it plays in alerting and energizing the body and mind. The instructor also explains that stress by itself is usually not the problem; instead, the reaction to stress is what determines a successful outcome. For example, a resident who seeks collaboration and support during a difficult rotation will cope better than a resident who avoids peer and faculty interaction and who believes that

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

they are incompetent. Residents learn to accept stress as part of their training and identify personal ways to become 'psychologically flexible' in the face of ongoing challenges.

One effective tool for teaching residents how to monitor stress levels and increase self-care is mindfulness which is the ability to focus on the present moment with purpose. One study of 70 physicians who participated in an eight-week intensive program of mindfulness training found improvements in well-being and attitudes associated with patient-centred care (Krasner, Epstein, Beckman, et al., 2009). Mindfulness allows residents to slow down, focus on their breathing and emotional state, and see themselves from a different perspective. For most of residency, a resident is either thinking about the patient she just treated or preparing herself mentally for the next one. The resident lives in the cognitive past and future of her mind on a daily basis. Mindfulness gives the resident permission to step out of the past-future dichotomy, create cognitive space for a moment, and connect with her present physical and emotional state.

Mindfulness also allows residents to develop important skills for monitoring stress. As a resident practices mindfulness on a daily basis, he becomes more in tune with physical and emotional signals of stress which empowers him to respond in healthy ways. Programmes can include mindfulness training as part of resident retreats or didactic conferences. Faculty can lead residents in mindfulness exercises at the beginning or end of a meeting or lecture. More simply, residents can incorporate deliberate moments of quiet reflection into their daily schedule (e.g., turning off the radio or phone while driving to work, spending five minutes in contemplation before leaving work at the end of the day).

Supportive programmes also teach residents how to recognise burnout and mental illness and what resources are available for support and treatment. Residents learn that burnout is a syndrome of emotional exhaustion and can lead to psychological numbness, loss of empathy, and a lack of connection with others. They learn that mental health treatment is effective and private and should not have any repercussions on job security, medical licensure, malpractice insurance, and disability coverage. Residents also learn how to access local-based treatment options and hotline-based mental health resources.

Screening

Mental health and physician wellness screening helps identify those residents at risk for mental health problems. Supportive programmes include a psychiatric and substance use history during required annual occupational health history and physical examinations. Programmes also use validated scales (e.g., Patient Health Questionnaire-9, Alcohol Use Disorders Identification Test, and Drug Abuse Screening Test) within the first three months of residency training, a vulnerable time period for new residents (Sen, Kranzler, Krystal, et al, 2010). Programmes assure residents that screening is confidential, not part of a formal evaluation process, and reviewed by a mental health professional who only discusses results with the resident and the programme director. Programmes encourage wide-spread participation by allowing residents time to complete the screening, using web-based programmes which deliver efficient data collection and analysis. Residents receive feedback about the screening from the web-based programme or a mental health professional who follows up in person. The resident understands the results of the screening and, if appropriate, receives a referral for treatment.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Treatment

The final part of the mental health programme is to make mental health treatment access on par with other medical conditions which includes providing a list of trusted professionals in the community who understand graduate medical education and are connected with residency faculty and staff. Residents also have access to confidential settings where they can discuss the challenges and successes of their training in a group or individual format. Some residents prefer a group format which fosters social connection and support. Groups are led by an experienced mental health professional and offered on a regular basis. Supportive programmes develop protocol for team debriefing when a seminal event occurs (e.g., resident leaves programme, patient's death, medical code situation, or a serious medical error). Team debriefing protects time for a resident to express his concerns and feelings, process his experience aloud while peers listen, and receive support and advice. They occur soon after the event and include an experienced faculty member who provides perspective and wisdom.

SOLUTIONS AND RECOMMENDATIONS

Residency programme directors need strategies for identifying and addressing mental health problems. Most residents will not experience depression or suicidal ideation during residency training. However, many will experience chronic stress which affects interprofessional relationships, patient care, and overall quality of life. The authors recommend that programmes adapt a comprehensive strategy that addresses at least these four domains: education, screening, treatment, and support. First, residents can learn the continuum of distress, from burnout to depression to suicide, ways to self-identity, and strategies for increasing resiliency and wellness. Second, programmes can require annual occupational health history and physical examination to screen for potential distress and depression. Staff should provide timely feedback on screening results including treatment options. Third, residents should have access to mental health treatment including counselling and psychiatric care. Faculty can also address any concerns about the potential repercussions of receiving mental health care on job security, state licensure, malpractice insurance, and disability coverage. Finally, residents can attend group support meeting especially during the first year to discuss the challenges of their experience in a confidential setting. Residents can also meet for team debriefings following the conclusion of a seminal event like a patient's death, a code situation, or a serious medical error.

CONCLUSION

Residency training is a time to prepare young physicians for a rewarding and fruitful career. Although residents will undoubtedly experience stress and be at-risk for mental health problems, programme directors and faculty can create an environment that mitigates the expected strain and pressure of training. The authors recommend that residency mental health programs include support, education, screening, and treatment as four pillars of prevention. If faculty do not have a programme in place, it is suggested that they partner with mental health professionals in the area who can consult with them in building a robust and systematic approach to strengthening residency resiliency and preventing physician burnout.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Residents will experience stress during residency training. Although it is unclear which interventions are best for supporting resident mental health, residency programmes can go a long way in preventing normal stress from turning into psychopathology.

KEY TERMS AND DEFINITIONS

Burnout: A syndrome of emotional exhaustion, loss of meaning in work, feelings of ineffectiveness, and a tendency to view people as objects rather than as human beings.

Chronic Stress: Prolonged states of arousal and alertness in response to stress.

Distress: A sense of real or implied threat that activates involuntary mechanisms.

Graduate Medical Education: Any type of formal medical education pursued after completion of medical school.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Intern: First-year medical resident.

Medical Resident: A physician in graduate medical education who practices medicine under the supervision of an attending physician.

Mental Health: A person's condition with regard to their psychological and emotional well-being.

Mental Illness: A wide range of mental health conditions that adversely affect moods, cognitions, and behaviours.

Chapter 63
Occupational Risk Factors and the Mental Health of Women Firefighters

Brittany Sara Hollerbach
National Development and Research Institutes, Inc., USA

ABSTRACT

Firefighting is an inherently dangerous occupation, yet little is known about the mental health of firefighters, and even less is known about women firefighters specifically. The purpose of this chapter is to examine relevant literature pertaining to firefighters and mental health with a specific focus on behavioral health aspects that may impact the mental health of women firefighters. There are key issues women in the fire service face that are likely related to their mental health including bullying and harassment, substance use, job satisfaction, fitness, protective gear, and injury. By identifying issues related to the mental health of women firefighters, the authors provide direction for future research and guidance for policy guidelines for the fire service.

INTRODUCTION

Firefighting is an inherently dangerous occupation, yet little is known about the mental health of firefighters, and even less is known about female firefighters. The objective of this chapter is to examine relevant literature pertaining to firefighters and mental health with a specific focus on behavioral health issues that may impact the mental health of women firefighters.

BACKGROUND

Firefighting is a dangerous and highly stressful occupation with high rates of injuries and line of duty deaths (Fahy, LeBlanc, & Molis, 2018; Evarts & Molis, 2018; Poplin, Harris, Pollack, Peate, & Burgess, 2011). The National Fire Protection Association (NFPA) estimated 58,835 firefighter injuries and 60

firefighter fatalities occurred in the line of duty in 2017 (Evarts & Molis, 2018). Additionally, there were 7,345 documented exposures to infectious diseases and 44,530 exposures to hazardous conditions (Evarts & Molis, 2018). Despite public perception of the sexy, muscular firefighter, firefighters also struggle with poor physical health (Jahnke, Poston, Haddock, & Jitnarin, 2013; Soteriades et al., 2005), high rates of being overweight and obesity (Soteriades et al., 2005; Kales, Polyhronopoulos, Aldrich, Leitao, & Christiani, 1999; Poston et al., 2011) and low fitness levels (Poston et al., 2011; Tsismenakis et al., 2009). On average, firefighters experience significant weight gain over the course of their career, and may put on 29-85 additional pounds (i.e., 1.15-3.4 lbs/year) (Tsismenakis et al., 2009). As a firefighter's weight increases, their cardiorespiratory fitness plummets and their risk of cardiovascular disease (CVD) increases (Durand et al., 2011). Other diseases related to being overweight and obesity include heart disease, stroke, type 2 diabetes, and certain types of cancers which are highly prevalent among the firefighter population (Poston et al., 2011; CDC, 2015). In 2017, 29 firefighters died while on duty due to cardiovascular events (Fahy et al., 2018). While there is a wealth of research that examines firefighters' physical health, there is limited data concerning the psychological health of these important tactical athletes.

Recent studies demonstrate that first responders suffer from elevated rates of depression, post-traumatic stress disorder (PTSD; Heyman, Dill, & Douglas, 2018). According to the Firefighter Behavioral Health Alliance (FBHA), 79 firefighters and 19 emergency medical technicians (EMTs) and paramedics died as the result of suicide in 2018 which is a rate higher than on-duty deaths (Firefighter Behavioral Health Alliance, 2018). Large metro departments have seen a spike in clustered firefighter suicides in recent years (Gist, Taylor, & Raak, 2011). With a rise in behavioral health issues amongst firefighters, the fire service is trying to address these issues through national standards, behavioral health programs, peer support, and research focused on these issues. Yet, often, academic research in the field of firefighter health and safety is not translated into fire service training nor reflected in policies and procedures. Although NFPA 1500: Standard on Fire Department Occupational Safety and Health Programs requires access to a behavioral health program that proposes assessment, counseling and treatment for such issues as stress, anxiety, and depression (National Fire Protection Association, 2018), many departments lack the resources to adequately implement such programs. Additionally, little is known about the physical or mental health impacts of firefighting for women (Jahnke et al., 2012; Stanley, Hom, Spencer-Thomas, & Joiner, 2017).

Women represent an incredibly small proportion of the fire service, even lower than the U.S. Marine Corps, where all members are expected to be combat ready (Women in Military Service for America Memorial Foundation, Inc. 2010). Despite representing a small percentage, over 85,100 women are on the front lines protecting communities across the U.S. (Haynes & Stein, 2017). According to the NFPA, women represent approximately 8.9% of volunteer and 3.7% of career firefighters (Haynes & Stein, 2017). Due to the fact that women represent a small percentage of the fire service, they often are overlooked in studies and excluded from statistical analysis due to their small sample size (Jahnke et al., 2012; Hollerbach et al., 2017). While all firefighters face environmental and occupational stressors, women in the fire service face additional barriers adversely affecting their health and wellness. The goal of this chapter is to explore what is known regarding the mental health of women in the fire service and to identify important gaps in that knowledge. Guidance for changing policies and procedures to better protect and diversify the fire service as a whole also will be addressed.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

MAIN FOCUS OF THE CHAPTER

Recruitment and Retention

According to iWomen, the largest organization of women firefighters in the U.S., the low proportion of women in the fire service results from a combination of limited recruitment and low retention rates (Hulett, Bendick, Thomas, & Moccio, 2008; Horvath, 2013). Despite statements from national fire service organizations, including the International Association of Firefighters (IAFF; Fox, Hornick, & Hardin, 2006) and the International Association of Fire Chiefs (IAFC, 2018), promoting gender diversity within the fire service, rates of women firefighters remain extremely low (Jahnke et al., 2012; Haynes & Stein, 2017). There are many possible explanations for such low numbers of women in the fire service, including the psychological and physical strains of firefighting. Additionally, the culture of the fire service has been traditionally unaccepting of women (Hollerbach et al., 2017; Hulett et al., 2008; Horvath, 2013).

The Person-Environment Fit (PE-FIT) Model suggests that as the burdens and demands of one's occupation begin to exceed the ability of an employee to deal with them, this "lack of fit" contributes to overload, burden, role ambiguity, and conflicting role demands (Quick & Tetrick, 2003, p. 187). The resulting physical and psychological stress can lead to adverse behavioral consequences such as reduced productivity, increased absenteeism, turnover, employee burnout, and health-related issues (Quick & Tetrick, 2003). Research has found that women often are often given 'feminized' job tasks that restrict and challenge their success in non-traditional occupations. The same employment practices that favor men effectively lessen women's opportunities for promotion and lowers their chances of being seen as authoritative in their role (Reskin & Bielby, 2005). There is still a certain air of masculinity associated with the fire service, limiting the entry of women into the occupation (Perrott, 2016).

The collective intelligence of a diverse organization allows for differing points of view and strengths in working together to achieve the department's mission. Just as a government and its elected officials and leadership should reflect the demographics of the community they serve, so too should government agencies, such as the fire service, be representative of the citizens they protect (McNeil, 2008). Further diversifying the fire service begins with an examination of mental health issues affecting women, a growing minority group within the fire service.

Bullying and Harassment

The effects of workplace harassment on mental health are well-defined in the literature (Kessler, Mickelson, & Williams, 1999; Todorova, Falcon, Lincoln, & Price, 2010). Rosell et al. (1995) analyzed the difference in behavioral health outcomes of women firefighters that reported being sexually harassed and those that did not. They found that sexually harassed women firefighters reported higher job stress, sexual stereotyping, and acts of violence. Participants feared coming to work and used more sick leave than their non-harassed peers (Rosell, Miller, & Barber, 1995). Research has found more than 80% of women firefighters reported experiencing differential treatment based on gender, although only a small proportion of men felt that way (14%; Hulett et al., 2008; Griffith, Roberts, & Wakeham, 2016). This differential treatment included high levels of shunning/isolation (50.8%), verbal harassment (42.9%), sexual advances (30.2%), and assault (6.3%; Hulett et al., 2008).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Over 40% of women firefighters in current research reported that they frequently felt they had to work twice as hard to get the same treatment or evaluation and that they were watched more closely than other workers (Jahnke et al., under review). Of the specific types of gender-based harassment, women firefighters reported experiencing verbal (37.5%) and written harassment (12.9%), hazing (16.9%), sexual advances (37.4%), and assaults (5.1%) because of their gender while in the fire service (Jahnke et al., under review).

Research consistently finds an association between discrimination and harassment and a variety of mental (e.g., anxiety, depression, PTSD, self-rated health) and physical health outcomes (e.g., blood pressure, cardiovascular disease, diabetes, overall stress response, and a number of other medical conditions; Hulett et al., 2008; Kessler et al., 1999; Todorova et al., 2010; Rosell et al., 1995; Hom, Stanley, Spencer-Thomas, & Joiner, 2017; Krieger, 1999; Okechukqu, Souza, Davis, & de Castro, 2014; Pascoe & Smart Richman, 2009; Williams, Neighbors, & Jackson, 2003). Current research indicated that female firefighters who experienced a high severity of bullying and harassment were 300% more likely to report significant depressive symptoms (Jahnke et al., under review). Women firefighters who experienced moderate and severe discrimination and harassment also had negative mental health outcomes including higher prevalence of depressive symptoms, anxiety, and symptoms of PTSD. Additionally, women who experienced severe discrimination and harassment reported over 40% more poor health days in the last 30 days (Jahnke et al., under review). Hom and et al. (2017) found that a history of sexual harassment, discrimination, and other threats/harassment were significantly associated with a history of career suicidal ideation, in addition to other severe psychiatric symptoms including heightened anxiety, depression, more severe PTSD, and insomnia. Discrimination and harassment have significant impacts on physical and mental health outcomes on women in the fire service. Prevention efforts, training, and peer-support programs focused on this issue should be further explored.

Depression and Anxiety

Although firefighters are incredibly resilient, research suggests that many suffer negative psychological consequences from their experiences in the fire service. Studies have found high rates of acute stress disorder (26.5%) and elevated rates of those currently in the range of concern for depression (10.8-16.4%) among men in the fire service (Carey, Al-Zaiti, Dean, Sessanna, & Finnell, 2011; Fullerton, Ursano, & Wang, 2004). This is extreme when compared to the national average for civilians; in 2016, only 6.7% of all U.S. adults had at least one major depressive episode (National Institutes of Mental Health, 2019). Additionally, studies have found that firefighters in the depressed range reported significantly more poor mental health days than those not in the depressed range (Pyle et al., 2009). Depressed firefighters are more likely to be sleep deprived and to display hazardous drinking behaviors as well (Carey et al., 2011). While only about 4% of respondents reported low levels of social bonding among firefighters, those with poor mental wellbeing were more likely to report poor social bonding (Carey et al., 2011) which is an important mechanism for firefighter coping.

Firefighters often experience increased stress due to repeated exposures to trauma and they seem to know their jobs put them at risk. A study by Jahnke et al. (2012) found that firefighters across the country actually expressed a belief that their career would shorten their lives. Firefighters are plagued by psychological stress resulting from repeated exposure to trauma, sleep disruptions, injuries, and the risk for infectious disease (Jahnke et al., 2012). There is an emotional toll from repeated exposure to trauma that can lead to adverse mental health consequences (Jahnke et al., 2012). However, firefighters

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

have consistently reported that talking with other firefighters was the most useful way of managing the emotional toll of their experiences, highlighting the importance of a supportive organization and access to peer support.

Jahnke et al. (2012) examined the health of women firefighters and found that, similar to their male colleagues, nearly a quarter of female firefighters were at risk for depression. Approximately 30% reported feeling nervous and stressed fairly or very often and 22% reported feeling angered because things were often outside of their control (Jahnke et al., 2012). To make matters worse, female firefighters with a history of discrimination or harassment on the job had significantly higher levels of anxiety and depression (Hom et al., 2017). Overall, female firefighters tend to have similar prevalence of mental health issues when compared to male firefighters. The problem arises when they are subject to adverse and pervasive differential treatment which has been shown to impact their health.

Posttraumatic Stress Disorder

Firefighters respond to incredibly dangerous and traumatic emergency incidents putting them at heightened risk of Posttraumatic Stress Disorder (PTSD). Depression and PTSD symptomatology (i.e., 'posttraumatic stress') often occur together (Martin et al., 2017) and, considering the high rates of depression found among firefighters, they are undoubtedly at risk for PTSD as well. Recent studies have, in fact, found between 14.0-31.8% of firefighters suffer from PTSD (Martin et al., 2017; Boffa et al., 2017; del Ben, Scotti, Chen, & Fortson, 2006) compared to only about 7-8% of the general population (US Department of Veterans Affairs, 2018). In addition, Boffa et al. (2017) found that 15.6% of firefighters in their study reported at least one suicide attempt during their firefighting career. PTSD has been shown to amplify the risk of suicide among firefighters (Boffa et al., 2017).

In addition to being linked to increased suicide risk, PTSD significantly impacts quality of life (QOL) and greater sleep disturbance (Chen et al., 2007). Jahnke et al. (2016) examined experiences of repeated exposure to trauma (RET) in a national sample of firefighters and found that RET resulted in a number of negative outcomes for firefighters including desensitization, irritability and cynicism, and intrusive flashbacks (Jahnke, Poston, Haddock, & Murphy, 2016). While some firefighters had a specific incident that they identified as negatively affecting them, most discussed the impact of repeatedly being exposed to traumatic events and the psychological toll that resulted from such experiences (Jahnke et al., 2016).

While research has examined PTSD among firefighters, published PTSD prevalence rates are not currently available for female firefighters. However, there have been numerous studies that show that differential treatment such as bullying, harassment, sexual assault, and other threats increase rates and severity of PTSD among women firefighters (Jahnke et al., under review; Hom et al., 2017). It is extremely important that more research be conducted to identify the prevalence of PTSD among firefighters, especially women. Additionally, interventions and treatment options should be explored to help firefighters manage PTSD symptoms.

Suicide

Elevated rates of depression and PTSD symptoms may be associated with increased suicide risk among firefighters (Stanley et al., 2019). Firefighters report high rates of suicidal ideation, plans, and attempts (46.8%, 19.2%, and 15.5%, respectively) when compared to both general (5.6–14.3%, 3.9%, and 1.9–8.7%, respectively) and military (3.8–13.9%, 5.3%, and 0.4–2.4%, respectively) populations (Nock et al., 2008;

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nock et al., 2014; Stanley, Horn, Hagan, & Joiner, 2015). The Firefighter Behavioral Health Alliance (FBHA) reported 98 firefighters died by suicide in 2017 (Firefighter Behavioral Health Alliance, 2019), which is more than the 86 total line of duty deaths that occurred in the fire service that year (US Fire Administration, 2019). The number of emergency responders who lose their lives to suicide may be even higher as the FBHA suggests that only approximately 40% of firefighter suicides are reported as such. Large metro departments have seen a spike in clustered firefighter suicides in recent years (Gist et al., 2011). Boffa et al. (2017) found 15.6% of the firefighters in their study reported at least one suicide attempt during their firefighting career.

So, what do we know about suicide and women firefighters? A recent CDC report on suicide rates by occupational group revealed that, among women workers, the highest rate of death by suicide was among protective service workers—a group that includes firefighters (Stanley et al., 2017; McIntosh, 2016). In 2017, Stanley et al. (2017) examined 313 women firefighters and found they reported elevated rates of suicidal thoughts and behaviors. For example, percentages of women firefighters reporting suicidal ideation, plans, and attempts were 37.7%, 10.9%, 3.5%, respectively (Stanley et al., 2017). While these rates may be higher than the general population, they appear lower than rates for men firefighters seen in the current literature. Further research is necessary to understand suicide risk among women firefighters. Further, research should explore firefighters' access to employee assistance including behavioral health programs tailored specifically to the fire service.

Substance Use

Substance use is common among first responders and includes problematic use of alcohol, tobacco, and prescription drug use, though little is known regarding the latter. According to the Dietary Guidelines for Americans 2015-2020 and the U.S. Department of Health and Human Services, moderate alcohol consumption is defined as up to one drink per day for women and up to two drinks per day for men. The National Institute on Alcohol Abuse and Alcoholism (NIAAA) defines "binge drinking" as a pattern of drinking that brings blood alcohol concentration (BAC) levels to 0.08 g/dL. This typically occurs after four drinks for women and five drinks for men, over a time span of two hours. Heavy alcohol use is defined as binge drinking on five or more days in the past month (National Institutes of Health, 2019). In similar populations (e.g. military), heavy drinking patterns can be as high as 67% among men and 9% among women, with binge drinking patterns occurring in 48% of men and 31% of women, higher than the general population (Fear et al., 2007).

Research has shown that firefighters "believed alcohol played an important role in the fire service, that high consumption was common, and the social norms supported alcohol consumption" (Jahnke, Poston, & Haddock, 2014). In a large study of male firefighters, Haddock et al. (2015) found that 85% of firefighters reported drinking alcohol, nearly half reported excessive drinking, and approximately one third reported binge drinking when off duty.

As with male firefighters, heavy and problem drinking are prevalent among women firefighters and are associated with negative occupational outcomes (Haddock, Poston, Jahnke, & Jitnarin, 2017). Haddock et al. (2017) examined over 1,000 women firefighters and found that more than 60% of the women in their study averaged two or more drinks (moderate to heavy drinking) on days when they consumed alcohol. Chief officers were more likely to consume two drinks per day compared to firefighters; otherwise, rank did not predict average consumption or binge drinking (Haddock et al., 2017). Problem drinking also was associated with negative health outcomes. For example, problem drinkers were more than 2.5

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

times more likely to have been diagnosed with depression or PTSD. Problem drinkers were nearly 40% more likely to have sustained an injury on the job in the past year and were less likely to recommend a career in the fire service to other women (Haddock et al., 2017). Recent research found that women experiencing moderate to high levels of workplace discrimination were also significantly more likely to be in the range of concern for alcohol misuse (Jahnke et al., under review).

Among 947 male firefighters, 21% were tobacco users. Of those who smoked, 34.5% used cigarettes, over half (53.2%) used smokeless tobacco (SLT), and 12.2% used both cigarettes and SLT (Jitnarin, Poston, Haddock, Jahnke, & Day, 2015). Tobacco users were significantly younger, had served fewer years in the fire service, were significantly more likely to engage in heavy and binge drinking, and were more likely to show signs of depressive symptoms compared to non-tobacco users (Jitnarin et al., 2015). Tobacco use rates were generally higher among women firefighters than their male colleagues and rates among women firefighters were similar to the rates of women in the military (Jahnke et al., 2012). Resources for substance use/misuse specific to firefighters should be identified and examined for validity in this population.

Job Satisfaction

Job satisfaction is an indicator of overall wellbeing and is related to individual health outcomes (Antecol & Cobb-Clark, 2006). Reported levels of job satisfaction are, however, difficult to accurately assess and may differ among different groups. For example, women and African Americans in the general population tend to report higher levels of job satisfaction even though on many objective measures their jobs are worse, which could stem from these groups having lower expectations (Antecol & Cobb-Clark, 2006; Bartel, 1981, & Clark, 1997). Most studies report that men firefighters have a high level of job satisfaction (Traut, Larsen, & Feimer, 2000; Wagner & O'Neill, 2012). Despite the barriers and differential treatment some women in the fire service face, those who stay in the profession tend to report higher levels of job satisfaction. In fact, 78% of the female firefighters in recent research reported they are satisfied with their job in the fire department (Jahnke et al., under review).

There are benefits of a collective and supportive fire service culture. The concept of "brotherhood" is deeply rooted in the American fire service (Crosby, 2007). The social bonds and connections among firefighters and within the firehouse are important factors in attenuating adverse mental health outcomes (Carey et al., 2011). It is important to feel a sense of belonging as a part of a group, as well as feeling supported by others. However, the adverse treatment many women in the fire service face can impact their job satisfaction, which research has shown impacts their health and their ability to do their jobs (Jahnke et al., under review).

Fitness

According to the Centers for Disease Control and Prevention (CDC; 2018), physical activity (PA) can be one of the best ways to improve both physical and mental health. However, male firefighters struggle with poor health and low levels of fitness. Overweight and obesity are highly prevalent, and in some cases >80% (Poston et al., 2011; Tsismenakis et al., 2009; Soteriades et al., 2008). Cardiac-related events consistently account for the majority of firefighter fatalities. In 2017, 29 line of duty deaths were related to sudden cardiac events (Fahy et al., 2018).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Female firefighters, on the other hand, seem to maintain a high level of fitness throughout their careers. For example, Jahnke et al. (2012) found that compared to male firefighters, women had more favorable body composition among both career and volunteers. Based on body mass index (BMI), the majority (66.7%) of female firefighters were classified in the normal weight category (range, 18.5–24.9 kg/m2), while only 16.7% were overweight and 16.7% were obese (Jahnke et al., 2012). Kirlin et al. (2017) found that, on average, female firefighters of all age groups met or exceeded the 12-MET professional standard for cardiorespiratory endurance; however, cardiovascular fitness declined with age (Kirlin, Nichols, Rusk, Parker, & Rauh, 2017; NFPA 1582; International Association of Firefighters, 2008). Current research found that 78% of female firefighters were regular exercisers according to the Self-Report Physical Activity Questionnaire (SRPA; Jahnke et al., under review). PA improves mental health and prevents weight gain (CDC, 2018). Fitness may be a key to improving the overall mental and physical health of firefighters. Research should examine women-specific fitness training for its efficacy in the fire service.

Gear

Most firefighters probably do not give the fit of their personal protective equipment (PPE) a second thought, but women often report ill-fitting PPE hinders their ability to do their job safely and effectively. According to iWomen in 2008, nearly 80% of the female firefighters surveyed reported ill-fitting protective gear. In addition, 14% reported ill-fitting self-contained breathing apparatus (SCBA) face pieces, a critical line of defense in a fire (Hulett et al., 2008). Nearly a decade later, a majority of the participants in a recent study still noted ill-fitting gear as a major threat to safety (Hollerbach et al., 2017). Women reported that bunker gear in their respective departments was made for men and they often had difficulty getting a good seal with an SCBA facepiece (Hollerbach et al., 2017). One participant said her department had to go through a lawsuit before they offered female-specific PPE (Hollerbach et al., 2017). Additionally, a number of chronic injuries may be due to inappropriately fitting gear. Feeling out of place or not having the necessary resources to do one's job has physical and psychological consequences such as lower productivity, absenteeism, turnover, burnout, and health-related issues (Quick & Tetrick, 2003). How can women be expected to survive in the fire service if they can't even get properly fitting PPE?

Injury

For years, the majority of fire service research has focused on male firefighters. The NFPA released its first report specific to the patterns of injury among women firefighters in 2017 (Campbell, 2017); however, unlike the NFPA annual injury report, this women-specific report only examined injuries that occurred on the fireground and likely underestimates the prevalence of injury among women firefighters. Despite its limitations, the report found that women firefighters experience similar injury causes (the majority overexertion/strain) on the fireground as their male counterparts (Evarts & Molis, 2018; Campbell, 2017). The NFPA report on women examined a five-year period and estimates that women firefighters sustained an average of 1260 injuries each year in the five-year period (from 2010-2014; Campbell, 2017).

Though they may experience the same types of injury, Liao et al. (2001) found that women firefighters experienced injuries more frequently than their male peers, with women firefighters reporting 33% more injuries than men. This relationship persisted even after controlling for factors such as age, race, tenure,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

personality, and secular trends (Liao, Arvey, Butler, & Nutting, 2001). Current research has shown that women often note a need to "prove" themselves in the firehouse and on the fireground, leading to taking on more than they are physically able or not asking for help, which puts them at increased risk of injury (Hollerbach et al., 2017). Further research should examine the types of injuries women firefighters sustain and policies and training programs should be explored to lessen the burden of injury in the fire service.

Reproductive Health

Limited research has examined reproductive health outcomes among firefighters. There is some data from the 1980's and '90s (Evanoff & Rosenstock, 1986) that reviewed the potential risks women firefighters face, but in general this area remains relatively unexplored. Reproductive risks for women include fireground and other hazardous response exposures (McDiarmid, Lees, Agnew, Midzenski, & Duffy, 1991), as well as the impact of shift work and sleep disturbances, high ambient temperatures, loud noises, and the physical and psychological strain of firefighting (Agnew, McDiarmid, Lees, & Duffy, 1991; Amani & Gill, 2013; Mahoney, 2010; Nurminen, 1998; Puttonen, Harma, & Hublin, 2010).

A recent study found an increased risk of male-factor infertility (46%) among Danish firefighters (Petersen, Hansen, Ebbehoej, & Bonde, 2018). It appears that the number of years serving as a firefighter attenuates the relationship with infertility, with those serving as a firefighter longer having a higher risk for infertility (Petersen et al., 2018). Firefighting hazards associated with increased risk of infertility include hyperthermia, loud noise, chemical and biological exposures, emotional trauma, and stress (Petersen et al., 2018). These hazards can reduce testosterone, weaken libido, and ultimately cause impotence (Agnew et al., 1991).

While there is some concern and limited research examining infertility in male firefighters, there is significant concern among women in the fire service who might want to have children (Jahnke, Poston, Jitnarin, & Haddock, 2018). Recent research suggests the uncertainty regarding the effects of firefighting on reproductive health may affect recruitment and retention of women in the fire service (Kehler et al., 2018). A study by Jahnke and colleagues found that only about a third of women firefighters reported a pregnancy during their career as a firefighter (Jahnke et al., 2018). It is unclear whether women firefighters choose to give birth before entering the fire service or if there are specific factors related to firefighting that discourage childbearing (Jahnke et al., 2018). Data suggests that, when women work in occupations in which formal limitations are high for reproduction (e.g. low benefit levels, gender segregated policies), women tend to delay or limit childbearing (Chesnais, 1996; Mills, Rindfuss, McDonald, & Te Velde, 2011; Neyer & Andersson, 2008). It is also possible given high rates of discrimination and harassment women face in the fire service (Hulett et al., 2008) that they decide against becoming pregnant because childbearing would limit their ability to fully participate in firefighting activities (Jahnke et al., 2018).

Additionally, for women in the fire service who do choose to get pregnant, few departments that have official policies in place to help them and their supervisors make decisions about when to restrict duties or disclose pregnancies to the department. Jahnke et al. (2018) found that, on average, women firefighters were at the end of their first trimester before they reported their pregnancy to their department, and most did not restrict their duties until the second or third trimester, while approximately 10% of women did not restrict their duties at all throughout their pregnancy (Jahnke et al., 2018). More research however is necessary to examine how long it is safe for women to remain on full active duty while pregnant.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

There also is very little guidance for women firefighters regarding breastfeeding and how long after battling a fire it is safe to save breast milk. The only guidance currently available is pilot data from Burgess et al. (2015), which suggests that in order to limit potential exposure of toxins to their breastfeeding infants, women firefighters should pump and discard their breastmilk following a structural fire for 72 hours, and supplement using an alternative source. Further research is necessary to identify links between firefighting and infertility, as well as mechanisms to protect firefighters and their offspring. Further, practitioners need guidance specific to firefighters to give appropriate advice for new and expecting mothers.

SOLUTIONS AND RECOMMENDATIONS

There are initiatives, such as the IAFC Bullying, Harassment, and Workplace Violence Prevention Task Group, The First Twenty Tactical High Performance Program (TF20), and the Front Line Behavioral Health Intervention, targeted at improving the health and wellness of firefighters. The overall goal of these initiatives is to create a culture of dignity and respect in the fire service and improve the physical and mental health of firefighters. The fire service should continue to collaborate and combine efforts such as those mentioned above to enhance firefighter safety and promote diversity within its ranks.

FUTURE RESEARCH DIRECTIONS

Further research should examine policies and training in other occupations that may transfer to the fire service culture. Additionally, resources for assessing and treating mental health issues among firefighters are warranted. Future research is necessary to better connect firefighters to behavioral health providers and physicians and better train the providers specially trained to work with this unique population.

CONCLUSION

In a properly supported department, these numbers look much better. It is not just the fire service that is dangerous, it is what goes on behind the scenes where there is a real impact of bullying, harassment, and sexual assault. Research has found high rates of mental health concerns among firefighters, but some speculate that elevated rates among women means they cannot do the job. When one evaluates mental health in supportive environments, women perform nearly the same as men. A lot of these issues related to women firefighters and mental health are the product of being in an unsupportive and potentially toxic job environment. Current research is limited for female firefighters, especially regarding mental health outcomes. The data that exists suggest that there are limited trainings or resources specific for female firefighters and that women are still experiencing significant differential treatment in the fire service (Jahnke et al., 2012; Hollerbach et al., 2017; Hulett et al., 2008; Horvath, 2013; Fox et al., 2006; IAFC, 2016; Griffith et al., 2016; Jahnke et al., under review; Sinden et al., 2013). The barriers female firefighters face (e.g., harassment, inadequate training, ill-fitting gear, and a lack of resources) may lead to poor coping mechanisms including substance use and abuse, poor mental health, and an increased risk of injury. These barriers and the associated poor health outcomes may contribute to the low rates of recruitment and retention of women in the fire service.

KEY TERMS AND DEFINITIONS

Behavioral Health: The study of one's behavior and its influence on their health (both mental and physical).

Differential Treatment: Negative and pervasive inappropriate behavior directed at an induvial or individuals including bullying, harassment, assault, sexual assault, and threats.

Mental Health: The state of health (lack of disease or impairment) specific to one's mental status including an examination of stress, depression, anxiety, sleep status, and PSTD.

National Fire Protection Association: U.S. national governing body responsible for development and standardization of standard operating procedures and guidelines for the U.S. fire service.

Occupational Risk Factors: Refers to health risk factors associated with one's occupation.

PTSD: Posttraumatic stress disorder as defined in the literature; referring to a clinical stressful reaction to a traumatic event.

Tactical Athlete: Referring to a worker in a physically demanding and often dangerous occupation usually including military, police, and firefighters.

Women Firefighters: Referring to females in the occupation of firefighting including firefighters as well as leaders such as captains and chief officers.

Chapter 64
Adolescent and Adult Mass Shooters:
Trauma, Mental Health Problems, and Early Prevention

Christopher A. Mallett
Cleveland State University, USA

ABSTRACT

Understanding why people commit mass shootings in the United States is perplexing and discerning perpetrators' motivations is difficult because there have been a fairly limited number of shootings. In addition, there is incomplete research on mitigating historical evidence about the perpetrators. Thus, this chapter takes a broader approach to understanding why these shootings may have happened by reviewing the empirical literature to identify possible correlations from childhood and adolescent trauma experiences (and subsequent mental health problems) to later adult violence. This review supports a hypothesis that these experiences are potential links to explaining mass shooting outcomes. The trauma experiences that are identified to be most impactful include maltreatment, poverty, witnessing violence, domestic violence, deaths (violent and non-violent) of family and friends, and adolescent bullying.

MASS SHOOTINGS

Mass shootings are rare events and the reasons for these tragedies are not well understood. Because so few mass shooting events have occurred, though their impact can be dramatic and disproportionate in media coverage or policy changes (Luca, Malhotra, & Poliquin, 2016), limited research on the perpetrators has been completed (Knoll & Annas, 2016). However, within such limitations, some themes have emerged.

The Federal Bureau of Investigations studied 150 mass shooter incidents and found 70 percent of the shootings took place at work or school locations, 98 percent were carried out by the person alone, 40 percent of the shooters committed suicide, and 96 percent were male (Blair & Schweit, 2014). In a more specific review of 37 targeted school violence incidents, the perpetrators had often considered

or attempted suicide before the violence, had leaked their intent to peers, or engaged in behaviors that showed intent - weapon seeking, disturbing writings, odd behaviors, et al. (Vossekuil, Fein, Reddy, Borum, & Modzeleski, 2002). And in a more limited review of five mass shooters, all were found to have been bullied during childhood and socially alienated as young adults, had paranoid tendencies, and held grudges and past humiliations that evolved into violent revenge fantasies (Mullen, 2004).

Mass shooting events have been most notably found to not be the result of a single event or incident that the perpetrator experienced, but a process of troubles and difficulties over time. Typically, it is the interaction and intersection of these difficulties that impact the person to such a degree that mass shootings and murders are the outcome (Fox & DeLateur, 2014). Across the research literature, these difficulties have been identified as psychopathology (to varying degrees), traumatic life events, emotional turmoil, and unique precipitating factors for each person (for example, job firing, home violence, or substance abuse) (Declercq & Audenaert, 2011; Knoll & Meloy, 2014; Martone, Mulvey, Yang, Nemoianu, Shugarman, & Soliman, 2013). Regarding psychopathology or mental health disorders, there is not a direct link from these difficulties to mass shootings or extreme violence. However, there are common characteristics (symptoms, not diagnoses) across mass shooting perpetrators – depression, suicidality, narcissism, and paranoid outlooks. Many of these symptoms are evident during the perpetrators' adolescent and young adult years (Knoll, 2012; Modzeleski, Freucht, Rand, Hall, Simon, Taylor, et al., 2008; Mullen, 2004).

Because of the empirical findings to date on mass shooters, this paper reviews two broad themes – childhood and adolescent trauma experiences and related mental health problems. It is postulated that these difficult younger person experiences do indeed have a lasting and cumulative (or comorbid) impact, and that in young adult and adulthood, the graver impact of other difficulties increases the risk to commit heinous crimes, including mass shootings. So by recognizing that the histories of mass shooters to date do include certain trauma histories, and that across the literature these experiences place adolescents and young adults at much greater risk of externalizing violence (a much more likely outcome for males), it is important to continue to research this possible link and to know there are prevention and intervention approaches available for younger people. Thus, this chapter first reviews the prevalence and impact of young people's trauma experiences and related mental health disorders, followed by an overview of prevention approaches that have been found effective in addressing these problems for this population.

The Prevalence of Childhood and Adolescent Trauma

Trauma impacts many children, adolescents, and their families. Some of these traumatic experiences are more readily identified – growing up in poverty, living in unsafe and violent neighborhoods, and being victimized by abuse. However, other traumas – including neglect, school bullying, and losing family members or friends (by death, prison, or other unexpected reasons) - are less frequently cited as significantly impactful, though may be just as difficult for young people to handle. These traumas often lead to nefarious difficulties both in the short- and long-term, including mental health problems, and for some, long-standing disorders. In addition, children's exposure to more than one form of trauma, referred to as **poly-victimization**, and traumas experienced over time are of serious concern, increasing the risk for school problems, youthful and adult offending, and violence. In other words, trauma is cumulative: the greater the number of experiences, the greater the impact on the young person's development, mental health, and offending behaviors (Greenwald, 2002; Klain, 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Child Maltreatment

There are four categories of child maltreatment: physical abuse, sexual abuse, emotional (psychological) abuse, and neglect (including medical), depending on state law definitions. Typically, the following definitions of these maltreatment types are found: physical abuse being the injuring or death of a child, not by an accident; sexual abuse being any act of sexual contact of any type toward a child; emotional abuse being chronic acts or attitudes by caregivers that interferes with or impedes the psychological or social development of a child; and neglect being inadequate or dangerous child-rearing practices by caregivers. Such maltreatment has increasingly been found to evoke serious, long-lasting repercussions for many of the victims (Buffington, Pierkhising, & Marsh, 2010). Both one-time and ongoing victimizations can be sufficiently traumatic to induce symptoms and to predispose young people to poor young adult trajectories and outcomes (Copeland, Keeler, & Angold, 2007; National Child Traumatic Stress Network, 2008; Widom, DuMont, & Czaja, 2007).

Maltreatment (abuse and neglect) reports are provided by the U.S. Department of Health and Human Services' Administration of Children and Families. There is concern by stakeholders that these counts underreport actual victimizations because of narrow state definitions of abuse. Nonetheless, with these official counts over the past ten years, approximately 680,000 to 1,000,000 children and adolescents nationwide each year have been victims of substantiated maltreatment. This represents approximately 20 percent of all referrals to children's services that are investigated (Administration for Children and Families, 2010; 2017).

Over the past five years, the majority of maltreatment victims have been neglect cases (75 to 80 percent; with an additional 2 percent for medical neglect), followed by physical abuse (17 to 18 percent), sexual abuse (8-9 percent), and emotional/psychological abuse (6-9 percent); with some significant variation across the states. Almost 10 percent of these victims had a reported disability, including learning, behavioral, intellectual, and/or physical. Over 91 percent of these victims' perpetrators were a parent, either acting alone or with other parental caregivers. Males and females were equally at risk; however, they were disproportionately younger (over 60 percent are under the age of 10 and 24 percent are less than one year old) and minority (black, American Indian, and Pacific Islander) (Administration for Children and Families, 2010; 2017).

Broader reviews of maltreatment victimization are available through nationally representative samples of victim self-reports and parental reports: the National Survey of Children's Exposure to Violence, the National Survey of Adolescents, and the National Comorbidity Study (Finkelhor, Turner, Shattuck, & Hamby, 2013; Kessler, Avenevoll, Costello, Green, Gruber, Heeringa, Merikangas, Pennell, Sampson, & Zaslavsky, 2009; McCart, Zajac, Danielson, Strachan, Ruggiero, Smith, Saunders, & Kilpatrick, 2011; Saunders & Adams, 2014). Additional trauma experience studies have utilized other (regional and local) school-based populations, though the findings are limited to just these localities (Banyard & Cross, 2008; Costello, Erkanli, Fairbank, & Angold, 2002; Drake, Lee, & Jonson-Reid, 2009).

Physical Assault and Abuse

Expanded physical assault and abuse definitions include acts of hitting, kicking, beating a child, or events that required medical attention. Correspondingly, lifetime prevalence rates of physical assault for adolescents are reportedly significantly higher and have been found to range from 17 to 71 percent (Finkelhor, et al., 2013; McCart, et al., 2011). In addition, some have identified and included threats,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

harassment, and bullying in identifying as physical abuse, with 29 percent of adolescents reporting these experiences during their lifetime (Finkelhor, Turner, Ormrod, & Hamby, 2009). Additionally, between 3 and 33 percent of high school students reported being shot at, and 6 to 16 percent being attacked with a knife, depending on location of the school (Finkelhor, Omrod, Turner, & Hamby, 2005; Kilpatrick & Saunders, 1997). Though these victimization rates at schools have been decreasing since 2003 (Carlton, 2017).

Sexual Victimization

Expanded sexual victimization definitions includes sexual assault, rape, sexual harassment, statutory sexual offenses, incest (abuse by family members) and sexual exposure by an adult. When including these offense types beyond the narrower child welfare system definitions, many more victims, and in particular adolescents, are identified. Between 8 and 11 percent of adolescents reported a history of at last one sexual assault (three times more likely for girls); 8 percent for attempted or completed rape (four times more likely for girls); and between 13 and 23 percent were victims of any sexual victimization in their lifetime (nearly twice as likely for girls) (Finkelhor, et al., 2013; McCart, et al., 2011). In total, it is estimated that between 8 and 10 percent of adolescents have been a victim of a sexual assault before the age of eighteen, with girls being more than three times more likely victims than boys (Saunders & Adams, 2014).

Witnessing Violence/Domestic Violence

Witnessing violent acts is common for many young people and has serious repercussions including trauma-induced fears, mental health difficulties, increased risk for substance use, and offending behaviors. Seventy percent of older adolescents reported they had witnessed at least one act of violence in their lifetime, and one-third reported witnessing some sort of family violence (Cuevas, Finkelhor, Shattuck, Turner, & Hamby, 2013; Finkelor, et al., 2009). Nearly 40 percent of adolescents have reported witnessing at least one serious community-based violent act (shooting, stabbing, or robbery, among others) over their lifetime, with boys more likely than girls (McCart et al., 2011; Zinzow, Ruggiero, Resnick, Hanson, Smith, Saunders, & Kirkpatrick, 2009).

Domestic violence acts can be either witnessed by a family member, or the family member could be the victim of the threats, assaults, and/or battering. These domestic violence problems - also called intimate partner violence or domestic abuse - include emotional abuse, threatened and actual physical abuse, or sexual violence between adults, both heterosexual and same-sex partners. Between three and ten million children are exposed to domestic violence in the United States annually - encompassing 9 to 10 percent of the child and adolescent population that witnessed a serious violent act between their parents or caregivers - with a majority of these children being younger than nine years of age (The National Child Traumatic Stress Network, 2016; Sickmund & Puzzanchera, 2015).

Deaths – Violent and Non-Violent

Violent deaths of family members and loved ones can be traumatic to young people. These types of deaths are caused by different events, many suicides and homicides. In 2013, over 41,000 people committed suicide and 16,000 people were homicide victims in the United States (Centers for Disease Control and

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Prevention, 2014a). Over 18 percent of adolescents nationwide have lost a family member (which accounts for 47 percent of the total) or close friend (53 percent) to a type of homicide. These homicides included criminal homicide, vehicular homicide, and negligent homicide, among others. When this death impacts younger people, it may cause what is called traumatic grief – whereby the young person cannot understand the death, and experiences very severe grief symptoms that lead to frightening thoughts and images of the deceased (Rheingold, Zinzow, Hawkins, Saunders, & Kilpatrick, 2011).

Non-violent deaths, which can be by natural causes or accidents, may also be traumatic and difficult situations for children and adolescents, particularly when this entails the death of a family member, parent, or peer. Death is often difficult for young people to understand and without support, many struggles to adapt to the new situation. Children and adolescents most at risk for non-violent death trauma experiences include those who were close physically and/or emotionally to the deceased, those with pre-existing mental health issues, those with pre-existing family difficulties or previous loss experiences, and those with a limited support network (Goodman, 2002).

Poverty

Poverty and living in low-income neighborhoods poses serious difficulties and stressor for many families. Living in poverty increases the number of trauma experiences that families and children have in trying to meet their regular daily living needs, leading often to a state of ongoing crisis (Collins, Connors, Donohue, Gardner, Goldblatt, Hayward, Kiser, Streider, & Thompson, 2010; Reeves, Rodrigue, & Kneebone, 2016). Children living in poverty, and in particular urban poverty, have high rates of reported trauma experiences (70 to 100 percent). Often, these experiences include exposure to violent neighborhood crime, drug activity, and family violence. For some children and adolescents these stressors lead to maladjustments, hyper-anxiety, and mental health and trauma-related problems. These trauma difficulties that are ongoing and multi-dimensional impact many children's development, psychological functioning, academic learning, and skill development. These impairments increase the risk for adolescent substance abuse, school failure, and suicide (Collins, et al., 2008; Cook, Blaustein, Spinazzola, & van der Kolk, 2003; Macy, Barry, & Noam, 2003).

Poverty, Violence, and Unsafe Schools

Decades of research has shown the link between poverty and education achievement, whereby poor children and adolescents are more likely to attend underachieving schools with some of the lower per pupil school funding. These children can learn as well as non-poor children, however, they are more prone to school transitions, family joblessness, and increased exposure to violence in the home and community (Books, 2004; Lee & Burkam, 2002). Poor schools in less advantaged neighborhoods also have more crime problems on and around the school campus, impacting the environment, exposing students to violence, and lowering high school graduation rates. Students exposed to violence, those who perpetrate violence (bullying, included), and those who are violence victims are more likely to experience emotional problems, door more poorly in school, and perpetuate the crime problems (Bureau of Justice Studies, 2014; Child Trends, 2015). These school environments can increase fears among students - whereby, in 2013, 18 percent of students reported carrying a weapon while in school, often for protective needs. High school male students were three times more likely to carry a weapon than female students, and white students almost twice as likely as minority students (Centers for Disease Control and Prevention, 2014b).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Bullying and Cyberbullying

Bullying includes three major types: physical, social, and verbal; and these victimizations may occur in person and through internet and social media connections (cyberbullying). Bullying takes many forms, including insults and name-calling, being threatened with harm, being subjected to rumors, physical assaults, forced to do things against your will, purposefully exclusion from activities, and property destruction. Cyberbullying also has numerous forms, including hurtful information on the internet; sharing private information; unwanted contact via email, texting, online gaming, and other social media sites; and purposeful exclusion from an online community (U.S. Department of Education, 2013).

Bullying is a common experience for children and adolescents, with many of these victimizations occurring on school grounds. National data on bullying across schools was not collected until 2005, when the Department of Education first reported that between 28 and 32 percent of all students were bullied during the school year. Bullying victims continued to report high number of experiences, though there has been a decrease to 21 percent in the 2015 academic reporting year. Female students report higher rates of bullying (23 percent) compared to male students (19 percent), as well as more victimizations due to cyberbullying (9 percent compared to 5 percent for male students). Younger students – grades sixth through ninth – are more likely to be bullied compared to older students – tenth to twelfth grades; with equal bullying victimization rates across low, middle, and high family incomes (U.S. Department of Education, 2013). Reasons for the recent decline in bullying reports are under investigation, though federal and state efforts have prioritized the problem, including a requirement that public elementary and secondary schools report incidents of harassment based on religion, sexual orientation, gender, race, color, national origin, and disability status (U.S. Department of Education, 2016).

Students who are victims of bullying do not perform as well academically in school and more often skip class and are truant. In addition, they are at significantly higher risk for using and abusing alcohol and drugs, suffer from depression, and having higher risk of suicide. Marginalized student populations, including the LGBT community, are most at risk for bullying victimization and these problematic outcomes (Hatzenbuehler & Keyes, 2013; Kowalski & Limber, 2013).

Poly-Victimization

Poly-victimization is the exposure to, and experience of, multiple forms of trauma and/or victimization. Multiple trauma experiences are common for some child and adolescent populations, with up to 20 percent of those ages 13 to 18 (disproportionately male and older) having experienced more than one type of trauma and over 41 percent of physical abuse, assault, or sexual abuse victims had also reported additional trauma experiences. More broadly, for all children and adolescents who experienced any direct victimization, more than two-thirds reported more than one type. Of concern is that there are a small number (between 6 and 8 percent) of adolescents reporting exposure from six to over 15 different traumatic experiences over their lifetime (Finkelhor, et al., 2005; Finkelhor, et al., 2013; McCart, et al., 2011).

Having certain traumatic experiences exposes the young person to much greater risk for another trauma. A young person who was physically assaulted would be five times as likely to have been sexually victimized and more than four times as likely to have been maltreated during a one-year period. And a young person who was physically assaulted during his or her lifetime would be more than six times as likely to have been sexually victimized and more than five times as likely to have been maltreated (any type) during his or her lifetime. The greater the number and severity of the trauma experiences, often

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the greater the impairment for adolescents, including mental health, academic, and behavioral problems. (Finkelhor, et al., 2009; Ford, Elhai, Conner, & Frueh, 2010; Ford, Grasso, Hawke, & Chapman, 2013). In addition, repeated trauma experiences have been found to double the risk for mental health disorders (anxiety, post-traumatic stress disorder, and depression, among others) and this impact lasts for up to three years after the traumas (Copeland, et al., 2007; Perkonigg, Kessler, Storz, & Wittchen, 2000).

Child and Adolescent Mental Health Problems

Risk Factors

Child and adolescent risk factors (experiences, traits, or issues that make the outcome more likely) for the development of mental health problems and disorders have been divided into individual, family, and neighborhood categories. Individual factors include the following: gender (type is dependent on mental health diagnoses); age (risk increases during adolescence for most diagnoses, though not all); ethnicity (dependent on mental health diagnoses); poorer overall physical health; lower cognitive function; exposure to illness; increased physical stress over time; substance use and abuse; poor nutrition; and lifetime history of environmental exposures to toxins, stress, and traumatic life events. Family factors include the following: lower parental education, lower economic and social class; poorer employment and work histories; a more extensive psychiatric and medical history; parental history of mental disorders; and poor family functioning and structure. Neighborhood factors include the following: increased number of trauma or violent events; lower income neighborhoods; and poor environmental health (Brauner & Stephens, 2006; Goodman, Hoven, Narrow, Cohen, Fielding, Alegria et al., 1998; New Freedom Commission Report, 2003).

Prevalence Rates/Treatment Access

Most children and adolescents do not suffer from mental health disorders. It is only between 3 and 20 percent of children and adolescents that have an identified mental health disorder that impairs their functioning to a moderate or significant degree. The impact for older children and adolescents, ages 9 to 17, is greater with 21 percent having a diagnosable mental health issue that causes moderate impairment to their daily living.

However, the risk and experiences with mental health problems and symptoms is more expansive than a medical diagnosis. In broader, self-report surveys of young people, nearly half of the adolescent population self-reported having met diagnostic criteria for at least one disorder over the lifetime, with 20 percent of this group reporting symptoms severe enough to impair their daily living; almost 10 percent reported a behavior disorder; more than 8 percent reported being severely impaired by an anxiety disorder; over 11 percent similarly impacted by a mood disorder; and 40 percent who reported one disorder also reported a comorbid second disorder, more often those with a mood disorder. Many of these difficulties began during childhood with symptoms of anxiety emerging at age 6 (median), behavior disorders by age 11, and mood disorders by age 13 (Angold, Erkanli, & Farmer, 2002; Costello, Mustillo, Erkanli, Keeler, & Angold, 2003; Costello, Mustillo, Keeler, & Angold, 2004; Costello, Egger, & Angold, 2005; Merikangas, Burstein, Swanson, Venevoli, Cui, Berjet et al., 2010; Roberts, Roberts, & Xing, 2007).

Unfortunately, when these problems are identified, upwards of 75 percent of this group does not access or receive adequate treatment or services. However, for those young people with the most severe

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

symptoms or mental health difficulties, most do access and receive community or school-based services. Reasons for this higher level of access to services is because of the young person's significant impairment, the family's recognition of the problem, comorbidity across other problem areas, and if there was a suicide attempt by the young person. Those who access services through their schools, though are unlikely to transition to community-based or specialty mental health programming when school services end (DeRigne, Porterfield, & Metz, 2009; Ford, 2008; Gudino, Lau, Yeh, McCabe, & Hough, 2009; Reddy, Newman, De Thomas, & Chun, 2008).

Behaviorally-based Disorders

Within the child and adolescent population that have professionally identified mental health problems, behaviorally-based disorders are some of the most common with between 4 and 14 percent prevalence rates. This includes lower rates in younger children – more often oppositional defiant disorder (ODD) and attention-deficit hyperactivity disorder (ADHD) – and higher rates for older school-age children – more often conduct disorder (CD) (Costello, Angold, Burns, Stangl, Tween, Erkanli, & Worthman, 1996; Nock, Kazdin, Hiripi, & Kessler, 2007). Oppositional defiant disorder – impacting slightly more than 3 percent of the child and adolescent population - and conduct disorder - impacting 4 percent - are characterized by persistent violation of age-appropriate societal rules and expected behavioral expectations, as well as persistence of these behaviors for a minimum period of time. Attention-deficit hyperactivity disorder has the opposite prevalence trends, with almost all diagnoses made prior to the age of 12 (prevalence is between 3 and 5 percent), though for many children the difficulties continue into the secondary school age period. All three of these disorders – conduct, oppositional defiant, and attention-deficit hyperactivity disorder – are twice as prevalent for boys than for girls (American Psychiatric Association, 2013; Costello, et al. 2005; Roberts, et al., 2007).

Anxiety Disorders

Anxiety disorders that are identified through professional diagnosis account for between 2 and 4 percent of the child and adolescent population with some significantly higher rates in a number of community-based surveys (median prevalence rate of 8 percent). These disorders impact both the primary and secondary school-age populations equally, though with different diagnoses for each group. Separation anxiety and some related anxiety difficulties are more often found in primary school-age children; while panic disorder, agoraphobia, social phobia, overanxious disorder, and generalized anxiety disorder are more often found within secondary school-age adolescents. Girls are slightly more often diagnosed with certain anxiety difficulties, primarily post-traumatic stress disorder and obsessive-compulsive disorders, and are overall at greater risk for any anxiety problems (American Psychiatric Association, 2013; Costello, et al., 1996; Kessler, Berglund, Dermier, Jin, Merikangas, & Walters, 2005; Merikangas, et al., 2005; Rappaport, Inoff-Germain, Weissman, Greenwald, Narrow, Jensen, et al., 2000).

Depression

Depression and related disorders are not common for children younger than 12 years of age, accounting for less than 2 percent of all cases identified through professional assessment. However, depression rates rise dramatically within the adolescent population, and impact between 4 and 5 percent of this group;

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

greatly increasing the risk for suicide (American Psychiatric Association, 2013; Costello, Pine, Hammen, March, Plotsky, Weissman, et al., 2002; Simonoff, Pickles, Meyer, Silberg, Maes, Loeber, et al., 1997). Depressive disorders, including major depressive disorder, have been found to be more prevalent within white adolescent populations when compared to black adolescent populations; as well as more common in female adolescents than male adolescents (Angold, et al., 2002; Gonzalez-Tejera, Canino, Rameriz,, Chavez, Shrout, Bird, et al., 2005).

Post-Traumatic Stress Disorder (PTSD)

Five percent of adolescents meet criteria for PTSD during their lifetime, with a higher prevalence rate for girls (8.3 percent) than boys (2.3 percent). Higher overall prevalence rates (7 to 11 percent) have been found in reviews of adolescents living in larger urban areas, with similar gender differences found in these populations (Kessler, et al., 2012).

Many children and adolescents who have experienced trauma, and in particular maltreatment, will develop symptoms, or partial symptoms, of PTSD (as well as other related anxiety or depression problems). Post-traumatic stress disorder can occur at any age, even for children as young as one or two years old; though there may be a delay of months or years before symptoms are able to be identified. Different reactions, stressors, and symptoms may vary over time and for children at different developmental stages. A diagnosis of PTSD includes a history of trauma(s) event exposure that impacts the person and leads to avoidance, negative reactions, and changes to daily living (American Psychiatric Association, 2013).

One of the symptoms of PTSD, and related trauma difficulties, is a state known as "hypervigilance." Often defined as "abnormally increased arousal, responsiveness to stimuli, and scanning of the environment for threats" (Buffington, et al., 2010, p. 3). For children and adolescents this can look like jumpiness, nervousness, quick to react or startle, high defensiveness, and/or an inability to feel calm or relax. Many highly traumatized young people are in a consistent state of hypervigilance, always worried or fearful of what trauma may impact them next. This "flight or fight" response can be debilitating for many, very tiring, and may look like symptoms of other problems: attention-deficit hyperactivity disorder, conduct problems, aggressive behaviors, paranoia, and social interaction or relationship difficulties.

A fight or flight response to trauma may also harm or damage a child's brain functioning and development. When traumatic events cause this response, stress hormones (cortisol and adrenaline) are released to prepare the body for either escaping the threat or staying and "fighting" the threat. Although this is an effective response for dealing with an immediate danger, children's and adolescents' bodies are not meant to live in this stressed state for extended periods of time. The hormones released during stressful events can have cumulative, long-term damages on the body. This is potentially harmful for those who are still experiencing sensitive periods of growth and development, and may have significant consequences on brain development. The child or adolescents' brain is adapting to help the individual survive in a traumatic and stress-filled environment. This stress-induced damage can disrupt normal development and lead to emotional, cognitive, and behavioral problems. Potential cognitive impacts include language delays, attentional issues, and memory difficulties. Behavioral issues may include increased aggression, poor social skills, an inability to moderate emotional responses, attachment problems, and an increase in risk-taking behaviors and impulsivity (Substance Abuse and Mental Health Services Administration, 2014).

Interplay of Mental Health and Trauma

Mental health and trauma problems are inexorably linked. Childhood abuse and neglect victimizations that lead to out-of-home placement into a foster home increase the risk for delinquency and recidivism to delinquency. These trauma experiences often also lead to more severe mental health problems (conduct and other externalizing type behavior problems, depressive episodes, and PTSD) that are linked to youthful offending outcomes, with the risk highest rate for those victimized during adolescence (Barrett, Katsiyannis, Zhang, & Zhang, 2013; Cottle, Lee, & Heilbrun, 2001).

Living in poverty also impacts children and adolescent's mental health, in that a far greater number report these problems: 21 percent of children in poverty in 2010 had diagnosed mental health disorders; those not living in poverty reported mental health disorders between 3 and 18 percent (Stagman & Cooper, 2010). Experiencing poverty, and particularly over time, is a dynamic process with some experiences impacting other difficulties (family violence, witnessing violence, substandard housing, unsafe neighborhoods, and family separation, among others) and these interacting further with children and adolescents' coping capacities. Also, poverty during earlier childhood and poverty experienced over time are linked to worsening and progressively harder to treat mental health problems for adolescents and young adults (Evans & Cassells, 2013; Yoshikawa, Aber, & Beardslee, 2012).

Trauma Assessment and Intervention

Identifying childhood and adolescent trauma experiences can be difficult. The type of trauma or stress, developmental stage (age), cognitive and emotional capacities, and levels of resiliency are all factors that impact the emergence of trauma symptoms Fortunately, there are a number of assessment measures that can be used to identify trauma experiences, PTSD, and related problems (See Table 1).

Trauma-Informed Care

Over the past decade, a proliferation of program development has occurred on what is commonly called "trauma-informed care." Significant advances in treatment for childhood trauma have been made, including some programs and interventions with strong or growing empirical support. Most of these programs range in treatment time from four to 36 sessions or weeks, and take place in the community family setting. Table 2 includes a number of trauma treatment programs; the last two on the table are specifically designed for use in schools (Duke University School of Medicine, 2015; The National Child Traumatic Stress Network, 2015):

One of the effective interventions is Trauma-focused Coping in Schools (also known as MMTT). This program uses a skills-based and peer-mediated group design to help with trauma and related difficulties for children (4th grade through high school). The curriculum is based upon cognitive-behavioral techniques focused on teaching coping skills around anger, grief, and anxiety. The intervention is most helpful when started at least one month after the traumatic event (fire, suicide, homicide, or other violence exposure), and typically includes 14 group session with six to eight students per group, held weekly during classroom time (Jaycox, Morse, Tanielian, & Stein, 2006).

Table 1. Trauma assessment

The CROPS (Child Report of Post-traumatic Symptoms) is a self-report measure for children and adolescents that assesses a broad range of post-traumatic symptoms, with or without an identified trauma, and can be used to measure changes in symptomatology over time.
The Child PTSD Symptom Scale (CPSS) is a self-report measure that assesses the frequency of all DSM-defined PTSD symptoms and was also designed to assess PTSD diagnosis. The first 17 items measure PTSD symptomatology and yield a total Symptom Severity score. Seven additional items assess daily functioning and functional impairment.
The CTSQ (Child Trauma Screening Questionnaire) is a 10-item self-report screening which helps in the identification of children at risk of developing PTSD. The questions are designed to assess traumatic stress reactions in children following a potentially traumatic event.
The Child's Reaction to Traumatic Events Scale is a 23-item self-report measure designed to assess psychological responses to stressful life events.
The Children's PTSD – Inventory (CPTSD-I) is a structured clinician-administered interview for those ages 6 to 18 years old that assesses PTSD symptoms and diagnoses, qualifying event, and current functioning.
The Clinically Administered PTSD Scale for Children (CAPS-CA) assesses the frequency and intensity of the 17 symptoms of PTSD, with items developed to be consistent with the DSM. It also evaluates the impact of the symptoms on the child's social, occupational, and developmental functioning; subjective distress; global severity; and validity of the interview. A global improvement rating since baseline can also be made, as can ratings of associated symptoms and Acute Stress Disorder symptoms.
The Parent Report of Post-traumatic Stress Symptoms (PROPS) is a parent-report measure for children and adolescents that assesses a broad range of post-traumatic symptoms, with or without an identified trauma, and can be used to measure changes in symptomatology over time.
The PTSD Semi-structured Interview and Observational Record is used to assess PTSD in children 0-7 years of age. The measure assesses whether the child has experienced 11 specific traumas or an alternative trauma; and collects data regarding the first occurrence, last occurrence, and the number of times the event occurred. It includes questions for caregivers and collection of information for observation of the child during the interview.
The Response to Childhood Incest Questionnaire (RCIQ) was developed to measure PTSD symptomatology and cognitive and affective stress response themes in female adult survivors of childhood incest.
The Trauma Symptom Checklist for Children (TSCC) measures severity of post-traumatic stress and related psychological symptomatology (anxiety, depression, anger, dissociation) in children ages 8-16 years who have experienced traumatic events, such as physical or sexual abuse, major loss, or natural disasters.
The Trauma Symptom Checklist for Young Children (TSCYC) is a 90-item caretaker-report instrument developed for the assessment of trauma-related symptoms in children ages 3-12. The scales allow a detailed evaluation of posttraumatic stress symptoms and a tentative PTSD diagnosis. It also provides information on other symptoms such as anxiety, depression, anger, and abnormal sexual behavior.
The UCLA PTSD Reaction Index is a self-report questionnaire to screen for exposure to traumatic events and assess PTSD symptoms in school-age children and adolescents. The scale assesses the frequency of occurrence of PTSD symptoms during the past month.

MENTAL HEALTH PREVENTION AND INTERVENTIONS

Effective child and adolescent interventions and programs to deal with the mental health problems have been developed and are available for use across community-based agencies, as well as other settings including schools and other youth-caring systems. These interventions are offered across numerous formats including individual, family, and group formats, among other approaches.

Children

Anxiety Disorders

Many children respond to a number of interventions that help decreasing or managing their anxiety symptoms and disorders, though other children are unresponsive and struggle with these problems into adolescence, even after intervention. Studies that examined a range of interventions found two with the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

greatest impact: cognitive-behavioral therapy and pharmacotherapy (medications), though he evidence is stronger for the former and thus should be utilized as an initial treatment (Muris & Broeren, 2009; Walkup, Albano, Piacentini, Birmaher, Compton, Sherrill, et al., 2008). When children do not respond well to the initial efforts by cognitive-behavioral therapy, then pharmacotherapy, in particular using Selective Serotonin Reuptake Inhibitors (SSRIs), can be recommended in addition to cognitive-behavioral therapy. It should be cautioned, though, that while this combination of interventions improves the symptoms in the short term, there are side effects and tolerance buildup, often in reaction to the pharmacotherapy regimen (American Academy of Child and Adolescent Psychiatry, 1997; RUPP Anxiety Group, 2001).

Effective behavioral and cognitive-behavioral therapies typically include components of different programming alternatives, including exposure therapy (systematic desensitization), cognitive restructuring, psycho-education on anxiety and its effects, contingent reinforcement, and modeling. Through the use of these components, children learn to recognize anxious feelings and reactions to anxiety, develop a coping mechanism for anxiety-inducing situations, clarify thoughts in anxious situations, and reinforce these new skills and behaviors (Amaya-Jackson & DeRosa, 2007; Kendall & Suveg, 2006; Suveg, Kendall, Comer, & Robin, 2006).

Table 2. Trauma-informed care

Alternatives for Families: A Cognitive Behavioral Therapy - ages 5 to 17; 20 sessions; most appropriate for physical abuse or excessive physical punishment victims
Trauma-Focused Cognitive Behavioral Therapy - ages 3 to 21; for sexual abuse, domestic violence, traumatic grief, and complex traumas experiences
Parent-Child Integrative Therapy - ages 2 to 12; for physical, sexual, or emotional abuse victims
Child and Family Traumatic Stress Intervention - ages 7 to 18; 4 sessions; for a wide range of trauma victims including poly-victimizations typically in early or acute stage
Integrative Treatment of Complex Trauma for Adolescents - ages 12 to 21; for a wide range of traumas
Trauma Affect Regulation: Guide for Education and Therapy - ages 10 and older; for complex and poly-victimization traumas
Trauma and Grief Component Therapy for Adolescents - ages 12 to 20; for interpersonal violence and traumatic loss
Attachment, Self-Regulation, and Competence: A Comprehensive Framework for Intervention with Complexly Traumatized Youth - ages 2 to 21, for complex traumas
Trauma-Focused Coping in Schools (MMTT) - ages 6 to 18; used in a classroom setting; a skills-based approach to address single incident trauma and PTSD symptoms; group setting with 6-8 participants
Cognitive Behavioral Intervention for Trauma in Schools - ages 10 to 15; addresses community and other violence, most appropriate with ethnic minority students; uses a skills-based group setting with 6-8 participants

Behaviorally-Based Disorders (Conduct and Oppositional Defiant Disorders)

Programs and interventions for dealing with behaviorally-based disorders target both parents and children. Parent management training, also called parent training and family training, has been found effective in working with children who have behaviorally-based and/or aggression problems, and particularly demonstrates short-term improvements in the development of pro-social behaviors and in minimizing maladaptive behaviors. Parent management training involves teaching parents how to respond consistently and more positively to their children while changing maladaptive interaction habits within the

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

relationship that lead to continued aggressive or antisocial behaviors. In doing so, this training, based on social learning theory, utilizes operant conditioning procedures to reduce these problem areas. It is important to provide interventions as early as possible because of the increased chance of additional behavioral disorders while the decreased chance of later adverse behaviors (Bernazzani & Tremblay, 2006; Farrington & Welsh, 2003; Piquero, Farrington, Welsh, Tremblay, & Jennings, 2008).

A related parent management training program type, sometimes called behavioral parent training, is also based in social learning theory but has a stronger focus on behavioral management. In this, the emphasis is on the importance of observing and modeling the behaviors and attitudes of others to help the child with behavior problems. The programs teach broad behavioral principles for producing and reinforcing positive child behaviors which can be adapted in the home environment through the use of rehearsing and coaching (Dretzke, Frew, Davenport, Barlow, Stewart-Brown, Sandercock, et al., 2004). Reviews of these programs have found that they are high quality and effective in decreasing children's behavior problems (Barlow & Parsons, 2002). A number of meta-analyses further supported these findings, with results showing effectiveness of behavioral parent training programs in a number of specific areas: working with children with conduct disorders (Gould & Richardson, 2006); improving overall child and parent functioning levels, in particular with older children (ages nine to eleven) (Serketick & Duman, 1996); in decreasing classroom disruptions (Wilson, Lipsey, & Derzon, 2003); and modifying behavior problems (Maughan, Christiansen, Jenson, Olympia, & Clark, 2005).

Because children with behaviorally-based disorders and problems often struggle in the home, school environments, and community, programs or interventions addressing multiple locations/environments may be necessary. Interventions that focus on behavioral and cognitive behavioral orientation treatment when working with children with behavioral problems and emotional disturbances have been found to have positive impacts (Beard & Sugai, 2004). Interventions include behavioral therapy, individualized therapy, social skills training, medication, and art/play therapy, with the social skills training and a behavioral approach to daily living (token economy model) being two of the more common (Reddy, Newman, DeThomas, & Chun, 2008).

The Promoting Alternative Thinking Strategies (PATHS) Curriculum is an effective school-based program that decreases aggressive behaviors and improves social problem solving through teaching children developmentally-based lessons and instructions on emotional literacy and ability to identify feelings, self-control, interpersonal problem-solving skills, and positive peer relations. Sessions take place two to three times a week in elementary classrooms, led by teachers, to connect cognitive understandings to the daily life situations that children face (Child Trends, 2011; Greenberg, Kusche, & Mihalic, 2006). This is one of numerous programs that have the therapeutic goal of improving self-control. These interventions focus on increasing skills for friendship and social skills, social problem-solving abilities, and understanding and communicating emotions. These can take place in multiple settings – school, home, or community – and involve the child, family, and/or peers. A thorough review of 34 programs found these efforts that attempt to improve self-control among children were an effective intervention in reducing problem and offending behavior risks for those under the age of ten (Piqueo, et al., 2010).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Adolescents

Behaviorally-Based Disorders (Conduct and Oppositional Defiant Disorders)

Cognitive-based parent training focuses on teaching practical skills to caregivers to address conflict and interpersonal problems and improve communication has been found effective. Cognitive-behavioral treatment interventions more broadly utilized with both adolescents and their families have demonstrated effectiveness in reducing aggressive and antisocial behaviors (Little, 2005). Additionally, these interventions improve positive behavioral and other psychological outcomes. Cognitive-behavioral interventions are designed to identify cognitions - thoughts, expressions, perceptions - and to then alter cognitions that are negative or detrimental in order to reduce maladaptive or dysfunctional thinking, attitudes, or behaviors. Such approaches may include teaching social skills, parenting skills, problem-solving skills, anger management, and related efforts (Andreassen, Armelius, Egeland, & Ogden, 2006; Lipsey & Landenberger, 2006; Turner, MacDonald, & Dennis, 2007).

Functional Family Therapy (FFT), a short-term program of that targets the family, is designed to motivate the adolescent and family members to change adolescent behaviors and family member's reactions to these behaviors. Interventions with eleven- to eighteen-year-old adolescents with behavioral disorders lasts from eight to thirty hours through various engagement and treatment phases, depending upon the level of problem severity. FFT has been found to significantly decrease delinquency offending as well as out-of-home placement due to family instability or delinquency involvement (Alexander, Barton, Gordon, Crotpeter, Hannson, Harrison, et al., 2007; Howell, 2009).

Schools can also have an impact on decreasing aggressive behaviors. Many adolescents report troubles dealing with violence, bullying, and related problems within their schools, leading a majority of school districts to offer some sort of preventative programming (Gottfredson, Gottfredson, Czeh, Cantor, Crosse, & Hantman, 2000). Most of these programs use social processing and cognitive-behavioral techniques to inform and educate students on improving problem-solving skills, identifying consequences to their plans, identifying aggression, and response options. These preventative and intervention programs are offered in both a universal format - to all students in a classroom - or on a selective, individualized basis – students who are identified as having aggression or violence problems. Both social skill development formats, universal and selective programming, have been found to significantly decrease adolescent aggressive and disruptive behaviors, and that the affect for some adolescents was long-term (Wilson & Lipsey, 2006a, 2006b).

Depression and Suicide Prevention

Numerous approaches have been utilized to decrease the symptoms and impact of adolescent depression and related disorders, including various individual and group therapeutic modalities, psychopharmacology, and public education, among others. While some of these approaches, primarily psychopharmacology, are important in stabilizing the most serious depressive symptoms including suicidal ideation and behaviors, others do not appear to be effective in achieving symptom reduction goals, including therapy, psychotherapy, and psychoanalysis (March, Silva, Petrycki, Curry, Wells, Fairbank, et al., 2004).

A smaller set of interventions may be helpful for some adolescents with significant depression problems. Interventions that are more likely to be effective include cognitive-behavioral approaches attuned to adolescent development and focused on peer to peer social activities, problem-solving abilities, new

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

thinking patterns, psycho-education for parents and adolescents, and mood and emotion regulation. However, little long-term follow-up research has been completed, so whether or not lasting effects can be achieved though these approaches is not yet known. In addition, when working with adolescents with multiple or comorbid problems that significantly complicate treatment planning and coordination efforts, care should be taken because, once again, only few long-term intervention outcomes targeting this population of adolescents are known (Clark, Boyde, Redditt, Foster-Johnson, Hardy, Kuhns, et al., 2001; Horowitz & Garber 2006).

A number of risk factors correlate with suicidal behaviors, though having suicidal risk factors does not always lead to suicidal tendencies. Risk factors include depression and other related mental health problems, a prior suicide attempt, a family history of suicide or family violence, firearms in the house, and incarceration. When working with adolescents, a number of suicidal behavior signs or symptoms can be identified, thus allowing immediate and concerted preventative actions. These signs include feelings of hopelessness or worthlessness, a decline in or lack of family or social activity participation, changes in sleeping or eating patterns, feelings of rage or need for revenge, consistent exhaustion, low concentration abilities at home and/or school, regular or frequent crying, lack of self-care, and reckless or impulsive behaviors (Centers for Disease Control and Prevention, 2015; National Institute of Mental Health, 2011).

Of concern among adolescents is the effect of comorbid problems that increase the risk for suicidal behavior. As the number of risk factors increases, the risk for suicidal behavior among adolescents also increases, though this is further complicated by the impact of other mental health or substance abuse problems. Depression, disruptive behavior disorders (conduct and oppositional defiant), and substance abuse are strongly linked to increased suicide risk (Conner & Goldston, 2007; Shaffer, Gould, Fisher, Trautman, Moreau, Kleinman, et al., 1996).

Chapter Summary

This chapter discusses the wide impact and prevalence of childhood and adolescent trauma and related mental health problems and reviews the empirical link to later life difficulties, including violence. In so doing it is postulated that these experiences are even more involved in the histories of mass shooters than reported to date and that increased use of preventative efforts may help decrease the risk of tragic outcomes. There are effective ways to both identify and treat trauma related problems and mental health difficulties for this younger population - in schools, their homes, and the community. This review includes some of the most effective evidence-based approaches to preventing youthful offending and violent outcomes by addressing these difficulties.

KEY TERMS AND DEFINITIONS

Behaviorally-Based Disorders: Mental health problems and disorders that are externalized; in other words, where acting out or physical violence is involved.

Child Maltreatment: There are four official, legal categories of child maltreatment: physical abuse, sexual abuse, emotional (psychological) abuse, and neglect (including medical), depending on state law definitions.

Cognitive Behavioral Therapy: A type of psychotherapy in which negative patterns of thought about the self and the world are challenged in order to alter unwanted behavior patterns or treat mood disorders such as depression.

Domestic Violence: Includes emotional abuse, threatened and actual physical abuse, or sexual violence between adults, both heterosexual and same-sex partners.

Functional Family Therapy: An effective intervention that attempts to modify individual behaviors and cognitions, with an emphasis on the larger family or groups as the focal area needing change rather than only on the adolescent.

Mental Health Disorders: A diagnosis by a mental health professional of a behavioral or mental pattern that may cause suffering or a poor ability to function in life. In the United States, diagnosis is through the use of the Diagnostic and Statistical Manual of Mental Disorders (DSM).

Poly-Victimization: The exposure to, and experience of, multiple forms of trauma and/or victimization.

Post-Traumatic Stress Disorder: A diagnosis of PTSD includes a history of trauma(s) event exposure that impacts the person and leads to avoidance, negative reactions, and changes to daily living

Risk Factors: Experiences, traits, or issues that make an outcome (delinquency or mental health problems, for example) more likely.

Seriously Emotionally Disturbed: A designation for young people who have ongoing mental health problems, often more severe and difficult to treat – including psychotic diagnoses, bi-polar disorder, and mood disorders.

Trauma: A deeply distressing or disturbing experience; one that impacts the person either in the short- or long-term.

Trauma-Informed Care: A treatment framework that involves understanding, recognizing, and responding to the effects (psychological, social, and biological) of all types of trauma.

Chapter 65
EHealth Interventions for People Suffering From Sleep Problems and Depressive Symptoms: Qualitative Findings and Future Research Directions

Sitwat Usman Langrial
Sur University College, Oman

Päivi Lappalainen
University of Jyväskylä, Finland

ABSTRACT

This chapter highlights qualitative findings from two field studies that focused on supporting people with sleeplessness (Study 1) and moderate depression (Study II). Both the studies were designed to examine the prospective impact of reminders and rehearsal on the effectiveness of web- based eHealth interventions. The interventions were incorporated with Acceptance and Commitment Therapy. In this chapter, qualitative findings are reported with an aim to highlight issues that are at times overlooked. Further, the findings are expected to help researchers better understand eHealth interventions for mental health care. Results from the two studies uncover interesting contrasts. While the participants of the Study I (Sleeplessness) generally did not find reminders to be helpful, on the contrary, the participants of study II (Moderate Depression) largely approved reminders especially in terms of task completion. In terms of rehearsal, participants from both the studies approved the virtual exercises in terms of learning desirable self-help behaviors. Finally, the chapter highlights some of the grey areas in the field of eHealth interventions for mental health care. The identified grey areas are expected to create opportunities for further research and advances in the field of mental health care.

1. BACKGROUND

A relatively under-studied area in the field of Mental Health Care is identifying the factors that contribute to continuous use of eHealth interventions for mental health care. In order to design and implement effective interventions, it is important to gain a richer insights about users' perspectives with a special focus on areas such as User-system feedback, Online support, Use of Reminders or prompts, Content of the interventions, Trust and Privacy. Despite bulk of published literature about Internet- and Mobile- based interventions for mental conditions, it appears that there is a lack of transparency as well as unified understanding on the part of system developers as well as researchers (Barak et al. 2009). In recent years, most of the studies in the area of mental health care have focused on areas such as adherence (Kelders et al. 2012), dropouts rates, perceived benefits (Drozd et al. 2012) and persuasiveness of eHealth interventions. Further, the overlap in terminologies as well as imprecise narratives (Langrial et al. 2012) have caused the field to become rather diffused and unnecessarily complex. Yet another issue in the area of mental health care is that there is more focus on technological aspects while designing the interventions and overlooking the significance of incorporating psychological content.

Technological advances have opened new opportunities to develop Internet- and Mobile- based Interventions that can support people suffering from mental conditions including but not limited to depressive symptoms, mild depression, acute depression, hypertension, stress, anxiety, trauma and sleeplessness. Both Internet- and Mobile- based interventions have shown promising results in supporting people with several mental conditions (Mohr et al. 2013). We propose that Internet- and Mobile- based eHealth interventions for psychological betterment is a step farther from more traditional behavior change interventions. Behavior change interventions have been studied and categorized differently; for example, Persuasive Technologies (PT), and Behavior Change Support Systems (BCSSs) (Langrial, 2012). However, we propose that designing an eHealth intervention is perhaps the easier part! The real challenge is to continuously monitor an intervention and make needed improvements by identifying the actual needs of users. In addition, involving users or in some cases their immediate caregivers would certainly help in re-shaping the very paradigm of Internet- and Mobile- based interventions for mental health care.

Information systems that are developed to support behavior and/or attitude change are often studied as digital interventions (Langrial, 2012). We cautiously argue that labeling behavior change technologies as digital interventions is a holistic approach. Research on eHealth interventions dates back to the early 90s where they were predominantly used for preventive medical area mostly through intermediations (paper- based and/or telephonic calls). A large number of studies have been carried out that aim to intervene health- related behaviors. For instance, Revere and Dunbar (2001) highlight that personalized digital interventions are moderately effective. Similarly, Langrial et al. (2014) propose that digital interventions have shown promise in supporting people's behavioral change process.

The research area of designing eHealth interventions that support people in improving mental health has received a great deal of attention (Eysenbach, 2000). Such interventions aim to support users in managing health- related disorders. Presently, different platforms are available for developing behavior change technologies i.e. Internet- and Mobile- based eHealth interventions delivered through portable devices and smart phones (Eysenbach, 2000). Still, the task of designing such interventions manifestly maintains its coherent challenges, for example, how would users interact with a given intervention and how would they process and experience the interaction (Or et al. 2011). Additionally, it is necessary that both researchers and system designers systematically understand how users anticipate benefiting from such technologies, what is their user experience (UX) and what are the factors that encourage them to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

continue using such interventions. The list of challenges in designing eHealth interventions aimed at supporting mental health care goes on like an endless loop.

Designing effective and engaging eHealth interventions is challenging for several reasons therefore designers need to concentrate on the actual needs and expectations of the users. Generally, there is a lack of understanding of theoretical paradigms that are aimed at changing or influencing human behavior (Benbasat, 2010) and, lack of emphasis on HCI- related methodologies being employed during the design process. According to Perkins et al. (2007), systems developed in the HCI discipline are neutral in nature however, this argument is subjective. On the contrary, bringing HCI into eHealth interventions can, for example, improve the aesthetics of the systems/intervention and lead to prolonged interaction. One of the decisive objectives of designing therapeutic eHealth interventions is to effectively support and guide users to achieve enduring self- confidence that would lead to a feeling of self-control and empowerment. Effective strategies influence users and their perceptions when behavior change techniques are supported by Socio- psychological theories. It is for this reason that several researchers from Health Informatics and behavior change technologies have highlighted the importance of theory- driven design for behavior change technologies and interventions (Consolvo et al. 2009).

It is a promising to observe that researchers and system designers have recognized the significance of theories in the design process. For instance, Consolvo et al. 2009 have proposed Theory- driven approaches for designing behavior change interventions and have incorporated the Transtheoratical Model and Presentation of Self in Everyday Life (Consolvo et al. 2009). A detailed conception of Socio-psychological theories is essential in the design process nevertheless there is a technical side for developing and implementing eHealth interventions. As discussed by Andersson and Cuijpers (2009), technical support ought to be incorporated in such a way that the system (intervention) integrates seamlessly in users' everyday lifestyle.

Effectiveness of eHealth interventions that are incorporated with Cognitive Behavioral Therapy (CBT)- based techniques are emphasized in available literature (Seligman & Ollendick, 2011). Practicality of CBT- based interventions for mental well-being is also supported by (Forman et al. 2010). It is frequently proposed that these treatments are superior to other forms of available treatments. Incorporation of psychological components in behavior change interventions has shown promising outcomes. While there are several studies that highlight the practicality of traditional behavioral therapies, Acceptance and Commitment Therapy (ACT)- based interventions are fairly understudied (Lappalainen et al. 2014) despite the fact that Acceptance and Commitment Therapy is recognized for its positive influence on psychological flexibility (Hayes & Strosahl, 1999).

This chapter presents qualitative findings from two field studies that focused on supporting people with sleeplessness (Study I) and moderate depression (Study II). Both the studies were designed to examine the prospective influence of reminders and rehearsal on the efficacy of the web- based interventions that were developed by employing selected persuasive software features and incorporated with Acceptance and Commitment Therapy- based exercises/modules. Sleeplessness and moderate depression were chosen because first, they are interrelated and, second, they are essential for an individual's mental health. Quality of life depends on different factors, and both sleeplessness and depression, if not attended, can lead to serious negative consequences. In this chapter, qualitative findings are reported with an aim to highlight underlying issues that are at times overlooked. The findings are expected to help designers better understand the dynamics of eHealth interventions that are developed for mental health care. For data collection, we used semi- structured interviews and Likert- scale questionnaires. Although, we used SPSS V. 20 to perform statistical analyses on pre- and post- study psychological measures for both Study

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

I and II, however in this chapter only qualitative findings are reported. This is because in the context of healthcare- related research, qualitative methodologies have been promoted as a practical approach. The results from the two studies reveal interesting differences. While the participants of the Study I (Sleeplessness) did not generally find reminders to be helpful, on the contrary, participants of study II (Moderate Depression) largely approved reminders, especially in terms of task completion. In terms of rehearsal, participants from both the studies approved the virtual exercises (ACT- based modules) in terms of learning desirable self- help behaviors. Based on the qualitative findings, we have identified six emerging themes that are expected to open further research opportunities for mental health care researchers.

1.1 Sleep Deprivation

Suitable amount and quality of sleep is necessary for healthy minds. Sleeplessness or insomnia is among serious mental disorders however this area is rather understudied (Langrial et al. 2014; Alhola & Polo-Kantola, 2007). Available literature suggests that sleep deprivation and insomnia are negatively correlated with an individual's intellectual performance (Water & Bucks, 2011; Durmer & Dinges, 2005; Aloha & Polo-Kantola, 2007). According to van Starten and Cuijpers (2009), physical fatigue, mood disorders, emotional anxiety and psychological stress are among the consequences of sleeplessness. It is generally argued that the consequences of sleeplessness and related disorders are alarming (Orzel-Gryglewska, 2010). For example, people who suffer from sleep deprivation face a higher risk of cardiovascular diseases, diabetes, despair and obesity (Faubel et al. 2009). There is a decent amount of litrature that focuses on promoting healthy diet and regular exercise with an aim to improve people's sleeps behaviors (Tang et al. 2010; Purpura et al. 2011; Albanina et al. 2009). However, it is surprising that less focus has been paid on managing sleeplessness and related disorders. It is essential that mental health care researchers accept the stern challenge of designing effective eHealth interventions that have the potential to provide novel health care solutions. The potential effect of Internet- and Mobile- based interventions when combined with Cognitive Behavioural Therapy (CBT) has been fairly well studied and encouraging findings have been reported for people suffering from Insomnia (Ong et al. 2012; Ritterband et al. 2009). Such findings highlight the potential of eHealth interventions that support people with sleeplessness and moderate depression.

1.2 Moderate Depression

Another major mental disorder is that of depressive thoughts, mild and/or moderate depression. It is well-known that sleeplessness and depression are positively correlated (Benca & Peterson, 2008). Depression whether mild or moderate, is among the most widespread mental disorders in modern day world (Johansson & Andersson, 2014; Kessler, 2012). It is a serious mental health condition that affects nearly 350 million people around the world (Lappalainen et al. 2015). Similar to sleeplessness, depression has been reported as a cause of high mortality rates, poor life quality, social isolation and even restlessness (Aromaa et al. 2011; Galatzer-Levy & Bonanno, 2014). Depression has also been correlated with tendency to commit suicide, alcoholism and social stigma (Langrial et al. 2014). Depressive disorders have been estimated to increase the ailment problem substantially by the year 2030 (Kleine-Budde et al. 2013). Health Information Systems (HIS) and Behavioural Psychology are well-studied research areas and provide ample openings for developing novel eHealth interventions for mental disorders such as depression especially by incorporating Cognitive Behavioural Therapies (Aromaa et al. 2011). Current literature

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

underlines that eHealth interventions that are developed for mental health care can be improved when augmented with Cognitive Behavioural Therapy (CBT) (Meyer et al. 2009; Warmerdam et al. 2008).

It is worth noting that various hindrances have been identified that prevents people from using online or more traditional treatments both for sleeplessness and depression. Some of the deterring reasons include but are not limited to low motivation, difficulty in finding psychological experts, lack or absence of professional services, unwillingness to discuss personal matters, high treatment costs and humiliation (Langrial et al. 2014). It is however encouraging to observe that researchers have been working on developing eHealth interventions (both Internet- and Mobile- based) that could help overcome the said limitations. Further, there is substantial evidence in the existing literature about the effectiveness of e Health interventions that employ Cognitive Behavioural Therapy (CBT) (Andrews et al. 2010; Andersson & Cuijpers, 2009). However, interventions that employ Acceptance and Commitment Therapy (ACT) are relatively uncommon (Lappalainen et al. 2015).

2. RELATED LITERATURE

According to Oh et al. (2005) computing technologies provide an appropriate medium to deliver healthcare solutions. This is particularly true because computing technologies support cost effective delivery of innovative methods and practices to promote sustainable healthcare solutions (Kuonanoja et al. 2015). Ritterband and Tate (2009) point out that healthcare interventions that are delivered over the Internet have shown promise mainly in terms of scalability and reduced costs. As a result, Internet- based healthcare interventions have received growing attention (Kraft & Yardley, 2009). Carefully designed eHealth interventions for mental health care can offer innovative solutions that are convenient for people who either cannot reach healthcare professionals or, are not motivated enough to discuss psychological problems in person (Kuonanoja et al. 2015, Langrial et al. 2014). Accessible literature also supports the effectiveness of Internet- based psychological interventions that are integrated with Cognitive Behavioural Therapy (CBT) (Andersson & Cuijpers, 2009). There is an obvious support for the effectiveness of CBT- based interventions for mental health care (Seligman et al. 2011). While Cognitive Behaviour literature underscores substantiation pertaining to the usefulness of CBT- based eHealth interventions, it is remarkable to observe that a few studies have focused on exploiting Acceptance and Commitment Therapy (ACT), which is the latest wave of CBT (Hayes et al. 2005). What makes Acceptance and Commitment Therapy (ACT) an effectual tool is that it is known to improve an individual's psychological flexibility and is therefore positively correlated with improved mental health (Lappalainen et al. 2015; Hayes et al. 2005). Research efforts have been made to comprehend the particulars of eHealth interventions that are developed to support people with mental health conditions including insomnia, depression, stress and anxiety. Researchers from the fields of Information Systems and Human Computer Interaction (HCI) have also developed and evaluated the efficacy of selected software features and their likely impact on task completion (Mohr et al. 2014), user satisfaction (Kelders et al. 2011), task adherence and overall psychological outcomes (Langrial et al. 2014).

HCI researchers have emphasized on designing eHealth interventions/information systems that simplify the process of behavior change. For an instance, Consolvo et al. (2009) support the use of Theory- driven design for such interventions. On the other hand, Choe et al. (2011) propose that information systems, eHealth interventions and technological innovations have the potential to improve mental health care. They further add that designing such interventions is a challenging task therefore there is a need for deeper

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

understanding of different aspects including cultural sensitivities, privacy issues, trust, user perceptions as well as individual drives and routines. While design strategies and broad agendas for theorizing and developing eHealth interventions for improved mental health care are frequently found in available literature, nevertheless it is manifest that the prospective influence of credible software features either in a selected combination or isolation have been generally ignored (Langrial et al. 2014). Reminders and cues have been among the most commonly reviewed software features that can be defined as prompts or triggers (see Masthoff et al. 2013) in the form of text messages, email- based messages, nudges or instant feedback that is delivered to users during their interaction with a given intervention (Lappalainen et al. 2015; Patrick et al. 2009; Neff & Fry, 2009). The effect of reminders could be further enhanced if they were to be supplemented by tailored content, appropriate timing and meaningful content. This could lead to more effective reminders designed for task completion (Schneider et al. 2013).

In contrast to reminders as a software feature, rehearsal/practicing has previously been used mostly in the area of Cognitive Behavior studies. Billet (2010) highlights that channelled learning practices when repeatedly exercised could help formation of new behaviours. Although Billet's work is focused on learning in the context of workplaces, however, we cautiously deduce that appropriate design and employment of learning methods, individuals' enthusiasm to learn and well-designed strategies could lead to the development of new skills and behaviours. Scholars from the field of Psychology have acknowledged cognitive progresses through performance- based processes (Thorpe et al. 1987). The basic idea of rehearsal could possibly be related with "learning through practice". According to Billet (2010), practice (rehearsal) pertains to routine exercise of a given skill, ability or vocation. It is further proposed that learning through practice is not only limited to developing an individual's faculties but equally to enable the user in dealing with existing or new tasks. Hence, we propose that exercising or practicing is related with rehearsal as a technique to learn new skills and behaviours. We have observed that there is little research in the area of mental health care that explores the prospective effect of rehearsal as a software feature. This research gap was identified and helped us in setting the tone for the two field studies concentrating on sleeplessness and moderate depression respectively.

Building upon Fogg's influential work (2002), several researchers have come up with their own theories and models. The Persuasive Systems Design Model (Oinas-Kukkonen & Harjumaa, 2009) is among one of them. Oinas-Kukkonen and Harjumaa (2009) propose that persuasive information systems should encourage users through reminders to perform desired behaviors. They further underline the use of virtual rehearsal as a software feature for assisting users in changing behaviors. Similarly, Fogg (2002) argues that rehearsal is a mean of providing a setting where people can rehearse and learn new behaviours. We propose that the concept of rehearsal as a method to learn new behaviours can be grounded on the Social Cognitive Theory (SCT) (Bandura, 1986). Bandura (1986) proposed that learning process is, "an information processing activity in which information about the structure of behaviour and about environmental events is transformed into symbolic representations that serve as cognitive guides for the construction of complex modes of behavior" (Bandura, 1986, p.51).

A persistent issue in e-Health interventions is low task completion and high dropout rates as pointed out by Eysenbach (2005). However, we have shifted away from a relatively well-studied area such as attrition rates and have focused more on task completion (by analysing the possible effect of reminders) and learning new behaviors (through the use of rehearsal). We propose that task completion is a distinctive phase of interaction that could lead to prolonged user commitment hence reducing dropout rates. Literature highlights valuable information about task completion, however, by emphasizing on the use of material rewards, admiration or social approval, and positive feedback (Volpp et al. 2008). We argue

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

that it is vital for healthcare researchers not to confuse adherence with low attrition or high drop out rates. For example, dropouts generally pertain to participants of a given intervention who do not fulfil the entire research protocol (Kelders, 2013). Eysenbach (2005) describes adherence as the extent to which participants of a given intervention "experience" the content. Adherence has also been reported as the extent to which participants' behaviours balance with the guidance and suggestions enthused by an intervention (Aronson, 2007). These interpretations provide a better understanding of a fairly overlapping phenomenon. However, we propose that task completion can be improved by developing engaging interventions that are supplemented with consequential and meaningful content. In other words, task completion is more about forming compliance, completing anticipated tasks and it could be the first step in overcoming lack of devotion and high drop out rates in the area of eHealth interventions for mental health care. We also propose that both researchers and system developers need to pay meticulous attention to psychological theories in order to recognise causal accounts for high dropouts. Further, it is our conjecture that task completion can not only decrease high dropout rates but can also helps users reach a state of higher self- efficacy leading to self- confidence in learning new skills and performing desired actions. The following part of the chapter highlights our attempts to examine the above-mentioned issues particularly. This is because low task adherence and complications in learning new skills remain a challenge when it comes to mental health care (Mohr et al. 2010).

2.1 The Field Studies

Both the studies were carried out using a mixed- method research approach, which is occasionally known as triangulation and is applied in various disciplines (Östlund et al. 2011; Brewer & Hunter, 1989). In addition, mixed- method approach helps researchers explore research problems by using a blend of qualitative and quantitative methods (Onwuegbuzie & Leech, 2005; Wood et al. 1999). The different methods complement each other by revealing exhaustive results. According to Kaplan and Duchon (1988), mixing qualitative and quantitative methodologies offer a greater understanding for inferring and authenticating research conclusions. Applying qualitative research method is known to be constructive as it helps in reducing uncertainties about analytical views and themes. In other words, it could be taken as a developmental approach that advances the overall understanding of a research problem and helps in gaining expressive responses (Sofaer, 1999). Qualitative research becomes particularly valuable for performing research analyses as it elucidates participants' experiences, behaviours, interactions and their social interactions (Strauss & Corbin, 1990). In the context of mental health care research, qualitative methodology has been highlighted as a constructive approach.

3. PROCEDURES

3.1 Recruitment

Study I was conducted between October 2013 and November 2013. Participants were enrolled through newspaper advertisements. The advertisements elucidated that we were seeking people who were suffering from sleep problems. The eligibility criteria were: 1) Access to Internet, 2) Having an email account, 3) Access to telephone, 4) Not being part of a therapy for sleep disorders in parallel, 5) and aged 18 years or over. In response, 122 individuals contacted the university clinic (Department of Psychology, Uni-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

versity of Jyväskylä, Finland) for initial screening process. From the 122 individuals, 14 were excluded, as they did not meet the inclusion criteria. Another 22 were excluded from the study because of limited research resources. Accordingly, the final number of participants for Study I was eighty-six (N=86).

Study II was carried out between September 2012 and January 2013. Participants were recruited through newspaper advertisements that described that we were seeking individuals who felt depressed. The inclusion criteria were: 1) Self-reported depressive symptoms, 2) Depressed mood, 3) No parallel therapy for depression, 4) Access to Internet, 5) Having an email account and 6) Age 18 years of over. In response, a total of 42 individuals contacted the university clinic (Department of Psychology, University of Jyväskylä, Finland) for initial screening. After initial screening, measurement packages and informed consent forms were sent out to the selected participants. One participant dropped out before the screening process and another two did not meet the inclusion criteria therefore the final number of the participants was Thirty-nine (N=39).

3.2 Ethical Approval

Because both the studies included people with sleep- related issues and depressive symptoms, the studies followed the Declaration of Helsinki and the Research. Further, Ethical Approval was officially obtained from the Ethical Committee at the University of Jyväskylä, Finland and the Central Finland Healthcare District (Diary no: 15U/2012).

3.3 Randomization Process

Randomization for Study II was performed on the 13th of September 2012. The participants were divided into two groups: (1) Intervention group 1 (n=19) that received the measurements, automated reminders and complete access to the weekly rehearsal modules, and (2) Intervention group 2 that first served as a waiting list control group and had to wait for a period of six-weeks before they could access the complete intervention. Although the Intervention group 2 had access to the weekly rehearsal modules, however, they did not receive automated weekly reminders. A total of 28 (71.8%) females and 11 (28.2%) males with an average age of 51 years comprised the total sample. Upon completion of the six weeks from Intervention group 1, login credentials for the intervention were sent to the participants of the Intervention group 2. For Study I, randomization was performed using a randomization tool (https://www.random.org/lists) on the 9th of October 2013. Again the participants were divided into two groups: (1) Intervention group (n=43) that received the measurements, and had complete access to the intervention supplemented with two automated weekly reminders, and (2) Wait-list control group (n=43). For ethical reasons, the Wait-list group received access to the complete intervention but no reminder were sent out. A total of 31 (72.1%) females and 12 (27.9%) males comprised the Intervention sample aged between 24 to 73 years.

3.4 Designing the Web- Based Interventions

The Web- based interventions were designed and developed in partnership between research groups from the Department of Information Processing Science, University of Oulu and Department of Psychology, University of Jyväskylä, Finland. A research team from the University of Oulu was responsible for implementing the software features whereas a research group from the University of Jyväskylä developed ACT- based rehearsal modules for both the studies. Rehearsal as a software feature was used to

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

improve mindfulness, acceptance skills, value- based actions, and psychological flexibility with the help of vigilantly created metaphors, experiential exercises and behavioural activation (Hayes et al. 2006). Table 1 and 2 exhibit an outline of the modules that were used for the rehearsal content for Study II and I respectively.

Table 1. Acceptance and commitment therapy modules for rehearsing to overcome moderate depression

Week	Acceptance and Commitment Therapy Modules Used for Rehearsal
1	Creative hopelessness and values
2	Value-based actions
3	Contact with the present
4	Cognitive defusion
5	Self as context
6	Acceptance

Table 2. Acceptance and commitment therapy modules for rehearsing to improve sleeplessness

Week	Theme	Content
1	Values and value-based actions	Knowing what matters the most for an individual in users' life and acting in accordance
2	The present moment	Living in the present moment (mindfulness)
3	Cognitive defusion	Understanding that an individual's thoughts could be different
4	The observer stance	Learning to view one's thoughts and feelings from an observer's stance
5	Acceptance	Accepting one's feelings, and thoughts and admitting that one cannot change things
6	Summary	Rehearsing ACT exercises from the past five weeks

3.5 Qualitative Data Collection

Upon completion of the Study II, the participants were asked questions about system usefulness, influence of reminders on task completion, effect of rehearsal on learning new behaviors, impact of rehearsal on self-confidence and their intent to practice newly learnt (if any) skills in future. The questionnaire used Five-point Likert-type scale ranging from 1 = Strongly agree to 5 = Strongly disagree. In addition, the participants were interviewed in a post- intervention sitting where their experiences and overall observations were recorded, coded and analyzed. In Study I, participants' experiences with the intervention and its general practicality was evaluated by employing Likert-scale (Likert, 1932) questionnaires at the beginning and end of the intervention. The questions focused on participants' anticipations and perceived practicality of the system (pre- study) while their actual experiences, system usefulness, ease of use, influence of reminders on task completion, effect of rehearsal on self-confidence and impact of rehearsal module to improve sleep behaviors (post- study). Finally, the participants were interviewed (exit interview) in a post- intervention satisfaction survey where their experiences and interpretations were recorded, coded and analyzed.

4. RESULTS

4.1 Moderate Depression

In Study II, email- based reminders were sent to Intervention Group I only, in order to assess how the participants perceived the influence of reminders on task completion. A high majority of the participants (83.3%) approved the reminders and gave encouraging comments that; for example, it is easy to forget important tasks in a chaotic world. Some of the descriptive remarks are listed below:

P1: *Reminders assured me to remember doing the assignments (weekly modules); I use my email very often.*
P2: *They (reminders) reminded me of doing my homework (weekly modules) and I found the link (URL to the system) very handy.*
P3: *Reminders give you a feeling that you are not alone. They encouraged (me) and gave a boost for replying to the (weekly) assignments (modules).*
P4: *In addition to email-based reminders, SMS could be beneficial.*
P5: *Add supportive criticism, enveloping criticism in a way that it won't depress the person.*

Participants from the intervention group that did not receive reminders however they pointed out that reminders would have been useful in helping them completing important tasks. Some of the representative quotes are as below:

P6: *…If one has a tendency towards forgetting things that need to be done (reminders would have helped a great deal).*
P7: *Yes (reminders would have been useful), because I forgot since there were no reminders, the due dates were hard to remember.*

There were some varied comments and a few representative quotes are stated below:

P8: *I did not need to be reminded. I was already committed to the program (intervention).*
P9: *I would try to make the reminders and rehearsal (exercise modules) less demanding.*

Majority of the participants acknowledged the effect of rehearsal in helping them to learn new skills. Some of the representative comments are listed below:

P10: *Exercises (weekly rehearsal modules) were good. All in all, the interaction (experience) was excellent.*
P11: *Weekly themes (modules) were very good. They brought me in touch with my (core) values and I learned to be consciously present in the moment.*
P12: *I found the rehearsal (content) to be supportive. It kept me on track.*
P13: *I think the weekly rehearsal (modules) improved my understanding about life.*

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.2 Sleeplessness

In Study I, 41 out of the 43 participants gave comments about reminders. Some of the representative statements are listed below:

P1: *Reminders worked fine. Adding SMS – based reminders would have been better.*
P2: *The system was good. I found the reminders and rehearsal to be beneficial.*
P3: *I expected a little more from the system. The rehearsals were good and so were the reminders (they were much needed).*

Participants generally appreciated the rehearsal feature as well as its content. Some of the representative quotes are listed below:

P4: *I go to know myself (better) and now I have new (better) viewpoints (about my life).*
P5: *I had no problems with the systems. It was (indeed) a positive experience. The entire program was well built (designed) both technically and content wise.*
P6: *There was a lot of new information. The program provided broad (comprehensive) approaches towards (tackling) sleep problems, it was engaging. Although my sleep problems are still the same, I will continue to rehearse.*
P7: *Rehearsals were easy to use and reasonable (logical). It was (indeed) an interesting experience. Now I can sleep and breathe better.*
P8: *It was a positive experience. Working the exercises (rehearsals) has improved my situation.*
P9: *It was a surprising and exciting experience. I committed myself to the program (intervention) and I learnt new skills.*
P10: *The system (rehearsal modules) taught me to listen, breathe and mediate well. It helped me accept that there are bad times. Thank you.*

Some mixed remarks were also noted. Some of the representative quotes are stated below:

P11: *A little more interaction (prolonged study period) would have been better (desirable).*
P12: *The program (intervention) did not help me. The study period should have been longer.*
P13: *I expected more from the system (intervention). However, my own laziness influenced my learning process.*

4.3 Identified Themes

Based on the collected responses and criticisms, we identified six themes for researchers in the area of mental health care using eHealth interventions:

- **Provision of Positive Feedback:** Participants of a given eHealth intervention appreciate receiving positive feedback. The process of providing the participants with constructive feedback can lead to improved interaction between the users and the intervention. It is generally accepted that positive feedback improves the learning process (Mitrivic et al. 2013). It has also been observed that positive feedback improves the overall interactivity and engagement (Schubart et al. 2011). The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

effect of positive feedback through technological interventions can motivate participants to develop what could be termed as a reciprocal relationship. If this stands true, enhanced adherence could be achieved (Mohr et al. 2011; Ritterband et al. 2009) Therefore, it is important that interventions for mental health care and support offer carefully crafted feedback (content) to the participants.

- **Provision of Constructive Criticism:** People with mental conditions are usually sensitive towards criticism however, some might benefit from it by focusing on the constructive content of the feedback. However, such a strategy would perhaps best suit those individuals who are willing to receive criticism and have the motivation to benefit from it for individual progress (Bergner, 1995). The significance of a balance between using positive and negative feedback (criticism) is also highlighted in several studies (Iwashita, 2003; Cinquin & Demongeot, 2002) This could be an interesting area for further research in the research field of mental health care eHealth interventions.
- **Use of SMS to Supplement Email-Based Reminders:** Email- based reminders could be supplemented with short messaging service (SMS). The use of SMS- based reminders has been recommended for e-Health interventions (Pop-Eleches et al. 2011). The role of SMS- based prompts has also been supported by researchers in the area of mental health care as well as in behavior change (Sims et al. 2012; Neff & Fry, 2009). It is argued that mobile phones are like constant partners therefore making it easier for the reminders to be sent. This could be particularly useful for people who do not have access to computers or they rarely check their emails.
- **Adding Supportive Content to the Reminders:** It is important that people suffering from mental conditions such as depressive symptoms, stress, anxiety and trauma are not left in a situation where they feel secluded. One of the key themes identified from the interviews was that participants emphasized on the need for adding supportive content to the reminders. We therefore propose that when developing the content of reminders, carefully crafted aspects of support and compassion should be incorporated. By adding the element of empathy, we can redesign the interventions that are more of supporting in nature and could lead to desired outcomes including higher adherence or lower dropout rates (Mohr et al. 2011). By virtue, human beings are social animals and the significance of social relationships can never be overlooked. It is hence argued that social relationships are highly significant for mental wellbeing. Sharma and colleagues (2015) also advocate use of proactive thinking in terms of designing supportive and empathetic interventions.
- **Reminding People of Their Core Values:** An intervention should be designed in a way that it prompts people and reminds them of their core values. Further, eHealth interventions for mental health care should assist the users to reflect upon their values (Ploderer et al. 2014). The content of the interventions should be designed in a way that it helps people to recognize what is really important for them, what are their aims and beliefs (Powers et al. 2009). Once people identify their core values, they are more likely to take actions to overcome challenging and impulsive circumstances hence making life easier for them (Kuonanoja et al. 2015). The use of behavioural therapies especially Acceptance and Commitment Therapy underscores the importance of core values in various studies in the area of mental health care (Lappalainen et al. 2014; Räsänen et al. 2016).
- **Engage Users by Developing Logical Content:** Mental health care eHealth interventions should be designed with an aim to provide participants with a rich and engaging user experience (Hefferman et al. 2016). In other words, the content of eHealth interventions for mental health should be meaningful and affective. By adding logical content, it would be easy to involve users emotionally because user engagement depends on elements that include but are not limited to be-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

havioural actions, cognition and threads of logical arguments (O'Brian, 2010). In addition, logical content could perhaps be related with rich user experience (UX). While there is an array of definitions about UX, we propose that UX under the umbrella of Human Computer Interaction could support users in achieving desired goals as well as adhering with the entire period of the intervention. Andersson and Kjerrman (2013) support our proposition by underlining the significance of pragmatic and logical arguments and their influence on task adherence.

5. DISCUSSION

The main objective of the chapter is to highlight qualitative findings from two field studies that focused on two mental conditions namely moderate depression and sleeplessness. In this chapter, participants' subjective considerations about web- based interventions' effectiveness, influence of reminders on task completion, effect of rehearsal on learning new skills and behaviors, and participants' general experiences with the interventions have been underscored with an aim to identify budding themes that could help researchers in designing efficient eHealth interventions for mental health care. It is noted that the participants of both studies generally regarded reminders as being useful. However, a noteworthy finding was the there was a lack of influence of the reminders on the overall psychological outcomes.

Yet, reminders supported participants in completing their weekly tasks (rehearsal modules). Rehearsal on the other hand, markedly enhanced participants' self-efficacy by subsiding cognitive burden and perplexity. The moderately lower influence of reminders could be attributed to the rich, engaging and logical content of the ACT- based rehearsal modules because the participants reported them as highly beneficial and effectual. Yet another reason could be the intrinsic motivation of the participants. This is because notwithstanding the distress from stern mental conditions, they volunteered to partake the studies without any financial enticements. This suggests that people have a natural propensity to look for and try out different means that can help them manage and perhaps overcome mental health care issues.

Whereas lack of effect for reminders was spotted, it is worth noting that some of the participants felt that while receiving the reminders, they were being treated on an individual basis. This is an exciting observation and opens up further research occasions to develop and evaluate tailored reminders. In terms of rehearsal, it was observed that nearly all participants from both the studies not only favoured but also found it as a positive method to learn new skills leading to improved state of self-confidence. This observation is not only supported by the post- study questionnaires and interviews but also by obvious decline in the severity of depression and sleeplessness. Therefore, we cautiously propose that while patients with mental conditions is largely dealt in face-to-face therapeutic sessions, however, vigilantly devised eHealth interventions with no or minimal face-to-face contact can be as effective in treating such conditions. In both the studies, we observed noteworthy improvements in post- study psychological measurements where participants felt better mental state and improved self- confidence to manage such conditions. However, reporting the psychological measurements and their outcomes is beyond the objective and scope this chapter.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

6. LIMITATIONS

Presented work has its limitations. First, an effort has been made to combine the qualitative findings from two field studies with slightly different research settings. The number of participants for the studies are not the same, however, it should be considered that the basic building block of the interventions for both the conditions was Acceptance and Commitment Therapy (ACT) that provides a solid ground to combine the qualitative findings. Second, the entire focus has been paid to qualitative comments and interpretations because reporting the quantitative and psychological measurements was outside of the objective and beyond the scope of this chapter. Further, even though presented work combines two field studies with real patients of moderate depression and sleeplessness, yet the overall sample size is rather small therefore it is hard to generalize the results.

7. CONCLUSION AND RESEARCH IMPLICATIONS

Presented chapter highlights qualitative findings from two field studies that examined the efficacy of reminders and rehearsal in web- based eHealth interventions for sleeplessness and moderate depression. The interventions were incorporated with Acceptance and Commitment Therapy (ACT), which is the latest wave of Cognitive Behavioural Therapy (CBT). Reminders were studied to observe their possible influence on task completion that is proposed to be a way forward to solve the established drawback of high dropout rates in health care interventions. Rehearsal was assessed to find out whether it could improve participants' self-efficacy and self-belief to manage mild to moderate mental conditions. The descriptive quotes underline participants' experiences with the interventions and offer notable insights that can have substantial implications for researchers in the area of mental health care. The chapter contributes to available literature relating with task completion and improved self- confidence and highlights the prospective usefulness of web- based eHealth interventions as a medium to deliver novel solutions for mental health care.

8. FUTURE RESEARCH AGENDA

Worldwide dissemination and acceptance of computing technologies have paved the way for developing novel eHealth solutions that can have a positive impact on the mental health of people suffering from a range of mental conditions. Irrespective of the economic conditions of a country, public access to eHealth interventions has already become a phenomenon. Hundreds of Web- and Mobile- based interventions / applications are available designed to promote general and mental health. However, from researchers' point of view, we argue that the field of eHealth interventions (web- and mobile- based) have various areas that need further investigation. These include the lack of clarity, biased designers' intent, overlapping terminologies, lack of communication between health care researchers, lack of collaborative efforts, overlooking the significance of privacy and ethical issues, and other issues such as continuous monitoring of the interventions, understanding users' expectations, involving users in the design process and trust in eHealth interventions. In future, we are planning to design an eHealth intervention for children's psychological wellbeing in collaboration with psychologists as well as prospective users for their feedback. We also aim to study various constructs especially "Perceived Concerns about Privacy",

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

"Soft Trust", "User Experience" and "User Involvement in the Design Process". We are hopeful that our future studies will lead to advancements in the area of eHealth interventions of mental health and make scientific advances.

ACKNOWLEDGMENT

The authors would like to thank Professor Harri Oinas-Kukkonen, Professor Raimo Lappalainen, the OASIS Research Group (University of Oulu, Finland) and the Research Team from the Department of Psychology (University of Jyväskylä, Finland) for their contribution to the previously published studies. Further, the authors would like to mention that the present chapter is developed from the studies that were supported by the SalWe Research Program for Mind and body (Tekes - The Finnish Funding Agency for Technology and Innovation Grant 1104/10).

KEY TERMS AND DEFINITIONS

ACT: Acceptance and Commitment Therapy.

CBT: Cognitive Behavioural Therapy.

Depression: Feeling of hopelessness, dejection and despondency.

eHealth Interventions: Healthcare solutions offered through technological platforms.

Persuasive Technology: Technologies developed with an aim to persuade people to adopt desirable behaviors.

Rehearsal: Software feature utilized in eHealth interventions to support users perform desired actions regularly.

Reminders: Software features utilized in eHealth interventions for reminding users to perform an action.

Sleeplessness: Lack of appropriate sleep.

Chapter 66
Facebook, Social Comparison, and Subjective Well-Being:
An Examination of the Interaction Between Active and Passive Facebook Use on Subjective Well-Being

Jessica J. Joseph
Mount Royal University, Canada

ABSTRACT

Facebook use has implications for subjective well-being. Previous research has revealed that passive Facebook use is typically related to deficits in subjective well-being, which is thought to be linked through upward social comparison. In contrast, active Facebook use is typically related to enhancements in subjective well-being. The main objective of the present study was to synthesize findings related to Facebook use and subjective well-being and to expand by proposing and testing whether the benefits associated with active Facebook use compensate for the negative effects associated with passive use. The second objective was to discuss policy and research directions. A total of 310 undergraduate students completed an online survey with questions regarding Facebook use, social comparison, and subjective well-being. Bootstrapping analyses revealed that active Facebook use did not buffer the negative effects for subjective well-being that occur during passive Facebook use. Recommendations for future research and education programs are discussed.

INTRODUCTION

Subjective well-being is a phenomenon that is comprised of people's personal evaluations of their lives, including emotional responses to life events, as well as a personal assessment of one's overall satisfaction with life (Diener, Suh, Lucus, & Smith, 1999). Subjective well-being is influenced by many factors (Diener, et al., 1999), but the factor most relevant to the current study is social comparison. Given that social media is pervasive among young adults today and offers, opportunities to connect with friends and

expose them to the successes of others, in other words offering ample opportunities to compare oneself to online friends, it too has the potential to contribute positively or negatively to subjective well-being. There are three aims of the present chapter: First, to provide an overview of how passively and actively using Facebook impacts users' subjective well-being; second, to further investigate these relationships by proposing and testing a model, as well as explore individuals' perceptions of the positive and negative consequences of Facebook use; and third, to provide recommendations for future research and potential policy applications.

AN OVERVIEW OF THE CURRENT LITERATURE

Social media has become pervasive in society today, with the potential to influence psychosocial functioning. Among the most popular of these sites includes the social networking site, Facebook. While on Facebook, users are able to create online profiles that contain personal information (photos, personal disclosures, memories and so on) about the self, which are then broadcasted to a network of individuals that the user deems a Facebook "friend." The content posted by a Facebook user is done so at the discretion of the profile owner and may be updated at any time. The information broadcasted on Facebook is then open to receiving both quantitative (i.e., likes, reactions), and/or qualitative (i.e., comments, messaging) feedback from the user's Facebook friends. Since Facebook was introduced to the public in 2005, the basic function of creating a personal profile, which is then viewed, and responded to, by friends has remained consistent, although Facebook has continued to create features (e.g., reactions, Facebook messenger) that make connecting with friends' content even easier (Gramlich, 2018).

Facebook has rapidly gained popularity since it's induction to the general public. Internationally, over 2.27 billion people visit Facebook every month, with over 1.49 billion visits taking place every day (Stats, 2018). In fact, in October 2018 the Pew Research Centre reported that Facebook remains the most popular social networking site among adults in the United States by a large margin (Gramlich, 2018). Further, Facebook was rated second in the United States (to video sharing site YouTube) for most visited social media website in 2018 (Gramlich, 2018). One of the potential reasons for its immense popularity is that there are a multitude of features on Facebook, as well as a variety of different ways to use the social networking site—all of which offer the user the ability to instantaneously connect with their friendship network. For instance, people can passively observe their Facebook friends by scrolling through the newsfeed, or browsing friends' photos/timelines; this type of Facebook behaviour is typically regarded as *passive Facebook use* (e.g. Ryan & Xenos, 2011; Tandoc, Ferrucci, & Duffy, 2015). In addition, people can engage more actively while on Facebook, such that users are able to disclose information about themselves in the form of photo and status updates (writing what is on a person's mind), as well as sharing links, memories, or memes that one affiliates with. These types of Facebook behaviours are typically referred to as *active Facebook use* (e.g., Ryan & Xenos, 2011). Due to the huge popularity and variety of social functions while on Facebook, researchers have begun to examine how this particular site may actually impact users' subjective well-being.

Early investigations of the relation between Facebook use and subjective well-being presented inconsistent results. Some research indicated that time spent on Facebook may be detrimental to users' subjective well-being (Valenzuela, Halpern, & Katz, 2014; Steers, Wickham, & Acitelli, 2014; Lou, Yan, Nickerson, & McMorris, 2012). Others found that time spent on Facebook may, in fact, enhance subjective well-being (Burke, Kraut, & Marlow, 2011; Valenzuela, Park, & Kee, 2009). Still, others suggested no

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

relation (Benjanin, Benjanin & Dimitijevic, 2014; Glynn, Huge, & Hoffman, 2012; Jelenchick, Eickhoff, & Moreno, 2013). While investigating the discrepancy among the preceding results, researchers found that the direction of the relationship between Facebook use and subjective well-being is dependent on how Facebook is used. Specifically, whether the user was actively (e.g., posting a photo/status update) or passively (e.g., browsing the Facebook newsfeed) engaged while on Facebook.

Typically, passive Facebook use is related to decreases in subjective well-being (Ryan & Xenos, 2011), while active Facebook use is associated with enhancements in subjective well-being (Burke & Kraut, 2016; Csepeli & Nagyfi, 2014; große Deters & Mehl, 2013). In an experiment, Verdyun et al. (2015) dichotomized Facebook use into two conditions, such that participants were asked to use Facebook either solely passively (scrolling through Facebook without posting or interacting), or solely actively (constantly posting, liking, or commenting) for 10 consecutive minutes. At the end of the day, participants were asked to answer questions regarding their affective well-being. The results revealed that participants in the passive Facebook condition experienced decreases in well-being, whereas participants in the active condition did not experience any negative effects (Verdyun et al., 2015). It should be noted that while there are a variety of factors that have been studied to explain *why* passively browsing Facebook leads to deficits in subjective well-being, most researchers agree that the underlying mechanism responsible for this negative relationship is upward social comparison (see Verdyun et al., 2017 for review). As such, the present study focuses on upward social comparison as the mediating variable in the relationship between passively browsing Facebook and subjective well-being.

The Link Between Passive Facebook Use and Subjective Well-being

Humans possess a fundamental drive to compare themselves with others viewed as similar to themselves (Festinger, 1954). Social comparison helps individuals establish their standing (Brown, Ferris, Heller, & Keeping, 2007), as well as provides information about what is considered attractive, acceptable, powerful, popular, and so on (Verduyn et al., 2017). Self-evaluation also depends on how one compares oneself with other people, with the evaluative outcomes depending on whether the comparisons being made are in an upward or downward direction (Major, Testa, & Bylsma, 1991). In upward comparisons, one perceives the other as better on a particular dimension, which typically leads to feelings of inadequacy, jealousy, or negative affect. Downward comparisons, on the other hand, are those comparisons for which the individual perceives the self as better than the target, which typically results in enhancements for subjective well-being.

Empirical research has well-established the influence of social comparison on subjective well-being (Fujita, 2008), such that people's emotions, moods, and subjective evaluations are significantly influenced by how people perceive they compare to the people in their social circle (Gilbert, 2000). When considering the structure of Facebook, where a mouse click can link users to friends' and friends of friends' social media posts, social comparisons can be carried out on an unprecedented scale. Because of this, when individuals passively browse through the social information posted on Facebook they are inundated with the power, popularity, and physical attractiveness exemplified by their Facebook friends and followers, and compelled to compare themselves accordingly (Tandeoc et al., 2015). This may be especially problematic given that Facebook also provides an opportunity for users to set-up, retake, and edit images which allows people to portray themselves in the most flattering ways, also referred to as selective self-presentation (Walther, 2007). When users do selectively self-present online, this can create an exaggerated expectation of power and attractiveness, which are then confirmed and reinforced through

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the social interactions that occur online (Walther, 2007). Evidence suggests that social comparisons, both upward and downward, do exist on Facebook, although only upward comparisons impact subjective well-being (Vogel, Rose, Roberts, & Eckles, 2014). Further, the upward social comparisons that exist on Facebook are consistently associated with deficits in subjective well-being (Nesi & Prinstein, 2015; Steers et al., 2014; Vogel et al., 2014). In other words, while Facebook users passively browse through their friends' information on Facebook they are comparing themselves, on a massive scale, to unrealistic targets, feeling as though they do not measure up, and thus feeling less satisfied in their own lives.

The current literature has well established that passive Facebook use leads to upward social comparison, and ultimately then deficits in subjective well-being (see Joseph, Desjarlais, & Herceg, 2019 for review). It is also clear that actively sharing/interacting on Facebook is at least marginally better for subjective well-being than passively browsing (Verdyun et al., 2015). However, one limitation in the literature is that when Facebook users are dichotomized into either passive or active users, researchers are not able to investigate the interaction effects of passive and active Facebook use on subjective well-being. In effect, this approach neglects the instances where users use some combination of both the passive and active features of Facebook. In a study by Joseph and Desjarlais (2016), participants were asked to indicate how passively or actively they used Facebook on a scale from 1 (*solely passively*) to 10 (*solely actively*). The results revealed that the vast majority of participants reported their Facebook use as a reasonably equal combination of both the passive and active features of Facebook, with some tendency to favour passive Facebook use. Thus Facebook use could potentially be viewed on a continuum where users use some combination of the active and passive features of Facebook, rather than in an either or fashion. Moreover, the findings suggest that all users passively observe Facebook and what differs among users is their level of active Facebook use. Considering that when using Facebook actively, to a greater extent, users exhibit increases in their subjective well-being (Csepeli & Nagyfi, 2014), or at the very least they do not experience the deficits for subjective well-being that are associated with passive Facebook use (Verdyun et al., 2015), the question that arises is: Could actively posting on Facebook compensate for the negative experiences associated with passively browsing Facebook? The current study addresses this question.

THE PRESENT STUDY

There are two main purposes for the current study. First, the author sought to replicate findings in the current literature and provide further support demonstrating passively browsing Facebook leads to upward social comparison, which then leads to deficits in subjective well-being. Second, the present study will expand the current literature by (1) identifying whether the preceding indirect relationship is moderated by active Facebook use by examining whether active Facebook use buffers the deficits in subjective well-being that result from the upward social comparison that takes place while passively browsing Facebook; and (2) examining individuals' perceptions of the positive and negative outcomes associated with using Facebook.

Based on the positive relationship between active Facebook use and subjective well-being reported previous research (Kim & Lee 2011), it is plausible that if users actively post on Facebook they feel better about themselves (Kim & Lee, 2011) and thus be less impacted by the upward social comparison that accompanies passive Facebook use. Specifically, the author hypothesized that: The negative indirect relationship between passive Facebook use and subjective well-being through upward social comparison

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

will only exist if the frequency of active behaviours is low. If the frequency of active Facebook use is high, users who passively use Facebook and negatively compare themselves to their friends will not experience the deficits in subjective well-being.

METHOD

Participants

A total of 310 introductory psychology students from a Canadian undergraduate university (76.77% female) between the ages of 17 and 50 years ($M = 21.21$ years; $SD = 4.26$) completed an online survey between November 1, 2016 and January 29, 2017. Participation lasted approximately 15 minutes as they completed the scales in the order listed below.

Materials

Demographic Variables

The following scales were included to gain information regarding who is using Facebook and how relevant Facebook is relative to other social networking sites, in order to investigate whether the impacts of Facebook use are still meaningful.

Understanding Facebook Use

The Facebook Intensity Scale (FBI; Ellison, Steinfield, & Lampe, 2007) was used to gain a better understanding of participants' Facebook use. The FBI assessed participants' level of Facebook engagement (i.e., the amount of time spent on Facebook), the size of participants' friendship networks on Facebook (i.e., number of Facebook friends), and participants' emotional connection to Facebook. This scale has demonstrated high internal consistency in previous research ($\alpha = .83$; Ellison et al., 2007; Whitman & Gottdiener, 2015).

- *Facebook Engagement*. To measure how engaged participants are on Facebook, the amount of time participants spend on Facebook was measured using the FBI (Ellison et al., 2007). Participants were asked to indicate how much time they spend on Facebook on a scale from 1 (*less than 10 minutes*) to 8 (*more than 3 hours*). Higher scores indicated more time spent on Facebook.
- *Number of Facebook Friends*. To gain an understanding of the size of friendship networks on Facebook across the sample, I used the number of friends subscale from the FBI (Ellison et al., 2007). Participants were asked to indicate the number of friends they currently have on Facebook on a scale from 1 (*10 or less*) to 9 (*more than 400*). Higher scores indicated a greater number of Facebook friends.
- *Emotional Connection to Facebook*. This FBI subscale (Ellison e al., 2007) assessed participants' emotional connection to Facebook. Participants were asked to indicate the extent to which they agree or disagree with six statements (e.g., I would be sorry if Facebook shut down) on a scale from 1 (*strongly disagree*) to 6 (*strongly agree*). The scores were then averaged, where higher

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

scores indicated higher levels of emotional attachment to Facebook. This subscale demonstrated high internal consistency ($\alpha = .88$).

General Social Media Use

To gain an understanding of the popularity of a variety social media sites used across the sample, a social media use scale was created. Participants were asked to indicate on a scale from 1 (*never*) to 7 (*several times a day*) how often they used a variety of social media websites, including social networking sites (e.g., Facebook, Twitter); photo sharing networking sites (e.g., Instagram, Snapchat); messaging networking sites (e.g., Facebook messenger, WhatsApp); and video sharing sites (e.g., YouTube). Higher scores indicated higher levels of engagement for each social media site presented.

Variables Included in the Hypothesized Model

Subjective Well-Being

Chan's (2013) adaptation of Diener et al.'s (2009) Psychological Well-being Scale, which included eight items, was used to assess participants' subjective well-being. Participants were asked to indicate the degree to which they agreed or disagreed with each of the eight statements (e.g., "I lead a purposeful and meaningful life") on a scale from 1 (*strongly disagree*) to 6 (*strongly agree*). The scores were then averaged, where higher scores indicated higher levels of subjective well-being ($M = 5.01$, $SD = 4.41$). This scale demonstrated high internal consistency ($\alpha = .89$).

Facebook Use

To get an accurate depiction of participants' use of both the passive and the active features of Facebook, the author collected the duration of passive Facebook use and the frequency of active use separately.

- *Passive Facebook Use.* Using a single item, participants indicated the amount of time they spend per day passively using Facebook (i.e., browsing their newsfeeds/friends timelines) on a scale from 1 (*Less than 10 minutes*) to 8 (*More than 3 hours*). Higher scores indicated more time spent passively using Facebook ($M = 2.79$, $SD = 0.48$).
- *Active Facebook Use.* Based on previous research assessing active Facebook use (Verduyn et al., 2015; Ryan & Xenos, 2011), the author created an active Facebook use scale for the current study. Participants indicated the frequency that they engage in five of the most prominent active Facebook features: Status updates, sharing links/memories, uploading photos, commenting on friends' posts, and like/reacting to friends' posts. Participants indicated how often they use each of the preceding five active features during a typical Facebook session on a scale from 1 (*never*) to 7 (*always*). The five scores were then averaged and higher scores indicated higher frequency of active Facebook use ($M = 3.24$, $SD = 1.18$). This scale demonstrated high internal consistency ($\alpha = .86$).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social Comparison

To assess participants' level and direction of social comparison while on Facebook, Allan and Gilbert's (1995) Positive and Negative Social Comparison Scale was adapted to be specific to Facebook. To address upward social comparison specifically, participants were asked to indicate on a scale from 1 (*never*) to 6 (*always*) how often they feel 11 negative constructs (e.g., inferior) when comparing themselves to their Facebook friends. The negative comparison scores were averaged for a total upward social comparison score, where higher scores indicated higher levels of upward social comparison on Facebook ($M = 2.71$, $SD = 1.07$). This scale demonstrated high internal consistency ($\alpha = .95$).

Supplementary Information

Qualitative Question

For supplementary information regarding participants' perception of the positive and negative consequences of Facebook use, one qualitative item was created. Participants were asked to reflect on their Facebook use and determine how Facebook has been either positive or negative in their lives. This was an open-ended question that was coded for common themes among participant responses.

RESULTS

Describing the Sample

To gain information regarding who is using Facebook and whether investing the impacts of Facebook use is still meaningful, frequency procedures were run on all demographic variables. The five most frequently used social media sites included Facebook ($M = 6.12$, $SD = 1.24$), Snapchat ($M = 5.92$, $SD = 1.90$), Instagram ($M = 5.81$, $SD = 1.98$), YouTube ($M = 5.18$, $SD = 1.72$), and Twitter ($M = 3.07$, $SD = 2.48$). Furthermore, as depicted in Table 1, participants were avid users of Facebook, who typically had over 400 friends (45.2%). Although participants were frequently engaged on Facebook, they were not typically emotionally connected to Facebook.

Testing the Model

The hypothesis was tested via bootstrapping analyses using the SPSS PROCESS macro developed by Hayes (2013). The bootstrapping analyses created a 5,000 participant sample from the original data set through a process of sampling with replacement, and constructed a 95% confidence interval (CI) around the proposed indirect effects. Indirect effects were significant when the range across the CI's did not contain a zero (Hayes, 2013).

It was predicted that the indirect negative association between passive Facebook use and subjective well-being, through upward social comparison, is moderated by active Facebook use. Active Facebook use was predicted to buffer the negative association between upward social comparison and subjective well-being after passively using Facebook. The hypothesis was analyzed using model 14 of the PROCESS macro (Hayes, 2013). This model simultaneously added active use, passive use, upward social

Table 1. Results for understanding Facebook use

	%
Time Spent (in Minutes)	
< 10	16.1
10 – 30	30.6
31 – 60	23.5
60 – 90	10
Number of Friends	
251 – 300	10.3
301 – 400	13.9
> 400	45.2
Emotional Connection to Facebook	
Not emotionally connected	57.3
Somewhat emotionally connected	22.7

Note. $N = 310$. % = Percentage of participants who reported each category.

comparison, and the interaction between upward social comparison and active use as predictors of subjective well-being. The analysis revealed that the overall model was significant, $F(4, 305) = 5.166$, $p = .001$, $R^2 = .122$; passive Facebook use was positively related to upward social comparison ($B = 0.095$, $t = 2.400$, $p = .017$), which was negatively related to subjective well-being ($B = -0.194$, $t = 4.053$, $p < .001$). Further, active Facebook use was positively related to subjective well-being ($B = 0.106$, $p < .05$). The interaction between upward social comparison and active Facebook use however, was not significant ($B = 0.051$, $t = 1.112$, $p = .267$). An index of moderation was also calculated (Hayes, 2013) and it was not significant, 0.005, $SE = .005$, 95% CI [-0.002, 0.019]. Thus, the moderated mediation did not occur, and deficits in subjective well-being that came from the upward social comparison that accompanies passive Facebook use were not buffered by active Facebook use.

Qualitative Analysis

The qualitative item was coded for major themes based on the frequency in which participants referred to specific subjects in their responses. A total of 292 of the 310 participants responded to this question. Multiple themes were identified for each participant. Overall, 125 participants indicated that Facebook was both positive and negative in their lives. In addition, 110 participants indicated that Facebook was only positive in their lives, 33 participants indicated that Facebook was only negative, and 24 participants indicated that Facebook did not affect them.

In total, 226 participants reported that Facebook positively impacts their lives. The most prominent positive outcomes reported were as follows: Relationship maintenance ($n = 193$), anytime participants indicated that they found Facebook was positive because they could be in touch or connect with their friends and family, this was coded as relationship maintenance; entertainment purposes ($n = 52$), anytime participants indicated that they found Facebook positive because of the news, memes, videos, or quotes found on the SNS this was coded as entertainment; and posting information about the self (n

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

= 7) anytime participants indicated that Facebook was positive because of the ability to post or share information about themselves, this was coded as posting personal information on Facebook.

On the other hand, 156 people reported that Facebook negatively affects their lives. The most frequently reported negative outcomes were as follows: Spending too much time on Facebook ($n = 64$), anytime participants indicated that they spent too much time, or waste their time on Facebook, this was coded as spending too much time on Facebook; negative social comparison ($n = 36$), anytime participants indicated that they negatively social compare on Facebook, or that they feel worse about themselves after comparing to their Facebook friends, this was coded as negative social comparison; and feeling bullied ($n = 8$), anytime participants indicated that they feel bullied, marginalized, or received mean comments on Facebook, this was coded as feeling bullied.

DISCUSSION

The purpose of the current study was to identify whether the positive effects of active Facebook use compensate for the negative effects of passive use on subjective well-being. Consistent with previous studies, and the fact that users in this sample typically reported that using Facebook positively impacted their lives, actively posting on Facebook was associated with enhancements for users' subjective well-being. Contrary to expectations however, the benefits associated with actively posting on Facebook were not strong enough to compensate for the deficits in subjective well-being that are produced by the upward social comparison that accompanies passive Facebook use.

Replicating previous findings, passively browsing Facebook led to increases in upward social comparison, which then led to decreases in subjective well-being. In addition, there were participants in this sample who referenced that negatively comparing themselves to their Facebook friends as a negative outcome for using Facebook. These findings reaffirm the negative consequences for subjective well-being that accompany passive Facebook use.

Although active use was associated with enhancements to users' subjective well-being, the enhancements were not strong enough to buffer the deficits in users' subjective well-being after passively browsing Facebook and negatively comparing themselves to their Facebook friends. In general, there are inconsistencies in the literature regarding whether active use does in fact enhance subjective well-being (see Verdyun et al., 2017 for review). Among the studies that have found that active Facebook use enhances subjective well-being, a commonality among them is including Facebook messaging when measuring active Facebook use (Ryan & Xenos, 2011; Kim & Lee, 2011). In fact, in a recent review of the relationship between Facebook and subjective well-being, active Facebook use was categorized as actively self-disclosing through communicating with Facebook friends (Verdyun et al., 2017). Considering that it is self-disclosure via communicating online has been linked to increases in friendship quality (Desjarlais & Joseph, 2017) and subjective well-being (Valkenburg & Peter, 2009), and that communication with friends on Facebook is typically accomplished through the chat and messaging and features (Pempek, Yermolayeva, & Calvert, 2009), it may be that the posting of photos, status updates, memes and so forth used to measure active Facebook use in the present study did not capture enough meaningful self-disclosure to enhance users' subjective well-being enough to compensate for the observed negative effects.

In addition, it may also be that how and why people use Facebook is evolving. In early Facebook research, social networking sites such as Facebook were typically used to publically share information to offline friends (boyd & Ellison, 2007), as well as maintain friendships (Davis, 2012). In the present

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

study, although users reported that Facebook positively impacted their lives via some form of relationship maintenance, few people reported using Facebook to post information about themselves or communicate with friends in any deep or intimate way. In fact, users more frequently reported enjoying the funny, or inspirational, memes and videos on Facebook than communicating or disclosing with friends. Furthermore, only one participant mentioned using social networking sites to express themself, and they indicated that they used Instagram and Snapchat to do so. In fact, more recent research has shown that Instagram and Snapchat are more popular than Facebook messenger (Lee, Lee, Moon, & Sung, 2015), especially among adolescents (Gramlich, 2018). Given the rise in popularity of Instagram and Snapchat among adolescents and emerging adults (Lee et al., 2017), it may be that Facebook is no longer being used to disclose information, but rather be entertained with friends online, and that disclosing about oneself on social media may now take place on either Instagram or Snapchat, which are more photo and feedback based sites as opposed to the sharing of content/memes that occur on Facebook.

Despite the rise in popularity of other social networking sites like Instagram and Snapchat, young adult users in this sample did report using Facebook more frequently than the preceding sites. However, due to the changes in the how people are using Facebook, it may be that studying the effects of actively posting on Facebook may not be as meaningful as it was in earlier studies. To clarify whether actively using Facebook enhances subjective well-being enough to buffer the deficits in subjective well-being associated with passively browsing Facebook, future research will need to target the features of Facebook that allow for meaningful communication and self-disclosure such as direct messaging via Facebook messenger.

RECOMMENDATIONS FOR RESEARCH AND POLICY

Although previous researchers have advocated for encouraging posting on Facebook to decrease the likelihood of experiencing negative effects, the results of the present study indicate that posting photos, status updates, and memes on Facebook are not enough to compensate for the negative effects from the upward social comparison that occurs while browsing Facebook. Therefore, the way people use Facebook is evolving and these changes should be reflected in how researchers study the effects of Facebook in future research.

As suggested in previous research, support networks such as clinicians, educators, and parents should be aware of negative consequences associated with browsing Facebook. If members of an individual's support network are aware of the effects on subjective well-being associated with browsing Facebook, they could encourage emerging adult users to lessen their browsing behaviours, or encourage them to recognize and avoid the negative social comparison that results from passive browsing. It should also be noted that the upward social comparison that occurs while passively browsing only accounted for 12% of the variability in subjective well-being. Thus, the effects found in the present study are meaningful, but not large enough to warrant a complete boycott of Facebook. Additionally, relatively few people in this sample recognized that they engaged in upward social comparison when using Facebook, and thus awareness alone may be enough to alleviate the deficits in subjective well-being and related constructs such as depression and loneliness.

In addition to awareness, positive strategies for coping with the upward social comparison that occurs online could also be promoted. For instance, Facebook users could be encouraged to develop self-compassion using mindfulness techniques while on Facebook (Rumsey, 2018). Given that social

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

comparison is an automatic process (Festinger, 1954), perhaps especially on Facebook (Vogel et al., 2014; Feinstein et al., 2013), users could be encouraged to employ mindfulness skills once they notice they are comparing themselves to their Facebook friends. For example, users could be encouraged to overcome any negative emotions by taking a moment to practice expressing gratitude for the things they do have, and compassion for themselves (Rumsey, 2018). Further, social comparison theory states that upward social comparison can be used as motivation for self growth and improvement (Festinger, 1954). As such, users could be encouraged to use the target's information to create goals for themselves and promote personal growth as opposed to feelings of inadequacy (Rumsey, 2018).

Social media users could also be encouraged to manage their Facebook newsfeeds to set themselves up for more positive experiences while browsing. In essence, users could organize the content they are exposed to on their Facebook newsfeeds by setting boundaries and removing content that triggers negative emotions. For example, users could block, or unfollow any accounts that make users feel badly about themselves (Rumsey, 2018). This could include removing friends, or celebrities, that consistently present themselves as perfect, removing friends who constantly boast about body image, or removing people that represent a negative part of their past, such as a former partner (Miller, 2017). In addition to blocking or unfollowing, which are more permanent forms of removing users on Facebook, in December 2017 Facebook unveiled a 'snooze' feature to help users organize their newsfeeds and prevent negative experiences (Muraleedharan, 2017). This feature allows users to take a 30 day break from Facebook users by temporarily unfollowing them for 30 days.

In what context should these techniques be taught and/or employed? Given that, roughly 85 percent of American adolescents (13-17 years) are exposed to online social environments (Anderson & Jiang, 2018), and that social comparisons and peer feedback is an imperative part of adolescents' self evaluations and development (Harter, 1999), an ideal setting to start conversations about the impact of social media and employ these techniques would be as part of the educational curriculum in middle schools. For instance, in May 2018 the New Democratic Party in Alberta, Canada suggested that the government donate 5 million dollars to Alberta schools to implement mental health education in schools (Ferguson, 2018). These programs were developed in response to complaints from parents and educators regarding the need for mental health programing in schools, and are aimed at reducing mental health stressors, including the stressors students face while on social media (Ferguson, 2018). These mental health programs could potentially then offer a venue for educators, parents, and counsellors to inform adolescents about the upward social comparison that occurs on Facebook, and the consequences for subjective well-being that ensue, possibly before social media becomes ubiquitous in their daily routine. Further, these programs could promote the preceding positive strategies that could act as protective factors and enable youth to combat the consequences for subjective well-being that accompany passive Facebook use. In essence, programs like these could be implemented in schools across North America to help young social media users avoid these deficits in subjective well-being.

CONCLUSION

A clear theme in the current literature, and consistent with the results of the present study, is that passively browsing Facebook leads to upward social comparison, which then leads to deficits in subjective well-being. Further, active Facebook use may produce some enhancements for subjective well-being, albeit not enough to compensate for the deficits associated with passive use. While the effects are not

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

large enough to encourage users to boycott Facebook altogether, users should be aware of the negative consequences for subjective well-being that accompany passive Facebook use. An avenue to spread awareness and employ protective strategies, such as using mindfulness skills and controlling content while browsing Facebook, would be in the education system. Given that parents, educators, and clinicians have advocated for mental health programs in schools, and that there is some notion of progress in some Canadian provinces (Rumsey, 2018), the author proposes that the consequences for subjective well-being associated with Facebook use, and the skills to combat them, be incorporated into such programs across North America.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. The author would like to acknowledge the support and guidance of Dr. Malinda Desjarlais during the completion of this project.

KEY TERMS AND DEFINITIONS

Active Facebook Use: An approach by which Facebook users interact with other users through sharing textual and pictorial information, sending messages, and reacting to others' posts. Instances where the targets of social comparison appear to be doing better than oneself.

Downward Social Comparison: Instances where the targets of social comparison appear to be doing worse than oneself.

Passive Facebook Use: An approach by which Facebook users surveil others through scrolling the newsfeed and browsing timelines.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Selective Self Presentation: The idea that users are able to manipulate the information presented about themselves on social media so that it is framed in the most attractive, desirable, socially acceptable way.

Social Comparison: A process by which individuals compare themselves to others as means of gaining information on what is most popular and acceptable, then making self-evaluations based on these observations.

Social Media: Any technological medium that enables individuals to connect with their social networks (e.g., texting, e mail, social networking sites).

Subjective Well-Being: The evaluation of one's own life including an assessment of overall life satisfaction and emotional responses to life events.

Upward Social Comparison: Instances where the targets of social comparison appear to be better than oneself.

Chapter 67
Interpreting in Mental Health, Anything Special?

Hanneke Bot
Independent Researcher, The Netherlands

ABSTRACT

This article discusses some of the key issues of mental health talk in general, both in attitude as well as in words, and dwells upon the difficulties this can pose for interpreters. Subsequently, ways to deal with these difficulties are given. The issue of empathic stress is touched upon. It is argued that, with general background knowledge of disorders and treatment methods and with support to deal with emotional situations, interpreting in mental healthcare will be a very rewarding type of work. Without such preparation and ongoing support, interpreters may not always be able to join into the therapeutic communication properly, which may harm the progress of the treatment and may also hamper their own feelings of well-being and job satisfaction.

INTRODUCTION

The medical sector is a wide and differentiated field. So, it is probably true that each medical specialisation poses specific challenges to interpreters and has its own specific requirements for them. In this chapter, the focus is on interpreting in mental healthcare which differs from the somatic sector on at least one very important point: complaints can nearly only be expressed in words, next to some additional observation of behaviour. Analyses of various bodily fluids, palpation, testing of reflexes, listening to bodily sounds et cetera are relevant in the somatic realm; in mental healthcare only as far as somatic checks relating to medication are at hand. In mental healthcare there is a strong dependency on words in interaction with the patient for both diagnosis and cure. For interpreters this implies a heavy responsibility. The objective of the chapter is to provide the reader with some background knowledge of the characteristics of mental health talk in general and the specific ways interpreters have to relate to these in order to do a good job and to ensure long lasting job-satisfaction.

Some of the key issues of mental health talk in general; both in attitude as in words will be outlined. After that, the influence of these issues on the attitude of the interpreter is described in some depth and the amendments that interpreters may need to make – deviations from most Codes of Conduct – in order to ensure effective communication. Following that, some problems that the words of both therapist and patient may give the interpreter, are outlined in some detail; solutions are discussed. Specific problems, interpersonal and emotional, can arise in mental health talk due to what is called 'empathic stress' and this is discussed as a third aspect. Empathic stress may pose a challenge to the emotional welfare of the interpreter and may affect his proper functioning in the sessions. As far as possible, issues are illustrated on the basis of scientific investigations of interpreter mediated mental health talk or on basis of the authors ample experience with interpreter-mediated mental health talk as a practising psychotherapist working with patients with severe psychiatric disorders and her discussions with interpreters both while working together in actual mental health talk and in training situations.

MAIN FOCUS OF THE CHAPTER

Within the field of mental health care there is much variation in aim, method and style that is impossible to capture in a single chapter. Necessarily, the focus is on the general characteristics and three important aspects of mental health talk.

The Therapeutic Relationship and Therapeutic Interaction

Psychotherapy both refers to a general psychotherapeutic conversation technique and to specific treatment methods.

First and foremost, in both modes, attitude is of utmost importance and there is remarkable agreement amongst the various schools of psychotherapeutic thought about how this attitude should be. The basic characteristics of the attitude of the therapist are: understanding and non-judgmental. The therapist has a positive approach, he conveys empathy, he is authentic and shows a healthy trust in his own treatment methods.

In fact, this psychotherapeutic attitude is seen as the 'common factor' in psychotherapies which, together with the relationship between therapist and patient, has proven to be the most important factor contributing to therapeutic improvement (Wampold, 2010; Wampold & Imel, 2015). Since the early 80's of last century, therapists' qualities as perceived by patients have been given research attention. Rating scales have been developed and the most important factors (does the patient see the therapist as attractive, trustworthy and as an expert) determined (Corrigan & Schmidt, 1983). Evidence is arising that the early (immediate) impression the patient has of the therapist has a significant effect on the outcome of the therapy (the better the impression, the better the outcome) (Reefhuis et al., 2019).

The relationship between therapist and patient is an asymmetric one. The patient talks about his problems and innermost feelings, thoughts and behaviour. The therapist listens and his reactions are directed at understanding the patient and helping him to improve. Sometimes, however, some talk about himself, by the therapist, can be helpful in the therapeutic process. In psychotherapeutic terms this is called call 'self-disclosure' and it may be used as a technique.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Secondly, therapeutic talk focuses on problems that are usually not spoken about frankly and openly in everyday social talk. Therapeutic topics are often connected with feelings of shame, guilt, aggression, jealousy; feelings that one usually finds difficult to admit and speak about.

Thirdly, therapeutic talk deals with feeling, thinking and behaving and focuses on changes that specifically fit this particular patient. Patients will only adhere to new ways of behaving, thinking, feeling, when these new ways feel 'good', are 'fitting' and when they have been actively involved in the process of finding, discovering and experiencing these new ways. This implies that therapists usually do not prescribe (new ways of feeling, thinking and behaving) but negotiate, suggest and in general encourage the patient to actively cooperate in finding these new ways. And sometimes, therapists just listen.

On top of this, the development of the interaction between therapist and patient and the evaluation thereof by the therapist, is a diagnostic tool in itself: it helps the therapist to understand some of psychological and relational problems and the psychodynamics of the patient. The (developing) interaction is also an important constituent part of the patients cure, as a 'corrective emotional experience' (term coined by Alexander & French, 1946). For example, the simple fact that the therapist has a genuine interest in the patient and his problems and listens actively and carefully can be a completely new and healing experience to a patient with a history of neglect and abuse.

Therapeutic Communication: Therapists Interventions and Patients' Utterances

As far as the words are concerned, the focus in this chapter is on general characteristics of psychotherapeutic talk, using mainly the classification of Hill called the Hill Counsellor and Client Verbal Response Modes Category System (Hill, 1986), which is meant to be pan-theoretical. The various psychotherapeutic schools of thought that have developed over the last century each have a specific terminology and a specific way of phrasing interventions of which only some salient features are mentioned.

Therapists phrase their interventions cautiously and meticulously and they listen carefully to the words the patient utters and observe his non- and paraverbal behaviour in order to build the therapeutic relationship, to involve the patient in the treatment and to make sure the treatment becomes a proper corrective emotional experience. Therapists do not only listen to the content of the patients' words, but also to how the patient phrases his utterances and which words he uses. He is also attentive to what the patient does not say.

In the 1980's Hill developed a pan-theoretical categorisation system that could and has been used both for research and for training (Hill, 1986). Very briefly, Hill's categories comprise the following. Therapists encourage the telling of the patient with minimal continuers such as mmm, yes, and go on. Silence is also used as a technique: the therapist listens and does not immediately react to patients' words. Either because he expects more to come, or because the thinks about what to say next or because he just feels some pause is necessary. Therapists give approval and support, they sometimes give information, they may give instructions about the therapeutic process itself or because homework needs to be done (exercises for example in behaviour therapy). They reformulate what patients just said and reflect on what has been expressed. Therapists ask numerous questions, both open and closed. These can be questions into facts or past events, or for feelings felt or they probe for feelings underlying the facts and happenings, or for feelings underlying the expressed feelings or they ask for a reflection on those feelings. They can also give feedback. Self-disclosure and social talk are also part of the toolbox of therapists. From this very brief overview it already becomes clear that there are many categories that are not as easy to understand and to differentiate between. Maybe it suffices to say that therapists' questions are

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

often geared to explore, dig up and understand feelings and thoughts that are hidden under the surface talk about facts and actions and that are often difficult to talk about.

On top of these categories, therapists also shape, at least partly, their attitude in words. They do this, for example, by using phatic communication, i.e. the use of words to build up social contact while it does not add to the content of the conversation. This often takes the form of short introductory statements to an interventions like 'you just said…'. Although those words do not add information to the conversation, they signal reciprocity, they signal 'I heard you' and thus add to the building of rapport.

Many therapeutic schools of thought exist, each with their own treatment methods. Most of them use specific vocabulary to phrase their interventions; often, ordinary words are used in a specific way with a specific meaning.

The reactions of patients to therapists' interventions are, of course, not bound to specific rules belonging to the school of psychotherapy they are treated in. For therapists it is important to know when their patients have a specific language-use that deviates from general norms. For example, are they using words that they have invented themselves, are they incoherent in their talk, speak unusually ungrammatical and so forth. Also, grammatical issues like speaking in a passive or active tense, are important. Does the patient speak about himself as an acting person, or as someone who is passively undergoing ('victim') things that happen (to him)? Does he maybe speak of himself in the third person? Does he use a specific style? Therapeutic listening comes to close 'reading' of what the patient conveys.

Empathic Stress

People who work a lot with other peoples' traumata, like physicians, nurses, psychotherapists and emergency workers, may develop symptoms in response to their patient's suffering. It can make them ill and it can also influence their attitude towards the work they do and the patients they treat: empathic stress.

The stress that their patients are experiencing is sometimes that overwhelming that health providers find it difficult to remain stable and professional. The originally felt empathy and compassion can turn into unproductive reactions and negative feelings and thoughts (such as disbelief, 'they are overdoing their stories') or they may feel their own effort is not enough and may feel helpless facing so much misery and start to do more than they should do like helping with practical issues (over-committed). The phenomenon has been thoroughly investigated for all sorts of health providers (see for example Pearlman & McCann, 1990; Pearlman & Mac Ian, 1995). Specifically, the empathy, necessary to understand the patient, is a risk factor for developing symptoms (Palm et al., 2004) which may not only lead to an unproductive stance in the work these health workers are doing but may also lead to their own burn-out due to secondary traumatisation.

It is not difficult to see that when an interpreter is engaged in the process of therapeutic talk, this will have an impact on the therapeutic relationship and on the interaction which are both shaped in words, but also in all sorts of nonverbal and paraverbal behaviour.

What Does This Mean for the Interpreter Attitude?

A Workgroup

In general, it means that interpreters have to be aware of the fact that in mental healthcare sessions, building, analysing and working with the relationship between therapist and patient is the main constituent part

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the cure. This relationship is shaped both with words and with gesture, gaze, posture and paraverbal means. Interpreting in such a situation means that the interpreter becomes part of this relationship – irrevocably, whether the interpreter wants this or not. In order to help the treatment, it is important that the interpreter plays a constructive role – supporting the therapeutic attitude.

How should this be done? It is important that the behaviour of therapist, interpreter and patient is well attuned, all for the common goal of a smooth-running session. A theoretical background to this importance of the cooperation between all three participants – therapist, interpreter and patient - comes from the group dynamical work of the British psychiatrist Bion in which he defines the term 'workgroup' (Bion,1961). A 'workgroup' is a group of people who work together constructively to achieve a common goal, it implies that they know how to solve problems in the cooperation might they arise. The trio therapist – interpreter - patient should function as a 'workgroup'. According to Bion, the formation of subgroups within such a group, is counter-productive. One person being out of tune may disrupt the working process. When in such a workgroup problems in the cooperation arises, they will be solved openly and effectively. For example, in a workgroup of therapist, interpreter and patient it sometimes happens that a patient does not agree with his therapist or with another professional he has to deal with, or with the interpreter. The patient may be angry with the therapist for example for not granting an extra session or with the co-treating psychiatrist for not prescribing certain medication, or with the interpreter for not 'translating well'. Any of these issues needs to be solved, not by siding with the patient against the person he is angry with – a subgroup would then emerge - but by talking about the issue at hand and encouraging the patient to deal with it. So, the issue about the extra session needs to be talked about with the therapist; the patient has to be encouraged into telling his psychiatrist that he is not happy with the medication he gets and thus finding out if anything can be done about it. And the problem with the interpreter can be talked about in the session with as a starting point: the interpreter tries to interpret faithfully but he might have misunderstood or misheard. How can we solve this? What did you mean to say? And of course, the interpreter has to interpret this discussion to both sides. Siding with the patient may seem helpful at first, the patient feels supported at that moment. But such formation of a subgroup hampers the cooperation within the group patient-interpreter-therapist or within the group of people involved in the treatment of this patient. And the patient does not learn to solve problems that arise in any relationship and that have to be talked about in order to make the relationship long-lasting and sustainable and the workgroup repaired. It means that the interpreter has to know and understand this principle and has to be willing to engage is such a discussion.

In order to be able to function as a workgroup it is necessary that the therapist and interpreter know about each other's 'trade'. The therapist has to understand that he cannot ask the interpreter to function as a 'cultural informant' as that would be way out of the interpreters' job description. He also has to know that 'faithful interpreting' does not mean that the interpreter renders a 100% equivalent of the patients (and the therapists) words. They both have to understand that it is sometimes necessary to meta-communicate about the meaning of words. And interpreters have to know that they sometimes have to step out of their role of neutral and uninvolved participants, in order to support the flow of communication in the session. Being too neutral can hamper feelings of security and thus the free flow of the conversation.

The First Impression

Patients' first or early impression of the therapist is a codeterminant for a positive treatment outcome. It seems safe to extrapolate these finding to the interpreter: a good first impression of the interpreter

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

helps to create an atmosphere in which the patient feels free to talk about sensitive issues. The three most important factors that are used to assess this first impression are: is the therapist seen as attractive, trustworthy and as an expert. These three factors are measured by asking the patient to rate the therapist on 12 factors: friendly, likeable, sociable, warm, experienced, expert, prepared, skillful, honest, reliable, sincere and trustworthy (Tracey et al 1988). It is wise for interpreters to keep these in mind. Although it is hard to tell how exactly one should manipulate one's behaviour in order to make this good impression, it is good to bear in mind that a favourable score on these factors may help in being experienced as professional and that this helps to create a favourable environment for treatment.

The Therapeutic Attitude and the Interpreter

Sometimes it is necessary for an interpreter to step across the line of non-involvement in order to fit into the therapeutic attitude. For therapists, some social talk and sometimes also self-disclosure, i.e. saying something about oneself (facts, opinions, feelings), is a necessary ingredient to a therapeutic session, to ease the conversation and strengthen the relationship. For interpreters counts the same. The next example shows that trespassing the neutrality-boundary can be helpful.

In a Dutch mental hospital setting, a therapist is working with a young woman from a war torn country. She has been heavily traumatised, she is psychotic and some personality problem is assumed. She feels 'the enemy' is still everywhere around her. The sessions with her are difficult as she mistrusts everyone, but especially her country-people. In the session here described, a female interpreter is involved. The interpreter is of Dutch origin and the therapist knows that. The patient, as expected, is mistrustful and wants to know where the interpreter comes from. The interpreter, professionally, renders this to the therapist and suggests she tells the patient she is Dutch. The therapist agrees, hoping this will diminish patients' distrust of the interpreter. The interpreter tells the patient she is Dutch and studied her language in the Netherlands.

So far so good. Here we see an interpreter who deals professionally with a request to cross a professional boundary. In 2003, I already wrote about this phenomenon (Bot, 2003):

In the psychotherapeutic literature, the difference between boundary transgressions and boundary violations is made (Gutheil & Gabbard 1993). Violations are crossings of the boundaries that are harmful to the patient and his or her treatment, while transgressions are made within the context of ethical and adequate treatment. In psychotherapy, it has become clear that boundary transgressions can be initial steps leading to boundary violations when the therapist has not specifically defined why this transgression can be made in this specific situation (Gutheil & Gabbard, 1993).

The boundary transgression in this case consisted of some self-disclosure that was in this case useful to therapeutic relationship building and meant to do just that by the therapist. Boundary transgressions are OK, but also tricky, as the sequel to the above example shows.

The above situation continues, and suddenly the therapist finds himself listening to an entire discussion in a language he does not understand. Sometime later the interpreter renders this to the therapist. They have been talking about the quality of some specific food that is much better over there than in the Netherlands. The interpreter then tells the patient that she regularly receives parcels with this specific

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

product from friends. This sparkles patients' mistrust again: as the interpreter receives parcels, she must have contacts with the secret service – is my patients' reasoning.

Here we see that, just as Gutheil and Gabbard (1993) warn for, one transgression leads to the next. The therapist knew why the first transgression was useful. The interpreter not trained in the intricacies of therapeutic boundary keeping and the ins-and-outs of this patient's diagnosis and treatment, was not aware of that and, seemingly happy to talk about some common interest, continued far beyond the first useful self-disclosing intervention. Informally, amongst therapists, the golden rule is to 'never volunteer information': answering a question from a patient is one thing, taking initiative in giving information about oneself is quite another. Not only can it give rise to undesired effects, as in the above example, it also directs the attention to oneself – and there it should not be – and turns the therapeutic sessions in a friendly tea-party. Self-disclosure should always be functional: concise, helping the therapy to takes a proper course.

In the above example, the patient addressed the interpreter directly, stemming from strong distrust based on severe traumatisation and a personality problem. A patient addressing the interpreter directly is a phenomenon that happens rather frequently when working with patients with severe mental illnesses specifically when personality problems are involved. In general, personality disorders have to do with problematic ways of making and establishing personal relationships, including problems in recognising, understanding and respecting (social) roles. The division of roles and tasks between therapist, interpreter and the patient him/herself is maybe not recognised and understood, and sometimes not respected. Specifically, with patients with a borderline personality disorder, a split between a good interpreter and a bad therapist - or the other way around is sometimes acted out aloud (Lidberg, 2001). It happens that interpreters get scolded or ridiculed, or praised far beyond reality, just as this happens to therapists. Interpreters have to know how to deal with this professionally. This means: being prepared (knowing that such a thing might happen); reacting calmly and friendly, not taking it personal and reacting offended, or too pleased; rendering the utterance of the patient to the therapist, asking (in words or gesture) the therapist how to deal with it, just as the interpreter did in the first part of the above example.

The patient presented here above was interested in the interpreters' origin. But patients may also ask for interpreters' opinion (about the therapist, about the treatment, about his or her own behaviour and actions et cetera) or help and can be quite persistent in demanding a reaction.

A patient is very angry with his therapist about something the therapist said in the session last week. When entering the therapy room, he is talking to the interpreter. The therapist does not understand, it sounds agitated and angry to her. The interpreter reacts to the patient, it sounds calm and soothing. As soon as they all sit down, the interpreter says something to the patient and renders this immediately: 'I just said to him that he should tell you what he just told me'. The patient still looks angry and fidgets in his chair. The therapist addresses him 'something seems the matter, can you tell me what it is about?' which is rendered by the interpreter.

Here we see an interpreter who takes an active role in the conversation after having been addressed directly just before the sessions start. Instead of refusing to get into contact with the patient (which probably would have increased his anger), the interpreter enters into a dialogue but directs it gently to the therapist – where it should be. Later on, the therapist asked, it turned out the interpreter told the patient 'what you say sounds serious, I think it is best you ask the therapist about what he meant with it'. The interpreter thus validated the feelings of the patient without giving an opinion (it sounds serious, not: it

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

is serious) and without entering into further communication. After this the patient talks about his anger and frustration and it is discussed further during the session. Talking about the irritation and misunderstanding strengthen the workgroup functions and the therapeutic relationship.

Now, an example of how things can go wrong. Here it shows that the interpreter lacks general knowledge of a therapeutic attitude and the goals and methods of mental healthcare.

A patient with a severe alcohol addiction is in treatment with a psychotherapist. He wants to stop drinking, he makes plans for a better life, start an education, get a job. He manages to abstain for a while, but then meets some of his old drinking-fellows, gets seduced and starts drinking again. As a result he has been truanting from school. The patient feels miserable about it and feels that all is lost now and he thinks that he will probably never manage to stay clean. The interpreter who helps them to communicate shows subtle discomfort during the session (sighs, slight frowns) and she tells the therapist after the session that she feels irritated and embarrassed by this fellow country-man who 'messes up', 'abuses the social services' and in general 'gives us migrants a bad press'. She feels 'the treatment is bound to fail'.

Although this feeling of irritation and embarrassment may be understandable, it is not a therapeutic attitude. The basic therapeutic attitude is being understanding and non-judgmental. And a therapist is empathic, positive, and authentic and has a healthy trust in his own treatment methods. The therapist knows that (a) it is very hard to abstain from an alcohol-addiction, that relapse occurs often and does not mean that 'all is lost' but that a restart needs to be made. In this particular case, he also knows (b) that there have been understandable reasons why the patient started drinking as a way of self-medication, (c) he supports the patient in his wish to improve and (d) has trust that the treatment may help the patient maybe not to abstain completely but at least to get some grip on his drinking behaviour. His attitude of 'understanding' may show in words that express his empathy with what has happened ('what a pity' and such words), he does not get angry nor judgmental but, contrary, gives hope by showing trust in the treatment ('good that you have started treatment here and that you tell me frankly that you relapsed last week, so we can work together in how you can possibly avoid this in the future'). The therapist does not judge the patient as a weak person who does not know how to resist temptation, but feels with the patient (empathy) about the disappointment, and is supportive. He may say something like 'it is hard to stop a habit with such a strong physical addictive power'. So, the therapist may, with the patient, have a negative attitude about this particular behaviour, but he will still be empathic with the patient as a person, struggling to overcome his addiction. Authenticity is maybe the hardest characteristic of therapeutic talk. It may show, in this case, in words that acknowledge the pleasant effect of a little alcohol on feelings of wellbeing. In general, it means that the therapist does really believe in his treatment and genuinely feels empathy with the patient and this will translate itself in non-verbal and paraverbal behaviour.

In this example, patient, therapist and interpreter did not function as a 'workgroup'. The critical and negative attitude of the interpreter showed. This was felt by the therapist, and probably by the patient too (he was not asked about it). It cost the therapist energy to overcome the feeling of being criticised.

In the above example, the interpreter doubted the use of the treatment and this affected the therapist negatively. Therapists are sensitive and do worry about what interpreters may think of them and the treatment they give (Bot 2005). This sometimes intensifies the therapist's own doubts and insecurities. One therapist said that she herself feels sometimes that she can do so little for the asylum seekers she treats, and she worries what the interpreter might think of her work. Therapists usually know that interpreters work with many different therapists and, especially inexperienced ones, fear the interpreter may judge

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

them negatively. This worry may be imagined, i.e. not felt by the interpreter. But interpreters should be aware that their expressions - verbal, nonverbal, paraverbal - count in all detail.

Summary

In general, it feels as helpful to therapists when interpreters follow their attitude towards the patient (Bot, 2005). They have to blend into the atmosphere of the session at hand. Preferably they shadow the therapist, i.e. they should portray the same attitude albeit in a somewhat softer way. For example, when the therapist laughs about something the patient said, the interpreter will smile. If, in that case, the interpreter would refrain from smiling and keep a 'poker face', this could hurt the patient (and therapist) in their sharing of something pleasant and may even give them the feeling of being ridiculed. 'Neutrality' can be perceived as 'not interested' and could as such form a hindrance to the patient; he may not feel invited to speak openly about his problems.

The therapist pays a lot of attention to shape a therapeutic relationship fitting this particular patient and the most he can hope for from the interpreter is to follow suit. Without feeling a real interest and empathy with the patient one is treating, it is hard, if not impossible, to do this type of work effectively. And the same applies to the interpreter. Without an interest in his clients (both therapist and patient) and the words they utter, he will not be able to blend in properly and to interpret faithfully

What About Interpreter Renditions?

Therapist Interventions and Patient Utterances

There is not much research that systematically focuses on the words and their renditions in interpreter-mediated (mental) health talk. Ever since Wadensjö's seminal work, more attention goes to the coordinating role of the interpreter (Wadensjö, 1998). Some people say, even therapists, that the exact words do not really matter. They emphasise the importance of attitude plus the fact that 'something' is being said. On the other hand, in psychotherapeutic theory and technique, there is an emphasis on the importance of wording experiences, feelings and thoughts (sharing, making them explicit, allowing to reflect); on 'finding new words' for these experiences and feelings and thoughts (giving a different perspective, meaning or to replace 'unrealistic thoughts') and on the importance, for therapists, to listen carefully to exactly how their patients phrase their utterances. The approach followed here is that words and attitude matter both. This is supported by findings of research in psychotherapy that attitude explains part of the therapeutic success, together with a properly explained and systematically carried out therapeutic technique. And technique is shaped in words. Which technique exactly is of less importance (Bot & Schaepkens, 2018). Also, rendering words of the primary speakers is the 'bread and butter' of the interpreter; it is their *raison d'être*.

In the introduction, the Hill Counsellor and Client Verbal Response Modes Category System (Hill, 1986) was mentioned. The author used this system to analyse interpreters renditions in the material collected for her PhD research to assess one of the aspects (therapeutic equivalence) of the equivalence concept that was developed to assess the interpreters' renditions: if the original utterance and its rendition scored in the same Hill category, the rendition was assessed as faithful on this aspect. Several of therapists' interventions were actually a sequence of several categories, glued together in one turn.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

A brief overview of the Hill categories and the difficulties in rendering some of these interventions follows here together with some reflection on what would help interpreters to render faithfully.

The first three categories of Hill's system seem simple enough: minimal encourager, silence and approval/support/reassurance. These usually concern short interventions. A minimal encourager is a neutral intervention, the therapist showing the patient that he is following, understanding, it serves mostly as a continuer and often overlaps with the primary speaker. Silence could be a thinking pause, it can serve as a time-out to let emotions either sink in or decrease; it may have an explicit function as time-out when irritation arises and seems to turn into aggression. Approval, support, and reassurance could also serve as a continuer, but is not neutral: it provides emotional support, approval or reinforcement - may imply sympathy or may be meant to alleviate anxiety. Although these three are simple interventions, they serve an important function. They often signal reciprocity (I'm listening; I'm hearing you; still with you), they steer the pace of the session and of emotional involvement, they convey empathy (good; you did well; yes, that is okay). Next to the words, the tone of voice is usually an important factor in its effect.

Very often the interpreter does not render such brief interventions. Often, they occur during the turn of the patient and are clear without translation (mmm, yes). But remarkably, when these kinds of interventions appear in the form of brief phrases, such as yes or good (often placed at the beginning of a much longer intervention) it is also relatively often skipped by the interpreter. Interpreters, so they told in an interview, see this often as unimportant 'fringe'. They seem to see it as phatic communication that does not deserve rendition. Albl-Mikasa and her research team found out that phatic tokens, just as modalisations, and hedges are often not rendered in doctor-patient communication (Albl-Mikasa et al., 2015). Interpreters do not see this as the core of the communication, while it serves an important role in the building of a therapeutic relationship, which is 'core business' and needs to be rendered.

It seems obvious that silence does not need to be interpreted; it is clear as it is. Specifically, when the interpreter works over the phone, it can give rise to misunderstandings. The interpreter does not hear anyone speaking and may think the line is disconnected and intervenes with 'do you still hear me', thus disrupting whatever was going on. Therapists should be aware of this and give some verbal clue to the interpreter that they are silent for a while. Some people find silence, in an on-going session, awkward. Interpreters should make sure they can bear it.

The categories of information giving and instruction do not usually pose many problems. Information, given by the therapist, may be about something external, information that does not concern the therapeutic process as such, but for example explains procedures in the asylum procedure of how to get help to find a house. Information can also be about the therapeutic process itself, explaining theoretical or technical aspects of the therapy. This information can also be helpful to the interpreter, as it explains the rationale of the therapy and as such gives background information that can help the interpreter to shape his renditions. The same applies to the category instruction, which can be a process-directive or advice or homework to be done by the patient. It also serves a double function as it may also help the interpreter to understand the process of the treatment.

In general, interventions that give most problems to interpreters are all sorts of questions and reflections that focus on the exploration of inner feelings or that reflect on expressed or underlying experiences (Bot, 2005). Therapists have the tendency to probe: to ask for feelings and emotions that lie beneath the surface and which may explain why the patient is suffering as he does and/or is so persistent in his problematic behaviour or distress. This often leads to series of questions, each going a step further into finding out what is 'really' the problem. Problems in rendering are sometimes related to questions that are phrased tentatively or differ only in a subtle way from what the patient had just said (Bot 2005). The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

interpreter might thus have problems in identifying the question-format or in recognising the difference in phrasing. An example is the following:

A therapist is exploring the feelings of a patient whose leg is amputated and which still gives him a lot of pain. He doesn't want to know the people around him to know he is suffering as he does not want to be pitied by them, that would be 'psychologically heavy' for him.

The therapist then asks 'can you explain why it is psychologically heavy for you when people express compassion?'

Which is rendered as 'can you tell me why you don't talk about it? Maybe because they will feel sorry for you?' (Bot, 2005)

Here we see that the interpreter, apart from rendering in a very loose way, does not translate the step to *why* getting compassion is difficult, but stays with 'getting compassion may be difficult', which is what the patient had just said himself.

Therapists can be taught to help the interpreter by wording their inventions clear and unambiguous. In this case, for example, they could introduce such a question with a short phrase in which they explain that they are going to ask a little further. For example, 'yes, I understand it is heavy for you but I would like to know why is it difficult when people are compassionate with you.' In this way both interpreter and patient are helped to understand the process they are in.

The above problem might have arisen because of ambiguous phrasing of the question by the therapist. However, there might also be another, underlying, problem at stake.

In training sessions (mental health specialisation for interpreters) the author makes use, amongst other training material, of training videos made for therapists. One of these is a training video for schema therapy for borderline patients and one of the episodes used is about a patient in the 'angry child' modus. Immediately after entering the treatment room the patient starts venting his anger, fulminating against the fabulous parking fees he has to pay when seeing his therapist, smashing his car-keys on the table. The therapist listens, does not go into the issue of the parking fees but starts asking what else the patient is angry about. Step by step, always asking 'what else' questions, therapist and patient arrive at fundamental issues between the patient and his father that still make him very, very angry, but also 'sad', 'not seen', over-asked' et cetera.

In these teaching sessions it has appeared that interpreters find this episode, the probing, 'odd' and sometimes 'ridiculous', they do not see 'the point' in those questions; they even become angry, finding the repetitive way of questioning nonsensical. And when interpreters find the interventions of the therapist strange, odd, ridiculous or when they make them angry, they will have some problems in carrying out their task: it will be hard to be empathic towards the therapist, to support his strategy and it probably also interferes with his capability to translate faithfully. If one doesn't understand the purpose of a question, it could be difficult to find the right words to render it. So, the problems found in these renditions may well have to do with a general lack of background knowledge of therapeutic techniques and their underlying principles with the interpreters.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Another issue in the 'questions category' is the difference between open and closed questions. Open questions are used by the therapist to invite a telling, to make the patient give information. But they are also used, more often, to invite the patient to probe his own mind and to come up with underlying feelings, motivations and thought. Most often, the therapist takes the 'not-knowing' stance and puts the patient in the 'expert' role: the patient is the expert, the knowing person, of his inner life. When an open question is rendered as a closed question, the therapist already points into a specific direction, putting him in a more 'knowing' position. And this happened relatively often in Bot's material (2005). The difference with reflections is also a difficult one. A reflection, from the part of the therapist, formally takes the form of a question. But because it reflects something the patient has just said, albeit most often in different words, it also has some element of a statement in it. An example is the following phrase, a reflection on an underlying feeling, from the therapist, directed at the patient: "because you feel in fact, you ask forgiveness, you feel in fact guilty to the fact that father has been in prison?" (Bot, 2005).

Just before this intervention, the patient had said that he asked his father forgiveness and it could be derived from former utterances that this was because father had been imprisoned and the patient thought that this had to do with his actions. 'You feel in fact' is a statement, but the phrase has a rising - question- intonation and is meant for the patient to think for himself whether this could be 'true' or not. Minor changes in the rendition - including a change in intonation profile – could thus change this turn into a statement with a therapist stating that the patient does feel guilty.

Some other categories did not clearly give problems in the interpretation per se, although of course here and there, deviations were found. The category 'self-disclosure' – as in self-disclosure by the therapist - did not give rise to specific interpretation problems. When asked of the interpreter it is a different story - as discussed here above.

Of course, the Hill system is only one way to categorise therapists' interventions and their renditions. Some psychotherapeutic techniques use ordinary words in a special meaning. For example, 'protecting' often gets a negative connotation as it is equated with 'over-protection'. But when the interpreter connects it with 'caring for' (Bot, 2005) it loses this negativity. In motivational conversation techniques, often used to help people overcome their ambivalences in therapy, it is customary that the therapist asks permission to touch a topic. He may say 'you just mentioned your drinking habits, is it alright with you if I ask some more questions about that?' Interpreters find this often a bit weird, specifically when this is done more often in a session. And when they find it weird, do not understand its purpose, they may often 'forget' to render it. So, the pitfalls are numerous and will of course never be covered completely. Even the wise advise 'if in doubt, ask' will not cover all misunderstandings. Sometimes you just do not know that you misunderstood.

Bot (2005) found few changes in therapeutic perspective in patients' turns. The Hill categories for patient turns are not dealt with in this chapter. Illustrated with examples, some general remarks can be made about difficulties specific to mental health, in rendering patients' turns.

In a mental health clinic, a judge interviews a patient in order to assess the justification for a forced admission in the clinic. The patient speaks French. In the Netherlands, judges have to speak Dutch in their official sessions ('Dutch is the language of the court'), a French interpreter is asked for. He works over the phone. The patient is a quiet man, who enters the session with some large dictionaries in his hand, which he puts before himself on the table. During the session he leafs through the books. After the judges first question, he starts a long monologue. After some minutes, the interpreter breaks in. He says: 'I'm very sorry, I can understand the words that are spoken, but I cannot interpret this for you'.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The judge replies in fluent French and says he completely understands the problem of the interpreter - he is not to blame and he thanks the interpreter for his meta-communication.

Here we see a proper way to use meta-communication: some patients speak in such a way that interpretation is impossible. A sequence of random words, maybe loosely connected through alliteration, could probably be translated, if one has enough time, but are nearly impossible to interpret. In those cases, the interpreter should explain the characteristics of patients' talk to the other primary speaker.

The style patients use to phrase their utterances may also pose problems sometimes.

A male patient, quite a rough type, has been working as construction worker before a war started that changed his life completely. He enters therapy, with an interpreter, because of serious anxiety problems. In a session, the interpreter suddenly, before rendering patients' words, turns towards the therapist and says 'he is using such beautiful words, I cannot interpret that properly, but you should know this, it is really poetic.' The therapist acknowledges this to the patient and he tells her that he used to read a lot, but now feels unable to do so because he cannot concentrate. Thus an entire new aspect of a patient's life was uncovered.

Also here the interpreter successfully meta-communicated about patients words which opened up new material in the treatment.

What About Empathetic Stress?

Empathy is a risk factor for the development of symptoms of secondary traumatisation and other stress reactions in care providers. Interpreters also need to be empathic in order to understand the clients they are working for. So, one would expect interpreters to be prone to secondary traumatisation as well. Baistow (2000) did a survey in several European countries and found that half of the respondents sometimes suffered from anxiety or changing moods due to the interpreting work. The fact that interpreters are often not very well paid, adds to their general personal stress levels which is also known as a risk factor for the development of this kind of negative reactions (Baets, 2013). Although these empathic stress reactions may occur in a lot of situations in health care, mental health care might be more burdening than other specialisations. In general, the level of expressed emotion is high in mental health talk. Interpreters have to render their patients' traumatic experiences, preferably in the 'I'-form, which may pose problems when talk is about ugly events (Wallmach, 2002). And when they have gone through traumatic events themselves this could evoke their own memories and feelings of distress. Interpreters, who have been asylum seekers themselves, do sometimes recognise their own experiences in their patients' stories. A sign language interpreter told in an intervision group about the difficulties she had in signing about sexual violence and its graphic nature in sign language.

So, there is reason to assume that interpreters run the risk of developing empathic stress reactions that may interfere with their functioning.

SOLUTIONS AND RECOMMENDATIONS

Unfortunately, in the Netherlands, the country this paper is written from, most interpreters have not been trained specifically for their work in (mental) healthcare, nor are they part of a team. They are being hired per session and have no information about the session beforehand. They usually have a training focussing on their work in the judicial realm in which they have been told to be 'impartial' and 'neutral', fitting with the adversarial system of the court. In therapeutic talk a somewhat different attitude is usually more helpful but as it implies deviating from the neutral stance, this sometimes feels 'risky' for the interpreter. The therapeutic attitude may be called 'neutral' and 'impartial' in the sense that the therapist is non-judgmental about the person of the patient; he may be judgemental of some actions of the patient, though. But more important, the therapist empathises with the patient; he is positive and authentic and the other adjectives mentioned above – and this differs from the neutral and impartial stance. It is not easy to shape such an attitude in coordination with the therapist: it means a continuous alignment between therapist and interpreter.

Interpreter-mediated session in mental healthcare ask for close cooperation between therapist and interpreter. Therapist, patient and interpreter together form the therapeutic relationship, which is necessary to make the treatment successful.

To make this happen, it is necessary that both interpreters and therapists be trained in this type of communication. Interpreters need generic knowledge of mental healthcare (its organisation, basic knowledge of the most important disorders and treatment methods) and skills training in attitude issues in mental health sessions. Therapists need training in the intricacies of interpreter-mediated talk. They should know what they can expect from an interpreter and how they can help the interpreter to blend into the session. They also need to be aware of the importance of chairing the session properly to avoid overlapping speech and too long turns. And they have to be aware of the importance of phrasing their interventions unambiguously, in properly constructed and grammatical sentences – which not only helps the interpreter to render faithfully but also helps to keep focus in therapy.

Finally, in order to keep empathic stress (also called vicarious trauma or secondary trauma) at bay, it is important that interpreters get support through intervision and supervision.

CONCLUSION

This chapter dealt with the question whether there is anything special about interpreting in health care. The answer is 'yes, there is'. Basically, there are five fields that ask for special attention.

Firstly, mental healthcare deviates not a small bit from 'ordinary' talk. Although the set-up of the sessions may not be very formal and may seemingly not follow a specific format, the topic of talk does not follow 'normally accepted' social rules. In mental health sessions patients talk about topics they do not speak about in social interactions because they may feel ashamed or do not want to be judged as 'crazy'. On top of that, therapists do not react to those stories in ordinarily accepted ways: they may be confronting, they 'ask permission to ask a question', they may 'bluntly' ask how the patient feels about the therapeutic relationship, and they may give very personal feedback. Instead of 'covering up' ugly histories, they may probe for all details. These are all things that we usually, in ordinary social talk, refrain from. The unaware and unprepared interpreter may feel awkward in such a situation. Notwith-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

standing, there are exceptions; for example, EMDR sessions do follow a strict format with prescribed wording of interventions.

Secondly, in mental health care, the relationship between therapist and patient is of utmost importance in order to create the atmosphere in which change can take place. But is also a diagnostic tool and is used as an instrument of change. The interpreter is part of the process and has to know how to fit into this process. This may include behaviour that does not fit into the, most often, very strictly formulated codes of conducts for interpreters.

Thirdly, in mental healthcare talk can be emotionally burdening for both the therapist and the interpreter. Rendering patients' words about trauma in the first person poses a heavy load. In sessions with asylum seekers and refugees, the stories of the patient may seem very familiar to an interpreter who shares the same asylum seekers background. The stories he has to render - about atrocities, a difficult flight and so on - may be very much like his own history. This can evoke emotional reactions that the interpreter has to deal with.

Fourthly, patients with severe mental disorders, specifically when personality disorders are concerned, may try to drag the interpreter into the conversation, as a conversation partner. Or they may be aggressive, overtly disrespectful or they may praise the interpreter beyond reality. To steer clear, the interpreter needs to know how far he can go in reacting directly; he should not take it personally but at the same time he should give a personal reaction that also fits in with the attitude of the therapist. Being neutral can easily be perceived as too neutral in such circumstances.

Fifthly, the language therapists use is sometimes difficult to understand as he may use words in a different connotation as we are used to; moreover, words that feel like 'fringe' are also of importance and need to be rendered. Patients can tell hard or impossible to understand stories, may use newly coined words and speak haphazardly – forcing the interpreter to meta-communicate with the therapist.

For the unprepared interpreter, who has only had a general training that is usually focussed on interpreting in the judicial realm, interpreting in mental healthcare may be rather difficult. The unprepared interpreter will find various situations in mental healthcare odd, he will not understand therapists interventions and / or patients utterances and will feel awkward when boundary crossings are clearly asked for but feel out of bound for him. Interpreters need to be prepared well for working in mental healthcare sessions: they need to know the background of interventions and have a basic knowledge of the most occurring disorders. And they need skills training to learn how to deal with interpersonal and emotional situations in practice. In order to cope with the mental burden of stories of trauma and other emotionally difficult situations, interpreters need to be embedded in intervision or supervision groups which can help them to stay clear from unproductive reactions.

Chapter 68
Health and Mental Health

Cheryl Green
Southern Connecticut State University, USA

ABSTRACT

As healthcare organizations use approaches such as structural empowerment theory and nurse residency programs to engage new graduate nurses in becoming productive members of the organizational culture, bullying and incivility experienced by these nurses can undermine organizations' efforts. Chapter 3 introduces the Reporting of Uncivil Conduct Chain of Command to provide support and direction to nurses that are experiencing bullying by perpetrators in the workplace. Unresolved and persistent uncivil conduct can result in health and mental health problems for affected nurses. Hence, in order to protect nurses' overall health and safety, it is necessary for organizations to adopt zero tolerance for bullying and incivility. Additionally, nurses may benefit from screening programs that can identify risks for self-harm secondary to stress and depression that could be caused by incivility in the workplace.

INTRODUCTION

Incivility impacts the health and mental health of affected nurses. For nurses, increased call-outs from work because of fatigue, frustration, anxiety, and depression associated with being bullied, not only places constraints on their colleagues, but impacts patient care. Annually, healthcare organizations have a financial loss of as much as $30,000 to $100,000 (Becher & Visovsky 2012) for each employee that has been effected by incivility within the workplace.

The very nature of the nursing profession and the interactions that nurses daily have with patients, families, and other health disciplines, can be emotionally and physically demanding. Nurses must arrive at the workplace attentive, well rested, and physically capable to complete patient assessments (i.e. physical, neurological, withdrawal from substances or alcohol), perform skilled care (i.e. wound dressings, administration of intravenous medications), and meet the psychosocial needs of patients and their family members. Bullying distracts nurses from performing well, the job they were trained to do, providing health care to patients.

Uncivil Behaviors Psychological Impact

Oyeleye, Hanson, O'Connor, and Dunn (2013) conducted a quantitative study using exploratory correlational methods. The purpose of the study was to explore the relationship of stress, burnout, and workplace incivility on nurses' turnover intentions (decision to leave their job) and psychological empowerment. A total of 61 nurses participated in the study; 87% (n= 53) were female and 28% (n= 8) were male. The ages of the participants ranged from 23 to 61 years and participants' races were white (n= 50, 82%), other, (n=1, 2%), African American (n=3, 5%), and Asian (n= 7, 12%). The nurses' years of experience in the profession varied from 1 year to 40 years.

Oyeleye et al. (2013) used the following five instruments in the study: Maslach Burnout Inventory (MBI), the Uncivil Workplace Incivility Scale (WIS), Spreitzer Psychological Empowerment Scale (PES), the Perceived Stress Scale (PSS10), and a Turnover Intention scale. Results indicated that there were statistically significant correlations between stress and burnout (p= .000), burnout and turnover intention (p= .005), and stress and incivility (p=.001). Study findings suggest that nurses experiencing increases in burnout and stress may leave their jobs.

Kang, Jeong, and Kong (2018) conducted a qualitative study using a grounded theory approach (Corbin and Strauss, 2015) to explore nursing students' experiences with incivility. Sixteen nursing students participated. The 16 nursing students had all experienced incivility during their clinical placement. Kang et al. (2018) invited the students to participate in one-on-one interviews. Results indicated that nursing students felt they were outsiders within the organizational hierarchy and culture of their clinical placement. Students verbalized feeling marginalized and in response became passive, submissive, and shocked that incivility had occurred in a professional setting.

Kang et al. (2018) concluded that when nursing students experience incivility during their academic preparation to enter the profession of nursing, their identity is threatened. Students undergo role conflict and have low self-esteem. Study findings suggest that nursing students that experience incivility should be provided counseling services and educational programs be developed by nursing programs to address the incivility and offer coping strategies. Schools of nursing are recommended to have guidelines that ensure students learn within supportive clinical environments that they feel safe within.

Structural Empowerment

Structural empowerment is a theory that views workplaces that empower employees as having a positive impact on work performance (Kanter, 1977). Power in the workplace can be attained both through informal and formal ways. Employees exhibit informal power when they form interpersonal allegiances and networks of peer groups, with subordinates and superiors within their organization, as well as outside of the organization. Formal power occurs within an organization when employees have roles that are visible and align with organizational missions and vision statements, and employees have jobs that have flexibility. According to Kanter (1977), employees tend to thrive, have job satisfaction, and are committed to their organizations success, when opportunities to learn and grow professionally are made available to them.

Structural empowerment, although developed in 1977, has been referenced within new graduate nurse residency programs such as the American Association of Colleges of Nursing Vizient (2019) programs, in the development of evidenced-based practice (EBP) projects as a prerequisite for completion of residency programs. The length of residency programs are usually one year and culminate in EBP projects such as

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

unit-based reduction of central access device infections or examining ways to reduce turnover intentions. These EBP projects are presented to the new graduate nurses' colleagues and key stakeholders within the organization (i.e. Vice President of Nursing Services, Chief Nursing Officers, Nurse Managers, or Healthcare Providers). Structural empowerment can be instrumental in health care facilities retaining nurses through engagement with their units and the organization as a whole.

Wing, Regan, and Laschinger (2015), used a predictive, non-experimental design to examine structural empowerment in relation to workplace incivility and new graduate nurses experience of mental health symptoms. Their sample size was 394 new graduate nurses working within a hospital in Ontario, Canada. Instruments used were the following: the Conditions for Work Effectiveness Questionnaire (CWEQ-II, Laschinger et al., 2001) to measure structural empowerment, the Workplace Incivility Scale (WIS, Cortina et al., 2001), and the State of Mind subscale from the Pressure Manager Indicator (PMI, Williams & Cooper, 1998). The CWEQ measured structural empowerment and had Cronbach alphas that range between 0.78 to 0.94. The WIS assessed incivility that was experienced by the new graduate nurses in their interactions with co-workers and supervisors. And lastly, PMI measured anxiety and depressive symptoms experienced by the new graduate nurses.

Wing et al. (2015) found that high levels of structural empowerment experienced by new graduate nurses, was associated with less mental health symptoms. Incivility experienced by the new graduate nurses, by supervisors and co-workers, was found to diminish the positive effect of the work environment. Hence, although health care facilities can strategically set in place, positive opportunities (i.e. training, promotions, awards, and career ladders) for nurses to grow and learn, uncivil behaviors in the workplace still can negatively impact the mental health of new graduate nurses.

An Attack on One's Self-Concept

Perpetrators of incivility seek to discredit their targets professionally by openly questioning their expertise (public humiliation) and knowledge in front of others. Additionally, the perpetrator may seek to sabotage the completion of work in progress or take credit (destabilization) for the nurse(s) work for whom they are bullying (TJC, 2016; WBI, 2016). Perpetrators further isolate their targets by withholding information. The latter behaviors can cause nurses that are experiencing bullying in the workplace to feel physically ill and mentally fatigued, anxious and depressed.

Case Study 4 is a hypothetical case study on workplace incivility. All characters within the case study are fictional. This case study explores the transition of a new graduate nurse from the academic environment to clinical practice.

Case Study 4: Maria

Maria graduated from college with a bachelor of science in nursing 11 months ago. She was hired to work at a large teaching hospital within her desired specialization of critical care nursing. Maria

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

relocated from a small town in the south, to a large metropolitan city in the north of the United States. Maria's orientation to her unit was comprehensive and her preceptor Ann was a critical care nurse for 31 years and enjoyed teaching her.

Maria's preceptor Ann was supportive, engaging, and provided her with opportunities to learn new skills daily. Ann and Maria even attended critical care conferences together. Maria had learned so much quickly, that her patients would inquire how long she had been a nurse because she was so confident and knowledgeable.

Ann, after commending Maria on her progression after 10 months of preceptorship, informed Maria that she would be retiring. After Ann retired, Maria still felt confident and enjoyed coming to work each day. One day, as Maria was talking to a patient and their family member, another nurse entered the patient's hospital room and started correcting the information that Maria had just provided. Maria felt humiliated and quickly excused herself and exited the room.

When Maria later approached the nurse to ask why she had interrupted her as she was talking to her patient, the nurse laughed and walked away. The nurse repeated this behavior the following week with a different patient. Although Maria tried to ignore the behaviors, the situation escalated out of control as the nurse began challenging her skills and humiliating her in front of co-workers and healthcare providers.

Maria hated going to work. She was depressed and felt alone and isolated. Maria developed acid reflux and experienced headaches. Her thoughts both at home and at work focused on the incivility she was experiencing at work.

Maria's nurse manager asked to meet with her after noticing on the unit schedule that she had begun to call-out from work ill several times during a one-month period. Maria was tearful as she explained to her manager what had happened and how the bullying she had been enduring had affected her health. The nurse manager instructed Maria to begin documenting the dates and times the bullying occurred and who was present. Three months after the bullying had begun, it abruptly ended when the nurse was placed on progressive disciplinary action by the nurse manager for uncivil conduct within the workplace.

The perpetrating nurse was placed on a different shift than Maria. The two nurses did not interact. Maria's acid reflux eventually resolved and her depression gradually lifted. Maria learned from this experience the importance of addressing bullying behaviors immediately. In addition, the necessity of informing a supervisor or manager of the bullying as soon as possible.

Maria' Story—Addressing the Problem

Maria's experience with being bullied in the workplace ended when a nurse manager, while addressing Maria's pattern of sick call-outs, discovered that Maria was experiencing incivility. Nurses being bullied in the workplace may feel isolated and that no one cares. This perception (Moola, Ehlers, & Hattingh, 2008) is not always accurate because it is clouded by the stress nurses experience related to the uncivil behavior from perpetrators. It is often when nurses begin to share their story of incivility experiences with a trusted source (i.e. a counselor, manager, peer, Human Resources representative), that healing can begin and recognition of the inappropriateness of the perpetrator's behavior can be processed and validated.

Nurse Residency Programs

Nurses that live in silence and tolerate the bullying, are at risk for not only physical and mental health problems, but job stress and burnout (Wu et al., 2007; Chen, Lin, Wang, & Hou, 2009). For retention

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of new graduate nurses, it is imperative that they receive support in addressing incivility during their period of orientation and acclamation to the nursing role. Many health care facilities, in response to the need to support new graduates and retention, have developed nurse residency programs.

The purpose of nurse residency programs are to support the Institute of Medicine (IOM, 2003) and Quality and Safety Education for Nurses (QSEN, 2019) initiatives of introducing patient-centered care, evidenced-based practice, informatics, quality improvement, safety, and teamwork and collaboration (QSEN, 2019) to new graduate nurses (and experienced nurses re-entering the field). Nurse residency programs focus on the development of nurses' roles within health care systems, evidenced-based practice, leadership skills, and awareness of how their work and roles impact patients' health outcomes. Nurse residency programs, have been instrumental in decreasing new graduate nurse turnover and preparing nurses to apply critical thinking and decision-making skills within the clinical environment (Vizient/AACN, 2016; Vizient/AACN, 2019).

Within nurse residency programs, new graduate nurses are trained in cohorts. The establishment of cohort training facilitates connectedness among the new graduates and creates a forum whereby the nurses can safely share their experiences on the clinical units; positive and negative, this includes incivility. For new graduate nurse Maria, sharing with her cohort or a member(s) of the cohort, could have also helped her address the uncivil conduct on her unit.

Coordinators of nurse residency programs are a wonderful resource for new nurses because they can maintain objectivity. The sole purpose of the coordinator role is to prepare new graduate nurses and nurses re-entering the nursing profession (or a new clinical area of practice) with their transition to the health care facility. Coordinators of nurse residency programs may hire the part-time assistance of what are referred to as nurse residency facilitators. Nurse residency facilitators are experienced nurses that meet with hired nurses to facilitate discussions on planned topics that the nurses may experience within the clinical environments such as when *patients' conditions decline, coping with the loss of a patient, providing support to family members in crisis, or coping with difficult relationships* in the health care environment.

Nurse residency programs are instrumental in helping new graduate nurses and nurses re-entering the field, recognize the importance of communication skills, respect in the workplace, coping with stress, self-care, being unafraid to challenge their colleagues when a potential procedural error is identified (i.e. a break in sterility during a surgical procedure or dressing change) or they disagree with a treatment regimen prescribed for a patient. The number of skills taught are too many to write. Nurse residency programs also encourage scholarly research, as nurse cohorts work collaboratively to identify areas in need of improvement on their units and develop EBP quality improvement projects that contribute greatly to patients and staff on their designated units they work on, as well as the health care facility itself.

Nurse residency programs serve as a reminder of the responsibility that each nurse has to educate the next generation of nurse professionals. New nurses must be well-informed of the nature of bullying in the workplace and the necessity of having an intolerance for incivility. Change begins with every nurse from multiple generations, novice to expert alike.

Case Study 5 is a hypothetical case study. All characters within this case study are fictional. This case study provides an example of a nurse who is a caregiver of older parents that must contend with bullying in the workplace.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Case Study 5: Maritza

Maritza has been a nurse for 32 years. She recently relocated to Florida from North Carolina to care for her aging parents. After three months residing in Florida, her father died of a heart attack. Maritza then became the primary caretaker for her mother who has Alzheimer's disease.

Maritza worked day shift at a local hospital and hired a nurse assistant as a companion to provide care to her mother while she was at work. Her mother became combative and paranoid. The nurse assistant was assaulted by Maritza's mother on a daily basis for a week and Maritza's mother constantly accused the nurse assistant of stealing money and jewelry. One day Maritza received a phone call at work from the agency that the nurse assistant was employed, and was informed that it was unsafe for them to provide companions for her mother. Effective that day, the companion service ended.

Martiza spoke with her nurse manager and assistant nurse manager about her dilemma. It was perfect timing, an evening shift nurse had resigned so Maritza took this position and started two days later. Working in the evening allowed Maritza to provide care to her mother during the day and provide overnight care of her mother as well. A neighbor who was a retired nurse, agreed to take care of her mother while she was at work. Maritza paid her neighbor $500.00 a week.

Ann, a new graduate nurse was hired to work the evening shift. Ann was very bossy and opinionated. She had already worked in three different hospitals since graduating 18 months ago. She was not experienced enough to make the clinical decisions she attempted to make on some of the unit's complex postoperative patient cases on the surgical unit. However, Ann, a skilled liar, would falsify her level of experience and clinical competency.

Concerned that Ann's lack of integrity and ethics could eventually place a patient or patients at risk for harm, Maritza decided to go and speak with the assistant nurse manager. The assistant nurse manager and Maritza spoke at length about ways to help Ann adjust to her role on the unit and feel more comfortable seeking advice and assistance with patient care from more experienced nursing staff.

I Don't Need Your Help

The following evening, Ann approached Maritza and pushed her left shoulder from behind, startling Maritza. Ann stated, "Oops, my mistake Maritza! By the way, do me a favor, don't talk about me to my boss and no, I don't need your help." Ann then walked down the hallway quietly as if the interaction had never taken place.

One evening after work as Maritza went into the hospital parking garage to prepare to go home, she noticed a deep scratch, on the driver's side of her car that covered the full car length. The following week, her tires were slashed. Maritza reported to the hospital security what had occurred. Because of the angle of the garage camera, the perpetrator could not be identified. As a caregiver to her elderly mother, Maritza was already stressed. However, the vandalism had taken her stress to a different level, as Maritza now feared for her safety.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

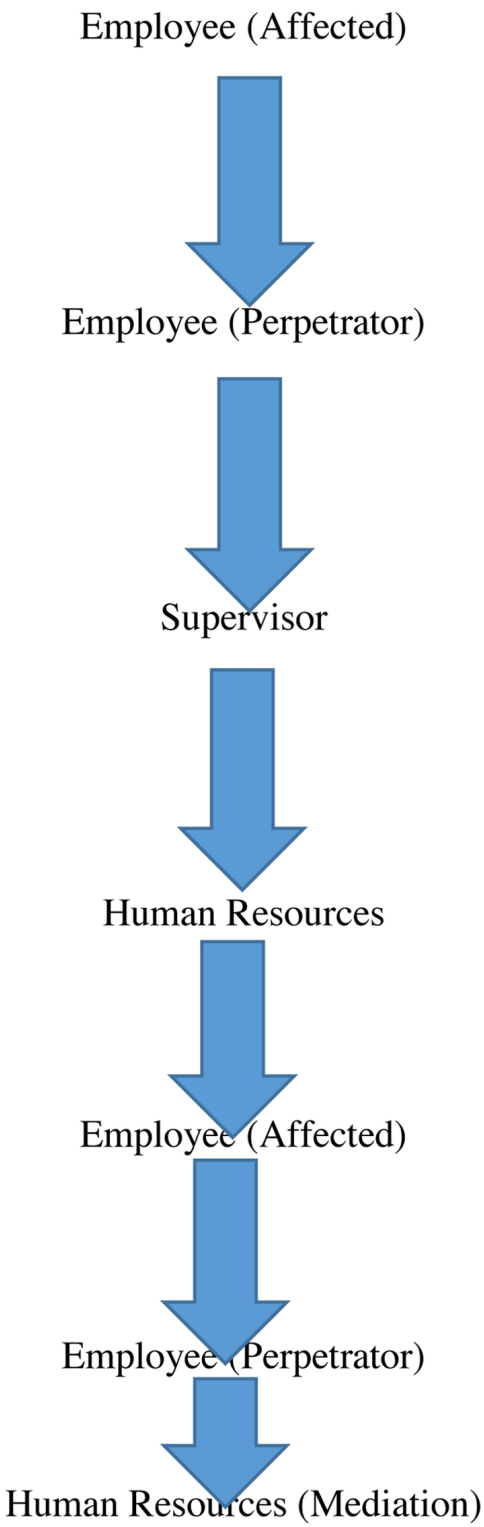
Maritza went to the Police Department to report the damage to her car. She was recommended to park her car in a well-lit area within the garage with clear visualization from a camera in the garage. Maritza began arriving early at work to secure parking near the surveillance cameras. Within nine days, Maritza's driver side window was smashed, glass covering the seat floor and dashboard. This time, surveillance cameras had a direct view, and a visitor exiting the garage on foot to spend the night with an ill family member had witnessed the event and reported it to a hospital security officer. Maritza was immediately notified.

Hospital security viewed the surveillance camera footage the following day and saw Ann, Maritza's co-worker, smashing her car window with a hammer. Maritza was informed, the police were contacted by the hospital security department and a statement was taken on the grounds of the hospital. The witness' description of the perpetrator and picture on camera, confirmed that it was Ann, Maritza's co-worker.

Ann was arrested and in court, denied any wrong doing. She later faced charges and Maritza acquired a restraining order. The hospital fired Ann. Maritza had no further problems, but the physical pushing and destructive damage to her car, left her shaken.

When Bullying Becomes Violent

When perpetrators physically lay hands on victims with the intention of intimidation or to do harm, it is important that these incidences are documented and reported. Maritza did not report the pushing incident on the unit, and Ann continued to escalate her attacks by damaging Maritza's property, her car. If a victim of bullying in anyway feels threatened for their safety or the safety of others in their workplace, follow the report of uncivil conduct (see Diagram 1.) chain of command and involve hospital security and or the police to document the pattern of deviant behaviors. Of concern would be if the bullying leads to self-harm or harm of others. Reported, deviant behaviors can be addressed and the perpetrators, witnesses, and victims, kept safe.



Professionalism and Confrontation

Nurses are encouraged in workplaces, to follow the chain of command. The chain of command consists of a hierarchy of leadership established for the maintenance of function and order within institutions. By following a chain of command, issues can potentially be rectified employee-to-employee, prior to being escalated to a manager, director, president, or vice president of a health care facility. Figure 1 is an example of a chain of command in an organization.

The restoration of order is the goal of the chain of command within organizations. Whenever possible, nurses should seek a solution to the bullying with the offending nurse. This provides the offending nurse the opportunity to explain their behavior, and if in fact they are aware of the implications of their patterns of communication. If bullying persists, nurses should then meet with their immediate manager or supervisor to discuss the situation.

The Hollow

Incivility may cause the affected individual to feel hurt, sad, misunderstood, and embittered. These feelings can be referred to as *the hollow*. *The hollow*, accompanied by perseveration of incidences of negative behaviors from the perpetrator to the victimized nurse, can lead to illness; both mental and physical. For nurses experiencing *the hollow*, symptomatically, they tend to lack energy, enthusiasm, and focus. These symptoms arise in-part, because of the perseveration component of the hollow. As nurses mentally recall negative words said to them and the situations in which they felt vulnerable and attacked by the bullying perpetrator, anxiety and frustration are heighted, as events are replayed over and over again.

The Hollow and Work Productivity

The term *the hollow* was created by the author to explain symptomatology that victims of incivility can experience. Nurses may feel overwhelmed by the bully's continuous attacks on their character and their abilities to perform the job. This can lead to nurses having the sensation that they are sinking and enveloped in deep sadness. Nurses affected by *the hollow* may experience intermittent periods of worry and anxiety, accompanied by perseveration on events at work involving the bully or bullies, and intermittent tearfulness.

Nurses experiencing *the hollow* will inevitably, have a change in their work productivity. Preoccupied in their thoughts with perseveration of the incidences of negative bullying interactions, affected nurses may have a decrease in their ability to concentrate, think logically, and think analytically. The danger of *the hollow* for nurses that are in direct care practice, is that intellectually, nurses' thought processes may become clouded and they may have difficulty critically thinking within the clinical environment. The latter may compromise nurses care of patients related to their disrupted thought processes, secondary to *the hollow*.

Nurses can overcome the feelings associated with *the hollow* by either deciding to leave their work environment shared with the perpetrator(s), request a change of shifts to avoid all interaction with the perpetrator(s), or report the perpetrator(s) and seek the mediation help of a nurse manager or Human Resource Department representative. Additionally, nurses should seek counseling through their company's employee assistance programs (EAP). Untreated, *the hollow* can develop into a clinical depression.

Case Study 6 is a hypothetical case study and all characters are fictional. In this case study, Alice, a nurse employed within a surgical intensive care unit (SICU) experiences bullying by her mentor and other nurses on the unit. Alice must learn self-care as she endures the bullying and incivility.

Case Study 6: Alice

Alice experienced bullying on her job. The bullying started shortly after she was hired to work as a critical care nurse within a surgical intensive care unit (SICU). Alice's bullies were four nurses; one of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the four was her mentor. The nurses would go out of their way to attempt to prove that Alice was incompetent in front of not only her patients and other healthcare disciplines, but other nursing colleagues. Alice had never did anything to these women. She did not have work a history with them or anyone in the hospital for that matter. Alice was new to the state and institution after deciding to relocate one year ago after a divorce.

For Alice, relocating to a new state seemed exciting since her ex-husband and she had no children; this was truly like starting over. Alice had worked as a critical care nurse for 10 years before marrying her former husband. She was an experienced nurse who was certified within her specialization.

Alice was already emotionally fragile when she relocated secondary to the divorce, so the bullying made it even more difficult. One evening as Alice prepared to leave work after completing a 12-hour shift, she walked into the nurses' breakroom to get a cup of coffee. She did not see that one of the perpetrators had placed their foot in the way to trip her. Alice fell and hot coffee spilled all over the floor and onto her uniform.

Alice informed her nurse manager about the bullying and that it was escalating, but her complaints seemingly were ignored. The perpetrators were comfortable bullying others because it was tolerated on the unit. No one questioned the perpetrators' behaviors.

Alice went to speak to Human Resources (HR) about the problem and they instructed her to "keep track of the incidences." Alice documented the dates and times of incidences and if a witness was present. The HR representative suggested Alice meet again with her nurse manager to discuss the problem. Alice met with the nurse manager who listened to her concerns, but did nothing.

Alice was not sleeping well, had lost weight, and had difficulty concentrating. She had a few friends in the apartment building she lived within and had shared with one, a nurse that worked at another hospital, what was happening at work. Alice's friend recommended she contact an attorney. Alice did not contact an attorney and continued to reach out to HR, but to no avail. Alice applied for a position on the cardiac intensive care unit (CCU); however, Alice's nurse manager delayed the transfer to the CCU because the SICU had a shortage of staff.

Alice seldom felt happy and was anxious upon arriving at work. Alice was very cautious when administering medications and completing procedures for her patients because her mind was so preoccupied with rewinding and playing back things that were said to her by the perpetrators. Alice's self-esteem and self-confidence had suffered a great deal. It was as if she had no experience in nursing at all. She felt depleted of energy and lived in a constant state of fatigue. Because Alice was alone in a new state, she felt that she could not just leave her job given her financial responsibilities.

Alice's thoughts were always racing and replaying the painful bullying events. She began to withdraw from friends, went only to work, and came home. Alice's sleep and appetite were poor. One night, while driving over a small bridge in the middle of the night coming from the grocery store, Alice stopped her car and stood on the bridge looking at the river below. Contemplating suicide and in turmoil, she changed her mind as she thought of her parents and her Catholic faith. She decided to return to her car and proceeded home.

One day while at work, Alice went to administer a morning injection of subcutaneous heparin (Porcine) to a patient. The patient's family member informed her that the night nurse had administered the injection at 6:00 a.m. The patient was nonverbal and on a ventilator and the family member, whom normally leaves at 6:30 a.m., had forgotten his reading glasses, returned to the patient's room to obtain them. The nurse had not signed off the order, and informed Alice during handoff report at 7:05 a.m. that the 6:00 a.m. heparin injection had not been administered. Alice agreed to do the injection.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Alice asked the nurse why she had not been informed that the nurse had decided to administer the heparin injection. However, the nurse, one of Alice's perpetrators, insisted that she had not administered the medication. The family member, overhearing their discussion, reiterated the story and verified that it had been administered. The patient's spouse said to the other nurse, "You told me when you came in my wife's room at 6:00 a.m. that you were giving her heparin. Did you tell me the truth or not?"

The nurse manager, entering the unit, overheard the conversation with the family member and Alice's co-worker at the nurses' station. The nurse manager listened intently to the family member and apologized for the "mix up." Alice felt set-up and her suspicions were confirmed when one of the nurses on the night shift shared the perpetrator had informed her that she would be administering the said patient's heparin injection at 6:00 a.m., her last medication for the night shift, as they spoke in front of the medication pyxis. Alice shared this with her nurse manager who stated, "Alice, you have been nothing but trouble since you got here. You work with good nurses that try to support you, why don't you do the same."

Alice was visibly shaken with what had just occurred. She attempted to continue to work, but after this last incident, felt unsupported, betrayed, set-up, and paranoid about protecting her license. She informed the nurses she was working with, her patients and the nurse manager, that she felt ill and would be going home to rest.

Alice went home and fell asleep crying. When she awoke at 5:00 p.m., she could not believe that had slept so long. She finally felt rested after weeks of disrupted sleep. She ordered a salad and sandwich from a local deli and ate the full meal. At about 7:00 p.m., one of Alice's friends in the apartment building came to show Alice a dress she had purchased. They laughed and spoke at length over cups of tea. At 10:00 p.m., Alice cleaned her apartment and sorted through her mail. At 12:00 midnight, she took a shower.

At 3:00 a.m., Alice left her apartment building and drove over the small bridge. She stepped out of her car and looking at the calm waters, climbed on top of the bridge and jumped into the river below. At 5:30 a.m., Alice's car was discovered. Alice's body was recovered at 8:00 a.m.

Examining Alice's Case

In examining Alice's case, one of the factors that may have led to her suicide, was her being bullied at work and feeling unsupported. However, risk factors involved in her being vulnerable were her recent divorce and resulting relocation to a new state. In a new state and still healing from her marital problems, Alice's support system of family and close friends, were no longer a part of her immediate community. Alice had become increasingly emotionally fragile because of the steady escalation of the bullying and for Alice, the final incident of her being set-up to make a potential medication error by one of her perpetrators, made her feel like she had no way out of the situation. Alice left work with the plan to harm herself.

Evidence of Alice's initial contemplation of self-harm was her stopping on the small bridge and viewing the river below. After the final incident with a perpetrator at work and an interaction with the nurse manager that brought no resolution to the situation, Alice decided to end her life. Actual evidence of Alice's decision to end her life was her sudden ability to sleep without disruption, eat and enjoy a meal, have renewed energy to clean her apartment, and spend time with a friend laughing and enjoying the moment. All of the latter had been disrupted secondary to the stress Alice experienced from the workplace bullying.

The Unspoken Observations

Alice had worked at the hospital for over a year and the bullying had begun shortly after she was hired. It is likely that other nurses observed Alice being bullied in the workplace. However, no one intervened.

Nurses and Suicide

Suicide is when a person decides to end his or her own life. Rates of suicide vary considerably with regard to ethnicity, age, religion, countries in which persons reside, and sex. In 2015, suicide deaths worldwide were 1.4%, and suicide was determined to be the seventeenth cause of death (WHO, 2018). For persons aged 15 to 29 years of age, suicide is the second leading cause of death globally. Approximately 800,000 people die each year related to suicide. The World Health Organization (2018), in examination of indicators for adult suicide, noted that for every successful suicide, there are about 20 self-harm attempts.

Rates and frequency of suicide were trended by occupation. The determination of rates of suicide were calculated by age and sex. According to McIntosh et al. (2016), persons working in the fishing industries, forestry, and farming were at the highest risk for suicide. The overall suicide rate for this group was 84.5 per 100,000 population and 90.5 males. For females, protective service occupations had the highest risk for suicide at 14.1. Library, training, and education had the lowest rates of suicide at 7.5.

A United Kingdom study performed in England over a period of five years; 2011 to 2015, examined occupation, gender, and age in relation to suicide. Results indicated that males within health professions, had a lower risk of suicide (16% lower risk, with a 37% lowered risk for males that were identified as medical practitioners). However, females in health professions risk for suicide was 24% higher than the female national average. The occupation of nursing was the reason the suicide risks was 23% higher than the national average; female health professionals often chose poisoning as a means to end their lives (Windsor-Shellard, 2017).

A National Academy of Medicine (NAM) discussion paper written by Davidson, Mendis, Stuck, DeMichele, and Zisook (2018), examined the lack of information available in the literature on suicides within the nursing profession. The authors conducted an internet search on suicide by rates, year and occupation within the United States. Data examined occupations that provided services to the public. These are the following professions that data were found on during the internet search: military officer (combat infantry closed to women- 37.2/100,000; combat infantry, engineer never deployed and closed to women- 41.2/100,000; combat support medical- 18.5/100,000, all data from 2004-2009), police officer (108 per year, 2016), physician (300 to 400 per year, data from 2015 to 2016), and educator (63 per year, data from 2011). No data were found on nurses.

There are approximately 3.4 million practicing nurses within the United States (ANA, 2017). Statistically, hospitals tend to trend data regarding nurses such as, injuries sustained on the job (worker's compensation), turnover in the hiring of nurses, and stress and burnout risks within the profession of nursing. However, when a nurse self-injures and ultimately commits suicide, none of these data are available by health care facilities. According to Davidson et al. (2018), for nurses that commit suicide, whispers of their death are heard among colleagues and no data to interpret the potential meaning of their loss of life, is known.

Nursing is a profession of caring whereby relationships are developed daily among colleagues, patients' families, and patients. The nurse regularly interfaces between varieties of different disciplines. Nurses must daily meet the needs of patients and the expectations of healthcare systems, while coping

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

with deaths of patients and peers they have grown close to. Nurses may also be attempting to thrive in work situations where they have had to cope with the criticism of other nurses, resulting in low self-esteem and disempowerment.

Suicide risks for nurses are similar to those of the public (CDC, 2018). For example, nurses that have a mental (or physical) illness may be at risk for self-harm during periods of exacerbation of symptoms and stress. Also, if a nurse has a history of addiction to drugs or alcohol, these also put the nurse at risk for poor impulse control and self-harm. Nurses that have a history of a relative that successfully committed suicide are also at risk for self-harm as well. Of greater concern for nurses that are suicidal is their clinical knowledge, skills, and accessibility to lethal means to end their lives. For example, nurses have access to a variety of different drugs via pills, injections, sublingual, transdermal patches, and intravenous routes that can abruptly end one's life.

Because of the daily physical, emotional, and spiritual intensity of the nursing profession, nurses experiencing personal problems at home such as divorce, caring for an ill family member, or child-rearing issues, may feel overwhelmed. As the nurse begins to feel overwhelmed, hopelessness and helplessness may become central to their daily thought processes, leaving the nurse feeling depressed. It is when the nurse feels depressed, hopeless and helpless, the potential contemplation for a plan of suicide (suicidal ideation), may develop.

Nurses can be educated on how to recognize and help other nurses who may be at risk for self-harm. Becoming aware of potential warning signs for suicide is a proactive way of understanding how to intervene to keep nurses alive. The following are examples of warning signs:

1. The nurse is preoccupied with dying and death; discussing people who have died or perhaps examining websites or YouTube videos about death
2. The nurse no longer takes an interest in their appearance and may even appear disheveled at times
3. The nurse begins to take risks that are unwarranted such as jumping off a cliff to swim or bungee jumping
4. The nurse talks about having difficulty sleeping and a change in appetite
5. The nurse has mood lability or changes in their behavior that is atypical to how they usually behave
6. The nurse no longer has an interest in work, hobbies, spending time with friends socially, or if a student, disinterested in school
7. The nurse has a prior history of a self-harm attempt
8. The nurse has recently had several losses such as the death of a spouse, child, close friend, the end of an intimate relationship with a partner, or a divorce
9. The nurse has recently suffered significant material, property, or financial loss
10. The nurse begins to use drugs and alcohol by their report, to calm themselves, for sleep and/or to reduce their stress
11. The nurse begins to give away material items of great significance to them
12. The nurse occasionally talks about suicide or brings up self-harm out of the context of a conversation focused on a different topic
13. The nurse visits a funeral home to make arrangements for death or makes out a will
14. The nurse, who is normally very religious, stops going to church and reading their primary religious text (i.e. Torah, Bible, Quran)

Verbalized Feelings of Suicide

Persons that are suicidal may sometimes voice their feelings, it is however important that someone listens. The subtle words of a person struggling with the decision to live or die can be misinterpreted or misunderstood. Below are statements that can be associated with a person contemplating life or death:

1. "I just can't sleep or eat anymore."
2. "This sadness just will not go away."
3. "No one pays attention to me anyway."
4. "No one listens to what I say."
5. "I just can't get my life together. It all feels out of control."
6. "I feel like I am always going to have pain in my life."
7. "I feel like no one cares for me or cares to be around me."
8. "Why would anyone think I'm smart?"
9. "I have felt depressed for a long time."
10. "It all seems so hopeless."
11. "I just feel so ambivalent about everything. I don't know how I am going to make this decision."
12. "I just cannot gather my thoughts."
13. "I am just in so much emotional and physical pain."
14. "I don't think there are any solutions. I just need to be left alone."
15. "This bullying has become too much for me to deal with. I feel like no one is ever going to help me."

Nurses Supporting Nurses

The American Nurses Association's Code of Ethics encourages collegiality among nurses. For nurses identifying and supporting colleagues at risk for self-harm, it is important to help affected nurses get help. Nurses experiencing the stress of bullying in addition to the normal stress of their job as a nurse and personal life stressors, may feel hopeless. Below are interventions that nurses can implement in helping other nurses who are contemplating suicide:

1. Discuss with the nurse that there are other alternatives
2. Immediately remove stockpiled pills, knives, guns, or other items that can be used by the nurse to harm themselves
3. Never promise to break a confidence or be sworn to secrecy
4. Never dare the nurse to harm themselves
5. Make yourself available for support
6. Show an interest in the nurse's health and well-being
7. Obtain assistance from agencies or a professional that has a specialization in suicide prevention and crisis intervention
8. Never come off as being judgmental toward your nurse colleague
9. Listen intently as they express their feelings. Do not judge them or offer your opinion

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

10. Openly discuss suicide and suicidal ideation. Ask your nurse colleague directly whether they are having thoughts of self-harm
11. Ask your nurse colleague if they have a plan to harm themselves. If they answer yes, ask them to describe the plan
12. Never act surprised or shocked about the nurse's disclosure of, or attempt to self-harm. Keep the conversation(s) open

Getting the Suicidal Nurse Help

When exploring available services for nurses who are at risk for self-harm, it is important to be aware of crisis intervention and available professionals in the surrounding area that are convenient and easily accessible. There are crisis intervention services available in every state. For nurses, it may be helpful to begin with contacting a professional through their employer's employment assistance program (EAP). For nurses that do not desire any contact directly or indirectly related to their employment, the Federal Communications Commission (2017) offers the dialing of 2-1-1, as a means to obtain information on available human service agencies in their local area. The 2-1-1 number is accessible to over 270 million people within the United States, Puerto Rico, and the District of Columbia. For nurses unaware if 211 is available in their local area, go to the 211 website, www.211.org.

The National Suicide Prevention Lifeline (NSPL, 2018) is a 24 hour service offered seven days a week. The NSPL is available to provide emotional support to persons in crisis. All information is confidential. The NSPL also provides information on available services within person's immediate areas where they reside, for crisis intervention. For nurses assisting nurses that may be struggling with thoughts of suicide, the NSPL number is 1-800-273-Talk.

Nurse Workplace Bullying and Incivility and the HEAR Program

In exploring a potential program that can be used to assist nurses that may be at risk for self-harm secondary to workplace bullying and incivility, the Healer Education, Assessment and Referral (HEAR) program can be an option. The HEAR program is used to identify doctors that are at risk for self-harm by applying two approaches in helping physicians not harm themselves. The first approach uses educational presentations on the topics of depression, suicide, and burnout. The second provides an anonymous confidential web-based assessment and screening tool for physicians to take privately. The web-based assessment and screening tool is encrypted and is an Interactive Survey Program (ISP) developed specifically to identify physicians at risk for self-harm and depression (Davidson et al., 2018).

At the University of California San Diego Health, a university affiliated health care institution, before the year 2009, each year, a faculty member, medical student, or resident, committed suicide (Davidson et al., 2018). A survey to assess the well-being of physicians was developed and findings revealed significant drinking among faculty and residents at 6%, self-reported depression at 29%, and active suicidal ideation at the rate of 3% or higher (Reinhardt, Chavez, Jackson, & Mathews, 2005). A committee was developed to investigate the creation of a program that could help prevent suicide within this population. The committee, entitled the Physician Well-being Committee (PWBC), working closely with the American Foundation for Suicide Prevention (AFSP), and developed the HEAR program (formerly known as the Suicide Prevention and Depression Awareness Program).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The HEAR program currently has helped to decrease the suicides at the University of California San Diego Health, from 1 suicide a year, to 1 suicide in 6 years. During the years 2009 to 2016, 502 medical faculty, 341 fellows, 90 residents, and 519 medical students, have completed the web-based survey. Approximately 63 met with a program counselor in person, 112 communicated online with a counselor online, and 9 spoke to a counselor on the telephone (Davidson, et al., 2018). The HEAR program is currently offered within 8 medical schools, over 60 medical teaching campuses, and continues to grow (Davidson, et al., 2018). The HEAR takes a proactive stance on suicide prevention.

Nurses, like physicians, work long hours, and have difficulty balancing their work and personal lives. Compassion fatigue, stress and burnout, workload demands, and one's own values and ethics conflicting with those of the health care organization, can also contribute to nurses feeling frustrated and depressed. Although nursing is a profession that requires collaboration with other health care disciplines and fellow nurse colleagues, nurses can feel isolated in their roles as healthcare professionals, especially when working within dysfunctional workplace cultures with bullying and lateral violence present.

Both nurses and physicians must have a keen eye for assessment and the ability to differentiate disease processes presenting in their patients with subtle symptomatology. Davidson et al. (2018) notes that persons who decide to become nurses, may have the characteristics of perfectionism and are compulsive with an acute attention to detail. While these traits can be beneficial, specifically to patients whom have placed their lives in the capable hands of these health professionals, these same traits increase the likelihood for stress.

Davidson et al. (2018) trialed the HEAR program with a participant group of nurses. Out of 2,475 nurses, 172 completed questionnaires. Upon completion of the questionnaires, data indicated that 98 (55%) nurses were at moderate risk for self-harm, 19 (11%) reported having previously attempted to harm themselves, and 12 (7%) had active thoughts or made actions to self-harm. Seventeen of these nurses agreed to receive help via a referral, for mental health treatment and 44 (26%) received either verbal or in-person counseling services. Based upon the data, nurses were found to have benefited from the HEAR program, and proactive screening for suicide is an effective means of identifying nurses at risk for self-harm.

RECOMMENDATIONS

Given the successful trial of the HEAR program with nurses, it may be beneficial for hospitals and other healthcare facilities to consider adopting this program for both nurses and physicians to promote healthy work environments. This program can help prevent self-harm with these vulnerable health professions. The HEAR program may help screen nurses whom are victims of workplace bullying. Because nurses experiencing bullying and incivility can have depression, stress, and anxiety, in addition to physiological symptoms, use of HEAR program within health care institutions may help identify these nurses early. By identifying nurses at risk for self-harm related to workplace incivility and bullying, nurses can be provided emotional support before suicide becomes an irreversible option.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Putting Yourself First

It is important that nurses put themselves first when it comes to coping and healing from experiences of bullying. Nurses who decide to place all of their energies into work solely, may feel emotionally empty and have difficulty managing frustrations related to their own victimization. For nurses experiencing uncivil conduct within the work environment, the ability to distance from the actual workplace and focus on the completion of work during actual work hours, can be healthy. Setting boundaries around self-care and the protection of one's mental and physical health, can be beneficial for affected nurses in the preservation of physiological and psychological homeostasis.

Appendix 2 contains activities that further explore job-related stress in relation to workplace bullying. Self-care and the importance of nurses being aware of suicide risks and prevention are discussed. Suicide resource support for nurses and their affected colleagues, are also provided.

APPENDIX

Exploration Activities

Directions: The purpose of the *Exploration Activities* are to encourage reflection on the issue of uncivil conduct in nursing by recording one's feelings about the act of incivility. Please answer the questions or statements independently or within a group for discussion.

In your opinion, should health care facilities be more in-tuned to the problem of incivility within the profession of nursing?

_____

Have you experienced job-related stress because of your interactions with an uncivil co-worker?

_____

Are you currently experiencing job-related burnout?

_____

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Do you plan to leave a job that you have enjoyed in the past, because of your experience with incivility?

_____

Do you feel that your decision to resign from a job that you enjoy because of a bully, is the wise choice to make at this time? If yes, why?

_____

If you are currently being bullied in the workplace, have you disclosed to anyone what is happening to you and how it makes you feel?

_____

Do you lose sleep at night replaying thoughts in your head regarding demeaning or stressful interactions you have had with someone that is intentionally bullying you at work?

_____

Have you suffered headaches or stomach discomfort the moment you get to work in anticipation of a stressful day working with a co-worker that is unnecessarily rude or negative toward you?

_____

Do you replay conversations of the uncivil behaviors of the person(s) whom is bullying you at work when you are driving home from work or when you are at home?

_____

Have you spent valuable time with family and friends discussing the stress you are experiencing at work because of a bully?

_____

Are you ready to disempower the negative effects that you have permitted the perpetrator(s) to have in your life? _____
_____

_____

Recognition that a bully exists solely because of their own insecurities, can lead to healing. Do you honestly feel that your bully is confident, or that their uncivil conduct is likely related to their own poor self-esteem and tendency to compare themselves to others?

Chapter 69
Medical Students' Quest Towards the Long White Coat:
Impact on Mental Health and Well-Being

Christina Ramirez Smith
https://orcid.org/0000-0001-6599-768X
University of the Bahamas, Bahamas

ABSTRACT

Every year across the globe, thousands of students begin the quest towards becoming a medical doctor and donning a long white coat. Global research indicates that after beginning medical education, medical students' mental health and well-being dramatically declines. The loss of well-being continues into the residency and practice of medicine. The aim of this chapter is to broadly examine the pressures unique to medical students within the context of medical education training, higher education, and the general population. A call for medical education to adopt innovative policy, plans, and administrative and curricular changes designed to foster a culture conducive to the long-term positive mental health and well-being of medical students during training and into the internship and long-term practice of medicine concludes the chapter.

INTRODUCTION

The 'long white coat' is the symbol of the medical profession and universally worn by physicians (Lippman, 2016). Patients, physicians themselves, medical and health professionals, and the community at large maintain some idea of what it represents. Each year across the world, new medical students slip on a short white coat and begin what the author terms a quest towards the achievement of wearing a long white coat, symbolising to everyone the successful completion of training at the undergraduate medical education level, followed by an internship and residency leading to practice as a doctor. Along the way, evidence-based research over the past eight decades (Rotenstein et al., 2016; Strecker, 1936) has revealed that the prevalence of stress, anxiety, and depression among medical students is higher than the general population (McManus et al., 2009).

Studies highlight medical students' mental health deterioration over time (Slavin, 2016; Wasson et al., 2016). Clearly, it has been established that the pressures of pursuing a medical degree have a negative impact upon some medical students' mental health and well-being. The problem is considered to have reached an epidemic level (Gunderman, 2016; Hafferty, 1998; Mousa et al., 2016; Slavin, 2016). Given what is known about the academic competencies and personality traits necessary for students to succeed in medical education (Abbiati et al., 2016; Gunderman, 2016; Rotenstein et al., 2016), this chapter offers a brief examination through five general questions of the problems, issues, and controversies contributing to the persistence of the crisis regarding student mental health and well-being during medical school.

- Who are medical students?
- What is the meaning of mental health and well-being and the significance of the long white coat?
- Globally, what pressures contribute to college students' mental health crises?
- What is medical student life like, and what pressures encountered during medical education negatively impact mental health and well-being?
- How can the culture of medicine and medical education create policy, planning, and administrative and curricular innovations to improve the mental health and well-being of future physicians?

BACKGROUND

Who Are Medical Students?

Across the globe, medical students generally have attained an undergraduate degree at a university or college followed by a medical programme of study of 4 to 5 years of medical school (GKEN, 2009). Upon completion of the medical school curriculum, which can include a couple of years of classroom instruction followed by another 2 years of practical experiences, the student is awarded a Doctor of Medicine (MD) or Doctor of Osteopathic Medicine (DO) degree. Graduation from medical school is followed by the residency, with the length of time and training varying according to the chosen speciality. Clinical speciality training can be as little as 3 years and up to 8 years and culminates with board certification. In the United States, medical school training includes a period of 10 to 16 years of higher education, and postgraduate training defines the pathway to becoming a doctor (American Medical Association, 2014).

Medical Student Characteristics

There is current debate on which personal competencies are important for students entering medical school (Abbiati et al., 2016) and which of these characteristics could predict future success as caring, efficient, professional, and empathic doctors (Koenig et al., 2013; Mahon et al., 2013). While the academic requirements necessary to handle the rigour of medical education training are well documented (Monroe et al., 2013; Povis, 2015; Richardson et al., 2013) and include standardised examinations such as the Medical School Admission Test (MCAT), high school GPA, and undergraduate GPA, how to assess the personality characteristics for handling stress, motivation, and learning traits is not a standard process.

Although there is no single answer to the question of what it takes to be a successful medical student, medical school admissions website list many of the following characteristics deemed desired and essential for students to be successful:

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Strong academic background. Students must possess knowledge of the basic scientific model, biology, and possess scores from college grades and medical school admissions tests indicating the potential to succeed.
- Time management skills. The daily schedule of attending classes, labs, and related requirements is incredibly time-consuming in addition to the long hours of study. These activities pull students in many directions at once, and the ability to prioritise, plan, and stick to a schedule is vital.
- Personal motivation and ambition. Students must be able to persist and persevere through the long and exhausting routines of medical education.
- Interpersonal skills. Students must demonstrate the ability to collaborate with peers, faculty, and staff and to work with healthcare teams. Oral and written communication skills are needed to share information and to convey empathy.
- Professional conduct. This is assessed by personal integrity, honesty, and ethical behaviour. Students must be aware of their own strengths and weaknesses and know when to ask for help. Owning prior experiences where compassion was evident and a commitment to improving the human condition are essential components of professional conduct.
- Genuine interest. This is the ability to delay gratification in social and personal areas of life in order to put in the long hours of work necessary to learn volumes of information. A love of the material and a sense of curiosity are needed to sustain the difficult and sometimes overwhelming challenges encountered.
- Stress management skills. Stress in medical school is a constant. An essential quality for navigating the process is students' abilities to take care of themselves when being intellectually pushed to their limits while being deprived of sleep and exercise. The ability to ask for help is crucial. Psychological resilience demonstrated through emotional stability, coping skills, maturity, an ability to endure hardship and sacrifice, and good judgement are fundamental skills.

In the United States, Belgium, and Canada, admissions departments have added strategies to evaluate personality traits of perspective students by use of the personal statement, letters of recommendation, involvement in extracurricular activities, on-campus interviews, and multiple mini-interviews. Situational judgement tests as well as psychological tests (Abbiati et al., 2016) are also used. Research conducted by Doherty and Nugent (2011) acknowledged that certain personality characteristics influence both medical students' and doctors' performance and that the personality trait recognised as conscientiousness has been found to be a significant predictor of performance in medical school. However, in the same study, the authors noted that the relationship between personality and performance becomes increasingly significant as learners advance through medical training. Other personality characteristics such as sociability (i.e., extraversion, openness, self-esteem, perfectionism, and neuroticism) can impact the mental health and well-being of medical students. Povis (2015) noted that good selection of medical students is 'an unresolved challenge'.

What Is the Meaning of Mental Health and Well-Being and the Significance of the Long White Coat?

The pilgrimage to obtain admission to and graduate from a medical programme is exceptionally competitive, and it is not surprising that the stress associated with undertaking a medical degree poses a significant problem for some students (Adsett, 1968; Dyrbye & Shanafelt, 2011; Hutchins, 1964; Lancet,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

1980; McGuire, 1966; Strecker, Palmer, & Braceland, 1936). Furthermore, as recently as December 6, 2016, a major research study on medical students' mental health released in the *Journal of the American Medical Association* confirmed information about medical students' mental health and well-being known to the medical profession, but it was a shock to many worldwide. Specifically, the study pooled data from more than 195 individual studies of medical student depression and suicide totalling 129,000 medical students from 43 countries and found that 27% of medical students were depressed or had depressive symptoms, while 11% reported thoughts of suicide, and 15% had sought psychiatric care (Rotenstein, 2016). According to this study, the results support the contention that more research efforts are necessary to improve the mental health and well-being of medical students. Specifically, the report stated, 'The overall prevalence of depressive symptoms among medical students in this study was higher than that reported in the general population, which underscores the need for effective preventive efforts and increased access to care for medical students.'

While some studies report the high incidence of medical student and physician suicide, others highlight the deterioration in mental health of medical students over time and attribute its cause to the outcome of stress related to poorer academic performance, substance abuse, eating disorders, decline in personal self-care, and loss of self-confidence in addition to myriad distress symptoms and behaviours such as competitiveness, preparing for examinations, and hidden curriculum issues (Doja et al., 2016; Williams, 2016).

These findings from evidence-based reports on documented medical student distress to the point of decline in this population's ability to embody humanistic qualities and empathy (Schwenk et al., 2010) is at odds with the primary goal of medical education to prepare and graduate knowledgeable, skilled, and professional physicians (Mayo Clinic, 2005). Similarly, other researchers suggested that, on a personal level, some aspects of medical education may have unintended consequences that negatively influence medical students' mental health and well-being (Association of American Medical Colleges, 2016; LCME, 2003; Noori et al., 2016).

In addition to the known stresses associated with medical training, an added pressure is assumed by many students because of the purported prestige and power family, friends, and society believe will be bestowed upon the medical student after graduation. To understand how the perception of wearing a long white coat is viewed in society in contrast to what it means in the health professions is helpful in conceptualising how its attainment may present another unintended negative stressor in the lives of medical students.

The Long White Coat

For centuries, a white coat has symbolised the medical doctor. The long white coat today demonstrates that a medical student has successfully navigated the pilgrimage from student to intern, to resident, and finally, to attending physician. All over the world, students don short white coats to symbolise the beginning of a career that embodies professionalism, caring, and trust. In the United States, a white-coat ceremony is intended to create a 'psychological, intellectual, and ethical contract for the profession and promotes empathy in the practice of medicine from the inception of a student medical education' (Columbia School of Physicians and Surgeons, 2017).

Furthermore, the tradition of wearing a white coat began in the early twentieth century, as doctors previously wore black, formal attire. It is considered that the white coat was adopted to enhance the credibility and image of doctors as learned scientists. At Columbia School of Physicians and Surgeons,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the tradition of the white-coat ceremony began in 1993 and is practised at more than 130 schools of osteopathy and medicine in America and at four medical schools in Israel and other countries. Today, a long white coat is still a symbol of status in the medical field and communities around the globe. Studies revealed that getting through medical school is challenging in a variety of ways, and the effects of the stress on the mental health and well-being of medical students has been documented (Dyrbye et al., 2005; Rotenstein et al., 2016; Slavin, 2016; Wasson et al., 2016).

MENTAL HEALTH

The beginning of a student's medical training is the best point at which medical schools should explain that mental health conditions are common and that there are students who had mental health issues in the past who went on to successful residencies and practices. Additionally, medical schools ought to clearly explain why it is critical for admissions officers to know about students' health conditions prior to the start of the programme. Open and honest discussions between students and the medical school is necessary so that proactive plans can be implemented on a student-by-student basis as opposed to the reactive measures most medical programmes offer in response to medical student distress. A powerful teaching point for medical schools is to clearly explain what sound mental health and well-being look like as a benchmark for students to understand how to manage their own self-care, and later, their patients' care. The consequences of these disorders in terms of lost health are tremendous. A sound state of mental health and well-being are fundamental to our collective and individual ability as humans to think, interact with one another, earn a living, and enjoy life. On this basis, the promotion, protection, and restoration of mental health can be regarded as a vital concern of individuals, communities, and societies throughout the world.

The implications, then, for medical educators, medical students, their families, and society at large are imperative in understanding what is considered good mental health and well-being.

The constitution of the World Health Organisation ([WHO], 1969) notes, 'Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity'. WHO (2016) defines mental health as a 'state of well-being in which an individual realises his or her own abilities, can cope with the normal stresses of life, can work productively and is able to make a contribution to his or her community'. The WHO (2016) definition clarifies an understanding of what constitutes positive mental health, and these traits can serve as benchmarks in recognizing the following:

- Mental health is more than the absence of mental disorders.
- Mental health is an integral part of health; indeed, there is no health without mental health.
- A range of socio-economic, biological, and environmental factors determines mental health.

According to WHO (2016), some factors to better understand the construct of mental health, as well as some related determinants of mental health, include the following:

- Multiple social, psychological, and biological factors determine a person's level of mental health at any point in time. For example, persistent socio-economic pressures are recognised risks to mental health for individuals and communities. The clearest evidence is associated with indicators of poverty, including low levels of education.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Poor mental health is also associated with rapid social change, stressful work conditions, gender discrimination, social exclusion, unhealthy lifestyle, risk of violence, physical ill health, and human rights violations.
- Specific psychological and personality factors also make people vulnerable to mental disorders.
- Lastly, there are some biological causes of mental disorders, including genetic factors, that contribute to imbalances in chemicals in the brain.

Another report released by WHO (2017) indicated that the number of people living with depression increased by more than 18% between 2005 and 2015. These statistics are also found in a study completed by Global Burden of Disease (2015). A study by Baxter (2013) supports the findings that reveal an overall growth trend of the global population mental health deterioration as well as a proportionate increase in the age groups at which depression is more prevalent. Syntheses of the available epidemiological literature on the prevalence of depression and other common mental disorders have been undertaken as part of earlier iterations of the Global Burden of Disease study and are available through WHO (2015). Globally, the total number of people with depression was estimated to exceed 300 million in 2015. Nearly that number again suffers from a range of anxiety disorders. Since many people experience both depression and anxiety disorders simultaneously (comorbidity), it is inappropriate to simply add these two figures together to arrive at a total for common mental disorders.

Sound mental health is comprised of the emotional resilience that allows us to enjoy life; survive pain, disappointments, and sadness; and contribute to and engage productively in our communities and society. There is a personal sense of self-worth as well as the same in others.

WELL-BEING

There are many documented definitions and models of well-being. In order for administrators, faculty, staff, medical professionals, families, and medical students to embrace the idea of a multidisciplinary approach to proactive care for distressed students, it is necessary to establish a common ground for understanding what well-being entails. In the 2017 book, *Attending: Medicine, Mindfulness, and Humanity*, Ronald Epstein addresses the meaning of well-being by considering the question: 'What is well-being, anyway?'

There is no universal consensus on what constitutes well-being. The foundations of human well-being may be discussed in terms of sustainability of the environment and human spirit. Yet there is no universally accepted definition of sustainability. Despite this lack, maintaining and fortifying the human foundations of well-being is an everyday challenge. The foundations of human well-being are freedom, self-determination, intimacy with another, a social community, protection from the elements, food, water, health, entertainment, accumulation of things of value to promote human well-being, knowledge and opportunity to prosper, and opportunity to use one's talents. These foundations generally are linked to the culture of a community—a tribe or government (Vachon, 2012).

Epstein (2017) noted that when people have a deep sense of meaning and fulfilment, attainment of superficial achievements tends to be less important and may actually serve as distractions. On the other hand, people with a 'sense of purpose, satisfaction, joy and meaning' experience an intrinsic sense of fulfilment, and it is this deeper kind of 'well-being' worth pursuing (Epstein, 2017, p. 168). Another definition of well-being is based upon the 12 pillars of well-being created by Rick Hanson and used in the Foundations of Well-Being Program by applying what Hanson refers to as the four sources of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

well-being—recognising, resourcing, programme, and relating—to three fundamental needs of safety, satisfaction, and connection. The model provides a comprehensive strategy for understanding and applying self-care techniques to improve the quality of life. Other important definitions of well-being are offered by organisations such as the Association of American Medical Colleges (2016), who, in response to the crisis of mental health concerns amongst its professionals and students, launched a new Web site on well-being in academic medicine.

A recent study by the Public Research Bureau (2015) defined well-being as:

[H]aving an objective dimension—by determining whether an individual's basic needs for food, shelter, economic security, social relationships, and health care are being met.

Most researchers have examined two main aspects of subjective well-being as a dimension of well-being and found that because these two measures capture different aspects of well-being, using them together can provide a rich picture of life satisfaction and quality. A third type of subjective well-being, known as *eudaimonic* well-being, measures an individual's sense that his or her life has meaning and purpose (Deci & Ryan, 2008). Although aspects of this measure overlap with the other two, it is distinct in that it is based upon an understanding that people are motivated by factors beyond their own personal happiness or satisfaction (National Research Council, 2013).

A Centres for Disease Control and Prevention (2016) concept paper offers this definition of well-being: 'Wellbeing as judging life positively and feeling good'. From this perspective, the ideal of well-being integrates mental health (mind) and physical health (body), resulting in a more holistic approach to health promotion and disease prevention (Dunn, 1973). Some researchers using experimental, longitudinal, and cross-sectional studies found that well-being is associated with factors in the social and physical environment, with numerous health-, job-, family-, and economically related benefits, such as social connectedness, mental and physical illness, longevity, self-perceived health, healthy behaviours, and productivity (Lyubomirsky et al., 2005). Higher levels of well-being are associated with decreased risk of disease, illness, and injury; better immune functioning; speedier recovery; and increased longevity. Some researchers purport the view that positive emotions—central components of well-being—are not merely the opposite of negative emotions but are independent dimensions of mental health that can and should be fostered (Bradburn, 1969; Dunn, 1973).

Other research has noted that a substantial proportion of the variance in well-being can be attributed to heritable factors (Barry, 2007; Lykken & Tellegen, 1996) and that environmental factors play an equally, if not more, important role (Diener et al., 2006; Frey & Stutzer, 2002). The bottom line in considering well-being is the idea that a good state of mental well-being is possible, although an individual might be diagnosed with mental illness. Another way of thinking about mental health and well-being is to examine how it relates to the concept of wellness. The founder of the National Wellness Institute (NWI), Bill Hetter (1996), developed a six-dimension wellness model that has proven to be effective in the helping professions. This holistic model focuses on the following six aspects of life related to wellness:

- **Occupational Health:** At least two different focus areas contribute to occupational wellness. The first is creating a healthy work environment that can help to reduce stress, such as staying hydrated at work and staying active in the office. The second area focuses on feeling fulfilled. This means the self-recognition of the importance of work in which one is engaged as well as holding the perception that one's career is fulfilling.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Emotional Health:** The ability to balance the different priorities in life contributes to emotional health. Examples include balancing work, volunteering, family, and downtime. Being emotionally healthy means being in control of one's emotions and a general feeling of good well-being.
- **Intellectual Health:** Learning new job skills, vocabulary, life skills, games, or fun habits are all ways to enhance intellectual health. The opportunity to learn new things is an important factor in intellectual health.
- **Social Health:** This involves creating and maintaining healthy relationships. These relationships can help build a strong support system. In today's society, social health can also encompass cultural health—another common wellness dimension.
- **Physical Health:** This includes everything from physical activity and nutrition to hydration and even illness. How a person's body physically functions entails physical health.
- **Spiritual Health:** This can be closely associated with emotional health. Some medical schools attempt to address emotional well-being through activities such as meditation, yoga, and mindfulness training. Spiritual health is generally associated with a range of connectedness, which in turn provides benefits for one's well-being.

According the National Wellness Institute (1996). 'Wellness is an active process through which people become aware of, and make choices toward, a more successful existence'. The following three questions were devised by the National Wellness Institute to help individuals and organisations assess the degree to which wellness is incorporated into a particular approach or programme:

- Does this help people achieve their full potential?
- Does this recognise and address the whole person (multidimensional approach)?
- Does this affirm and mobilise peoples' positive qualities and strengths?

Supporting Hetter's (1996) wellness model, the Centres for Diseases Control and Prevention (2016) suggest that 'Wellness focuses on improving how one's body works rather than meditating or reflecting on a current state of being'. This definition of wellness places the focus on progress. This type of thinking can be useful in helping medical students create and maintain small healthy habits that amount to a complete wellness.

Well-Being and Wellness: Alike or Different?

Well-being and wellness are related concepts. Well-being is associated with numerous health, job, family, and economically related benefits. For example, higher levels of well-being are associated with decreased risk of disease, illness, and injury; better immune functioning; speedier recovery; and increased longevity (Pressman, 2005). Individuals with high levels of well-being are more productive at work and are more likely to contribute to their communities (Frey, 2002; Tov, 2008).

Well-being is a holistic state of being. It is an overall positive existence that includes being emotionally, spiritually, socially, and mentally grounded. A positive state of well-being is characterised by overall contentment and balance in one's life. To ensure a holistic approach to helping medical students cope with the pressures of medical education, concepts of mental health, well-being, and wellness are useful constructs from which the question becomes less about what the problem is and more about promoting

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

high levels of mental health, something research has proven is associated with productivity, increased learning, prosocial behaviour, and positive social connections (Diener, 2009; Herrman, 2005).

Ultimately, the author contends that mental health is complex. Having a common ground from which an understanding of what is meant by mental health, well-being, and wellness will go a long way in helping everyone concerned about the deteriorating mental health and well-being of medical students to contribute to the prevention of mental health conditions in an open and honest environment. Students will have different needs and variance in their experience of mental health problems, including how they choose to think about their issues and whether they want to share their difficulties. Therefore, keeping in mind that mental illness or mental health difficulties can beset students at any point in the academic career is essential. All mental health problems are not directly related to the stressors and pressures of medical education. Slavin (2016) called for medical education professionals to recognise that the 'responsibility for student well-being should not be limited to one office and one administrator; student wellness must be everyone's concern'.

ISSUES, CONTROVERSIES, AND PROBLEMS

Globally, What Pressures Contribute to College Students' Mental Health Crises?

University and related organisations worldwide are grappling with many of the same pressures to manage the growing crisis of college students' mental health and well-being. A global scan of the literature in higher education associated with mental health problems and mental illnesses reveals a problem of great magnitude.

Kadison and Digeronimo (2004) noted that the mental health of university students in the United States has suggested that there is a crisis in mental healthcare in colleges. Research conducted by the National Alliance on Mental Illness (2017) on mental health on college campuses shows that the top five mental health issues facing students included depression, anxiety, suicide, eating disorders, and addiction. Other statistics noted from the same study showed the following:

- One in four college students has a diagnoseable illness.
- Forty per cent of college students do not seek help.
- Eighty per cent of college students feel overwhelmed by their responsibilities.
- Fifty per cent of college students have been so anxious they struggled in school.

Mascaskill (2012) found that the rates of mental illness in students equalled those of the general population, but only 5.1% were currently receiving treatment. Second-year students reported the most significant increases in psychiatric symptoms (Maunder et al., 2010). In their work on mental health problems and help-seeking behaviour among college students, Hunt and Eisenberg (2010) summarised much of the current literature on the prevalence of mental health problems in college-age students. The key findings when compared to the mental health state of nonattending college peers include the following:

- A lower prevalence of drug use disorders and nicotine use,
- A higher prevalence of alcohol use disorders,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Approximately the same overall 12-month prevalence of mental disorders.

A summary of the scope and prevalence of data examined from the Centre for Collegiate Mental Health Report (2010) confirms that 'There is a general consensus amongst colleges and university counselling centres that the prevalence and severity of college student mental health is on the rise' (p. 16). Canada, the United Kingdom, and Australia were amongst the leading countries noted as having a strong interest in the mental health of youth, including college and university students. Adlaf et al. (2004) cited results from the Canadian Campus Survey that described the prevalence of mental health problems among Canadian undergraduate students. Four key findings from the survey indicated that students seeking higher education were found to present mental health issues, hazardous and harmful drinking, alcohol and other drug use, and gambling.

In the United Kingdom, an increased awareness of the importance of mental health and well-being at the government level is evident in the 2011 publication, *No Health Without Mental Health: A Cross-Governmental Health Outcomes Strategy for People of All Ages*, which sets forth a framework for its mental health system to focus on individuals by combining efforts with the community at large to improve mental health and well-being and to promote mental well-being for all citizens. Similarly, Scotland's (2012) mental health strategy was created to integrate system-wide quality for people with mental health issues. Wales's 10-year plan, *Together for Mental Health: A Strategy for Mental Health and Wellbeing in Wales* (Wales, 2010), demonstrates the international commitment to improving the mental health and well-being of citizens at large.

Factors contributing to the increase in students presenting with mental health issues are linked to the findings in the literature on mental health generally. For discussion purposes in this chapter, these findings are organised into three broad areas: general societal pressures, pressures associated with higher education settings, and pre-existing mental health issues.

General Societal Pressures

Support for the contention that anxiety and depression are a possible source of the mental health distress seen around the world in higher education settings is based upon recent statistics from WHO (2017), indicating that more than 350 million people in the world suffer from depression and related disorders. It can be said that today's students are living in an age of anxiety, and depression reports similar to WHO's statistics indicate clear trends in the increase of depression. Depression is a common mental disorder—it is one of the main causes of disability worldwide—and more women are affected than men. Specifically, in the WHO European region, statistics show that if anxiety and depression were combined, then 4 out of 15 people are affected by these mental health and related disorders.

Studies show that the rates of depression in America have risen dramatically in the past 50 years. Anxiety disorders are the most common mental illnesses in the United States, affecting 40 million adults age 18 and older, or 18% of the population (National Institute of Mental Health). Nearly half of those diagnosed with depression are also diagnosed with an anxiety disorder. It is not uncommon for a person with an anxiety disorder to also suffer from depression or vice versa (Anxiety and Depression Association of America, 2016).

A possible explanation from the data regarding the college student mental health crisis is the fact that mental health and well-being distress are a global phenomenon. Underlying this assumption, questions about what is causing the deterioration of mental health in society at large should be considered. The

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

causes are speculative in nature, but some scholars in the area of mental health and well-being suggest that the current mental health crisis has been influenced by rapid social and academic changes over the past few decades. Some examples of critical areas of change have been observed in areas such as the following:

- Psychopharmacology and the increase of the disease-pill model of mental illness has skyrocketed over the past few decades, reflecting the use of medication to manage psychological symptoms (America's State of Mind, 2011). It is worrisome that an entire report is an inventory of pill usage for the treatment of psychological and behavioural problems.
- Disintegration of the traditional family structure has been viewed as a source of contention globally, as research documented many problems that stem from the unstable environment and lack of structure needed for children to build a secure base. Instances of divorce, 'modern families', and confusion of roles have been cited as an enigma to providing what some scholars consider necessary so that children get what they need the most: predictable family structures and stable, loving, and supportive homes.
- Loss of moral compass and purpose, according to Barry Schwartz in his book *Battle for Human Nature: Science, Morality, and Modern Life* (1987). His work offers a fascinating sociological explanation for the impact the emergence of science has had on society, both positively and negatively. In particular, Schwartz describes how religion has been de-emphasised and replaced by a focus on materialism and hedonism, both associated with lower levels of well-being. Furthermore, Schwartz contends that the displacement of religion in society opens a door for people to construct their own lives based upon their own moral decisions. As a result, people are fundamentally uncertain of what they believe and why. They lack a philosophy of life.
- Along the same lines, another insightful book that presents a view on the inability of today's young adults to ground their actions from a moral perspective is *Lost in Transition: The Dark Side of Emerging Adulthood* by Christian Smith, Kari Christoffersen, Hilary Davidson, and Patricia Snell Herzog (2011). One characteristic described is the confused state of purpose from which deep-seated problems may be created, such as depression, anxiety, and other mental illnesses. Students appear to be pursuing higher education to ensure long-term financial gain as opposed to developing a meaningful philosophy of life.

These examples must be viewed from a context of the larger societal values. It is important to bear in mind that the terminology *emerging adulthood* was coined in 2000 by Jeffrey Arnett to describe a whole additional period of development in the lifespan (18–37 years of age). It is attributed to the rise of the modern society and its complexities, thus requiring a longer period of development before functioning independently. This development is worth considering in respect to its impact on mental health and well-being.

Another possible issue impacting mental health and well-being is the fact that the economic upheaval worldwide in 2008 continues to wreak havoc for many people. The fallout of the economic depression is relevant to college-seeking youth, as more of them have to work to pay for college, fight the rising costs of attending an institution of choice, and live with the uncertainty of job prospects at the end of college. Mounting personal debt at the beginning of adulthood is overwhelming and discouraging, as unemployment or underemployment still pervades (FRB, 2003).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Pressures Associated With Higher Education Settings

College was traditionally reserved for society's elite until several decades ago. Major strides have made higher education more accessible to a diverse population. As a result, through legal changes, accommodations and support for students with mental health difficulties are available as part of most campus services. However, the transition is extremely stressful, in particular for those students in the traditional age range. In a time of 'helicopter' and 'snowplough' parenting, some students are totally unprepared for the stressful environment and competitiveness encountered.

The significant social upheaval experienced by students seeking higher education is a concern because a major risk factor for affective mood disorders can result from a lack of social support, especially when coupled with major stressors (Kashani et al., 1994). The stress associated with the transition to university life adds additional risk factors (e.g., Bryde & Milburn, 1990; Chemers et al. 2001; Gall, 2000; Montgomery & Côté, 2003). This frequently involves living away from home for the first time, having to make new friends, handling finances, adjusting to new learning regimes, and creating a new identity as a student (Scanlon, Rowling, & Weber, 2010).

Academic expectation and performance factors are often a surprise for students. In particular, those in the traditional age group who have been accustomed to getting top grades in high school may be unprepared when faced with college-level academic performance. Consequently, a vicious cycle of stress associated with poor academic skills and unpreparedness for the rigours of the higher education environment can result in some students' failure in the face of greater pressure to succeed.

Other sources of major distress for students are associated with the spiralling cost of higher education, especially in the United States, where the rise in college fees and tuitions has outpaced the rate of inflation while funding for higher education has continued to be reduced. The financial burden experienced as a result of policy decisions directly impacts students' abilities to attend college without working. In many instances, students work beyond the recommended part-time 10–20 hours; instead, some are forced to work full time, thus resulting in delayed graduation. Other noteworthy areas of problems and issues that have increased include drug and alcohol abuse, sexual assault, gender problems, family and relationship problems, and grief.

Previous Mental Health Issues

Mental illness is more publicised today than it was in the past; yet, in many circles, stigma still follows the people with the problem and is avoided by those around them. The attitude towards mental illness remains a dynamic that requires massive education, awareness, access to care, and a system that fosters well-being rather than avoiding these problems. Mackean (2011) confirmed that students experience mental health challenges right at the period of development in which they are entering the higher education system:

- The years between 15 and 25 are a natural age for the onset of mental disorders, an age where young people are pursuing higher education.
- Pre-existing mental health issues are more prevalent amongst students pursuing higher education.
- The prevailing stigma toward mental illness forces students and families not to disclose pre-existing conditions due to the fear and shame attached to these struggles.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

The literature suggests that the failure of students and their families to disclose information about existing mental health difficulties during the recruitment and admission process creates another barrier at the onset of higher education pursuits. In addition to students' omission of mental health problems, a worrisome trend on many campuses is the inability of counselling departments to keep up with the demands for service from those who do seek help in a timely fashion.

There is a growing recognition that students with clinically recognised levels of mental difficulties are studying in larger numbers. It is important to note that some level of stress does not necessarily have to have a negative impact and can be stimulating. For all students, engaging in higher education can also make a positive contribution to mental well-being in that it contributes to the following:

- Provides a purposeful environment.
- Provides opportunities for personal and academic achievement that can lead to a fuller life, creating a sense of identity and increased self-esteem.
- Offers opportunities to build confidence, as new experiences provide the chance to manage a variety of demands.
- Extends through more diverse student bodies the chance to build new relationships.
- Provides an opportunity to make a contribution to a community while learning how to take care of oneself.

The evidence suggests that, with young people, early intervention can play a crucial role in outcome (Kosky & Hardy, 1992), so the task for universities is to make it easier for students to access specialist treatment by ensuring they provide adequately resourced services. Additionally, institutions need to help students capitalise on the positive mental health benefits of higher education while identifying and providing appropriate support to those who are more vulnerable to its pressures. Research on what causes pressures in students pursuing higher education holds many implications for medical education to benefit from the lessons learnt around the world in a variety of university and college settings.

Models of wellness to support students suffering with mental health issues require higher education institutions to promote self-agency, resilience, and independence in an academic environment that is not based upon a deficit model where only students who reach crisis points are offered support. Higher education institutions are not only seeking to improve the environment for students, faculty and staff, for the sake of students. By its nature, much of the core business of higher education means that student, faculty, and staff concerns are interrelated and interdependent.

The Healthy Universities Initiative (Healthy Universities Network, 2010) is a model for how higher education institutions can create holistic healthy settings for the support and management of mental health issues and problems. Healthy settings are physical and social settings, such as schools, workplaces, hospitals, and communities, that serve as supportive environments for health protection and health promotion activities (Yusoff et al., 2013)

Other lessons from higher education include the awareness that the response to mental ill health is the job of everyone in the institution. But it is imperative to remember that students often prefer to get help from those they know and trust—for example, family and friends. For mental well-being-related information to be effective, dissemination routes should encompass the whole institutional population.

Research on what causes pressures in higher education students holds many implications for medical education to benefit from the lessons learnt around the world in a variety of university and college settings. A conclusion drawn from research by Douce and Keeling (p. 6. 2014) reminds us that 'not all

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

students who could benefit from mental or behavioural health services will come to the counselling centre today, or any day. Students may not recognise the need for or recognise the availability of services'.

The purpose of this literature scan was to explore the extent to which the crisis has been documented globally and why this crisis holds implications for medical education. The scan does not purport to be a depth-and-breadth review of the literature on this subject matter. Providing a connected culture of care will maximise learning and produce resilient and healthy world citizens.

What Is Medical Student Life Like, and What Pressures Encountered During Medical Education Negatively Impact Mental Health and Well-Being?

The lived experience of medical students involves a range of activities, pressures, and outcomes. In general, students perceive the medical profession as one that brings power and status. As early as the beginning of medical education, medical students experience feelings of omnipotence reflecting the role of physicians in society. However, at the same time, they face situations of pain, suffering, death, and social realities different from their own. Some students may experience an ambivalence of feeling satisfied coupled with the fears, demands, pressures, and insecurities of the medical profession. They consider that a medical school demands exclusive dedication, and indeed, they devote a large part of their time to it, to the detriment of other areas of their lives. When they compare themselves to other young people from other programmes, they feel that more is demanded from them. They also feel more stressed, more responsible, and less capable of managing their personal and financial lives. Considering these ambivalent experiences, students must learn to leave this 'mesh' and differentiate good from bad experiences in academic life. Thus, in the midst of this mix of sacrifice and renouncement, they also recognise rewards and satisfaction, leading to a sense of personal pride.

The fact that stress is cited as the single greatest impediment to academic achievement by both genders, with depression and anxiety ranked as the top reasons for the crisis in college student mental health distress, is significant. Similarly, issues of depression, stress, anxiety, and related tensions are common pressures experienced by some medical students during the years of medical education. To support this well-known situation, researchers from Singapore analysed 77 studies, examining nearly 63,000 medical students across the globe (Puthran et al., 2016). The results from this meta-analysis found that 28% of medical students are depressed and that 5.8% have considered suicide.

Distress in medical students is not just a first-world problem. The percentage of students with depression or depressive symptoms ranged from 20% in Europe to 31.8% in the Middle East. Medical students in North America had the second highest prevalence at 30.3%. Still, there were no statistically significant differences in depression by region, sex, or even between medical students and nonmedical students (Yusoff et al., 2013). Yusoff et al.'s study supports views that medical training is not an optimal environment for the psychological health of medical students.

It is important to note that the following discussion is a general overview of pressures associated with medical training and the fact that suicide, depression, anxiety, and related tensions appear to be the most prevalent problems experienced by medical students globally and that awareness of the cultural impact on students in different countries will vary. For example, in China, acceptance to medical school is not necessarily as prestigious as it is in the United States. Students with the highest scores pursue careers in computer science; for those whose examination scores are not high enough, medicine is the second career choice

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

To understand the range of pressures medical students are exposed to, the author attempted to synthesise from a scan of the literature how these problems manifest into issues, problems, and even controversy during the pursuit of medical education. The discussion is organised into the following three broad categories: academic pressures, social and personal pressures, and medical school debt on medical students' mental health and well-being (American Medical Association, 2015; Claassen et al., 2016; Edwards & Zimet, 1976; Tempski et al. 2012).

Academic Pressures

- **Formal Curriculum Stressors:**

The academic pressures associated with obtaining a medical education exemplify a culture of high achievement, commitment, connection, and focus. However, the configuration of many medical education curricula into three distinct learning and teaching segments as denoted by a formal, informal, and hidden curriculum provides a systematic method of thinking about the particular types of stresses experienced by medical students.

The formal curriculum includes what is to be taught, while the informal curriculum may be defined by how teachers teach and how students and teachers interact. The most controversial area of a medical school culture is known as the hidden curriculum. Hafferty (1998) proposed that a set of influences that function at the organisational structure and culture of a medical school is deemed the hidden curriculum. However, characteristics of the hidden curriculum, such as a commonly held understanding of how to behave, what is really expected of students, and what issues or problems should not be taken on, is implicit in student interactions with administration, staff, and faculty. The controversial nature of the hidden curriculum still needs to be studied in respect to its impact on medical student distress.

Most medical students will admit to becoming stressed out or panicked about life in medical school on a fairly regular basis. The programme of study varies across medical schools around the world in the scope, sequence, and length of preparation. What is common, however, is the transitions that students experience as they progress from one stage of training to another—for example, first year versus third year, then internships followed by residencies requires adaption to new a transition.

Noteworthy pressures experienced by medical students may include some of the following stressors closely related to the formal and informal curriculum.

- **Colossal Information Overload:**

Students are shocked by the extraordinary amount of medical information to be memorised and applied at some point in the near future. For many students, the realization that it is impossible to remember every detail from the extensive medical information, as well as master it, can forge feelings of stress. The vast amount of information in medical school is overwhelming, and during the first half of the programme, many students drop out (Karpf, Perman, & Higdon, 2006; Lazin & Nuemann, 1991; Lorgren et al., 2006).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Fear of Failing:**

The author informally discussed this topic with a third-year medical student who summed up just how distressing the underlying fear of failure can be for students beyond passing the medical school formal curriculum, boards, and other forms of evaluation along the pilgrimage towards becoming a physician: 'Just graduating is fine, but it does not matter if you do not match for residency'.

- **Peer Competition:**

Competitiveness among peers has been reported due to concerns related to continuing education in highly requested residency programmes (usually those with specialisation in areas of potentially better income). For many students, medical school is the first time they encounter equally smart, or perceived smarter, people. They deem them as threats, and this in turn might impact academic performance (Supe, 1998).

- **Mastering Medical Knowledge:**

The ability to not only learn a massive amount of information but also to attempt to master the material at a rapid pace can be a source of distress. This challenge is amplified for students with learning disabilities (Stewart et al., 1999). Additionally, students are faced with learning in an unstructured environment to prepare for the continuous high-stakes examinations at the end of each course and between transition years, such as the USMELE 1 or COMLEX 1, which determine academic advancement. The distress that may result from constant evaluation is also heightened because, as students rotate through clinical training, medical knowledge becomes more specialised, and rather than highlighting students' progress, deficiencies are amplified.

- **Bad Role Models**:

Unfortunately, it has been documented that medical school training is characterised by a decline in humanitarianism and empathy (Crandall et al., 1993; Woloschuk Harasym, 2004). & These traits are highly valued in the helping professions; yet, the apparent cynicism towards students by medical academic faculty, staff, and administrators appears for some to be a normal strategy for interacting with students. Statements such as 'Medical school is extremely rigorous', 'If students are not strong enough to handle the stress, then another career should be pursued', or just the dismay expressed towards students when additional help is needed can negatively impact students (Hafferty, 1998).

In a qualitative research study, Tempski et al. (2009) noted an insensitivity to students' needs and students' perceptions by insensitive faculty: 'Bad teachers and coordinators, and classes without a didactic approach worsen quality of life'. Much of medical student training involves performing in front of colleagues and peers. Students report extreme distress when faced with the negativity commonly observed during routine medical teaching and learning situations. Most medical students have a memory of a negative incident whereby, for example, 'pimping' resulted in a wrong response, and the resident insulted the student. The pain and distress associated with this teaching method—teaching by intimidation—has been reported as adversely affecting the mental health of students. The extent to which this type of teaching strategy is used in medical training is described in the book *How Doctors Think* by (Groopman, 2007),

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

in which he explains that physicians are trained to always entertain the worst-case scenarios first in order not to miss important diagnoses. Instructors rely on the dynamic known as negativity bias and use it as a technique for pushing students to think critically. Unfortunately, negative experiences seem to have more influence than positive experiences. This is the thinking behind the continued use of the pimping teaching strategy, to the emotional demise of students (Vaish et al., 2008).

Personal and Social Pressures

- **Hidden and Informal Curriculum:** The pressures associated with the adjustment to the medical school environment extend beyond the stressors related to academic expectations and academic performance. Other sources of distress for many students, such as a deficit in hours of sleep, physical activity, lack of social interactions, and adapting to the myriad behaviours inherent in the informal and hidden curriculum of medical education, are problematic as well as controversial (Lempe, 2004; Parkernson et al., 1990; Tempski et al., 2009).

Students reported a variety of difficulties and crises during medical school (Tempski et al., 2012) that affected them personally and socially. According to Goldman, Shah, and Bernstein (2015), 'Medical training involves numerous risk factors for mental illness, such as role transition, decreased sleep, relocation resulting in fewer available support systems, and feelings of isolation'. Issues associated with the hidden and informal curriculum add to the personal burdens and internal struggles for students that include an inability to handle problems related to the bureaucratised medical school culture.

- **Bureaucratised Medical School Culture:** The organisational structure of many medical programmes is a source of contention for students, and in some instances, for staff and faculty. Specifically, the academic side of the medical programme is operated independently of the student affairs division, as each has its own responsibilities and budgets. Historically, the integration and collaboration between these two divisions remained separated. While this model seems effective, the resources allocated to each has a direct impact on the ability of the medical institution to provide a plethora of services that might be needed to support the mental health of students. For example, most dedicated funds are allocated to the academic side of the institution to support faculty salaries, research, and continuous improvements to the academic environment. The student affairs division that handles the counselling, learning support, and advising of students in academic, personal, and extracurricular activities is usually unable to meet student demands for help in a timely fashion. Additionally, students resist using many of the services offered by the student affairs division for fear that confidentiality might be compromised, thereby forcing a student to go outside the institution for help. Overall, the lack of coordination in meeting student needs between these two divisions is likely to be a barrier to students receiving timely support.
- **Informal Curriculum:** The messages students pick up from interactions with faculty, administrators, other students, and eventually, from residents and physicians appear to negatively influence and impact them. Medical students report being at the bottom of the medical system hierarchy, where they are often disrespected and subjected to abuse by allied health professionals and unsatisfied physicians, are unlikely to take proactive actions in self-defence. Adding to these stressors is the student's need to ensure strong evaluations and recommendations to advance to the next stage of medical training by making good impressions on supervisors.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **No Time to Be Sick:** Some students' mental and physical health is compromised because they have not engaged with a personal physician. Others ascribe to the 'hidden' messages collected in the hallways of medical schools, hospitals, and related environments. For example, some students reported a lack of care associated with their own health and well-being according to the harmful habits observed and adopted by teachers (Thislethwaite et al., 2010).

When it comes to mental health and well-being, students afraid of stigma resort to self-care and suffer silently. The hypocrisy endemic in the medical school culture, although being addressed, is far from a reactive disease approach rather than a preventive model. Such a model would advocate first for the health of students and doctors before giving them the responsibility of ensuring the health of society at large. Many reasons are reported for student lack of self-care in addition to problematic scheduling to allow for personal well checks and follow ups with a primary doctor. Finally, studies have shown that doctors self-manage, self-treat, and enter into hallway conversations about their own health needs (Cohen & Rhydderch, 2013). Where issues of ill health are minimised and resilience expected, medical students learn coping methods from the informal and hidden curriculum. Furthermore, students learn to self-manage illness early in the process of medical education, which increases during training, where access to drugs becomes more available.

- **Student Abuse:** Amongst medical students, the perception of being taken advantage of or abused is common and most noted during the clinical years. However, institutional abuse, such as racial discrimination and unfair grades, has been attributed to prolonged stress and anxiety, hostility, low self-esteem, and increased use of alcohol by students who were affected by abuse (Silver & Glicken, 1990). Verbal abuse is the most common stressor within this category of abuse and includes cases of pimping, which involves being humiliated in front of peers, residents, and staff and produces high levels of pressure. The severity of verbal abuse is not reported due to student perceptions of potential reprisals or repercussions on performance evaluations (Elnicki et al., 2002).
- **Gender and Race:** The syndrome known as the invisible white coat describes the behaviour of patients who assume that the student is a nurse even though a white coat is being worn. This issue is a double-edged sword for women of colour (Russo et al.2006; Swift, 2017). used data from a documented study to analyse gender differences in perceived pressures and distress in medical students. Their findings revealed that female students appeared to be at a higher risk for anxiety than male students. Related to the higher level of anxiety found in female students was peer competition compared to male students who reported more anxiety in regards to the long hours. The stress associated with gender and race adds a significant burden to medical students who have to deal with an additional source of stress.
- **General Personal Life Events:** Personal life events such as marriage have proven to have a positive impact on students' stress levels, although having children has proven more stressful for females while in medical school (Katz et al., 2000). Personal illness and death of a family member adds to distress. Greater study into the impact of family member deaths and the illness of peers on medical students is needed.
- **Forming Professional Identity:** Due to the variations in medical school structures, curriculum, missions, and values, many important facets of forming a professional identity are left to incidents and information gathered by medical students' observations, perceptions, and exposures during formal training. Sources of distress related to managing the transition, especially in the third year

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

of medical education when students go from classroom and laboratory settings to rotations where decisions and first-time experiences in dealing with patients, presenting cases, dealing with death and suffering, or being present at an unexpected death causes students enormous distress, as most have had very limited training, if any, on how to handle these aspects of the profession. Student training is deficient in this area of the curriculum. The informal curriculum conveys powerful messages about professional norms, values, and character. The unfortunate models of cynicism and unethical behaviour witnessed by students in the clinical setting is often shocking and contradicts the lessons taught in medical school (formal/structured curriculum) versus those learnt in practice. Students are left with conflicted emotions and an ethical conflict between doing what is right or following the examples of seasoned practitioners to whom they rely upon for recommendations to advance. As one third-year medical student noted, finding a balance between being assertive and being an annoying 'gunner' is difficult.

- **Social Pressures:** Educational and clinical demands leave little time for the health and social activities that promote well-being. Many medical schools have buddy schemes and a wide range of societies to help combat isolation; yet, studying medicine can still seem exceedingly lonely. Medical students' schedules are different, which can be a barrier to establishing or maintaining relationships. Some students may not reach the typical milestones of same-aged peers because instead of thinking about buying a house or starting a family, the focus is on studying and working towards the next phase of the pilgrimage towards obtaining a long white coat.

There are varying attributes of social pressures experienced or perceived by medical students, and although not a mental disorder, the issue of the 'imposter syndrome' may cause distress. The imposter syndrome is characterised by chronic feelings of self-doubt and fear of being discovered as an intellectual fraud. The personal expectation set by students once they announce a medical school career to family and friends may compound the problem of pressures. It behoves medical educators to reconsider facets of medical education (i.e., shame-based learning and overall teaching style) and to optimise the medical learning environment (Villwock et al., 2016).

- **Medical School Debt:** Financial debt is a key determinant that predisposes students to depression, as noted by Jenkins et al., (2008) who established a clear link between financial debt and poor mental health. The impact of debt on the mental health of medical students has not been studied to a great extent. However, in the first study of its kind, Walsemann et al. (2015) posed two important questions: 'What is the association between the amounts that students accrue during studies and their wellbeing post-graduation when they are between the ages of 25–31?' and 'What is the association between annual loan student borrowing and the mental wellbeing of currently enrolled students?' This is the first nationally known study in the United States that attempted to examine the effects of student loans on health. According to Walsemann et al., the possible impact of these high debts could influence other life decisions, such as occupational choices. This finding is already evident in the medical profession, where a study by Phillips et al. (2014) indicated that medical students are staying away from family medicine practice because the income and rate of debts owed are not panning out, thus a significant shortage in primary healthcare providers by 2025 is anticipated and will be a be a major issue for healthcare. While medical student debt is increasing, the effect of debt on student well-being and performance remains unclear (Morra et al., 2016).

Having surveyed the types of pressures associated with the challenges and barriers confronting medical students, what lessons have been learnt, and what ought to be done to prevent medical student distress? The solutions and recommendations offered next result from the considerations of lessons students with similar challenges to mental health and wellbeing: college students, graduate and doctoral level learners.

SOLUTIONS AND RECOMMENDATIONS

How Can the Culture of Medicine and Medical Education Create Policy, Planning, and Administrative and Curricular Innovations to Improve the Mental Health and Well-Being of Future Physicians?

Currently, many of the proposed solutions to address student mental distress are externally designed and managed through changes in the resource allocation of the medical school, institutional policies, and evaluation activities that do not bear on the internal or intrinsic needs of future physicians. Although the hidden curriculum may hold convoluted messages of self-sacrifice that stop students from seeking help, there are solutions aimed at the prevention of common pressures associated with medical training at each major transition point in medical education designed to promote sound mental health and well-being. The following solutions and recommendations are general ideas that warrant further exploration and research:

1. A global network of curricular benchmarks and best practices to help students adapt to entry into medical education, thus preparing them for the huge academic requirements and fostering critical thinking and a realistic understanding of how to take care of themselves.
2. Specific strategies aimed at solutions for subpopulations of medical students who experienced other pressures within the medical school structure. Women, students with disabilities, and students from ethnically and culturally diverse backgrounds in many cases require more support in managing medical school challenges. All struggling students require opportunities for individualised support.
3. Train the trainers programmes designed to teach medical educators how to organise the massive amount of information deemed necessary for students to traverse the medical school system. Pedagogical training in teaching methods will provide a structure within the curriculum to avoid both faculty and student burnout. Research is needed to determine how medical faculty are deciding what, how much, and the rate which medical knowledge should be imparted to students. Collaborative teaching strategies, where two teachers are actually in a classroom at the same time as opposed to the singular approach used to deliver high volumes of information, are more appealing to students. The dynamics of co-teaching have been proven successful in other teaching institutions. Furthermore, the overemphasis on rote learning has been proven ineffective for long-term memorisation and understanding. Bloom's Taxonomy (Bloom 1956) exists as proof that teaching scientific concepts, critical thinking, and higher-order learning techniques whereby subject matter is interrelated contributes to long-term learning.
4. The focus on students' internal motivation when entering medical training where traits such as strong work ethic, altruism, and intrinsic motivation provide a basis for reducing the stress associated with the overreliance on GPA rankings. The success of future doctors as caring, compassionate,

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

and competent physicians has to be based upon something other than GPA and high ratings on the board examinations as the strongest indicators for future success.

5. Stakeholders at the national, regional, and institutional levels must collaborate on how funding is to be implemented within the medical education structure to provide prevention education in the systems associated with training physicians. Funding is necessary to train the trainers and to increase staff in the student development and counselling areas so that students receive treatment immediately for problems encountered.
6. Common ground training for recruiters of prospective medical students beginning at the middle-school levels and into college.
7. Common ground information for families, spouses, and professionals close to medical students in layman's terms. Topics should include how to recognise change within the student and how to provide support for and information about what is generally being experienced by the student. The awareness that students have to learn a lot of information does not describe student daily lived experiences of attending lectures and learning massive amounts of material in addition to earlier immersion in hospital settings where they encounter life-and-death situations, sometimes before being academically prepared.
8. Common and realistic pre-entry training for medical school students that includes basic testing for pre-existing mental health problems, learning problems, and issues related to becoming ready to matriculate into the academic rigours associated with medical training. Similar processes are deemed necessary to prepare students to transition between classroom training, labs, early entrance into hospitals, and working with patients to managing the internship and residency experiences. Sharing known literature and best practices based upon practical knowledge of seasoned doctors can help students learn in advance how to prepare for transitions, thus preventing trial-and-error experiences.
9. Revamp the structure of medical education. Theories of how adults learn and lessons learnt from medical schools with best practices should be embraced. The culture of medicine warrants changes in the components of the formal, informal, and hidden curriculum; institutional policies; and culture of medical schools from academically driven agendas to development of physicians as complete people.

FUTURE RESEARCH DIRECTIONS

While new and innovative strategies designed to assist medical students with mental health issues include changing grading systems from letter grades to pass/fail, voluntary classes in mindfulness, and creation of wellness initiatives in many more medical educational institutions, future research is imminent. The following questions remain to be addressed:

- What is the best structure for medical education?
- How do medical students learn best?
- What is the best type of curriculum change requisite to ensure that medical education prepares students on a spectrum of well-being and wellness areas to extend into social, personal, financial, emotional, and physical well-being?

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

- How can medical schools educate the public, prospective students, and their families about the rigours associated with medical training?
- How can students seek help without the stigma associated with mental illness impacting future internships, residencies, and job placements?
- How can the dollars and human resources in medical education be allocated beyond the academic side of the programmes to include proactive well-being student support services?

Finally, more research is needed from the perspective of the medical student on the pressures associated with medical school at each stage of training. Outside of medical student blogs, there is insufficient literature from the student perspective.

CONCLUSION

Medical school is supposed to be a time of personal and professional development. There is enough data to show that medical training leads to mental ill health in medical students and residents. The moment to re-engineer medical education is present, and all our lives depend upon drastic measures designed to help medical students navigate medical education with sound mental health and well-being.

KEY TERMS AND DEFINITIONS

Graduate Medical Education (GME): The period after graduation from a medical education programme. Recognised by entry into an internship and residency period ranging from 3 or more years, depending upon the speciality area of study.

Healthy Universities: Institutions with initiatives designed to create holistic settings that incorporate many interrelated factors in the academic environment. These factors include academic, social, economic, and environmental areas that may impact the mental health of students.

Higher Education: Education provided by a college or university.

Medical Education: Education related to the training of being a medical doctor or physician. The process of obtaining a medical education generally begins after the completion of higher education at the bachelor and/or master's degree level. Across the world, training varies in academic requirements and programme lengths. Generally, medical education programmes include 4 years or more of undergraduate medical training. This programme of study is followed by what is known as graduate medical education and encompasses an internship, residency, and fellowship training. The residency and fellowship training periods vary according to specialities. Graduate medical education leads to licensure. Some countries, such as the United States, the United Kingdom, Canada, and Australia, have specific continuing medical education activities designed to help physicians increase the knowledge, skills, and professional performance necessary to stay current.

Medical School: The educational organisation providing a basic (undergraduate) programme in medicine. It is synonymous with medical faculty, medical college, medical academy, or medical university.

Mental Health Promotion: Improving the capacity of everyone to take control of their lives and to improve their mental health. At the community level, it involves public policy to enhance the personal skills and services necessary for achieving optimal mental health.

Mental Ill Health: A mental health problem can feel just as bad, or worse, than any other physical illness, only you cannot see it.

Chapter 70
Deliberate Self-Harm and Suicide Ideology in Medical Students

Vinod Gopalan
Griffith University, Australia

Erick Chan
Griffith University, Australia

Debbie Thao Thanh Ho
Griffith University, Australia

ABSTRACT

The risk of deliberate self-harm (DSH) and suicide ideology in medical students is a pertinent issue that has received a surge in attention over recent years. Medical students are at risk of normalisation of DSH and suicide ideology despite their mental health literacy levels and are still susceptible to the stigma of help-seeking for their mental wellbeing. This chapter will explore assessment, preventative and management strategies to improve education, awareness and ultimately reduce the rates of DSH and suicide risk. A comprehensive review of practices and techniques that medical training community and their family members could utilise to aid medical students to adequately and safety manage DSH and suicide ideology. This will assist in identifying crucial areas for future research to aid students, professionals, family and friends in supporting medical student health to optimise mental health overall wellbeing of medical students.

BACKGROUND

The risk of deliberate self-harm (DSH) and suicide ideology in medical students is a pertinent issue that has received a surge in attention over recent years (Wu et al., 2016, Rotenstein et al., 2016). Rates of suicide among general adolescents are increasing at staggering rates. This population of young adults

are considered 'at risk' in 33% of countries around the world (Miletic, Lukovic, Ratkovic, Aleksic, & Grgurevic, 2014). Rotenstein et al. extracted suicidal prevalence data from 24 cross-sectional studies from 15 countries resulting in a pooled prevalence of suicidal ideation of 11.1% in medical students. Wu et al. conducted a cross-sectional study of over 4000 students from 22 Chinese medical universities, and found that prevalence of DSH was 9.6% over 12 months. It is, therefore, important for medical students, professionals, parents, and friends to understand the impact of DSH and suicide ideology on an academic and psychosocial level. Furthermore, because DSH and suicide ideology prevalence can be reduced with early intervention, it is all too important to know how to screen for early signs and symptoms as well as provide appropriate intervention (Downs et al., 2014).

Medical students are a unique population as they are learning about the organic and psychosocial impacts of mental health, including factors that may contribute to poor mental health, whilst being exposed to these exact factors. Stressors that are prominent in medical students include increased contact hours, high academic pressure, assessments, exposure to high-intensity workloads, high-performance expectations, strained social balance and workplace bullying (Chan, Batterham, Christensen, & Galletly, 2014; Osama et al., 2014; Wu et al., 2016). There are multiple factors contributing towards negative mental health sequelae among medical students and it can lead to undeniably anxious and stressful times during their academic and clinical career. These sequelae may involve more common psychiatric presentations such as anxiety and depression, to more formidable presentations such as DSH and suicidal ideology (Wege, Muth, Li, & Angerer, 2016).

Medical schools have an inherent requirement to produce safe working graduates and they must also ensure that students are primed to cope with stress, burnout, and failure. Addressing the negative mental health sequelae is therefore in the best interest of every medical school. Promoting and enhancing medical student well-being will be beneficial for each trainee throughout their career, with benefits in overall education, physician resilience, personal fulfilment, professionalism and of course patient care (Dunn, Iglewicz & Moutier, 2008).

DSH is most commonly associated with borderline personality disorder and is often associated with major depression, antisocial personality disorder, dissociative identity disorder, posttraumatic stress disorder, eating disorders, autism, developmental disabilities and Lesch-Nyhan syndrome (Stanley et al., 2010). At a molecular level, serotonergic and dopaminergic dysfunctions do not appear to be related to DSH, however, it has been demonstrated that those who self-harm have lower levels of CSF ß-endorphins and met-enkephalins, both of which are opioids involved in emotion-induced and physical pain analgesia (Stanley et al., 2010). This is an important distinguishing factor as serotonergic and dopaminergic dysfunctions are usually associated with suicidal behaviour and depression, whereas endogenous opioid deficiency plays a more prominent role in DSH without suicidal intent (Stanley et al., 2010). This relationship will be discussed further in the following sections.

For the purposes of addressing medical student stress, this chapter refers to medicine as traditional Western medicine, not inclusive of any alternative medicine fields.

DEFINING DELIBERATE SELF-HARM

Deliberate self-harm may seem to be a straightforward definition in and of itself, however, many more aspects must be considered, including the frequency and time-period that DSH may occur, the purpose or expectations by the individual and the associations that DSH may have with concurrent moods, feel-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

ings, and thoughts. This section will discuss various definitions of DSH, the types of self-harm and its relation to other mental health disorders.

The definition of deliberate self-harm has been argued in the scientific community without a resolute definition for many years. This phenomenon has also been known as self-harm, self-injurious behaviour, repeated self-injury, self-wounding, para suicide, self-mutilation, episodic and repetitive self-injury and autodestructive behaviour (Mangnall, 2008). Current literature has conflicting definitions including the intention to kill and intention to not kill, which convolutes the distinction of DSH from suicide ideology, as discussed later in this chapter. Based on the literature, DSH may be defined as a 'direct behaviour that causes minor to moderate physical injury, that is undertaken without conscious suicidal intent and that occurs in the absence of psychoses and/or organic intellectual impairment' (Mangnall, 2008).

This definition addresses both cause and purpose of DSH and this is further expanded upon in the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) criteria for diagnosis (See Figure 1) (Diagnostic and statistical manual of mental disorders, 2013). Key diagnostic features focus around repeated infliction of shallow yet painful injuries with a purpose to reduce negative emotions, such as tension, anxiety, self-reproach and/or to resolve an interpersonal difficulty though with an absence of suicidal intent. The individual may exhibit a behavioural pattern resembling an addiction or describe a compulsive nature due to an immediate sensation of relief during the self-harming process.

Figure 1. Proposed Criteria for Non-Suicidal Self-Injury
Source: Adapted from Diagnostic and Statistical Manual of Mental Disorders, 2013

NONSUICIDAL SELF-INJURY

Proposed Criteria

A. In the last year, the individual has, on 5 or more days, engaged in intentional self-inflicted damage to the surface of his or her body of a sort likely to induce bleeding, bruising, pain (e.g. cutting, burning, stabbing, hitting, excessive rubbing), with the expectation that the injury will lead to only minor or moderate physical harm (i.e. there is no suicidal intent.)
NOTE: The absence of suicidal intent has either been stated by the individual or can be inferred by the individual's repeated engagement in a behaviour that the individual knows, or has learned, is not likely to results in death.

B. The individual engages in the self-injurious behaviour with one or more of the following expectations :
   1. To obtain relief from a negative feeling or cognitive state
   2. To resolve an interpersonal difficulty
   3. To induce a positive feeling state

C. The intentional self-injury is associated with at least one of the following:
   1. Interpersonal difficulties or negative feelings or thoughts, such as depression, anxiety, tension, anger, generalised distress, or self-criticism, occurring in the period immediately prior to self-injurious act.
   2. Prior to engaging in the act, a period of preoccupation with the intended behaviour that is difficult to control.
   3. Thinking about self-injury that occurs frequently, even when it is not acted upon.

D. The behaviour is not socially sanctioned (e.g. body piercing, tattooing, part of a religious or cultural ritual) and is not restricted to picking a scab or nail biting.

E. The behaviour or its consequences cause clinically significant distress or interference in interpersonal, academic, or other important areas of functioning.

F. The behaviour does not occur exclusively during psychotic episodes, delirium, substance intoxication, or substance withdrawal. In individuals with a neurodevelopmental disorder, the behaviour is not part of a pattern of repetitive stereotypes. The behaviour is not better explained by another mental disorder or medical condition (e.g. psychotic disorder, autism spectrum disorder, intellectual disability, Lesch-Nyhan syndrome, stereotypic movement disorder with self-injury, trichotillomania (hair-pulling disorder), excoriation (skin-picking) disorder.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Self-harm may present in a multitude of ways and can be divided into two broad groups: self-injury and self-poisoning (Lilley et al., 2008). Self-injury most commonly presents by cutting oneself, whilst less commonly presenting as swallowing objects, putting objects inside the body, burning, self-bruising or breaking bones. On the other hand, self-poisoning involves overdosing with medicine(s), often over-the-counter medication or swallowing a poisonous substance (Lilley et al., 2008). It should be noted that there are no specifications as to whether the self-harming act is planned or unplanned and infrequent or frequent.

Unfortunately, the large majority of individuals who engage in self-harm do not seek clinical attention, although people who self-poison are most likely to seek professional medical assistance (Diagnostic and statistical manual of mental disorders, 2013; Lilley et al., 2008). It is hypothesised that the positive experiences gained by an individual who is self-harming may deter them from seeking treatment, whilst the absent suicidal intent is apparent in those who self-poison yet present to the emergency department (Diagnostic and statistical manual of mental disorders, 2013; Mangnall, 2008). These positive experiences may include a separation or disconnection from the individual's feelings or pain, and can develop as a method of coping with overwhelming situations or feelings.

DEFINING SUICIDE AND SUICIDE IDEOLOGY

The World Health Organisation defines suicide as the act of deliberately killing oneself. Suicidal ideology encompasses the contemplation of suicide, ranging from a detailed plan to a fleeting consideration. A suicide attempt is defined as a self-inflicted, potentially injurious behaviour with intent to die, however not resulting in death (Wasserman et. al. 2011). The DSM-5 further specifies a proposed criterion for Suicidal Behaviour Disorder, which makes a clear distinction from deliberate self-harm (See Figure 2).

Figure 2. Proposed criteria for Suicidal Behaviour Disorder
Source: Adapted from Diagnostic and statistical manual of mental disorders, 2013

SUICIDAL BEHAVIOUR DISORDER

Proposed Criteria

A. Within the last 24 months, the individual has made a suicide attempt.
   NOTE: A suicide attempt is a self-initiated sequence of behaviours by an individual who, at the time of initiation, expected that the set of actions would lead to his or her own death. The 'time of initiation' is the time when a behaviour took place that involved applying a method
B. The act does not meet criteria for nonsuicidal self-injury – that is, it does not involve self-injury directed to the surface of the body undertaken to induce relief from a negative feeling or cognitive state or to achieve a positive mood state
C. The diagnosis is not applied to suicidal ideation or to preparatory acts.
D. The act was not initiated during a state of delirium or confusion.
E. The act was not undertaken solely for a political or religious objective

Specify if
- **Current:** Not more than 12 months since the last attempt.
- **In Early Remission:** 12-24 months since the last attempt.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Suicidal behaviour can be categorised into violent and non-violent behaviours. For example, some violent behaviours include jumping from a life-threatening height and firearms, whilst non-violent behaviours may include overdosing with legal or illegal substances (Ajdacic-Gross, 2008). Suicidal behaviour can be associated with a wide variety of mental disorders, including bipolar disorder, major depressive disorder, schizophrenia, anxiety disorders and eating disorders to name a few (Diagnostic and statistical manual of mental disorders, 2013).

Wasserman et al. discuss suicide from the perspective of the Stress-Vulnerability model which explains that genetic make-up and acquired susceptibility both contribute to a person's predisposition or vulnerability to suicidal behaviour. This suicidal process involves an interaction of biological, psychological, environmental and situational factors. The vulnerability may be increased due to early traumatic life experiences, chronic illness, alcohol and drug use and environmental and social factors (Wasserman et al., 2011). The reasons for why people may attempt suicide include, though are not limited to, severe depression, impulsivity, psychosis, lack of help or social support and philosophical desire. Most importantly, many suicidal processes decline and subside by means of individual coping or treatment strategies (Wasserman et al., 2011).

THE RELATIONSHIP BETWEEN DELIBERATE SELF-HARM AND SUICIDE IDEOLOGY

Based on the definitions outlined thus far, the key distinction between deliberate self-harm and suicide ideology is that suicidal intent is absent in deliberate self-harm actions. Despite this difference, evidence suggests that those who engage in self-harm are at an increased risk of likelihood of attempting suicide (Wan, Y., Gao, R., Tao, X., Tao, F., & Hu, C., 2012; Whitlock et al., 2013). Whitlock et al. conducted a longitudinal study of 1466 students across five colleges in the United States and concluded that a history of deliberate self-harm among students significantly leads to concurrent or later suicide ideology. The risk of suicide ideology is usually predicted by the occurrence of >20-lifetime non-suicidal self-injurious incidents and by the history of mental health treatments. The act of self-harm has two important risk factors for suicide; the experience of emotional distress and the experience of self-inflicted pain/injury (Klonsky, May, & Glenn, 2013). This is particularly important because addressing the risk factors, protective factors, finding an appropriate method of screening and determining effective treatment should take consideration of the relation between DSH and suicide ideology.

EPIDEMIOLOGY OF DELIBERATE SELF-HARM AND SUICIDE IDEOLOGY AMONG MEDICAL STUDENTS

Deliberate self-harm and suicide ideology are increasingly common in young adolescents, with particular prevalence in medical students. This section will detail the epidemiology of DSH and suicide ideology amongst the general public and medical students.

According to the World Health Organisation, 'self-inflicted injury [defined as deliberate self-harm and suicide] is the fourth leading cause of death and sixth leading cause of morbidity and disability amongst people aged 15-44 years' around the world (Wu et al., 2016). This is evidently a serious public health concern, although, can be prevented with timely, evidence-based and often low-cost interventions (Wasserman et. al. 2011).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

Deliberate Self-Harm

Prevalence of DSH is difficult to ascertain as individual concealment and unwillingness to seek help can substantially underestimate the true prevalence of DSH. Higher prevalence of DSH amongst general population of students is a universal finding with 12-month prevalence of 7% and lifetime prevalence of 17% in American students, life-time prevalence of 15% in Turkish students, 12-month prevalence of 33% in Indian students and 11-33% in Chinese students (Wu et al., 2016). According to the Royal College of Psychiatrists, 1 in 3 people who self-harm for the first time will have a repeat episode in the following year, whilst 3 in 100 people who self-harm over 15 years will actually kill themselves (Bateman, 2014). The short-term recurrence and long-term consequences further highlight the importance of assessment and treatment.

In a recent study that examined deliberate self-harm among Chinese medical students, the 12-month prevalence was found to be 9.6%. This was lower in comparison to the general student population, however, is possibly due to their 'academic background' which may increase their understanding and implementation of self-care (Wu et al., 2016). Despite this the prevalence being lower than the general population of students, this remains to be an important issue that needs to be addressed. Previous studies from the UK and the USA have found that the amount of self-reporting in medical students is indeed higher than other college students, thereby increasing their likelihood of receiving treatment (Wu et al., 2016). Amongst medical students, male students reported a higher prevalence of DSH than females with one study finding that 11.51% of males self-reported DSH compared to 8.71% of females. The most common types of DSH being hitting in males and scratching among females (Wu et al., 2016).

Several key demographics are found to be linked to DSH including age, academic background and household income (Wu et al., 2016). DSH has become more prevalent among adolescents, young adults and college students, with DSH prevalence highest among freshmen and receding with progression through college. Also, low socioeconomic status has also been associated with higher prevalence of DSH (Wu et al., 2016). DSH appears to be higher amongst students in general, due to both their psychosocial stage of development as an adolescent and added pressures of higher education which predispose them to significant stressors of physical separation from parents, academic demands, independence and new social networks making them more vulnerable to self-harming acts (Amiri et al., 2013; Wu et al., 2016).

Suicide

On a global scale it is estimated that over 1 million people die due to suicide annually (Wasserman et. al. 2011). In fact, suicide itself is the second leading cause of death amongst 15 - 29-year-olds, which is, of course, the key age group of students (Wasserman et. al. 2011). Stressors for students include information and input overload, lack of leisure time, financial indebtedness and work pressures (Amiri et al., 2013).

Worldwide statistics show that medical students and even doctors are at a higher risk of suicide than the general population (Chan, Batterham, Christensen, & Galletly, 2014; Downs et al., 2014). In Australia, 14% of medical students have been found to experience suicidal ideation (Chan, Batterham, Christensen, & Galletly, 2014). In the United States of America, 4% of medical students considered committing suicide during their studies in the medical school (Schwenk, Davis, & Wimsatt, 2010). Additionally, the lifetime prevalence of suicide was between 16.8% and 51.5% and suicide attempts between 1.4 to 5.9% in Norwegian, Austrian, Indian and Turkish medical students (Eskin et al., 2011; Etzersdorfer, Vijaya-

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

kumar, Schöny, Grausgruber, & Sonneck, 1998; Tyssen et al., 2001). Studies in developing countries such as Pakistan have also found that '35.6% medical students have considered suicide in the past 12 months and 4.8% had attempted suicide in their lifetime' (Osama et al., 2014).

RISK FACTORS

Deliberate self-harm and suicide ideology are associated with a number of risk factors, some of which are common across both domains and a few of which are specific for medical students. A multitude of biological, social, psychological, economic and cultural factors influence both suicide and deliberate self-harm in young people (Miletic, Lukovic, Ratkovic, Aleksic, & Grgurevic, 2014; Osama et al., 2014).

Generally, major risk factors for deliberate self-harm and suicidal ideology include psychiatric disorders, hopelessness, and impulsivity. Other general factors that have been found to be precipitating factors including male gender, young age, short duration of illness, multiple admissions, recent discharge from hospital, previous and recent suicide attempt, comorbid depression, drug abuse, poor medication compliance, poor treatment adherence, adaptation to new environments, high IQ and suicidal ideations, (Miletic, Lukovic, Ratkovic, Aleksic, & Grgurevic, 2014; Osama et al., 2014). Social exclusion in the form of being institutionalised, imprisoned or homeless, as well as parental neglect, has also been noted as contributing factors (Osama et al., 2014). It should be noted that presence of these risk factors increase the risk of DSH and suicide, however, other internal factors, resilience and coping strategies may influence whether that suicide ideology or DSH eventually manifests (Dunn, Iglewicz & Moutier, 2008).

In medical students, there is increased the risk of DSH and suicide ideology due to specific risk factors which can be classified into medical student stressors, self-care and the culture of medicine (Dunn, Iglewicz & Moutier, 2008). Medical students must withstand more overwhelming levels of psychological stress compared to others of similar demographic in the general population (Chan, Batterham, Christensen, & Galletly, 2014). Medical student stressors arise from various sources including transition into medical school, high-self expectations, time and energy demands, internal conflict and negative personal life events. Most unique to medical students is the transition from being a high academic achiever in secondary school to being surrounded by similarly talented students in medical school (Dunn, Iglewicz & Moutier, 2008). This creates a competitive atmosphere in which they may no longer be able to meet their high self-expectations – this is a major shift which may predispose to increased anxiety and depression.

The time and energy required to maintain a strong academic portfolio alongside high expectations can take a toll on students' physical and mental stamina. The constant drive for knowledge and performance through independent study or extracurricular activities minimises the opportunity for health promoting and socialising activities, not to mention physical and mental fatigue and sleep deprivation. This consequently results in a lack of self-care which further increases the risk of DSH and suicidality. Because medical career paths are arduous in nature, students may often feel ambivalent, conflicted and, even at times, dysphoric about their career path. This internal conflict can drain their emotional reservoir and hinder their ability to cope with the sheer stress of medical training and may even drive them towards utilising negative coping mechanisms, such as substance abuse (Dunn, Iglewicz & Moutier, 2008). Substance abuse was found to increase the risk of suicide among medicals students by 28 fold due to impaired verbal intellectual ability, poor psychomotor processing, and problematic behaviour. Parental neglect in these students is also thought to be associated with increased risk possibly due to lack of internal resources to cope with difficult times and situations (Osama et al., 2014).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition to the stressors already outlined, students are often at the age where negative life events can arise (Chan, Batterham, Christensen, & Galletly, 2014). These may include family breakdown, sickness or death, relationship issues which may compromise their ability to cope, and impact their academic performance (Dunn, Iglewicz & Moutier, 2008). Overall, such risk factors make them more vulnerable to DSH and suicidal tendencies (Wu et al., 2016).

Due to the 'Culture of Medicine', seeking help is often viewed as a sign of weakness rather than empowering act, resulting in stigma and pressure when vulnerable students need support (Dunn, Iglewicz & Moutier, 2008). Furthermore, medical students tend to withhold from help-seeking behaviour due to fear of career implications', 'physician heal thyself' culture, time pressures and concerns for confidentiality (Chan, Batterham, Christensen, & Galletly, 2014; Downs et al., 2014; Yousuf, Beh, & Wong, 2013). Another factor that influences help-seeking behaviour is attitudes towards suicide. Permissive attitudes are associated with more help-seeking behaviour where stigmatisation and sanctioning of suicide leads to the deterrence of help-seeking behaviour (Yousuf, Beh, & Wong, 2013). Attitudes vary among countries with some cultures being more restrictive and others more permissive (Amiri et al., 2013). For example, students in India were found to be more restrictive than Austrian students and Japanese students were more likely to normalise suicide than American medical students (Amiri et al., 2013). Additionally, clinical experience and exposure to suicidal patients may improve knowledge but lead to more negative attitudes to informal help-seeking (Chan, Batterham, Christensen, & Galletly, 2014). Avoidance of and barriers to help-seeking behaviour can, therefore, increase the risk of DHS and suicidal ideations (Wasserman et. al. 2011).

PROTECTIVE FACTORS

Whilst there are numerous factors that precipitate an increased risk of deliberate self-harm and suicide in general, there are also common protective factors. These protective factors range from lifestyle factors such as maintaining a good diet, good sleeping hygiene and keeping an active lifestyle, to personality factors such as one's coping strategy, sense of personal value, confidence, ability to seek help and communicate (Wasserman et. al. 2011). Other protective factors such as social support and family connectedness are also valuable (Goldsmith, 2002).

Similarly, in medical students, general protective factors for mental well-being include psychosocial support and activities, internal characteristics and coping strategy as well as mentorship and intellectual stimulation. (Dunn, Iglewicz & Moutier, 2008). Presence of psychosocial support from family, friends, peers, medical school administration, therapists and religious affiliations and social activities, either spontaneous or structured, act as protective factors which may prevent or reduce DSH and suicide ideations. (Dunn, Iglewicz & Moutier, 2008).

Internal characteristics such as students' personal traits, temperament, and coping style are built upon the developmental task of young adulthood, gender-specific issues, and cultural/ethnic role expectations. Internal characteristics describe students coping reserve and resilience, which may vary between students, can be adaptive and protective. (Dunn, Iglewicz & Moutier, 2008).

Uniquely to medical students, the presence of mentorship from clinical preceptors, research mentors, assigned faculty mentors and/or peers may serve as role models and as one that students may be comfortable to disclose personal information or issues (Dunn, Iglewicz & Moutier, 2008). Additionally, intellectual stimulation whereby students start to appreciate the clinical significance and correlation of

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

the basic sciences may serve as protective factors. This may be through enhancing enthusiasm for their career path (Dunn, Iglewicz & Moutier, 2008).

The factors mentioned above are general protective factors that relate to overall mental health and well-being. Unfortunately, as there is limited information in the literature, specific protective factors for DSH and suicide in medical students was not available. Further research in this area would be of interest and yield worthwhile information.

SOLUTIONS AND RECOMMENDATIONS

In this section, the authors explore assessment, preventative and management strategies to improve education, awareness and ultimately reduce the rates of DSH and suicide risk. Presented is a comprehensive review of practises and techniques that medical professionals and medical educators could utilise to aid medical students to adequately and safely manage DSH and suicide ideology. This will include highlighting the benefits of using surveys and questionnaires to assess and identify at-risk medical students, counselling and educational group programmes to increase education and literacy as well as referring for further treatment (Yousuf, Beh, & Wong, 2013). The solutions and recommendations will aim to improve mental health literacy, alleviate the stigma and normalisation of suicide that exists amongst medical students as well as increase self-care principles (Chan, Batterham, Christensen, & Galletly, 2014).

As discussed previously, medical students are at risk of normalisation of DSH and suicide ideology despite their mental health literacy levels and are still susceptible to the stigma of help-seeking for their mental well-being (Yousuf, Beh, & Wong, 2013). Medical students receive minimal training in suicide and DSH prevention (Yousuf, Beh, & Wong, 2013).

Both DSH and suicidal behaviour can be prevented with timely, evidence-based and often low-cost interventions (Wasserman et al., 2011; Muehlenkamp, Walsh, & McDade, 2009). Current approaches towards the prevention of DSH and suicidal ideology targets early screening programmes and psychoeducational interventions.

Primary Prevention

Focusing on preventing DSH and suicidal ideology in medical students should begin with targeted psychoeducational interventions early in their career. The purpose of this is to raise mental health literacy, reduce stigmatising attitudes, limiting normalisation/glorification of suicide (Chan, Batterham, Christensen, & Galletly, 2014).

Suicide prevention and education modules can lead to positive attitudes towards understanding suicide and are well received by medical students (Yousuf, Beh, & Wong, 2013). Specifically, it can reduce negative attitudes towards and stigmatisation of suicide (Yousuf, Beh, & Wong, 2013). For example, a 2-week special studies module (SSM) on suicidology and suicide prevention for undergraduate medical students resulted in reduced negative appraisal, reduced stigmatisation and increased sensitivity towards suicide literacy, all of which are positive attitudes towards suicide (Yousuf, Beh, & Wong, 2013). The course itself covered a variety of topics from risk assessment to prevention and intervention strategies, suicide among health professionals, life, and death as well as skills for overcoming stress through a diverse range of teaching modalities such as presentations, discussions, skills-based training sessions and films.

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

DSH primary prevention should idealistically work in the same manner as suicide primary prevention, unfortunately, no specific studies currently exist for medical students. There are, however, prevention programmes which have been trialed in adolescents in a school-based prevention program. Muehlenkamp, Walsh & McDale discuss the use of the Signs of Self-Injury (SOSI) programme which is designed for both staff and students. The programme is divided into two modules, with the staff module providing psychoeducational material about DSH as well as warning signs and methods of response. The student module utilises multimedia presentation to overview DSH signs and symptoms and how to approach for help. This is followed by a group discussion to consolidate all the information. The results indicated that students had improved help-seeking attitudes and intentions and preliminary data demonstrated that the programme may be an effective prevention programme for schools (Muehlenkamp, Walsh, & McDade, 2009). This may be a viable option if adapted for medical students as well as medical teaching faculty.

Secondary Prevention

There is insufficient data to support that suicide screening of the general population in primary care will reduce mortality (LeFevre, 2014; O'Connor, Gaynes, Burda, Soh, & Whitlock, 2013). Despite this, identification of cases based upon risk factors, sensitivity to high-risk situations in depressed patients, and assessment of suicidality in patients treated for depression is appropriate and can reveal occasional patients with suicidal intent and can benefit from interjection and intervention (LeFevre, 2014; O'Connor, Gaynes, Burda, Soh, & Whitlock, 2013).

For medical students, secondary and tertiary prevention strategies should be utilised to ensure early intervention. One example of a screening and referral system is The Healer Education Assessment and Referral (HEAR) programme. This encompassed a two-tiered programme involving educational models followed by anonymous screening using 9-item Patient Health Questionnaire (PHQ-9) to identify affective disorders and suicide risk in medical students (Simon et al., 2013). Students who were found to be at risk were then assessed further and referred for care if necessary (See Figure 3) ("The Patient Health Questionnaire (PHQ-9)", 1999). This study found that a significant number of 'at-risk' students were not in treatment (Downs et al., 2014). Programmes like this have the potential to identify, refer and treat 'at-risk' students with depression and increased suicide risk with the ultimate goal of reducing suicide behaviour, death from suicide, deliberate self-harm, education, treatment, screening, engagement, and follow-up. The Royal College of Psychiatrists actually endorses repeated assessments and screening, as they can actually increase engagement in treatment (Self-harm, suicide, and risk: a summary, 2010).

Screening for deliberate self-harm has proven more challenging due to aforementioned reasons of individual concealment and unwillingness to seek help. Despite this, the Columbia-Suicide Severity Rating Scale (C-SSRS) has been developed to assess suicidal ideation, lethality, and severity of suicide attempt as well as DSH without suicidal intent (Wasserman et al., 2011). The C-SSRS differs from the PHQ-9 in that it more thoroughly assesses suicidal intent, a key factor in differing suicide ideation and deliberate self-harm (Viguera et al., 2015). Unfortunately, neither the C-SSRS or the PHQ-9 have been evaluated for their sensitivity or specificity in identifying deliberate self-harm in medical students.

Figure 3. 9-Item Patient Health Questionnaire (PHQ-9)
Source: Adapted from The Patient Health Questionnaire (PHQ-9, 1999)

Over the past 2 weeks, how often have you been bothered by any of the following problems?	Not At All	Several Days	More Than Half the Days	Nearly Every Day
1. Little interest or pleasure in doing things	0	1	2	3
2. Feeling down, depressed or hopeless	0	1	2	3
3. Trouble falling asleep, staying asleep or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself – or that you're a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed. Or, the opposite – being so fidgety or restless that you have been moving around a lot more than usual	0	1	2	3
9. Thoughts that you would be better off dead or off hurting yourself in some way	0	1	2	3

Tertiary Prevention

Any acute, life-threatening incidences of suicide attempts or self-harm should be managed promptly by appropriately trained staff and acute psychiatric services (Carter et al., 2016; Hirschfeld & Russell, 1997). Ongoing treatment and follow up should be conducted by a health professional unrelated to the medical school to prevent any conflicts of interest. Any discussion between the medical school and treating team about a medical student's mental health should only be made with explicit consent of the patient.

According to the Royal College of Psychiatrists, there is insufficient evidence to clearly define the best therapy for those who have self-harmed or plan to self-harm (Bateman, 2014). This is further supported by the Royal Australian and New Zealand College of Psychiatrists, who define clinical practise guidelines for specific population sub-groups, none of which focus on medical student demographics (Carter et al., 2016). There is limited randomised controlled trial evidence to support pharmacological treatment for DSH, in fact, it has demonstrated an unfavourable risk-benefit ratio (Carter et al., 2016; Suarez & Saunders, 2012). Psychological or psychosocial interventions such as problem-solving therapy, cognitive-behavioural therapy and psychodynamic interpersonal therapy have been effective in reducing the number of recurrent DSH events (Carter et al., 2016). A health professional should make a tailored approach based on each individual's problems.

Suicidal behaviour is a serious psychiatric emergency with complex treatment. This treatment strategy serves as tertiary prevention to prevent progression of condition or a successful attempt. In acute cases, patients require evaluation and either inpatient or outpatient care (O'Connor, Gaynes, Burda, Soh, & Whitlock, 2013). The decision whether to admit patients to psychiatric ward is difficult due to the circumstances of each case, use of economic resources as well as negative effects of hospitalisation (Wasserman et al., 2011).

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

In acute suicidal cases, the early phase is when patients are most at risk (Wasserman et al., 2011). An empathetic and supportive approach should be taken and encompass symptomatic, pharmacological treatment. Medications prescribed should be supervised by family or community services and given in small packages (Wasserman et al., 2011). Adequate monitoring and follow-up are of paramount importance as the risk of suicide increases in days and initial weeks after discharge (Hirschfeld & Russell, 1997).

Long-term management should be commenced immediately and include follow-up consultations e.g. active involvement of family members, telephone contacts, appointments and social network evaluation (Wasserman et al., 2011). Prevention of suicidal behaviours is achieved by treating underlying psychiatric disorders and symptoms. The treatment regime varies and depends largely on the specific cause which will not be discussed here as it is beyond the scope of this chapter.

Psychological treatment includes cognitive behavioural therapy (CBT) which is the evidence-based method of treatment, however this is not specific to medical students (O'Connor, Gaynes, Burda, Soh, & Whitlock, 2013). Other forms of psychological treatment which may be useful includes dialectical behaviour therapy, in-home interpersonal psychotherapy, family psychotherapy developmental group therapy and psycho dynamic therapy however further research is needed to confirm effectiveness of these treatment methods. Irrespective of psychotherapy employed, effective strategies require a good therapeutic relationship between patient and therapist, treatment fidelity, compliance, targeting identifiable skills and emphasis on personal responsibility (Wasserman et al., 2011).

Community resources are recommended as patients struggle with existential crises. These may involve support from family and friends, helplines, crisis centres, mental health centres, religious counsellor (Wasserman et al., 2011). The goal of elevating psychosocial support is to enhance sense of meaning in life. Such strategies can be implemented into medical school policies for both students and educators, as discussed in the following section.

Recommendations for Medical Schools and Educators

Implementation of prevention strategies to reduce suicide and deliberate self-harm amongst medical students requires an integrated and committed effort from both medical schools and educators (Hughes, Kent, & Bowman, 2008). Such entities have important roles in ensuring the success of intervention strategies and therefore reduce stigma and barriers seeking health services (Thornicroft et al., 2016).

Whilst no current literature supports any specific mental health interventions in medical students, a multitude of research has been conducted regarding guidelines for tertiary education institutions in support students with a mental illness. A 2013 Delphi consensus study conducted with 74 Australian professionals and 35 consumers supported 155 strategies that addressed mental illness in all students at tertiary institutions. These strategies encompassed generating policies in a variety of domains to assist students such as promotion, enhancement and accessibility of support services, education, and training of staff as well as funding, research and evaluation (Reavley, Ross, Killackey & Jorm, 2013). The authors will continue to discuss methods through which medical schools and educators can promote awareness and implement strategies in their institution, specifically with regards to university policy, support services and staff and student education.

University policies should address the promotion of mental health awareness, prevention of mental illness and provide the foundation for services for students with a mental illness (Reavley, Ross, Killackey & Jorm, 2013). Mental health awareness should be employed by leading executives and professors of the faculty in conjunction with student associations and representatives from external services. Most

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

importantly, institutions should develop a plan for communicating this mental health policy to all staff and students. A report from the Australian Medical Students' Association in 2013 outlined several student-based initiatives such as mentoring programmes, wellbeing events including guest speakers on self-care, yoga and meditation as well as providing student-friendly external services such as general practitioners and psychologists. A collaborative approach from students and staff is essential in ensuring student participation (Australia Medical Students' Association Student Mental Health and Wellbeing Committee, 2013; Reavley, Ross, Killackey & Jorm, 2013).

Institution support services such as student counsellors, telephone counselling, online services and support groups should be made available to all staff and students. As discussed previously, barriers to seeking help play a large role in a medical student's decision and universities should adopt an easy access, non-judgemental approach to entry for assessment and treatment, a method that Hughes, Kent & Bowman address as the 'no wrong door' policy (Hughes, Kent, & Bowman, 2008).

As discussed in primary prevention, psychoeducational modules would be beneficial in conveying information to staff and students. This should clearly detail signs, symptoms, causes, treatment and the benefits of early intervention and prevention (Reavley, Ross, Killackey & Jorm, 2013). Staff should also be trained to use non-judgemental listening skills, respond appropriately when a student discloses a mental illness to them, techniques for motivating students and raising self-esteem and most importantly how to handle a mental health crisis (Reavley, Ross, Killackey & Jorm, 2013). These skills can be taught to staff over on-going professional development sessions and online training, to be accessible and thorough, yet not create a high burden of work. The university and staff should also provide 'reasonable adjustments' for assessments to encourage and assist students in coping with their mental illness and to ensure that high workload demands or expectations do not negatively impact an already stressed student (Hughes, Kent, & Bowman, 2008). Furthermore, this process should be made open and transparent for the fairness of all students.

Major limitations to these prevention strategies are due to lack of funding and resources. Despite this, medical schools should endeavour to allocate adequate funds and seek funding opportunities to enhance student mental health services to benefit their students. Additionally, these services should be followed up and evaluated in ongoing research to monitor the efficacy of such interventions.

The combination of university policy support services and staff and student education is a useful intervention strategy but an area that still requires further research in the medical school domain. As discussed in the sections above, implementation of intervention strategies is vital as they target all facets of prevention to ultimately reduce the risk of suicide and self-harm in this vulnerable population (Wasserman et al., 2011).

FUTURE RESEARCH DIRECTIONS

Deliberate self-harm and suicide ideology is an important, emerging issue amongst medical students. Current literature on this issue only scratches the surface of a deeper problem and requires further research to explore the depth and breadth of the issues. Future research is needed to quantify the severity and predisposing factors contributing to this issue, to ascertain student perspectives and engage students in finding solutions. Similarly, the perspectives and roles of medical educators and administrators in medical schools should also be examined. The downstream impact of deliberate self-harm and suicide ideology during medical school on well-being and performance in future clinical practise could also be

EBSCOhost - printed on 2/10/2023 10:45 PM via . All use subject to https://www.ebsco.com/terms-of-use

explored. Implementation of the proposed solutions and recommendations can be a stepping stone to addressing deliberate self-harm and suicide in medical students and will also serve as future research opportunities to evaluate the usefulness and effectiveness of such strategies.

CONCLUSION

Deliberate self-harm and suicide ideology are pertinent issues amongst medical students. The relation between deliberate self-harm and suicide ideology is important and helpful for understanding the risk factors and preventative factors behind both diagnoses. Early screening assessment and intervention are evidence-based and often low-cost, meaning their implementation can be quick and effective.

KEY TERMS AND DEFINITIONS

Deliberate Self-Harm: Direct behaviour that causes minor to moderate physical injury, that is undertaken without conscious suicidal intent and that occurs in the absence of psychoses and/or organic intellectual impairment.

Primary Prevention: Intervention or action that aims to prevent disease or injury before it ever occurs.

Psycho-Educational Intervention: A broad range of activities, combining education, counselling and support interventions. These may be delivered individually or in groups, may be tailored or standardised.

Secondary Prevention: Intervention or action that aims to reduce the impact of a disease or injury that has already occurred through screening, early detection or halting.

Suicide: The act of deliberately killing oneself.

Suicide Ideology: Concerns, thoughts about or unusual preoccupation with suicide. Also known as suicide ideation.

Tertiary Prevention: Intervention, action or treatment for disease or injury that prevents complication and/or progression.

This research was previously published in Exploring the Pressures of Medical Education From a Mental Health and Wellness Perspective; pages 122-143, copyright year 2018 by Medical Information Science Reference (an imprint of IGI Global).
